# Virtual machines in Azure

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

Azure virtual machines are one of several types of [on-demand, scalable computing resources](#) that Azure offers. Typically, you choose a virtual machine when you need more control over the computing environment than the other choices offer. This article gives you information about what you should consider before you create a virtual machine, how you create it, and how you manage it.

An Azure virtual machine gives you the flexibility of virtualization without having to buy and maintain the physical hardware that runs it. However, you still need to maintain the virtual machine by performing tasks, such as configuring, patching, and installing the software that runs on it.

Azure virtual machines can be used in various ways. Some examples are:

- **Development and test** – Azure virtual machines offer a quick and easy way to create a computer with specific configurations required to code and test an application.
- **Applications in the cloud** – Because demand for your application can fluctuate, it might make economic sense to run it on a virtual machine in Azure. You pay for extra virtual machines when you need them and shut them down when you don't.
- **Extended datacenter** – virtual machines in an Azure virtual network can easily be connected to your organization's network.

The number of virtual machines that your application uses can scale up and out to whatever is required to meet your needs.

## What do I need to think about before creating a virtual machine?

There is always a multitude of [design considerations](#) when you build out an application infrastructure in Azure. These aspects of a virtual machine are important to think about before you start:

- The names of your application resources
- The location where the resources are stored
- The size of the virtual machine
- The maximum number of virtual machines that can be created
- The operating system that the virtual machine runs
- The configuration of the virtual machine after it starts
- The related resources that the virtual machine needs

### Locations

There are multiple [geographical regions](#) around the world where you can create Azure resources. Usually, the region is called **location** when you create a virtual machine. For a virtual machine, the location specifies where the virtual hard disks will be stored.

This table shows some of the ways you can get a list of available locations.

METHOD	DESCRIPTION
Azure portal	Select a location from the list when you create a virtual machine.

METHOD	DESCRIPTION
Azure PowerShell	Use the <a href="#">Get-AzLocation</a> command.
REST API	Use the <a href="#">List locations</a> operation.
Azure CLI	Use the <a href="#">az account list-locations</a> operation.

## Availability

There are multiple options to manage the availability of your virtual machines in Azure.

- **Availability Zones** are physically separated zones within an Azure region. Availability zones guarantee you will have virtual machine Connectivity to at least one instance at least 99.99% of the time when you have two or more instances deployed across two or more Availability Zones in the same Azure region.
- **Virtual machine scale sets** let you create and manage a group of load balanced virtual machines. The number of virtual machine instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide high availability to your applications, and allow you to centrally manage, configure, and update many virtual machines. Virtual machines in a scale set can also be deployed into multiple availability zones, a single availability zone, or regionally.
- **Proximity Placement Groups** are a grouping construct used to ensure Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

For more information see [Availability options for Azure virtual machines](#) and [SLA for Azure virtual machines](#).

## Virtual machine size

The [size](#) of the virtual machine that you use is determined by the workload that you want to run. The size that you choose then determines factors such as processing power, memory, storage capacity, and network bandwidth. Azure offers a wide variety of sizes to support many types of uses.

Azure charges an [hourly price](#) based on the virtual machine's size and operating system. For partial hours, Azure charges only for the minutes used. Storage is priced and charged separately.

## Virtual machine limits

Your subscription has default [quota limits](#) in place that could impact the deployment of many virtual machines for your project. The current limit on a per subscription basis is 20 virtual machines per region. Limits can be raised by [filing a support ticket requesting an increase](#)

## Managed Disks

Managed Disks handles Azure Storage account creation and management in the background for you, and ensures that you do not have to worry about the scalability limits of the storage account. You specify the disk size and the performance tier (Standard or Premium), and Azure creates and manages the disk. As you add disks or scale the virtual machine up and down, you don't have to worry about the storage being used. If you're creating new virtual machines, [use the Azure CLI](#) or the Azure portal to create virtual machines with Managed OS and data disks. If you have virtual machines with unmanaged disks, you can [convert your virtual machines to be backed with Managed Disks](#).

You can also manage your custom images in one storage account per Azure region, and use them to create hundreds of virtual machines in the same subscription. For more information about Managed Disks, see the

## Distributions

Microsoft Azure supports a variety of Linux and Windows distributions. You can find available distributions in the [marketplace](#), Azure portal or by querying results using CLI, PowerShell and REST APIs.

This table shows some ways that you can find the information for an image.

METHOD	DESCRIPTION
Azure portal	The values are automatically specified for you when you select an image to use.
Azure PowerShell	<code>Get-AzVMImagePublisher</code> -Location <i>location</i> <code>Get-AzVMImageOffer</code> -Location <i>location</i> -Publisher <i>publisherName</i> <code>Get-AzVMImageSku</code> -Location <i>location</i> -Publisher <i>publisherName</i> -Offer <i>offerName</i>
REST APIs	<a href="#">List image publishers</a> <a href="#">List image offers</a> <a href="#">List image skus</a>
Azure CLI	<code>az vm image list-publishers --location <i>location</i></code> <code>az vm image list-offers --location <i>location</i> --publisher <i>publisherName</i></code> <code>az vm image list-skus --location <i>location</i> --publisher <i>publisherName</i> --offer <i>offerName</i></code>

Microsoft works closely with partners to ensure the images available are updated and optimized for an Azure runtime. For more information on Azure partner offers, see the following links:

- Linux on Azure - [Endorsed Distributions](#)
- SUSE - [Azure Marketplace](#) - SUSE Linux Enterprise Server
- Red Hat - [Azure Marketplace](#) - Red Hat Enterprise Linux
- Canonical - [Azure Marketplace](#) - Ubuntu Server
- Debian - [Azure Marketplace](#) - Debian
- FreeBSD - [Azure Marketplace](#) - FreeBSD
- Flatcar - [Azure Marketplace](#) - Flatcar Container Linux
- RancherOS - [Azure Marketplace](#) - RancherOS
- Bitnami - [Bitnami Library for Azure](#)
- Mesosphere - [Azure Marketplace](#) - Mesosphere DC/OS on Azure
- Docker - [Azure Marketplace](#) - Docker images
- Jenkins - [Azure Marketplace](#) - CloudBees Jenkins Platform

## Cloud-init

To achieve a proper DevOps culture, all infrastructures must be code. When all the infrastructure lives in code it can easily be recreated. Azure works with all the major automation tooling like Ansible, Chef, SaltStack, and Puppet. Azure also has its own tooling for automation:

- [Azure Templates](#)
- [Azure VMaccess](#)

Azure supports for [cloud-init](#) across most Linux Distros that support it. We are actively working with our endorsed Linux distro partners in order to have cloud-init enabled images available in the Azure marketplace. These images will make your cloud-init deployments and configurations work seamlessly with virtual machines and virtual machine scale sets.

- [Using cloud-init on Azure Linux virtual machines](#)

## Storage

- [Introduction to Microsoft Azure Storage](#)
- [Add a disk to a Linux virtual machine using the azure-cli](#)
- [How to attach a data disk to a Linux virtual machine in the Azure portal](#)

## Networking

- [Virtual Network Overview](#)
- [IP addresses in Azure](#)
- [Opening ports to a Linux virtual machine in Azure](#)
- [Create a Fully Qualified Domain Name in the Azure portal](#)

## Data residency

In Azure, the feature to enable storing customer data in a single region is currently only available in the Southeast Asia Region (Singapore) of the Asia Pacific Geo and Brazil South (Sao Paulo State) Region of Brazil Geo. For all other regions, customer data is stored in Geo. For more information, see [Trust Center](#).

## Next steps

Create your first virtual machine!

- [Azure CLI](#)
- [PowerShell](#)

# Quickstart: Create a Linux virtual machine with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This quickstart shows you how to use the Azure CLI to deploy a Linux virtual machine (VM) in Azure. The Azure CLI is used to create and manage Azure resources via either the command line or scripts.

In this tutorial, we will be installing the latest Debian image. To show the VM in action, you'll connect to it using SSH and install the NGINX web server.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also open Cloud Shell in a separate browser tab by going to <https://shell.azure.com/bash>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and select **Enter** to run it.

If you prefer to install and use the CLI locally, this quickstart requires Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create a resource group

Create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name myResourceGroup --location eastus
```

## Create virtual machine

Create a VM with the [az vm create](#) command.

The following example creates a VM named *myVM* and adds a user account named *azureuser*. The `--generate-ssh-keys` parameter is used to automatically generate an SSH key, and put it in the default key location (`~/.ssh`). To use a specific set of keys instead, use the `--ssh-key-values` option.

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image Debian \
--admin-username azureuser \
--generate-ssh-keys
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

```
{  
    "fqdns": "",  
    "id":  
        "/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",  
    "location": "eastus",  
    "macAddress": "00-0D-3A-23-9A-49",  
    "powerState": "VM running",  
    "privateIpAddress": "10.0.0.4",  
    "publicIpAddress": "40.68.254.142",  
    "resourceGroup": "myResourceGroup"  
}
```

Make a note of the `publicIpAddress` to use later.

## Install web server

To see your VM in action, install the NGINX web server. Update your package sources and then install the latest NGINX package.

```
az vm run-command invoke \  
-g myResourceGroup \  
-n myVM \  
--command-id RunShellScript \  
--scripts "sudo apt-get update && sudo apt-get install -y nginx"
```

## Open port 80 for web traffic

By default, only SSH connections are opened when you create a Linux VM in Azure. Use `az vm open-port` to open TCP port 80 for use with the NGINX web server:

```
az vm open-port --port 80 --resource-group myResourceGroup --name myVM
```

## View the web server in action

Use a web browser of your choice to view the default NGINX welcome page. Use the public IP address of your VM as the web address. The following example shows the default NGINX web site:

## Clean up resources

When no longer needed, you can use the `az group delete` command to remove the resource group, VM, and all

related resources.

```
az group delete --name myResourceGroup
```

## Next steps

In this quickstart, you deployed a simple virtual machine, opened a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Create a Linux virtual machine in the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create Azure resources. This quickstart shows you how to use the Azure portal to deploy a Linux virtual machine (VM) running Ubuntu 18.04 LTS. To see your VM in action, you also SSH to the VM and install the NGINX web server.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Sign in to Azure

Sign in to the [Azure portal](#).

## Create virtual machine

1. Enter *virtual machines* in the search.
2. Under **Services**, select **Virtual machines**.
3. In the **Virtual machines** page, select **Create** and then **Virtual machine**. The **Create a virtual machine** page opens.
4. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and then choose to **Create new resource group**. Enter *myResourceGroup* for the name.\*.

**Project details**

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

<b>Subscription</b> * ⓘ	<input type="text" value="Pay-As-You-Go"/>
<b>Resource group</b> * ⓘ	<input type="text" value="(New) myResourceGroup"/> <a href="#">Create new</a>

5. Under **Instance details**, enter *myVM* for the **Virtual machine name**, and choose *Ubuntu 18.04 LTS - Gen2* for your **Image**. Leave the other defaults. The default size and pricing is only shown as an example. Size availability and pricing are dependent on your region and subscription.

**Instance details**

Virtual machine name *	myVM
Region *	(US) East US
Availability options	No infrastructure redundancy required
Security type	Standard
Image *	Ubuntu Server 18.04 LTS - Gen2
See all images   Configure VM generation	
Azure Spot instance	<input type="checkbox"/>
Size *	Standard_DS1_v2 - 1 vcpu, 3.5 GiB memory
See all sizes	

#### NOTE

Some users will now see the option to create VMs in multiple zones. To learn more about this new capability, see [Create virtual machines in an availability zone](#).

Availability zone *	Zones 1
You can now select multiple zones. Selecting multiple zones will create one VM per zone.	

6. Under **Administrator account**, select **SSH public key**.
7. In **Username** enter *azureuser*.
8. For **SSH public key source**, leave the default of **Generate new key pair**, and then enter *myKey* for the **Key pair name**.

**Administrator account**

Authentication type	<input checked="" type="radio"/> SSH public key <input type="radio"/> Password
Username *	azureuser
SSH public key source	Generate new key pair
Key pair name *	myKey

9. Under **Inbound port rules > Public inbound ports**, choose **Allow selected ports** and then select **SSH (22)** and **HTTP (80)** from the drop-down.

**Inbound port rules**

Select which virtual machine network ports are accessible from the public internet. You can specify more limited or granular network access on the Networking tab.

Public inbound ports *	<input type="radio"/> None <input checked="" type="radio"/> Allow selected ports
Select inbound ports *	HTTP (80), SSH (22)
This will allow all IP addresses to access your virtual machine. This is only recommended for testing. Use the Advanced controls in the Networking tab to create rules to limit inbound traffic to known IP addresses.	

10. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.
11. On the **Create a virtual machine** page, you can see the details about the VM you are about to create.

When you are ready, select **Create**.

12. When the **Generate new key pair** window opens, select **Download private key and create resource**. Your key file will be download as **myKey.pem**. Make sure you know where the **.pem** file was downloaded; you will need the path to it in the next step.
13. When the deployment is finished, select **Go to resource**.
14. On the page for your new VM, select the public IP address and copy it to your clipboard.

## Connect to virtual machine

Create an SSH connection with the VM.

1. If you are on a Mac or Linux machine, open a Bash prompt and set read-only permission on the **.pem** file using `chmod 400 ~/Downloads/myKey.pem`. If you are on a Windows machine, open a PowerShell prompt.
2. At your prompt, open an SSH connection to your virtual machine. Replace the IP address with the one from your VM, and replace the path to the **.pem** with the path to where the key file was downloaded.

```
ssh -i ~/Downloads/myKey.pem azureuser@10.111.12.123
```

### TIP

The SSH key you created can be used the next time you create a VM in Azure. Just select the **Use a key stored in Azure for SSH public key source** the next time you create a VM. You already have the private key on your computer, so you won't need to download anything.

## Install web server

To see your VM in action, install the NGINX web server. From your SSH session, update your package sources and then install the latest NGINX package.

```
sudo apt-get -y update  
sudo apt-get -y install nginx
```

When done, type `exit` to leave the SSH session.

## View the web server in action

Use a web browser of your choice to view the default NGINX welcome page. Type the public IP address of the VM as the web address. The public IP address can be found on the VM overview page or as part of the SSH connection string you used earlier.

## Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources. To do so, select the resource group for the virtual machine, select **Delete**, then confirm the name of the resource group to delete.

## Next steps

In this quickstart, you deployed a simple virtual machine, created a Network Security Group and rule, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Create a Linux virtual machine in Azure with PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to deploy a Linux virtual machine (VM) in Azure. This quickstart uses the Ubuntu 18.04 LTS marketplace image from Canonical. To see your VM in action, you'll also SSH to the VM and install the NGINX web server.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create a resource group

Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which Azure resources are deployed and managed:

```
New-AzResourceGroup -Name 'myResourceGroup' -Location 'EastUS'
```

## Create a virtual machine

We will be automatically generating an SSH key pair to use for connecting to the VM. The public key that is created using `-GenerateSshKey` will be stored in Azure as a resource, using the name you provide as `SshKeyName`. The SSH key resource can be reused for creating additional VMs. Both the public and private keys will also be downloaded for you. When you create your SSH key pair using the Cloud Shell, the keys are stored in a [storage account that is automatically created by Cloud Shell](#). Don't delete the storage account, or the file share in it, until after you have retrieved your keys or you will lose access to the VM.

You will be prompted for a user name that will be used when you connect to the VM. You will also be asked for a password, which you can leave blank. Password login for the VM is disabled when using an SSH key.

In this example, you create a VM named *myVM*, in *East US*, using the *Standard\_B2s* VM size.

```
New-AzVm ` 
    -ResourceGroupName 'myResourceGroup' ` 
    -Name 'myVM' ` 
    -Location 'East US' ` 
    -Image Debian ` 
    -size Standard_B2s ` 
    -PublicIpAddressName myPubIP ` 
    -OpenPorts 80 ` 
    -GenerateSshKey ` 
    -SshKeyName mySSHKey
```

The output will give you the location of the local copy of the SSH key. For example:

```
Private key is saved to /home/user/.ssh/1234567891
Public key is saved to /home/user/.ssh/1234567891.pub
```

It will take a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

## Install NGINX

To see your VM in action, install the NGINX web server.

```
Invoke-AzVMRunCommand ` 
    -ResourceGroupName 'myResourceGroup' ` 
    -Name 'myVM' ` 
    -CommandId 'RunShellScript' ` 
    -ScriptString 'sudo apt-get update && sudo apt-get install -y nginx'
```

The `-ScriptString` parameter requires version 4.27.0 or later of the `'Az.Compute'` module.

## View the web server in action

Get the public IP address of your VM:

```
Get-AzPublicIpAddress -Name myPubIP -ResourceGroupName myResourceGroup | select "IpAddress"
```

Use a web browser of your choice to view the default NGINX welcome page. Enter the public IP address of the VM as the web address.

A screenshot of a web browser window. The address bar shows the IP address 40.68.254.142. The main content area displays the text "Welcome to nginx on Debian!". Below it, there is a message: "If you see this page, the nginx web server is successfully installed and working on Debian. Further configuration is required." Further down, it says: "For online documentation and support please refer to [nginx.org](http://nginx.org)". At the bottom, there is a note: "Please use the reportbug tool to report bugs in the nginx package with Debian. However, check [existing bug reports](#) before reporting a new bug." The browser interface includes standard controls like back, forward, and search.

**Welcome to nginx on Debian!**

If you see this page, the nginx web server is successfully installed and working on Debian. Further configuration is required.

For online documentation and support please refer to [nginx.org](http://nginx.org)

Please use the `reportbug` tool to report bugs in the `nginx` package with Debian. However, check [existing bug reports](#) before reporting a new bug.

*Thank you for using debian and nginx.*

## Clean up resources

When no longer needed, you can use the [Remove-AzResourceGroup](#) cmdlet to remove the resource group, VM, and all related resources:

```
Remove-AzResourceGroup -Name 'myResourceGroup'
```

## Next steps

In this quickstart, you deployed a simple virtual machine, created a Network Security Group and rule, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Use Terraform to create a Linux VM

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Article tested with the following Terraform and Terraform provider versions:

- [Terraform v1.2.7](#)
- [AzureRM Provider v3.20.0](#)

This article shows you how to create a complete Linux environment and supporting resources with Terraform. Those resources include a virtual network, subnet, public IP address, and more.

Terraform enables the definition, preview, and deployment of cloud infrastructure. Using Terraform, you create configuration files using [HCL syntax](#). The HCL syntax allows you to specify the cloud provider - such as Azure - and the elements that make up your cloud infrastructure. After you create your configuration files, you create an *execution plan* that allows you to preview your infrastructure changes before they're deployed. Once you verify the changes, you apply the execution plan to deploy the infrastructure.

In this article, you learn how to:

- Create a virtual network
- Create a subnet
- Create a public IP address
- Create a network security group and SSH inbound rule
- Create a virtual network interface card
- Connect the network security group to the network interface
- Create a storage account for boot diagnostics
- Create SSH key
- Create a virtual machine
- Use SSH to connect to virtual machine

## NOTE

The example code in this article is located in the [Microsoft Terraform GitHub repo](#). See more [articles and sample code showing how to use Terraform to manage Azure resources](#)

## Prerequisites

- **Azure subscription:** If you don't have an Azure subscription, create a [free account](#) before you begin.
- [Install and configure Terraform](#)

## Implement the Terraform code

1. Create a directory in which to test the sample Terraform code and make it the current directory.
2. Create a file named `providers.tf` and insert the following code:

```

terraform {
  required_version = ">=0.12"

  required_providers {
    azurerm = {
      source  = "hashicorp/azurerm"
      version = "~>2.0"
    }
    random = {
      source  = "hashicorp/random"
      version = "~>3.0"
    }
    tls = {
      source  = "hashicorp/tls"
      version = "~>4.0"
    }
  }
}

provider "azurerm" {
  features {}
}

```

3. Create a file named `main.tf` and insert the following code:

```

resource "random_pet" "rg_name" {
  prefix = var.resource_group_name_prefix
}

resource "azurerm_resource_group" "rg" {
  location = var.resource_group_location
  name     = random_pet.rg_name.id
}

# Create virtual network
resource "azurerm_virtual_network" "my_terraform_network" {
  name          = "myVnet"
  address_space = ["10.0.0.0/16"]
  location      = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
}

# Create subnet
resource "azurerm_subnet" "my_terraform_subnet" {
  name          = "mySubnet"
  resource_group_name = azurerm_resource_group.rg.name
  virtual_network_name = azurerm_virtual_network.my_terraform_network.name
  address_prefixes = ["10.0.1.0/24"]
}

# Create public IPs
resource "azurerm_public_ip" "my_terraform_public_ip" {
  name          = "myPublicIP"
  location      = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
  allocation_method = "Dynamic"
}

# Create Network Security Group and rule
resource "azurerm_network_security_group" "my_terraform_nsg" {
  name          = "myNetworkSecurityGroup"
  location      = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  security_rule {
    name          = "SSH"
  }
}

```

```

        priority          = 1001
        direction        = "Inbound"
        access           = "Allow"
        protocol         = "Tcp"
        source_port_range = "*"
        destination_port_range = "22"
        source_address_prefix = "*"
        destination_address_prefix = "*"
    }
}

# Create network interface
resource "azurerm_network_interface" "my_terraform_nic" {
    name            = "myNIC"
    location        = azurerm_resource_group.rg.location
    resource_group_name = azurerm_resource_group.rg.name

    ip_configuration {
        name          = "my_nic_configuration"
        subnet_id     = azurerm_subnet.my_terraform_subnet.id
        private_ip_address_allocation = "Dynamic"
        public_ip_address_id       = azurerm_public_ip.my_terraform_public_ip.id
    }
}

# Connect the security group to the network interface
resource "azurerm_network_interface_security_group_association" "example" {
    network_interface_id      = azurerm_network_interface.my_terraform_nic.id
    network_security_group_id = azurerm_network_security_group.my_terraform_nsg.id
}

# Generate random text for a unique storage account name
resource "random_id" "random_id" {
    keepers = {
        # Generate a new ID only when a new resource group is defined
        resource_group = azurerm_resource_group.rg.name
    }

    byte_length = 8
}

# Create storage account for boot diagnostics
resource "azurerm_storage_account" "my_storage_account" {
    name          = "diag${random_id.random_id.hex}"
    location      = azurerm_resource_group.rg.location
    resource_group_name = azurerm_resource_group.rg.name
    account_tier      = "Standard"
    account_replication_type = "LRS"
}

# Create (and display) an SSH key
resource "tls_private_key" "example_ssh" {
    algorithm = "RSA"
    rsa_bits   = 4096
}

# Create virtual machine
resource "azurerm_linux_virtual_machine" "my_terraform_vm" {
    name            = "myVM"
    location        = azurerm_resource_group.rg.location
    resource_group_name = azurerm_resource_group.rg.name
    network_interface_ids = [azurerm_network_interface.my_terraform_nic.id]
    size           = "Standard_DS1_v2"

    os_disk {
        name          = "myOsDisk"
        caching        = "ReadWrite"
        storage_account_type = "Premium_LRS"
    }
}

```

```

source_image_reference {
  publisher = "Canonical"
  offer     = "UbuntuServer"
  sku       = "18.04-LTS"
  version   = "latest"
}

computer_name          = "myvm"
admin_username         = "azureuser"
disable_password_authentication = true

admin_ssh_key {
  username  = "azureuser"
  public_key = tls_private_key.example_ssh.public_key_openssh
}

boot_diagnostics {
  storage_account_uri = azurerm_storage_account.my_storage_account.primary_blob_endpoint
}
}

```

4. Create a file named `variables.tf` and insert the following code:

```

variable "resource_group_location" {
  default      = "eastus"
  description = "Location of the resource group."
}

variable "resource_group_name_prefix" {
  default      = "rg"
  description = "Prefix of the resource group name that's combined with a random ID so name is unique
in your Azure subscription."
}

```

5. Create a file named `outputs.tf` and insert the following code:

```

output "resource_group_name" {
  value = azurerm_resource_group.rg.name
}

output "public_ip_address" {
  value = azurerm_linux_virtual_machine.my_terraform_vm.public_ip_address
}

output "tls_private_key" {
  value      = tls_private_key.example_ssh.private_key_pem
  sensitive = true
}

```

## Initialize Terraform

Run `terraform init` to initialize the Terraform deployment. This command downloads the Azure modules required to manage your Azure resources.

```
terraform init
```

## Create a Terraform execution plan

Run [terraform plan](#) to create an execution plan.

```
terraform plan -out main.tfplan
```

#### Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.
- To read more about persisting execution plans and security, see the [security warning section](#).

## Apply a Terraform execution plan

Run [terraform apply](#) to apply the execution plan to your cloud infrastructure.

```
terraform apply main.tfplan
```

#### Key points:

- The `terraform apply` command above assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

## Verify the results

To use SSH to connect to the virtual machine, do the following steps:

1. Run [terraform output](#) to get the SSH private key and save it to a file.

```
terraform output -raw tls_private_key > id_rsa
```

2. Run [terraform output](#) to get the virtual machine public IP address.

```
terraform output public_ip_address
```

3. Use SSH to connect to the virtual machine.

```
ssh -i id_rsa azureuser@<public_ip_address>
```

#### Key points:

- Depending on the permissions of your environment, you might get an error when trying to ssh into the virtual machine using the `id_rsa` key file. If you get an error stating that the private key file is unprotected and can't be used, try running the following command: `chmod 600 id_rsa`, which will restrict read and write access to the owner of the file.

## Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run `terraform plan` and specify the `-destroy` flag.

```
terraform plan -destroy -out main.destroy.tfplan
```

#### Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.
- To read more about persisting execution plans and security, see the [security warning section](#).

2. Run `terraform apply` to apply the execution plan.

```
terraform apply main.destroy.tfplan
```

## Troubleshoot Terraform on Azure

[Troubleshoot common problems when using Terraform on Azure](#)

## Next steps

In this quickstart, you deployed a simple virtual machine using Terraform. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Create an Ubuntu Linux virtual machine using a Bicep file

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This quickstart shows you how to use a Bicep file to deploy an Ubuntu Linux virtual machine (VM) in Azure.

**Bicep** is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

## Prerequisites

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Review the Bicep file

The Bicep file used in this quickstart is from [Azure Quickstart Templates](#).

```
@description('The name of your Virtual Machine.')
param vmName string = 'simpleLinuxVM'

@description('Username for the Virtual Machine.')
param adminUsername string

@description('Type of authentication to use on the Virtual Machine. SSH key is recommended.')
@allowed([
    'sshPublicKey'
    'password'
])
param authenticationType string = 'password'

@description('SSH Key or password for the Virtual Machine. SSH key is recommended.')
@secure()
param adminPasswordOrKey string

@description('Unique DNS Name for the Public IP used to access the Virtual Machine.')
param dnsLabelPrefix string = toLower('${vmName}-${uniqueString(resourceGroup().id)}')

@description('The Ubuntu version for the VM. This will pick a fully patched image of this given Ubuntu
version.')
@allowed([
    '12.04.5-LTS'
    '14.04.5-LTS'
    '16.04.0-LTS'
    '18.04-LTS'
])
param ubuntuOSVersion string = '18.04-LTS'

@description('Location for all resources.')
param location string = resourceGroup().location

@description('The size of the VM')
param vmSize string = 'Standard_B2s'

@description('Name of the VNET')
param virtualNetworkName string = 'vNet'
```

```

@description('Name of the subnet in the virtual network')
param subnetName string = 'Subnet'

@description('Name of the Network Security Group')
param networkSecurityGroupName string = 'SecGroupNet'

var publicIPAddressName = '${vmName}PublicIP'
var networkInterfaceName = '${vmName}NetInt'
var osDiskType = 'Standard_LRS'
var subnetAddressPrefix = '10.1.0.0/24'
var addressPrefix = '10.1.0.0/16'
var linuxConfiguration = {
    disablePasswordAuthentication: true
    ssh: [
        {
            publicKeys: [
                {
                    path: '/home/${adminUsername}/.ssh/authorized_keys'
                    keyData: adminPasswordOrKey
                }
            ]
        }
    ]
}

resource nic 'Microsoft.Network/networkInterfaces@2021-05-01' = {

                properties: {
                    priority: 1000
                    protocol: 'Tcp'
                    access: 'Allow'
                    direction: 'Inbound'
                    sourceAddressPrefix: '*'
                    sourcePortRange: '*'
                    destinationAddressPrefix: '*'
                    destinationPortRange: '22'
                }
            }
        ]
    }
}

```

```

resource vnet 'Microsoft.Network/virtualNetworks@2021-05-01' = {
  name: virtualNetworkName
  location: location
  properties: {
    addressSpace: {
      addressPrefixes: [
        addressPrefix
      ]
    }
  }
}

resource subnet 'Microsoft.Network/virtualNetworks/subnets@2021-05-01' = {
  parent: vnet
  name: subnetName
  properties: {
    addressPrefix: subnetAddressPrefix
    privateEndpointNetworkPolicies: 'Enabled'
    privateLinkServiceNetworkPolicies: 'Enabled'
  }
}

resource publicIP 'Microsoft.Network/publicIPAddresses@2021-05-01' = {
  name: publicIPAddressName
  location: location
  sku: {
    name: 'Basic'
  }
  properties: {
    publicIPAllocationMethod: 'Dynamic'
    publicIPAddressVersion: 'IPv4'
    dnsSettings: {
      domainNameLabel: dnsLabelPrefix
    }
    idleTimeoutInMinutes: 4
  }
}

resource vm 'Microsoft.Compute/virtualMachines@2021-11-01' = {
  name: vmName
  location: location
  properties: {
    hardwareProfile: {
      vmSize: vmSize
    }
    storageProfile: {
      osDisk: {
        createOption: 'FromImage'
        managedDisk: {
          storageAccountType: osDiskType
        }
      }
      imageReference: {
        publisher: 'Canonical'
        offer: 'UbuntuServer'
        sku: ubuntuOSVersion
        version: 'latest'
      }
    }
    networkProfile: {
      networkInterfaces: [
        {
          id: nic.id
        }
      ]
    }
    osProfile: {
      computerName: vmName
    }
  }
}

```

```

        adminUsername: adminUsername
        adminPassword: adminPasswordOrKey
        linuxConfiguration: ((authenticationType == 'password') ? null : linuxConfiguration)
    }
}

output adminUsername string = adminUsername
output hostname string = publicIP.properties.dnsSettings.fqdn
output sshCommand string = 'ssh ${adminUsername}@${publicIP.properties.dnsSettings.fqdn}'

```

Several resources are defined in the Bicep file:

- [Microsoft.Network/virtualNetworks/subnets](#): create a subnet.
- [Microsoft.Storage/storageAccounts](#): create a storage account.
- [Microsoft.Network/networkInterfaces](#): create a NIC.
- [Microsoft.Network/networkSecurityGroups](#): create a network security group.
- [Microsoft.Network/virtualNetworks](#): create a virtual network.
- [Microsoft.Network/publicIPAddresses](#): create a public IP address.
- [Microsoft.Compute/virtualMachines](#): create a virtual machine.

## Deploy the Bicep file

1. Save the Bicep file as `main.bicep` to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.

- [CLI](#)
- [PowerShell](#)

```

az group create --name exampleRG --location eastus

az deployment group create --resource-group exampleRG --template-file main.bicep --parameters
adminUsername=<admin-username>

```

### NOTE

Replace `<admin-username>` with a unique username. You'll also be prompted to enter `adminPasswordOrKey`.

When the deployment finishes, you should see a message indicating the deployment succeeded.

## Review deployed resources

Use the Azure portal, Azure CLI, or Azure PowerShell to list the deployed resources in the resource group.

- [CLI](#)
- [PowerShell](#)

```

az resource list --resource-group exampleRG

```

## Clean up resources

When no longer needed, use the Azure portal, Azure CLI, or Azure PowerShell to delete the VM and all of the

resources in the resource group.

- [CLI](#)
- [PowerShell](#)

```
az group delete --name exampleRG
```

## Next steps

In this quickstart, you deployed a simple virtual machine using a Bicep file. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Create an Ubuntu Linux virtual machine using an ARM template

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This quickstart shows you how to use an Azure Resource Manager template (ARM template) to deploy an Ubuntu Linux virtual machine (VM) in Azure.

An [ARM template](#) is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

 Deploy to Azure

## Prerequisites

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Review the template

The template used in this quickstart is from [Azure Quickstart Templates](#).

    "sshCommand": {
        "type": "string",
        "value": "[format('ssh {0}@{1}', parameters('adminUsername'),
reference(resourceId('Microsoft.Network/publicIPAddresses',
variables('publicIPAddressName'))).dnsSettings.fqdn)]"
    }
}
}

```

Several resources are defined in the template:

- **Microsoft.Network/virtualNetworks/subnets**: create a subnet.
- **Microsoft.Storage/storageAccounts**: create a storage account.
- **Microsoft.Network/networkInterfaces**: create a NIC.
- **Microsoft.Network/networkSecurityGroups**: create a network security group.
- **Microsoft.Network/virtualNetworks**: create a virtual network.
- **Microsoft.Network/publicIPAddresses**: create a public IP address.
- **Microsoft.Compute/virtualMachines**: create a virtual machine.

## Deploy the template

1. Select the following image to sign in to Azure and open a template. The template creates a key vault and a secret.

2. Select or enter the following values. Use the default values, when available.

- **Subscription:** select an Azure subscription.
- **Resource group:** select an existing resource group from the drop-down, or select **Create new**, enter a unique name for the resource group, and then click **OK**.
- **Location:** select a location. For example, **Central US**.
- **Admin username:** provide a username, such as *azureuser*.
- **Authentication type:** You can choose between using an SSH key or a password.
- **Admin Password Or Key** depending on what you choose for authentication type:
  - If you choose **password**, the password must be at least 12 characters long and meet the [defined complexity requirements](#).
  - If you choose **sshPublicKey**, paste in the contents of your public key.
- **DNS label prefix:** enter a unique identifier to use as part of the DNS label.
- **Ubuntu OS version:** select which version of Ubuntu you want to run on the VM.
- **Location:** the default is the same location as the resource group, if it already exists.
- **VM size:** select the [size](#) to use for the VM.
- **Virtual Network Name:** name to be used for the vNet.
- **Subnet Name:** name for the subnet the VM should use.
- **Network Security Group Name:** name for the NSG.

3. Select **Review + create**. After validation completes, select **Create** to create and deploy the VM.

The Azure portal is used to deploy the template. In addition to the Azure portal, you can also use the Azure CLI, Azure PowerShell, and REST API. To learn other deployment methods, see [Deploy templates](#).

## Review deployed resources

You can use the Azure portal to check on the VM and other resource that were created. After the deployment is finished, select **Go to resource group** to see the VM and other resources.

## Clean up resources

When no longer needed, delete the resource group, which deletes the VM and all of the resources in the resource group.

1. Select the **Resource group**.
2. On the page for the resource group, select **Delete**.
3. When prompted, type the name of the resource group and then select **Delete**.

## Next steps

In this quickstart, you deployed a simple virtual machine using an ARM template. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Linux virtual machine tutorials](#)

# Quickstart: Create a Windows virtual machine with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to deploy a virtual machine (VM) in Azure that runs Windows Server 2019. To see your VM in action, you then RDP to the VM and install the IIS web server.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/bash>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

## Create a resource group

Create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name myResourceGroup --location eastus
```

## Create virtual machine

Create a VM with [az vm create](#). The following example creates a VM named *myVM*. This example uses *azureuser* for an administrative user name.

You will need to supply a password that meets the [password requirements for Azure VMs](#).

Using the example below, you will be prompted to enter a password at the command line. You could also add the the `--admin-password` parameter with a value for your password. The user name and password will be used later, when you connect to the VM.

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image Win2022AzureEditionCore \
  --public-ip-sku Standard \
  --admin-username azureuser
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

```
{  
  "fqdns": "",  
  "id":  
    "/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",  
  "location": "eastus",  
  "macAddress": "00-0D-3A-23-9A-49",  
  "powerState": "VM running",  
  "privateIpAddress": "10.0.0.4",  
  "publicIpAddress": "52.174.34.95",  
  "resourceGroup": "myResourceGroup"  
}
```

Note your own `publicIpAddress` in the output from your VM. This address is used to access the VM in the next steps.

## Install web server

To see your VM in action, install the IIS web server.

```
az vm run-command invoke -g MyResourceGroup -n MyVm --command-id RunPowerShellScript --scripts "Install-WindowsFeature -name Web-Server -IncludeManagementTools"
```

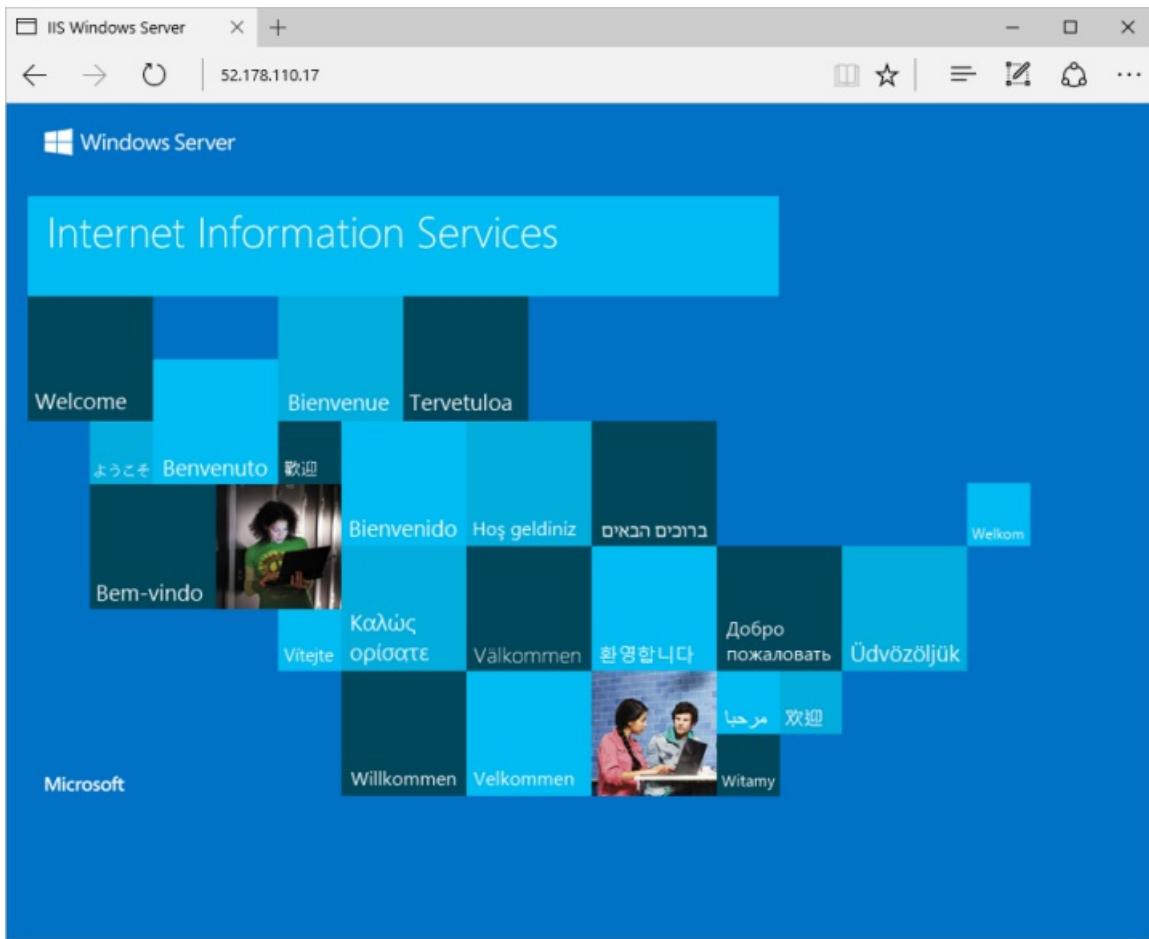

## Open port 80 for web traffic

By default, only RDP connections are opened when you create a Windows VM in Azure. Use `az vm open-port` to open TCP port 80 for use with the IIS web server:

```
az vm open-port --port 80 --resource-group myResourceGroup --name myVM
```

## View the web server in action

With IIS installed and port 80 now open on your VM from the Internet, use a web browser of your choice to view the default IIS welcome page. Use the public IP address of your VM obtained in a previous step. The following example shows the default IIS web site:

## Clean up resources

When no longer needed, you can use the [az group delete](#) command to remove the resource group, VM, and all related resources:

```
az group delete --name myResourceGroup
```

## Next steps

In this quickstart, you deployed a simple virtual machine, open a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Windows VMs.

[Azure Windows virtual machine tutorials](#)

# Quickstart: Create a Windows virtual machine in the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Azure virtual machines (VMs) can be created through the Azure portal. This method provides a browser-based user interface to create VMs and their associated resources. This quickstart shows you how to use the Azure portal to deploy a virtual machine (VM) in Azure that runs Windows Server 2019. To see your VM in action, you then RDP to the VM and install the IIS web server.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Sign in to Azure

Sign in to the Azure portal at <https://portal.azure.com>.

## Create virtual machine

1. Enter *virtual machines* in the search.
2. Under **Services**, select **Virtual machines**.
3. In the **Virtual machines** page, select **Create** and then **Azure virtual machine**. The **Create a virtual machine** page opens.
4. Under **Instance details**, enter *myVM* for the **Virtual machine name** and choose **Windows Server 2019 Datacenter - Gen 2** for the **Image**. Leave the other defaults.

Instance details

Virtual machine name *	myVM
Region *	(US) West US
Availability options	No infrastructure redundancy required
Security type	Standard
Image *	<input checked="" type="checkbox"/> Windows Server 2019 Datacenter - Gen2 <a href="#">See all images</a>   <a href="#">Configure VM generation</a>
VM architecture	<input type="radio"/> Arm64 <input checked="" type="radio"/> x64  <small>ⓘ Arm64 is not supported with the selected image.</small>

### NOTE

Some users will now see the option to create VMs in multiple zones. To learn more about this new capability, see [Create virtual machines in an availability zone](#).

Availability zone *	Zones 1
<small>⚡ You can now select multiple zones. Selecting multiple zones will create one VM per zone.</small>	

5. Under **Administrator account**, provide a username, such as *azureuser* and a password. The password must be at least 12 characters long and meet the [defined complexity requirements](#).

Administrator account

Username * ⓘ	azureuser	✓
Password * ⓘ	*****	✓
Confirm password * ⓘ	*****	✓

6. Under **Inbound port rules**, choose **Allow selected ports** and then select **RDP (3389)** and **HTTP (80)** from the drop-down.

**Inbound port rules**

Select which virtual machine network ports are accessible from the public internet. You can specify more limited or granular network access on the Networking tab.

Public inbound ports \* ⓘ

None  
 Allow selected ports

Select inbound ports \*

RDP (3389) ▾

**⚠ This will allow all IP addresses to access your virtual machine.** This is only recommended for testing. Use the Advanced controls in the Networking tab to create rules to limit inbound traffic to known IP addresses.

7. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.

**Licensing**

Save up to 49% with a license you already own using Azure Hybrid Benefit. [Learn more ↗](#)

Would you like to use an existing Windows Server license? \* ⓘ

[Review Azure hybrid benefit compliance](#)

**Review + create**

< Previous

Next : Disks >

8. After validation runs, select the **Create** button at the bottom of the page.

## Create a virtual machine

Validation passed

### Basics

Subscription	myAzureSubscription
Resource group	(new) myVM_group_08290738
Virtual machine name	myVM
Region	East US
Availability options	No infrastructure redundancy required
Security type	Standard
Image	Windows Server 2022 Datacenter: Azure Edition - Gen2
VM architecture	x64
Size	Standard D2s v3 (2 vcpus, 8 GiB memory)
Username	azureuser
Public inbound ports	RDP

Already have a Windows license?  No

**Create**

< Previous

Next >

Download a template for automation

- After deployment is complete, select **Go to resource**.

### Next steps

- [Setup auto-shutdown](#) Recommended
- [Monitor VM health, performance and network dependencies](#) Recommended
- [Run a script inside the virtual machine](#) Recommended

**Go to resource**

[Create another VM](#)

## Connect to virtual machine

Create a remote desktop connection to the virtual machine. These directions tell you how to connect to your VM from a Windows computer. On a Mac, you need an RDP client such as this [Remote Desktop Client](#) from the Mac App Store.

- On the overview page for your virtual machine, select the **Connect > RDP**.

The screenshot shows the Azure portal interface for a virtual machine named 'myVM'. At the top, there's a navigation bar with 'Home > myVM'. Below it is a card for 'myVM' with a 'Virtual machine' icon. A search bar labeled 'Search (Ctrl+ /)' is on the left. To its right is a 'Connect' button, which is highlighted with a red box. Other buttons in the top row include 'Start', 'Restart', 'Stop', 'Capture', 'Delete', and 'Refresh'. Below the search bar is a 'Overview' section with tabs for 'Overview' and 'Activity log'. The 'Overview' tab is selected. It displays the following details: Resource group: myResourceGroup (with a 'Change' link), Status: Running, and Location: East US.

- In the **Connect with RDP** tab, keep the default options to connect by IP address, over port 3389, and click **Download RDP file**.

## Connect with RDP

✓ Suggested method for connecting

To connect to your virtual machine via RDP, select an IP address, optionally change the port number, and download the RDP file.

IP address \*

Public IP address (192.168.1.253)

Port number \*

3389

**Download RDP File**

3. Open the downloaded RDP file and click **Connect** when prompted.
4. In the **Windows Security** window, select **More choices** and then **Use a different account**. Type the username as `localhost\username`, enter the password you created for the virtual machine, and then click **OK**.
5. You may receive a certificate warning during the sign-in process. Click **Yes** or **Continue** to create the connection.

## Install web server

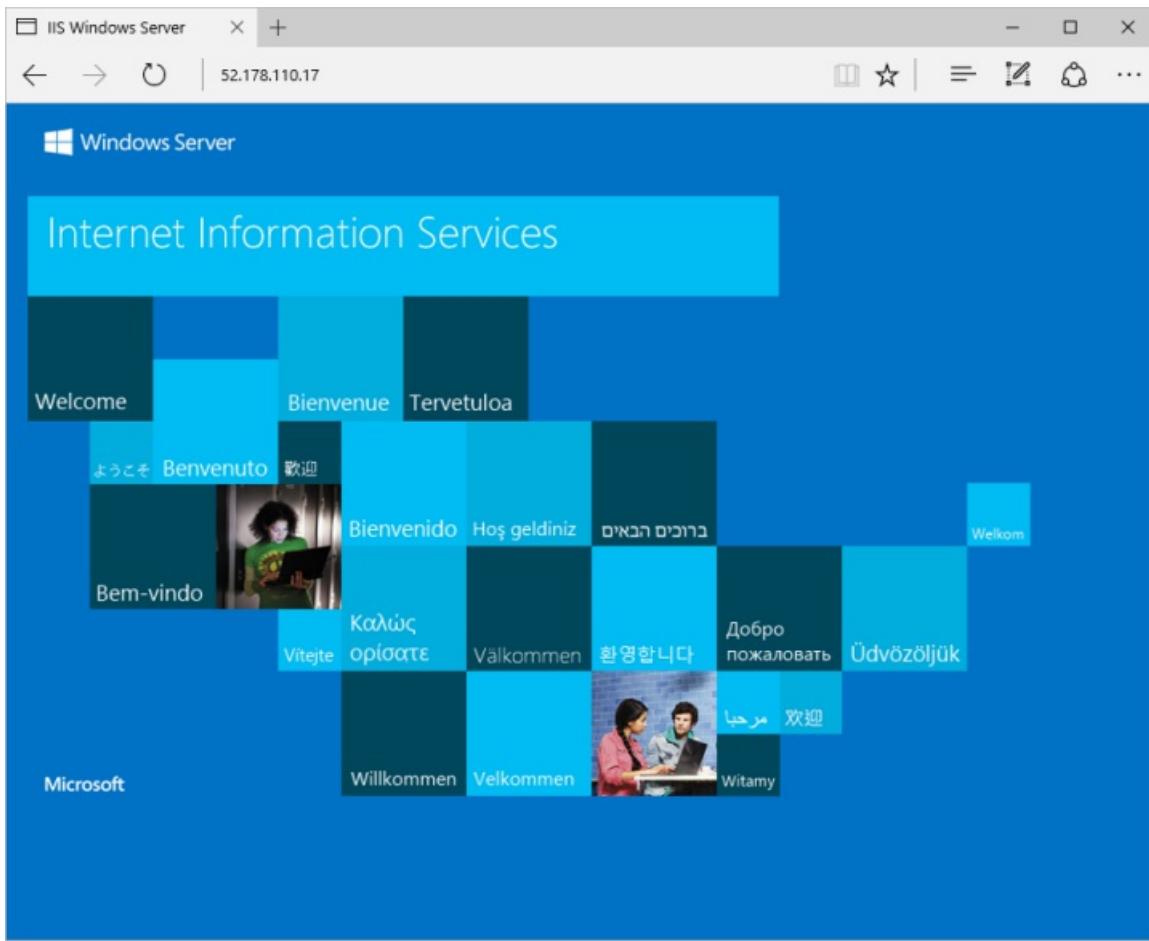

To see your VM in action, install the IIS web server. Open a PowerShell prompt on the VM and run the following command:

```
Install-WindowsFeature -name Web-Server -IncludeManagementTools
```

When done, close the RDP connection to the VM.

## View the IIS welcome page

In the portal, select the VM and in the overview of the VM, hover over the IP address to show **Copy to clipboard**. Copy the IP address and paste it into a browser tab. The default IIS welcome page will open, and should look like this:

## Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources.

1. On the Overview page for the VM, select the **Resource group** link.
2. At the top of the page for the resource group, select **Delete resource group**.
3. A page will open warning you that you are about to delete resources. Type the name of the resource group and select **Delete** to finish deleting the resources and the resource group.

## Next steps

In this quickstart, you deployed a simple virtual machine, opened a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Windows VMs.

[Azure Windows virtual machine tutorials](#)

# Quickstart: Create a Windows virtual machine in Azure with PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to deploy a virtual machine (VM) in Azure that runs Windows Server 2016. You will also RDP to the VM and install the IIS web server, to show the VM in action.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create resource group

Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which Azure resources are deployed and managed.

```
New-AzResourceGroup -Name 'myResourceGroup' -Location 'EastUS'
```

## Create virtual machine

Create a VM with [New-AzVm](#). Provide names for each of the resources and the `New-AzVm` cmdlet creates if they don't already exist.

When prompted, provide a username and password to be used as the sign-in credentials for the VM:

```
New-AzVm ` 
-ResourceGroupName 'myResourceGroup' ` 
-Name 'myVM' ` 
-Location 'East US' ` 
-VirtualNetworkName 'myVnet' ` 
-SubnetName 'mySubnet' ` 
-SecurityGroupName 'myNetworkSecurityGroup' ` 
-PublicIpAddressName 'myPublicIpAddress' ` 
-OpenPorts 80,3389
```

## Install web server

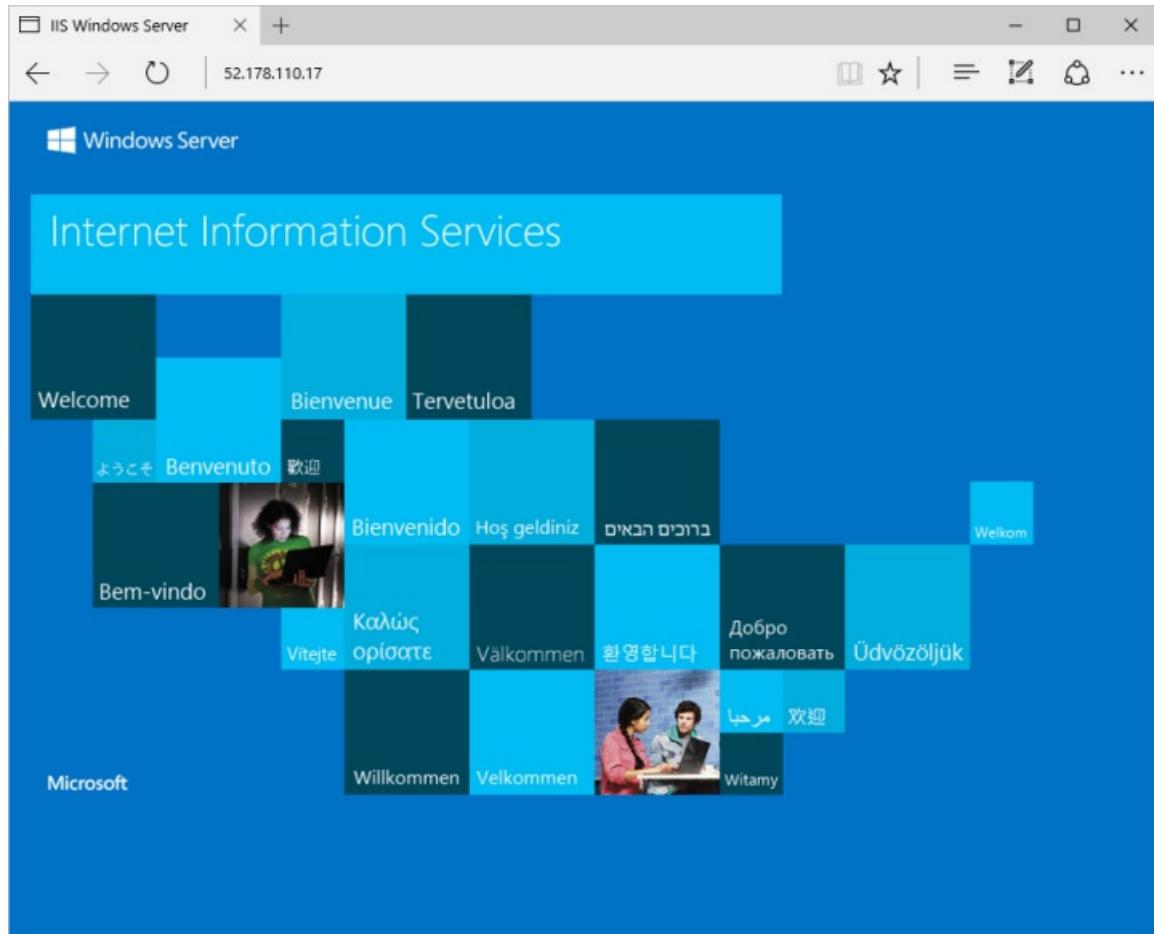

To see your VM in action, install the IIS web server. Open a PowerShell prompt on the VM and run the following command:

```
Invoke-AzVMRunCommand -ResourceGroupName 'myResourceGroup' -VMName 'myVM' -CommandId 'RunPowerShellScript' -  
ScriptString  
'Install-WindowsFeature -Name Web-Server -IncludeManagementTools'
```

The `-ScriptString` parameter requires version `4.27.0` or later of the `Az.Compute` module.

## View the web server in action

With IIS installed and port 80 now open on your VM from the Internet, use a web browser of your choice to view the default IIS welcome page. Use the public IP address of your VM obtained in a previous step. The following example shows the default IIS web site:

## Clean up resources

When no longer needed, you can use the [Remove-AzResourceGroup](#) cmdlet to remove the resource group, VM, and all related resources:

```
Remove-AzResourceGroup -Name 'myResourceGroup'
```

## Next steps

In this quickstart, you deployed a simple virtual machine, opened a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Windows VMs.

[Azure Windows virtual machine tutorials](#)

# Quickstart: Create a Windows virtual machine using a Bicep file

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This quickstart shows you how to use a Bicep file to deploy a Windows virtual machine (VM) in Azure.

[Bicep](#) is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

## Prerequisites

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Review the Bicep file

The Bicep file used in this quickstart is from [Azure Quickstart Templates](#).

```
@description('Username for the Virtual Machine.')
param adminUsername string

@description('Password for the Virtual Machine.')
@param minLength(12)
@secure()
param adminPassword string

@description('Unique DNS Name for the Public IP used to access the Virtual Machine.')

  }
}

```

```
        }
    }
}

output hostname string = pip.properties.dnsSettings.fqdn
```

Several resources are defined in the Bicep file:

- [Microsoft.Network/virtualNetworks/subnets](#): create a subnet.
- [Microsoft.Storage/storageAccounts](#): create a storage account.
- [Microsoft.Network/publicIPAddresses](#): create a public IP address.
- [Microsoft.Network/networkSecurityGroups](#): create a network security group.
- [Microsoft.Network/virtualNetworks](#): create a virtual network.
- [Microsoft.Network/networkInterfaces](#): create a NIC.
- [Microsoft.Compute/virtualMachines](#): create a virtual machine.

## Deploy the Bicep file

1. Save the Bicep file as **main.bicep** to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.
  - [CLI](#)
  - [PowerShell](#)

```
az group create --name exampleRG --location eastus
az deployment group create --resource-group exampleRG --template-file main.bicep --parameters
adminUsername=<admin-username>
```

### NOTE

Replace <**admin-username**> with a unique username. You'll also be prompted to enter adminPassword. The minimum password length is 12 characters.

When the deployment finishes, you should see a message indicating the deployment succeeded.

## Review deployed resources

Use the Azure portal, Azure CLI, or Azure PowerShell to list the deployed resources in the resource group.

- [CLI](#)
- [PowerShell](#)

```
az resource list --resource-group exampleRG
```

## Clean up resources

When no longer needed, use the Azure portal, Azure CLI, or Azure PowerShell to delete the VM and all of the resources in the resource group.

- [CLI](#)

- [PowerShell](#)

```
az group delete --name exampleRG
```

## Next steps

In this quickstart, you deployed a simple virtual machine using a Bicep file. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Windows virtual machine tutorials](#)

# Quickstart: Create a Windows virtual machine using an ARM template

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This quickstart shows you how to use an Azure Resource Manager template (ARM template) to deploy a Windows virtual machine (VM) in Azure.

An [ARM template](#) is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

 Deploy to Azure

## Prerequisites

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Review the template

The template used in this quickstart is from [Azure Quickstart Templates](#).

        "value": "[reference(resourceId('Microsoft.Network/publicIPAddresses',
parameters('publicIpName'))).dnsSettings.fqdn]"
    }
}
}

```

Several resources are defined in the template:

- **Microsoft.Network/virtualNetworks/subnets**: create a subnet.
- **Microsoft.Storage/storageAccounts**: create a storage account.
- **Microsoft.Network/publicIPAddresses**: create a public IP address.
- **Microsoft.Network/networkSecurityGroups**: create a network security group.
- **Microsoft.Network/virtualNetworks**: create a virtual network.
- **Microsoft.Network/networkInterfaces**: create a NIC.
- **Microsoft.Compute/virtualMachines**: create a virtual machine.

## Deploy the template

1. Select the following image to sign in to Azure and open a template. The template creates a key vault and a secret.

2. Select or enter the following values. Use the default values, when available.

- **Subscription**: select an Azure subscription.
- **Resource group**: select an existing resource group from the drop-down, or select **Create new**, enter a unique name for the resource group, and then click **OK**.
- **Location**: select a location. For example, **Central US**.
- **Admin username**: provide a username, such as *azureuser*.
- **Admin password**: provide a password to use for the admin account. The password must be at least 12 characters long and meet the **defined complexity requirements**.
- **DNS label prefix**: enter a unique identifier to use as part of the DNS label.
- **Windows OS version**: select which version of Windows you want to run on the VM.
- **VM size**: select the **size** to use for the VM.
- **Location**: the default is the same location as the resource group, if it already exists.

3. Select **Review + create**. After validation completes, select **Create** to create and deploy the VM.

The Azure portal is used to deploy the template. In addition to the Azure portal, you can also use the Azure PowerShell, Azure CLI, and REST API. To learn other deployment methods, see [Deploy templates](#).

## Review deployed resources

You can use the Azure portal to check on the VM and other resource that were created. After the deployment is finished, select **Go to resource group** to see the VM and other resources.

## Clean up resources

When no longer needed, delete the resource group, which deletes the VM and all of the resources in the resource group.

1. Select the **Resource group**.
2. On the page for the resource group, select **Delete**.
3. When prompted, type the name of the resource group and then select **Delete**.

## Next steps

In this quickstart, you deployed a simple virtual machine using an ARM template. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

[Azure Windows virtual machine tutorials](#)

# Tutorial: Create and Manage Linux VMs with the Azure CLI

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure virtual machines provide a fully configurable and flexible computing environment. This tutorial covers basic Azure virtual machine deployment items such as selecting a VM size, selecting a VM image, and deploying a VM. You learn how to:

- Create and connect to a VM
- Select and use VM images
- View and use specific VM sizes
- Resize a VM
- View and understand VM state

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create resource group

Create a resource group with the `az group create` command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In this example, a resource group named `myResourceGroupVM` is created in the `eastus` region.

```
az group create --name myResourceGroupVM --location eastus
```

The resource group is specified when creating or modifying a VM, which can be seen throughout this tutorial.

## Create virtual machine

Create a virtual machine with the `az vm create` command.

When you create a virtual machine, several options are available such as operating system image, disk sizing, and administrative credentials. The following example creates a VM named `myVM` that runs Ubuntu Server. A user account named `azureuser` is created on the VM, and SSH keys are generated if they do not exist in the default key location (`~/.ssh`):

```
az vm create \
  --resource-group myResourceGroupVM \
  --name myVM \
  --image UbuntuLTS \
  --admin-username azureuser \
  --generate-ssh-keys
```

It may take a few minutes to create the VM. Once the VM has been created, the Azure CLI outputs information about the VM. Take note of the `publicIpAddress`, this address can be used to access the virtual machine..

```
{  
    "fqdns": "",  
    "id": "/subscriptions/d5b9d4b7-6fc1-0000-0000-  
000000000000/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/virtualMachines/myVM",  
    "location": "eastus",  
    "macAddress": "00-0D-3A-23-9A-49",  
    "powerState": "VM running",  
    "privateIpAddress": "10.0.0.4",  
    "publicIpAddress": "52.174.34.95",  
    "resourceGroup": "myResourceGroupVM"  
}
```

## Connect to VM

You can now connect to the VM with SSH in the Azure Cloud Shell or from your local computer. Replace the example IP address with the `publicIpAddress` noted in the previous step.

```
ssh azureuser@52.174.34.95
```

Once logged in to the VM, you can install and configure applications. When you are finished, you close the SSH session as normal:

```
exit
```

## Understand VM images

The Azure marketplace includes many images that can be used to create VMs. In the previous steps, a virtual machine was created using an Ubuntu image. In this step, the Azure CLI is used to search the marketplace for a CentOS image, which is then used to deploy a second virtual machine.

To see a list of the most commonly used images, use the [az vm image list](#) command.

```
az vm image list --output table
```

The command output returns the most popular VM images on Azure.

openSUSE-Leap	SUSE	42.2	SUSE:openSUSE-Leap:42.2:latest
openSUSE-Leap		latest	
RHEL	RedHat	7.3	RedHat:RHEL:7.3:latest
RHEL		latest	
SLES	SUSE	12-SP2	SUSE:SLES:12-SP2:latest
SLES		latest	
Debian	credativ	8	credativ:Debian:8:latest
Debian		latest	
CoreOS	CoreOS	Stable	CoreOS:CoreOS:Stable:latest
CoreOS		latest	

A full list can be seen by adding the `--all` parameter. The image list can also be filtered by `--publisher` or `--offer`. In this example, the list is filtered for all images with an offer that matches *CentOS*.

```
az vm image list --offer CentOS --all --output table
```

Partial output:

Offer	Publisher	Sku	Urn	Version
CentOS	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.201501	6.5.201501
Centos	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.201503	6.5.201503
Centos	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.201506	6.5.201506
Centos	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.20150904	6.5.20150904
Centos	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.20160309	6.5.20160309
CentOS	OpenLogic	6.5	OpenLogic:CentOS:6.5:6.5.20170207	6.5.20170207

To deploy a VM using a specific image, take note of the value in the *Urn* column, which consists of the publisher, offer, SKU, and optionally a version number to [identify](#) the image. When specifying the image, the image version number can be replaced with `latest`, which selects the latest version of the distribution. In this example, the `--image` parameter is used to specify the latest version of a CentOS 6.5 image.

```
az vm create --resource-group myResourceGroupVM --name myVM2 --image OpenLogic:CentOS:6.5:latest --generate-ssh-keys
```

## Understand VM sizes

A virtual machine size determines the amount of compute resources such as CPU, GPU, and memory that are made available to the virtual machine. Virtual machines need to be sized appropriately for the expected work load. If workload increases, an existing virtual machine can be resized.

### VM Sizes

The following table categorizes sizes into use cases.

TYPE	COMMON SIZES	DESCRIPTION
General purpose	B, Dsv3, Dv3, DSv2, Dv2, Av2, DC	Balanced CPU-to-memory. Ideal for dev / test and small to medium applications and data solutions.
Compute optimized	Fsv2	High CPU-to-memory. Good for medium traffic applications, network appliances, and batch processes.
Memory optimized	Esv3, Ev3, M, DSv2, Dv2	High memory-to-core. Great for relational databases, medium to large caches, and in-memory analytics.
Storage optimized	Lsv2, Ls	High disk throughput and IO. Ideal for Big Data, SQL, and NoSQL databases.
GPU	NV, NVv2, NC, NCv2, NCv3, ND	Specialized VMs targeted for heavy graphic rendering and video editing.
High performance	H	Our most powerful CPU VMs with optional high-throughput network interfaces (RDMA).

## Find available VM sizes

To see a list of VM sizes available in a particular region, use the [az vm list-sizes](#) command.

```
az vm list-sizes --location eastus --output table
```

Partial output:

ResourceDiskSizeInMb	MaxDataDiskCount	MemoryInMb	Name	NumberofCores	OsDiskSizeInMb
7168	2	3584	Standard_DS1	1	1047552
14336	4	7168	Standard_DS2	2	1047552
28672	8	14336	Standard_DS3	4	1047552
57344	16	28672	Standard_DS4	8	1047552
28672	4	14336	Standard_DS11	2	1047552
57344	8	28672	Standard_DS12	4	1047552
114688	16	57344	Standard_DS13	8	1047552
229376	32	114688	Standard_DS14	16	1047552
20480	1	768	Standard_A0	1	1047552
71680	2	1792	Standard_A1	1	1047552
138240	4	3584	Standard_A2	2	1047552
291840	8	7168	Standard_A3	4	1047552
138240	4	14336	Standard_A5	2	1047552
619520	16	14336	Standard_A4	8	1047552
291840	8	28672	Standard_A6	4	1047552
619520	16	57344	Standard_A7	8	1047552

## Create VM with specific size

In the previous VM creation example, a size was not provided, which results in a default size. A VM size can be selected at creation time using `az vm create` and the `--size` parameter.

```
az vm create \
    --resource-group myResourceGroupVM \
    --name myVM3 \
    --image UbuntuLTS \
    --size Standard_F4s \
    --generate-ssh-keys
```

## Resize a VM

After a VM has been deployed, it can be resized to increase or decrease resource allocation. You can view the current size of a VM with `az vm show`:

```
az vm show --resource-group myResourceGroupVM --name myVM --query hardwareProfile.vmSize
```

Before resizing a VM, check if the desired size is available on the current Azure cluster. The `az vm list-vm-resize-options` command returns the list of sizes.

```
az vm list-vm-resize-options --resource-group myResourceGroupVM --name myVM --query [].name
```

If the desired size is available, the VM can be resized from a powered-on state, however it is rebooted during the operation. Use the [az vm resize](#) command to perform the resize.

```
az vm resize --resource-group myResourceGroupVM --name myVM --size Standard_DS4_v2
```

If the desired size is not on the current cluster, the VM needs to be deallocated before the resize operation can occur. Use the [az vm deallocate](#) command to stop and deallocate the VM. Note, when the VM is powered back on, any data on the temp disk may be removed. The public IP address also changes unless a static IP address is being used.

```
az vm deallocate --resource-group myResourceGroupVM --name myVM
```

Once deallocated, the resize can occur.

```
az vm resize --resource-group myResourceGroupVM --name myVM --size Standard_GS1
```

After the resize, the VM can be started.

```
az vm start --resource-group myResourceGroupVM --name myVM
```

## VM power states

An Azure VM can have one of many power states. This state represents the current state of the VM from the standpoint of the hypervisor.

### Power states

POWER STATE	DESCRIPTION
Starting	Indicates the virtual machine is being started.
Running	Indicates that the virtual machine is running.
Stopping	Indicates that the virtual machine is being stopped.
Stopped	Indicates that the virtual machine is stopped. Virtual machines in the stopped state still incur compute charges.
Deallocating	Indicates that the virtual machine is being deallocated.
Deallocated	Indicates that the virtual machine is removed from the hypervisor but still available in the control plane. Virtual machines in the Deallocated state do not incur compute charges.
-	Indicates that the power state of the virtual machine is unknown.

### Find the power state

To retrieve the state of a particular VM, use the [az vm get-instance-view](#) command. Be sure to specify a valid name for a virtual machine and resource group.

```
az vm get-instance-view \
--name myVM \
--resource-group myResourceGroupVM \
--query instanceView.statuses[1] --output table
```

Output:

Code	DisplayStatus	Level
PowerState/running	VM running	Info

To retrieve the power state of all the VMs in your subscription, use the [Virtual Machines - List All API](#) with parameter `statusOnly` set to *true*.

## Management tasks

During the life-cycle of a virtual machine, you may want to run management tasks such as starting, stopping, or deleting a virtual machine. Additionally, you may want to create scripts to automate repetitive or complex tasks. Using the Azure CLI, many common management tasks can be run from the command line or in scripts.

### Get IP address

This command returns the private and public IP addresses of a virtual machine.

```
az vm list-ip-addresses --resource-group myResourceGroupVM --name myVM --output table
```

### Stop virtual machine

```
az vm stop --resource-group myResourceGroupVM --name myVM
```

### Start virtual machine

```
az vm start --resource-group myResourceGroupVM --name myVM
```

### Deleting VM resources

You can delete a VM, but by default this only deletes the VM resource, not the disks and networking resources the VM uses. You can change the default behavior to delete other resources when you delete the VM. For more information, see [Delete a VM and attached resources](#).

Deleting a resource group also deletes all resources contained within, such as the VM, virtual network, and disk. The `--no-wait` parameter returns control to the prompt without waiting for the operation to complete. The `--yes` parameter confirms that you wish to delete the resources without an additional prompt to do so.

```
az group delete --name myResourceGroupVM --no-wait --yes
```

## Next steps

In this tutorial, you learned about basic VM creation and management such as how to:

- Create and connect to a VM
- Select and use VM images
- View and use specific VM sizes

- Resize a VM
- View and understand VM state

Advance to the next tutorial to learn about VM disks.

[Create and Manage VM disks](#)

# Tutorial - Manage Azure disks with the Azure CLI

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure virtual machines (VMs) use disks to store the operating system, applications, and data. When you create a VM, it is important to choose a disk size and configuration appropriate to the expected workload. This tutorial shows you how to deploy and manage VM disks. You learn about:

- OS disks and temporary disks
- Data disks
- Standard and Premium disks
- Disk performance
- Attaching and preparing data disks
- Disk snapshots

## Default Azure disks

When an Azure virtual machine is created, two disks are automatically attached to the virtual machine.

**Operating system disk** - Operating system disks can be sized up to 2 TB, and hosts the VMs operating system. The OS disk is labeled `/dev/sda` by default. The disk caching configuration of the OS disk is optimized for OS performance. Because of this configuration, the OS disk **should not** be used for applications or data. For applications and data, use data disks, which are detailed later in this tutorial.

**Temporary disk** - Temporary disks use a solid-state drive that is located on the same Azure host as the VM. Temp disks are highly performant and may be used for operations such as temporary data processing. However, if the VM is moved to a new host, any data stored on a temporary disk is removed. The size of the temporary disk is determined by the VM size. Temporary disks are labeled `/dev/sdb` and have a mountpoint of `/mnt`.

## Azure data disks

To install applications and store data, additional data disks can be added. Data disks should be used in any situation where durable and responsive data storage is desired. The size of the virtual machine determines how many data disks can be attached to a VM.

## VM disk types

Azure provides two types of disks.

**Standard disks** - backed by HDDs, and delivers cost-effective storage while still being performant. Standard disks are ideal for a cost effective dev and test workload.

**Premium disks** - backed by SSD-based, high-performance, low-latency disk. Perfect for VMs running production workload. VM sizes with an S in the [size name](#), typically support Premium Storage. For example, DS-series, DSv2-series, GS-series, and FS-series VMs support premium storage. When you select a disk size, the value is rounded up to the next type. For example, if the disk size is more than 64 GB, but less than 128 GB, the disk type is P10.

PRE MIU M SSD SIZ ES	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
Eligi ble for rese rvat ion	No	No	No	No	No	No	No	No	Yes, up to one yea r	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year

\*Applies only to disks with on-demand bursting enabled.

When you provision a premium storage disk, unlike standard storage, you are guaranteed the capacity, IOPS, and throughput of that disk. For example, if you create a P50 disk, Azure provisions 4,095-GB storage capacity, 7,500 IOPS, and 250-MB/s throughput for that disk. Your application can use all or part of the capacity and performance. Premium SSD disks are designed to provide low single-digit millisecond latencies and target IOPS and throughput described in the preceding table 99.9% of the time.

While the above table identifies max IOPS per disk, a higher level of performance can be achieved by striping multiple data disks. For instance, 64 data disks can be attached to Standard\_GS5 VM. If each of these disks is sized as a P30, a maximum of 80,000 IOPS can be achieved. For detailed information on max IOPS per VM, see [VM types and sizes](#).

## Launch Azure Cloud Shell

Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open Cloud Shell, select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create and attach disks

Data disks can be created and attached at VM creation time or to an existing VM.

### Attach disk at VM creation

Create a resource group with the [az group create](#) command.

```
az group create --name myResourceGroupDisk --location eastus
```

Create a VM using the [az vm create](#) command. The following example creates a VM named *myVM*, adds a user account named *azureuser*, and generates SSH keys if they do not exist. The `--datadisk-sizes-gb` argument is used to specify that an additional disk should be created and attached to the virtual machine. To create and attach more than one disk, use a space-delimited list of disk size values. In the following example, a VM is created with two data disks, both 128 GB. Because the disk sizes are 128 GB, these disks are both configured as P10s, which provide maximum 500 IOPS per disk.

```
az vm create \
--resource-group myResourceGroupDisk \
--name myVM \
--image UbuntuLTS \
--size Standard_DS2_v2 \
--admin-username azureuser \
--generate-ssh-keys \
--data-disk-sizes-gb 128 128
```

## Attach disk to existing VM

To create and attach a new disk to an existing virtual machine, use the [az vm disk attach](#) command. The following example creates a premium disk, 128 gigabytes in size, and attaches it to the VM created in the last step.

```
az vm disk attach \
--resource-group myResourceGroupDisk \
--vm-name myVM \
--name myDataDisk \
--size-gb 128 \
--sku Premium_LRS \
--new
```

## Prepare data disks

Once a disk has been attached to the virtual machine, the operating system needs to be configured to use the disk. The following example shows how to manually configure a disk. This process can also be automated using cloud-init, which is covered in a [later tutorial](#).

Create an SSH connection with the virtual machine. Replace the example IP address with the public IP of the virtual machine.

```
ssh azureuser@10.101.10.10
```

Partition the disk with `parted`.

```
sudo parted /dev/sdc --script mklabel gpt mkpart xfspart xfs 0% 100%
```

Write a file system to the partition by using the `mkfs` command. Use `partprobe` to make the OS aware of the change.

```
sudo mkfs.xfs /dev/sdc1
sudo partprobe /dev/sdc1
```

Mount the new disk so that it is accessible in the operating system.

```
sudo mkdir /datadrive && sudo mount /dev/sdc1 /datadrive
```

The disk can now be accessed through the `/datadrive` mountpoint, which can be verified by running the `df -h` command.

```
df -h | grep -i "sd"
```

The output shows the new drive mounted on `/datadrive`.

Filesystem	Size	Used	Avail	Use%	Mounted on
<code>/dev/sda1</code>	29G	2.0G	27G	7%	/
<code>/dev/sda15</code>	105M	3.6M	101M	4%	/boot/efi
<code>/dev/sdb1</code>	14G	41M	13G	1%	/mnt
<code>/dev/sdc1</code>	50G	52M	47G	1%	/datadrive

To ensure that the drive is remounted after a reboot, it must be added to the `/etc/fstab` file. To do so, get the UUID of the disk with the `blkid` utility.

```
sudo -i blkid
```

The output displays the UUID of the drive, `/dev/sdc1` in this case.

```
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e" TYPE="xfs"
```

#### NOTE

Improperly editing the `/etc/fstab` file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the `/etc/fstab` file is created before editing.

Open the `/etc/fstab` file in a text editor as follows:

```
sudo nano /etc/fstab
```

Add a line similar to the following to the `/etc/fstab` file, replacing the UUID value with your own.

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e /datadrive xfs defaults,nofail 1 2
```

When you are done editing the file, use `Ctrl+O` to write the file and `Ctrl+X` to exit the editor.

Now that the disk has been configured, close the SSH session.

```
exit
```

## Take a disk snapshot

When you take a disk snapshot, Azure creates a read only, point-in-time copy of the disk. Azure VM snapshots are useful to quickly save the state of a VM before you make configuration changes. In the event of an issue or error, VM can be restored using a snapshot. When a VM has more than one disk, a snapshot is taken of each disk independently of the others. To take application consistent backups, consider stopping the VM before you take disk snapshots. Alternatively, use the [Azure Backup service](#), which enables you to perform automated backups while the VM is running.

### Create snapshot

Before you create a snapshot, you need the ID or name of the disk. Use `az vm show` to show the disk ID. In this example, the disk ID is stored in a variable so that it can be used in a later step.

```
osdiskid=$(az vm show \
-g myResourceGroupDisk \
-n myVM \
--query "storageProfile.osDisk.managedDisk.id" \
-o tsv)
```

Now that you have the ID, use [az snapshot create](#) to create a snapshot of the disk.

```
az snapshot create \
--resource-group myResourceGroupDisk \
--source "$osdiskid" \
--name osDisk-backup
```

## Create disk from snapshot

This snapshot can then be converted into a disk using [az disk create](#), which can be used to recreate the virtual machine.

```
az disk create \
--resource-group myResourceGroupDisk \
--name mySnapshotDisk \
--source osDisk-backup
```

## Restore virtual machine from snapshot

To demonstrate virtual machine recovery, delete the existing virtual machine using [az vm delete](#).

```
az vm delete \
--resource-group myResourceGroupDisk \
--name myVM
```

Create a new virtual machine from the snapshot disk.

```
az vm create \
--resource-group myResourceGroupDisk \
--name myVM \
--attach-os-disk mySnapshotDisk \
--os-type linux
```

## Reattach data disk

All data disks need to be reattached to the virtual machine.

Find the data disk name using the [az disk list](#) command. This example places the name of the disk in a variable named `datadisk`, which is used in the next step.

```
datadisk=$(az disk list \
-g myResourceGroupDisk \
--query "[?contains(name,'myVM')].[id]" \
-o tsv)
```

Use the [az vm disk attach](#) command to attach the disk.

```
az vm disk attach \
-g myResourceGroupDisk \
--vm-name myVM \
--name $datadisk
```

## Next steps

In this tutorial, you learned about VM disks topics such as:

- OS disks and temporary disks
- Data disks
- Standard and Premium disks
- Disk performance
- Attaching and preparing data disks
- Disk snapshots

Advance to the next tutorial to learn about automating VM configuration.

[Automate VM configuration](#)

# Tutorial - How to use cloud-init to customize a Linux virtual machine in Azure on first boot

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In a previous tutorial, you learned how to SSH to a virtual machine (VM) and manually install NGINX. To create VMs in a quick and consistent manner, some form of automation is typically desired. A common approach to customize a VM on first boot is to use [cloud-init](#). In this tutorial you learn how to:

- Create a cloud-init config file
- Create a VM that uses a cloud-init file
- View a running Node.js app after the VM is created
- Use Key Vault to securely store certificates
- Automate secure deployments of NGINX with cloud-init

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Cloud-init overview

[Cloud-init](#) is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. As cloud-init runs during the initial boot process, there are no additional steps or required agents to apply your configuration.

Cloud-init also works across distributions. For example, you don't use `apt-get install` or `yum install` to install a package. Instead you can define a list of packages to install. Cloud-init automatically uses the native package management tool for the distro you select.

We are working with our partners to get cloud-init included and working in the images that they provide to Azure. For detailed information cloud-init support for each distribution, see [Cloud-init support for VMs in Azure](#).

## Create cloud-init config file

To see cloud-init in action, create a VM that installs NGINX and runs a simple 'Hello World' Node.js app. The following cloud-init configuration installs the required packages, creates a Node.js app, then initialize and starts the app.

At your bash prompt or in the Cloud Shell, create a file named `cloud-init.txt` and paste the following configuration. For example, type `sensible-editor cloud-init.txt` to create the file and see a list of available editors. Make sure that the whole cloud-init file is copied correctly, especially the first line:

```

#cloud-config
package_upgrade: true
packages:
- nginx
- nodejs
- npm
write_files:
- owner: www-data:www-data
  path: /etc/nginx/sites-available/default
  content: |
    server {
      listen 80;
      location / {
        proxy_pass http://localhost:3000;
        proxy_http_version 1.1;
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection keep-alive;
        proxy_set_header Host $host;
        proxy_cache_bypass $http_upgrade;
      }
    }
- owner: azureuser:azureuser
  path: /home/azureuser/myapp/index.js
  content: |
    var express = require('express')
    var app = express()
    var os = require('os');
    app.get('/', function (req, res) {
      res.send('Hello World from host ' + os.hostname() + '!')
    })
    app.listen(3000, function () {
      console.log('Hello world app listening on port 3000!')
    })
runcmd:
- service nginx restart
- cd "/home/azureuser/myapp"
- npm init
- npm install express -y
- nodejs index.js

```

For more information about cloud-init configuration options, see [cloud-init config examples](#).

## Create virtual machine

Before you can create a VM, create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroupAutomate* in the *eastus* location:

```
az group create --name myResourceGroupAutomate --location eastus
```

Now create a VM with [az vm create](#). Use the `--custom-data` parameter to pass in your cloud-init config file. Provide the full path to the *cloud-init.txt* config if you saved the file outside of your present working directory. The following example creates a VM named *myVM*:

```
az vm create \
--resource-group myResourceGroupAutomate \
--name myAutomatedVM \
--image UbuntuLTS \
--admin-username azureuser \
--generate-ssh-keys \
--custom-data cloud-init.txt
```

It takes a few minutes for the VM to be created, the packages to install, and the app to start. There are background tasks that continue to run after the Azure CLI returns you to the prompt. It may be another couple of minutes before you can access the app. When the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access the Node.js app via a web browser.

To allow web traffic to reach your VM, open port 80 from the Internet with [az vm open-port](#):

```
az vm open-port --port 80 --resource-group myResourceGroupAutomate --name myAutomatedVM
```

## Test web app

Now you can open a web browser and enter `http://<publicIpAddress>` in the address bar. Provide your own public IP address from the VM create process. Your Node.js app is displayed as shown in the following example:

## Inject certificates from Key Vault

This optional section shows how you can securely store certificates in Azure Key Vault and inject them during the VM deployment. Rather than using a custom image that includes the certificates baked-in, this process ensures that the most up-to-date certificates are injected to a VM on first boot. During the process, the certificate never leaves the Azure platform or is exposed in a script, command-line history, or template.

Azure Key Vault safeguards cryptographic keys and secrets, such as certificates or passwords. Key Vault helps streamline the key management process and enables you to maintain control of keys that access and encrypt your data. This scenario introduces some Key Vault concepts to create and use a certificate, though is not an exhaustive overview on how to use Key Vault.

The following steps show how you can:

- Create an Azure Key Vault
- Generate or upload a certificate to the Key Vault
- Create a secret from the certificate to inject in to a VM
- Create a VM and inject the certificate

### Create an Azure Key Vault

First, create a Key Vault with [az keyvault create](#) and enable it for use when you deploy a VM. Each Key Vault requires a unique name, and should be all lower case. Replace `mykeyvault` in the following example with your own unique Key Vault name:

```
keyvault_name=mykeyvault
az keyvault create \
    --resource-group myResourceGroupAutomate \
    --name $keyvault_name \
    --enabled-for-deployment
```

### Generate certificate and store in Key Vault

For production use, you should import a valid certificate signed by trusted provider with [az keyvault certificate import](#). For this tutorial, the following example shows how you can generate a self-signed certificate with [az keyvault certificate create](#) that uses the default certificate policy:

```
az keyvault certificate create \
--vault-name $keyvault_name \
--name mycert \
--policy "$(az keyvault certificate get-default-policy --output json)"
```

## Prepare certificate for use with VM

To use the certificate during the VM create process, obtain the ID of your certificate with [az keyvault secret list-versions](#). The VM needs the certificate in a certain format to inject it on boot, so convert the certificate with [az vm secret format](#). The following example assigns the output of these commands to variables for ease of use in the next steps:

```
secret=$(az keyvault secret list-versions \
--vault-name $keyvault_name \
--name mycert \
--query "[?attributes.enabled].id" --output tsv)
vm_secret=$(az vm secret format --secret "$secret" --output json)
```

## Create cloud-init config to secure NGINX

When you create a VM, certificates and keys are stored in the protected `/var/lib/waagent`/directory. To automate adding the certificate to the VM and configuring NGINX, you can use an updated cloud-init config from the previous example.

Create a file named `cloud-init-secured.txt` and paste the following configuration. If you use the Cloud Shell, create the cloud-init config file there and not on your local machine. For example, type

```
sensible-editor cloud-init-secured.txt
```

 to create the file and see a list of available editors. Make sure that the whole cloud-init file is copied correctly, especially the first line:

```

#cloud-config
package_upgrade: true
packages:
- nginx
- nodejs
- npm
write_files:
- owner: www-data:www-data
  path: /etc/nginx/sites-available/default
  content: |
    server {
      listen 80;
      listen 443 ssl;
      ssl_certificate /etc/nginx/ssl/mycert.cert;
      ssl_certificate_key /etc/nginx/ssl/mycert.prv;
      location / {
        proxy_pass http://localhost:3000;
        proxy_http_version 1.1;
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection keep-alive;
        proxy_set_header Host $host;
        proxy_cache_bypass $http_upgrade;
      }
    }
- owner: azureuser:azureuser
  path: /home/azureuser/myapp/index.js
  content: |
    var express = require('express')
    var app = express()
    var os = require('os');
    app.get('/', function (req, res) {
      res.send('Hello World from host ' + os.hostname() + '!')
    })
    app.listen(3000, function () {
      console.log('Hello world app listening on port 3000!')
    })
runcmd:
- secretsname=$(find /var/lib/waagent/ -name "*.prv" | cut -c -57)
- mkdir /etc/nginx/ssl
- cp $secretsname.crt /etc/nginx/ssl/mycert.cert
- cp $secretsname.prv /etc/nginx/ssl/mycert.prv
- service nginx restart
- cd "/home/azureuser/myapp"
- npm init
- npm install express -y
- nodejs index.js

```

## Create secure VM

Now create a VM with `az vm create`. The certificate data is injected from Key Vault with the `--secrets` parameter. As in the previous example, you also pass in the cloud-init config with the `--custom-data` parameter:

```

az vm create \
--resource-group myResourceGroupAutomate \
--name myVMWithCerts \
--image UbuntuLTS \
--admin-username azureuser \
--generate-ssh-keys \
--custom-data cloud-init-secured.txt \
--secrets "$vm_secret"

```

It takes a few minutes for the VM to be created, the packages to install, and the app to start. There are background tasks that continue to run after the Azure CLI returns you to the prompt. It may be another couple of minutes before you can access the app. When the VM has been created, take note of the `publicIpAddress`

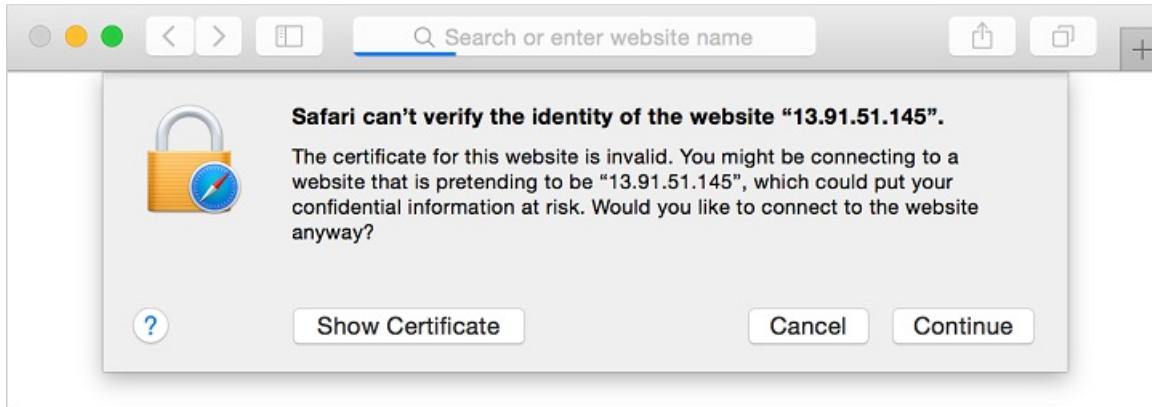

displayed by the Azure CLI. This address is used to access the Node.js app via a web browser.

To allow secure web traffic to reach your VM, open port 443 from the Internet with [az vm open-port](#):

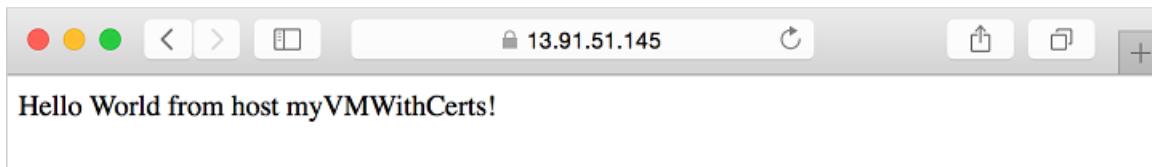

```
az vm open-port \
--resource-group myResourceGroupAutomate \
--name myVMWithCerts \
--port 443
```

### Test secure web app

Now you can open a web browser and enter `https://<publicIpAddress>` in the address bar. Provide your own public IP address as shown in the output of the previous VM create process. Accept the security warning if you used a self-signed certificate:

Your secured NGINX site and Node.js app is then displayed as in the following example:

## Next steps

In this tutorial, you configured VMs on first boot with cloud-init. You learned how to:

- Create a cloud-init config file
- Create a VM that uses a cloud-init file
- View a running Node.js app after the VM is created
- Use Key Vault to securely store certificates
- Automate secure deployments of NGINX with cloud-init

Advance to the next tutorial to learn how to create custom VM images.

[Create custom VM images](#)

# Tutorial: Create a custom image of an Azure VM with the Azure CLI

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations. In this tutorial, you create your own custom image of an Azure virtual machine. You learn how to:

- Create an Azure Compute Gallery (formerly known as Shared Image Gallery)
- Create an image definition
- Create an image version
- Create a VM from an image
- Share a gallery

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.35.0 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Overview

An [Azure Compute Gallery](#) simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations.

The Azure Compute Gallery lets you share your custom VM images with others. Choose which images you want to share, which regions you want to make them available in, and who you want to share them with.

The Azure Compute Gallery feature has multiple resource types:

RESOURCE	DESCRIPTION
<b>Image source</b>	This is a resource that can be used to create an <a href="#">image version</a> in a gallery. An image source can be an existing Azure VM that is either <a href="#">generalized or specialized</a> , a managed image, a snapshot, or an image version in another gallery.
<b>Gallery</b>	Like the Azure Marketplace, a <a href="#">gallery</a> is a repository for managing and sharing images and <a href="#">VM applications</a> , but you control who has access.
<b>Image definition</b>	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.

RESOURCE	DESCRIPTION
Image version	An <b>image version</b> is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an <b>image version</b> to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

## Before you begin

The steps below detail how to take an existing VM and turn it into a reusable custom image that you can use to create new VM instances.

To complete the example in this tutorial, you must have an existing virtual machine. If needed, you can see the [CLI quickstart](#) to create a VM to use for this tutorial. When working through the tutorial, replace the resource names where needed.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create a gallery

A gallery is the primary resource used for enabling image sharing.

Allowed characters for gallery name are uppercase or lowercase letters, digits, dots, and periods. The gallery name cannot contain dashes. Gallery names must be unique within your subscription.

Create a gallery using [az sig create](#). The following example creates a resource group named gallery named *myGalleryRG* in *East US*, and a gallery named *myGallery*.

```
az group create --name myGalleryRG --location eastus
az sig create --resource-group myGalleryRG --gallery-name myGallery
```

## Get information about the VM

You can see a list of VMs that are available using [az vm list](#).

```
az vm list --output table
```

Once you know the VM name and what resource group it is in, get the ID of the VM using [az vm get-instance-view](#).

```
az vm get-instance-view -g MyResourceGroup -n MyVm --query id
```

Copy the ID of your VM to use later.

# Create an image definition

Image definitions create a logical grouping for images. They are used to manage information about the image versions that are created within them.

Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes, and periods.

For more information about the values you can specify for an image definition, see [Image definitions](#).

Create an image definition in the gallery using `az sig image-definition create`.

In this example, the image definition is named `myImageDefinition`, and is for a [specialized](#) Linux OS image.

```
az sig image-definition create \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--publisher myPublisher \
--offer myOffer \
--sku mySKU \
--os-type Linux \
--os-state specialized
```

Copy the ID of the image definition from the output to use later.

## Create the image version

Create an image version from the VM using `az sig image-version create`.

Allowed characters for image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion.MinorVersion.Patch*.

In this example, the version of our image is `1.0.0` and we are going to create 2 replicas in the *West Central US* region, 1 replica in the *South Central US* region and 1 replica in the *East US 2* region using zone-redundant storage. The replication regions must include the region the source VM is located.

Replace the value of `--managed-image` in this example with the ID of your VM from the previous step.

```
az sig image-version create \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--gallery-image-version 1.0.0 \
--target-regions "westcentralus" "southcentralus=1" "eastus=1=standard_zrs" \
--replica-count 2 \
--managed-image "/subscriptions/<SubscriptionID>/resourceGroups/MyResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM"
```

### NOTE

You need to wait for the image version to completely finish being built and replicated before you can use the same managed image to create another image version.

You can also store your image in Premium storage by adding `--storage-account-type premium_lrs`, or [Zone Redundant Storage](#) by adding `--storage-account-type standard_zrs` when you create the image version.

## Create the VM

Create the VM using `az vm create` using the `--specialized` parameter to indicate the image is a specialized image.

Use the image definition ID for `--image` to create the VM from the latest version of the image that is available.

You can also create the VM from a specific version by supplying the image version ID for `--image`.

In this example, we are creating a VM from the latest version of the *myImageDefinition* image.

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
  --name myVM2 \
  --image "/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myGallery/images/myImageDefinition" \
  --specialized
```

## Share the gallery

You can share images across subscriptions using Azure role-based access control (Azure RBAC). You can share images at the gallery, image definition or image version level. Any user that has read permissions to an image version, even across subscriptions, will be able to deploy a VM using the image version.

We recommend that you share with other users at the gallery level. To get the object ID of your gallery, use `az sig show`.

```
az sig show \
  --resource-group myGalleryRG \
  --gallery-name myGallery \
  --query id
```

Use the object ID as a scope, along with an email address and `az role assignment create` to give a user access to the Azure Compute Gallery. Replace `<email-address>` and `<gallery ID>` with your own information.

```
az role assignment create \
  --role "Reader" \
  --assignee <email address> \
  --scope <gallery ID>
```

For more information about how to share resources using Azure RBAC, see [Add or remove Azure role assignments using Azure CLI](#).

## Azure Image Builder

Azure also offers a service, built on Packer, [Azure VM Image Builder](#). Simply describe your customizations in a template, and it will handle the image creation.

## Next steps

In this tutorial, you created a custom VM image. You learned how to:

- Create an Azure Compute Gallery
- Create an image definition
- Create an image version
- Create a VM from an image
- Share a gallery

Advance to the next tutorial to learn about highly available virtual machines.

Create highly available VMs

# Create and deploy virtual machines in an availability set using Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

In this tutorial, you learn how to increase the availability and reliability of your Virtual Machine solutions on Azure using a capability called Availability Sets. Availability sets ensure that the VMs you deploy on Azure are distributed across multiple isolated hardware clusters. Doing this ensures that if a hardware or software failure within Azure happens, only a subset of your VMs is impacted and that your overall solution remains available and operational.

In this tutorial, you learn how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create an availability set

You can create an availability set using `az vm availability-set create`. In this example, the number of update and fault domains is set to 2 for the availability set named *myAvailabilitySet* in the *myResourceGroupAvailability* resource group.

First, create a resource group with [az group create](#), then create the availability set:

```
az group create --name myResourceGroupAvailability --location eastus

az vm availability-set create \
    --resource-group myResourceGroupAvailability \
    --name myAvailabilitySet \
    --platform-fault-domain-count 2 \
    --platform-update-domain-count 2
```

Availability Sets allow you to isolate resources across fault domains and update domains. A **fault domain** represents an isolated collection of server + network + storage resources. In the preceding example, the availability set is distributed across at least two fault domains when the VMs are deployed. The availability set is also distributed across two **update domains**. Two update domains ensure that when Azure performs software updates, the VM resources are isolated, preventing all the software that runs on the VM from being updated at the same time.

## Create VMs inside an availability set

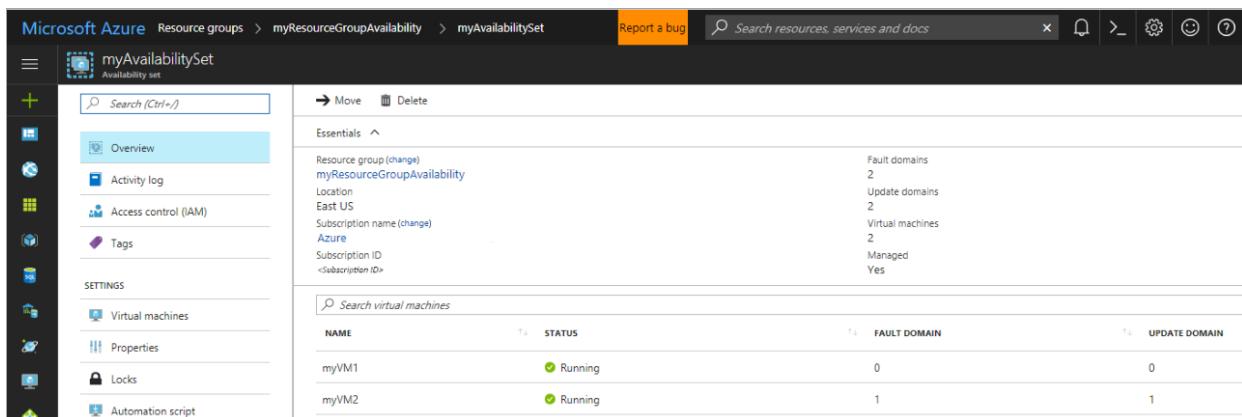

VMs must be created within the availability set to make sure they are correctly distributed across the hardware. An existing VM cannot be added to an availability set after it is created.

When a VM is created with [az vm create](#), use the `--availability-set` parameter to specify the name of the availability set.

```
for i in `seq 1 2`; do
    az vm create \
        --resource-group myResourceGroupAvailability \
        --name myVM$i \
        --availability-set myAvailabilitySet \
        --size Standard_DS1_v2 \
        --vnet-name myVnet \
        --subnet mySubnet \
        --image UbuntuLTS \
        --admin-username azureuser \
        --generate-ssh-keys
done
```

There are now two virtual machines within the availability set. Because they are in the same availability set, Azure ensures that the VMs and all their resources (including data disks) are distributed across isolated physical hardware. This distribution helps ensure much higher availability of the overall VM solution.

The availability set distribution can be viewed in the portal by going to Resource Groups > myResourceGroupAvailability > myAvailabilitySet. The VMs are distributed across the two fault and update domains, as shown in the following example:

NAME	STATUS	FAULT DOMAIN	UPDATE DOMAIN
myVM1	Running	0	0
myVM2	Running	1	1

## Check for available VM sizes

Additional VMs can be added to the availability set later, where VM sizes are available on the hardware. Use [az vm availability-set list-sizes](#) to list all the available sizes on the hardware cluster for the availability set:

```
az vm availability-set list-sizes \
    --resource-group myResourceGroupAvailability \
    --name myAvailabilitySet \
    --output table
```

## Next steps

In this tutorial, you learned how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes

Advance to the next tutorial to learn about virtual machine scale sets.

[Create a virtual machine scale set](#)

- To learn more about availability zones, visit the [Availability Zones documentation](#).
- More documentation about both availability sets and availability zones is also available at [Availability options for Azure Virtual Machines](#).
- To try out availability zones, visit [Create a Linux virtual machine in an availability zone with the Azure CLI](#)

# Tutorial: Create a virtual machine scale set and deploy a highly available app on Linux

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Uniform scale sets

Virtual machine scale sets with [Flexible orchestration](#) let you create and manage a group of load balanced VMs. The number of VM instances can automatically increase or decrease in response to demand or a defined schedule.

In this tutorial, you deploy a virtual machine scale set in Azure and learn how to:

- Create a resource group.
- Create a Flexible scale set with a load balancer.
- Add nginx to the scale set instances.
- Open port 80 to HTTP traffic.
- Test the scale set.

## Scale Set overview

Scale sets provide the following key benefits:

- Easy to create and manage multiple VMs
- Provides high availability and application resiliency by distributing VMs across fault domains
- Allows your application to automatically scale as resource demand changes
- Works at large-scale

With Flexible orchestration, Azure provides a unified experience across the Azure VM ecosystem. Flexible orchestration offers high availability guarantees (up to 1000 VMs) by spreading VMs across fault domains in a region or within an Availability Zone. This enables you to scale out your application while maintaining fault domain isolation that is essential to run quorum-based or stateful workloads, including:

- Quorum-based workloads
- Open-source databases
- Stateful applications
- Services that require high availability and large scale
- Services that want to mix virtual machine types or leverage Spot and on-demand VMs together
- Existing Availability Set applications

Learn more about the differences between Uniform scale sets and Flexible scale sets in [Orchestration Modes](#).

## Create a scale set

Use the Azure portal to create a Flexible scale set.

1. Open the [Azure portal](#).
2. Search for and select **Virtual machine scale sets**.
3. Select **Create** on the **Virtual machine scale sets** page. The **Create a virtual machine scale set** will open.
4. Select the subscription that you want to use for **Subscription**.

5. For **Resource group**, select **Create new** and type *myVMSSRG* for the name and then select **OK**.

#### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	myAzureSubscription
Resource group *	(New) myVMSS_group
<a href="#">Create new</a>	

6. For **Virtual machine scale set name**, type *myVMSS*.

7. For **Region**, select a region that is close to you like *East US*.

#### Scale set details

Virtual machine scale set name *	myVMSS
Region *	(US) East US
Availability zone ⓘ	None

8. Leave **Availability zone** as blank for this example.

9. For **Orchestration mode**, select **Flexible**.

10. Leave the default of **1** for fault domain count or choose another value from the drop-down.

#### Orchestration

A scale set has a "scale set model" that defines the attributes of virtual machine instances (size, number of data disks, etc). As the number of instances in the scale set changes, new instances are added based on the scale set model.

[Learn more about the scale set model](#)

Orchestration mode \* ⓘ

- Uniform**: optimized for large scale stateless workloads with identical instances  
 **Flexible (preview)**: achieve high availability at scale with identical or multiple virtual machine types

**!** This virtual machine scale set will be created as a scale set with flexible orchestration mode (preview). To enable the preview, you must register your subscription. [Learn more](#)

Fault domain count \* ⓘ

1

11. For **Image**, select *Ubuntu 18.04 LTS*.

12. For **Size**, leave the default value or select a size like *Standard\_E2s\_V3*.

13. In **Username** type *azureuser*.

14. For **SSH public key source**, leave the default of **Generate new key pair**, and then type *myKey* for the **Key pair name**.

#### Administrator account

Authentication type ⓘ

- Password  
 SSH public key

Username \* ⓘ

azureuser

SSH public key source

Generate new key pair

Key pair name \*

myVMSSKey

15. On the **Networking** tab, under **Load balancing**, select **Use a load balancer**.

16. For **Load balancing options**, leave the default of **Azure load balancer**.

17. For **Select a load balancer**, select **Create new**.

## Load balancing

You can place this virtual machine scale set in the backend pool of an existing Azure load balancing solution. [Learn more ↗](#)

Use a load balancer

### Load balancing settings

- **Application Gateway** is an HTTP/HTTPS web traffic load balancer with URL-based routing, SSL termination, session persistence, and web application firewall. [Learn more about Application Gateway ↗](#)
- **Azure Load Balancer** supports all TCP/UDP network traffic, port-forwarding, and outbound flows. [Learn more about Azure Load Balancer ↗](#)

Load balancing options * ⓘ	Azure load balancer
Select a load balancer * ⓘ	(new) myVMSS2021-lb <a href="#">Create new</a>
Select a backend pool * ⓘ	(new) bepool <a href="#">Create new</a>

18. On the **Create a load balancer** page, type in a name for your load balancer and **Public IP address name**.
19. For **Domain name label**, type in a name to use as a prefix for your domain name. This name must be unique.
20. When you are done, select **Create**.

## Create a load balancer X

Azure Load Balancer enables you to scale your applications and create high availability for your services. Load Balancer supports inbound and outbound scenarios, provides low latency and high throughput, and scales up to millions of flows for all TCP and UDP applications. [Learn more about Azure Load Balancer. ↗](#)

Your load balancer will be placed in the same subscription, resource group, and region as your virtual machine scale set. Azure will configure basic settings for the frontend IP, backend address pools, NAT rules, and NAT pools for this load balancer automatically.

Name * ⓘ	myVMSS-lb
Public IP address name * ⓘ	myVMSS-ip
Domain name label ⓘ	myvmss2021 <span style="float: right;">✓ .eastus.cloudapp.azure.com</span>
SKU	Standard
Type	Public
Availability zone ⓘ	Zone-redundant

**Create** **Discard**

21. Back on the **Networking** tab, leave the default name for the backend pool.
22. On the **Scaling** tab, leave the default instance count as *2*, or add in your own value. This is the number of VMs that will be created, so be aware of the costs and the limits on your subscription if you change this value.
23. Leave the **Scaling policy** set to *Manual*.

An Azure virtual machine scale set can automatically increase or decrease the number of VM instances that run your application. This automated and elastic behavior reduces the management overhead to monitor and optimize the performance of your application. [Learn more about VMSS scaling](#)

Initial instance count \* ⓘ

2

#### Scaling

Scaling policy ⓘ

Manual

Custom

#### Scale-In policy

Configure the order in which virtual machines are selected for deletion during a scale-in operation.

[Learn more about scale-in policies](#)

Scale-in policy

Default - Balance across availability zones and fault domains, then delete ...

Scale-in policy is not supported for virtual machine scale sets with flexible orchestration mode (preview).

24. Select the **Advanced** tab.

25. Under **Custom data and cloud init**, copy the following and paste it into the **Custom data** text box:

```

#cloud-config
package_upgrade: true
packages:
- nginx
- nodejs
- npm
write_files:
- owner: www-data:www-data
- path: /etc/nginx/sites-available/default
  content: |
    server {
      listen 80;
      location / {
        proxy_pass http://localhost:3000;
        proxy_http_version 1.1;
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection keep-alive;
        proxy_set_header Host $host;
        proxy_cache_bypass $http_upgrade;
      }
    }
- owner: azureuser:azureuser
- path: /home/azureuser/myapp/index.js
  content: |
    var express = require('express')
    var app = express()
    var os = require('os');
    app.get('/', function (req, res) {
      res.send('Hello World from host ' + os.hostname() + '!')
    })
    app.listen(3000, function () {
      console.log('Hello world app listening on port 3000!')
    })
runcmd:
- service nginx restart
- cd "/home/azureuser/myapp"
- npm init
- npm install express -y
- nodejs index.js

```

26. When you are done, select **Review + create**.
27. Once you see that validation has passed, you can select **Create** at the bottom of the page to deploy your scale set.
28. When the **Generate new key pair** window opens, select **Download private key and create resource**. Your key file will be download as **myKey.pem**. Make sure you know where the **.pem** file was downloaded, you will need the path to it in the next step.
29. When the deployment is complete, select **Go to resource** to see your scale set.

## View the VMs in your scale set

On the page for the scale set, select **Instances** from the left menu.

You will see a list of VMs that are part of your scale set. This list includes:

- The name of the VM
- The computer name used by the VM.
- The current status of the VM, like *Running*.
- The *Provisioning state* of the VM, like *Succeeded*.

Name	Computer name	Status	Provisioning state
myVMSS_351a2d68	myvmss6nEQF9OO	Running	Succeeded
myVMSS_c4dac4c9	myvmss6nGESCAF	Running	Succeeded

## Open port 80

Open port 80 on your scale set by adding an inbound rule to your network security group (NSG).

1. On the page for your scale set, select **Networking** from the left menu. The **Networking** page will open.
2. Select **Add inbound port rule**. The **Add inbound security rule** page will open.
3. Under **Service**, select *HTTP* and then select **Add** at the bottom of the page.

## Test your scale set

Test your scale set by connecting to it from a browser.

1. On the **Overview** page for your scale set, copy the Public IP address.
2. Open another tab in your browser and paste the IP address into the address bar.
3. When the page loads, take a note of the compute name that is shown.
4. Refresh the page until you see the computer name change.

## Delete your scale set

When you are done, you should delete the resource group, which will delete everything you deployed for your scale set.

1. On the page for your scale set, select the **Resource group**. The page for your resource group will open.
2. At the top of the page, select **Delete resource group**.
3. In the **Are you sure you want to delete** page, type in the name of your resource group and then select **Delete**.

## Next steps

In this tutorial, you created a virtual machine scale set. You learned how to:

- Create a resource group.
- Create a Flexible scale set with a load balancer.
- Add nginx to the scale set instances.
- Open port 80 to HTTP traffic.
- Test the scale set.

Advance to the next tutorial to learn more about load balancing concepts for virtual machines.

[Load balance virtual machines](#)

# Tutorial: Load balance VMs for high availability

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Load balancing provides a higher level of availability by spreading incoming requests across multiple virtual machines. In this tutorial, you learn about the different components of the Azure load balancer that distribute traffic and provide high availability. You learn how to:

- Create a load balancer
- Create a health probe
- Create traffic rules
- Use cloud-init to install a basic Node.js app
- Create virtual machines and attach them to the load balancer
- View the load balancer in action
- Add and remove VMs from the load balancer

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Azure load balancer overview

An Azure load balancer is a Layer-4 (TCP, UDP) load balancer that provides high availability by distributing incoming traffic among healthy VMs. A load balancer health probe monitors a given port on each VM and only distributes traffic to an operational VM.

You define a front-end IP configuration that contains one or more public IP addresses. This front-end IP configuration allows your load balancer and applications to be accessible over the Internet.

Virtual machines connect to a load balancer using their virtual network interface card (NIC). To distribute traffic to the VMs, a back-end address pool contains the IP addresses of the virtual (NICs) connected to the load balancer.

To control the flow of traffic, you define load balancer rules for specific ports and protocols that map to your VMs.

If you followed the previous tutorial to [create a virtual machine scale set](#), a load balancer was created for you. All these components were configured for you as part of the scale set.

## Create Azure load balancer

This section details how you can create and configure each component of the load balancer. Before you can create your load balancer, create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroupLoadBalancer* in the *eastus* location:

```
az group create --name myResourceGroupLoadBalancer --location eastus
```

### Create a public IP address

To access your app on the Internet, you need a public IP address for the load balancer. Create a public IP address with [az network public-ip create](#). The following example creates a public IP address named *myPublicIP* in the *myResourceGroupLoadBalancer* resource group:

```
az network public-ip create \
--resource-group myResourceGroupLoadBalancer \
--name myPublicIP
```

## Create a load balancer

Create a load balancer with [az network lb create](#). The following example creates a load balancer named *myLoadBalancer* and assigns the *myPublicIP* address to the front-end IP configuration:

```
az network lb create \
--resource-group myResourceGroupLoadBalancer \
--name myLoadBalancer \
--frontend-ip-name myFrontEndPool \
--backend-pool-name myBackEndPool \
--public-ip-address myPublicIP
```

## Create a health probe

To allow the load balancer to monitor the status of your app, you use a health probe. The health probe dynamically adds or removes VMs from the load balancer rotation based on their response to health checks. By default, a VM is removed from the load balancer distribution after two consecutive failures at 15-second intervals. You create a health probe based on a protocol or a specific health check page for your app.

The following example creates a TCP probe. You can also create custom HTTP probes for more fine grained health checks. When using a custom HTTP probe, you must create the health check page, such as *healthcheck.js*. The probe must return an HTTP 200 OK response for the load balancer to keep the host in rotation.

To create a TCP health probe, you use [az network lb probe create](#). The following example creates a health probe named *myHealthProbe*:

```
az network lb probe create \
--resource-group myResourceGroupLoadBalancer \
--lb-name myLoadBalancer \
--name myHealthProbe \
--protocol tcp \
--port 80
```

## Create a load balancer rule

A load balancer rule is used to define how traffic is distributed to the VMs. You define the front-end IP configuration for the incoming traffic and the back-end IP pool to receive the traffic, along with the required source and destination port. To make sure only healthy VMs receive traffic, you also define the health probe to use.

Create a load balancer rule with [az network lb rule create](#). The following example creates a rule named *myLoadBalancerRule*, uses the *myHealthProbe* health probe, and balances traffic on port 80:

```
az network lb rule create \
--resource-group myResourceGroupLoadBalancer \
--lb-name myLoadBalancer \
--name myLoadBalancerRule \
--protocol tcp \
--frontend-port 80 \
--backend-port 80 \
--frontend-ip-name myFrontEndPool \
--backend-pool-name myBackEndPool \
--probe-name myHealthProbe
```

## Configure virtual network

Before you deploy some VMs and can test your balancer, create the supporting virtual network resources. For more information about virtual networks, see the [Manage Azure Virtual Networks](#) tutorial.

### Create network resources

Create a virtual network with [az network vnet create](#). The following example creates a virtual network named *myVnet* with a subnet named *mySubnet*.

```
az network vnet create \
--resource-group myResourceGroupLoadBalancer \
--name myVnet \
--subnet-name mySubnet
```

To add a network security group, you use [az network nsg create](#). The following example creates a network security group named *myNetworkSecurityGroup*.

```
az network nsg create \
--resource-group myResourceGroupLoadBalancer \
--name myNetworkSecurityGroup
```

Create a network security group rule with [az network nsg rule create](#). The following example creates a network security group rule named *myNetworkSecurityGroupRule*.

```
az network nsg rule create \
--resource-group myResourceGroupLoadBalancer \
--nsg-name myNetworkSecurityGroup \
--name myNetworkSecurityGroupRule \
--priority 1001 \
--protocol tcp \
--destination-port-range 80
```

Virtual NICs are created with [az network nic create](#). The following example creates three virtual NICs. (One virtual NIC for each VM you create for your app in the following steps). You can create additional virtual NICs and VMs at any time and add them to the load balancer:

```
for i in `seq 1 3`; do
    az network nic create \
        --resource-group myResourceGroupLoadBalancer \
        --name myNic$i \
        --vnet-name myVnet \
        --subnet mySubnet \
        --network-security-group myNetworkSecurityGroup \
        --lb-name myLoadBalancer \
        --lb-address-pools myBackEndPool
done
```

When all three virtual NICs are created, continue on to the next step

## Create virtual machines

### Create cloud-init config

In a previous tutorial on [How to customize a Linux virtual machine on first boot](#), you learned how to automate VM customization with cloud-init. You can use the same cloud-init configuration file to install NGINX and run a simple 'Hello World' Node.js app in the next step. To see the load balancer in action, at the end of the tutorial you access this simple app in a web browser.

In your current shell, create a file named *cloud-init.txt* and paste the following configuration. For example, create the file in the Cloud Shell not on your local machine. Enter `sensible-editor cloud-init.txt` to create the file and see a list of available editors. Make sure that the whole cloud-init file is copied correctly, especially the first line:

```

#cloud-config
package_upgrade: true
packages:
- nginx
- nodejs
- npm
write_files:
- owner: www-data:www-data
- path: /etc/nginx/sites-available/default
  content: |
    server {
      listen 80;
      location / {
        proxy_pass http://localhost:3000;
        proxy_http_version 1.1;
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection keep-alive;
        proxy_set_header Host $host;
        proxy_cache_bypass $http_upgrade;
      }
    }
- owner: azureuser:azureuser
- path: /home/azureuser/myapp/index.js
  content: |
    var express = require('express')
    var app = express()
    var os = require('os');
    app.get('/', function (req, res) {
      res.send('Hello World from host ' + os.hostname() + '!')
    })
    app.listen(3000, function () {
      console.log('Hello world app listening on port 3000!')
    })
runcmd:
- service nginx restart
- cd "/home/azureuser/myapp"
- npm init
- npm install express -y
- nodejs index.js

```

## Create virtual machines

To improve the high availability of your app, place your VMs in an availability set. For more information about availability sets, see the previous [How to create highly available virtual machines](#) tutorial.

Create an availability set with [az vm availability-set create](#). The following example creates an availability set named *myAvailabilitySet*.

```

az vm availability-set create \
--resource-group myResourceGroupLoadBalancer \
--name myAvailabilitySet

```

Now you can create the VMs with [az vm create](#). The following example creates three VMs and generates SSH keys if they do not already exist:

```

for i in `seq 1 3`; do
    az vm create \
        --resource-group myResourceGroupLoadBalancer \
        --name myVM$i \
        --availability-set myAvailabilitySet \
        --nics myNic$i \
        --image UbuntuLTS \
        --admin-username azureuser \
        --generate-ssh-keys \
        --custom-data cloud-init.txt \
        --no-wait
done

```

There are background tasks that continue to run after the Azure CLI returns you to the prompt. The `--no-wait` parameter does not wait for all the tasks to complete. It may be another couple of minutes before you can access the app. The load balancer health probe automatically detects when the app is running on each VM. Once the app is running, the load balancer rule starts to distribute traffic.

## Test load balancer

Obtain the public IP address of your load balancer with [az network public-ip show](#). The following example obtains the IP address for *myPublicIP* created earlier:

```

az network public-ip show \
    --resource-group myResourceGroupLoadBalancer \
    --name myPublicIP \
    --query [ipAddress] \
    --output tsv

```

You can then enter the public IP address in to a web browser. Remember - it takes a few minutes for the VMs to be ready before the load balancer starts to distribute traffic to them. The app is displayed, including the hostname of the VM that the load balancer distributed traffic to as in the following example:

To see the load balancer distribute traffic across all three VMs running your app, you can force-refresh your web browser.

## Add and remove VMs

You may need to perform maintenance on the VMs running your app, such as installing OS updates. To deal with increased traffic to your app, you may need to add additional VMs. This section shows you how to remove or add a VM from the load balancer.

### Remove a VM from the load balancer

You can remove a VM from the backend address pool with [az network nic ip-config address-pool remove](#). The following example removes the virtual NIC for *myVM2* from *myLoadBalancer*.

```
az network nic ip-config address-pool remove \
--resource-group myResourceGroupLoadBalancer \
--nic-name myNic2 \
--ip-config-name ipConfig1 \
--lb-name myLoadBalancer \
--address-pool myBackEndPool
```

To see the load balancer distribute traffic across the remaining two VMs running your app you can force-refresh your web browser. You can now perform maintenance on the VM, such as installing OS updates or performing a VM reboot.

To view a list of VMs with virtual NICs connected to the load balancer, use [az network lb address-pool show](#). Query and filter on the ID of the virtual NIC as follows:

```
az network lb address-pool show \
--resource-group myResourceGroupLoadBalancer \
--lb-name myLoadBalancer \
--name myBackEndPool \
--query backendIpConfigurations \
--output tsv | cut -f4
```

The output is similar to the following example, which shows that the virtual NIC for VM 2 is no longer part of the backend address pool:

```
/subscriptions/<guid>/resourceGroups/myResourceGroupLoadBalancer/providers/Microsoft.Network/networkInterfaces/myNic1/ipConfigurations/ipconfig1
/subscriptions/<guid>/resourceGroups/myResourceGroupLoadBalancer/providers/Microsoft.Network/networkInterfaces/myNic3/ipConfigurations/ipconfig1
```

## Add a VM to the load balancer

After performing VM maintenance, or if you need to expand capacity, you can add a VM to the backend address pool with [az network nic ip-config address-pool add](#). The following example adds the virtual NIC for *myVM2* to *myLoadBalancer*.

```
az network nic ip-config address-pool add \
--resource-group myResourceGroupLoadBalancer \
--nic-name myNic2 \
--ip-config-name ipConfig1 \
--lb-name myLoadBalancer \
--address-pool myBackEndPool
```

To verify that the virtual NIC is connected to the backend address pool, use [az network lb address-pool show](#) again from the preceding step.

## Next steps

In this tutorial, you created a load balancer and attached VMs to it. You learned how to:

- Create an Azure load balancer
- Create a load balancer health probe
- Create load balancer traffic rules
- Use cloud-init to create a basic Node.js app
- Create virtual machines and attach to a load balancer
- View a load balancer in action

- Add and remove VMs from a load balancer

Advance to the next tutorial to learn more about Azure virtual network components.

[Manage VMs and virtual networks](#)

# Tutorial: Create and manage Azure virtual networks for Linux virtual machines with the Azure CLI

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure virtual machines use Azure networking for internal and external network communication. This tutorial walks through deploying two virtual machines and configuring Azure networking for these VMs. The examples in this tutorial assume that the VMs are hosting a web application with a database back-end, however an application is not deployed in the tutorial. In this tutorial, you learn how to:

- Create a virtual network and subnet
- Create a public IP address
- Create a front-end VM
- Secure network traffic
- Create a back-end VM

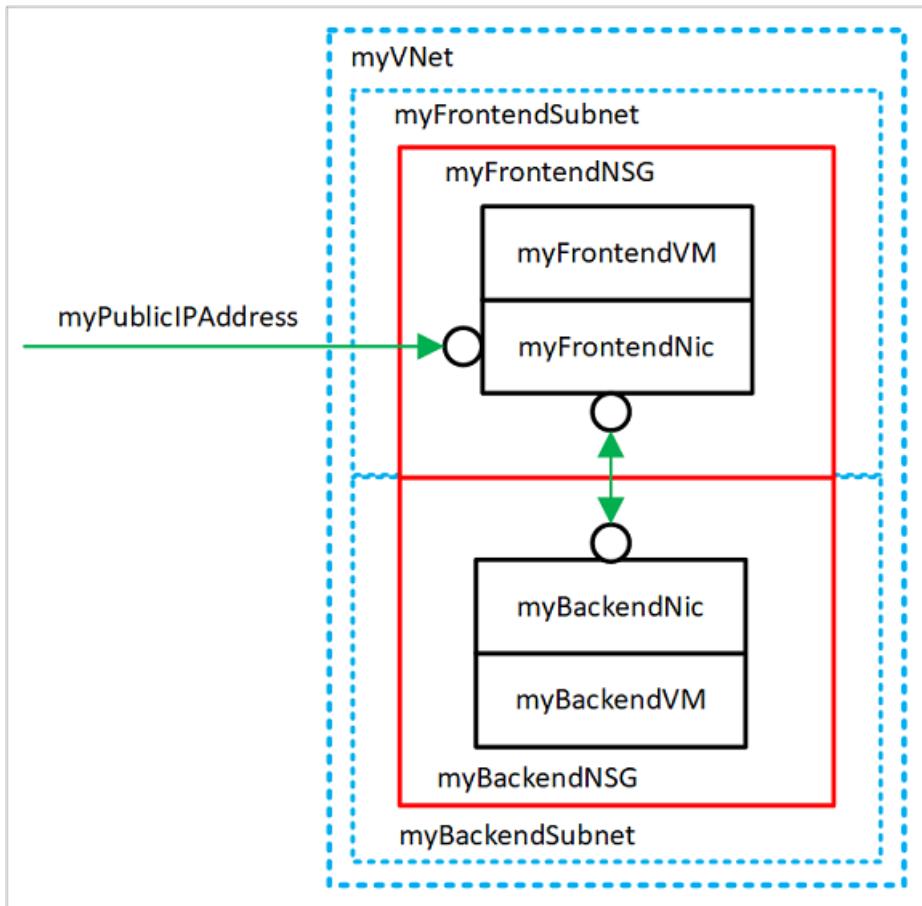

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## VM networking overview

Azure virtual networks enable secure network connections between virtual machines, the internet, and other Azure services such as Azure SQL Database. Virtual networks are broken down into logical segments called subnets. Subnets are used to control network flow, and as a security boundary. When deploying a VM, it generally includes a virtual network interface, which is attached to a subnet.

As you complete the tutorial, the following virtual network resources are created:

- *myVNet* - The virtual network that the VMs use to communicate with each other and the internet.
- *myFrontendSubnet* - The subnet in *myVNet* used by the front-end resources.
- *myPublicIPAddress* - The public IP address used to access *myFrontendVM* from the internet.
- *myFrontendNic* - The network interface used by *myFrontendVM* to communicate with *myBackendVM*.
- *myFrontendVM* - The VM used to communicate between the internet and *myBackendVM*.
- *myBackendNSG* - The network security group that controls communication between the *myFrontendVM* and *myBackendVM*.
- *myBackendSubnet* - The subnet associated with *myBackendNSG* and used by the back-end resources.
- *myBackendNic* - The network interface used by *myBackendVM* to communicate with *myFrontendVM*.
- *myBackendVM* - The VM that uses port 22 and 3306 to communicate with *myFrontendVM*.

## Create a virtual network and subnet

For this tutorial, a single virtual network is created with two subnets. A front-end subnet for hosting a web application, and a back-end subnet for hosting a database server.

Before you can create a virtual network, create a resource group with [az group create](#). The following example creates a resource group named *myRGNetwork* in the *eastus* location.

```
az group create --name myRGNetwork --location eastus
```

### Create virtual network

Use the [az network vnet create](#) command to create a virtual network. In this example, the network is named *mvVNet* and is given an address prefix of *10.0.0.0/16*. A subnet is also created with a name of *myFrontendSubnet* and a prefix of *10.0.1.0/24*. Later in this tutorial a front-end VM is connected to this subnet.

```
az network vnet create \
--resource-group myRGNetwork \
--name myVNet \
--address-prefix 10.0.0.0/16 \
--subnet-name myFrontendSubnet \
--subnet-prefix 10.0.1.0/24
```

## Create subnet

A new subnet is added to the virtual network using the [az network vnet subnet create](#) command. In this example, the subnet is named *myBackendSubnet* and is given an address prefix of *10.0.2.0/24*. This subnet is used with all back-end services.

```
az network vnet subnet create \
--resource-group myRGNetwork \
--vnet-name myVNet \
--name myBackendSubnet \
--address-prefix 10.0.2.0/24
```

At this point, a network has been created and segmented into two subnets, one for front-end services, and another for back-end services. In the next section, virtual machines are created and connected to these subnets.

## Create a public IP address

A public IP address allows Azure resources to be accessible on the internet. The allocation method of the public IP address can be configured as dynamic or static. By default, a public IP address is dynamically allocated. Dynamic IP addresses are released when a VM is deallocated. This behavior causes the IP address to change during any operation that includes a VM deallocation.

The allocation method can be set to static, which ensures that the IP address remains assigned to a VM, even during a deallocated state. When using a statically allocated IP address, the IP address itself cannot be specified. Instead, it is allocated from a pool of available addresses.

```
az network public-ip create --resource-group myRGNetwork --name myPublicIPAddress
```

When creating a VM with the [az vm create](#) command, the default public IP address allocation method is dynamic. When creating a virtual machine using the [az vm create](#) command, include the `--public-ip-address-allocation static` argument to assign a static public IP address. This operation is not demonstrated in this tutorial, however in the next section a dynamically allocated IP address is changed to a statically allocated address.

## Change allocation method

The IP address allocation method can be changed using the [az network public-ip update](#) command. In this example, the IP address allocation method of the front-end VM is changed to static.

First, deallocate the VM.

```
az vm deallocate --resource-group myRGNetwork --name myFrontendVM
```

Use the [az network public-ip update](#) command to update the allocation method. In this case, the `--allocation-method` is being set to *static*.

```
az network public-ip update --resource-group myRGNetwork --name myPublicIPAddress --allocation-method static
```

Start the VM.

```
az vm start --resource-group myRGNetwork --name myFrontendVM --no-wait
```

## No public IP address

Often, a VM does not need to be accessible over the internet. To create a VM without a public IP address, use the `--public-ip-address ""` argument with an empty set of double quotes. This configuration is demonstrated later in this tutorial.

## Create a front-end VM

Use the `az vm create` command to create the VM named *myFrontendVM* using *myPublicIPAddress*.

```
az vm create \
--resource-group myRGNetwork \
--name myFrontendVM \
--vnet-name myVNet \
--subnet myFrontendSubnet \
--nsg myFrontendNSG \
--public-ip-address myPublicIPAddress \
--image UbuntuLTS \
--generate-ssh-keys
```

## Secure network traffic

A network security group (NSG) contains a list of security rules that allow or deny network traffic to resources connected to Azure Virtual Networks (VNet). NSGs can be associated to subnets or individual network interfaces. When an NSG is associated with a network interface, it applies only to the associated VM. When an NSG is associated to a subnet, the rules apply to all resources connected to the subnet.

### Network security group rules

NSG rules define networking ports over which traffic is allowed or denied. The rules can include source and destination IP address ranges so that traffic is controlled between specific systems or subnets. NSG rules also include a priority (between 1—and 4096). Rules are evaluated in the order of priority. A rule with a priority of 100 is evaluated before a rule with priority 200.

All NSGs contain a set of default rules. The default rules cannot be deleted, but because they are assigned the lowest priority, they can be overridden by the rules that you create.

The default rules for NSGs are:

- **Virtual network** - Traffic originating and ending in a virtual network is allowed both in inbound and outbound directions.
- **Internet** - Outbound traffic is allowed, but inbound traffic is blocked.
- **Load balancer** - Allow Azure's load balancer to probe the health of your VMs and role instances. If you are not using a load balanced set, you can override this rule.

### Create network security groups

A network security group can be created at the same time as a VM using the `az vm create` command. When doing so, the NSG is associated with the VMs network interface and an NSG rule is auto created to allow traffic on port 22 from any source. Earlier in this tutorial, the front-end NSG was auto-created with the front-end VM. An NSG rule was also auto created for port 22.

In some cases, it may be helpful to pre-create an NSG, such as when default SSH rules should not be created, or when the NSG should be attached to a subnet.

Use the [az network nsg create](#) command to create a network security group.

```
az network nsg create --resource-group myRGNetwork --name myBackendNSG
```

Instead of associating the NSG to a network interface, it is associated with a subnet. In this configuration, any VM that is attached to the subnet inherits the NSG rules.

Update the existing subnet named *myBackendSubnet* with the new NSG.

```
az network vnet subnet update \
--resource-group myRGNetwork \
--vnet-name myVNet \
--name myBackendSubnet \
--network-security-group myBackendNSG
```

## Secure incoming traffic

When the front-end VM was created, an NSG rule was created to allow incoming traffic on port 22. This rule allows SSH connections to the VM. For this example, traffic should also be allowed on port *80*. This configuration allows a web application to be accessed on the VM.

Use the [az network nsg rule create](#) command to create a rule for port *80*.

```
az network nsg rule create \
--resource-group myRGNetwork \
--nsg-name myFrontendNSG \
--name http \
--access allow \
--protocol Tcp \
--direction Inbound \
--priority 200 \
--source-address-prefix "*" \
--source-port-range "*" \
--destination-address-prefix "*" \
--destination-port-range 80
```

The front-end VM is only accessible on port 22 and port *80*. All other incoming traffic is blocked at the network security group. It may be helpful to visualize the NSG rule configurations. Return the NSG rule configuration with the [az network rule list](#) command.

```
az network nsg rule list --resource-group myRGNetwork --nsg-name myFrontendNSG --output table
```

## Secure VM to VM traffic

Network security group rules can also apply between VMs. For this example, the front-end VM needs to communicate with the back-end VM on port 22 and *3306*. This configuration allows SSH connections from the front-end VM, and also allow an application on the front-end VM to communicate with a back-end MySQL database. All other traffic should be blocked between the front-end and back-end virtual machines.

Use the [az network nsg rule create](#) command to create a rule for port 22. Notice that the

--source-address-prefix argument specifies a value of *10.0.1.0/24*. This configuration ensures that only traffic from the front-end subnet is allowed through the NSG.

```
az network nsg rule create \
--resource-group myRGNetwork \
--nsg-name myBackendNSG \
--name SSH \
--access Allow \
--protocol Tcp \
--direction Inbound \
--priority 100 \
--source-address-prefix 10.0.1.0/24 \
--source-port-range "*" \
--destination-address-prefix "*" \
--destination-port-range "22"
```

Now add a rule for MySQL traffic on port 3306.

```
az network nsg rule create \
--resource-group myRGNetwork \
--nsg-name myBackendNSG \
--name MySQL \
--access Allow \
--protocol Tcp \
--direction Inbound \
--priority 200 \
--source-address-prefix 10.0.1.0/24 \
--source-port-range "*" \
--destination-address-prefix "*" \
--destination-port-range "3306"
```

Finally, because NSGs have a default rule allowing all traffic between VMs in the same VNet, a rule can be created for the back-end NSGs to block all traffic. Notice here that the `--priority` is given a value of *300*, which is lower than both the NSG and MySQL rules. This configuration ensures that SSH and MySQL traffic is still allowed through the NSG.

```
az network nsg rule create \
--resource-group myRGNetwork \
--nsg-name myBackendNSG \
--name denyAll \
--access Deny \
--protocol Tcp \
--direction Inbound \
--priority 300 \
--source-address-prefix "*" \
--source-port-range "*" \
--destination-address-prefix "*" \
--destination-port-range "*"
```

## Create back-end VM

Now create a virtual machine, which is attached to the *myBackendSubnet*. Notice that the `--nsg` argument has a value of empty double quotes. An NSG does not need to be created with the VM. The VM is attached to the back-end subnet, which is protected with the pre-created back-end NSG. This NSG applies to the VM. Also, notice here that the `--public-ip-address` argument has a value of empty double quotes. This configuration creates a VM without a public IP address.

```
az vm create \
--resource-group myRGNetwork \
--name myBackendVM \
--vnet-name myVNet \
--subnet myBackendSubnet \
--public-ip-address "" \
--nsg "" \
--image UbuntuLTS \
--generate-ssh-keys
```

The back-end VM is only accessible on port 22 and port 3306 from the front-end subnet. All other incoming traffic is blocked at the network security group. It may be helpful to visualize the NSG rule configurations. Return the NSG rule configuration with the [az network rule list](#) command.

```
az network nsg rule list --resource-group myRGNetwork --nsg-name myBackendNSG --output table
```

## Next steps

In this tutorial, you created and secured Azure networks as related to virtual machines. You learned how to:

- Create a virtual network and subnet
- Create a public IP address
- Create a front-end VM
- Secure network traffic
- Create back-end VM

To learn about protecting your VM disks, see [Backup and disaster recovery for disks](#).

# Tutorial: Create and Manage Windows VMs with Azure PowerShell

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Azure virtual machines provide a fully configurable and flexible computing environment. This tutorial covers basic Azure virtual machine (VM) deployment tasks like selecting a VM size, selecting a VM image, and deploying a VM. You learn how to:

- Create and connect to a VM
- Select and use VM images
- View and use specific VM sizes
- Resize a VM
- View and understand VM state

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create resource group

Create a resource group with the [New-AzResourceGroup](#) command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In the following example, a resource group named *myResourceGroupVM* is created in the *EastUS* region:

```
New-AzResourceGroup  
  -ResourceGroupName "myResourceGroupVM"  
  -Location "EastUS"
```

The resource group is specified when creating or modifying a VM, which can be seen throughout this tutorial.

## Create a VM

When creating a VM, several options are available like operating system image, network configuration, and administrative credentials. This example creates a VM named *myVM*, running the default version of Windows Server 2016 Datacenter.

Set the username and password needed for the administrator account on the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Create the VM with [New-AzVM](#).

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroupVM" ` 
    -Name "myVM" ` 
    -Location "EastUS" ` 
    -VirtualNetworkName "myVnet" ` 
    -SubnetName "mySubnet" ` 
    -SecurityGroupName "myNetworkSecurityGroup" ` 
    -PublicIpAddressName "myPublicIpAddress" ` 
    -Credential $cred
```

## Connect to VM

After the deployment has completed, create a remote desktop connection with the VM.

Run the following commands to return the public IP address of the VM. Take note of this IP Address so you can connect to it with your browser to test web connectivity in a future step.

```
Get-AzPublicIpAddress ` 
    -ResourceGroupName "myResourceGroupVM" | Select IpAddress
```

Use the following command, on your local machine, to create a remote desktop session with the VM. Replace the IP address with the *publicIpAddress* of your VM. When prompted, enter the credentials used when creating the VM.

```
mstsc /v:<publicIpAddress>
```

In the **Windows Security** window, select **More choices** and then **Use a different account**. Type the username and password you created for the VM and then click **OK**.

## Understand marketplace images

The Azure marketplace includes many images that can be used to create a new VM. In the previous steps, a VM was created using the Windows Server 2016 Datacenter image. In this step, the PowerShell module is used to search the marketplace for other Windows images, which can also be used as a base for new VMs. This process consists of finding the publisher, offer, SKU, and optionally a version number to **identify** the image.

Use the [Get-AzVMImagePublisher](#) command to return a list of image publishers:

```
Get-AzVMImagePublisher -Location "EastUS"
```

Use the [Get-AzVMImageOffer](#) to return a list of image offers. With this command, the returned list is filtered on the specified publisher named `MicrosoftWindowsServer`:

```
Get-AzVMImageOffer ` 
    -Location "EastUS" ` 
    -PublisherName "MicrosoftWindowsServer"
```

The results will look something like this example:

Offer	PublisherName	Location
Windows-HUB	MicrosoftWindowsServer	EastUS
WindowsServer	MicrosoftWindowsServer	EastUS
WindowsServer-HUB	MicrosoftWindowsServer	EastUS

The [Get-AzVMImageSku](#) command will then filter on the publisher and offer name to return a list of image names.

```
Get-AzVMImageSku ` 
    -Location "EastUS" ` 
    -PublisherName "MicrosoftWindowsServer" ` 
    -Offer "WindowsServer"
```

The results will look something like this example:

Skus	Offer	PublisherName	Location
2008-R2-SP1	WindowsServer	MicrosoftWindowsServer	EastUS
2008-R2-SP1-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2012-Datacenter	WindowsServer	MicrosoftWindowsServer	EastUS
2012-Datacenter-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2012-R2-Datacenter	WindowsServer	MicrosoftWindowsServer	EastUS
2012-R2-Datacenter-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-Server-Core	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-Server-Core-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-with-Containers	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-with-Containers-smalldisk	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Datacenter-with-RDSH	WindowsServer	MicrosoftWindowsServer	EastUS
2016-Nano-Server	WindowsServer	MicrosoftWindowsServer	EastUS

This information can be used to deploy a VM with a specific image. This example deploys a VM using the latest version of a Windows Server 2016 with Containers image.

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroupVM" ` 
    -Name "myVM2" ` 
    -Location "EastUS" ` 
    -VirtualNetworkName "myVnet" ` 
    -SubnetName "mySubnet" ` 
    -SecurityGroupName "myNetworkSecurityGroup" ` 
    -PublicIpAddressName "myPublicIpAddress2" ` 
    -ImageName "MicrosoftWindowsServer:WindowsServer:2016-Datacenter-with-Containers:latest" ` 
    -Credential $cred ` 
    -AsJob
```

The `-AsJob` parameter creates the VM as a background task, so the PowerShell prompts return to you. You can view details of background jobs with the [Get-Job](#) cmdlet.

## Understand VM sizes

The VM size determines the amount of compute resources like CPU, GPU, and memory that are made available to the VM. Virtual machines should be created using a VM size appropriate for the workload. If a workload increases, an existing virtual machine can also be resized.

### VM Sizes

The following table categorizes sizes into use cases.

Type	Common Sizes	Description
General purpose	B, Dsv3, Dv3, DSv2, Dv2, Av2, DC	Balanced CPU-to-memory. Ideal for dev / test and small to medium applications and data solutions.
Compute optimized	Fsv2	High CPU-to-memory. Good for medium traffic applications, network appliances, and batch processes.
Memory optimized	Esv3, Ev3, M, DSv2, Dv2	High memory-to-core. Great for relational databases, medium to large caches, and in-memory analytics.
Storage optimized	Lsv2, Ls	High disk throughput and IO. Ideal for Big Data, SQL, and NoSQL databases.
GPU	NV, NVv2, NC, NCv2, NCv3, ND	Specialized VMs targeted for heavy graphic rendering and video editing.
High performance	H	Our most powerful CPU VMs with optional high-throughput network interfaces (RDMA).

## Find available VM sizes

To see a list of VM sizes available in a particular region, use the [Get-AzVMSize](#) command.

```
Get-AzVMSize -Location "EastUS"
```

## Resize a VM

After a VM has been deployed, it can be resized to increase or decrease resource allocation.

Before resizing a VM, check if the size you want is available on the current VM cluster. The [Get-AzVMSize](#) command returns a list of sizes.

```
Get-AzVMSize -ResourceGroupName "myResourceGroupVM" -VMName "myVM"
```

If the size is available, the VM can be resized from a powered-on state, however it is rebooted during the operation.

```
$vm = Get-AzVM ` 
-ResourceGroupName "myResourceGroupVM" ` 
-VMName "myVM"
$vm.HardwareProfile.VmSize = "Standard_DS3_v2"
Update-AzVM ` 
-VM $vm ` 
-ResourceGroupName "myResourceGroupVM"
```

If the size you want isn't available on the current cluster, the VM needs to be deallocated before the resize operation can occur. Deallocation of a VM will remove any data on the temp disk, and the public IP address will change unless a static IP address is being used.

```

Stop-AzVM ` 
  -ResourceGroupName "myResourceGroupVM" ` 
  -Name "myVM" -Force
$vm = Get-AzVM ` 
  -ResourceGroupName "myResourceGroupVM" ` 
  -VMName "myVM"
$vm.HardwareProfile.VmSize = "Standard_E2s_v3"
Update-AzVM -VM $vm ` 
  -ResourceGroupName "myResourceGroupVM"
Start-AzVM ` 
  -ResourceGroupName "myResourceGroupVM" ` 
  -Name $vm.name

```

## VM power states

An Azure VM can have one of many power states.

POWER STATE	DESCRIPTION
Starting	The virtual machine is being started.
Running	The virtual machine is running.
Stopping	The virtual machine is being stopped.
Stopped	The VM is stopped. Virtual machines in the stopped state still incur compute charges.
Deallocating	The VM is being deallocated.
Deallocated	Indicates that the VM is removed from the hypervisor but is still available in the control plane. Virtual machines in the <code>Deallocated</code> state do not incur compute charges.
-	The power state of the VM is unknown.

To get the state of a particular VM, use the [Get-AzVM](#) command. Be sure to specify a valid name for a VM and resource group.

```

Get-AzVM ` 
  -ResourceGroupName "myResourceGroupVM" ` 
  -Name "myVM" ` 
  -Status | Select @{n="Status"; e={$_.Statuses[1].Code}}

```

The output will look something like this example:

```

Status
-----
PowerState/running

```

To retrieve the power state of all the VMs in your subscription, use the [Virtual Machines - List All API](#) with parameter `statusOnly` set to `true`.

## Management tasks

During the lifecycle of a VM, you may want to run management tasks like starting, stopping, or deleting a VM. Additionally, you may want to create scripts to automate repetitive or complex tasks. Using Azure PowerShell, many common management tasks can be run from the command line or in scripts.

## Stop a VM

Stop and deallocate a VM with [Stop-AzVM](#):

```
Stop-AzVM ` 
-ResourceGroupName "myResourceGroupVM" ` 
-Name "myVM" -Force
```

If you want to keep the VM in a provisioned state, use the `-StayProvisioned` parameter.

## Start a VM

```
Start-AzVM ` 
-ResourceGroupName "myResourceGroupVM" ` 
-Name "myVM"
```

## Deleting VM resources

You can delete a VM, but by default this only deletes the VM resource, not the disks and networking resources the VM uses. You can change the default behavior to delete other resources when you delete the VM. For more information, see [Delete a VM and attached resources](#).

## Next steps

In this tutorial, you learned about basic VM creation and management such as how to:

- Create and connect to a VM
- Select and use VM images
- View and use specific VM sizes
- Resize a VM
- View and understand VM state

Advance to the next tutorial to learn about VM disks.

[Create and Manage VM disks](#)

# Tutorial: Manage disks with Azure PowerShell

9/21/2022 • 12 minutes to read • [Edit Online](#)

Azure virtual machines (VMs) use disks to store operating systems (OS), applications, and data. When you create a VM, it's important to choose an appropriate disk size and configuration for the expected workload.

This tutorial covers deployment and management of VM disks. In this tutorial, you learn how to:

- Create, attach, and initialize a data disk
- Verify a disk's status
- Initialize a disk
- Expand and upgrade a disk
- Detach and delete a disk

## Prerequisites

You must have an Azure account with an active subscription. If you don't have an Azure subscription, create a [free account](#) before you begin.

## Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

OPTION	EXAMPLE/LINK
Select <b>Try It</b> in the upper-right corner of a code or command block. Selecting <b>Try It</b> doesn't automatically copy the code or command to Cloud Shell.	
Go to <a href="https://shell.azure.com">https://shell.azure.com</a> , or select the <b>Launch Cloud Shell</b> button to open Cloud Shell in your browser.	
Select the <b>Cloud Shell</b> button on the menu bar at the upper right in the <a href="#">Azure portal</a> .	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl+Shift+V** on Windows and Linux, or by selecting **Cmd+Shift+V** on macOS.
4. Select **Enter** to run the code or command.

# Create a VM

The exercises in this tutorial require a VM. Follow the steps in this section to create one.

Before you begin, find the `$azRegion` variable located in the first line of sample code and update the value to reflect your desired region. For example, to specify the Central US region, use `$azRegion = "Central US"`. Next, use the code to deploy a VM within a new resource group. You're prompted for username and password values for the VM's local administrator account.

```
$azRegion = "[Your Region]"
$azResourceGroup = "myDemoResourceGroup"
$azVMName = "myDemoVM"
$azDataDiskName = "myDemoDataDisk"

New-AzVm ` 
    -Location $azRegion ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName ` 
    -Size "Standard_D2s_v3" ` 
    -VirtualNetworkName "myDemoVnet" ` 
    -SubnetName "myDemoSubnet" ` 
    -SecurityGroupName "myDemoNetworkSecurityGroup" ` 
    -PublicIpAddressName "myDemoPublicIpAddress"
```

The output confirms the VM's successful creation.

```
ResourceGroupName      : myDemoResourceGroup
Id                   :
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Microsoft.Compute/virtualMachines/myDemoT
estVM
VmId                : [{GUID}]
Name                 : myDemoVM
Type                 : Microsoft.Compute/virtualMachines
Location             : centralus
Tags                 : {}
HardwareProfile       : {VmSize}
NetworkProfile        : {NetworkInterfaces}
OSProfile            : {ComputerName, AdminUsername, WindowsConfiguration, AllowExtensionOperations,
RequireGuestProvisionSignal}
ProvisioningState     : Succeeded
StorageProfile        : {ImageReference, OsDisk, DataDisks}
FullyQualifiedDomainName : mydemovm-abc123.Central US.cloudapp.azure.com
```

The VM is provisioned, and two disks are automatically created and attached.

- An **operating system disk**, which hosts the virtual machine's operating system.
- A **temporary disk**, which is primarily used for operations such as temporary data processing.

## Add a data disk

We recommend that you separate application and user data from OS-related data when possible. If you need to store user or application data on your VM, you'll typically create and attach additional data disks.

Follow the steps in this section to create, attach, and initialize a data disk on the VM.

### Create the data disk

This section guides you through the creation of a data disk.

1. Before a data disk can be created, you must first create a disk object. The following code sample uses the [New-AzDiskConfig](#) cmdlet to configure a disk object.

```
$diskConfig = New-AzDiskConfig ` 
    -Location $azRegion ` 
    -CreateOption Empty ` 
    -DiskSizeGB 128 ` 
    -SkuName "Standard_LRS"
```

2. After the disk object is created, use the [New-AzDisk](#) cmdlet to provision a data disk.

```
$dataDisk = New-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $azDataDiskName ` 
    -Disk $diskConfig
```

You can use the [Get-AzDisk](#) cmdlet to verify that the disk was created.

```
Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $azDataDiskName
```

In this example, the output confirms that the disk was created. The `DiskState` and `ManagedBy` property values confirm that the disk is not yet attached.

```
ResourceGroupName      : myDemoResourceGroup
ManagedBy              :
ManagedByExtended      : {}
OsType                 :
DiskSizeGB             : 128
DiskSizeBytes          : 137438953472
ProvisioningState      : Succeeded
DiskIOPSReadWrite      : 500
DiskMBpsReadWrite      : 60
DiskState               : Unattached
Name                   : myDemoDataDisk
```

## Attach the data disk

A data disk must be attached to a VM before the VM can access it. Complete the steps in this section to create a reference for the VM, connect the disk, and update the VM's configuration.

1. Get the VM to which you'll attach the data disk. The following sample code uses the [Get-AzVM](#) cmdlet to create a reference to the VM.

```
$vm = Get-AzVM ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName
```

2. Next, attach the data disk to the VM's configuration with the [Add-AzVMDataDisk](#) cmdlet.

```
$vm = Add-AzVMDataDisk ` 
    -VM $vm ` 
    -Name $azDataDiskName ` 
    -CreateOption Attach ` 
    -ManagedDiskId $dataDisk.Id ` 
    -Lun 1
```

3. Finally, update the VM's configuration with the [Update-AzVM](#) cmdlet.

```
Update-AzVM  
    -ResourceGroupName $azResourceGroup  
    -VM $vm
```

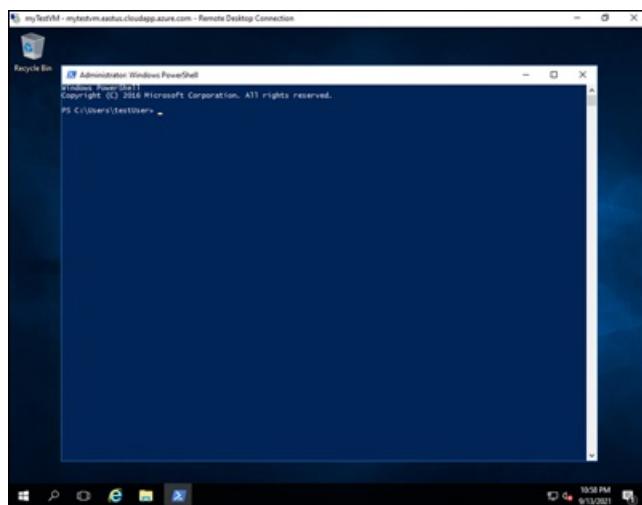

After a brief pause, the output confirms a successful attachment.

RequestId	IsSuccessStatusCode	StatusCode	ReasonPhrase
True	OK	OK	

## Initialize the data disk

After a data disk is attached to the VM, the OS needs to be configured to use the disk. The following section provides guidance on how to connect to the remote VM and configure the first disk added.

1. Sign in to the [Azure portal](#).
2. Locate the VM to which you've attached the data disk. Create a Remote Desktop Protocol (RDP) connection and sign in as the local administrator.
3. After you establish an RDP connection to the remote VM, select the Windows **Start** menu. Enter **PowerShell** in the search box and select **Windows PowerShell** to open a PowerShell window.

4. In the open PowerShell window, run the following script.

```
Get-Disk | Where PartitionStyle -eq 'raw' |  
Initialize-Disk -PartitionStyle MBR -PassThru |  
New-Partition -AssignDriveLetter -UseMaximumSize |  
Format-Volume -FileSystem NTFS -NewFileSystemLabel "myDemoDataDisk" -Confirm:$false
```

The output confirms a successful initialization.

DriveLetter	FileSystemLabel	FileSystem	DriveType	HealthStatus	OperationalStatus	SizeRemaining	Size
F	myDemoDataDisk	NTFS	Fixed	Healthy	OK	127.89 GB	128 GB

## Expand a disk

You can expand Azure disks to provide extra storage capacity when your VM is low on available disk space.

Some scenarios require data to be stored on the OS disk. For example, you may be required to support legacy

applications that install components on the OS drive. You may also have the need to migrate an on-premises physical PC or VM with a larger OS drive. In such cases, it may become necessary to expand a VM's OS disk.

Shrinking an existing disk isn't supported, and can potentially result in data loss.

## Update the disk's size

Follow the steps below to resize either the OS disk or a data disk.

1. Select the VM that contains the disk that you'll resize with the `Get-AzVM` cmdlet.

```
$vm = Get-AzVM ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName
```

2. Before you can resize a VM's disk, you must stop the VM. Use the `Stop-AzVM` cmdlet to stop the VM. You'll be prompted for confirmation.

### IMPORTANT

Before you initiate a VM shutdown, always confirm that there are no important resources or data that could be lost.

```
Stop-AzVM ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName
```

After a short pause, the output confirms that the machine is successfully stopped.

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status       : Succeeded
StartTime    : 9/13/2021 7:10:23 PM
EndTime      : 9/13/2021 7:11:12 PM
Error        :
```

3. After the VM is stopped, get a reference to either the OS or data disk attached to the VM with the `Get-AzDisk` cmdlet.

The following example selects the VM's OS disk.

```
$disk= Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $vm.StorageProfile.OsDisk.Name
```

The following example selects the VM's first data disk.

```
$disk= Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $vm.StorageProfile.DataDisks[0].Name
```

4. Now that you have a reference to the disk, set the size of the disk to 250 GiB.

## IMPORTANT

The new size should be greater than the existing disk size. The maximum allowed is 4,095 GiB for OS disks.

```
$disk.DiskSizeGB = 250
```

5. Next, update the disk image with the `Update-AzDisk` cmdlet.

```
Update-AzDisk `  
-ResourceGroupName $azResourceGroup `  
-Disk $disk -DiskName $disk.Name
```

The disk image is updated, and the output confirms the disk's new size.

```
ResourceGroupName      : myDemoResourceGroup  
ManagedBy             :  
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Microsoft.Compute/virtualMachines/  
myDemoVM  
Sku                  : Microsoft.Azure.Management.Compute.Models.DiskSku  
TimeCreated           : 9/13/2021 6:41:10 PM  
CreationData          : Microsoft.Azure.Management.Compute.Models.CreationData  
DiskSizeGB            : 250  
DiskSizeBytes         : 268435456000  
UniqueId              : {GUID}  
ProvisioningState     : Succeeded  
DiskIOPSReadWrite     : 500  
DiskMBpsReadWrite    : 60  
DiskState              : Reserved  
Encryption            : Microsoft.Azure.Management.Compute.Models.Encryption  
Id                   :  
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Microsoft.Compute/disks/myDemoData  
Disk  
Name                 : myDemoDataDisk  
Type                 : Microsoft.Compute/disks  
Location              : centralus
```

6. Finally, restart the VM with the `Start-AzVM` cmdlet.

```
Start-AzVM `  
-ResourceGroupName $azResourceGroup `  
-Name $azVMName
```

After a short pause, the output confirms that the machine is successfully started.

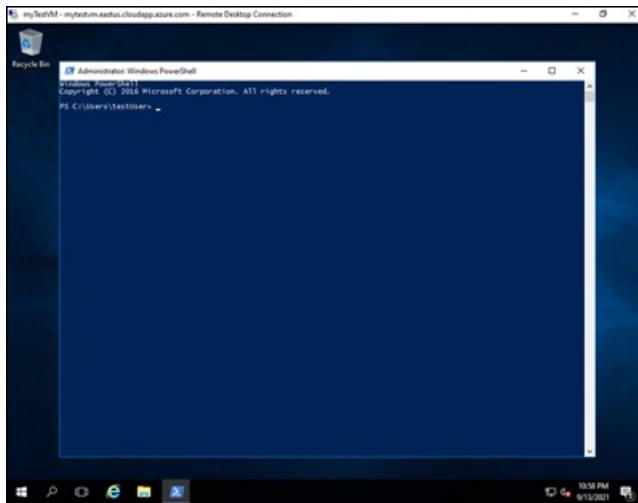

```
OperationId : abcd1234-ab12-cd34-123456abcdef  
Status      : Succeeded  
StartTime   : 9/13/2021 7:44:54 PM  
EndTime     : 9/13/2021 7:45:15 PM  
Error       :
```

## Expand the disk volume in the OS

Before you can take advantage of the new disk size, you need to expand the volume within the OS. Follow the steps below to expand the disk volume and take advantage of the new disk size.

1. Sign in to the [Azure portal](#).

- Locate the VM to which you've attached the data disk. Create a Remote Desktop Protocol (RDP) connection and sign in. If you no longer have access to an administrative account, create a credential object for a specified user name and password with the [Get-Credential](#) cmdlet.
- After you've established an RDP connection to the remote VM, select the Windows **Start** menu. Enter **PowerShell** in the search box and select **Windows PowerShell** to open a PowerShell window.

- Open PowerShell and run the following script. Change the value of the `-DriveLetter` variable as appropriate. For example, to resize the partition on the F: drive, use `$driveLetter = "F"`.

```
$driveLetter = "[Drive Letter]"
GetSize = (Get-PartitionSupportedSize -DriveLetter $driveLetter)
Resize-Partition ` 
    -DriveLetter $driveLetter ` 
    -Size $size.SizeMax
```

- Minimize the RDP window and switch back to Azure Cloud Shell. Use the [Get-AzDisk](#) cmdlet to verify that the disk was resized successfully.

```
Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup | Out-Host -Paging
```

## Upgrade a disk

There are several ways to respond to changes in your organization's workloads. For example, you may choose to upgrade a standard HDD to a premium SSD to handle increased demand.

Follow the steps in this section to upgrade a managed disk from standard to premium.

- Select the VM that contains the disk that you'll upgrade with the [Get-AzVM](#) cmdlet.

```
$vm = Get-AzVM ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName
```

- Before you can upgrade a VM's disk, you must stop the VM. Use the [Stop-AzVM](#) cmdlet to stop the VM. You'll be prompted for confirmation.

### IMPORTANT

Before you initiate a VM shutdown, always confirm that there are no important resources or data that could be lost.

```
Stop-AzVM ` 
    -ResourceGroupName $azResourceGroup ` 
    -Name $azVMName
```

After a short pause, the output confirms that the machine is successfully stopped.

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status       : Succeeded
StartTime    : 9/13/2021 7:10:23 PM
EndTime      : 9/13/2021 7:11:12 PM
Error        :
```

3. After the VM is stopped, get a reference to either the OS or data disk attached to the VM with the `Get-AzDisk` cmdlet.

The following example selects the VM's OS disk.

```
$disk= Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $vm.StorageProfile.OsDisk.Name
```

The following example selects the VM's first data disk.

```
$disk= Get-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -DiskName $vm.StorageProfile.DataDisks[0].Name
```

4. Now that you have a reference to the disk, set the disk's SKU to **Premium\_LRS**.

```
$disk.Sku = [Microsoft.Azure.Management.Compute.Models.DiskSku]::new('Premium_LRS')
```

5. Next, update the disk image with the `Update-AzDisk` cmdlet.

```
Update-AzDisk ` 
    -ResourceGroupName $azResourceGroup ` 
    -Disk $disk -DiskName $disk.Name
```

The disk image is updated. Use the following example code to validate that the disk's SKU has been upgraded.

```
$disk.Sku.Name
```

The output confirms the disk's new SKU.

```
Premium_LRS
```

6. Finally, restart the VM with the `Start-AzVM` cmdlet.

```
Start-AzVM ` 
-ResourceGroupName $azResourceGroup ` 
-Name $azVMName
```

After a short pause, the output confirms that the machine is successfully started.

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status       : Succeeded
StartTime    : 9/13/2021 7:44:54 PM
EndTime      : 9/13/2021 7:45:15 PM
Error        :
```

## Detach a data disk

You can detach a data disk from a VM when you want to attach it to a different VM, or when it's no longer needed. By default, detached disks are not deleted to prevent unintentional data loss. A detached disk will continue to incur storage charges until it's deleted.

1. First, select the VM to which the disk is attached with the `Get-AzVM` cmdlet.

```
$vm = Get-AzVM ` 
-ResourceGroupName $azResourceGroup ` 
-Name $azVMName
```

2. Next, detach the disk from the VM with the `Remove-AzVMDataDisk` cmdlet.

```
Remove-AzVMDataDisk ` 
-VM $vm ` 
-Name $azDataDiskName
```

3. Update the state of the VM with the `Update-AzVM` cmdlet to remove the data disk.

```
Update-AzVM ` 
-ResourceGroupName $azResourceGroup ` 
-VM $vm
```

After a short pause, the output confirms that the VM is successfully updated.

```
RequestId IsSuccess StatusCode ReasonPhrase
----- -----
True      OK      OK
```

## Delete a data disk

When you delete a VM, data disks attached to the VM remain provisioned and continue to incur charges until they're deleted. This default behavior helps prevent data loss caused by unintentional deletion.

You can use the following sample PowerShell script to delete unattached disks. The retrieval of disks is limited to the `myDemoResourceGroup` because the `-ResourceGroupName` switch is used with the `Get-AzDisk` cmdlet.

```

# Get all disks in resource group $azResourceGroup
$allDisks = Get-AzDisk -ResourceGroupName $azResourceGroup

# Determine the number of disks in the collection
if($allDisks.Count -ne 0) {

    Write-Host "Found $($allDisks.Count) disks."

    # Iterate through the collection
    foreach ($disk in $allDisks) {

        # Use the disk's "ManagedBy" property to determine if it is unattached
        if($disk.ManagedBy -eq $null) {

            # Confirm that the disk can be deleted
            Write-Host "Deleting unattached disk $($disk.Name)."
            $confirm = Read-Host "Continue? (Y/N)"
            if ($confirm.ToUpper() -ne 'Y') { break }
            else {

                # Delete the disk
                $disk | Remove-AzDisk -Force
                Write-Host "Unattached disk $($disk.Name) deleted."
            }
        }
    }
}

```

The unattached data disk is deleted as shown by the output.

```

Name      : abcd1234-ab12-cd34-ef56-abcdef123456
StartTime : 9/13/2021 10:14:05 AM
EndTime   : 9/13/2021 10:14:35 AM
Status    : Succeeded
Error     :

```

## Clean up resources

When no longer needed, delete the resource group, VM, and all related resources. You can use the following sample PowerShell script to delete the resource group created earlier in this tutorial.

**Caution**

Use caution when deleting a resource group. To avoid the loss of important data, always confirm that there are no important resources or data contained within the resource group before it is deleted.

```
Remove-AzResourceGroup -Name $azResourceGroup
```

You're prompted for confirmation. After a short pause, the `True` response confirms that the `myDemoResourceGroup` is successfully deleted.

```

Confirm
Are you sure you want to remove resource group 'myDemoResourceGroup'
[Y] Yes [N] No [S] Suspend [?] Help (default is "Y"): Y
True

```

## Next steps

In this tutorial, you learned how to:

- Create, attach, and initialize a data disk
- Verify a disk's status
- Initialize a disk
- Expand and upgrade a disk
- Detach and delete a disk

Advance to the next tutorial to learn how to automate VM configuration.

[Automate VM configuration](#)

# Tutorial - Deploy applications to a Windows virtual machine in Azure with the Custom Script Extension

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Window ✓ Flexible scale sets ✓ Uniform scale sets

To configure virtual machines (VMs) in a quick and consistent manner, you can use the [Custom Script Extension for Windows](#). In this tutorial you learn how to:

- Use the Custom Script Extension to install IIS
- Create a VM that uses the Custom Script Extension
- View a running IIS site after the extension is applied

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Custom script extension overview

The Custom Script Extension downloads and executes scripts on Azure VMs. This extension is useful for post deployment configuration, software installation, or any other configuration / management task. Scripts can be downloaded from Azure storage or GitHub, or provided to the Azure portal at extension run time.

The Custom Script extension integrates with Azure Resource Manager templates, and can also be run using the Azure CLI, PowerShell, Azure portal, or the Azure Virtual Machine REST API.

You can use the Custom Script Extension with both Windows and Linux VMs.

## Create virtual machine

Set the administrator username and password for the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Now you can create the VM with [New-AzVM](#). The following example creates a VM named *myVM* in the *EastUS* location. If they do not already exist, the resource group *myResourceGroupAutomate* and supporting network resources are created. To allow web traffic, the cmdlet also opens port *80*.

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroupAutomate" ` 
    -Name "myVM" ` 
    -Location "East US" ` 
    -VirtualNetworkName "myVnet" ` 
    -SubnetName "mySubnet" ` 
    -SecurityGroupName "myNetworkSecurityGroup" ` 
    -PublicIpAddressName "myPublicIpAddress" ` 
    -OpenPorts 80 ` 
    -Credential $cred
```

It takes a few minutes for the resources and VM to be created.

## Automate IIS install

Use [Set-AzVMExtension](#) to install the Custom Script Extension. The extension runs

```
powershell Add-WindowsFeature Web-Server
```

 to install the IIS webserver and then updates the *Default.htm* page to show the hostname of the VM:

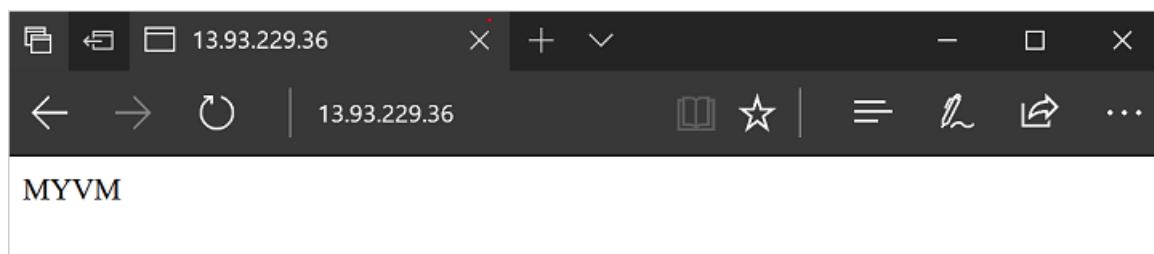

```
Set-AzVMExtension -ResourceGroupName "myResourceGroupAutomate" ` 
    -ExtensionName "IIS" ` 
    -VMName "myVM" ` 
    -Location "EastUS" ` 
    -Publisher Microsoft.Compute ` 
    -ExtensionType CustomScriptExtension ` 
    -TypeHandlerVersion 1.8 ` 
    -SettingString '{"commandToExecute":"powershell Add-WindowsFeature Web-Server; powershell Add-Content -Path \"C:\\inetpub\\wwwroot\\Default.htm\" -Value $($env:computername)"}'
```

## Test web site

Obtain the public IP address of your load balancer with [Get-AzPublicIPAddress](#). The following example obtains the IP address for *myPublicIPAddress* created earlier:

```
Get-AzPublicIPAddress ` 
    -ResourceGroupName "myResourceGroupAutomate" ` 
    -Name "myPublicIPAddress" | select IpAddress
```

You can then enter the public IP address in to a web browser. The website is displayed, including the hostname of the VM that the load balancer distributed traffic to as in the following example:

## Next steps

In this tutorial, you automated the IIS install on a VM. You learned how to:

- Use the Custom Script Extension to install IIS
- Create a VM that uses the Custom Script Extension
- View a running IIS site after the extension is applied

Advance to the next tutorial to learn how to create custom VM images.

[Create custom VM images](#)

# Tutorial: Create Windows VM images with Azure PowerShell

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Images can be used to bootstrap deployments and ensure consistency across multiple VMs. In this tutorial, you create your own specialized image of an Azure virtual machine using PowerShell and store it in an Azure Compute Gallery (formerly known as Shared Image Gallery). You learn how to:

- Create an Azure Compute Gallery
- Create an image definition
- Create an image version
- Create a VM from an image
- Share a gallery

## Before you begin

The steps below detail how to take an existing VM and turn it into a re-usable custom image that you can use to create new VMs.

To complete the example in this tutorial, you must have an existing virtual machine. If needed, you can see the [PowerShell quickstart](#) to create a VM to use for this tutorial. When working through the tutorial, replace the resource names where needed.

## Overview

An [Azure Compute Gallery](#) simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations.

The Azure Compute Gallery lets you share your custom VM images with others. Choose which images you want to share, which regions you want to make them available in, and who you want to share them with.

The Azure Compute Gallery feature has multiple resource types:

RESOURCE	DESCRIPTION
Image source	This is a resource that can be used to create an <a href="#">image version</a> in a gallery. An image source can be an existing Azure VM that is either <a href="#">generalized or specialized</a> , a managed image, a snapshot, or an image version in another gallery.
Gallery	Like the Azure Marketplace, a <a href="#">gallery</a> is a repository for managing and sharing images and <a href="#">VM applications</a> , but you control who has access.

RESOURCE	DESCRIPTION
Image definition	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
Image version	An <b>image version</b> is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an <b>image version</b> to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Get the VM

You can see a list of VMs that are available in a resource group using [Get-AzVM](#). Once you know the VM name and what resource group, you can use `Get-AzVM` again to get the VM object and store it in a variable to use later. This example gets an VM named *sourceVM* from the "myResourceGroup" resource group and assigns it to the variable `$sourceVM`.

```
$sourceVM = Get-AzVM ` 
-Name sourceVM ` 
-ResourceGroupName myResourceGroup
```

## Create a resource group

Create a resource group with the [New-AzResourceGroup](#) command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. In the following example, a resource group named *myGalleryRG* is created in the *EastUS* region:

```
$resourceGroup = New-AzResourceGroup ` 
-Name 'myGalleryRG' ` 
-Location 'EastUS'
```

## Create a gallery

A gallery is the primary resource used for enabling image sharing. Allowed characters for gallery name are uppercase or lowercase letters, digits, dots, and periods. The gallery name cannot contain dashes. Gallery names must be unique within your subscription.

Create a gallery using [New-AzGallery](#). The following example creates a gallery named *myGallery* in the *myGalleryRG* resource group.

```
$gallery = New-AzGallery ` 
    -GalleryName 'myGallery' ` 
    -ResourceGroupName $resourceGroup.ResourceGroupName ` 
    -Location $resourceGroup.Location ` 
    -Description 'Azure Compute Gallery for my organization'
```

## Create an image definition

Image definitions create a logical grouping for images. They are used to manage information about the image versions that are created within them. Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes and periods. For more information about the values you can specify for an image definition, see [Image definitions](#).

Create the image definition using [New-AzGalleryImageDefinition](#). In this example, the gallery image is named `myGalleryImage` and is created for a specialized image.

```
$galleryImage = New-AzGalleryImageDefinition ` 
    -GalleryName $gallery.Name ` 
    -ResourceGroupName $resourceGroup.ResourceGroupName ` 
    -Location $gallery.Location ` 
    -Name 'myImageDefinition' ` 
    -OsState specialized ` 
    -OsType Windows ` 
    -Publisher 'myPublisher' ` 
    -Offer 'myOffer' ` 
    -Sku 'mySKU'
```

## Create an image version

Create an image version from a VM using [New-AzGalleryImageVersion](#).

Allowed characters for image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion.MinorVersion.Patch*.

In this example, the image version is `1.0.0` and it's replicated to both *East US* and *South Central US* datacenters. When choosing target regions for replication, you need to include the *source* region as a target for replication.

To create an image version from the VM, use `$vm.Id.ToString()` for the `-Source`.

```
$region1 = @{Name='South Central US';ReplicaCount=1} 
$region2 = @{Name='East US';ReplicaCount=2} 
$targetRegions = @($region1,$region2)

New-AzGalleryImageVersion ` 
    -GalleryImageDefinitionName $galleryImage.Name ` 
    -GalleryImageVersionName '1.0.0' ` 
    -GalleryName $gallery.Name ` 
    -ResourceGroupName $resourceGroup.ResourceGroupName ` 
    -Location $resourceGroup.Location ` 
    -TargetRegion $targetRegions ` 
    -Source $sourceVM.Id.ToString() ` 
    -PublishingProfileEndOfLifeDate '2030-12-01'
```

It can take a while to replicate the image to all of the target regions.

## Create a VM

Once you have a specialized image, you can create one or more new VMs. Using the [New-AzVM](#) cmdlet. To use

the image, use `Set-AzVMSourceImage` and set the `-Id` to the image definition ID (`$galleryImage.Id` in this case) to always use the latest image version.

Replace resource names as needed in this example.

```
# Create some variables for the new VM.
$resourceGroup = "myResourceGroup"
$location = "South Central US"
$vmName = "mySpecializedVM"

# Create a resource group
New-AzResourceGroup -Name $resourceGroup -Location $location

# Create the network resources.
$subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork -ResourceGroupName $resourceGroup -Location $location ` 
    -Name MYvNET -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig
$pip = New-AzPublicIpAddress -ResourceGroupName $resourceGroup -Location $location ` 
    -Name "mypublicdns$(Get-Random)" -AllocationMethod Static -IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name myNetworkSecurityGroupRuleRDP -Protocol Tcp ` 
    -Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange * -DestinationAddressPrefix * ` 
    -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName $resourceGroup -Location $location ` 
    -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface -Name $vmName -ResourceGroupName $resourceGroup -Location $location ` 
    -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration using $imageVersion.Id to specify the image version.
$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1_v2 | ` 
    Set-AzVMSourceImage -Id $galleryImage.Id | ` 
    Add-AzVMNetworkInterface -Id $nic.Id

# Create a virtual machine
New-AzVM -ResourceGroupName $resourceGroup -Location $location -VM $vmConfig
```

## Share the gallery

We recommend that you share access at the gallery level. Use an email address and the [Get-AzADUser](#) cmdlet to get the object ID for the user, then use [New-AzRoleAssignment](#) to give them access to the gallery. Replace the example email, `alinne_montes@contoso.com` in this example, with your own information.

```
# Get the object ID for the user
$user = Get-AzADUser -StartsWith alinne_montes@contoso.com
# Grant access to the user for our gallery
New-AzRoleAssignment ` 
    -ObjectId $user.Id ` 
    -RoleDefinitionName Reader ` 
    -ResourceName $gallery.Name ` 
    -ResourceType Microsoft.Compute/galleries ` 
    -ResourceGroupName $resourceGroup.ResourceGroupName
```

## Clean up resources

When no longer needed, you can use the [Remove-AzResourceGroup](#) cmdlet to remove the resource group, and all related resources:

```
# Delete the gallery  
Remove-AzResourceGroup -Name myGalleryRG  
  
# Delete the VM  
Remove-AzResourceGroup -Name myResourceGroup
```

## Azure Image Builder

Azure also offers a service, built on Packer, [Azure VM Image Builder](#). Simply describe your customizations in a template, and it will handle the image creation.

## Next steps

In this tutorial, you created a specialized VM image. You learned how to:

- Create an Azure Compute Gallery
- Create an image definition
- Create an image version
- Create a VM from an image
- Share a gallery

Advance to the next tutorial to learn about how to create highly available virtual machines.

[Create highly available VMs](#)

# Create and deploy virtual machines in an availability set using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this tutorial, you learn how to increase the availability and reliability of your Virtual Machines (VMs) using Availability Sets. Availability Sets make sure the VMs you deploy on Azure are distributed across multiple, isolated hardware nodes, in a cluster.

In this tutorial, you learn how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes
- Check Azure Advisor

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create an availability set

The hardware in a location is divided into multiple update domains and fault domains. An **update domain** is a group of VMs and underlying physical hardware that can be rebooted at the same time. VMs in the same **fault domain** share common storage as well as a common power source and network switch.

You can create an availability set using [New-AzAvailabilitySet](#). In this example, the number of both update and fault domains is 2 and the availability set is named *myAvailabilitySet*.

Create a resource group.

```
New-AzResourceGroup ` 
-Name myResourceGroupAvailability ` 
-Location EastUS
```

Create a managed availability set using [New-AzAvailabilitySet](#) with the `-sku aligned` parameter.

```
New-AzAvailabilitySet ` 
-Location "EastUS" ` 
-Name "myAvailabilitySet" ` 
-ResourceGroupName "myResourceGroupAvailability" ` 
-Sku aligned ` 
-PlatformFaultDomainCount 2 ` 
-PlatformUpdateDomainCount 2
```

# Create VMs inside an availability set

VMs must be created within the availability set to make sure they're correctly distributed across the hardware. You can't add an existing VM to an availability set after it's created.

When you create a VM with [New-AzVM](#), you use the `-AvailabilitySetName` parameter to specify the name of the availability set.

First, set an administrator username and password for the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Now create two VMs with [New-AzVM](#) in the availability set.

```
for ($i=1; $i -le 2; $i++)
{
    New-AzVm ` 
        -ResourceGroupName "myResourceGroupAvailability" ` 
        -Name "myVM$i" ` 
        -Location "East US" ` 
        -VirtualNetworkName "myVnet" ` 
        -SubnetName "mySubnet" ` 
        -SecurityGroupName "myNetworkSecurityGroup" ` 
        -PublicIpAddressName "myPublicIpAddress$i" ` 
        -AvailabilitySetName "myAvailabilitySet" ` 
        -Credential $cred
}
```

It takes a few minutes to create and configure both VMs. When finished, you have two virtual machines distributed across the underlying hardware.

If you look at the availability set in the portal by going to **Resource Groups > myResourceGroupAvailability > myAvailabilitySet**, you should see how the VMs are distributed across the two fault and update domains.

The screenshot shows the Azure portal interface for managing an availability set. The top navigation bar includes 'Microsoft Azure', 'Resource groups', 'myResourceGroupAvailability', 'myAvailabilitySet', and a search bar. The main content area displays the 'myAvailabilitySet' details under the 'Essentials' tab. It lists the resource group as 'myResourceGroupAvailability', location as 'East US', subscription name as 'Azure', and subscription ID as '<Subscription ID>'. It also indicates there are 2 fault domains and 2 update domains, with 2 virtual machines (myVM1 and myVM2) managed by the set. Below this, a table shows the status of the two VMs: myVM1 is running in Fault Domain 0 and Update Domain 0, while myVM2 is also running in Fault Domain 1 and Update Domain 1.

NAME	STATUS	FAULT DOMAIN	UPDATE DOMAIN
myVM1	Running	0	0
myVM2	Running	1	1

#### NOTE

Under certain circumstances, 2 VMs in the same AvailabilitySet could share the same FaultDomain. This can be confirmed by going into your availability set and checking the Fault Domain column. This can be caused by the following sequence of events while deploying the VMs:

1. The 1st VM is Deployed
2. The 1st VM is Stopped/Deallocated
3. The 2nd VM is Deployed. Under these circumstances, the OS Disk of the 2nd VM might be created on the same Fault Domain as the 1st VM, and so the 2nd VM will also land on the same FaultDomain. To avoid this issue, it's recommended to not stop/deallocate the VMs between deployments.

## Check for available VM sizes

When you create a VM inside a availability set, you need to know what VM sizes are available on the hardware. Use [Get-AzVMSize](#) command to get all available sizes for virtual machines that you can deploy in the availability set.

```
Get-AzVMSize ` 
    -ResourceGroupName "myResourceGroupAvailability" ` 
    -AvailabilitySetName "myAvailabilitySet"
```

## Check Azure Advisor

You can also use Azure Advisor to get more information on how to improve the availability of your VMs. Azure Advisor analyzes your configuration and usage telemetry, then recommends solutions that can help you improve the cost effectiveness, performance, availability, and security of your Azure resources.

Sign in to the [Azure portal](#), select **All services**, and type **Advisor**. The Advisor dashboard shows personalized recommendations for the selected subscription. For more information, see [Get started with Azure Advisor](#).

## Next steps

In this tutorial, you learned how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes
- Check Azure Advisor

Advance to the next tutorial to learn about virtual machine scale sets.

[Create a VM scale set](#)

# Tutorial: Create a virtual machine scale set and deploy a highly available app on Windows

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Virtual machine scale sets with [Flexible orchestration](#) let you create and manage a group of load balanced VMs. The number of VM instances can automatically increase or decrease in response to demand or a defined schedule.

In this tutorial, you deploy a virtual machine scale set in Azure and learn how to:

- Create a resource group.
- Create a Flexible scale set with a load balancer.
- Add IIS to the scale set instances using the [Run command](#).
- Open port 80 to HTTP traffic.
- Test the scale set.

## Scale Set overview

Scale sets provide the following key benefits:

- Easy to create and manage multiple VMs
- Provides high availability and application resiliency by distributing VMs across fault domains
- Allows your application to automatically scale as resource demand changes
- Works at large-scale

With Flexible orchestration, Azure provides a unified experience across the Azure VM ecosystem. Flexible orchestration offers high availability guarantees (up to 1000 VMs) by spreading VMs across fault domains in a region or within an Availability Zone. This enables you to scale out your application while maintaining fault domain isolation that is essential to run quorum-based or stateful workloads, including:

- Quorum-based workloads
- Open-source databases
- Stateful applications
- Services that require high availability and large scale
- Services that want to mix virtual machine types or leverage Spot and on-demand VMs together
- Existing Availability Set applications

Learn more about the differences between Uniform scale sets and Flexible scale sets in [Orchestration Modes](#).

## Create a scale set

Use the Azure portal to create a Flexible scale set.

1. Open the [Azure portal](#).
2. Search for and select **Virtual machine scale sets**.
3. Select **Create** on the **Virtual machine scale sets** page. The **Create a virtual machine scale set** will open.
4. Select the subscription that you want to use for **Subscription**.

5. For **Resource group**, select **Create new** and type *myVMSSRG* for the name and then select **OK**.

#### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	myAzureSubscription
Resource group *	(New) myVMSS_group
<a href="#">Create new</a>	

6. For **Virtual machine scale set name**, type *myVMSS*.

7. For **Region**, select a region that is close to you like *East US*.

#### Scale set details

Virtual machine scale set name *	myVMSS
Region *	(US) East US
Availability zone ⓘ	None

8. Leave **Availability zone** as blank for this example.

9. For **Orchestration mode**, select **Flexible**.

10. Leave the default of **1** for fault domain count or choose another value from the drop-down.

#### Orchestration

A scale set has a "scale set model" that defines the attributes of virtual machine instances (size, number of data disks, etc). As the number of instances in the scale set changes, new instances are added based on the scale set model.

[Learn more about the scale set model ↗](#)

Orchestration mode \* ⓘ

- Uniform**: optimized for large scale stateless workloads with identical instances  
 **Flexible (preview)**: achieve high availability at scale with identical or multiple virtual machine types

**!** This virtual machine scale set will be created as a scale set with flexible orchestration mode (preview). To enable the preview, you must register your subscription. [Learn more ↗](#)

Fault domain count \* ⓘ

1

11. For **Image**, select *Windows Server 2019 Datacenter - Gen 1*.

12. For **Size**, leave the default value or select a size like *Standard\_E2s\_V3*.

13. For **Username**, type the name to use for the administrator account, like *azureuser*.

14. In **Password** and **Confirm password**, type a strong password for the administrator account.

15. On the **Networking** tab, under **Load balancing**, select **Use a load balancer**.

16. For **Load balancing options**, leave the default of **Azure load balancer**.

17. For **Select a load balancer**, select **Create new**.

## Load balancing

You can place this virtual machine scale set in the backend pool of an existing Azure load balancing solution. [Learn more](#)

Use a load balancer

### Load balancing settings

- **Application Gateway** is an HTTP/HTTPS web traffic load balancer with URL-based routing, SSL termination, session persistence, and web application firewall. [Learn more about Application Gateway](#)
- **Azure Load Balancer** supports all TCP/UDP network traffic, port-forwarding, and outbound flows. [Learn more about Azure Load Balancer](#)

Load balancing options * ⓘ	Azure load balancer
Select a load balancer * ⓘ	(new) myVMSS2021-lb
	<a href="#">Create new</a>
Select a backend pool * ⓘ	(new) bepool
	<a href="#">Create new</a>

18. On the **Create a load balancer** page, type in a name for your load balancer and **Public IP address name**.
19. For **Domain name label**, type in a name to use as a prefix for your domain name. This name must be unique.
20. When you are done, select **Create**.

### Create a load balancer

Azure Load Balancer enables you to scale your applications and create high availability for your services. Load Balancer supports inbound and outbound scenarios, provides low latency and high throughput, and scales up to millions of flows for all TCP and UDP applications. [Learn more about Azure Load Balancer](#)

Your load balancer will be placed in the same subscription, resource group, and region as your virtual machine scale set. Azure will configure basic settings for the frontend IP, backend address pools, NAT rules, and NAT pools for this load balancer automatically.

Name * ⓘ	myVMSS-lb
Public IP address name * ⓘ	myVMSS-ip
Domain name label ⓘ	myvmss2021.eastus.cloudapp.azure.com
SKU	Standard
Type	Public
Availability zone ⓘ	Zone-redundant

**Create** **Discard**

21. Back on the **Networking** tab, leave the default name for the backend pool.
22. On the **Scaling** tab, leave the default instance count as 2, or add in your own value. This is the number of VMs that will be created, so be aware of the costs and the limits on your subscription if you change this value.
23. Leave the **Scaling policy** set to *Manual*.

An Azure virtual machine scale set can automatically increase or decrease the number of VM instances that run your application. This automated and elastic behavior reduces the management overhead to monitor and optimize the performance of your application. [Learn more about VMSS scaling](#)

Initial instance count \*

**Scaling**

Scaling policy [\(i\)](#)

Manual  
 Custom

**Scale-In policy**

Configure the order in which virtual machines are selected for deletion during a scale-in operation.  
[Learn more about scale-in policies](#)

Scale-in policy  [\(i\)](#)

**Info** Scale-in policy is not supported for virtual machine scale sets with flexible orchestration mode (preview).

24. When you are done, select **Review + create**.
25. Once you see that validation has passed, you can select **Create** at the bottom of the page to deploy your scale set.
26. When the deployment is complete, select **Go to resource** to see your scale set.

## View the VMs in your scale set

On the page for the scale set, select **Instances** from the left menu.

You will see a list of VMs that are part of your scale set. This list includes:

- The name of the VM
- The computer name used by the VM.
- The current status of the VM, like *Running*.
- The *Provisioning state* of the VM, like *Succeeded*.

Name	Computer name	Status	Provisioning state
myVMSS_351a2d68	myvmss6nEQF90O	Running	Succeeded
myVMSS_c4dac4c9	myvmss6nGESCAF	Running	Succeeded

## Enable IIS using RunCommand

To test the scale-set, we can enable IIS on each of the VMs using the [Run Command](#).

1. Select the first VM in the list of **Instances**.
2. In the left menu, under **Operations**, select **Run command**. The **Run command** page will open.
3. Select **RunPowerShellScript** from the list of commands. The **Run Command Script** page will open.
4. Under **PowerShell Script**, paste in the following snippet:

```
Add-WindowsFeature Web-Server  
Set-Content -Path "C:\inetpub\wwwroot\Default.htm" -Value "Hello world from host $($env:computername)  
!"
```

5. When you are done, select **Run**. You will see the progress in the **Output** window.
6. Once the script is complete on the first VM, you can select the X in the upper-right to close the page.
7. Go back to your list of scale set instances and use the **Run command** on each VM in the scale set.

## Open port 80

Open port 80 on your scale set by adding an inbound rule to your network security group (NSG).

1. On the page for your scale set, select **Networking** from the left menu. The **Networking** page will open.
2. Select **Add inbound port rule**. The **Add inbound security rule** page will open.
3. Under **Service**, select *HTTP* and then select **Add** at the bottom of the page.

## Test your scale set

Test your scale set by connecting to it from a browser.

1. On the **Overview** page for your scale set, copy the Public IP address.
2. Open another tab in your browser and paste the IP address into the address bar.
3. When the page loads, take a note of the compute name that is shown.
4. Refresh the page until you see the computer name change.

## Delete your scale set

When you are done, you should delete the resource group, which will delete everything you deployed for your scale set.

1. On the page for your scale set, select the **Resource group**. The page for your resource group will open.
2. At the top of the page, select **Delete resource group**.
3. In the **Are you sure you want to delete** page, type in the name of your resource group and then select **Delete**.

## Next steps

In this tutorial, you created a virtual machine scale set. You learned how to:

- Create a resource group.
- Create a Flexible scale set with a load balancer.
- Add IIS to the scale set instances using the **Run command**.
- Open port 80 to HTTP traffic.
- Test the scale set.

Advance to the next tutorial to learn more about load balancing concepts for virtual machines.

[Load balance virtual machines](#)

# Tutorial: Load balance Windows virtual machines in Azure to create a highly available application with Azure PowerShell

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Uniform scale sets

Load balancing provides a higher level of availability by spreading incoming requests across multiple virtual machines. In this tutorial, you learn about the different components of the Azure load balancer that distribute traffic and provide high availability. You learn how to:

- Create an Azure load balancer
- Create a load balancer health probe
- Create load balancer traffic rules
- Use the Custom Script Extension to create a basic IIS site
- Create virtual machines and attach to a load balancer
- View a load balancer in action
- Add and remove VMs from a load balancer

## Azure load balancer overview

An Azure load balancer is a Layer-4 (TCP, UDP) load balancer that provides high availability by distributing incoming traffic among healthy VMs. A load balancer health probe monitors a given port on each VM and only distributes traffic to an operational VM.

You define a front-end IP configuration that contains one or more public IP addresses. This front-end IP configuration allows your load balancer and applications to be accessible over the Internet.

Virtual machines connect to a load balancer using their virtual network interface card (NIC). To distribute traffic to the VMs, a back-end address pool contains the IP addresses of the virtual (NICs) connected to the load balancer.

To control the flow of traffic, you define load balancer rules for specific ports and protocols that map to your VMs.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create Azure load balancer

This section details how you can create and configure each component of the load balancer. Before you can create your load balancer, create a resource group with [New-AzResourceGroup](#). The following example creates a resource group named *myResourceGroupLoadBalancer* in the *EastUS* location:

```
New-AzResourceGroup ` 
-ResourceGroupName "myResourceGroupLoadBalancer" ` 
-Location "EastUS"
```

## Create a public IP address

To access your app on the Internet, you need a public IP address for the load balancer. Create a public IP address with [New-AzPublicIpAddress](#). The following example creates a public IP address named *myPublicIP* in the *myResourceGroupLoadBalancer* resource group:

```
$publicIP = New-AzPublicIpAddress ` 
-ResourceGroupName "myResourceGroupLoadBalancer" ` 
-Location "EastUS" ` 
-AllocationMethod "Static" ` 
-Name "myPublicIP"
```

## Create a load balancer

Create a frontend IP pool with [New-AzLoadBalancerFrontendIpConfig](#). The following example creates a frontend IP pool named *myFrontEndPool* and attaches the *myPublicIP* address:

```
$frontendIP = New-AzLoadBalancerFrontendIpConfig ` 
-Name "myFrontEndPool" ` 
-PublicIpAddress $publicIP
```

Create a backend address pool with [New-AzLoadBalancerBackendAddressPoolConfig](#). The VMs attach to this backend pool in the remaining steps. The following example creates a backend address pool named *myBackEndPool*:

```
$backendPool = New-AzLoadBalancerBackendAddressPoolConfig ` 
-Name "myBackEndPool"
```

Now, create the load balancer with [New-AzLoadBalancer](#). The following example creates a load balancer named *myLoadBalancer* using the frontend and backend IP pools created in the preceding steps:

```
$lb = New-AzLoadBalancer ` 
-ResourceGroupName "myResourceGroupLoadBalancer" ` 
-Name "myLoadBalancer" ` 
-Location "EastUS" ` 
-FrontendIpConfiguration $frontendIP ` 
-BackendAddressPool $backendPool
```

## Create a health probe

To allow the load balancer to monitor the status of your app, you use a health probe. The health probe dynamically adds or removes VMs from the load balancer rotation based on their response to health checks. By default, a VM is removed from the load balancer distribution after two consecutive failures at 15-second intervals. You create a health probe based on a protocol or a specific health check page for your app.

The following example creates a TCP probe. You can also create custom HTTP probes for more fine grained health checks. When using a custom HTTP probe, you must create the health check page, such as *healthcheck.aspx*. The probe must return an **HTTP 200 OK** response for the load balancer to keep the host in rotation.

To create a TCP health probe, you use [Add-AzLoadBalancerProbeConfig](#). The following example creates a health probe named *myHealthProbe* that monitors each VM on *TCP port 80*:

```
Add-AzLoadBalancerProbeConfig ` 
-Name "myHealthProbe" ` 
-LoadBalancer $lb ` 
-Protocol tcp ` 
-Port 80 ` 
-IntervalInSeconds 15 ` 
-ProbeCount 2
```

To apply the health probe, update the load balancer with [Set-AzLoadBalancer](#):

```
Set-AzLoadBalancer -LoadBalancer $lb
```

### Create a load balancer rule

A load balancer rule is used to define how traffic is distributed to the VMs. You define the front-end IP configuration for the incoming traffic and the back-end IP pool to receive the traffic, along with the required source and destination port. To make sure only healthy VMs receive traffic, you also define the health probe to use.

Create a load balancer rule with [Add-AzLoadBalancerRuleConfig](#). The following example creates a load balancer rule named *myLoadBalancerRule* and balances traffic on *TCP* port *80*:

```
$probe = Get-AzLoadBalancerProbeConfig -LoadBalancer $lb -Name "myHealthProbe"

Add-AzLoadBalancerRuleConfig ` 
-Name "myLoadBalancerRule" ` 
-LoadBalancer $lb ` 
-FrontendIpConfiguration $lb.FrontendIpConfigurations[0] ` 
-BackendAddressPool $lb.BackendAddressPools[0] ` 
-Protocol Tcp ` 
-FrontendPort 80 ` 
-BackendPort 80 ` 
-Probe $probe
```

Update the load balancer with [Set-AzLoadBalancer](#):

```
Set-AzLoadBalancer -LoadBalancer $lb
```

## Configure virtual network

Before you deploy some VMs and can test your balancer, create the supporting virtual network resources. For more information about virtual networks, see the [Manage Azure Virtual Networks](#) tutorial.

### Create network resources

Create a virtual network with [New-AzVirtualNetwork](#). The following example creates a virtual network named *myVnet* with *mySubnet*.

```

# Create subnet config
$subnetConfig = New-AzVirtualNetworkSubnetConfig ` 
    -Name "mySubnet" ` 
    -AddressPrefix 192.168.1.0/24

# Create the virtual network
$vnet = New-AzVirtualNetwork ` 
    -ResourceGroupName "myResourceGroupLoadBalancer" ` 
    -Location "EastUS" ` 
    -Name "myVnet" ` 
    -AddressPrefix 192.168.0.0/16 ` 
    -Subnet $subnetConfig

```

Virtual NICs are created with [New-AzNetworkInterface](#). The following example creates three virtual NICs. (One virtual NIC for each VM you create for your app in the following steps). You can create additional virtual NICs and VMs at any time and add them to the load balancer:

```

for ($i=1; $i -le 3; $i++)
{
    New-AzNetworkInterface ` 
        -ResourceGroupName "myResourceGroupLoadBalancer" ` 
        -Name myVM$i ` 
        -Location "EastUS" ` 
        -Subnet $vnet.Subnets[0] ` 
        -LoadBalancerBackendAddressPool $lb.BackendAddressPools[0]
}

```

## Create virtual machines

To improve the high availability of your app, place your VMs in an availability set.

Create an availability set with [New-AzAvailabilitySet](#). The following example creates an availability set named *myAvailabilitySet*.

```

$availabilitySet = New-AzAvailabilitySet ` 
    -ResourceGroupName "myResourceGroupLoadBalancer" ` 
    -Name "myAvailabilitySet" ` 
    -Location "EastUS" ` 
    -Sku aligned ` 
    -PlatformFaultDomainCount 2 ` 
    -PlatformUpdateDomainCount 2

```

Set an administrator username and password for the VMs with [Get-Credential](#):

```
$cred = Get-Credential
```

Now you can create the VMs with [New-AzVM](#). The following example creates three VMs and the required virtual network components if they do not already exist:

```

for ($i=1; $i -le 3; $i++)
{
    New-AzVm ` 
        -ResourceGroupName "myResourceGroupLoadBalancer" ` 
        -Name "myVM$i" ` 
        -Location "East US" ` 
        -VirtualNetworkName "myVnet" ` 
        -SubnetName "mySubnet" ` 
        -SecurityGroupName "myNetworkSecurityGroup" ` 
        -OpenPorts 80 ` 
        -AvailabilitySetName "myAvailabilitySet" ` 
        -Credential $cred ` 
        -AsJob
}

```

The `-AsJob` parameter creates the VM as a background task, so the PowerShell prompts return to you. You can view details of background jobs with the `Job` cmdlet. It takes a few minutes to create and configure all three VMs.

### Install IIS with Custom Script Extension

In a previous tutorial on [How to customize a Windows virtual machine](#), you learned how to automate VM customization with the Custom Script Extension for Windows. You can use the same approach to install and configure IIS on your VMs.

Use [Set-AzVMExtension](#) to install the Custom Script Extension. The extension runs

`powershell Add-WindowsFeature Web-Server` to install the IIS webserver and then updates the *Default.htm* page to show the hostname of the VM:

```

for ($i=1; $i -le 3; $i++)
{
    Set-AzVMExtension ` 
        -ResourceGroupName "myResourceGroupLoadBalancer" ` 
        -ExtensionName "IIS" ` 
        -VMName myVM$i ` 
        -Publisher Microsoft.Compute ` 
        -ExtensionType CustomScriptExtension ` 
        -TypeHandlerVersion 1.8 ` 
        -SettingString '{"commandToExecute":"powershell Add-WindowsFeature Web-Server; powershell Add-Content -Path \'C:\\inetpub\\wwwroot\\Default.htm\' -Value $($env:computername)"}' ` 
        -Location EastUS
}

```

## Test load balancer

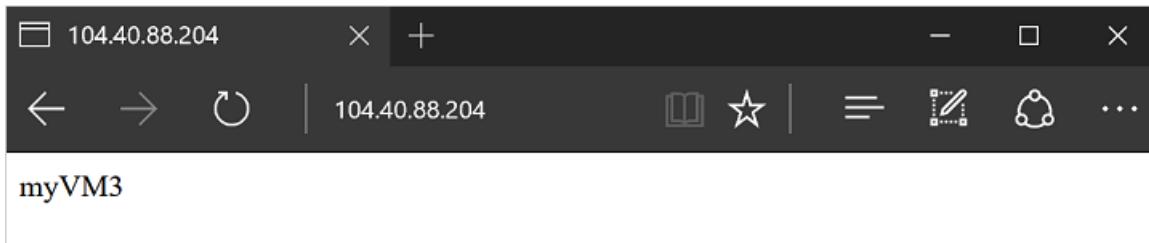

Obtain the public IP address of your load balancer with [Get-AzPublicIPAddress](#). The following example obtains the IP address for *myPublicIP* created earlier:

```

Get-AzPublicIPAddress ` 
    -ResourceGroupName "myResourceGroupLoadBalancer" ` 
    -Name "myPublicIP" | select IpAddress

```

You can then enter the public IP address in to a web browser. The website is displayed, including the hostname of the VM that the load balancer distributed traffic to as in the following example:

To see the load balancer distribute traffic across all three VMs running your app, you can force-refresh your web browser.

## Add and remove VMs

You may need to perform maintenance on the VMs running your app, such as installing OS updates. To deal with increased traffic to your app, you may need to add additional VMs. This section shows you how to remove or add a VM from the load balancer.

### Remove a VM from the load balancer

Get the network interface card with [Get-AzNetworkInterface](#), then set the *LoadBalancerBackendAddressPools* property of the virtual NIC to `$null`. Finally, update the virtual NIC:

```
$nic = Get-AzNetworkInterface `  
    -ResourceGroupName "myResourceGroupLoadBalancer" `  
    -Name "myVM2"  
$nic.IpConfigurations[0].LoadBalancerBackendAddressPools=$null  
Set-AzNetworkInterface -NetworkInterface $nic
```

To see the load balancer distribute traffic across the remaining two VMs running your app you can force-refresh your web browser. You can now perform maintenance on the VM, such as installing OS updates or performing a VM reboot.

### Add a VM to the load balancer

After performing VM maintenance, or if you need to expand capacity, set the *LoadBalancerBackendAddressPools* property of the virtual NIC to the *BackendAddressPool* from [Get-AzLoadBalancer](#):

Get the load balancer:

```
$lb = Get-AzLoadBalancer `  
    -ResourceGroupName myResourceGroupLoadBalancer `  
    -Name myLoadBalancer  
$nic.IpConfigurations[0].LoadBalancerBackendAddressPools=$lb.BackendAddressPools[0]  
Set-AzNetworkInterface -NetworkInterface $nic
```

## Next steps

In this tutorial, you created a load balancer and attached VMs to it. You learned how to:

- Create an Azure load balancer
- Create a load balancer health probe
- Create load balancer traffic rules
- Use the Custom Script Extension to create a basic IIS site
- Create virtual machines and attach to a load balancer
- View a load balancer in action
- Add and remove VMs from a load balancer

Advance to the next tutorial to learn how to manage VM networking.

[Manage VMs and virtual networks](#)

# Tutorial: Create and manage Azure virtual networks for Windows virtual machines with Azure PowerShell

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

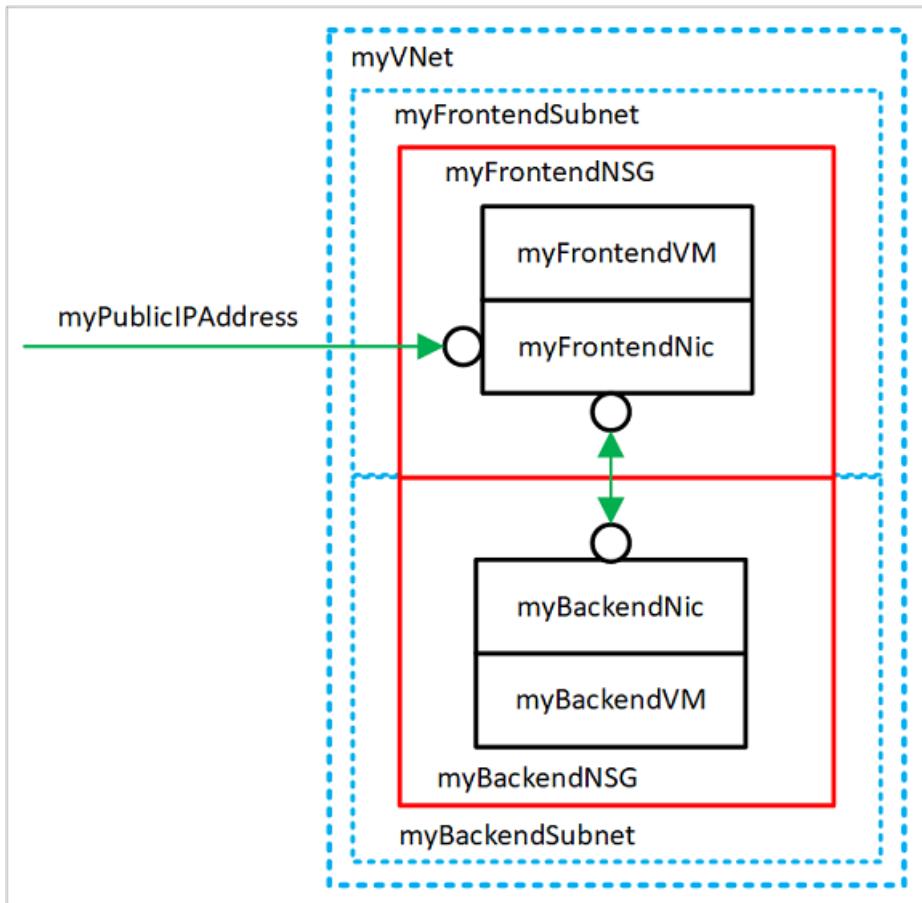

Azure virtual machines use Azure networking for internal and external network communication. This tutorial walks through deploying two virtual machines and configuring Azure networking for these VMs. The examples in this tutorial assume that the VMs are hosting a web application with a database back-end, however an application isn't deployed in the tutorial. In this tutorial, you learn how to:

- Create a virtual network and subnet
- Create a public IP address
- Create a front-end VM
- Secure network traffic
- Create back-end VM

## VM networking overview

Azure virtual networks enable secure network connections between virtual machines, the internet, and other Azure services such as Azure SQL Database. Virtual networks are broken down into logical segments called subnets. Subnets are used to control network flow, and as a security boundary. When deploying a VM, it generally includes a virtual network interface, which is attached to a subnet.

While completing this tutorial, you can see these resources created:

- `myVNet` - The virtual network that the VMs use to communicate with each other and the internet.
- `myFrontendSubnet` - The subnet in `myVNet` used by the front-end resources.
- `myPublicIPAddress` - The public IP address used to access `myFrontendVM` from the internet.
- `myFrontendNic` - The network interface used by `myFrontendVM` to communicate with `myBackendVM`.
- `myFrontendVM` - The VM used to communicate between the internet and `myBackendVM`.
- `myBackendNSG` - The network security group that controls communication between the `myFrontendVM` and `myBackendVM`.
- `myBackendSubnet` - The subnet associated with `myBackendNSG` and used by the back-end resources.
- `myBackendNic` - The network interface used by `myBackendVM` to communicate with `myFrontendVM`.
- `myBackendVM` - The VM that uses port 1433 to communicate with `myFrontendVM`.

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create subnet

For this tutorial, a single virtual network is created with two subnets. A front-end subnet for hosting a web application, and a back-end subnet for hosting a database server.

Before you can create a virtual network, create a resource group using [New-AzResourceGroup](#). The following example creates a resource group named `myRGNetwork` in the `EastUS` location:

```
New-AzResourceGroup -ResourceGroupName myRGNetwork -Location EastUS
```

Create a subnet configuration named *myFrontendSubnet* using [New-AzVirtualNetworkSubnetConfig](#):

```
$frontendSubnet = New-AzVirtualNetworkSubnetConfig `  
-Name myFrontendSubnet `  
-AddressPrefix 10.0.0.0/24
```

And, create a subnet configuration named *myBackendSubnet*:

```
$backendSubnet = New-AzVirtualNetworkSubnetConfig `  
-Name myBackendSubnet `  
-AddressPrefix 10.0.1.0/24
```

## Create virtual network

Create a VNET named *myVNet* using *myFrontendSubnet* and *myBackendSubnet* using [New-AzVirtualNetwork](#):

```
$vnet = New-AzVirtualNetwork `  
-ResourceGroupName myRGNetwork `  
-Location EastUS `  
-Name myVNet `  
-AddressPrefix 10.0.0.0/16 `  
-Subnet $frontendSubnet, $backendSubnet
```

At this point, a network has been created and segmented into two subnets, one for front-end services, and another for back-end services. In the next section, virtual machines are created and connected to these subnets.

## Create a public IP address

A public IP address allows Azure resources to be accessible on the internet. The allocation method of the public IP address can be configured as dynamic or static. By default, a public IP address is dynamically allocated. Dynamic IP addresses are released when a VM is deallocated. This behavior causes the IP address to change during any operation that includes a VM deallocation.

The allocation method can be set to static, which makes sure that the IP address stays assigned to a VM, even during a deallocated state. If you are using a static IP address, the IP address itself can't be specified. Instead, it's allocated from a pool of available addresses.

Create a public IP address named *myPublicIPAddress* using [New-AzPublicIpAddress](#):

```
$pip = New-AzPublicIpAddress `  
-ResourceGroupName myRGNetwork `  
-Location EastUS `  
-AllocationMethod Dynamic `  
-Name myPublicIPAddress
```

You could change the *-AllocationMethod* parameter to `static` to assign a static public IP address.

## Create a front-end VM

For a VM to communicate in a virtual network, it needs a virtual network interface (NIC). Create a NIC using [New-AzNetworkInterface](#):

```
$frontendNic = New-AzNetworkInterface `  
    -ResourceGroupName myRGNetwork `  
    -Location EastUS `  
    -Name myFrontend `  
    -SubnetId $vnet.Subnets[0].Id `  
    -PublicIpAddressId $pip.Id
```

Set the username and password needed for the administrator account on the VM using [Get-Credential](#). You use these credentials to connect to the VM in additional steps:

```
$cred = Get-Credential
```

Create the VMs using [New-AzVM](#).

```
New-AzVM `  
    -Credential $cred `  
    -Name myFrontend `  
    -PublicIpAddressName myPublicIPAddress `  
    -ResourceGroupName myRGNetwork `  
    -Location "EastUS" `  
    -Size Standard_D1 `  
    -SubnetName myFrontendSubnet `  
    -VirtualNetworkName myVNet
```

## Secure network traffic

A network security group (NSG) contains a list of security rules that allow or deny network traffic to resources connected to Azure Virtual Networks (VNet). NSGs can be associated to subnets or individual network interfaces. An NSG that is associated with a network interface only applies to the associated VM. When an NSG is associated to a subnet, the rules apply to all resources connected to the subnet.

### Network security group rules

NSG rules define networking ports over which traffic is allowed or denied. The rules can include source and destination IP address ranges so that traffic is controlled between specific systems or subnets. NSG rules also include a priority (between 1—and 4096). Rules are evaluated in the order of priority. A rule with a priority of 100 is evaluated before a rule with priority 200.

All NSGs contain a set of default rules. The default rules can't be deleted, but because they are assigned the lowest priority, they can be overridden by the rules that you create.

- **Virtual network** - Traffic originating and ending in a virtual network is allowed both in inbound and outbound directions.
- **Internet** - Outbound traffic is allowed, but inbound traffic is blocked.
- **Load balancer** - Allow Azure's load balancer to probe the health of your VMs and role instances. If you are not using a load balanced set, you can override this rule.

### Create network security groups

Create an inbound rule named *myFrontendNSGRule* to allow incoming web traffic on *myFrontendVM* using [New-AzNetworkSecurityRuleConfig](#):

```
$nsgFrontendRule = New-AzNetworkSecurityRuleConfig ` 
-Name myFrontendNSGRule ` 
-Protocol Tcp ` 
-Direction Inbound ` 
-Priority 200 ` 
-SourceAddressPrefix * ` 
-SourcePortRange * ` 
-DestinationAddressPrefix * ` 
-DestinationPortRange 80 ` 
-Access Allow
```

You can limit internal traffic to *myBackendVM* from only *myFrontendVM* by creating an NSG for the back-end subnet. The following example creates an NSG rule named *myBackendNSGRule*.

```
$nsgBackendRule = New-AzNetworkSecurityRuleConfig ` 
-Name myBackendNSGRule ` 
-Protocol Tcp ` 
-Direction Inbound ` 
-Priority 100 ` 
-SourceAddressPrefix 10.0.0.0/24 ` 
-SourcePortRange * ` 
-DestinationAddressPrefix * ` 
-DestinationPortRange 1433 ` 
-Access Allow
```

Add a network security group named *myFrontendNSG* using [New-AzNetworkSecurityGroup](#):

```
$nsgFrontend = New-AzNetworkSecurityGroup ` 
-ResourceGroupName myRGNetwork ` 
-Location EastUS ` 
-Name myFrontendNSG ` 
-SecurityRules $nsgFrontendRule
```

Now, add a network security group named *myBackendNSG* using [New-AzNetworkSecurityGroup](#):

```
$nsgBackend = New-AzNetworkSecurityGroup ` 
-ResourceGroupName myRGNetwork ` 
-Location EastUS ` 
-Name myBackendNSG ` 
-SecurityRules $nsgBackendRule
```

Add the network security groups to the subnets:

```
$vnet = Get-AzVirtualNetwork ` 
-ResourceGroupName myRGNetwork ` 
-Name myVNet
$frontendSubnet = $vnet.Subnets[0]
$backendSubnet = $vnet.Subnets[1]
$frontendSubnetConfig = Set-AzVirtualNetworkSubnetConfig ` 
-VirtualNetwork $vnet ` 
-Name myFrontendSubnet ` 
-AddressPrefix $frontendSubnet.AddressPrefix ` 
-NetworkSecurityGroup $nsgFrontend
$backendSubnetConfig = Set-AzVirtualNetworkSubnetConfig ` 
-VirtualNetwork $vnet ` 
-Name myBackendSubnet ` 
-AddressPrefix $backendSubnet.AddressPrefix ` 
-NetworkSecurityGroup $nsgBackend
Set-AzVirtualNetwork -VirtualNetwork $vnet
```

## Create a back-end VM

The easiest way to create the back-end VM for this tutorial is by using a SQL Server image. This tutorial only creates the VM with the database server, but doesn't provide information about accessing the database.

Create *myBackendNic*.

```
$backendNic = New-AzNetworkInterface `  
    -ResourceGroupName myRGNetwork `  
    -Location EastUS `  
    -Name myBackend `  
    -SubnetId $vnet.Subnets[1].Id
```

Set the username and password needed for the administrator account on the VM with Get-Credential:

```
$cred = Get-Credential
```

Create *myBackendVM*.

```
New-AzVM `  
    -Credential $cred `  
    -Name myBackend `  
    -ImageName "MicrosoftSQLServer:SQL2016SP1-WS2016:Enterprise:latest" `  
    -ResourceGroupName myRGNetwork `  
    -Location "EastUS" `  
    -SubnetName MyBackendSubnet `  
    -VirtualNetworkName myVNet
```

The image in this example has SQL Server installed, but it isn't used in this tutorial. It's included to show you how you can configure a VM to handle web traffic and a VM to handle database management.

## Next steps

In this tutorial, you created and secured Azure networks as related to virtual machines.

- Create a virtual network and subnet
- Create a public IP address
- Create a front-end VM
- Secure network traffic
- Create a back-end VM

To learn about protecting your VM disks, see [Backup and disaster recovery for disks](#).

# Azure Resource Graph sample queries for Azure Virtual Machines

9/21/2022 • 18 minutes to read • [Edit Online](#)

This page is a collection of [Azure Resource Graph](#) sample queries for Azure Virtual Machines. For a complete list of Azure Resource Graph samples, see [Resource Graph samples by Category](#) and [Resource Graph samples by Table](#).

## Sample queries

### Count of OS update installation done

Returns a list of status of OS update installation runs done for your machines in last 7 days.

```
PatchAssessmentResources  
| where type !has 'softwarepatches'  
| extend machineName = tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)),  
    rgName = split(id, '/', 4)  
| extend prop = parse_json(properties)  
| extend lTime = todatetime(prop.lastModifiedDateTime), OS = tostring(prop.osType), installedPatchCount =  
    tostring(prop.installedPatchCount), failedPatchCount = tostring(prop.failedPatchCount), pendingPatchCount =  
    tostring(prop.pendingPatchCount), excludedPatchCount = tostring(prop.excludedPatchCount),  
    notSelectedPatchCount = tostring(prop.notSelectedPatchCount)  
| where lTime > ago(7d)  
| project lTime, RunID=name, machineName, rgName, resourceType, OS, installedPatchCount, failedPatchCount,  
    pendingPatchCount, excludedPatchCount, notSelectedPatchCount
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "PatchAssessmentResources | where type !has 'softwarepatches' | extend machineName =  
    tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)), rgName = split(id, '/',  
    4)) | extend prop = parse_json(properties) | extend lTime = todatetime(prop.lastModifiedDateTime), OS =  
    tostring(prop.osType), installedPatchCount = tostring(prop.installedPatchCount), failedPatchCount =  
    tostring(prop.failedPatchCount), pendingPatchCount = tostring(prop.pendingPatchCount), excludedPatchCount =  
    tostring(prop.excludedPatchCount), notSelectedPatchCount = tostring(prop.notSelectedPatchCount) | where  
    lTime > ago(7d) | project lTime, RunID=name, machineName, rgName, resourceType, OS, installedPatchCount,  
    failedPatchCount, pendingPatchCount, excludedPatchCount, notSelectedPatchCount"
```

### Count of virtual machines by availability state and Subscription Id

Returns the count of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by their availability state across each of your subscriptions.

```
HealthResources  
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'  
| summarize count() by subscriptionId, AvailabilityState = tostring(properties.availabilityState)
```

- [Azure CLI](#)
- [Azure PowerShell](#)

- [Portal](#)

```
az graph query -q "HealthResources | where type =~ 'microsoft.resourcehealth/availabilitystatuses' | summarize count() by subscriptionId, AvailabilityState = tostring(properties.availabilityState)"
```

## Count of virtual machines by power state

Returns count of virtual machines (type `Microsoft.Compute/virtualMachines`) categorized according to their power state. For more information on power states, please see [Power states overview](#).

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| summarize count() by PowerState = tostring(properties.extended.instanceView.powerState.code)
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type == 'microsoft.compute/virtualmachines' | summarize count() by PowerState = tostring(properties.extended.instanceView.powerState.code)"
```

## Count virtual machines by OS type

Building on the previous query, we're still limiting by Azure resources of type

`Microsoft.Compute/virtualMachines`, but are no longer limiting the number of records returned. Instead, we used `summarize` and `count()` to define how to group and aggregate the values by property, which in this example is `properties.storageProfile.osDisk.osType`. For an example of how this string looks in the full object, see [explore resources - virtual machine discovery](#).

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| summarize count() by tostring(properties.storageProfile.osDisk.osType)
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type =~ 'Microsoft.Compute/virtualMachines' | summarize count() by tostring(properties.storageProfile.osDisk.osType)"
```

## Count virtual machines by OS type with extend

A different way to write the 'Count virtual machines by OS type' query is to `extend` a property and give it a temporary name for use within the query, in this case `os`. `os` is then used by `summarize` and `count()` as in the referenced example.

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| extend os = properties.storageProfile.osDisk.osType
| summarize count() by tostring(os)
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type =~ 'Microsoft.Compute/virtualMachines' | extend os = properties.storageProfile.osDisk.osType | summarize count() by tostring(os)"
```

### Get all New alerts from the past 30 days

This query provides a list of all the user's New alerts, from the past 30 days.

```
iotsecurityresources
| where type == 'microsoft.iotsecurity/locations/devicegroups/alerts'
| where todatetime(properties.startTimeUtc) > ago(30d) and properties.status == 'New'
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "iotsecurityresources | where type ==
'microsoft.iotsecurity/locations/devicegroups/alerts' | where todatetime(properties.startTimeUtc) > ago(30d)
and properties.status == 'New'"
```

### Get virtual machine scale set capacity and size

This query looks for virtual machine scale set resources and gets various details including the virtual machine size and the capacity of the scale set. The query uses the `toint()` function to cast the capacity to a number so that it can be sorted. Finally, the columns are renamed into custom named properties.

```
Resources
| where type=~ 'microsoft.compute/virtualmachinescalesets'
| where name contains 'contoso'
| project subscriptionId, name, location, resourceGroup, Capacity = toint(sku.capacity), Tier = sku.name
| order by Capacity desc
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type=~ 'microsoft.compute/virtualmachinescalesets' | where name
contains 'contoso' | project subscriptionId, name, location, resourceGroup, Capacity = toint(sku.capacity),
Tier = sku.name | order by Capacity desc"
```

### List all extensions installed on a virtual machine

First, this query uses `extend` on the virtual machines resource type to get the ID in uppercase (`toupper()`) the ID, get the operating system name and type, and get the virtual machine size. Getting the resource ID in uppercase is a good way to prepare to join to another property. Then, the query uses `join` with `kind as leftouter` to get virtual machine extensions by matching an uppercase `substring` of the extension ID. The portion of the ID before "/extensions/<ExtensionName>" is the same format as the virtual machines ID, so we use this property for the `join`. `summarize` is then used with `make_list` on the name of the virtual machine extension to combine the name of each extension where `id`, `OSName`, `OSType`, and `VMSize` are the same into a

single array property. Lastly, we `order by` lowercase *OSName* with `asc`. By default, `order by` is descending.

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| extend
  JoinID = toupper(id),
  OSName = tostring(properties.osProfile.computerName),
  OSType = tostring(properties.storageProfile.osDisk.osType),
  VMSize = tostring(properties.hardwareProfile.vmSize)
| join kind=leftouter(
  Resources
  | where type == 'microsoft.compute/virtualmachines/extensions'
  | extend
    VMId = toupper(substring(id, 0, indexof(id, '/extensions'))),
    ExtensionName = name
) on $left.JoinID == $right.VMId
| summarize Extensions = make_list(ExtensionName) by id, OSName, OSType, VMSize
| order by tolower(OSName) asc
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type == 'microsoft.compute/virtualmachines' | extend JoinID =
toupper(id), OSName = tostring(properties.osProfile.computerName), OSType =
tostring(properties.storageProfile.osDisk.osType), VMSize = tostring(properties.hardwareProfile.vmSize) |
join kind=leftouter( Resources | where type == 'microsoft.compute/virtualmachines/extensions' | extend VMId =
toupper(substring(id, 0, indexof(id, '/extensions'))), ExtensionName = name ) on \$left.JoinID ==
\$right.VMId | summarize Extensions = make_list(ExtensionName) by id, OSName, OSType, VMSize | order by
tolower(OSName) asc"
```

## List available OS updates for all your machines grouped by update category

Returns a list of pending OS for your machines.

```
PatchAssessmentResources
| where type !has 'softwarepatches'
| extend prop = parse_json(properties)
| extend lastTime = properties.lastModifiedDateTime
| extend updateRollupCount = prop.availablePatchCountByClassification.updateRollup, featurePackCount =
prop.availablePatchCountByClassification.featurePack, servicePackCount =
prop.availablePatchCountByClassification.servicePack, definitionCount =
prop.availablePatchCountByClassification.definition, securityCount =
prop.availablePatchCountByClassification.security, criticalCount =
prop.availablePatchCountByClassification.critical, updatesCount =
prop.availablePatchCountByClassification.updates, toolsCount =
prop.availablePatchCountByClassification.tools, otherCount = prop.availablePatchCountByClassification.other,
OS = prop.osType
| project lastTime, id, OS, updateRollupCount, featurePackCount, servicePackCount, definitionCount,
securityCount, criticalCount, updatesCount, toolsCount, otherCount
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```

az graph query -q "PatchAssessmentResources | where type !has 'softwarepatches' | extend prop =
parse_json(properties) | extend lastTime = properties.lastModifiedDateTime | extend updateRollupCount =
prop.availablePatchCountByClassification.updateRollup, featurePackCount =
prop.availablePatchCountByClassification.featurePack, servicePackCount =
prop.availablePatchCountByClassification.servicePack, definitionCount =
prop.availablePatchCountByClassification.definition, securityCount =
prop.availablePatchCountByClassification.security, criticalCount =
prop.availablePatchCountByClassification.critical, updatesCount =
prop.availablePatchCountByClassification.updates, toolsCount =
prop.availablePatchCountByClassification.tools, otherCount = prop.availablePatchCountByClassification.other,
OS = prop.osType | project lastTime, id, OS, updateRollupCount, featurePackCount, servicePackCount,
definitionCount, securityCount, criticalCount, updatesCount, toolsCount, otherCount"

```

## List of Linux OS update installation done

Returns a list of status of Linux Server - OS update installation runs done for your machines in last 7 days.

```

PatchAssessmentResources
| where type has 'softwarepatches' and properties has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)),
tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id, '/', 10))
| extend prop = parse_json(properties)
| extend lTime = todatetime(prop.lastModifiedDateTime), patchName = tostring(prop.patchName), version =
tostring(prop.version), installationState = tostring(prop.installationState), classifications =
tostring(prop.classifications)
| where lTime > ago(7d)
| project lTime, RunID, machineName, rgName, resourceType, patchName, version, classifications,
installationState
| sort by RunID

```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```

az graph query -q "PatchAssessmentResources | where type has 'softwarepatches' and properties has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)),
tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id, '/', 10)) | extend prop =
parse_json(properties) | extend lTime = todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), version = tostring(prop.version), installationState =
tostring(prop.installationState), classifications = tostring(prop.classifications) | where lTime > ago(7d) |
project lTime, RunID, machineName, rgName, resourceType, patchName, version, classifications,
installationState | sort by RunID"

```

## List of virtual machines and associated availability states by Resource Ids

Returns the latest list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by availability state. The query also provides the associated Resource Id based on `properties.targetResourceId`, for easy debugging and mitigation. Availability states can be one of four values: Available, Unavailable, Degraded and Unknown. For more details on what each of the availability states mean, please see [Azure Resource Health overview](#).

```

HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| summarize by ResourceId = tolower(tostring(properties.targetResourceId)), AvailabilityState =
tostring(properties.availabilityState)

```

- [Azure CLI](#)
- [Azure PowerShell](#)

- [Portal](#)

```
az graph query -q "HealthResources | where type =~ 'microsoft.resourcehealth/availabilitystatuses' | summarize by ResourceId = tolower(tostring(properties.targetResourceId)), AvailabilityState = tostring(properties.availabilityState)"
```

### List of virtual machines by availability state and power state with Resource Ids and resource Groups

Returns list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated on their power state and availability state to provide a cohesive state of health for your virtual machines. The query also provides details on the resource group and resource Id associated with each entry for detailed visibility into your resources.

```
Resources
| where type =~ 'microsoft.compute/virtualmachines'
| project resourceGroup, Id = tolower(id), PowerState = tostring(
properties.extended.instanceView.powerState.code)
| join kind=leftouter (
HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| where tostring(properties.targetResourceType) =~ 'microsoft.compute/virtualmachines'
| project targetResourceId = tolower(tostring(properties.targetResourceId)), AvailabilityState =
tostring(properties.availabilityState))
on $left.Id == $right.targetResourceId
| project-away targetResourceId
| where PowerState != 'PowerState/deallocated'
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type =~ 'microsoft.compute/virtualmachines' | project resourceGroup, Id = tolower(id), PowerState = tostring( properties.extended.instanceView.powerState.code) | join kind=leftouter ( HealthResources | where type =~ 'microsoft.resourcehealth/availabilitystatuses' | where tostring(properties.targetResourceType) =~ 'microsoft.compute/virtualmachines' | project targetResourceId = tolower(tostring(properties.targetResourceId)), AvailabilityState = tostring(properties.availabilityState)) on \$left.Id == \$right.targetResourceId | project-away targetResourceId | where PowerState != 'PowerState/deallocated'"
```

### List of virtual machines that are not Available by Resource Ids

Returns the latest list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by their availability state. The populated list only highlights virtual machines whose availability state is not "Available" to ensure you are aware of all the concerning states your virtual machines are in. When all your virtual machines are Available, you can expect to receive no results.

```
HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| where tostring(properties.availabilityState) != 'Available'
| summarize by ResourceId = tolower(tostring(properties.targetResourceId)), AvailabilityState = tostring(properties.availabilityState)
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "HealthResources | where type =~ 'microsoft.resourcehealth/availabilitystatuses' | where
tostring(properties.availabilityState) != 'Available' | summarize by ResourceId =
tolower(tostring(properties.targetResourceId)), AvailabilityState = tostring(properties.availabilityState)"
```

## List of Windows Server OS update installation done

Returns a list of status of Windows Server - OS update installation runs done for your machines in last 7 days.

```
PatchAssessmentResources
| where type has 'softwarepatches' and properties !has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)),
tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id, '/', 10))
| extend prop = parse_json(properties)
| extend lTime = todatetime(prop.lastModifiedDateTime), patchName = tostring(prop.patchName), kbId =
tostring(prop.kbId), installationState = tostring(prop.installationState), classifications =
tostring(prop.classifications)
| where lTime > ago(7d)
| project lTime, RunID, machineName, rgName, resourceType, patchName, kbId, classifications,
installationState
| sort by RunID
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "PatchAssessmentResources | where type has 'softwarepatches' and properties !has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/', 0)),
tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id, '/', 10)) | extend prop =
parse_json(properties) | extend lTime = todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), kbId = tostring(prop.kbId), installationState = tostring(prop.installationState),
classifications = tostring(prop.classifications) | where lTime > ago(7d) | project lTime, RunID,
machineName, rgName, resourceType, patchName, kbId, classifications, installationState | sort by RunID"
```

## List virtual machines with their network interface and public IP

This query uses two **leftouter join** commands to bring together virtual machines created with the Resource Manager deployment model, their related network interfaces, and any public IP address related to those network interfaces.

```

Resources
| where type =~ 'microsoft.compute/virtualmachines'
| extend nics=array_length(properties.networkProfile.networkInterfaces)
| mv-expand nic=properties.networkProfile.networkInterfaces
| where nics == 1 or nic.properties.primary =~ 'true' or isempty(nic)
| project vmId = id, vmName = name, vmSize=toString(properties.hardwareProfile.vmSize), nicId =
toString(nic.id)
| join kind=leftouter (
    Resources
    | where type =~ 'microsoft.network/networkinterfaces'
    | extend ipConfigsCount=array_length(properties.ipConfigurations)
    | mv-expand ipconfig=properties.ipConfigurations
    | where ipConfigsCount == 1 or ipconfig.properties.primary =~ 'true'
    | project nicId = id, publicIpId = toString(ipconfig.properties.publicIPAddress.id))
on nicId
| project-away nicId1
| summarize by vmId, vmName, vmSize, nicId, publicIpId
| join kind=leftouter (
    Resources
    | where type =~ 'microsoft.network/publicipaddresses'
    | project publicIpId = id, publicIpAddress = properties.ipAddress)
on publicIpId
| project-away publicIpId1

```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```

az graph query -q "Resources | where type =~ 'microsoft.compute/virtualmachines' | extend
nics=array_length(properties.networkProfile.networkInterfaces) | mv-expand
nic=properties.networkProfile.networkInterfaces | where nics == 1 or nic.properties.primary =~ 'true' or
isempty(nic) | project vmId = id, vmName = name, vmSize=toString(properties.hardwareProfile.vmSize), nicId =
toString(nic.id) | join kind=leftouter ( Resources | where type =~ 'microsoft.network/networkinterfaces' |
extend ipConfigsCount=array_length(properties.ipConfigurations) | mv-expand
ipconfig=properties.ipConfigurations | where ipConfigsCount == 1 or ipconfig.properties.primary =~ 'true' |
project nicId = id, publicIpId = toString(ipconfig.properties.publicIPAddress.id)) on nicId | project-away
nicId1 | summarize by vmId, vmName, vmSize, nicId, publicIpId | join kind=leftouter ( Resources | where type
=~ 'microsoft.network/publicipaddresses' | project publicIpId = id, publicIpAddress = properties.ipAddress)
on publicIpId | project-away publicIpId1"

```

### Show all virtual machines ordered by name in descending order

To list only virtual machines (which are type `Microsoft.Compute/virtualMachines`), we can match the property `type` in the results. Similar to the previous query, `desc` changes the `order by` to be descending. The `=~` in the type match tells Resource Graph to be case insensitive.

```

Resources
| project name, location, type
| where type =~ 'Microsoft.Compute/virtualMachines'
| order by name desc

```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```

az graph query -q "Resources | project name, location, type | where type =~
'Microsoft.Compute/virtualMachines' | order by name desc"

```

## Show first five virtual machines by name and their OS type

This query uses `top` to only retrieve five matching records that are ordered by name. The type of the Azure resource is `Microsoft.Compute/virtualMachines`. `project` tells Azure Resource Graph which properties to include.

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| project name, properties.storageProfile.osDisk.osType
| top 5 by name desc
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type =~ 'Microsoft.Compute/virtualMachines' | project name,
properties.storageProfile.osDisk.osType | top 5 by name desc"
```

## Summarize virtual machine by the power states extended property

This query uses the [extended properties](#) on virtual machines to summarize by power states.

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| summarize count() by tostring(properties.extended.instanceView.powerState.code)
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type == 'microsoft.compute/virtualmachines' | summarize count() by
tostring(properties.extended.instanceView.powerState.code)"
```

## Virtual machines matched by regex

This query looks for virtual machines that match a [regular expression](#) (known as *regex*). The `matches regex @` allows us to define the regex to match, which is `^Contoso(.*)[0-9]+$`. That regex definition is explained as:

- `^` - Match must start at the beginning of the string.
- `Contoso` - The case-sensitive string.
- `(.*)` - A subexpression match:
  - `.` - Matches any single character (except a new line).
  - `*` - Matches previous element zero or more times.
- `[0-9]` - Character group match for numbers 0 through 9.
- `+` - Matches previous element one or more times.
- `$` - Match of the previous element must occur at the end of the string.

After matching by name, the query projects the name and orders by name ascending.

```
Resources
| where type =~ 'microsoft.compute/virtualmachines' and name matches regex @'^Contoso(.*?[0-9]+$'
| project name
| order by name asc
```

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)

```
az graph query -q "Resources | where type =~ 'microsoft.compute/virtualmachines' and name matches regex
@'^Contoso(.*?[0-9]+$' | project name | order by name asc"
```

# Red Hat workloads on Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Red Hat workloads are supported through a variety of offerings on Azure. Red Hat Enterprise Linux (RHEL) images are at the core of RHEL workloads, as is the Red Hat Update Infrastructure (RHUI).

## Red Hat Enterprise Linux images

Azure offers a wide offering of RHEL images on Azure. These images are made available through two different licensing models: pay-as-you-go and bring-your-own-subscription (BYOS). New RHEL images on Azure are published when new RHEL versions are released and updated throughout their lifecycles, as necessary.

### Pay-as-you-go images

Azure offers a variety of RHEL pay-as-you-go images. These images come properly entitled for RHEL and are attached to a source of updates (Red Hat Update Infrastructure). These images charge a premium fee for the RHEL entitlement and updates. RHEL pay-as-you-go image variants include:

- RHEL
- RHEL for SAP
- RHEL for SAP with High Availability (HA) and Update Services

You might want to use the pay-as-you-go images if you don't want to worry about paying separately for the appropriate number of subscriptions.

### Red Hat Gold Images

Azure also offers Red Hat Gold Images (`rhel1-byos`). These images might be useful to customers who have existing Red Hat subscriptions and want to use them in Azure. You're required to enable your existing Red Hat subscriptions for Red Hat Cloud Access before you can use them in Azure. Access to these images is granted automatically when your Red Hat subscriptions are enabled for Cloud Access and meet the eligibility requirements. Using these images allows a customer to avoid double billing that might be incurred from using the pay-as-you-go images.

- Learn how to [enable your Red Hat subscriptions for Cloud Access with Azure](#).
- Learn how to [locate Red Hat Gold Images in the Azure portal, the Azure CLI, or PowerShell cmdlet](#).

#### NOTE

Double billing is incurred when a user pays twice for RHEL subscriptions. This scenario usually happens when a customer uses Red Hat Subscription-Manager to attach an entitlement on a RHEL pay-as-you-go VM. For example, a customer who uses Subscription-Manager to attach an entitlement for SAP packages on a RHEL pay-as-you-go image is indirectly double billed because they pay twice for RHEL. They pay once through the pay-as-you-go premium fee and once through their SAP subscription. This scenario doesn't happen to BYOS image users.

## Generation 2 images

Generation 2 virtual machines (VMs) provide some newer features compared to Generation 1 VMs. For more information, see the [Generation 2 documentation](#). The key difference from a RHEL image perspective is that Generation 2 VMs use a UEFI instead of BIOS firmware interface. They also use a GUID Partition Table (GPT) instead of a master boot record (MBR) on boot time. Use of a GPT allows for, among other things, OS disk sizes

larger than 2 TB. In addition, the [Mv2 series VMs](#) run only on Generation 2 images.

RHEL Generation 2 images are available in the Azure Marketplace. Look for "gen2" in the image SKU in the list of all images that appears when you use the Azure CLI. Go to the **Advanced** tab in the VM deploy process to deploy a Generation 2 VM.

## Red Hat Update Infrastructure

Azure provides Red Hat Update Infrastructure only for pay-as-you-go RHEL VMs. RHUI is effectively a mirror of the Red Hat CDNs but is only accessible to the Azure pay-as-you-go RHEL VMs. You have access to the appropriate packages depending on which RHEL image you've deployed. For example, a RHEL for SAP image has access to the SAP packages in addition to base RHEL packages.

### RHUI update behavior

RHEL images connected to RHUI update by default to the latest minor version of RHEL when a `yum update` is run. This behavior means that a RHEL 7.4 VM might get upgraded to RHEL 7.7 if a `yum update` operation is run on it. This behavior is by design for RHUI. To mitigate this upgrade behavior, switch from regular RHEL repositories to [Extended Update Support repositories](#).

## Red Hat Middleware

Microsoft and Azure have partnered to develop a variety of solutions for running Red Hat Middleware on Azure. Learn more about JBoss EAP on Azure Virtual Machines and Azure App service at [Red Hat JBoss EAP on Azure](#).

# OpenShift in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

OpenShift is an open and extensible container application platform that brings Docker and Kubernetes to the enterprise.

OpenShift includes Kubernetes for container orchestration and management. It adds developer-centric and operations-centric tools that enable:

- Rapid application development.
- Easy deployment and scaling.
- Long-term lifecycle maintenance for teams and applications.

There are multiple versions of OpenShift available. Of these versions, only two are available today for customers to deploy in Azure: OpenShift Container Platform and OKD (formerly OpenShift Origin).

## Azure Red Hat OpenShift

Microsoft Azure Red Hat OpenShift is a fully managed offering of OpenShift running in Azure. This service is jointly managed and supported by Microsoft and Red Hat. For more details, see the [Azure Red Hat OpenShift Service](#) documentation.

## OpenShift Container Platform

Container Platform is an enterprise-ready [commercial version](#) from and supported by Red Hat. With this version, customers purchase the necessary entitlements for OpenShift Container Platform and are responsible for installation and management of the entire infrastructure.

Because customers "own" the entire platform, they can install it in their on-premises datacenter, or in a public cloud (such as Azure).

## OKD

OKD is an [open-source](#) upstream project of OpenShift that's community supported. OKD can be installed on CentOS or Red Hat Enterprise Linux (RHEL).

## Next steps

- [Configure common prerequisites for OpenShift in Azure](#)
- [Deploy OpenShift Container Platform in Azure](#)
- [Deploy OpenShift Container Platform Self-Managed Marketplace Offer](#)

- [Troubleshoot OpenShift deployment](#)

# Deploy OpenShift Container Platform 4.x in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Deployment of OpenShift Container Platform (OCP) 4.2 is now supported in Azure via the Installer-Provisioned Infrastructure (IPI) model. The landing page for trying OpenShift 4 is [try.openshift.com](https://try.openshift.com). To install OCP 4.2 in Azure, visit the [Red Hat OpenShift Cluster Manager](#) page. Red Hat credentials are required to access this site.

## Notes

- An Azure Active Directory (AAD) Service Principal (SP) is required to install and run OCP 4.x in Azure
  - The SP must be granted the API permission of **Application.ReadWrite.OwnedBy** for Azure Active Directory Graph
  - An AAD Tenant Administrator must grant Admin Consent for this API permission to take effect
  - The SP must be granted **Contributor** and **User Access Administrator** roles to the subscription
- The installation model for OCP 4.x is different than 3.x and there are no Azure Resource Manager templates available for deploying OCP 4.x in Azure
- If issues are encountered during the installation process, contact the appropriate company (Microsoft or Red Hat)

ISSUE DESCRIPTION	CONTACT POINT
Azure specific issues (AAD, SP, Azure Subscription, etc.)	Microsoft
OpenShift-specific issues (Installation failures / errors, Red Hat subscription, etc.)	Red Hat

## Next steps

- [Getting started with OpenShift Container Platform](#)

# Common prerequisites for deploying OpenShift Container Platform 3.11 in Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article describes common prerequisites for deploying OpenShift Container Platform or OKD in Azure.

The installation of OpenShift uses Ansible playbooks. Ansible uses Secure Shell (SSH) to connect to all cluster hosts to complete installation steps.

When ansible makes the SSH connection to the remote hosts, it can't enter a password. For this reason, the private key can't have a password (passphrase) associated with it or deployment fails.

Because the virtual machines (VMs) deploy via Azure Resource Manager templates, the same public key is used for access to all VMs. The corresponding private key must be on the VM that executes all the playbooks as well. To perform this action securely, an Azure key vault is used to pass the private key into the VM.

If there's a need for persistent storage for containers, then persistent volumes are required. OpenShift supports Azure virtual hard disks (VHDs) for persistent volumes, but Azure must first be configured as the cloud provider.

In this model, OpenShift:

- Creates a VHD object in an Azure storage account or a managed disk.
- Mounts the VHD to a VM and formats the volume.
- Mounts the volume to the pod.

For this configuration to work, OpenShift needs permissions to perform these tasks in Azure. A service principal is used for this purpose. The service principal is a security account in Azure Active Directory that is granted permissions to resources.

The service principal needs to have access to the storage accounts and VMs that make up the cluster. If all OpenShift cluster resources deploy to a single resource group, the service principal can be granted permissions to that resource group.

This guide describes how to create the artifacts associated with the prerequisites.

- Create a key vault to manage SSH keys for the OpenShift cluster.
- Create a service principal for use by the Azure Cloud Provider.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Sign in to Azure

Sign in to your Azure subscription with the [az login](#) command and follow the on-screen directions, or click Try it to use Cloud Shell.

```
az login
```

## Create a resource group

Create a resource group with the [az group create](#) command. An Azure resource group is a logical container into

which Azure resources are deployed and managed. You should use a dedicated resource group to host the key vault. This group is separate from the resource group into which the OpenShift cluster resources deploy.

The following example creates a resource group named *keyvaultrg* in the *eastus* location:

```
az group create --name keyvaultrg --location eastus
```

## Create a key vault

Create a key vault to store the SSH keys for the cluster with the [az keyvault create](#) command. The key vault name must be globally unique and must be enabled for template deployment or the deployment will fail with "KeyVaultParameterReferenceSecretRetrieveFailed" error.

The following example creates a key vault named *keyvault* in the *keyvaultrg* resource group:

```
az keyvault create --resource-group keyvaultrg --name keyvault \
    --enabled-for-template-deployment true \
    --location eastus
```

## Create an SSH key

An SSH key is needed to secure access to the OpenShift cluster. Create an SSH key pair by using the [ssh-keygen](#) command (on Linux or macOS):

```
ssh-keygen -f ~/.ssh/openshift_rsa -t rsa -N ''
```

### NOTE

Your SSH key pair can't have a password / passphrase.

For more information on SSH keys on Windows, see [How to create SSH keys on Windows](#). Be sure to export the private key in OpenSSH format.

## Store the SSH private key in Azure Key Vault

The OpenShift deployment uses the SSH key you created to secure access to the OpenShift master. To enable the deployment to securely retrieve the SSH key, store the key in Key Vault by using the following command:

```
az keyvault secret set --vault-name keyvault --name keysecret --file ~/.ssh/openshift_rsa
```

## Create a service principal

OpenShift communicates with Azure by using a username and password or a service principal. An Azure service principal is a security identity that you can use with apps, services, and automation tools like OpenShift. You control and define the permissions as to which operations the service principal can perform in Azure. It's best to scope the permissions of the service principal to specific resource groups rather than the entire subscription.

Create a service principal with [az ad sp create-for-rbac](#) and output the credentials that OpenShift needs.

The following example creates a service principal and assigns it contributor permissions to a resource group named *openshifttrg*.

First, create the resource group named *openshiftrg*.

```
az group create -l eastus -n openshiftrg
```

Create service principal:

```
az group show --name openshiftrg --query id
```

Save the output of the command and use in place of \$scope in next command

```
az ad sp create-for-rbac --name openshiftsp \
--role Contributor --scopes $scope \
```

Take note of the appId property and password returned from the command:

```
{
  "appId": "11111111-abcd-1234-efgh-111111111111",
  "displayName": "openshiftsp",
  "name": "http://openshiftsp",
  "password": {Strong Password},
  "tenant": "XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX"
}
```

#### WARNING

Be sure to write down the secure password as it will not be possible to retrieve this password again.

For more information on service principals, see [Create an Azure service principal with Azure CLI](#).

## Prerequisites applicable only to Resource Manager template

Secrets will need to be created for the SSH private key (**sshPrivateKey**), Azure AD client secret (**aadClientSecret**), OpenShift admin password (**openshiftPassword**), and Red Hat Subscription Manager password or activation key (**rhsmPasswordOrActivationKey**). Additionally, if custom TLS/SSL certificates are used, then six additional secrets will need to be created - **routingcafile**, **routingcertfile**, **routingkeyfile**, **mastercafile**, **mastercertfile**, and **masterkeyfile**. These parameters will be explained in more detail.

The template references specific secret names so you **must** use the bolded names listed above (case sensitive).

### Custom Certificates

By default, the template will deploy an OpenShift cluster using self-signed certificates for the OpenShift web console and the routing domain. If you want to use custom TLS/SSL certificates, set 'routingCertType' to 'custom' and 'masterCertType' to 'custom'. You'll need the CA, Cert, and Key files in .pem format for the certificates. It is possible to use custom certificates for one but not the other.

You'll need to store these files in Key Vault secrets. Use the same Key Vault as the one used for the private key. Rather than require 6 additional inputs for the secret names, the template is hard-coded to use specific secret names for each of the TLS/SSL certificate files. Store the certificate data using the information from the following table.

SECRET NAME	CERTIFICATE FILE
mastercafile	master CA file
mastercertfile	master CERT file
masterkeyfile	master Key file
routingcafile	routing CA file
routingcertfile	routing CERT file
routingkeyfile	routing Key file

Create the secrets using the Azure CLI. Below is an example.

```
az keyvault secret set --vault-name KeyVaultName -n mastercafile --file ~/certificates/masterca.pem
```

## Next steps

This article covered the following topics:

- Create a key vault to manage SSH keys for the OpenShift cluster.
- Create a service principal for use by the Azure Cloud Solution Provider.

Next, deploy an OpenShift cluster:

- [Deploy OpenShift Container Platform](#)
- [Deploy OpenShift Container Platform Self-Managed Marketplace Offer](#)

# Deploy OpenShift Container Platform 3.11 in Azure

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You can use one of several methods to deploy OpenShift Container Platform 3.11 in Azure:

- You can manually deploy the necessary Azure infrastructure components and then follow the [OpenShift Container Platform documentation](#).
- You can also use an existing [Resource Manager template](#) that simplifies the deployment of the OpenShift Container Platform cluster.
- Another option is to use the Azure Marketplace offer.

For all options, a Red Hat subscription is required. During the deployment, the Red Hat Enterprise Linux instance is registered to the Red Hat subscription and attached to the Pool ID that contains the entitlements for OpenShift Container Platform. Make sure you have a valid Red Hat Subscription Manager (RHSM) username, password, and Pool ID. You can use an Activation Key, Org ID, and Pool ID. You can verify this information by signing in to <https://access.redhat.com>.

## Deploy using the OpenShift Container Platform Resource Manager 3.11 template

### Private Clusters

Deploying private OpenShift clusters requires more than just not having a public IP associated to the master load balancer (web console) or to the infra load balancer (router). A private cluster generally uses a custom DNS server (not the default Azure DNS), a custom domain name (such as contoso.com), and pre-defined virtual network(s). For private clusters, you need to configure your virtual network with all the appropriate subnets and DNS server settings in advance. Then use `existingMasterSubnetReference`, `existingInfraSubnetReference`, `existingCnsSubnetReference`, and `existingNodeSubnetReference` to specify the existing subnet for use by the cluster.

If private master is selected (`masterClusterType=private`), a static private IP needs to be specified for `masterPrivateClusterIp`. This IP will be assigned to the front end of the master load balancer. The IP must be within the CIDR for the master subnet and not in use. `masterClusterDnsType` must be set to "custom" and the master DNS name must be provided for `masterClusterDns`. The DNS name must map to the static Private IP and will be used to access the console on the master nodes.

If private router is selected (`routerClusterType=private`), a static private IP needs to be specified for `routerPrivateClusterIp`. This IP will be assigned to the front end of the infra load balancer. The IP must be within the CIDR for the infra subnet and not in use. `routingSubDomainType` must be set to "custom" and the wildcard DNS name for routing must be provided for `routingSubDomain`.

If private masters and private router are selected, the custom domain name must also be entered for `domainName`

After successful deployment, the Bastion Node is the only node with a public IP that you can ssh into. Even if the master nodes are configured for public access, they aren't exposed for ssh access.

To deploy using the Resource Manager template, you use a parameters file to supply the input parameters. To further customize the deployment, fork the GitHub repo and change the appropriate items.

Some common customization options include, but aren't limited to:

- Bastion VM size (variable in azuredeploy.json)
- Naming conventions (variables in azuredeploy.json)
- OpenShift cluster specifics, modified via hosts file (deployOpenShift.sh)

## Configure the parameters file

The [OpenShift Container Platform template](#) has multiple branches available for different versions of OpenShift Container Platform. Based on your needs, you can deploy directly from the repo or you can fork the repo and make custom changes to the templates or scripts before deploying.

Use the `appId` value from the service principal you created earlier for the `aadClientId` parameter.

The following example shows a parameters file named `azuredeploy.parameters.json` with all the required inputs.

```
{
  "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentParameters.json#",

    "routingCertType": {
        "value": "selfsigned"
    },
    "masterCertType": {
        "value": "selfsigned"
    }
}
}

```

Replace the parameters with your specific information.

Different releases may have different parameters so verify the necessary parameters for the branch you use.

## azuredeploy.Parameters.json file explained

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>_artifactsLocation</code>	URL for artifacts (json, scripts, etc.)		<a href="https://raw.githubusercontent.com/Microsoft/openshift-container-platform/master">https://raw.githubusercontent.com/Microsoft/openshift-container-platform/master</a>
<code>location</code>	Azure region to deploy resources to		
<code>masterVmSize</code>	Size of the Master VM. Select from one of the allowed VM sizes listed in the azuredeploy.json file		Standard_E2s_v3
<code>infraVmSize</code>	Size of the Infra VM. Select from one of the allowed VM sizes listed in the azuredeploy.json file		Standard_D4s_v3
<code>nodeVmSize</code>	Size of the App Node VM. Select from one of the allowed VM sizes listed in the azuredeploy.json file		Standard_D4s_v3
<code>cnsVmSize</code>	Size of the Container Native Storage (CNS) Node VM. Select from one of the allowed VM sizes listed in the azuredeploy.json file		Standard_E4s_v3
<code>osImageType</code>	The RHEL image to use. defaultgallery: On-Demand; marketplace: third-party image	defaultgallery marketplace	defaultgallery
<code>marketplaceOsImage</code>	If <code>osImageType</code> is marketplace, then enter the appropriate values for 'publisher', 'offer', 'sku', 'version' of the marketplace offer. This parameter is an object type		
<code>storageKind</code>	The type of storage to be used	managed unmanaged	managed
<code>openshiftClusterPrefix</code>	Cluster Prefix used to configure hostnames for all nodes. Between 1 and 20 characters		mycluster
<code>minoVersion</code>	The minor version of OpenShift Container Platform 3.11 to deploy		69
<code>masterInstanceCount</code>	Number of Masters nodes to deploy	1, 3, 5	3

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>infraInstanceCount</code>	Number of infra nodes to deploy	1, 2, 3	3
<code>nodeInstanceCount</code>	Number of Nodes to deploy	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30	2
<code>cnsInstanceCount</code>	Number of CNS nodes to deploy	3, 4	3
<code>osDiskSize</code>	Size of OS disk for the VM (in GB)	64, 128, 256, 512, 1024, 2048	64
<code>dataDiskSize</code>	Size of data disk to attach to nodes for Docker volume (in GB)	32, 64, 128, 256, 512, 1024, 2048	64
<code>cnsGlusterDiskSize</code>	Size of data disk to attach to CNS nodes for use by glusterfs (in GB)	32, 64, 128, 256, 512, 1024, 2048	128
<code>adminUsername</code>	Admin username for both OS (VM) login and initial OpenShift user		ocpadmin
<code>enableMetrics</code>	Enable Metrics. Metrics require more resources so select proper size for Infra VM	true false	false
<code>enableLogging</code>	Enable Logging. elasticsearch pod requires 8 GB RAM so select proper size for Infra VM	true false	false
<code>enableCNS</code>	Enable Container Native Storage	true false	false
<code>rhsmUsernameOrOrgId</code>	Red Hat Subscription Manager Username or Organization ID		
<code>rhsmPoolId</code>	The Red Hat Subscription Manager Pool ID that contains your OpenShift entitlements for compute nodes		

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>rhsmBrokerPoolId</code>	The Red Hat Subscription Manager Pool ID that contains your OpenShift entitlements for masters and infra nodes. If you don't have different pool IDs, enter same pool ID as ' <code>rhsmPoolId</code> '		
<code>sshPublicKey</code>	Copy your SSH Public Key here		
<code>keyVaultSubscriptionId</code>	The Subscription ID of the subscription that contains the Key Vault		
<code>keyVaultResourceGroup</code>	The name of the Resource Group that contains the Key Vault		
<code>keyVaultName</code>	The name of the Key Vault you created		
<code>enableAzure</code>	Enable Azure Cloud Provider	true false	true
<code>aadClientId</code>	Azure Active Directory Client ID also known as Application ID for Service Principal		
<code>domainName</code>	Name of the custom domain name to use (if applicable). Set to "none" if not deploying fully private cluster		none
<code>masterClusterDnsType</code>	Domain type for OpenShift web console. 'default' will use DNS label of master infra public IP. 'custom' allows you to define your own name	default custom	default
<code>masterClusterDns</code>	The custom DNS name to use to access the OpenShift web console if you selected 'custom' for <code>masterClusterDnsType</code>		console.contoso.com
<code>routingSubDomainType</code>	If set to <code>nipio</code> , <code>routingSubDomain</code> will use <code>nip.io</code> . Use 'custom' if you have your own domain that you want to use for routing	<code>nipio</code> custom	<code>nipio</code>

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>routingSubDomain</code>	The wildcard DNS name you want to use for routing if you selected 'custom' for <code>routingSubDomainType</code>		apps.contoso.com
<code>virtualNetworkNewOrExisting</code>	Select whether to use an existing Virtual Network or create a new Virtual Network	existing new	new
<code>virtualNetworkResourceGroupName</code>	Name of the Resource Group for the new Virtual Network if you selected 'new' for <code>virtualNetworkNewOrExisting</code>		resourceGroup().name
<code>virtualNetworkName</code>	The name of the new Virtual Network to create if you selected 'new' for <code>virtualNetworkNewOrExisting</code>		openshiftvnet
<code>addressPrefixes</code>	Address prefix of the new virtual network		10.0.0.0/14
<code>masterSubnetName</code>	The name of the master subnet		mastersubnet
<code>masterSubnetPrefix</code>	CIDR used for the master subnet - needs to be a subset of the addressPrefix		10.1.0.0/16
<code>infraSubnetName</code>	The name of the infra subnet		infrasubnet
<code>infraSubnetPrefix</code>	CIDR used for the infra subnet - needs to be a subset of the addressPrefix		10.2.0.0/16
<code>nodeSubnetName</code>	The name of the node subnet		nodesubnet
<code>nodeSubnetPrefix</code>	CIDR used for the node subnet - needs to be a subset of the addressPrefix		10.3.0.0/16
<code>existingMasterSubnetReference</code>	Full reference to existing subnet for master nodes. Not needed if creating new vNet / Subnet		
<code>existingInfraSubnetReference</code>	Full reference to existing subnet for infra nodes. Not needed if creating new vNet / Subnet		

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>existingCnsSubnetReference</code>	Full reference to existing subnet for CNS nodes. Not needed if creating new vNet / Subnet		
<code>existingNodeSubnetReference</code>	Full reference to existing subnet for compute nodes. Not needed if creating new vNet / Subnet		
<code>masterClusterType</code>	Specify whether the cluster uses private or public master nodes. If private is chosen, the master nodes won't be exposed to the Internet via a public IP. Instead, it will use the private IP specified in the <code>masterPrivateClusterIp</code>	public private	public
<code>masterPrivateClusterIp</code>	If private master nodes are selected, then a private IP address must be specified for use by the internal load balancer for master nodes. This static IP must be within the CIDR block for the master subnet and not already in use. If public master nodes are selected, this value won't be used but must still be specified		10.1.0.200
<code>routerClusterType</code>	Specify whether the cluster uses private or public infra nodes. If private is chosen, the infra nodes won't be exposed to the Internet via a public IP. Instead, it will use the private IP specified in the <code>routerPrivateClusterIp</code>	public private	public
<code>routerPrivateClusterIp</code>	If private infra nodes are selected, then a private IP address must be specified for use by the internal load balancer for infra nodes. This static IP must be within the CIDR block for the infra subnet and not already in use. If public infra nodes are selected, this value won't be used but must still be specified		10.2.0.200

PROPERTY	DESCRIPTION	VALID OPTIONS	DEFAULT VALUE
<code>routingCertType</code>	Use custom certificate for routing domain or the default self-signed certificate - follow instructions in <b>Custom Certificates</b> section	selfsigned custom	selfsigned
<code>masterCertType</code>	Use custom certificate for master domain or the default self-signed certificate - follow instructions in <b>Custom Certificates</b> section	selfsigned custom	selfsigned

## Deploy using Azure CLI

### NOTE

The following command requires Azure CLI 2.0.8 or later. You can verify the CLI version with the `az --version` command. To update the CLI version, see [Install Azure CLI](#).

The following example deploys the OpenShift cluster and all related resources into a resource group named `openshiftrg`, with a deployment name of `myOpenShiftCluster`. The template is referenced directly from the GitHub repo, and a local parameters file named `azuredeploy.parameters.json` file is used.

```
az deployment group create -g openshiftrg --name myOpenShiftCluster \
    --template-uri https://raw.githubusercontent.com/Microsoft/openshift-container-
platform/master/azuredeploy.json \
    --parameters @./azuredeploy.parameters.json
```

The deployment takes at least 60 minutes to complete, based on the total number of nodes deployed and options configured. The Bastion DNS FQDN and URL of the OpenShift console prints to the terminal when the deployment finishes.

```
{
  "Bastion DNS FQDN": "bastiondns4hawllzaavu6g.eastus.cloudapp.azure.com",
  "OpenShift Console URL": "http://openshiftlb.eastus.cloudapp.azure.com/console"
}
```

If you don't want to tie up the command line waiting for the deployment to complete, add `--no-wait` as one of the options for the group deployment. The output from the deployment can be retrieved from the Azure portal in the deployment section for the resource group.

## Connect to the OpenShift cluster

When the deployment finishes, retrieve the connection from the output section of the deployment. Connect to the OpenShift console with your browser by using the **OpenShift Console URL**. You can also SSH to the Bastion host. Following is an example where the admin username is `clusteradmin` and the bastion public IP DNS FQDN is `bastiondns4hawllzaavu6g.eastus.cloudapp.azure.com`:

```
$ ssh clusteradmin@bastiondns4hawllzaavu6g.eastus.cloudapp.azure.com
```

## Clean up resources

Use the [az group delete](#) command to remove the resource group, OpenShift cluster, and all related resources when they're no longer needed.

```
az group delete --name openshifttrg
```

## Next steps

- [Post-deployment tasks](#)
- [Troubleshoot OpenShift deployment in Azure](#)
- [Getting started with OpenShift Container Platform](#)

# Configure prerequisites

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Before using the Marketplace offer to deploy a self-managed OpenShift Container Platform 3.11 cluster in Azure, a few prerequisites must be configured. Read the [OpenShift prerequisites](#) article for instructions to create an ssh key (without a passphrase), Azure key vault, key vault secret, and a service principal.

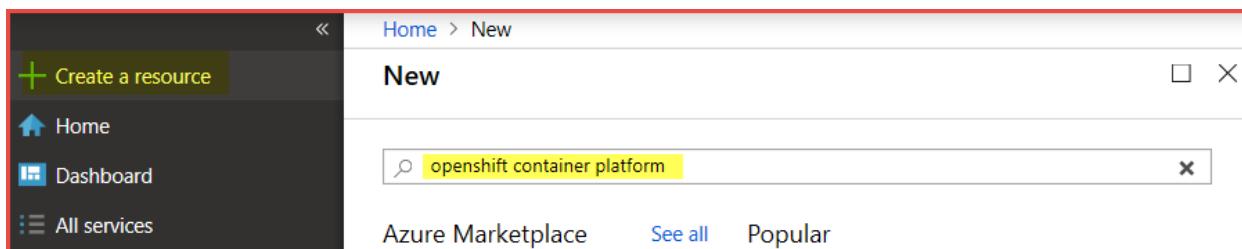

## Deploy using the Marketplace offer

The simplest way to deploy a self-managed OpenShift Container Platform 3.11 cluster into Azure is to use the Azure Marketplace offer.

This option is the simplest, but it also has limited customization capabilities. The Marketplace offer deploys OpenShift Container Platform 3.11.82 and includes the following configuration options:

- **Master Nodes:** Three (3) Master Nodes with configurable instance type.
- **Infra Nodes:** Three (3) Infra Nodes with configurable instance type.
- **Nodes:** The number of Nodes (between 1 and 9) and the instance type are configurable.
- **Disk Type:** Managed Disks are used.
- **Networking:** Support for new or existing Network and custom CIDR range.
- **CNS:** CNS can be enabled.
- **Metrics:** Hawkular Metrics can be enabled.
- **Logging:** EFK Logging can be enabled.
- **Azure Cloud Provider:** Enabled by default, can be disabled.

In the upper left of the Azure portal, click **Create a resource**, enter 'openshift container platform' into the search box and hit Enter.

The Results page will open with **Red Hat OpenShift Container Platform 3.11 Self-Managed** in the list.

Results		
NAME	PUBLISHER	CATEGORY
 Red Hat OpenShift Container Platform Self-Managed	Red Hat	Compute

Click the offer to view details of the offer. To deploy this offer, click **Create**. The UI to enter necessary parameters will appear. The first screen is the **Basics** blade.

**Red Hat OpenShift Container Platform Self-Managed**

Red Hat

Red Hat

[Create](#) [Save for later](#)

**This is the Self-Managed offer**

Read [Deployment Guide](#) for Azure Marketplace before deploying.

Red Hat OpenShift Container Platform helps organizations develop, deploy, and manage container-based applications seamlessly across physical, virtual, and public cloud infrastructures. OpenShift Container Platform brings application development and IT operations teams together in order to modernize applications, accelerate development processes, and deliver new services faster.

**OpenShift Highlights:**

- Simple to use with powerful tools for developers
- For traditional, stateful, and cloud-native applications
- Built on proven open source technologies including Red Hat Enterprise Linux, Kubernetes, and Docker
- Enterprise-grade security, compliance, and container management
- Expanded applications support with new and updated runtimes

This offering includes one bastion host, three master nodes, three infrastructure nodes, and a customizable number and size of application nodes.

- The number of application nodes is configurable between one and nine hosts with six options for the size of the virtual machines.
- The bastion host serves as a jump host for access to the OpenShift cluster nodes and system management.

## Basics

To get help on any of the input parameters, hover over the *i* next to the parameter name.

Enter values for the input parameters and click **OK**.

INPUT PARAMETER	PARAMETER DESCRIPTION
VM Admin User Name	The administrator user to be created on all VM instances
SSH Public Key for Admin User	SSH public key used to log into VM - must not have a passphrase
Subscription	Azure subscription to deploy cluster into
Resource Group	Create a new resource group or select an existing empty resource group for cluster resources
Location	Azure region to deploy cluster into

## Infrastructure Settings

Enter values for the input parameters and click OK.

INPUT PARAMETER	PARAMETER DESCRIPTION
OCP Cluster Name Prefix	Cluster Prefix used to configure hostnames for all nodes. Between 1 and 20 characters
Master Node Size	Accept the default VM size or click <b>Change size</b> to select a different VM size. Select appropriate VM size for your work load
Infrastructure Node Size	Accept the default VM size or click <b>Change size</b> to select a different VM size. Select appropriate VM size for your work load
Number of Application Nodes	Accept the default VM size or click <b>Change size</b> to select a different VM size. Select appropriate VM size for your work load
Application Node Size	Accept the default VM size or click <b>Change size</b> to select a different VM size. Select appropriate VM size for your work load
Bastion Host Size	Accept the default VM size or click <b>Change size</b> to select a different VM size. Select appropriate VM size for your work load

INPUT PARAMETER	PARAMETER DESCRIPTION
New or Existing Virtual Network	Create a new vNet (Default) or use an existing vNet
Choose Default CIDR Settings or customize IP Range (CIDR)	Accept default CIDR ranges or Select <b>Custom IP Range</b> and enter custom CIDR information. Default Settings will create vNet with CIDR of 10.0.0.0/14, master subnet with 10.1.0.0/16, infra subnet with 10.2.0.0/16, and compute and cns subnet with 10.3.0.0/16
Key Vault Resource Group Name	The name of the Resource Group that contains the Key Vault
Key Vault Name	The name of the Key Vault that contains the secret with the ssh private key. Only alphanumeric characters and dashes are allowed, and be between 3 and 24 characters
Secret Name	The name of the secret that contains the ssh private key. Only alphanumeric characters and dashes are allowed

## OpenShift Container Platform 3.11

Enter values for the Input Parameters and click OK

INPUT PARAMETER	PARAMETER DESCRIPTION
OpenShift Admin User Password	Password for the initial OpenShift user. This user will also be the cluster admin
Confirm OpenShift Admin User Password	Retype the OpenShift Admin User Password
Red Hat Subscription Manager User Name	User Name to access your Red Hat Subscription or Organization ID. This credential is used to register the RHEL instance to your subscription and will not be stored by Microsoft or Red Hat
Red Hat Subscription Manager User Password	Password to access your Red Hat Subscription or Activation Key. This credential is used to register the RHEL instance to your subscription and will not be stored by Microsoft or Red Hat
Red Hat Subscription Manager OpenShift Pool ID	Pool ID that contains OpenShift Container Platform entitlement. Ensure you have enough entitlements of OpenShift Container Platform for the installation of the cluster
Red Hat Subscription Manager OpenShift Pool ID for Broker / Master Nodes	Pool ID that contains OpenShift Container Platform entitlements for Broker / Master Nodes. Ensure you have enough entitlements of OpenShift Container Platform for the installation of the cluster. If not using broker / master pool ID, enter the pool ID for Application Nodes
Configure Azure Cloud Provider	Configure OpenShift to use Azure Cloud Provider. Necessary if using Azure disk attach for persistent volumes. Default is Yes

INPUT PARAMETER	PARAMETER DESCRIPTION
Azure AD Service Principal Client ID GUID	Azure AD Service Principal Client ID GUID - also known as AppID. Only needed if Configure Azure Cloud Provider set to Yes
Azure AD Service Principal Client ID Secret	Azure AD Service Principal Client ID Secret. Only needed if Configure Azure Cloud Provider set to Yes

## Additional Settings

The Additional Settings blade allows the configuration of CNS for glusterfs storage, Logging, Metrics, and Router Sub domain. The default won't install any of these options and will use nip.io as the router sub domain for testing purposes. Enabling CNS will install three additional compute nodes with three additional attached disks that will host glusterfs pods.

Enter values for the Input Parameters and click OK

INPUT PARAMETER	PARAMETER DESCRIPTION
-----------------	-----------------------

INPUT PARAMETER	PARAMETER DESCRIPTION
Configure Container Native Storage (CNS)	Installs CNS in the OpenShift cluster and enable it as storage. Will be default if Azure Provider is disabled
Configure Cluster Logging	Installs EFK logging functionality into the cluster. Size infra nodes appropriately to host EFK pods
Configure Metrics for the Cluster	Installs Hawkular metrics into the OpenShift cluster. Size infra nodes appropriately to host Hawkular metrics pods
Default Router Sub domain	Select nipio for testing or custom to enter your own sub domain for production

Create Red Hat OpenShift Co... X Additional Settings □ X

The screenshot shows the 'Create Red Hat OpenShift Container Platform' wizard. Step 4, 'Additional Settings', is currently selected. On the left, a vertical navigation bar lists steps 1 through 6: 1. Basics (Done), 2. Infrastructure Settings (Done), 3. OpenShift Container Platform (Done), 4. Additional Settings (selected), 5. Summary, and 6. Buy. Step 4 contains three configuration options:

- Configure Container Native Storage (CNS) - A toggle switch set to 'Yes'.
- Configure Cluster Logging - A toggle switch set to 'No'.
- Configure Metrics for the Cluster - A toggle switch set to 'Yes'.

Below these is a dropdown menu for 'Default Router Subdomain' set to 'nipio'. The 'Buy' button at the bottom right of the step 4 panel is highlighted in blue.

#### Additional Settings - Extra Parameters

INPUT PARAMETER	PARAMETER DESCRIPTION
(CNS) Node Size	Accept the default node size or select <b>Change size</b> to select a new VM size
Enter your custom subdomain	The custom routing domain to be used for exposing applications via the router on the OpenShift cluster. Be sure to create the appropriate wildcard DNS entry]

Red Hat OpenShift Container Platform Self-Managed by Red Hat  
[Terms of use](#) | [privacy policy](#)

Deploying this template will result in various actions being performed, which may include the deployment of one or more Azure resources or Marketplace offerings and/or transmission of the information you provided as part of the deployment process to one or more parties, as specified in the template. You are responsible for reviewing the text of the template to determine which actions will be performed and which resources or offerings will be deployed, and for locating and reviewing the pricing and legal terms associated with those resources or offerings.

Current retail prices for Azure resources are set forth [here](#) and may not reflect discounts applicable to your Azure subscription.

Prices for Marketplace offerings are set forth [here](#), and the legal terms associated with any Marketplace offering may be found in the Azure portal; both are subject to change at any time prior to deployment.

Neither subscription credits nor monetary commitment funds may be used to purchase non-Microsoft offerings. These purchases are billed separately. If any Microsoft products are included in a Marketplace offering (e.g., Windows Server or SQL Server), such products are licensed by Microsoft and not by any third party.

**Template deployment is intended for advanced users only.** If you are uncertain which actions will be performed by this template, which resources or offerings will be deployed, or what prices or legal terms pertain to those resources or offerings, do not deploy this template.

**Terms of use**

By clicking "Create", I (a) agree to the legal terms and privacy statement(s) provided above as well as the legal terms and privacy statement(s) associated with each Marketplace offering that will be deployed using this template, if any; (b) authorize Microsoft to charge or bill my current payment method for the fees associated with my use of the offering(s), including applicable taxes, with the same billing frequency as my Azure subscription, until I discontinue use of the offering(s); (c) agree that Microsoft may share my contact information and transaction details with any third-party sellers of the offering(s); and (d) give Microsoft permission to share my contact information so that the provider of the template can contact me regarding this product and related products. Microsoft assumes no responsibility for any actions performed by third-party templates and does not provide rights for third-party products or services. See the [Azure Marketplace Terms](#) for additional terms.

**By clicking Create, you give Microsoft permission to use or share your account information so that the provider or Microsoft can contact you regarding this product and related products.**

Name:

\* Preferred e-mail address:

\* Preferred phone number:

**Create**

## Connect to the OpenShift cluster

When the deployment finishes, retrieve the connection from the output section of the deployment. Connect to the OpenShift console with your browser by using the **OpenShift Console URL**. You can also SSH to the Bastion host. Following is an example where the admin username is clusteradmin and the bastion public IP DNS FQDN is bastiondns4hawllzaavu6g.eastus.cloudapp.azure.com:

```
$ ssh clusteradmin@bastiondns4hawllzaavu6g.eastus.cloudapp.azure.com
```

## Clean up resources

Use the [az group delete](#) command to remove the resource group, OpenShift cluster, and all related resources when they're no longer needed.

```
az group delete --name openshifttrg
```

# Deploy OpenShift Container Platform or OKD to Azure Stack Hub

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

[OpenShift](#) can be deployed in Azure Stack Hub. There are some key differences between Azure and Azure Stack Hub so deployment will differ slightly and capabilities will also differ slightly.

Currently, the Azure Cloud Provider doesn't work in Azure Stack Hub. You won't be able to use disk attach for persistent storage in Azure Stack Hub. Instead, you can configure other storage options such as NFS, iSCSI, and GlusterFS. Or, you can enable CNS and use GlusterFS for persistent storage. If CNS is enabled, three more nodes will be deployed with storage for GlusterFS usage.

## Deploy OpenShift 3.x On Azure Stack Hub

You can use one of several methods to deploy OpenShift Container Platform or OKD in Azure Stack Hub:

- You can manually deploy the necessary Azure infrastructure components and then follow the [OpenShift Container Platform documentation](#) or [OKD documentation](#).
- You can also use an existing [Azure Resource Manager template](#) that simplifies the deployment of the OpenShift Container Platform cluster.
- You can also use an existing [Azure Resource Manager template](#) that simplifies the deployment of the OKD cluster.

If using the Azure Resource Manager template, select the proper branch (azurestack-release-3.x). The templates for Azure won't work as the API versions are different between Azure and Azure Stack Hub. The RHEL image reference is currently hard-coded as a variable in the azuredeploy.json file and will need to be changed to match your image.

```
"imageReference": {  
    "publisher": "Redhat",  
    "offer": "RHEL-OCP",  
    "sku": "7-4",  
    "version": "latest"  
}
```

For all options, a Red Hat subscription is required. During the deployment, the Red Hat Enterprise Linux instance is registered to the Red Hat subscription and attached to the Pool ID that contains the entitlements for OpenShift Container Platform. Make sure you have a valid Red Hat Subscription Manager (RHSM) username, password, and Pool ID. Alternatively, you can use an Activation Key, Org ID, and Pool ID. You can verify this information at <https://access.redhat.com>.

### Azure Stack Hub prerequisites

An RHEL image (OpenShift Container Platform) or CentOS image (OKD) needs to be added to your Azure Stack Hub environment to deploy an OpenShift cluster. Contact your Azure Stack Hub cloud operator to add these images. Instructions can be found here:

- [Add and remove a custom VM image to Azure Stack Hub](#)
- [Azure Marketplace items available for Azure Stack Hub](#)

- Offer a Red Hat-based virtual machine for Azure Stack Hub

## Deploy by using the OpenShift Container Platform or OKD Azure Resource Manager template

To deploy by using the Azure Resource Manager template, you use a parameters file to supply the input parameters. To further customize the deployment, fork the GitHub repo and change the appropriate items.

Some common customization options include, but aren't limited to:

- Bastion VM size (variable in `azuredploy.json`)
- Naming conventions (variables in `azuredploy.json`)
- OpenShift cluster specifics, modified via hosts file (`deployOpenShift.sh`)
- RHEL image reference (variable in `azuredploy.json`)

For the steps to deploy using the Azure CLI, follow the appropriate section in the [OpenShift Container Platform](#) section or the [OKD](#) section.

## Deploy OpenShift 4.x On Azure Stack Hub

Red Hat manages the Red Hat Enterprise Linux CoreOS (RHCOS) image for OpenShift 4.x. The deployment process gets the image from a Red Hat endpoint. As a result, the user (tenant) doesn't need to get an image from the Azure Stack hub Marketplace.

You can follow the steps in the OpenShift documentation at [Installing a cluster on Azure Stack Hub using ARM templates](#).

### WARNING

If you have an issue with OpenShift, please contact Red Hat for support.

## Next steps

- [Post-deployment tasks](#)
- [Troubleshoot OpenShift deployment in Azure](#)

# Post-deployment tasks

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

After you deploy an OpenShift cluster, you can configure additional items. This article covers:

- How to configure single sign-on by using Azure Active Directory (Azure AD)
- How to configure Azure Monitor logs to monitor OpenShift
- How to configure metrics and logging
- How to install Open Service Broker for Azure (OSBA)

## Configure single sign-on by using Azure Active Directory

To use Azure Active Directory for authentication, first you need to create an Azure AD app registration. This process involves two steps: creating the app registration, and configuring permissions.

### Create an app registration

These steps use the Azure CLI to create the app registration, and the GUI (portal) to set the permissions. To create the app registration, you need the following five pieces of information:

- Display name: App registration name (for example, OCPAzureAD)
- Home page: OpenShift console URL (for example,  
`https://masterdns343khde.westus.cloudapp.azure.com/console`)
- Identifier URI: OpenShift console URL (for example,  
`https://masterdns343khde.westus.cloudapp.azure.com/console`)
- Reply URL: Master public URL and the app registration name (for example,  
`https://masterdns343khde.westus.cloudapp.azure.com/oauth2callback/OCPAzureAD`)
- Password: Secure password (use a strong password)

The following example creates an app registration by using the preceding information:

```
az ad app create --display-name OCPAzureAD --homepage  
https://masterdns343khde.westus.cloudapp.azure.com/console --reply-urls  
https://masterdns343khde.westus.cloudapp.azure.com/oauth2callback/hwocpadint --identifier-uris  
https://masterdns343khde.westus.cloudapp.azure.com/console --password {Strong Password}
```

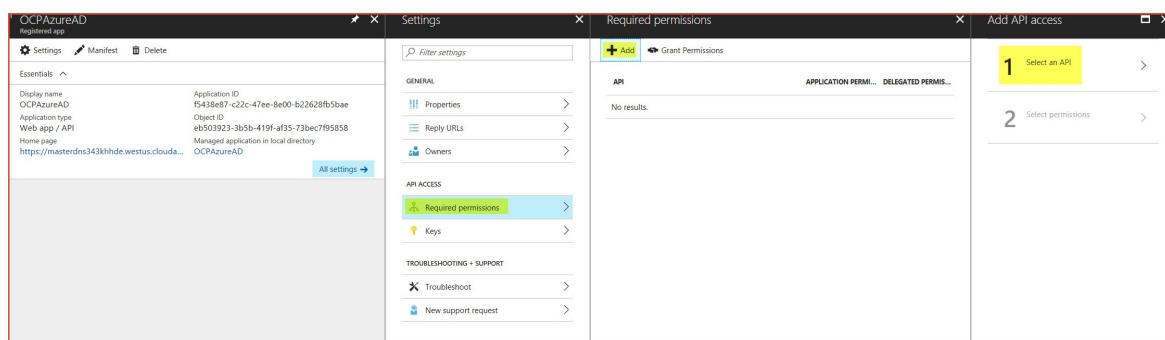

If the command is successful, you get a JSON output similar to:

```
{
  "appId": "12345678-ca3c-427b-9a04-ab12345cd678",
  "appPermissions": null,
  "availableToOtherTenants": false,
  "displayName": "OCPAzureAD",
  "homepage": "https://masterdns343khhde.westus.cloudapp.azure.com/console",
  "identifierUris": [
    "https://masterdns343khhde.westus.cloudapp.azure.com/console"
  ],
  "objectId": "62cd74c9-42bb-4b9f-b2b5-b6ee88991c80",
  "objectType": "Application",
  "replyUrls": [
    "https://masterdns343khhde.westus.cloudapp.azure.com/oauth2callback/OCPAzureAD"
  ]
}
```

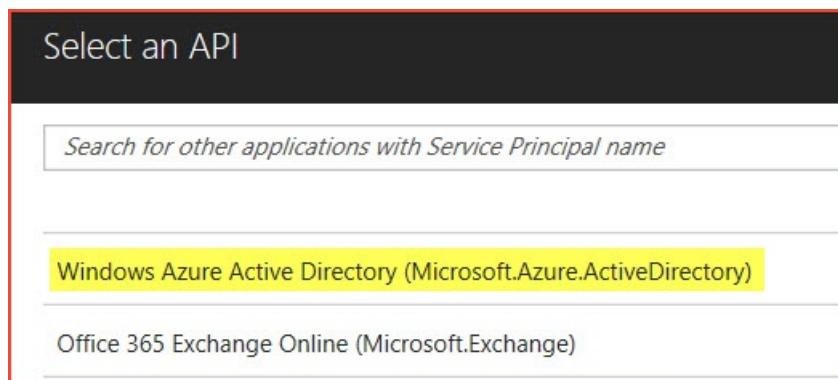

Take note of the appId property returned from the command for a later step.

In the Azure portal:

1. Select **Azure Active Directory > App Registration**.
2. Search for your app registration (for example, OCPAzureAD).
3. In the results, click the app registration.
4. Under **Settings**, select **Required permissions**.
5. Under **Required Permissions**, select **Add**.

6. Click Step 1: Select API, and then click **Windows Azure Active Directory (Microsoft.Azure.ActiveDirectory)**. Click **Select** at the bottom.

7. On Step 2: Select Permissions, select **Sign in and read user profile** under **Delegated Permissions**, and then click **Select**.

## Enable Access

□ X

APPLICATION PERMISSIONS	REQUIRES ADMIN
Read directory data	✓ Yes

8. Select Done.

### Configure OpenShift for Azure AD authentication

To configure OpenShift to use Azure AD as an authentication provider, the /etc/origin/master/master-config.yaml file must be edited on all master nodes.

Find the tenant ID by using the following CLI command:

```
az account show
```

In the yaml file, find the following lines:

```
oauthConfig:
  assetPublicURL: https://masterdns343khhde.westus.cloudapp.azure.com/console/
  grantConfig:
    method: auto
  identityProviders:
    - challenge: true
      login: true
      mappingMethod: claim
      name: htpasswd_auth
      provider:
        apiVersion: v1
        file: /etc/origin/master/htpasswd
        kind: HTPasswdPasswordIdentityProvider
```

Insert the following lines immediately after the preceding lines:

```
- name: <App Registration Name>
  challenge: false
  login: true
  mappingMethod: claim
  provider:
    apiVersion: v1
    kind: OpenIDIdentityProvider
    clientID: <appId>
    clientSecret: <Strong Password>
    claims:
      id:
      - sub
    preferredUsername:
      - unique_name
    name:
      - name
    email:
      - email
  urls:
    authorize: https://login.microsoftonline.com/<tenant Id>/oauth2/authorize
    token: https://login.microsoftonline.com/<tenant Id>/oauth2/token
```

Make sure the text aligns correctly under identityProviders. Find the tenant ID by using the following CLI command: `az account show`

Restart the OpenShift master services on all master nodes:

```
sudo /usr/local/bin/master-restart api
sudo /usr/local/bin/master-restart controllers
```

In the OpenShift console, you now see two options for authentication: htpasswd\_auth and [App Registration].

## Monitor OpenShift with Azure Monitor logs

There are three ways to add the Log Analytics agent to OpenShift.

- Install the Log Analytics agent for Linux directly on each OpenShift node
- Enable Azure Monitor VM Extension on each OpenShift node
- Install the Log Analytics agent as an OpenShift daemon-set

Read the full [instructions](#) for more details.

## Configure metrics and logging

Based on the branch, the Azure Resource Manager templates for OpenShift Container Platform and OKD may provide input parameters for enabling metrics and logging as part of the installation.

The OpenShift Container Platform Marketplace offer also provides an option to enable metrics and logging during cluster installation.

If metrics / logging wasn't enabled during the installation of the cluster, they can easily be enabled after the fact.

### Azure Cloud Provider in use

SSH to the bastion node or first master node (based on template and branch in use) using the credentials provided during deployment. Issue the following command:

```
ansible-playbook /usr/share/ansible/openshift-ansible/playbooks/openshift-metrics/config.yml \
-e openshift_metrics_install_metrics=True \
-e openshift_metrics_cassandra_storage_type=dynamic

ansible-playbook /usr/share/ansible/openshift-ansible/playbooks/openshift-logging/config.yml \
-e openshift_logging_install_logging=True \
-e openshift_logging_es_pvc_dynamic=true
```

### Azure Cloud Provider not in use

```
ansible-playbook /usr/share/ansible/openshift-ansible/playbooks/openshift-metrics/config.yml \
-e openshift_metrics_install_metrics=True

ansible-playbook /usr/share/ansible/openshift-ansible/playbooks/openshift-logging/config.yml \
-e openshift_logging_install_logging=True
```

## Install Open Service Broker for Azure (OSBA)

Open Service Broker for Azure, or OSBA, lets you provision Azure Cloud Services directly from OpenShift. OSBA in an Open Service Broker API implementation for Azure. The Open Service Broker API is a spec that defines a common language for cloud providers that cloud native applications can use to manage cloud services without lock-in.

To install OSBA on OpenShift, follow the instructions located here: <https://github.com/Azure/open-service-broker-azure#openshift-project-template>.

#### NOTE

Only complete the steps in the OpenShift Project Template section and not the entire Installing section.

## Next steps

- [Getting started with OpenShift Container Platform](#)

# Troubleshoot OpenShift Container Platform 3.11 deployment in Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

If the OpenShift cluster doesn't deploy successfully, the Azure portal will provide error output. The output may be difficult to read which makes it difficult to identify the problem. Quickly scan this output for exit code 3, 4 or 5. The following provides information on these three exit codes:

- Exit code 3: Your Red Hat Subscription User Name / Password or Organization ID / Activation Key is incorrect
- Exit code 4: Your Red Hat Pool ID is incorrect or there are no entitlements available
- Exit code 5: Unable to provision Docker Thin Pool Volume

For all other exit codes, connect to the host(s) via ssh to view the log files.

## OpenShift Container Platform 3.11

SSH to the ansible playbook host. For the template or the Marketplace offer, use the bastion host. From the bastion, you can SSH to all other nodes in the cluster (master, infra, CNS, compute). You'll need to be root to view the log files. Root is disabled for SSH access by default so don't use root to SSH to other nodes.

## OKD

SSH to the ansible playbook host. For the OKD template (version 3.9 and earlier), use the master-0 host. For the OKD template (version 3.10 and later), use the bastion host. From the ansible playbook host, you can SSH to all other nodes in the cluster (master, infra, CNS, compute). You'll need to be root (sudo su -) to view the log files. Root is disabled for SSH access by default so don't use root to SSH to other nodes.

## Log files

The log files (stderr and stdout) for the host preparation scripts are located in

`/var/lib/waagent/custom-script/download/0` on all hosts. If an error occurred during the preparation of the host, view these log files to determine the error.

If the preparation scripts ran successfully, then the log files in the `/var/lib/waagent/custom-script/download/1` directory of the ansible playbook host will need to be examined. If the error occurred during the actual installation of OpenShift, the stdout file will display the error. Use this information to contact Support for further assistance.

Example output

```

TASK [openshift_storage_glusterfs : Load heketi topology] ****

INSTALLER STATUS ****
Initialization          : Complete (0:00:39)
Health Check           : Complete (0:00:24)
etcd Install           : Complete (0:01:24)
Master Install          : Complete (0:14:59)
Master Additional Install: Complete (0:01:10)
Node Install            : Complete (0:10:58)
GlusterFS Install       : In Progress (0:03:33)
This phase can be restarted by running: playbooks/openshift-glusterfs/config.yml

Failure summary:

1. Hosts: mycluster-master-0
Play: Configure GlusterFS
Task: Load heketi topology
Message: Failed without returning a message.

```

The most common errors during installation are:

1. Private key has passphrase
2. Key vault secret with private key wasn't created correctly
3. Service principal credentials were entered incorrectly
4. Service principal doesn't have contributor access to the resource group

### Private Key has a passphrase

You'll see an error that permission was denied for ssh. ssh to the ansible playbook host to check for a passphrase on the private key.

### **Key vault secret with private key wasn't created correctly**

The private key is copied into the ansible playbook host - `~/.ssh/id_rsa`. Confirm this file is correct. Test by opening an SSH session to one of the cluster nodes from the ansible playbook host.

### **Service principal credentials were entered incorrectly**

When providing the input to the template or Marketplace offer, the incorrect information was provided. Make sure you use the correct appId (clientId) and password (clientSecret) for the service principal. Verify by issuing the following azure cli command.

```
az login --service-principal -u <client id> -p <client secret> -t <tenant id>
```

### **Service principal doesn't have contributor access to the resource group**

If the Azure cloud provider is enabled, then the service principal used must have contributor access to the resource group. Verify by issuing the following azure cli command.

```
az group update -g <openshift resource group> --set tags.sptest=test
```

## Additional tools

For some errors, you can also use the following commands to get more information:

1. `systemctl status <service>`
2. `journalctl -xe`

# Deploy OKD in Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You can use one of two ways to deploy OKD (formerly OpenShift Origin) in Azure:

- You can manually deploy all the necessary Azure infrastructure components, and then follow the [OKD documentation](#).
- You can also use an existing [Resource Manager template](#) that simplifies the deployment of the OKD cluster.

## Deploy using the OKD template

To deploy using the Resource Manager template, you use a parameters file to supply the input parameters. To further customize the deployment, fork the GitHub repo and change the appropriate items.

Some common customization options include, but aren't limited to:

- Bastion VM size (variable in azuredeploy.json)
- Naming conventions (variables in azuredeploy.json)
- OpenShift cluster specifics, modified via hosts file (deployOpenShift.sh)

The [OKD template](#) has multiple branches available for different versions of OKD. Based on your needs, you can deploy directly from the repo or you can fork the repo and make custom changes before deploying.

Use the `appId` value from the service principal that you created earlier for the `aadClientId` parameter.

The following is an example of a parameters file named `azuredeploy.parameters.json` with all the required inputs.

```
{
  "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentParameters.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
    "masterVmSize": {
      "value": "Standard_E2s_v3"
    },
    "infraVmSize": {
      "value": "Standard_E2s_v3"
    },
    "nodeVmSize": {
      "value": "Standard_E2s_v3"
    },
    "storageKind": {
      "value": "managed"
    },
    "openshiftClusterPrefix": {
      "value": "mycluster"
    },
    "masterInstanceCount": {
      "value": 3
    },
    "infraInstanceCount": {
      "value": 2
    },
    "nodeInstanceCount": {
      "value": 2
    }
  }
}
```

```
"dataDiskSize": {
    "value": 128
},
"adminUsername": {
    "value": "clusteradmin"
},
"openshiftPassword": {
    "value": "{Strong Password}"
},
"sshPublicKey": {
    "value": "{SSH Public Key}"
},
"enableMetrics": {
    "value": "true"
},
"enableLogging": {
    "value": "false"
},
"keyVaultResourceGroup": {
    "value": "keyvaultrg"
},
"keyVaultName": {
    "value": "keyvault"
},
"keyVaultSecret": {
    "value": "keysecret"
},
"enableAzure": {
    "value": "true"
},
"aadClientId": {
    "value": "11111111-abcd-1234-efgh-111111111111"
},
"aadClientSecret": {
    "value": "{Strong Password}"
},
"defaultSubDomainType": {
    "value": "nipro"
}
}
```

Replace the parameters with your specific information.

Different releases may have different parameters so please verify the necessary parameters for the branch you use.

## Deploy using Azure CLI

### NOTE

The following command requires Azure CLI 2.0.8 or later. You can verify the CLI version with the `az --version` command. To update the CLI version, see [Install Azure CLI](#).

The following example deploys the OKD cluster and all related resources into a resource group named openshiftrg, with a deployment name of myOpenShiftCluster. The template is referenced directly from the GitHub repo while using a local parameters file named azuredeploy.parameters.json.

```
az deployment group create -g openshiftrg --name myOpenShiftCluster \
    --template-uri https://raw.githubusercontent.com/Microsoft/openshift-origin/master/azuredeploy.json \
    --parameters ./azuredeploy.parameters.json
```

The deployment takes at least 30 minutes to finish, based on the total number of nodes deployed. The URL of

the OpenShift console and the DNS name of the OpenShift master prints to the terminal when the deployment finishes. Alternatively, you can view the outputs section of the deployment from the Azure portal.

```
{  
  "OpenShift Console Url": "http://openshiftlb.cloudapp.azure.com/console",  
  "OpenShift Master SSH": "ssh -p 2200 clusteradmin@myopenshiftmaster.cloudapp.azure.com"  
}
```

If you don't want to tie up the command line waiting for the deployment to complete, add `--no-wait` as one of the options for the group deployment. The output from the deployment can be retrieved from the Azure portal in the deployment section for the resource group.

## Connect to the OKD cluster

When the deployment finishes, connect to the OpenShift console with your browser using the `OpenShift Console Url`. Alternatively, you can SSH to the OKD master. Following is an example that uses the output from the deployment:

```
$ ssh -p 2200 clusteradmin@myopenshiftmaster.cloudapp.azure.com
```

## Clean up resources

Use the `az group delete` command to remove the resource group, OpenShift cluster, and all related resources when they're no longer needed.

```
az group delete --name openshiftrg
```

# Use Azure to host and run SAP workload scenarios

9/21/2022 • 28 minutes to read • [Edit Online](#)

When you use Microsoft Azure, you can reliably run your mission-critical SAP workloads and scenarios on a scalable, compliant, and enterprise-proven platform. You get the scalability, flexibility, and cost savings of Azure. With the expanded partnership between Microsoft and SAP, you can run SAP applications across development and test and production scenarios in Azure and be fully supported. From SAP NetWeaver to SAP S/4HANA, SAP BI on Linux to Windows, and SAP HANA to SQL Server, Oracle, Db2, etc, we've got you covered.

Besides hosting SAP NetWeaver and S/4HANA scenarios with the different DBMS on Azure, you can host other SAP workload scenarios, like SAP BI on Azure.

We just announced our new services of Azure Center for SAP solutions and Azure Monitor for SAP 2.0 entering the public preview stage. These services will give you the possibility to deploy SAP workload on Azure in a highly automated manner in an optimal architecture and configuration. And monitor your Azure infrastructure, OS, DBMS, and ABAP stack deployments on one single pane of glass.

For customers and partners who are focussed on deploying and operating their assets in public cloud through Terraform and Ansible, leverage our SAP Deployment Automation Framework (SDAF) to jump start your SAP deployments into Azure using our public Terraform and Ansible modules on [github](#).

Hosting SAP workload scenarios in Azure also can create requirements of identity integration and single sign-on. This situation can occur when you use Azure Active Directory (Azure AD) to connect different SAP components and SAP software-as-a-service (SaaS) or platform-as-a-service (PaaS) offers. A list of such integration and single sign-on scenarios with Azure AD and SAP entities is described and documented in the section "Azure AD SAP identity integration and single sign-on."

## Changes to the SAP workload section

Changes to documents in the SAP on Azure workload section are listed at the [end of this article](#). The entries in the change log are kept for around 180 days.

## You want to know

If you have specific questions, we are going to point you to specific documents or flows in this section of the start page. You want to know:

- What Azure VMs and HANA Large Instance units are supported for which SAP software releases and which operating system versions. Read the document [What SAP software is supported for Azure deployment](#) for answers and the process to find the information
- What SAP deployment scenarios are supported with Azure VMs and HANA Large Instances. Information about the supported scenarios can be found in the documents:
  - [SAP workload on Azure virtual machine supported scenarios](#)
  - [Supported scenarios for HANA Large Instance](#)
- What Azure Services, Azure VM types and Azure storage services are available in the different Azure regions, check the site [Products available by region](#)
- Are third-party HA frameworks, besides Windows and Pacemaker supported? Check bottom part of [SAP support note #1928533](#)
- What Azure storage is best for my scenario? Read [Azure Storage types for SAP workload](#)
- Is the Red Hat kernel in Oracle Enterprise Linux supported by SAP? Read SAP [SAP support note #1565179](#)

- Why are the Azure [Da\(s\)v4/Ea\(s\)](#) VM families not certified for SAP HANA? The Azure Das/Eas VM families are based on AMD processor-driven hardware. SAP HANA does not support AMD processors, not even in virtualized scenarios
- Why am I still getting the message: 'The cpu flags for the RDTSCP instruction or the cpu flags for constant\_tsc or nonstop\_tsc are not set or current\_clocksource and available\_clocksource are not correctly configured' with SAP HANA, despite the fact that I am running the most recent Linux kernels. For the answer, check [SAP support note #2791572](#)
- Where can I find architectures for deploying SAP Fiori on Azure? Check out the blog [SAP on Azure: Application Gateway Web Application Firewall \(WAF\) v2 Setup for Internet facing SAP Fiori Apps](#)

## Documentation space

In the SAP workload documentation space, you can find the following areas:

- **SAP on Azure Large Instances:** This documentation section is covering a bare-metal service that originally was named HANA Large Instances. Different topics around this technology are covered in this section
- **Plan and Deploy (Azure VMs):** Deploying SAP workload into Azure Infrastructure as a Service, you should go through the documents in this section first to learn more about the principle Azure components used and guidelines
- **Storage (Azure VMs):** This section includes documents that give recommendations how to use the different Azure storage types when deploying SAP workload on Azure
- **DBMS Guides (Azure VMs):** The section DBMS Guides covers specifics around deploying different DBMS that are supported for SAP workload in Azure IaaS
- **High Availability (Azure VMs):** In this section, many of the high availability configurations around SAP workload on Azure is covered. This section includes detailed documentation around deploying Windows clustering and Pacemaker cluster configuration for the different SAP components and different database systems
- **Automation Framework (Azure VMs):** Automation Framework documentation is covering an a [Terraform and Ansible based automation framework](#) that allows automation of Azure infrastructure and SAP software
- **Azure Monitor for SAP solutions:** Microsoft developed monitoring solutions specifically for SAP supported OS and DBMS, as well as S/4HANA and NetWeaver. This section documents the deployment and usage of the service
- **Integration with Microsoft Services and References** contain different links to integration between SAP and other Microsoft services. The list may not be complete.

## Change Log

- September 14, 2022 Release of updated SAP on Oracle guide with new and updated content [Azure Virtual Machines Oracle DBMS deployment for SAP workload](#)
- September 8, 2022: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES](#) to add instructions for deploying /hana/shared (only) on NFS on Azure Files
- September 6, 2022: Add managed identity for pacemaker fence agent [Set up Pacemaker on SUSE Linux Enterprise Server \(SLES\) in Azure](#) on SLES and [Setting up Pacemaker on RHEL in Azure](#) RHEL
- August 22, 2022: Release of cost optimization scenario [Deploy PAS and AAS with SAP NetWeaver HA cluster on RHEL](#)
- August 09, 2022: Release of scenario [HA for SAP ASCS/ERS with NFS simple mount](#) on SLES 15 for SAP Applications
- July 18, 2022: Clarify statement around Pacemaker support on Oracle Linux in [Azure Virtual Machines Oracle DBMS deployment for SAP workload](#)
- June 29, 2022: Add recommendation and links to Pacemaker usage for Db2 versions 11.5.6 and higher in the documents [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#), [High availability of IBM](#)

[Db2 LUW on Azure VMs on SUSE Linux Enterprise Server with Pacemaker](#), and [High availability of IBM Db2 LUW on Azure VMs on Red Hat Enterprise Linux Server](#)

- June 08, 2022: Change in [HA for SAP NW on Azure VMs on SLES with ANF](#) and [HA for SAP NW on Azure VMs on RHEL with ANF](#) to adjust timeouts when using NFSv4.1 (related to NFSv4.1 lease renewal) for more resilient Pacemaker configuration
- June 02, 2022: Change in the [SAP Deployment Guide](#) to add a link to RHEL in-place upgrade documentation
- June 02, 2022: Change in [HA for SAP NetWeaver on Azure VMs on Windows with Azure NetApp Files\(SMB\)](#), [HA for SAP NW on Azure VMs on SLES with ANF](#) and [HA for SAP NW on Azure VMs on RHEL with ANF](#) to add sizing considerations
- May 11, 2022: Change in [Cluster an SAP ASCS/SCS instance on a Windows failover cluster by using a cluster shared disk in Azure](#), [Prepare the Azure infrastructure for SAP HA by using a Windows failover cluster and shared disk for SAP ASCS/SCS](#) and [SAP ASCS/SCS instance multi-SID high availability with Windows server failover clustering and Azure shared disk](#) to update instruction about the usage of Azure shared disk for SAP deployment with PPG.
- May 10, 2022: Change in [HA for SAP HANA scale-up with ANF on RHEL](#), [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#), [HA for SAP HANA Scale-up with Azure NetApp Files on SLES](#), [SAP HANA scale-out with standby node on Azure VMs with ANF on SLES](#), [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES](#) and [SAP HANA scale-out with standby node on Azure VMs with ANF on RHEL](#) to adjust parameters per SAP note 3024346
- April 26, 2022: Changes in [Setting up Pacemaker on SUSE Linux Enterprise Server in Azure](#) to add Azure Identity Python module to installation instructions for Azure Fence Agent
- March 30, 2022: Adding information that Red Hat Gluster Storage is being phased out [GlusterFS on Azure VMs on RHEL](#)
- March 30, 2022: Correcting DNN support for older releases of SQL Server in [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#)
- March 28, 2022: Formatting changes and reorganizing ILB configuration instructions in: [HA for SAP HANA on Azure VMs on SLES](#), [HA for SAP HANA Scale-up with Azure NetApp Files on SLES](#), [HA for SAP HANA on Azure VMs on RHEL](#), [HA for SAP HANA scale-up with ANF on RHEL](#), [HA for SAP NW on SLES with NFS on Azure Files](#), [HA for SAP NW on Azure VMs on SLES with ANF](#), [HA for SAP NW on Azure VMs on SLES for SAP applications](#), [HA for NFS on Azure VMs on SLES](#), [HA for SAP NNW on Azure VMs on SLES multi-SID guide](#), [HA for SAP NW on RHEL with NFS on Azure Files](#), [HA for SAP NW on Azure VMs on RHEL with ANF](#), [HA for SAP NW on Azure VMs on RHEL for SAP applications](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#)
- March 15, 2022: Corrected rsize and wsize mount option settings for ANF in [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#)
- March 1, 2022: Corrected note about database snapshots with multiple database containers in [SAP HANA Large Instances high availability and disaster recovery on Azure](#)
- February 28, 2022: Added E(d)sv5 VM storage configurations to [SAP HANA Azure virtual machine storage configurations](#)
- February 13, 2022: Corrected broken links to HANA hardware directory in the following documents: SAP Business One on Azure Virtual Machines, Available SKUs for HANA Large Instances, Certification of SAP HANA on Azure (Large Instances), Installation of SAP HANA on Azure virtual machines, SAP workload planning and deployment checklist, SAP HANA infrastructure configurations and operations on Azure, SAP HANA on Azure Large Instance migration to Azure Virtual Machines, Install and configure SAP HANA (Large Instances) ,on Azure, High availability of SAP HANA scale-out system on Red Hat Enterprise Linux, High availability for SAP HANA scale-out system with HSR on SUSE Linux Enterprise Server, High availability of SAP HANA on Azure VMs on SUSE Linux Enterprise Server, Deploy a SAP HANA scale-out system with standby node on Azure VMs by using Azure NetApp Files on SUSE Linux Enterprise Server, SAP workload on Azure virtual machine supported scenarios, What SAP software is supported for Azure deployments
- February 13, 2022: Change in [HA for SAP NetWeaver on Azure VMs on Windows with Azure NetApp](#)

[Files\(SMB\)](#) to add instructions about adding the SAP installation user as [Administrators Privilege user](#) to avoid SWPM permission errors

- February 09, 2022: Add more information around 4K sectors usage of Db2 11.5 in [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#)
- February 08, 2022: Style changes in [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#)
- February 07, 2022: Adding new functionality [ANF application volume groups for HANA](#) in documents [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#) and [Azure proximity placement groups for optimal network latency with SAP applications](#)
- January 30, 2022: Adding context about SQL Server proportional fill and expectations that SQL Server data files should be the same size and should have the same free space in [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#)
- January 24, 2022: Change in [HA for SAP NW on SLES with NFS on Azure Files](#), [HA for SAP NW on Azure VMs on SLES with ANF](#), [HA for SAP NW on Azure VMs on SLES for SAP applications](#), [HA for NFS on Azure VMs on SLES](#), [HA for SAP NNW on Azure VMs on SLES multi-SID guide](#), [HA for SAP NW on RHEL with NFS on Azure Files](#), [HA for SAP NW on Azure VMs on RHEL for SAP applications](#) and [HA for SAP NW on Azure VMs on RHEL with ANF](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#) to remove cidr\_netmask from Pacemaker configuration to allow the resource agent to determine the value automatically.
- January 12, 2022: Change in [HA for SAP NetWeaver on Azure VMs on Windows with Azure NetApp Files\(SMB\)](#) to remove obsolete information for the SAP kernel that supports the scenario.
- December 08, 2021: Change in [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#) to clarify Azure Load Balancer settings.
- December 08, 2021: Release of scenario [HA of SAP HANA Scale-up with Azure NetApp Files on SLES](#)
- December 07, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) to clarify that the instructions are applicable for both RHEL 7 and RHEL 8
- December 07, 2021: Change in [HA for SAP NW on SLES with NFS on Azure Files](#), [HA for SAP NW on Azure VMs on SLES with ANF](#) and [HA for SAP NW on Azure VMs on SLES for SAP applications](#) to adjust the instructions for configuring SWAP file.
- December 02, 2021: Introduction of new fencing method in [Setting up Pacemaker on SUSE Linux Enterprise Server in Azure](#) using Azure shared disk SBD device
- December 01, 2021: Change in [SAP ASCS/SCS instance with WSFC and file share](#), [HA for SAP NetWeaver on Azure VMs on Windows with Azure NetApp Files\(SMB\)](#) and [HA for SAP NetWeaver on Azure VMs on Windows with Azure Files\(SMB\)](#) to update the SAP kernel version, required to support clustering SAP on Windows with file share
- November 30, 2021: Added [Using Windows DFS-N to support flexible SAPMNT share creation for SMB-based file share](#)
- November 22, 2021: Change in [HA for SAP NW on SLES with NFS on Azure Files](#) and [HA for SAP NW on RHEL with NFS on Azure Files](#) to clarify the guidelines for J2EE SAP systems and share consolidations per storage account.
- November 16, 2021: Release of high availability guides for SAP ASCS/ERS with NFS on Azure files [HA for SAP NW on SLES with NFS on Azure Files](#) and [HA for SAP NW on RHEL with NFS on Azure Files](#)
- November 15, 2021: Introduction of new proximity placement architecture for zonal deployments in [Azure proximity placement groups for optimal network latency with SAP applications](#)
- November 02, 2021: Changed [Azure Storage types for SAP workload](#) and [SAP ASE Azure Virtual Machines DBMS deployment for SAP workload](#) to declare SAP ASE support for NFS on Azure NetApp Files.
- November 02, 2021: Changed [SAP workload configurations with Azure Availability Zones](#) to move Singapore SouthEast to regions for active/active configurations
- November 02, 2021: Change in [High availability of SAP HANA on Azure VMs on Red Hat Enterprise Linux](#) to update instructions for HANA scale-up Active/Active (Read Enabled) configuration.

- October 26, 2021: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) to update resource names in HANA scale-out Active/Active (Read Enabled) configuration
- October 19, 2021: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) to add instructions for HANA scale-out Active/Active (Read Enabled) configuration
- October 11, 2021: Change in [Cluster an SAP ASCS/SCS instance on a Windows failover cluster by using a cluster shared disk in Azure](#), [Prepare the Azure infrastructure for SAP HA by using a Windows failover cluster and shared disk for SAP ASCS/SCS](#) and [SAP ASCS/SCS instance multi-SID high availability with Windows server failover clustering and Azure shared disk](#) to add instructions about zone redundant storage (ZRS) for Azure shared disk support
- October 08, 2021: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES](#), [HA for SAP HANA scale-up with ANF on RHEL](#) and [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) to add defaults in sudoers file and update for HANA scale-out(for HANA srHook)
- October 01, 2021: Added link to new Azure Backup architecture for SAP HANA backup document into table of content. Added link to Azure Backup service for Oracle DBMS into [Azure Virtual Machines Oracle DBMS deployment for SAP workload](#)
- September 24, 2021: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES](#), [HA for SAP HANA scale-up with ANF on RHEL](#) and [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) to adjust the instructions for creating sudoers file (for HANA srHook)
- September 16, 2021: Release of [HA for SAP NetWeaver on Azure VMs on Windows with Azure Files\(SMB\)](#)
- September 15, 2021: Introducing new HADR configuration for SAP ASE in [SAP ASE Azure Virtual Machines DBMS deployment for SAP workload](#)
- September 08, 2021: Adding manual QoS capacity pool into [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#)
- August 26, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) and [Setting up Pacemaker on SLES in Azure](#) to correct the role definition JSON for Azure Fence Agent
- August 17, 2021: Changes in [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#), [Azure Storage types for SAP workload](#), and [SAP workload on Azure virtual machine supported scenarios](#) to introduce support for IBM Db2 using NFS volumes hosted on ANF
- August 02, 2021: Change in [HA for SAP NW on Azure VMs on SLES for SAP applications](#), [HA for SAP NW on Azure VMs on SLES with ANF](#), [HA for SAP NW on Azure VMs on RHEL for SAP applications](#) and [HA for SAP NW on Azure VMs on RHEL with ANF](#) to clarify the behavior (ENSA1/ENSA2) for a test scenario, simulating enqueue server failure
- August 11, 2021: Change in [HA for SAP NW on Azure VMs on RHEL for SAP applications](#), [HA for SAP NW on Azure VMs on RHEL with ANF](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#) to adjust cluster resources stickiness, migration thresholds and order constraints
- August 11, 2021: Release of [SAP BW-Near Line Storage \(NLS\) implementation guide with SAP IQ on Azure](#)
- July 29, 2021: Introduce combined two-node Windows cluster for ASCS/SCS and DBMS in [High availability for SAP NetWeaver on Azure VMs on Windows with Azure NetApp Files\(SMB\) for SAP applications](#) and [Cluster an SAP ASCS/SCS instance on a Windows failover cluster by using a cluster shared disk in Azure](#)
- July 26, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) and [Setting up Pacemaker on SLES in Azure](#) to replace role assignment instructions with links to the RBAC documentation in the sections describing the set up for Azure Fence Agent
- July 22, 2021: Change in [HA for SAP NW on Azure VMs on RHEL for SAP applications](#), [HA for SAP NW on Azure VMs on RHEL with ANF](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#) to remove `failure-timeout` for the ASCS cluster resource (ENSA2 only)
- July 16, 2021: Restructuring of the SAP on Azure documentation Table of contents(TOC) for more streamlined navigation
- July 2, 2021: Change in [Backup and restore of SAP HANA on HANA Large Instances](#) to remove duplicate content for azacsnap tool and backup and restore of HANA Large Instances
- July 2, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) to add information how to avoid fence race

in two node Pacemaker cluster and a link to KB, explaining how to reduce failover delays when using optional fencing configuration with `fence_kdump`

- July 1, 2021: Adding new certified HANA Large Instances SKUs in [Available SKUs for HLI](#)
- June 30, 2021: Change in [HA guide for SAP ASCS/SCS with WSFC and Azure NetApp Files\(SMB\)](#) to add a section for recommended SAP profile parameters
- June 29, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) to add optional fencing configuration with `fence_kdump`
- June 28, 2021: Change in [HA guide for SAP ASCS/SCS with WSFC and Azure NetApp Files\(SMB\)](#) to add a statement that the SMB Server (Computer Account) Prefix should be no longer than 8 characters to avoid running into SAP hostname length limitation
- June 17, 2020: Change in [High availability of SAP HANA on Azure VMs on RHEL](#) to remove meta keyword from HANA resource creation command (RHEL 8.x)
- June 09, 2021: Correct VM SKU names for M192---\_v2 in [SAP HANA Azure virtual machine storage configurations](#)
- May 26, 2021: Change in [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES, HA for SAP HANA scale-up with ANF on RHEL](#) and [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) to add configuration to prepare the OS for running HANA on ANF
- May 13, 2021: Change in [Setting up Pacemaker on SLES in Azure](#) to clarify how resource agent `azure-events` operates
- April 30, 2021: Change in [Setting up Pacemaker on SLES in Azure](#) to include warning about incompatible change with Azure Fence Agent in a version of package `python3-azure-mgmt-compute` (SLES 15)
- April 27, 2021: Change in [SAP ASCS/SCS instance with WSFC and file share](#) to add links to important SAP notes in the prerequisites section
- April 27, 2021: Added new Msv2, Mdsv2 VMs into HANA storage configuration in [SAP HANA Azure virtual machine storage configurations](#)
- April 27, 2021: Added requirement for using same storage types in HANA System Replication across all VMs of HSR configuration in [SAP HANA Azure virtual machine storage configurations](#)
- April 27, 2021: Added requirement for using same storage types in DBMS replication scenarios across all VMs of DBMS high availability replication configurations in [Azure Storage types for SAP workload](#)
- April 23, 2021: Added section to configure private link for Azure database for MySQL and some minor changes in [SAP BusinessObjects BI platform deployment guide for linux on Azure](#)
- April 22, 2021: Release of SAP BusinessObjects BI Platform for Windows on Azure documentation, [SAP BusinessObjects BI platform deployment guide for Windows on Azure](#)
- April 21, 2021: Add explanation why HCMT/HWCCT storage tests on M32ts and M32ls might fall short of HANA KPIs when enabling read cache for the Premium storage disks in article [SAP HANA Azure virtual machine storage configurations](#)
- April 20, 2021: Clarify storage block sizes for IBM Db2 with different Azure block storage in article [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#)
- April 12, 2021: Change in [HA for SAP HANA on Azure VMs on SLES, HA for SAP HANA on Azure VMs on RHEL](#) and [HA for SAP HANA scale-up with ANF on RHEL](#) to add configuration instructions for SAP HANA system replication Python hook
- April 12, 2021: Replaced backup documentation for SAP HANA by documents of [SAP HANA backup/restore with Azure Backup service](#)
- April 12, 2021: Release of [SAP HANA scale-out HSR with Pacemaker on Azure VMs on SLES](#) configuration guide
- April 07, 2021: Clarified support for SQL Server multi-instance and multi-database support in [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#)
- April 07, 2021: Added information related to secondary IP addresses in [Azure Virtual Machines planning and implementation for SAP NetWeaver](#)

- April 07, 2021: added support for Oracle DBMS support on ANF in [Azure Storage types for SAP workload](#)
- March 17, 2021: Change in [HA for SAP HANA on Azure VMs on SLES](#), [HA for SAP HANA on Azure VMs on RHEL](#) and [HA for SAP HANA scale-up with ANF on RHEL](#) to add instructions for HANA Active/Read-enabled system replication in Pacemaker cluster
- March 15, 2021: Change in [SAP ASCS/SCS instance with WSFC and file share](#),[Install SAP ASCS/SCS instance with WSFC and file share](#) and [SAP ASCS/SCS multi-SID with WSFC and file share](#) to clarify that the SAP ASCS/SCS instances and the SOFS share must be deployed in separate clusters
- March 03, 2021: Change in [HA guide for SAP ASCS/SCS with WSFC and Azure NetApp Files\(SMB\)](#) to add a cautionary statement that elevated privileges are required for the user running SWPM, during the installation of the SAP system
- February 11, 2021: Changes in [High availability of IBM Db2 LUW on Azure VMs on Red Hat Enterprise Linux Server](#) to amend pacemaker cluster commands for RHEL 8.x
- February 03, 2021: Change in [Setting up Pacemaker on RHEL in Azure](#) to update pcmk\_host\_map in the `stonith create` command
- February 03, 2021: Change in [Setting up Pacemaker on SLES in Azure](#) to add pcmk\_host\_map in the `stonith create` command
- February 03, 2021: More details on I/O scheduler settings for SUSE in article [SAP HANA Azure virtual machine storage configurations](#)
- February 01, 2021: Change in [HA for SAP HANA scale-up with ANF on RHEL](#), [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#), [SAP HANA scale-out with standby node on Azure VMs with ANF on SLES](#) and [SAP HANA scale-out with standby node on Azure VMs with ANF on RHEL](#) to add a link to [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#)
- January 23, 2021: Introduce the functionality of HANA data volume partitioning as functionality to stripe I/O operations against HANA data files across different Azure disks or NFS shares without using a disk volume manager in articles [SAP HANA Azure virtual machine storage configurations](#) and [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#)
- January 18, 2021: Added support of Azure net Apps Files based NFS for Oracle in [Azure Virtual Machines Oracle DBMS deployment for SAP workload](#) and adjusting decimals in table in document [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#)
- January 11, 2021: Minor changes in [HA for SAP NW on Azure VMs on RHEL for SAP applications](#), [HA for SAP NW on Azure VMs on RHEL with ANF](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#) to adjust commands to work for both RHEL8 and RHEL7, and ENSA1 and ENSA2
- January 05, 2021: Changes in [SAP HANA scale-out with standby node on Azure VMs with ANF on SLES](#) and [SAP HANA scale-out with standby node on Azure VMs with ANF on RHEL](#), revising the recommended configuration to allow SAP Host Agent to manage the local port range
- January 04, 2021: Add new Azure regions supported by HLI into [What is SAP HANA on Azure \(Large Instances\)](#)
- December 29, 2020: Add architecture recommendations for specific Azure regions in [SAP workload configurations with Azure Availability Zones](#)
- December 21, 2020: Add new certifications to SKUs of HANA Large Instances in [Available SKUs for HLI](#)
- December 12, 2020: Added pointer to SAP note clarifying details on Oracle Enterprise Linux support by SAP to [What SAP software is supported for Azure deployments](#)
- November 26, 2020: Adapt [SAP HANA Azure virtual machine storage configurations](#) and [Azure Storage types for SAP workload](#) to changed single VM SLAs
- November 05, 2020: Changing link to new SAP note about HANA supported file system types in [SAP HANA Azure virtual machine storage configurations](#)
- October 26, 2020: Changing some tables for Azure premium storage configuration to clarify provisioned versus burst throughput in [SAP HANA Azure virtual machine storage configurations](#)
- October 22, 2020: Change in [HA for SAP NW on Azure VMs on SLES for SAP applications](#), [HA for SAP NW on](#)

Azure VMs on SLES with ANF, HA for SAP NW on Azure VMs on RHEL for SAP applications and HA for SAP NW on Azure VMs on RHEL with ANF to adjust the recommendation for net.ipv4.tcp\_keepalive\_time

- October 16, 2020: Change in HA of IBM Db2 LUW on Azure VMs on SLES with Pacemaker, HA for SAP NW on Azure VMs on RHEL for SAP applications, HA of IBM Db2 LUW on Azure VMs on RHEL, HA for SAP NW on Azure VMs on RHEL multi-SID guide, HA for SAP NW on Azure VMs on RHEL with ANF, HA for SAP NW on Azure VMs on SLES for SAP applications, HA for SAP NNW on Azure VMs on SLES multi-SID guide, HA for SAP NW on Azure VMs on SLES with ANF for SAP applications, HA for NFS on Azure VMs on SLES, HA of SAP HANA on Azure VMs on SLES, HA for SAP HANA scale-up with ANF on RHEL, HA of SAP HANA on Azure VMs on RHEL, SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL, Prepare Azure infrastructure for SAP ASCS/SCS with WSFC and shared disk, multi-SID HA guide for SAP ASCS/SCS with WSFC and Azure shared disk and multi-SID HA guide for SAP ASCS/SCS with WSFC and shared disk to add a statement that floating IP is not supported in load-balancing scenarios on secondary IPs
- October 16, 2020: Adding documentation to control storage snapshots of HANA Large Instances in [Backup and restore of SAP HANA on HANA Large Instances](#)
- October 15, 2020: Release of SAP BusinessObjects BI Platform on Azure documentation, [SAP BusinessObjects BI platform planning and implementation guide on Azure](#) and [SAP BusinessObjects BI platform deployment guide for linux on Azure](#)
- October 05, 2020: Release of [SAP HANA scale-out HSR with Pacemaker on Azure VMs on RHEL](#) configuration guide
- September 30, 2020: Change in [High availability of SAP HANA on Azure VMs on RHEL](#), [HA for SAP HANA scale-up with ANF on RHEL](#) and [Setting up Pacemaker on RHEL in Azure](#) to adapt the instructions for RHEL 8.1
- September 29, 2020: Making restrictions and recommendations around usage of PPG more obvious in the article [Azure proximity placement groups for optimal network latency with SAP applications](#)
- September 28, 2020: Adding a new storage operation guide for SAP HANA using Azure NetApp Files with the document [NFS v4.1 volumes on Azure NetApp Files for SAP HANA](#)
- September 23, 2020: Add new certified SKUs for HLI in [Available SKUs for HLI](#)
- September 20, 2020: Changes in documents [Considerations for Azure Virtual Machines DBMS deployment for SAP workload](#), [SQL Server Azure Virtual Machines DBMS deployment for SAP NetWeaver](#), [Azure Virtual Machines Oracle DBMS deployment for SAP workload](#), [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#) to adapt to new configuration suggestion that recommends separation of DBMS binaries and SAP binaries into different Azure disks. Also adding Ultra disk recommendations to the different guides.
- September 08, 2020: Change in [High availability of SAP HANA on Azure VMs on SLES](#) to clarify fencing definitions
- September 03, 2020: Change in [SAP HANA Azure virtual machine storage configurations](#) to adapt to minimal 2 IOPS per 1 GB capacity with Ultra disk
- September 02, 2020: Change in [Available SKUs for HLI](#) to get more transparent in what SKUs are HANA certified
- August 25, 2020: Change in [HA for SAP NW on Azure VMs on SLES with ANF](#) to fix typo
- August 25, 2020: Change in [HA guide for SAP ASCS/SCS with WSFC and shared disk](#), [Prepare Azure infrastructure for SAP ASCS/SCS with WSFC and shared disk](#) and [Install SAP NW HA with WSFC and shared disk](#) to introduce the option of using Azure shared disk and document SAP ERS2 architecture
- August 25, 2020: Release of [multi-SID HA guide for SAP ASCS/SCS with WSFC and Azure shared disk](#)
- August 25, 2020: Change in [HA guide for SAP ASCS/SCS with WSFC and Azure NetApp Files\(SMB\)](#), [Prepare Azure infrastructure for SAP ASCS/SCS with WSFC and file share](#), [multi-SID HA guide for SAP ASCS/SCS with WSFC and shared disk](#) and [multi-SID HA guide for SAP ASCS/SCS with WSFC and SOFS file share](#) as a result of the content updates and restructuring in the HA guides for SAP ASCS/SCS with WFC and shared disk
- August 21, 2020: Adding new OS release into [Compatible Operating Systems for HANA Large Instances](#) as available operating system for HLI units of type I and II

- August 18, 2020: Release of [HA for SAP HANA scale-up with ANF on RHEL](#)
- August 17, 2020: Add information about using Azure Site Recovery for moving SAP NetWeaver systems from on-premises to Azure in article [Azure Virtual Machines planning and implementation for SAP NetWeaver](#)
- 08/14/2020: Adding disk configuration advice for Db2 in article [IBM Db2 Azure Virtual Machines DBMS deployment for SAP workload](#)
- August 11, 2020: Adding RHEL 7.6 into [Compatible Operating Systems for HANA Large Instances](#) as available operating system for HLI units of type I
- August 10, 2020: Introducing cost conscious SAP HANA storage configuration in [SAP HANA Azure virtual machine storage configurations](#) and making some updates to [SAP workloads on Azure: planning and deployment checklist](#)
- August 04, 2020: Change in [Setting up Pacemaker on SLES in Azure](#) and [Setting up Pacemaker on RHEL in Azure](#) to emphasize the importance of reliable name resolution for Pacemaker clusters
- August 04, 2020: Change in [SAP NW HA on WFCs with file share](#), [SAP NW HA on WFCs with shared disk](#), [HA for SAP NW on Azure VMs](#), [HA for SAP NW on Azure VMs on SLES](#), [HA for SAP NW on Azure VMs on SLES with ANF](#), [HA for SAP NW on Azure VMs on SLES multi-SID guide](#), [High availability for SAP NetWeaver on Azure VMs on RHEL](#), [HA for SAP NW on Azure VMs on RHEL with ANF](#) and [HA for SAP NW on Azure VMs on RHEL multi-SID guide](#) to clarify the use of parameter `enqueue/encni/set_so_keepalive`
- July 23, 2020: Added the [Save on SAP HANA Large Instances with an Azure reservation](#) article explaining what you need to know before you buy an SAP HANA Large Instances reservation and how to make the purchase
- July 16, 2020: Describe how to use Azure PowerShell to install new VM Extension for SAP in the [Deployment Guide](#)
- July 04, 2020: Release of [Azure Monitor for SAP solutions \(preview\)](#)
- July 01, 2020: Suggesting less expensive storage configuration based on Azure premium storage burst functionality in document [SAP HANA Azure virtual machine storage configurations](#)
- June 24, 2020: Change in [Setting up Pacemaker on SLES in Azure](#) to release new improved Azure Fence Agent and more resilient fencing configuration for devices, based on Azure Fence Agent
- June 24, 2020: Change in [Setting up Pacemaker on RHEL in Azure](#) to release more resilient fencing configuration
- June 23, 2020: Changes to [Azure Virtual Machines planning and implementation for SAP NetWeaver](#) guide and introduction of [Azure Storage types for SAP workload](#) guide
- June 22, 2020: Add installation steps for new VM Extension for SAP to the [Deployment Guide](#)
- June 16, 2020: Change in [Public endpoint connectivity for VMs using Azure Standard ILB in SAP HA scenarios](#) to add a link to SUSE Public Cloud Infrastructure 101 documentation
- June 10, 2020: Adding new HLI SKUs into [Available SKUs for HLI](#) and [SAP HANA \(Large Instances\) storage architecture](#)

# Create an Oracle Database in an Azure VM

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This guide details using the Azure CLI to deploy an Azure virtual machine from the [Oracle marketplace gallery image](#) in order to create an Oracle 19c database. Once the server is deployed, you will connect via SSH in order to configure the Oracle database.

If you don't have an Azure subscription, create a [free account](#) before you begin.

If you choose to install and use the CLI locally, this quickstart requires that you are running the Azure CLI version 2.0.4 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create a resource group

Create a resource group with the `az group create` command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group named `rg-oracle` in the `eastus` location.

```
az group create --name rg-oracle --location eastus
```

## Create virtual machine

To create a virtual machine (VM), use the `az vm create` command.

The following example creates a VM named `vmoracle19c`. It also creates SSH keys, if they do not already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option.

```
az vm create ^
--resource-group rg-oracle ^
--name vmoracle19c ^
--image Oracle:oracle-database-19-3:oracle-database-19-0904:latest ^
--size Standard_DS2_v2 ^
--admin-username azureuser ^
--generate-ssh-keys ^
--public-ip-address-allocation static ^
--public-ip-address-dns-name vmoracle19c
```

After you create the VM, Azure CLI displays information similar to the following example. Note the value for `publicIpAddress`. You use this address to access the VM.

```
{  
  "fqdns": "",  
  "id": "/subscriptions/{snip}/resourceGroups/rg-oracle/providers/Microsoft.Compute/virtualMachines/vmoracle19c",  
  "location": "eastus",  
  "macAddress": "00-0D-3A-36-2F-56",  
  "powerState": "VM running",  
  "privateIpAddress": "10.0.0.4",  
  "publicIpAddress": "13.64.104.241",  
  "resourceGroup": "rg-oracle"  
}
```

## Create and attach a new disk for Oracle datafiles and FRA

```
az vm disk attach --name oradata01 --new --resource-group rg-oracle --size-gb 64 --sku StandardSSD_LRS --vm-name vmoracle19c
```

## Open ports for connectivity

In this task you must configure some external endpoints for the database listener to use by setting up the Azure Network Security Group that protects the VM.

1. To open the endpoint that you use to access the Oracle database remotely, create a Network Security Group rule as follows:

```
az network nsg rule create ^  
  --resource-group rg-oracle ^  
  --nsg-name vmoracle19cNSG ^  
  --name allow-oracle ^  
  --protocol tcp ^  
  --priority 1001 ^  
  --destination-port-range 1521
```

2. To open the endpoint that you use to access Oracle remotely, create a Network Security Group rule with az network nsg rule create as follows:

```
az network nsg rule create ^  
  --resource-group rg-oracle ^  
  --nsg-name vmoracle19cNSG ^  
  --name allow-oracle-EM ^  
  --protocol tcp ^  
  --priority 1002 ^  
  --destination-port-range 5502
```

3. If needed, obtain the public IP address of your VM again with az network public-ip show as follows:

```
az network public-ip show ^  
  --resource-group rg-oracle ^  
  --name vmoracle19cPublicIP ^  
  --query "ipAddress" ^  
  --output tsv
```

## Prepare the VM environment

1. Connect to the VM

To create an SSH session with the VM, use the following command. Replace the IP address with the `<publicIpAddress>` value for your VM.

```
ssh azureuser@<publicIpAddress>
```

## 2. Switch to the root user

```
sudo su -
```

## 3. Check for last created disk device that we will format for use holding Oracle datafiles

```
ls -alt /dev/sd*|head -1
```

The output will be similar to this:

```
brw-rw----. 1 root disk 8, 16 Dec 8 22:57 /dev/sdc
```

## 4. Format the device. As root user run parted on the device

First create a disk label:

```
parted /dev/sdc mklabel gpt
```

Then create a primary partition spanning the whole disk:

```
parted -a optimal /dev/sdc mkpart primary 0GB 64GB
```

Finally check the device details by printing its metadata:

```
parted /dev/sdc print
```

The output should look similar to this:

```
# parted /dev/sdc print
Model: Msft Virtual Disk (scsi)
Disk /dev/sdc: 68.7GB
Sector size (logical/physical): 512B/4096B
Partition Table: gpt
Disk Flags:
Number  Start   End     Size    File system  Name     Flags
 1      1049kB  64.0GB  64.0GB  ext4        primary
```

## 5. Create a filesystem on the device partition

```
mkfs -t ext4 /dev/sdc1
```

## 6. Create a mount point

```
mkdir /u02
```

7. Mount the disk

```
mount /dev/sdc1 /u02
```

8. Change permissions on the mount point

```
chmod 777 /u02
```

9. Add the mount to the /etc/fstab file.

```
echo "/dev/sdc1           /u02           ext4      defaults      0 0" >> /etc/fstab
```

10. Update the */etc/hosts* file with the public IP and hostname.

Change the *Public IP and VMname* to reflect your actual values:

```
echo "<Public IP> <VMname>.eastus.cloudapp.azure.com <VMname>" >> /etc/hosts
```

11. Update the hostname file

Use the following command to add the domain name of the VM to the */etc/hostname* file. This assumes you have created your resource group and VM in the **eastus** region:

```
sed -i 's/$/.eastus\.cloudapp\.azure\.com &/' /etc/hostname
```

12. Open firewall ports

As SELinux is enabled by default on the Marketplace image we need to open the firewall to traffic for the database listening port 1521, and Enterprise Manager Express port 5502. Run the following commands as root user:

```
firewall-cmd --zone=public --add-port=1521/tcp --permanent  
firewall-cmd --zone=public --add-port=5502/tcp --permanent  
firewall-cmd --reload
```

## Create the database

The Oracle software is already installed on the Marketplace image. Create a sample database as follows.

1. Switch to the **oracle** user:

```
sudo su - oracle
```

2. Start the database listener

```
lsnrctl start
```

The output is similar to the following:

```
LSNRCTL for Linux: Version 19.0.0.0.0 - Production on 20-OCT-2020 01:58:18

Version        TNSLSNR for Linux: Version 19.0.0.0.0 - Production
Start Date      20-OCT-2020 01:58:18
Uptime         0 days 0 hr. 0 min. 0 sec
Trace Level    off
Security        ON: Local OS Authentication
SNMP           OFF
Listener Log File   /u01/app/oracle/diag/tnslsnr/vmoracle19c/listener/alert/log.xml
Listening Endpoints Summary...
  (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=vmoracle19c.eastus.cloudapp.azure.com)(PORT=1521)))
The listener supports no services
The command completed successfully
```

### 3. Create a data directory for the Oracle data files:

```
mkdir /u02/oradata
```

### 4. Run the Database Creation Assistant:

```
dbca -silent \
-createDatabase \
-templateName General_Purpose.dbc \
-gdbname oratest1 \
-sid oratest1 \
-responseFile NO_VALUE \
-characterSet AL32UTF8 \
-sysPassword OraPasswd1 \
-systemPassword OraPasswd1 \
-createAsContainerDatabase false \
-databaseType MULTIPURPOSE \
-automaticMemoryManagement false \
-storageType FS \
-datafileDestination "/u02/oradata/" \
-ignorePreReqs
```

It takes a few minutes to create the database.

You will see output that looks similar to the following:

```
Prepare for db operation
10% complete
Copying database files
40% complete
Creating and starting Oracle instance
42% complete
46% complete
50% complete
54% complete
60% complete
Completing Database Creation
66% complete
69% complete
70% complete
Executing Post Configuration Actions
100% complete
Database creation complete. For details check the logfiles at:
/u01/app/oracle/cfgtoollogs/dbca/oratest1.
Database Information:
Global Database Name:oratest1
System Identifier(SID):oratest1
Look at the log file "/u01/app/oracle/cfgtoollogs/dbca/oratest1/oratest1.log" for further details.
```

## 5. Set Oracle variables

Before you connect, you need to set the environment variable *ORACLE\_SID*:

```
export ORACLE_SID=oratest1
```

You should also add the *ORACLE\_SID* variable to the `oracle` users `.bashrc` file for future sign-ins using the following command:

```
echo "export ORACLE_SID=oratest1" >> ~oracle/.bashrc
```

## Automate database startup and shutdown

The Oracle database by default doesn't automatically start when you restart the VM. To set up the Oracle database to start automatically, first sign in as root. Then, create and update some system files.

### 1. Sign on as root

```
sudo su -
```

### 2. Run the following command to change the automated startup flag from `N` to `Y` in the `/etc/oratab` file:

```
sed -i 's/:N/:Y/' /etc/oratab
```

### 3. Create a file named `/etc/init.d/dbora` and paste the following contents:

```
#!/bin/sh
# chkconfig: 345 99 10
# Description: Oracle auto start-stop script.
#
# Set ORA_HOME to be equivalent to $ORACLE_HOME.
ORA_HOME=/u01/app/oracle/product/19.0.0/dbhome_1
ORA_OWNER=oracle

case "$1" in
'start')
    # Start the Oracle databases:
    # The following command assumes that the Oracle sign-in
    # will not prompt the user for any values.
    # Remove "&" if you don't want startup as a background process.
    su - $ORA_OWNER -c "$ORA_HOME/bin/dbstart $ORA_HOME" &
    touch /var/lock/subsys/dbora
    ;;
'stop')
    # Stop the Oracle databases:
    # The following command assumes that the Oracle sign-in
    # will not prompt the user for any values.
    su - $ORA_OWNER -c "$ORA_HOME/bin/dbshut $ORA_HOME" &
    rm -f /var/lock/subsys/dbora
    ;;
esac
```

4. Change permissions on files with `chmod` as follows:

```
chgrp dba /etc/init.d/dbora
chmod 750 /etc/init.d/dbora
```

5. Create symbolic links for startup and shutdown as follows:

```
ln -s /etc/init.d/dbora /etc/rc.d/rc0.d/K01dbora
ln -s /etc/init.d/dbora /etc/rc.d/rc3.d/S99dbora
ln -s /etc/init.d/dbora /etc/rc.d/rc5.d/S99dbora
```

6. To test your changes, restart the VM:

```
reboot
```

## Clean up resources

Once you have finished exploring your first Oracle database on Azure and the VM is no longer needed, you can use the [az group delete](#) command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroup
```

## Next steps

Understand how to protect your database in Azure with [Oracle Backup Strategies](#)

Learn about other [Oracle solutions on Azure](#).

Try the [Installing and Configuring Oracle Automated Storage Management](#) tutorial.

# Install the Elastic Stack (ELK) on an Azure VM

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article walks you through how to deploy [Elasticsearch](#), [Logstash](#), and [Kibana](#), on an Ubuntu VM in Azure. To see the Elastic Stack in action, you can optionally connect to Kibana and work with some sample logging data.

In this tutorial you learn how to:

- Create an Ubuntu VM in an Azure resource group
- Install Elasticsearch, Logstash, and Kibana on the VM
- Send sample data to Elasticsearch with Logstash
- Open ports and work with data in the Kibana console

This deployment is suitable for basic development with the Elastic Stack. For more on the Elastic Stack, including recommendations for a production environment, see the [Elastic documentation](#) and the [Azure Architecture Center](#).

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This article requires version 2.0.4 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group

Create a resource group with the `az group create` command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group named `myResourceGroup` in the `eastus` location.

```
az group create --name myResourceGroup --location eastus
```

# Create a virtual machine

Create a VM with the [az vm create](#) command.

The following example creates a VM named *myVM* and creates SSH keys if they do not already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option.

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image UbuntuLTS \
    --admin-username azureuser \
    --generate-ssh-keys
```

When the VM has been created, the Azure CLI shows information similar to the following example. Take note of the `publicIpAddress`. This address is used to access the VM.

```
{
  "fqdns": "",
  "id": "/subscriptions/<subscription
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "40.68.254.142",
  "resourceGroup": "myResourceGroup"
}
```

## SSH into your VM

If you don't already know the public IP address of your VM, run the [az network public-ip list](#) command:

```
az network public-ip list --resource-group myResourceGroup --query [].ipAddress
```

Use the following command to create an SSH session with the virtual machine. Substitute the correct public IP address of your virtual machine. In this example, the IP address is *40.68.254.142*.

```
ssh azureuser@40.68.254.142
```

## Install the Elastic Stack

Import the Elasticsearch signing key and update your APT sources list to include the Elastic package repository:

```
wget -qO - https://artifacts.elastic.co/GPG-KEY-elasticsearch | sudo apt-key add -
echo "deb https://artifacts.elastic.co/packages/5.x/apt stable main" | sudo tee -a
/etc/apt/sources.list.d/elastic-5.x.list
```

Install the Java Virtual on the VM and configure the `JAVA_HOME` variable-this is necessary for the Elastic Stack components to run.

```
sudo apt update && sudo apt install openjdk-8-jre-headless
export JAVA_HOME=/usr/lib/jvm/java-8-openjdk-amd64
```

Run the following commands to update Ubuntu package sources and install Elasticsearch, Kibana, and Logstash.

```
sudo apt update && sudo apt install elasticsearch kibana logstash
```

**NOTE**

Detailed installation instructions, including directory layouts and initial configuration, are maintained in [Elastic's documentation](#)

## Start Elasticsearch

Start Elasticsearch on your VM with the following command:

```
sudo systemctl start elasticsearch.service
```

This command produces no output, so verify that Elasticsearch is running on the VM with this `curl` command:

```
sudo curl -XGET 'localhost:9200/'
```

If Elasticsearch is running, you see output like the following:

```
{
  "name" : "w6Z4NwR",
  "cluster_name" : "elasticsearch",
  "cluster_uuid" : "SDzCajBoSK2EkXmHvJVaDQ",
  "version" : {
    "number" : "5.6.3",
    "build_hash" : "1a2f265",
    "build_date" : "2017-10-06T20:33:39.012Z",
    "build_snapshot" : false,
    "lucene_version" : "6.6.1"
  },
  "tagline" : "You Know, for Search"
}
```

## Start Logstash and add data to Elasticsearch

Start Logstash with the following command:

```
sudo systemctl start logstash.service
```

Test Logstash in interactive mode to make sure it's working correctly:

```
sudo /usr/share/logstash/bin/logstash -e 'input { stdin { } } output { stdout {} }'
```

This is a basic Logstash [pipeline](#) that echoes standard input to standard output.

```
The stdin plugin is now waiting for input:
hello azure
2017-10-11T20:01:08.904Z myVM hello azure
```

Set up Logstash to forward the kernel messages from this VM to Elasticsearch. Create a new file in an empty directory called `vm-syslog-logstash.conf` and paste in the following Logstash configuration:

```
input {
    stdin {
        type => "stdin-type"
    }

    file {
        type => "syslog"
        path => [ "/var/log/*.log", "/var/log/*/*.log", "/var/log/messages", "/var/log/syslog" ]
        start_position => "beginning"
    }
}

output {
    stdout {
        codec => rubydebug
    }
    elasticsearch {
        hosts => "localhost:9200"
    }
}
```

Test this configuration and send the syslog data to Elasticsearch:

```
sudo /usr/share/logstash/bin/logstash -f vm-syslog-logstash.conf
```

You see the syslog entries in your terminal echoed as they are sent to Elasticsearch. Use `CTRL+C` to exit out of Logstash once you've sent some data.

## Start Kibana and visualize the data in Elasticsearch

Edit `/etc/kibana/kibana.yml` and change the IP address Kibana listens on so you can access it from your web browser.

```
server.host: "0.0.0.0"
```

Start Kibana with the following command:

```
sudo systemctl start kibana.service
```

Open port 5601 from the Azure CLI to allow remote access to the Kibana console:

```
az vm open-port --port 5601 --resource-group myResourceGroup --name myVM
```

Open up the Kibana console and select **Create** to generate a default index based on the syslog data you sent to Elasticsearch earlier.

The screenshot shows the Kibana Management interface. On the left, there's a sidebar with icons for Discover, Visualize, Dashboard, Timelion, Dev Tools, and Management. The main area is titled 'Configure an index pattern' and contains instructions about index patterns. It has sections for 'Index pattern' (with 'logstash-\*' selected), 'Time Filter field name' (set to '@timestamp'), and checkboxes for 'Expand index pattern when searching [DEPRECATED]' and 'Use event times to create index names [DEPRECATED]'. A large blue 'Create' button at the bottom is highlighted with a red box.

Select **Discover** on the Kibana console to search, browse, and filter through the syslog events.

The screenshot shows the Kibana Discover interface. The sidebar on the left has 'Discover' selected. The main area displays a histogram with a single bar at 14:05:00, indicating a count of approximately 12. Below the histogram is a table of log entries. The table columns are Time, @timestamp, @version, message, and type. The first entry is:

Time	@timestamp	@version	message	type
October 13th 2017, 14:05:25.688	October 13th 2017, 14:05:25.688	1	[2017-10-13T21:05:24,910] [WARN ] [o.e.d.i.m.TypeParsers ] field [include_in_all] is deprecated, as [._all] is deprecated, and will be disallowed in 6.0, use [copy_to] instead.	syslog

There are two more entries in the table, both with identical details.

## Next steps

In this tutorial, you deployed the Elastic Stack into a development VM in Azure. You learned how to:

- Create an Ubuntu VM in an Azure resource group
- Install Elasticsearch, Logstash, and Kibana on the VM
- Send sample data to Elasticsearch from Logstash
- Open ports and work with data in the Kibana console

# Mainframe rehosting on Azure virtual machines

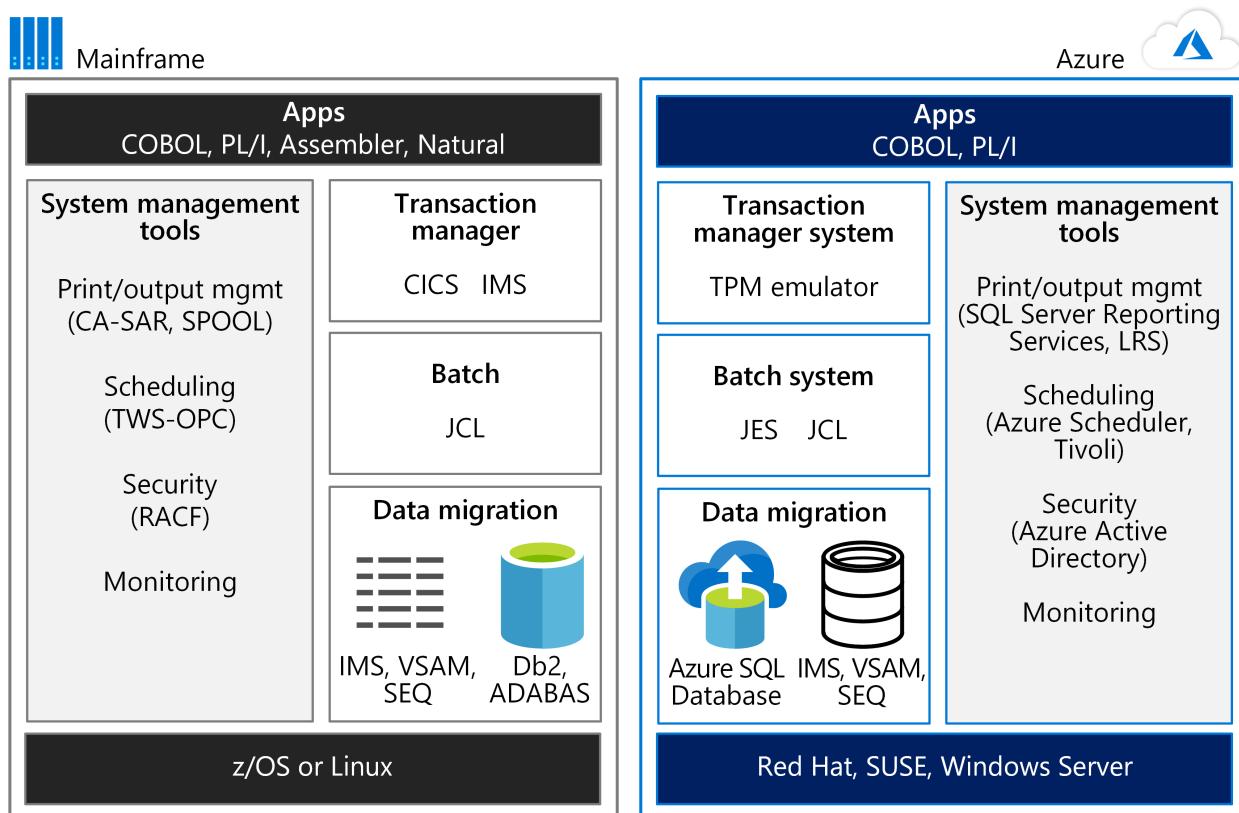

9/21/2022 • 4 minutes to read • [Edit Online](#)

Migrating workloads from mainframe environments to the cloud enables you to modernize your infrastructure and often save on costs. Many workloads can be transferred to Azure with only minor code changes, such as updating the names of databases.

Generally speaking, the term *mainframe* means a large computer system. Specifically, the vast majority currently in use are IBM System Z servers or IBM plug-compatible systems that run MVS, DOS, VSE, OS/390, or z/OS.

An Azure virtual machine (VM) is used to isolate and manage the resources for a specific application on a single instance. Mainframes such as IBM z/OS use Logical Partitions (LPARS) for this purpose. A mainframe might use one LPAR for a CICS region with associated COBOL programs, and a separate LPAR for IBM Db2 database. A typical [n-tier application on Azure](#) deploys Azure VMs into a virtual network that can be segmented into subnets for each tier.

Azure VMs can run mainframe emulation environments and compilers that support lift-and-shift scenarios. Development and testing are often among the first workloads to migrate from a mainframe to an Azure dev/test environment. Common server components that you can emulate include online transaction process (OLTP), batch, and data ingestion systems as the following figure shows.

Some mainframe workloads can be migrated to Azure with relative ease, while others can be rehosted on Azure using a partner solution. For detailed guidance about choosing a partner solution, the [Azure Mainframe Migration center](#) can help.

## Mainframe migration

Rehost, rebuild, replace, or retire? IaaS or PaaS? To determine the right migration strategy for your mainframe application, see the [Mainframe migration](#) guide in the Azure Architecture Center.

## Micro Focus rehosting platform

Micro Focus Enterprise Server is one of the largest mainframe rehosting platforms available. You can use it run your z/OS workloads on a less expensive x86 platform on Azure.

To get started:

- [Install Enterprise Server and Enterprise Developer on Azure](#)
- [Set up CICS BankDemo for Enterprise Developer on Azure](#)
- [Run Enterprise Server in a Docker Container on Azure](#)

## TmaxSoft OpenFrame on Azure

TmaxSoft OpenFrame is a popular mainframe rehosting solution used in lift-and-shift scenarios. An OpenFrame environment on Azure is suitable for development, demos, testing, or production workloads.

To get started:

- [Get started with TmaxSoft OpenFrame](#)
- [Download the ebook](#)

## IBM zD&T 12.0

IBM Z Development and Test Environment (IBM zD&T) sets up a non-production environment on Azure that you can use for development, testing, and demos of z/OS-based applications.

The emulation environment on Azure can host different kinds of Z instances through Application Developers Controlled Distributions (ADCDs). You can run zD&T Personal Edition, zD&T Parallel Sysplex, and zD&T Enterprise Edition on Azure and Azure Stack.

To get started:

- [Set up IBM zD&T 12.0 on Azure](#)
- [Set up ADCD on zD&T](#)

## IBM DB2 pureScale on Azure

The IBM DB2 pureScale environment provides a database cluster for Azure. It's not identical to the original environment, but it delivers similar availability and scale as IBM DB2 for z/OS running in a Parallel Sysplex setup.

To get started, see [IBM DB2 pureScale on Azure](#).

## Considerations

When you migrate mainframe workloads to Azure infrastructure as a service (IaaS), you can choose from several types of on-demand, scalable computing resources, including Azure VMs. Azure offers a range of [Linux](#) and [Windows](#) VMs.

### Compute

Azure compute power compares favorably to a mainframe's capacity. If you're thinking of moving a mainframe workload to Azure, compare the mainframe metric of one million instructions per second (MIPS) to virtual CPUs.

Learn how to [move mainframe compute to Azure](#).

### High availability and failover

Azure offers commitment-based service-level agreements (SLAs). Multiple-nines availability is the default, and SLAs can be optimized with local or geo-based replication of services. The full [Azure SLA](#) explains the

guaranteed availability of Azure as a whole.

With Azure IaaS such as a VM, specific system functions provide failover support—for example, failover clustering instances and availability sets. When you use Azure platform as a service (PaaS) resources, the platform handles failover automatically. Examples include [Azure SQL Database](#) and [Azure Cosmos DB](#).

## Scalability

Mainframes typically scale up, while cloud environments scale out. Azure offers a range of [Linux](#) and [Windows](#) sizes to meet your needs. The cloud also scales up or down to match exact user specifications. Compute power, storage, and services [scale on demand](#) under a usage-based billing model.

## Storage

In the cloud, you have a range of flexible, scalable storage options, and you pay only for what you need. [Azure Storage](#) offers a massively scalable object store for data objects, a file system service for the cloud, a reliable messaging store, and a NoSQL store. For VMs, managed and unmanaged disks provide persistent, secure disk storage.

Learn how to [move mainframe storage to Azure](#).

## Backup and recovery

Maintaining your own disaster recovery site can be an expensive proposition. Azure has easy-to-implement and cost-effective options for [backup](#), [recovery](#), and [redundancy](#) at local or regional levels, or via geo-redundancy.

## Azure Government for mainframe migrations

Many public sector entities would love to move their mainframe applications to a more modern, flexible platform. Microsoft Azure Government is a physically separated instance of the global Microsoft Azure platform—packaged for federal, state, and local government systems. It provides world-class security, protection, and compliance services specifically for United States government agencies and their partners.

Azure Government earned a Provisional Authority to Operate (P-ATO) for FedRAMP High Impact for systems that need this type of environment.

To get started, download [Microsoft Azure Government cloud for mainframe applications](#).

## Next steps

Ask our [partners](#) to help you migrate or rehost your mainframe applications.

# What is confidential computing?

9/21/2022 • 2 minutes to read • [Edit Online](#)

Confidential computing is an industry term defined by the [Confidential Computing Consortium \(CCC\)](#) - a foundation dedicated to defining and accelerating the adoption of confidential computing. The CCC defines confidential computing as: The protection of data in use by performing computations in a hardware-based Trusted Execution Environment (TEE).

A TEE is an environment that enforces execution of only authorized code. Any data in the TEE can't be read or tampered with by any code outside that environment. The confidential computing threat model aims at removing or reducing the ability for a cloud provider operator and other actors in the tenant's domain to access code and data while being executed.

When used with data encryption at rest and in transit, confidential computing eliminates the single largest barrier of encryption - encryption while in use - by protecting sensitive or highly regulated data sets and application workloads in a secure public cloud platform. Confidential computing extends beyond generic data protection. TEEs are also being used to protect proprietary business logic, analytics functions, machine learning algorithms, or entire applications.

## Lessen the need for trust

Running workloads on the cloud requires trust. You give this trust to various providers enabling different components of your application.

- **App software vendors:** Trust software by deploying on-premises, using open-source, or by building in-house application software.
- **Hardware vendors:** Trust hardware by using on-premises hardware or in-house hardware.
- **Infrastructure providers:** Trust cloud providers or manage your own on-premises data centers.

## Reducing the attack surface

The trusted computing base (TCB) refers to all of a system's hardware, firmware, and software components that provide a secure environment. The components inside the TCB are considered "critical". If one component inside the TCB is compromised, the entire system's security may be jeopardized. A lower TCB means higher security. There's less risk of exposure to various vulnerabilities, malware, attacks, and malicious people.

## Next steps

[Microsoft's offerings](#) for confidential computing extend from Infrastructure as a Service (IaaS) to Platform as a Service (PaaS) and as well as developer tools to support your journey to data and code confidentiality in the cloud. Learn more about confidential computing on Azure

[Overview of Azure Confidential Computing](#)

# Sizes for virtual machines in Azure

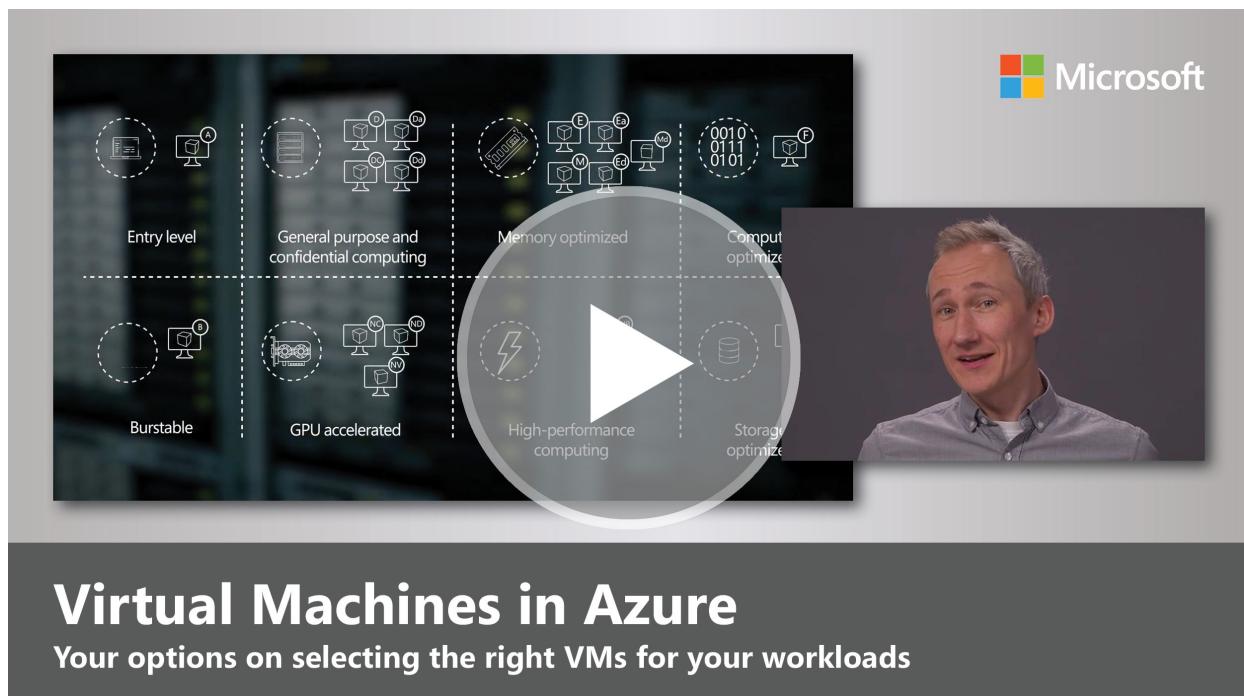

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes the available sizes and options for the Azure virtual machines you can use to run your apps and workloads. It also provides deployment considerations to be aware of when you're planning to use these resources.

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

## Virtual Machines in Azure

Your options on selecting the right VMs for your workloads

Type	Sizes	Description
General purpose	B, Dsv3, Dv3, Dasv4, Dav4, DSv2, Dv2, Av2, DC, DCv2, Dpdsv5, Dplds5, Dpsv5, Dplsv5, Dv4, Dsv4, Ddv4, Ddsv4, Dv5, Dsv5, Ddv5, Ddsv5, Dasv5, Dadsv5	Balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.
Compute optimized	F, Fs, Fsv2, FX	High CPU-to-memory ratio. Good for medium traffic web servers, network appliances, batch processes, and application servers.
Memory optimized	Esv3, Ev3, Easv4, Eav4, Epdsv5, Epsv5, Ev4, Esv4, Edv4, Edsv4, Ev5, Esv5, Edv5, Edsv5, Easv5, Eads5, Mv2, M, DSv2, Dv2	High memory-to-CPU ratio. Great for relational database servers, medium to large caches, and in-memory analytics.

Type	Sizes	Description
Storage optimized	Lsv2, Lsv3, Lasv3	High disk throughput and IO ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases.
GPU	NC, NCv2, NCv3, NCasT4_v3, ND, NDv2, NV, NVv3, NVv4, NDAsrA100_v4, NDm_A100_v4	Specialized virtual machines targeted for heavy graphic rendering and video editing, as well as model training and inferencing (ND) with deep learning. Available with single or multiple GPUs.
High performance compute	HB, HBv2, HBv3, HC, H	Our fastest and most powerful CPU virtual machines with optional high-throughput network interfaces (RDMA).

- For information about pricing of the various sizes, see the pricing pages for [Linux](#) or [Windows](#).
- For availability of VM sizes in Azure regions, see [Products available by region](#).
- To see general limits on Azure VMs, see [Azure subscription and service limits, quotas, and constraints](#).
- For more information on how Azure names its VMs, see [Azure virtual machine sizes naming conventions](#).

## REST API

For information on using the REST API to query for VM sizes, see the following:

## Manage costs

Azure services cost money. Azure Cost Management helps you set budgets and configure alerts to keep spending under control. Analyze, manage, and optimize your Azure costs with Cost Management. To learn more, see the [quickstart on analyzing your costs](#).

## Next steps

Learn more about the different VM sizes that are available:

- [General purpose](#)
- [Compute optimized](#)
- [Memory optimized](#)

- Storage optimized
- GPU
- High performance compute
- Check the [Previous generation](#) page for A Standard, Dv1 (D1-4 and D11-14 v1), and A8-A11 series

# General purpose virtual machine sizes

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers. This article provides information about the offerings for general purpose computing.

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

- The [Av2-series](#) VMs can be deployed on various hardware types and processors. A-series VMs have CPU performance and memory configurations best suited for entry level workloads like development and test. This size is throttled, based on the hardware. The size offers consistent processor performance for the running instance, regardless of the hardware it's deployed on. To determine the physical hardware on which this size is deployed, query the virtual hardware from within the Virtual Machine. Example use cases include development and test servers, low traffic web servers, small to medium databases, proof-of-concepts, and code repositories.
- [B-series burstable](#) VMs are ideal for workloads that don't need the full performance of the CPU continuously, like web servers, small databases and development and test environments. These workloads typically have burstable performance requirements. The B-Series provides these customers the ability to purchase a VM size with a price conscious baseline performance that allows the VM instance to build up credits when the VM is utilizing less than its base performance. When the VM has accumulated credit, the VM can burst above the VM's baseline using up to 100% of the CPU when your application requires the higher CPU performance.
- The [DCv2-series](#) can help protect the confidentiality and integrity of your data and code while it's processed in the public cloud. These machines are backed by the latest generation of Intel XEON E-2288G Processor with SGX technology. With the Intel Turbo Boost Technology, these machines can go up to 5.0 GHz. DCv2 series instances enable customers to build secure enclave-based applications to protect their code and data while it's in use.
- The [Dpsv5 and Dpdsv5-series](#) and [Dplsv5 and Dpldsv5-series](#) are ARM64-based VMs featuring the 80 core, 3.0 GHz Ampere Altra processor. These series are designed for common enterprise workloads. They're optimized for database, in-memory caching, analytics, gaming, web, and application servers running on Linux.
- [Dv2 and Dsv2-series](#) VMs, a follow-on to the original D-series, features a more powerful CPU and optimal CPU-to-memory configuration making them suitable for most production workloads. The Dv2-series is about 35% faster than the D-series. Dv2-series run on 2nd Generation Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors with the Intel Turbo Boost Technology 2.0. The Dv2-series has the same memory and disk configurations as the D-series.
- The [Dv3 and Dsv3-series](#) runs on 2nd Generation Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors. These series run in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads. Memory has

been expanded (from ~3.5 GiB/vCPU to 4 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Dv3-series no longer has the high memory VM sizes of the D/Dv2-series. Those sizes have been moved to the memory optimized [Ev3](#) and [Esv3-series](#).

- [Dav4 and Dasv4-series](#) are new sizes utilizing AMD's 2.35Ghz EPYC™ 7452 processor in a multi-threaded configuration with up to 256 MB L3 cache dedicating 8 MB of that L3 cache to every eight cores increasing customer options for running their general purpose workloads. The Dav4-series and Dasv4-series have the same memory and disk configurations as the D & Dsv3-series.
- The [Dv4 and Dsv4-series](#) runs on the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. It features an all core Turbo clock speed of 3.4 GHz.
- The [Ddv4 and Ddsv4-series](#) runs on the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. It features an all core Turbo clock speed of 3.4 GHz, [Intel® Turbo Boost Technology 2.0](#), [Intel® Hyper-Threading Technology](#) and [Intel® Advanced Vector Extensions 512 \(Intel® AVX-512\)](#). They also support [Intel® Deep Learning Boost](#). These new VM sizes will have 50% larger local storage, and better local disk IOPS for both read and write compared to the [Dv3/Dsv3](#) sizes with [Gen2 VMs](#).
- The [Dasv5 and Dadsv5-series](#) utilize AMD's 3rd Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache, increasing customer options for running their general purpose workloads. These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most enterprise workloads. For example, you can use these series with small-to-medium databases, low-to-medium traffic web servers, application servers, and more.
- The [Dv5 and Dsv5-series](#) run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper-threaded configuration. The Dv5 and Dsv5 virtual machine sizes don't have any temporary storage thus lowering the price of entry. The Dv5 VM sizes offer a combination of vCPUs and memory to meet the requirements associated with most enterprise workloads. For example, you can use these series with small-to-medium databases, low-to-medium traffic web servers, application servers, and more.
- The [Ddv5 and Ddsv5-series](#) run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. This new processor features an all core Turbo clock speed of 3.5 GHz, [Intel® Hyper-Threading Technology](#), [Intel® Turbo Boost Technology](#), [Intel® Advanced-Vector Extensions 512 \(Intel® AVX-512\)](#) and [Intel® Deep Learning Boost](#).

# Av1-series retirement

9/21/2022 • 2 minutes to read • [Edit Online](#)

On August 31, 2024, we retire Basic and Standard A-series virtual machines (VMs). Before that date, migrate your workloads to Av2-series VMs, which provide more memory per vCPU and faster storage on solid-state drives (SSDs).

## NOTE

In some cases, you must deallocate the VM prior to resizing. This can happen if the new size is not available on the hardware cluster that is currently hosting the VM.

## Migrate workloads to Av2-series VMs

You can resize your virtual machines to the Av2-series using the [Azure portal](#), [PowerShell](#), or the [CLI](#). Below are examples on how to resize your VM using the Azure portal and PowerShell.

## IMPORTANT

Resizing a virtual machine results in a restart. We recommend that you perform actions that result in a restart during off-peak business hours.

### Azure portal

1. Open the [Azure portal](#).
2. Type *virtual machines* in the search.
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select the virtual machine you want to resize.
5. In the left menu, select **size**.
6. Pick a new Av2 size from the list of available sizes and select **Resize**.

### Azure PowerShell

1. Set the resource group and VM name variables. Replace the values with information of the VM you want to resize.

```
$resourceGroup = "myResourceGroup"  
$vmName = "myVM"
```

2. List the VM sizes that are available on the hardware cluster where the VM is hosted.

```
Get-AzVMSize -ResourceGroupName $resourceGroup -VMName $vmName
```

3. Resize the VM to the new size.

```
$vm = Get-AzVM -ResourceGroupName $resourceGroup -VMName $vmName  
$vm.HardwareProfile.VmSize = "<newAv2VmSize>"  
Update-AzVM -VM $vm -ResourceGroupName $resourceGroup
```

## Help and support

If you have questions, ask community experts in [Microsoft Q&A](#). If you have a support plan and need technical help, create a support request:

1. In the [Help + support](#) page, select **Create a support request**. Follow the [New support request](#) page instructions. Use the following values:
  - For **Issue type**, select **Technical**.
  - For **Service**, select **My services**.
  - For **Service type**, select **Virtual Machine running Windows/Linux**.
  - For **Resource**, select your VM.
  - For **Problem type**, select **Assistance with resizing my VM**.
  - For **Problem subtype**, select the option that applies to you.

Follow instructions in the **Solutions** and **Details** tabs, as applicable, and then **Review + create**.

# Av2-series

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Av2-series VMs can be deployed on a variety of hardware types and processors. Av2-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), the Intel® Xeon® Platinum 8272CL (Cascade Lake), the Intel® Xeon® 8171M 2.1 GHz (Skylake), the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors. Av2-series VMs have CPU performance and memory configurations best suited for entry level workloads like development and test. The size is throttled to offer consistent processor performance for the running instance, regardless of the hardware it is deployed on. To determine the physical hardware on which this size is deployed, query the virtual hardware from within the Virtual Machine. Some example use cases include development and test servers, low traffic web servers, small to medium databases, proof-of-concepts, and code repositories.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# B-series burstable virtual machine sizes

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The B-series VMs can be deployed on a variety of hardware types and processors, so competitive bandwidth allocation is provided. B-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), the Intel® Xeon® Platinum 8272CL (Cascade Lake), the Intel® Xeon® 8171M 2.1 GHz (Skylake), the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors. B-series VMs are ideal for workloads that do not need the full performance of the CPU continuously, like web servers, proof of concepts, small databases and development build environments. These workloads typically have burstable performance requirements. To determine the physical hardware on which this size is deployed, query the virtual hardware from within the virtual machine. The B-series provides you with the ability to purchase a VM size with baseline performance that can build up credits when it is using less than its baseline. When the VM has accumulated credits, the VM can burst above the baseline using up to 100% of the vCPU when your application requires higher CPU performance.

The B-series comes in the following VM sizes:

[Azure Compute Unit \(ACU\)](#): Varies\*

[Premium Storage](#): Supported

[Premium Storage caching](#): Not Supported

[Live Migration](#): Supported

[Memory Preserving Updates](#): Supported

[VM Generation Support](#): Generation 1 and 2

[Accelerated Networking](#): Supported\*\*

[Ephemeral OS Disks](#): Supported

[Nested Virtualization](#): Not Supported

\*B-series VMs are burstable and thus ACU numbers will vary depending on workloads and core usage.

\*\*Accelerated Networking is only supported for *Standard\_B12ms*, *Standard\_B16ms* and *Standard\_B20ms*.

<sup>1</sup> B-series VMs can [burst](#) their disk performance and get up to their bursting max for up to 30 minutes at a time.

<sup>2</sup> B1Is is supported only on Linux

## Workload example

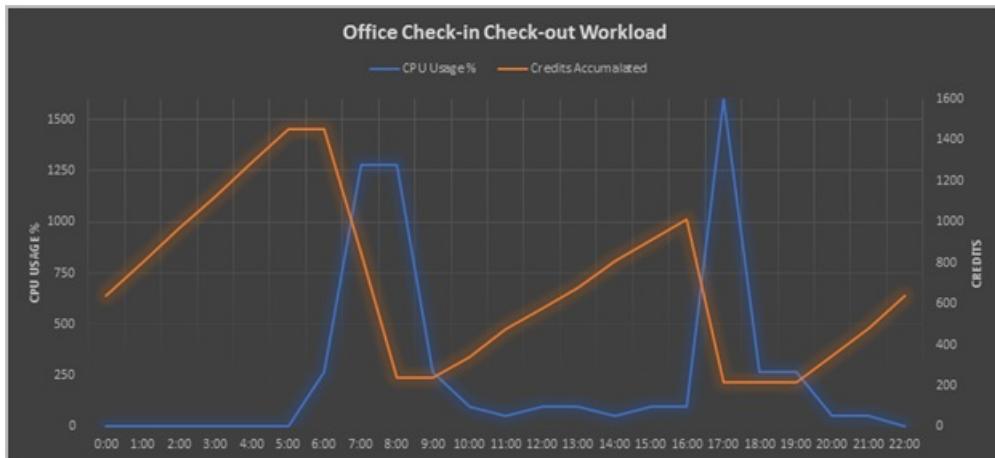

Consider an office check-in/out application. The application needs CPU bursts during business hours, but not a lot of computing power during off hours. In this example, the workload requires a 16vCPU virtual machine with 64GiB of RAM to work efficiently.

The table shows the hourly traffic data and the chart is a visual representation of that traffic.

B16 characteristics:

Max CPU perf:  $16\text{vCPU} * 100\% = 1600\%$

Baseline: 270%

SCENARIO	TIME	CPU USAGE (%)	CREDITS ACCUMULATED <sup>1</sup>	CREDITS AVAILABLE
B16ms Deployment	Deployment	Deployment	480 (Initial Credits)	480
No traffic	0:00	0	162	642
No traffic	1:00	0	162	804
No traffic	2:00	0	162	966
No traffic	3:00	0	162	1128
No traffic	4:00	0	162	1290
No traffic	5:00	0	162	1452
Low Traffic	6:00	270	0	1452
Employees come to office (app needs 80% vCPU)	7:00	1280	-606	846
Employees continue coming to office (app needs 80% vCPU)	8:00	1280	-606	240
Low Traffic	9:00	270	0	240

SCENARIO	TIME	CPU USAGE (%)	CREDITS ACCUMULATED	CREDITS AVAILABLE
Low Traffic	10:00	100	102	342
Low Traffic	11:00	50	132	474
Low Traffic	12:00	100	102	576
Low Traffic	13:00	100	102	678
Low Traffic	14:00	50	132	810
Low Traffic	15:00	100	102	912
Low Traffic	16:00	100	102	1014
Employees checking out (app needs 100% vCPU)	17:00	1600	-798	216
Low Traffic	18:00	270	0	216
Low Traffic	19:00	270	0	216
Low Traffic	20:00	50	132	348
Low Traffic	21:00	50	132	480
No traffic	22:00	0	162	642
No traffic	23:00	0	162	804

<sup>1</sup> Credits accumulated/credits used in an hour is equivalent to:

$$((\text{Base CPU perf of VM} - \text{CPU Usage}) / 100) * 60 \text{ minutes}$$

For a D16s\_v3 which has 16 vCPUs and 64 GiB of memory the hourly rate is \$0.936 per hour (monthly \$673.92) and for B16ms with 16 vCPUs and 64 GiB memory the rate is \$0.794 per hour (monthly \$547.86). This results in 15% savings!

## Q & A

### Q: What happens when my credits run out?

A: When the credits are exhausted, the VM returns to the baseline performance.

### Q: How do you get 135% baseline performance from a VM?

A: The 135% is shared amongst the 8 vCPU's that make up the VM size. For example, if your application uses 4 of the 8 cores working on batch processing and each of those 4 vCPU's are running at 30% utilization the total amount of VM CPU performance would equal 120%. Meaning that your VM would be building credit time based on the 15% delta from your baseline performance. But it also means that when you have credits available that same VM can use 100% of all 8 vCPU's giving that VM a Max CPU performance of 800%.

### Q: How can I monitor my credit balance and consumption?

A: The Credit metric allows you to view how many credits your VM have been banked and the

**ConsumedCredit** metric will show how many CPU credits your VM has consumed from the bank. You will be able to view these metrics from the metrics pane in the portal or programmatically through the Azure Monitor APIs.

For more information on how to access the metrics data for Azure, see [Overview of metrics in Microsoft Azure](#).

**Q: How are credits accumulated and consumed?**

A: The VM accumulation and consumption rates are set such that a VM running at exactly its base performance level will have neither a net accumulation or consumption of bursting credits. A VM will have a net increase in credits whenever it is running below its base performance level and will have a net decrease in credits whenever the VM is utilizing the CPU more than its base performance level.

**Example:** I deploy a VM using the B1ms size for my small time and attendance database application. This size allows my application to use up to 20% of a vCPU as my baseline, which is 0.2 credits per minute I can use or bank.

My application is busy at the beginning and end of my employees work day, between 7:00-9:00 AM and 4:00 - 6:00PM. During the other 20 hours of the day, my application is typically at idle, only using 10% of the vCPU. For the non-peak hours, I earn 0.2 credits per minute but only consume 0.1 credits per minute, so my VM will bank  $0.1 \times 60 = 6$  credits per hour. For the 20 hours that I am off-peak, I will bank 120 credits.

During peak hours my application averages 60% vCPU utilization, I still earn 0.2 credits per minute but I consume 0.6 credits per minute, for a net cost of 0.4 credits a minute or  $0.4 \times 60 = 24$  credits per hour. I have 4 hours per day of peak usage, so it costs  $4 \times 24 = 96$  credits for my peak usage.

If I take the 120 credits I earned off-peak and subtract the 96 credits I used for my peak times, I bank an additional 24 credits per day that I can use for other bursts of activity.

**Q: How can I calculate credits accumulated and used?**

A: You can use the following formula:

$(\text{Base CPU perf of VM} - \text{CPU Usage}) / 100 = \text{Credits bank or use per minute}$

e.g in above instance your baseline is 20% and if you use 10% of the CPU you are accumulating  $(20\%-10\%)/100 = 0.1$  credit per minute.

**Q: Does the B-Series support Premium Storage data disks?**

A: Yes, all B-Series sizes support Premium Storage data disks.

**Q: Why is my remaining credit set to 0 after a redeploy or a stop/start?**

A : When a VM is redeployed and the VM moves to another node, the accumulated credit is lost. If the VM is stopped/started, but remains on the same node, the VM retains the accumulated credit. Whenever the VM starts fresh on a node, it gets an initial credit, for Standard\_B8ms it is 240.

**Q: What happens if I deploy an unsupported OS image on B1ls?**

A : B1ls only supports Linux images and if you deploy any another OS image you might not get the best customer experience.

# DCsv2-series

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The DCsv2-series virtual machines help protect the confidentiality and integrity of your data and code while it's processed in the public cloud. DCsv2-series leverage Intel® Software Guard Extensions, which enable customers to use secure enclaves for protection.

These machines are backed by 3.7 GHz Intel® Xeon E-2288G (Coffee Lake) with SGX technology. With Intel® Turbo Boost Max Technology 3.0 these machines can go up to 5.0 GHz.

## NOTE

Hyperthreading is disabled for added security posture. Pricing is the same as Dv5 and Dsv5-series per physical core.

Example confidential use cases include: databases, blockchain, multiparty data analytics, fraud detection, anti-money laundering, usage analytics, intelligence analysis and machine learning.

## Configuration

[Turbo Boost Max 3.0](#): Supported (Tenant VM will report 3.7 GHz, but will reach Turbo Speeds)

[Hyper-Threading](#): Not Supported

[Premium Storage](#): Supported (Not Supported for Standard\_DC8\_v2)

[Premium Storage Caching](#): Supported

[Live Migration](#): Not Supported

[Memory Preserving Updates](#): Not Supported

[VM Generation Support](#): Generation 2

[Accelerated Networking](#): Not Supported

[Ephemeral OS Disks](#): Supported

[Nested Virtualization](#): Not Supported

# DCsv3 and DCcsv3-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The DCsv3 and DCcsv3-series Azure Virtual Machines help protect the confidentiality and integrity of your code and data while they're being processed in the public cloud. By using Intel® Software Guard Extensions and Intel® Total Memory Encryption - Multi Key, customers can ensure their data is always encrypted and protected in use.

These machines are powered by the latest 3rd Generation Intel® Xeon Scalable processors, and use Intel® Turbo Boost Max Technology 3.0 to reach 3.5 GHz.

With this generation, CPU Cores have increased 6x (up to a maximum of 48 physical cores). Encrypted Memory (EPC) has increased 1500x to 256 GB. Regular Memory has increased 12x to 384 GB. All these changes substantially improve the performance and unlock new entirely new scenarios.

## NOTE

Hyperthreading is disabled for added security posture. Pricing is the same as Dv5 and Dsv5-series per physical core.

There are two variants for each series, depending on whether the workload benefits from a local disk or not. You can attach remote persistent disk storage to all VMs, whether or not the VM has a local disk. As always, remote disk options (such as for the VM boot disk) are billed separately from the VMs in any case.

DCsv3-series instances run on a 3rd Generation Intel® Xeon Scalable Processor 8370C. The base All-Core frequency is 2.8 GHz. [Turbo Boost Max 3.0](#) is enabled with a max frequency of 3.5 GHz.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Dv2 and DSv2-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dv2 and DSv2-series, a follow-on to the original D-series, feature a more powerful CPU and optimal CPU-to-memory configuration making them suitable for most production workloads. The Dv2-series is about 35% faster than the D-series. Dv2-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors with the Intel Turbo Boost Technology 2.0. The Dv2-series has the same memory and disk configurations as the D-series.

## Dv2-series

Dv2-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors with Intel Turbo Boost Technology 2.0.

# Dv3 and Dsv3-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dv3-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads. Memory has been expanded (from ~3.5 GiB/vCPU to 4 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Dv3-series no longer has the high memory VM sizes of the D/Dv2-series, those have been moved to the memory optimized [Ev3 and Esv3-series](#).

Example D-series use cases include enterprise-grade applications, relational databases, in-memory caching, and analytics.

## Dv3-series

Dv3-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors with [Intel® Turbo Boost Technology 2.0](#). The Dv3-series sizes offer a combination of vCPU, memory, and temporary storage for most production workloads.

Data disk storage is billed separately from virtual machines. To use premium storage disks, use the Dsv3 sizes. The pricing and billing meters for Dsv3 sizes are the same as Dv3-series.

Dv3-series VMs feature Intel® Hyper-Threading Technology.

# Dv4 and Dsv4-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dv4 and Dsv4-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. It features an all core Turbo clock speed of 3.4 GHz, Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology and Intel® Advanced Vector Extensions 512 (Intel® AVX-512). They also support Intel® Deep Learning Boost.

## NOTE

For frequently asked questions, see [Azure VM sizes with no local temp disk](#).

## Dv4-series

Dv4-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake). The Dv4-series sizes offer a combination of vCPU, memory and remote storage options for most production workloads. Dv4-series VMs feature Intel® Hyper-Threading Technology.

Remote Data disk storage is billed separately from virtual machines. To use premium storage disks, use the Dsv4 sizes. The pricing and billing meters for Dsv4 sizes are the same as Dv4-series.

## NOTE

After a restart, a file named *Data\_loss\_warning.txt* might appear beside drive C (the first data disk attached from the Azure portal). In this scenario, despite the file name, no data loss has occurred on the disk. In general, the *Data\_loss\_warning.txt* file usually is copied on the temporary drive. If you're using a VM that doesn't have a temp drive, WindowsAzureGuestAgent incorrectly copies the file to the first drive letter. In v4 VMs, the first drive letter is a data disk.

A resolution for this issue was applied in the latest version (version 2.7.41491.999) of the VM agent.

<sup>1</sup> Dasv4-series VMs can **burst** their disk performance and get up to their bursting max for up to 30 minutes at a time.

<sup>2</sup> Accelerated networking can only be applied to a single NIC.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion,

application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTTCP\)](#).

# Ddv4 and Ddsv4-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Ddv4 and Ddsv4-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. It features an all core Turbo clock speed of 3.4 GHz, Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology and Intel® Advanced Vector Extensions 512 (Intel® AVX-512). They also support Intel® Deep Learning Boost. These new VM sizes will have 50% larger local storage, as well as better local disk IOPS for both read and write compared to the Dv3/Dsv3 sizes with Gen2 VMs.

D-series use cases include enterprise-grade applications, relational databases, in-memory caching, and analytics.

## Ddv4-series

Ddv4-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake). The Ddv4-series offer a combination of vCPU, memory and temporary disk for most production workloads.

The new Ddv4 VM sizes include fast, larger local SSD storage (up to 2,400 GiB) and are designed for applications that benefit from low latency, high-speed local storage, such as applications that require fast reads/ writes to temp storage or that need temp storage for caches or temporary files. You can attach Standard SSDs and Standard HDDs storage to the Ddv4 VMs. Remote Data disk storage is billed separately from virtual machines.

# Dv5 and Dsv5-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dv5 and Dsv5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a [hyper threaded](#) configuration, providing a better value proposition for most general-purpose workloads. This new processor features an all core turbo clock speed of 3.5 GHz with [Intel® Turbo Boost Technology](#), [Intel® Advanced-Vector Extensions 512 \(Intel® AVX-512\)](#) and [Intel® Deep Learning Boost](#). These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most enterprise workloads, such as small-to-medium databases, low-to-medium traffic web servers, application servers and more. The Dv5 and Dsv5-series provide a better value proposition for workloads that don't require local temp disk. For information about similar virtual machines with local disk, see [Ddv5 and Ddsv5-series VMs](#).

## NOTE

For frequently asked questions, see [Azure VM sizes with no local temp disk](#).

## Dv5-series

Dv5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor reaching an all core turbo clock speed of up to 3.5 GHz. These virtual machines offer up to 96 vCPU and 384 GiB of RAM. Dv5-series virtual machines provide a better value proposition for most general-purpose workloads compared to the prior generation (for example, increased scalability and an upgraded CPU class).

Dv5-series virtual machines do not have any temporary storage thus lowering the price of entry. You can attach Standard SSDs, and Standard HDDs disk storage to these virtual machines. To use Premium SSD or Ultra Disk storage, select Dsv5-series virtual machines. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

Standard_D96ds_v5	96	384	3600	32	450000/4000	80000/2600	80000/4000	8	35000

\* These IOPs values can be guaranteed by using [Gen2 VMs](#)

<sup>1</sup> Accelerated networking is required and turned on by default on all Ddsv5 virtual machines.

<sup>2</sup> Accelerated networking can be applied to two NICs.

<sup>3</sup> Ddsv5-series virtual machines can [burst](#) their disk performance and get up to their bursting max for up to 30 minutes at a time.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to

## None.

- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Dasv5 and Dadsv5-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dasv5-series and Dadsv5-series utilize AMD's 3rd Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache, increasing customer options for running their general purpose workloads. These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most enterprise workloads, such as small-to-medium databases, low-to-medium traffic web servers, application servers and more.

## Dasv5-series

Dasv5-series VMs utilize AMD's 3rd Generation EPYC™ 7763v processors that can achieve a boosted maximum frequency of 3.5GHz. The Dasv5-series sizes offer a combination of vCPU and memory for most production workloads. The new VMs with no local disk provide a better value proposition for workloads that do not require local temp disk.

### NOTE

For frequently asked questions, see [Azure VM sizes with no local temp disk](#).

Dasv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

**Premium Storage:** Supported

**Premium Storage caching:** Supported

**Live Migration:** Supported

**Memory Preserving Updates:** Supported

**VM Generation Support:** Generation 1 and 2

**Accelerated Networking:** Supported

**Ephemeral OS Disks:** Not Supported

**Nested Virtualization:** Supported

## Dadsv5-series

Dadsv5-series utilize AMD's 3rd Generation EPYC™ 7763v processors that can achieve a boosted maximum frequency of 3.5GHz. The Dadsv5-series sizes offer a combination of vCPU, memory and temporary storage for most production workloads. The new VMs have 50% larger local storage, as well as better local disk IOPS for both read and write compared to the [Dav4/Dasv4](#) sizes with [Gen2](#) VMs.

Dadsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

# DCasv5 and DCadsv5-series confidential VMs

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

The DCasv5-series and DCadsv5-series are [confidential VMs](#) for use in Confidential Computing.

These confidential VMs use AMD's third-Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache. These processors can achieve a boosted maximum frequency of 3.5 GHz. Both series offer Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP). SEV-SNP provides hardware-isolated VMs that protect data from other VMs, the hypervisor, and host management code. Confidential VMs offer hardware-based VM memory encryption. These series also offer OS disk pre-encryption before VM provisioning with different key management solutions.

## DCasv5-series

DCasv5-series VMs offer a combination of vCPU and memory for most production workloads. These VMs with no local disk provide a better value proposition for workloads where you don't need a local temporary disk. For more information, see the [FAQ for Azure VM sizes with no local temporary disk](#).

This series supports Standard SSD, Standard HDD, and Premium SSD disk types. Billing for disk storage and VMs is separate. To estimate your costs, use the [Pricing Calculator](#).

### NOTE

There are some [pricing differences based on your encryption settings](#) for confidential VMs.

### DCasv5-series feature support

*Supported* features in DCasv5-series VMs:

- [Premium Storage](#)
- [Premium Storage caching](#)
- [VM Generation 2](#)

*Unsupported* features in DCasv5-series VMs:

- [Live Migration](#)
- [Memory Preserving Updates](#)
- [Accelerated Networking](#)
- [Ephemeral OS Disks](#)
- [Nested Virtualization](#)

### DCasv5-series products

# Dpsv5 and Dpdsv5-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Dpsv5-series and Dpdsv5-series virtual machines are based on the Arm architecture, delivering outstanding price-performance for general-purpose workloads. These virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer a range of vCPU sizes, up to 4 GiB of memory per vCPU, and temporary storage options able to meet the requirements of scale-out and most enterprise workloads such as web and application servers, small to medium databases, caches, and more.

## Dpsv5-series

Dpsv5-series virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer up to 64 vCPU and 208 GiB of RAM and are optimized for scale-out and most enterprise workloads. Dpsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types with no local-SSD support. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

Accelerated networking is required and turned on by default on all Dplsv5 machines.

## Dpldsv5-series

Dpldsv5-series virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer up to 64 vCPU, 128 GiB of RAM, and fast local SSD storage up to 2,400 GiB built for scale-out, non-memory-intensive workloads that require local disk. Dpldsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all

NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Compute optimized virtual machine sizes

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

Compute optimized VM sizes have a high CPU-to-memory ratio. These sizes are good for medium traffic web servers, network appliances, batch processes, and application servers. This article provides information about the number of vCPUs, data disks, and NICs. It also includes information about storage throughput and network bandwidth for each size in this grouping.

- The [Fsv2-series](#) runs on 2nd Generation Intel® Xeon® Platinum 8272CL (Cascade Lake) processors and Intel® Xeon® Platinum 8168 (Skylake) processors. It features a sustained all core Turbo clock speed of 3.4 GHz and a maximum single-core turbo frequency of 3.7 GHz. Intel® AVX-512 instructions are new on Intel Scalable Processors. These instructions provide up to a 2X performance boost to vector processing workloads on both single and double precision floating point operations. In other words, they're really fast for any computational workload. At a lower per-hour list price, the Fsv2-series is the best value in price-performance in the Azure portfolio based on the Azure Compute Unit (ACU) per vCPU.
- The [FX-series](#) runs on the Intel® Xeon® Gold 6246R (Cascade Lake) processors. It features an all-core-turbo frequency of 4.0GHz, 21GB RAM per vCPU, up to 1TB total RAM, and local temporary storage. It will benefit workloads which require a high CPU clock speed and high memory to CPU ratio, workloads with high per-core licensing costs, and applications requiring high a single-core performance. A typical use case for FX-series is the Electronic Design Automation (EDA) workload.

## Other sizes

# Memory optimized virtual machine sizes

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Memory optimized VM sizes offer a high memory-to-CPU ratio that is great for relational database servers, medium to large caches, and in-memory analytics. This article provides information about the number of vCPUs, data disks and NICs. You can also learn about storage throughput and network bandwidth for each size in this grouping.

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

- **Dv2 and DSv2-series**, a follow-on to the original D-series, features a more powerful CPU. The Dv2-series is about 35% faster than the D-series. It runs on the Intel® Xeon® 8171M 2.1 GHz (Skylake) or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors, and with the Intel Turbo Boost Technology 2.0. The Dv2-series has the same memory and disk configurations as the D-series.

Dv2 and DSv2-series are ideal for applications that demand faster vCPUs, better temporary storage performance, or have higher memory demands. They offer a powerful combination for many enterprise-grade applications.

- The **Eav4 and Easv4-series** utilize AMD's 2.35Ghz EPYC™ 7452 processor in a multi-threaded configuration with up to 256 MB L3 cache, increasing options for running most memory optimized workloads. The Eav4-series and Easv4-series have the same memory and disk configurations as the Ev4 & Esv3-series.
- The **Ebsv5 and Ebdsv5 series** deliver higher remote storage performance in each VM size than the Ev4 series. The increased remote storage performance of the Ebsv5 and Ebdsv5 VMs is ideal for storage throughput-intensive workloads, such as relational databases and data analytics applications.
- The **Ev3 and Esv3-series** feature the Intel® Xeon® 8171M 2.1 GHz (Skylake) or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) processor in a hyper-threaded configuration. This configuration provides a better value proposition for most general purpose workloads, and brings the Ev3 into alignment with the general purpose VMs of most other clouds. Memory has been expanded (from 7 GiB/vCPU to 8 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyper-threading. The Ev3 is the follow up to the high memory VM sizes of the D/Dv2 families.
- The **Ev4 and Esv4-series** runs on 2nd Generation Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, are ideal for various memory-intensive enterprise applications and feature up to 504 GiB of RAM. It features the [Intel® Turbo Boost Technology 2.0](#), [Intel® Hyper-Threading Technology](#) and [Intel® Advanced Vector Extensions 512 \(Intel AVX-512\)](#). The Ev4 and Esv4-series don't include a local temp disk. For more information, see [Azure VM sizes with no local temp disk](#).
- The **Edv4 and Edsv4-series** runs on 2nd Generation Intel® Xeon® Platinum 8272CL (Cascade Lake) processors, ideal for extremely large databases or other applications that benefit from high vCPU counts and large amounts of memory. Additionally, these VM sizes include fast, larger local SSD storage for applications that benefit from low latency, high-speed local storage. It features an all core Turbo clock

speed of 3.4 GHz, Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology and Intel® Advanced Vector Extensions 512 (Intel AVX-512).

- The [Easv5 and Eadsv5-series](#) utilize AMD's 3rd Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache, increasing customer options for running most memory optimized workloads. These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most memory-intensive enterprise applications, such as relational database servers and in-memory analytics workloads.
- The [Edv5 and Edsv5-series](#) run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processors in a hyper-threaded configuration. These series are ideal for various memory-intensive enterprise applications. They feature up to 672 GiB of RAM, Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology and Intel® Advanced Vector Extensions 512 (Intel® AVX-512). The series also support Intel® Deep Learning Boost. These new VM sizes have 50% larger local storage, and better local disk IOPS for both read and write compared to the [Ev3/Esv3](#) sizes with [Gen2 VMs](#). It features an all core Turbo clock speed of 3.4 GHz.
- The [Epsv5 and Epdsv5-series](#) are ARM64-based VMs featuring the 80 core, 3.0 GHz Ampere Altra processor. These series are designed for common enterprise workloads. They're optimized for database, in-memory caching, analytics, gaming, web, and application servers running on Linux.
- The [Ev5 and Esv5-series](#) runs on the Intel® Xeon® Platinum 8272CL (Ice Lake) processors in a hyper-threaded configuration, are ideal for various memory-intensive enterprise applications and feature up to 512 GiB of RAM. It features an all core Turbo clock speed of 3.4 GHz.
- The [M-series](#) offers a high vCPU count (up to 128 vCPUs) and a large amount of memory (up to 3.8 TiB). It's also ideal for extremely large databases or other applications that benefit from high vCPU counts and large amounts of memory.
- The [Mv2-series](#) offers the highest vCPU count (up to 416 vCPUs) and largest memory (up to 11.4 TiB) of any VM in the cloud. It's ideal for extremely large databases or other applications that benefit from high vCPU counts and large amounts of memory.

Azure Compute offers virtual machine sizes that are isolated to a specific hardware type and dedicated to a single customer. These virtual machine sizes are best suited for workloads that require a high degree of isolation from other customers for workloads involving elements like compliance and regulatory requirements. Customers can also choose to further subdivide the resources of these isolated virtual machines by using [Azure support for nested virtual machines](#). See the pages for virtual machine families below for your isolated VM options.

<sup>3</sup> Constrained core sizes available.

<sup>4</sup> 25000 Mbps with Accelerated Networking.

## Size table definitions

- Storage capacity is shown in units of GiB or 1024<sup>3</sup> bytes. When you compare disks measured in GB

( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.

- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Ev3 and Esv3-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Ev3 and Esv3-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) processor in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads, and bringing the Ev3 into alignment with the general purpose VMs of most other clouds. Memory has been expanded (from 7 GiB/vCPU to 8 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Ev3 is the follow up to the high memory VM sizes of the D/Dv2 families.

## Ev3-series

Ev3-series instances run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) processors, and feature Intel Turbo Boost Technology 2.0. Ev3-series instances are ideal for memory-intensive enterprise applications.

Data disk storage is billed separately from virtual machines. To use premium storage disks, use the ESv3 sizes. The pricing and billing meters for ESv3 sizes are the same as Ev3-series.

Ev3-series VM's feature Intel® Hyper-Threading Technology.

# Edv4 and Edsv4-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Edv4 and Edsv4-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, and are ideal for various memory-intensive enterprise applications and feature up to 504 GiB of RAM, [Intel® Turbo Boost Technology 2.0](#), [Intel® Hyper-Threading Technology](#) and [Intel® Advanced Vector Extensions 512 \(Intel® AVX-512\)](#). They also support [Intel® Deep Learning Boost](#). These new VM sizes will have 50% larger local storage, as well as better local disk IOPS for both read and write compared to the [Ev3/Esv3](#) sizes with [Gen2](#) VMs. It features an all core Turbo clock speed of 3.4 GHz.

## Edv4-series

Edv4-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors. The Edv4 virtual machine sizes feature up to 504 GiB of RAM, in addition to fast and large local SSD storage (up to 2,400 GiB). These virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage. You can attach Standard SSDs and Standard HDDs disk storage to the Edv4 VMs.

<sup>3</sup> Instance is isolated to hardware dedicated to a single customer.

<sup>4</sup> Accelerated networking can only be applied to a single NIC.

<sup>5</sup> Attaching Ultra Disk or Premium v2 SSDs to **Standard\_E80ids\_v4** results in higher IOPs and MBps than standard premium disks:

- Max uncached Ultra Disk and Premium v2 SSD throughput (IOPS/ MBps): 120000/1800
- Max burst uncached Ultra Disk and Premium v2 SSD disk throughput (IOPS/ MBps): 120000/2000

## Size table definitions

- Storage capacity is shown in units of GiB or 1024^3 bytes. When you compare disks measured in GB (1000^3 bytes) to disks measured in GiB (1024^3) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.

- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Ev4 and Esv4-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Ev4 and Esv4-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, are ideal for various memory-intensive enterprise applications and feature up to 504GiB of RAM. It features an all core Turbo clock speed of 3.4 GHz.

## NOTE

For frequently asked questions, refer to [Azure VM sizes with no local temp disk](#).

## Ev4-series

Ev4-series sizes run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel Xeon® Platinum 8272CL (Cascade Lake). The Ev4-series instances are ideal for memory-intensive enterprise applications. Ev4-series VMs feature Intel® Hyper-Threading Technology.

Remote Data disk storage is billed separately from virtual machines. To use premium storage disks, use the Esv4 sizes. The pricing and billing meters for Esv4 sizes are the same as Ev4-series.

# Ev5 and Esv5-series

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Ev5 and Esv5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a [hyper threaded](#) configuration, providing a better value proposition for most general-purpose workloads. This new processor features an all core turbo clock speed of 3.5 GHz with [Intel® Turbo Boost Technology](#), [Intel® Advanced-Vector Extensions 512 \(Intel® AVX-512\)](#) and [Intel® Deep Learning Boost](#). Featuring up to 672 GiB of RAM, these virtual machines are ideal for memory-intensive enterprise applications, relational database servers, and in-memory analytics workloads. The Ev5 and Esv5-series provide a better value proposition for workloads that don't require local temp disk. For information about similar virtual machines with local disk, see [Edv5 and Edsv5-series VMs](#).

## NOTE

For frequently asked questions, see [Azure VM sizes with no local temp disk](#).

## Ev5-series

Ev5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor reaching an all core turbo clock speed of up to 3.5 GHz. These virtual machines offer up to 104 vCPU and 672 GiB of RAM. Ev5-series virtual machines don't have temporary storage thus lowering the price of entry.

Ev5-series supports Standard SSD and Standard HDD disk types. To use Premium SSD or Ultra Disk storage, select Esv5-series virtual machines. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

# Ebdsv5 and Ebsv5 series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The memory-optimized Ebsv5 and Ebdsv5 Azure virtual machine (VM) series deliver higher remote storage performance in each VM size than the [Ev4 series](#). The increased remote storage performance of the Ebsv5 and Ebdsv5 VMs is ideal for storage throughput-intensive workloads. For example, relational databases and data analytics applications.

The Ebsv5 and Ebdsv5 VMs offer up to 120000 IOPS and 4000 MBps of remote disk storage throughput. Both series also include up to 512 GiB of RAM. The Ebdsv5 series has local SSD storage up to 2400 GiB. Both series provide a 3X increase in remote storage performance of data-intensive workloads compared to prior VM generations. You can use these series to consolidate existing workloads on fewer VMs or smaller VM sizes while achieving potential cost savings. The Ebdsv5 series comes with a local disk and Ebsv5 is without a local disk. Standard SSDs and Standard HDD disk storage aren't supported in the Ebsv5 series.

The Ebdsv5 and Ebsv5 series run on the Intel® Xeon® Platinum 8370C (Ice Lake) processors in a hyper-threaded configuration. The series are ideal for various memory-intensive enterprise applications. They feature:

- Up to 512 GiB of RAM
- [Intel® Turbo Boost Technology 2.0](#)
- [Intel® Hyper-Threading Technology](#)
- [Intel® Advanced Vector Extensions 512 \(Intel® AVX-512\)](#)
- Support for [Intel® Deep Learning Boost](#)

## IMPORTANT

- Accelerated networking is required and turned on by default on all Ebsv5 and Ebdsv5 VMs.
- Accelerated networking can be applied to two NICs.
- Ebsv5 and Ebdsv5-series VMs can [burst their disk performance](#) and get up to their bursting max for up to 30 minutes at a time.

## Ebdsv5 series

Ebdsv5-series sizes run on the Intel® Xeon® Platinum 8370C (Ice Lake) processors. The Ebdsv5 VM sizes feature up to 512 GiB of RAM, in addition to fast and large local SSD storage (up to 2400 GiB). These VMs are ideal for memory-intensive enterprise applications and applications that benefit from high remote storage performance, low latency, high-speed local storage. Remote Data disk storage is billed separately from VMs.

- [Premium Storage](#): Supported

The Edv5 and Edsv5-series Virtual Machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a [hyper threaded](#) configuration, providing a better value proposition for most general-purpose workloads. This new processor features an all core turbo clock speed of 3.5 GHz with [Intel® Turbo Boost Technology](#), [Intel® Advanced-Vector Extensions 512 \(Intel® AVX-512\)](#) and [Intel® Deep Learning Boost](#). Featuring up to 672 GiB of RAM, these virtual machines are ideal for memory-intensive enterprise applications, relational database servers, and in-memory analytics workloads. These VMs also feature fast and large local SSD storage (up to 3,900 GiB).

## Edv5-series

Edv5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor reaching an all core turbo clock speed of up to 3.5 GHz. These virtual machines offer up to 104 vCPU and 672 GiB of RAM and fast, local SSD storage up to 3800 GiB. Edv5-series virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage.

Edv5-series virtual machines support Standard SSD and Standard HDD disk types. To use Premium SSD or Ultra Disk storage, select Edsv5-series virtual machines. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

<sup>3</sup> [Constrained Core](#) sizes available.

<sup>4</sup> Instance is [isolated](#) to hardware dedicated to a single customer.

<sup>5</sup> Edsv5-series virtual machines can [burst](#) their disk performance and get up to their bursting max for up to 30

minutes at a time.

<sup>6</sup> Attaching Ultra Disk or Premium v2 SSDs to **Standard\_E104ids\_v5** results in higher IOPs and MBps than standard premium disks:

- Max uncached Ultra Disk and Premium v2 SSD throughput (IOPS/ MBps): 160000/4000
- Max burst uncached Ultra Disk and Premium v2 SSD disk throughput (IOPS/ MBps): 160000/4000

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Easv5 and Eadsv5-series

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Easv5-series and Eadsv5-series utilize AMD's 3rd Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache, increasing customer options for running most memory optimized workloads. These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most memory-intensive enterprise applications, such as relational database servers and in-memory analytics workloads.

## Easv5-series

Easv5-series utilize AMD's 3rd Generation EPYC™ 7763v processors that can achieve a boosted maximum frequency of 3.5GHz. The Easv5-series sizes offer a combination of vCPU and memory that is ideal for memory-intensive enterprise applications. The new VMs with no local disk provide a better value proposition for workloads that do not require local temp disk.

### NOTE

For frequently asked questions, see [Azure VM sizes with no local temp disk](#).

Easv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

## Eadsv5-series

Eadsv5-series utilize AMD's 3rd Generation EPYC™ 7763v processors that can achieve a boosted maximum frequency of 3.5GHz. The Eadsv5-series sizes offer a combination of vCPU, memory and temporary storage that is ideal for memory-intensive enterprise applications. The new VMs have 50% larger local storage, as well as better local disk IOPS for both read and write compared to the [Eav4/Easv4](#) sizes with [Gen2](#) VMs.

Eadsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual

machines. [See pricing for disks](#).

# ECasv5 and ECadsv5-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

The ECasv5-series and ECadsv5-series are [confidential VMs](#) for use in Confidential Computing.

These confidential VMs use AMD's third-Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache. This processor can achieve a boosted maximum frequency of 3.5 GHz. Both series offer Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP). SEV-SNP provides hardware-isolated VMs that protect data from other VMs, the hypervisor, and host management code. Confidential VMs offer hardware-based VM memory encryption. These series also offer OS disk pre-encryption before VM provisioning with different key management solutions.

These VM series also offer a combination of vCPUs and memory to meet the requirements of most memory-intensive enterprise applications.

## ECasv5-series

ECasv5-series VMs offer a combination of vCPU and memory for memory-intensive enterprise applications.

These VMs with no local disk provide a better value proposition for workloads where you don't need a local temp disk. For more information, see the [FAQ for Azure VM sizes with no local temporary disk](#).

This series supports Standard SSD, Standard HDD, and Premium SSD disk types. Billing for disk storage and VMs is separate. To estimate your costs, use the [Pricing Calculator](#).

### NOTE

There are some [pricing differences based on your encryption settings](#) for confidential VMs.

### ECasv5-series feature support

*Supported* features in ECasv5-series VMs:

- [Premium Storage](#)
- [Premium Storage caching](#)
- [VM Generation 2](#)

*Unsupported* features in ECasv5-series VMs:

- [Live Migration](#)
- [Memory Preserving Updates](#)
- [Accelerated Networking](#)
- [Ephemeral OS Disks](#)
- [Nested Virtualization](#)

### ECasv5-series products

# Epsv5 and Epdsv5-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Epsv5-series and Epdsv5-series virtual machines are based on the Arm architecture, delivering outstanding price-performance for memory-intensive workloads. These virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer a range of vCPU sizes, up to 8 GiB of memory per vCPU, and are best suited for memory-intensive scale-out and enterprise workloads, such as relational database servers, large databases, data analytics engines, in-memory caches, and more.

## Epsv5-series

Epsv5-series virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer up to 32 vCPU and 208 GiB of RAM and are ideal for memory-intensive scale-out and most Enterprise workloads. Epsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types with no local-SSD support. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

## EpdsV5-series

EpdsV5-series virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer up to 32 vCPU, 208 GiB of RAM, and fast local SSD storage up to 1,200 GiB and are ideal for memory-intensive scale-out and most Enterprise workloads. EpdsV5-series virtual machines support Standard SSD, Standard HDD, and premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. [See pricing for disks](#).

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see

Bandwidth/Throughput testing (NTTCP).

# M-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The M-series offers a high vCPU count (up to 128 vCPUs) and a large amount of memory (up to 3.8 TiB). It's also ideal for extremely large databases or other applications that benefit from high vCPU counts and large amounts of memory. M-series sizes are supported both on the Intel® Xeon® CPU E7-8890 v3 @ 2.50GHz and on the Intel® Xeon® Platinum 8280M (Cascade Lake).

M-series VM's feature Intel® Hyper-Threading Technology.

# Msv2 and Mdsv2-series Medium Memory

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Msv2 and Mdsv2 Medium Memory VM Series features Intel® Xeon® Platinum 8280 (Cascade Lake) processor with an all core base frequency of 2.7 GHz and 4.0 GHz single core turbo frequency. With these VMs, customers achieve increased flexibility with local disk and diskless options. Customers also have access to a set of new isolated VM sizes with more CPU and memory that go up to 192 vCPU with 4 TiB of memory.

## NOTE

Msv2 and Mdsv2 Medium Memory VMs are generation 2 only. For more information on generation 2 virtual machines, see [Support for generation 2 VMs on Azure](#).

# Mv2-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The Mv2-series features high throughput, low latency platform running on a hyper-threaded Intel® Xeon® Platinum 8180M 2.5GHz (Skylake) processor with an all core base frequency of 2.5 GHz and a max turbo frequency of 3.8 GHz. All Mv2-series virtual machine sizes can use both standard and premium persistent disks. Mv2-series instances are memory optimized VM sizes providing unparalleled computational performance to support large in-memory databases and workloads, with a high memory-to-CPU ratio that is ideal for relational database servers, large caches, and in-memory analytics.

# Constrained vCPU capable VM sizes

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## TIP

Try the [Virtual Machine selector tool](#) to find other sizes that best fit your workload.

Some database workloads like SQL Server require high memory, storage, and I/O bandwidth, but not a high core count. Many database workloads are not CPU-intensive. Azure offers certain VM sizes where you can lower the VM vCPU count to reduce the cost of software licensing, while maintaining the same memory, storage, and I/O bandwidth.

The available vCPU count can be reduced to one half or one quarter of the original VM specification. These new VM sizes have a suffix that specifies the number of available vCPUs to make them easier for you to identify. There are no additional cores available that can be used by the VM.

For example, the current VM size Standard\_E32s\_v5 comes with 32 vCPUs, 256 GiB RAM, 32 disks, and 80,000 IOPs or 2 GB/s of I/O bandwidth. The new VM sizes Standard\_E32-16s\_v5 and Standard\_E32-8s\_v5 comes with 16 and 8 active vCPUs respectively, while maintaining the rest of the specs of the Standard\_E32s\_v5 for memory, storage, and I/O bandwidth.

The licensing fees charged for SQL Server are based on the avaialble vCPU count. Third party products should count the available vCPU which represents the max to be used and licensed. This results in a 50% to 75% increase in the ratio of the VM specs to available (billable) vCPUs. These new VM sizes allow customer workloads to use the same memory, storage, and I/O bandwidth while optimizing their software licensing cost. At this time, the compute cost, which includes OS licensing, remains the same one as the original size. For more information, see [Azure VM sizes for more cost-effective database workloads](#).

# Storage optimized virtual machine sizes

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Storage optimized virtual machine (VM) sizes offer high disk throughput and IO, and are ideal for Big Data, SQL, NoSQL databases, data warehousing, and large transactional databases. Examples include Cassandra, MongoDB, Cloudera, and Redis. This article provides information about the number of vCPUs, data disks, NICs, local storage throughput, and network bandwidth for each optimized size.

## TIP

Try the [virtual machines selector tool](#) to find other sizes that best fit your workload.

The Lsv3, Lasv3, and Lsv2-series feature high-throughput, low latency, directly mapped local NVMe storage. These VM series come in sizes from 8 to 80 vCPU. There are 8 GiB of memory per vCPU, and one 1.92TB NVMe SSD device per 8 vCPUs, with up to 19.2TB (10x1.92TB) available on the largest VM sizes.

- The [Lsv3-series](#) runs on the third Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a [hyper-threaded configuration](#). This new processor features an all-core turbo clock speed of 3.5 GHz with [Intel® Turbo Boost Technology](#), [Intel® Advanced-Vector Extensions 512 \(Intel® AVX-512\)](#) and [Intel® Deep Learning Boost](#).
- The [Lasv3-series](#) runs on the AMD 3rd Generation EPYC™ 7763v processor. This series runs in a multi-threaded configuration with up to 256 MB L3 cache, which can achieve a boosted maximum frequency of 3.5 GHz.
- The [Lsv2-series](#) runs on the [AMD EPYC™ 7551 processor](#) with an all-core boost of 2.55 GHz and a max boost of 3.0 GHz.

# Lsv2-series

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale sets

The Lsv2-series features high throughput, low latency, directly mapped local NVMe storage running on the [AMD EPYC™ 7551 processor](#) with an all core boost of 2.55GHz and a max boost of 3.0GHz. The Lsv2-series VMs come in sizes from 8 to 80 vCPU in a simultaneous multi-threading configuration. There is 8 GiB of memory per vCPU, and one 1.92TB NVMe SSD M.2 device per 8 vCPUs, with up to 19.2TB (10x1.92TB) available on the L80s v2.

## NOTE

The Lsv2-series VMs are optimized to use the local disk on the node attached directly to the VM rather than using durable data disks. This allows for greater IOPs / throughput for your workloads. The Lsv2 and Ls-series do not support the creation of a local cache to increase the IOPs achievable by durable data disks.

The high throughput and IOPs of the local disk makes the Lsv2-series VMs ideal for NoSQL stores such as Apache Cassandra and MongoDB which replicate data across multiple VMs to achieve persistence in the event of the failure of a single VM.

To learn more, see Optimize performance on the Lsv2-series virtual machines for [Windows](#) or [Linux](#).

<sup>1</sup> Lsv2-series VMs have a standard SCSI based temp resource disk for OS paging/swap file use (D: on Windows, /dev/sdb on Linux). This disk provides 80 GiB of storage, 4,000 IOPS, and 80 MBps transfer rate for every 8 vCPUs (e.g. Standard\_L80s\_v2 provides 800 GiB at 40,000 IOPS and 800 MBPS). This ensures the NVMe drives can be fully dedicated to application use. This disk is Ephemeral, and all data will be lost on stop/deallocate.

<sup>2</sup> Local NVMe disks are ephemeral, data will be lost on these disks if you stop/deallocate your VM. Local NVMe disks aren't encrypted by [Azure Storage encryption](#), even if you enable [encryption at host](#).

<sup>3</sup> Hyper-V NVMe Direct technology provides unthrottled access to local NVMe drives mapped securely into the guest VM space. Achieving maximum performance requires using either the latest WS2019 build or Ubuntu 18.04 or 16.04 from the Azure Marketplace. Write performance varies based on IO size, drive load, and capacity utilization.

<sup>4</sup> Lsv2-series VMs do not provide host cache for data disk as it does not benefit the Lsv2 workloads.

<sup>5</sup> Lsv2-series VMs can [burst](#) their disk performance for up to 30 minutes at a time.

<sup>6</sup> VMs with more than 64 vCPUs require one of these supported guest operating systems:

- Windows Server 2016 or later
- Ubuntu 16.04 LTS or later, with Azure tuned kernel (4.15 kernel or later)
- SLES 12 SP2 or later
- RHEL or CentOS version 6.7 through 6.10, with Microsoft-provided LIS package 4.3.1 (or later) installed
- RHEL or CentOS version 7.3, with Microsoft-provided LIS package 4.2.1 (or later) installed
- RHEL or CentOS version 7.6 or later
- Oracle Linux with UEF4 or later
- Debian 9 with the backports kernel, Debian 10 or later
- CoreOS with a 4.14 kernel or later

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When comparing disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- If you want to get the best performance for your VMs, you should limit the number of data disks to 2 disks per vCPU.
- **Expected network bandwidth** is the maximum aggregated [bandwidth allocated per VM type](#) across all NICs, for all destinations. Upper limits are not guaranteed, but are intended to provide guidance for selecting the right VM type for the intended application. Actual network performance will depend on a variety of factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimizing network throughput for Windows and Linux](#). To achieve the expected network performance on Linux or Windows, it may be necessary to select a specific version or optimize your VM. For more information, see [How to reliably test for virtual machine throughput](#).

- Temp disk:** Lsv3-series VMs have a standard SCSI-based temp resource disk for use by the OS paging or swap file (`D:` on Windows, `/dev/sdb` on Linux). This disk provides 80 GiB of storage, 4,000 IOPS, and 80 MBps transfer rate for every 8 vCPUs. For example, Standard\_L80s\_v3 provides 800 GiB at 40000 IOPS and 800 MBPS. This configuration ensures the NVMe drives can be fully dedicated to application use. This disk is ephemeral, and all data is lost on stop or deallocation.
- NVMe Disks:** NVMe disk throughput can go higher than the specified numbers. However, higher performance isn't guaranteed. Local NVMe disks are ephemeral. Data is lost on these disks if you stop or deallocate your VM. Local NVMe disks aren't encrypted by [Azure Storage encryption](#), even if you enable [encryption at host](#).
- NVMe Disk throughput:** Hyper-V NVMe Direct technology provides unthrottled access to local NVMe drives mapped securely into the guest VM space. Lsv3 NVMe disk throughput can go higher than the specified numbers, but higher performance isn't guaranteed. To achieve maximum performance, see how to optimize performance on the Lsv3-series [Windows-based VMs](#) or [Linux-based VMs](#). Read/write performance varies based on IO size, drive load, and capacity utilization.
- Max burst uncached data disk throughput:** Lsv3-series VMs can [burst their disk performance](#) for up to 30 minutes at a time.

#### NOTE

Lsv3-series VMs don't provide host cache for data disk as it doesn't benefit the Lsv3 workloads.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may

appear smaller. For example, 1023 GiB = 1098.4 GB.

- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). - Temp disk:** Lasv3-series VMs have a standard SCSI-based temp resource disk for use by the OS paging or swap file (`D:` on Windows, `/dev/sdb` on Linux). This disk provides 80 GiB of storage, 4000 IOPS, and 80 MBps transfer rate for every 8 vCPUs. For example, Standard\_L80as\_v3 provides 800 GiB at 40000 IOPS and 800 MBPS. This configuration ensures that the NVMe drives can be fully dedicated to application use. This disk is ephemeral, and all data is lost on stop or deallocation.
- NVMe Disks:** NVMe disk throughput can go higher than the specified numbers. However, higher performance isn't guaranteed. Local NVMe disks are ephemeral. Data is lost on these disks if you stop or deallocate your VM. Local NVMe disks aren't encrypted by [Azure Storage encryption](#), even if you enable [encryption at host](#).
- NVMe Disk throughput:** Hyper-V NVMe Direct technology provides unthrottled access to local NVMe drives mapped securely into the guest VM space. Lasv3 NVMe disk throughput can go higher than the specified numbers, but higher performance isn't guaranteed. To achieve maximum performance, see how to optimize performance on Lasv3-series [Windows-based VMs](#) or [Linux-based VMs](#). Read/write performance varies based on IO size, drive load, and capacity utilization.
- Max burst uncached data disk throughput:** Lasv3-series VMs can [burst their disk performance](#) for up to 30 minutes at a time.

#### NOTE

Lasv3-series VMs don't provide a host cache for the data disk because this configuration doesn't benefit the Lasv3 workloads.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =

$10^6$  bytes/sec.

- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# Optimize performance on Lsv3, Lasv3, and Lsv2-series Linux VMs

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Uniform scale sets

Lsv3, Lasv3, and Lsv2-series Azure Virtual Machines (Azure VMs) support various workloads that need high I/O and throughput on local storage across a wide range of applications and industries. The L-series is ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases, including Cassandra, MongoDB, Cloudera, and Redis.

Several builds are available Azure Marketplace due to work with partners in Linux. These builds are optimized for Lsv3, Lasv3, and Lsv2-series performance. Available builds include the following and later versions of:

- Ubuntu 16.04
- RHEL 8.0 and clones, including CentOS, Rocky Linux, and Alma Linux
- Debian 9
- SUSE Linux 15
- Oracle Linux 8.0

This article provides tips and suggestions to ensure your workloads and applications achieve the maximum performance designed into the VMs.

## AMD EPYC™ chipset architecture

Lasv3 and Lsv2-series VMs use AMD EPYC™ server processors based on the Zen micro-architecture. AMD developed Infinity Fabric (IF) for EPYC™ as scalable interconnect for its NUMA model that can be used for on-die, on-package, and multi-package communications. Compared with QPI (Quick-Path Interconnect) and UPI (Ultra-Path Interconnect) used on Intel modern monolithic-die processors, AMD's many-NUMA small-die architecture can bring both performance benefits and challenges. The actual effects of memory bandwidth and latency constraints might vary depending on the type of workloads running.

## Tips to maximize performance

- If you're uploading a custom Linux GuestOS for your workload, Accelerated Networking is turned off by default. If you intend to enable Accelerated Networking, enable it at the time of VM creation for best performance.
- To gain max performance, run multiple jobs with deep queue depth per device.
- Avoid mixing NVMe admin commands (for example, NVMe SMART info query, etc.) with NVMe I/O commands during active workloads. Lsv3, Lasv3, and Lsv2 NVMe devices are backed by Hyper-V NVMe Direct technology, which switches into "slow mode" whenever any NVMe admin commands are pending. Lsv3, Lasv3, and Lsv2 users might see a dramatic performance drop in NVMe I/O performance if that happens.
- Lsv2 users aren't recommended to rely on device NUMA information (all 0) reported from within the VM for data drives to decide the NUMA affinity for their apps. The recommended way for better performance is to spread workloads across CPUs if possible.
- The maximum supported queue depth per I/O queue pair for Lsv3, Lasv3, and Lsv2 VM NVMe device is 1024. Lsv3, Lasv3, and Lsv2 users are recommended to limit their (synthetic) benchmarking workloads to queue depth 1024 or lower to avoid triggering queue full conditions, which can reduce performance.

- The best performance is obtained when I/O is done directly to each of the raw NVMe devices with no partitioning, no file systems, no RAID config, etc. Before starting a testing session, ensure the configuration is in a known fresh/clean state by running `blkdiscard` on each of the NVMe devices.

## Utilizing local NVMe storage

Local storage on the 1.92 TB NVMe disk on all Lsv3, Lasv3, and Lsv2 VMs is ephemeral. During a successful standard reboot of the VM, the data on the local NVMe disk persists. The data doesn't persist on the NVMe if the VM is redeployed, de-allocated, or deleted. Data doesn't persist if another issue causes the VM, or the hardware it's running on, to become unhealthy. When scenario happens, any data on the old host is securely erased.

There are also cases when the VM needs to be moved to a different host machine, for example, during a planned maintenance operation. Planned maintenance operations and some hardware failures can be anticipated with [Scheduled Events](#). Use Scheduled Events to stay updated on any predicted maintenance and recovery operations.

In the case that a planned maintenance event requires the VM to be recreated on a new host with empty local disks, the data needs to be resynchronized (again, with any data on the old host being securely erased). This scenario occurs because Lsv3, Lasv3, and Lsv2-series VMs don't currently support live migration on the local NVMe disk.

There are two modes for planned maintenance.

### **Standard VM customer-controlled maintenance**

- The VM is moved to an updated host during a 30-day window.
- Lsv3, Lasv3, and Lsv2 local storage data could be lost, so backing-up data prior to the event is recommended.

### **Automatic maintenance**

- Occurs if the customer doesn't execute customer-controlled maintenance, or because of emergency procedures, such as a security zero-day event.
- Intended to preserve customer data, but there's a small risk of a VM freeze or reboot.
- Lsv3, Lasv3, and Lsv2 local storage data could be lost, so backing-up data prior to the event is recommended.

For any upcoming service events, use the controlled maintenance process to select a time most convenient to you for the update. Prior to the event, back up your data in premium storage. After the maintenance event completes, you can return your data to the refreshed Lsv3, Lasv3, and Lsv2 VMs local NVMe storage.

Scenarios that maintain data on local NVMe disks include:

- The VM is running and healthy.
- The VM is rebooted in place (by you or Azure).
- The VM is paused (stopped without de-allocation).
- Most the planned maintenance servicing operations.

Scenarios that securely erase data to protect the customer include:

- The VM is redeployed, stopped (de-allocated), or deleted (by you).
- The VM becomes unhealthy and has to service heal to another node due to a hardware issue.
- A few of the planned maintenance servicing operations that require the VM to be reallocated to another host for servicing.

## Frequently asked questions

The following are frequently asked questions about these series.

### **How do I start deploying L-series VMs?**

Much like any other VM, use the [Portal](#), [Azure CLI](#), or [PowerShell](#) to create a VM.

### **Does a single NVMe disk failure cause all VMs on the host to fail?**

If a disk failure is detected on the hardware node, the hardware is in a failed state. When this problem occurs, all VMs on the node are automatically de-allocated and moved to a healthy node. For Lsv3, Lasv3, and Lsv2-series VMs, this problem means that the customer's data on the failing node is also securely erased. The customer needs to recreate the data on the new node.

### **Do I need to change the blk\_mq settings?**

RHEL/CentOS 7.x automatically uses blk-mq for the NVMe devices. No configuration changes or settings are necessary.

## **Next steps**

See specifications for all [VMs optimized for storage performance](#) on Azure

# Optimize performance on Lsv3, Lasv3, and Lsv2-series Windows VMs

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Uniform scale sets

Lsv3, Lasv3, and Lsv2-series Azure Virtual Machines (Azure VMs) support various workloads that need high I/O and throughput on local storage across a wide range of applications and industries. The L-series is ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases, including Cassandra, MongoDB, Cloudera, and Redis.

Lsv3, Lasv3, and Lsv2-series VMs are designed to work with the needs of Windows and Linux operating systems for better performance with hardware and the software.

Software and hardware tuning resulted in the optimized version of [Windows Server 2019 Datacenter](#), released to the Azure Marketplace (and later versions), which support maximum performance on the NVMe devices in L-series VMs.

This article provides tips and suggestions to ensure your workloads and applications achieve the maximum performance designed into the VMs.

## AMD EPYC™ chipset architecture

Lasv3 and Lsv2-series VMs use AMD EPYC™ server processors based on the Zen micro-architecture. AMD developed Infinity Fabric (IF) for EPYC™ as a scalable interconnect for its NUMA model that can be used for on-die, on-package, and multi-package communications. Compared with QPI (Quick-Path Interconnect) and UPI (Ultra-Path Interconnect), used on Intel modern monolithic-die processors, AMD's many-NUMA small-die architecture can bring both performance benefits and challenges. The actual effects of memory bandwidth and latency constraints can vary depending on the type of workloads.

## Tips for maximizing performance

- To gain max performance, run multiple jobs with deep queue depth per device.
- Avoid mixing NVMe admin commands (for example, NVMe SMART info query) with NVMe I/O commands during active workloads. Lsv3, Lasv3, and Lsv2 NVMe devices are backed by Hyper-V NVMe Direct technology, which switches into "slow mode" whenever any NVMe admin commands are pending. Lsv3, Lasv3, and Lsv2 users might see a dramatic performance drop in NVMe I/O performance if that scenario happens.
- It's not recommended for Lsv2 users to rely on device NUMA information (all 0) reported from within the VM for data drives to decide the NUMA affinity for their apps. For better performance, it's recommended to spread workloads across CPUs if possible.
- The maximum supported queue depth per I/O queue pair for Lsv3, Lasv3, and Lsv2 VM NVMe device is 1024. Lsv3, Lasv3, and Lsv2 users are recommended to limit their (synthetic) benchmarking workloads to queue depth 1024 or lower to avoid triggering queue full conditions, which can reduce performance.
- The best performance is obtained when I/O is done directly to each of the raw NVMe devices with no partitioning, no file systems, no RAID config, etc.

# Utilizing local NVMe storage

Local storage on the 1.92 TB NVMe disk on all Lsv3, Lasv3, and Lsv2 VMs is ephemeral. During a successful standard reboot of the VM, the data on the local NVMe disk persists. The data doesn't persist on the NVMe if the VM is redeployed, deallocated, or deleted. Data doesn't persist if another issue causes the VM, or the hardware on which the VM is running, to become unhealthy. When this scenario happens, any data on the old host is securely erased.

There are also cases when the VM needs to be moved to a different host machine; for example, during a planned maintenance operation. Planned maintenance operations and some hardware failures can be anticipated with [Scheduled Events](#). Use Scheduled Events to stay updated on any predicted maintenance and recovery operations.

In the case that a planned maintenance event requires the VM to be recreated on a new host with empty local disks, the data needs to be resynchronized (again, with any data on the old host being securely erased). This scenario occurs because Lsv3, Lasv3, and Lsv2-series VMs don't currently support live migration on the local NVMe disk.

There are two modes for planned maintenance: [standard VM customer-controlled maintenance](#) and [automatic maintenance](#).

For any upcoming service events, use the controlled maintenance process to select a time most convenient to you for the update. Prior to the event, back up your data in premium storage. After the maintenance event completes, return your data to the refreshed Lsv2 VMs local NVMe storage.

Scenarios that maintain data on local NVMe disks include when:

- The VM is running and healthy.
- The VM is rebooted in place by you or by Azure.
- The VM is paused (stopped without deallocation).
- Most planned maintenance servicing operations.

Scenarios that securely erase data to protect the customer include when:

- The VM is redeployed, stopped (deallocated), or deleted by you.
- The VM becomes unhealthy and has to service heal to another node due to a hardware issue.
- A few the planned maintenance servicing operations that require the VM to be reallocated to another host for servicing.

## **Standard VM customer-controlled maintenance**

In standard VM customer-controlled maintenance, the VM is moved to an updated host during a 30-day window.

Lsv3, Lasv3, and Lsv2 local storage data might be lost, so backing-up data prior to the event is recommended.

## **Automatic maintenance**

Automatic maintenance occurs if the customer doesn't execute customer-controlled maintenance. Automatic maintenance can also occur because of emergency procedures, such as a security zero-day event.

This type of maintenance is intended to preserve customer data, but there's a small risk of a VM freeze or reboot.

Lsv3, Lasv3, and Lsv2 local storage data might be lost, so backing-up data prior to the event is recommended.

## Frequently asked questions

The following are frequently asked questions about these series.

## **How do I start deploying L-series VMs?**

Much like any other VM, create a VM using the [Azure portal](#), [through the Azure Command-Line Interface \(Azure CLI\)](#), or [through PowerShell](#).

## **Does a single NVMe disk failure cause all VMs on the host to fail?**

If a disk failure is detected on the hardware node, the hardware is in a failed state. When this problem occurs, all VMs on the node are automatically deallocated and moved to a healthy node. For Lsv3, Lasv3, and Lsv2-series VMs, this scenario means that the customer's data on the failing node is also securely erased. The customer needs to recreate the data on the new node.

## **Do I need to make polling adjustments in Windows Server 2012 or Windows Server 2016?**

NVMe polling is only available on Windows Server 2019 and later versions on Azure.

## **Can I switch back to a traditional interrupt service routine (ISR) model?**

Lasv3, and Lsv2-series VMs are optimized for NVMe polling. Updates are continuously provided to improve polling performance.

## **Can I adjust the polling settings in Windows Server 2019 or later versions?**

The polling settings aren't user adjustable.

## **Next steps**

See specifications for all [VMs optimized for storage performance](#) on Azure.

# GPU optimized virtual machine sizes

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

GPU optimized VM sizes are specialized virtual machines available with single, multiple, or fractional GPUs. These sizes are designed for compute-intensive, graphics-intensive, and visualization workloads. This article provides information about the number and type of GPUs, vCPUs, data disks, and NICs. Storage throughput and network bandwidth are also included for each size in this grouping.

- The [NCv3-series](#) and [NC T4\\_v3-series](#) sizes are optimized for compute-intensive GPU-accelerated applications. Some examples are CUDA and OpenCL-based applications and simulations, AI, and Deep Learning. The NC T4 v3-series is focused on inference workloads featuring NVIDIA's Tesla T4 GPU and AMD EPYC2 Rome processor. The NCv3-series is focused on high-performance computing and AI workloads featuring NVIDIA's Tesla V100 GPU.
- The [ND A100 v4-series](#) size is focused on scale-up and scale-out deep learning training and accelerated HPC applications. The ND A100 v4-series uses 8 NVIDIA A100 TensorCore GPUs, each available with a 200 Gigabit Mellanox InfiniBand HDR connection and 40 GB of GPU memory.
- [NV-series](#) and [NVv3-series](#) sizes are optimized and designed for remote visualization, streaming, gaming, encoding, and VDI scenarios using frameworks such as OpenGL and DirectX. These VMs are backed by the NVIDIA Tesla M60 GPU.
- [NVv4-series](#) VM sizes optimized and designed for VDI and remote visualization. With partitioned GPUs, NVv4 offers the right size for workloads requiring smaller GPU resources. These VMs are backed by the AMD Radeon Instinct MI25 GPU. NVv4 VMs currently support only Windows guest operating system.
- [NDm A100 v4-series](#) virtual machine is a new flagship addition to the Azure GPU family, designed for high-end Deep Learning training and tightly-coupled scale-up and scale-out HPC workloads. The NDm A100 v4 series starts with a single virtual machine (VM) and eight NVIDIA Ampere A100 80GB Tensor Core GPUs.

## Supported operating systems and drivers

To take advantage of the GPU capabilities of Azure N-series VMs, NVIDIA or AMD GPU drivers must be installed.

- For VMs backed by NVIDIA GPUs, the [NVIDIA GPU Driver Extension](#) installs appropriate NVIDIA CUDA or GRID drivers. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the [NVIDIA GPU Driver Extension documentation](#) for supported operating systems and deployment steps. For general information about VM extensions, see [Azure virtual machine extensions and features](#).

Alternatively, you may install NVIDIA GPU drivers manually. See [Install NVIDIA GPU drivers on N-series VMs running Windows](#) or [Install NVIDIA GPU drivers on N-series VMs running Linux](#) for supported operating systems, drivers, installation, and verification steps.

- For VMs backed by AMD GPUs, the [AMD GPU driver extension](#) installs appropriate AMD drivers. Install or

manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. For general information about VM extensions, see [Azure virtual machine extensions and features](#).

Alternatively, you may install AMD GPU drivers manually. See [Install AMD GPU drivers on N-series VMs running Windows](#) for supported operating systems, drivers, installation, and verification steps.

## Deployment considerations

- For availability of N-series VMs, see [Products available by region](#).
- N-series VMs can only be deployed in the Resource Manager deployment model.
- N-series VMs differ in the type of Azure Storage they support for their disks. NC and NV VMs only support VM disks that are backed by Standard Disk Storage (HDD). All other GPU VMs support VM disks that are backed by Standard Disk Storage and Premium Disk Storage (SSD).
- If you want to deploy more than a few N-series VMs, consider a pay-as-you-go subscription or other purchase options. If you're using an [Azure free account](#), you can use only a limited number of Azure compute cores.
- You might need to increase the cores quota (per region) in your Azure subscription, and increase the separate quota for NC, NCv2, NCv3, ND, NDv2, NV, or NVv2 cores. To request a quota increase, [open an online customer support request](#) at no charge. Default limits may vary depending on your subscription category.

# NCv2-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

NCv2-series VMs are powered by NVIDIA Tesla P100 GPUs. These GPUs can provide more than 2x the computational performance of the NC-series. Customers can take advantage of these updated GPUs for traditional HPC workloads such as reservoir modeling, DNA sequencing, protein analysis, Monte Carlo simulations, and others. In addition to the GPUs, the NCv2-series VMs are also powered by Intel Xeon E5-2690 v4 (Broadwell) CPUs.

The NC24rs v2 configuration provides a low latency, high-throughput network interface optimized for tightly coupled parallel computing workloads.

# NCv3-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

NCv3-series VMs are powered by NVIDIA Tesla V100 GPUs. These GPUs can provide 1.5x the computational performance of the NCv2-series. Customers can take advantage of these updated GPUs for traditional HPC workloads such as reservoir modeling, DNA sequencing, protein analysis, Monte Carlo simulations, and others. The NC24rs v3 configuration provides a low latency, high-throughput network interface optimized for tightly coupled parallel computing workloads. In addition to the GPUs, the NCv3-series VMs are also powered by Intel Xeon E5-2690 v4 (Broadwell) CPUs.

**Premium Storage:** Supported

**Premium Storage caching:** Supported

**Ultra Disks:** Supported ([Learn more](#) about availability, usage and performance)

**Live Migration:** Not Supported

**Memory Preserving Updates:** Not Supported

**VM Generation Support:** Generation 1 and 2

**Accelerated Networking:** Not Supported

**Ephemeral OS Disks:** Supported

Nvidia NVLink Interconnect: Not Supported

**Nested Virtualization:** Not Supported

## IMPORTANT

For this VM series, the vCPU (core) quota in your subscription is initially set to 0 in each region. [Request a vCPU quota increase](#) for this series in an [available region](#). These SKUs aren't available to trial or Visual Studio Subscriber Azure subscriptions. Your subscription level might not support selecting or deploying these SKUs.

SIZE	VCPUs	MEMORY: GIB	TEMP STORAGE (SSD) GIB	GPU	GPU MEMORY: GIB	MAX DATA DISKS	MAX UNCACHED DISK THROUROUGHPUT: IOPS/MBPS	MAX NICs

1 GPU = one V100 card.

\*RDMA capable

## Supported operating systems and drivers

To take advantage of the GPU capabilities of Azure N-series VMs, NVIDIA GPU drivers must be installed.

The [NVIDIA GPU Driver Extension](#) installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the [NVIDIA GPU Driver Extension documentation](#) for supported operating systems and deployment steps. For general information about VM extensions, see [Azure virtual machine extensions and features](#).

If you choose to install NVIDIA GPU drivers manually, see [N-series GPU driver setup for Windows](#) or [N-series GPU driver setup for Linux](#) for supported operating systems, drivers, installation, and verification steps.

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. # NCasT4\_v3-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The NCasT4\_v3-series virtual machines are powered by [Nvidia Tesla T4](#) GPUs and AMD EPYC 7V12(Rome) CPUs. The VMs feature up to 4 NVIDIA T4 GPUs with 16 GB of memory each, up to 64 non-multithreaded AMD EPYC 7V12 (Rome) processor cores(base frequency of 2.45 GHz, all-cores peak frequency of 3.1 GHz and single-core peak frequency of 3.3 GHz) and 440 GiB of system memory. These virtual machines are ideal for deploying AI services- such as real-time inferencing of user-generated requests, or for interactive graphics and visualization workloads using NVIDIA's GRID driver and virtual GPU technology. Standard GPU compute workloads based around CUDA, TensorRT, Caffe, ONNX and other frameworks, or GPU-accelerated graphical applications based on OpenGL and DirectX can be deployed economically, with close proximity to users, on the NCasT4\_v3 series.

# NC A100 v4-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The NC A100 v4 series virtual machine (VM) is a new addition to the Azure GPU family. You can use this series for real-world Azure Applied AI training and batch inference workloads.

The NC A100 v4 series is powered by NVIDIA A100 PCIe GPU and 3rd-generation AMD EPYC™ 7V13 (Milan) processors. The VMs feature up to 4 NVIDIA A100 PCIe GPUs with 80GB memory each, up to 96 non-multithreaded AMD EPYC Milan processor cores and 880 GiB of system memory. These VMs are ideal for real-world Applied AI workloads, such as:

- GPU-accelerated analytics and databases
- Batch inferencing with heavy pre- and post-processing
- Autonomy model training
- Oil and gas reservoir simulation
- Machine learning (ML) development
- Video processing
- AI/ML web services

## Supported features

To get started with NC A100 v4 VMs, refer to [HPC Workload Configuration and Optimization](#) for steps including driver and network configuration.

Due to increased GPU memory I/O footprint, the NC A100 v4 requires the use of [Generation 2 VMs](#) and marketplace images. While the [Azure HPC images](#) are strongly recommended, Azure HPC Ubuntu 18.04, 20.04 and Azure HPC CentOS 7.9, CentOS 8.4, RHEL 7.9, RHEL 8.5, Windows Service 2019, and Windows Service 2022 images are supported.

Note: The Ubuntu-HPC 18.04-ncv4 image is only valid during preview and deprecated on 7/29/2022. All changes have been merged into standard Ubuntu-HPC 18.04 image. Please follow instruction [Azure HPC images](#) for configuration.

# ND A100 v4-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The ND A100 v4 series virtual machine is a new flagship addition to the Azure GPU family, designed for high-end Deep Learning training and tightly-coupled scale-up and scale-out HPC workloads.

The ND A100 v4 series starts with a single virtual machine (VM) and eight NVIDIA Ampere A100 40GB Tensor Core GPUs. ND A100 v4-based deployments can scale up to thousands of GPUs with an 1.6 Tb/s of interconnect bandwidth per VM. Each GPU within the VM is provided with its own dedicated, topology-agnostic 200 Gb/s NVIDIA Mellanox HDR InfiniBand connection. These connections are automatically configured between VMs occupying the same virtual machine scale set, and support GPUDirect RDMA.

Each GPU features NVLINK 3.0 connectivity for communication within the VM, and the instance is also backed by 96 physical 2nd-generation AMD Epyc™ 7V12 (Rome) CPU cores.

These instances provide excellent performance for many AI, ML, and analytics tools that support GPU acceleration 'out-of-the-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks. Additionally, the scale-out InfiniBand interconnect is supported by a large set of existing AI and HPC tools built on NVIDIA's NCCL2 communication libraries for seamless clustering of GPUs.

## IMPORTANT

To get started with ND A100 v4 VMs, refer to [HPC Workload Configuration and Optimization](#) for steps including driver and network configuration. Due to increased GPU memory I/O footprint, the ND A100 v4 requires the use of [Generation 2 VMs](#) and marketplace images. The [Azure HPC images](#) are strongly recommended. Azure HPC Ubuntu 18.04, 20.04 and Azure HPC CentOS 7.9 images are supported.

# Updated NDv2-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The NDv2-series virtual machine is a new addition to the GPU family designed for the needs of the most demanding GPU-accelerated AI, machine learning, simulation, and HPC workloads.

NDv2 is powered by 8 NVIDIA Tesla V100 NVLINK-connected GPUs, each with 32 GB of GPU memory. Each NDv2 VM also has 40 non-HyperThreaded Intel Xeon Platinum 8168 (Skylake) cores and 672 GiB of system memory.

NDv2 instances provide excellent performance for HPC and AI workloads utilizing CUDA GPU-optimized computation kernels, and the many AI, ML, and analytics tools that support GPU acceleration 'out-of-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks.

Critically, the NDv2 is built for both computationally intense scale-up (harnessing 8 GPUs per VM) and scale-out (harnessing multiple VMs working together) workloads. The NDv2 series now supports 100-Gigabit InfiniBand EDR backend networking, similar to that available on the HB series of HPC VM, to allow high-performance clustering for parallel scenarios including distributed training for AI and ML. This backend network supports all major InfiniBand protocols, including those employed by NVIDIA's NCCL2 libraries, allowing for seamless clustering of GPUs.

## IMPORTANT

When [enabling InfiniBand](#) on the ND40rs\_v2 VM, please use the 4.7-1.0.0.1 Mellanox OFED driver.

Due to increased GPU memory, the new ND40rs\_v2 VM requires the use of [Generation 2 VMs](#) and marketplace images.

Please note: The ND40s\_v2 featuring 16 GB of per-GPU memory is no longer available for preview and has been superceded by the updated ND40rs\_v2.

**Premium Storage:** Supported

**Premium Storage caching:** Supported

**Ultra Disks:** Supported ([Learn more](#) about availability, usage and performance)

**Live Migration:** Not Supported

## Supported operating systems and drivers

To take advantage of the GPU capabilities of Azure N-series VMs, NVIDIA GPU drivers must be installed.

The [NVIDIA GPU Driver Extension](#) installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. For general information about VM extensions, see [Azure virtual machine extensions and features](#).

If you choose to install NVIDIA GPU drivers manually, see [N-series GPU driver setup for Linux](#).

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# NV-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## IMPORTANT

NV and NV\_Promo series Azure virtual machines (VMs) will be retired on August 31st, 2023. For more information, see the [NV and NV\\_Promo retirement information](#). For how to migrate your workloads to other VM sizes, see the [NV and NV\\_Promo series migration guide](#).

This retirement announcement doesn't apply to NVv3 and NVv4 series VMs.

The NV-series virtual machines are powered by [NVIDIA Tesla M60](#) GPUs and NVIDIA GRID technology for desktop accelerated applications and virtual desktops where customers are able to visualize their data or simulations. Users are able to visualize their graphics intensive workflows on the NV instances to get superior graphics capability and additionally run single precision workloads such as encoding and rendering. NV-series VMs are also powered by Intel Xeon E5-2690 v3 (Haswell) CPUs.

Each GPU in NV instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

# NVv3-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The NVv3-series virtual machines are powered by [NVIDIA Tesla M60](#) GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These virtual machines are targeted for GPU accelerated graphics applications and virtual desktops where customers want to visualize their data, simulate results to view, work on CAD, or render and stream content. Additionally, these virtual machines can run single precision workloads such as encoding and rendering. NVv3 virtual machines support Premium Storage and come with twice the system memory (RAM) when compared with its predecessor NV-series.

Each GPU in NVv3 instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

# Install NVIDIA GPU drivers on N-series VMs running Linux

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

To take advantage of the GPU capabilities of Azure N-series VMs backed by NVIDIA GPUs, you must install NVIDIA GPU drivers. The [NVIDIA GPU Driver Extension](#) installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as the Azure CLI or Azure Resource Manager templates. See the [NVIDIA GPU Driver Extension documentation](#) for supported distributions and deployment steps.

If you choose to install NVIDIA GPU drivers manually, this article provides supported distributions, drivers, and installation and verification steps. Manual driver setup information is also available for [Windows VMs](#).

For N-series VM specs, storage capacities, and disk details, see [GPU Linux VM sizes](#).

## Supported distributions and drivers

### NVIDIA CUDA drivers

For the latest CUDA drivers and supported operating systems, visit the [NVIDIA](#) website. Ensure that you install or upgrade to the latest supported CUDA drivers for your distribution.

#### NOTE

The latest supported CUDA drivers for NC-series VMs is currently 470.82.01. Later driver versions are not supported on the K80 cards in NC.

#### TIP

As an alternative to manual CUDA driver installation on a Linux VM, you can deploy an Azure [Data Science Virtual Machine](#) image. The DSVM editions for Ubuntu 16.04 LTS or CentOS 7.4 pre-install NVIDIA CUDA drivers, the CUDA Deep Neural Network Library, and other tools.

### NVIDIA GRID drivers

Microsoft redistributes NVIDIA GRID driver installers for NV and NVv3-series VMs used as virtual workstations or for virtual applications. Install only these GRID drivers on Azure NV VMs, only on the operating systems listed in the following table. These drivers include licensing for GRID Virtual GPU Software in Azure. You do not need to set up a NVIDIA vGPU software license server.

The GRID drivers redistributed by Azure do not work on most non-NV series VMs like NC, NCv2, NCv3, ND, and NDv2-series VMs but works on NCsT4v3 series.

DISTRIBUTION	DRIVER
Ubuntu 16.04 LTS, 18.04 LTS, 20.04 LTS, 22.04 LTS	NVIDIA GRID 14.1, driver branch <a href="#">R510(.exe)</a>
Red Hat Enterprise Linux 7.9	
SUSE Linux Enterprise Server 15 SP2+, 15 SP2	

#### NOTE

The Azure NVads A10 v5 VMs only support GRID 14.1(510.73) or higher driver versions. Ubuntu 20.04 is not yet supported on Azure NVads A10 v5 VMs

Visit [GitHub](#) for the complete list of all previous Nvidia GRID driver links.

#### WARNING

Installation of third-party software on Red Hat products can affect the Red Hat support terms. See the [Red Hat Knowledgebase article](#).

## Install CUDA drivers on N-series VMs

Here are steps to install CUDA drivers from the NVIDIA CUDA Toolkit on N-series VMs.

C and C++ developers can optionally install the full Toolkit to build GPU-accelerated applications. For more information, see the [CUDA Installation Guide](#).

To install CUDA drivers, make an SSH connection to each VM. To verify that the system has a CUDA-capable GPU, run the following command:

```
lspci | grep -i NVIDIA
```

You will see output similar to the following example (showing an NVIDIA Tesla K80 card):

```
af8a:00:00.0 3D controller: NVIDIA Corporation GK210GL [Tesla K80] (rev a1)
```

`lspci` lists the PCIe devices on the VM, including the InfiniBand NIC and GPUs, if any. If `lspci` doesn't return successfully, you may need to install LIS on CentOS/RHEL (instructions below). Then run installation commands specific for your distribution.

#### Ubuntu

1. Download and install the CUDA drivers from the NVIDIA website.

#### NOTE

The example below shows the CUDA package path for Ubuntu 16.04. Replace the path specific to the version you plan to use.

Visit the [Nvidia Download Center](#) for the full path specific to each version.

```
CUDA_REPO_PKG=cuda-repo-ubuntu1604_10.0.130-1_amd64.deb  
wget -O /tmp/${CUDA_REPO_PKG}  
https://developer.download.nvidia.com/compute/cuda/repos/ubuntu1604/x86\_64/\${CUDA\_REPO\_PKG}  
  
sudo dpkg -i /tmp/${CUDA_REPO_PKG}  
sudo apt-key adv --fetch-keys  
https://developer.download.nvidia.com/compute/cuda/repos/ubuntu1604/x86\_64/3bf863cc.pub  
rm -f /tmp/${CUDA_REPO_PKG}  
  
sudo apt-get update  
sudo apt-get install cuda-drivers
```

The installation can take several minutes.

2. To optionally install the complete CUDA toolkit, type:

```
sudo apt-get install cuda
```

3. Reboot the VM and proceed to verify the installation.

#### CUDA driver updates

We recommend that you periodically update CUDA drivers after deployment.

```
sudo apt-get update  
sudo apt-get upgrade -y  
sudo apt-get dist-upgrade -y  
sudo apt-get install cuda-drivers  
  
sudo reboot
```

#### CentOS or Red Hat Enterprise Linux

1. Update the kernel (recommended). If you choose not to update the kernel, ensure that the versions of `kernel-devel` and `dkms` are appropriate for your kernel.

```
sudo yum install kernel kernel-tools kernel-headers kernel-devel  
sudo reboot
```

2. Install the latest [Linux Integration Services for Hyper-V and Azure](#). Check if LIS is required by verifying the results of `lspci`. If all GPU devices are listed as expected (and documented above), installing LIS is not required.

Please note that LIS is applicable to Red Hat Enterprise Linux, CentOS, and the Oracle Linux Red Hat Compatible Kernel 5.2-5.11, 6.0-6.10, and 7.0-7.7. Please refer to the [Linux Integration Services documentation](#) for more details. Skip this step if you plan to use CentOS/RHEL 7.8 (or higher versions) as LIS is no longer required for these versions.

```
wget https://aka.ms/lis  
tar xvzf lis  
cd LISISO  
  
sudo ./install.sh  
sudo reboot
```

3. Reconnect to the VM and continue installation with the following commands:

```
sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm  
sudo yum install dkms  
  
sudo wget https://developer.download.nvidia.com/compute/cuda/repos/rhel7/x86_64/cuda-rhel7.repo -O  
/etc/yum.repos.d/cuda-rhel7.repo  
  
sudo yum install cuda-drivers
```

The installation can take several minutes.

**NOTE**

Visit [Fedora](#) and [Nvidia CUDA repo](#) to pick the correct package for the CentOS or RHEL version you want to use.

For example, CentOS 8 and RHEL 8 will need the following steps.

```
sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm  
sudo yum install dkms  
  
sudo wget https://developer.download.nvidia.com/compute/cuda/repos/rhel8/x86_64/cuda-rhel8.repo -O  
/etc/yum.repos.d/cuda-rhel8.repo  
  
sudo yum install cuda-drivers
```

4. To optionally install the complete CUDA toolkit, type:

```
sudo yum install cuda
```

**NOTE**

If you see an error message related to missing packages like vulkan-filesystem then you may need to edit /etc/yum.repos.d/rh-cloud , look for optional-rpms and set enabled to 1

5. Reboot the VM and proceed to verify the installation.

### Verify driver installation

To query the GPU device state, SSH to the VM and run the [nvidia-smi](#) command-line utility installed with the driver.

If the driver is installed, you will see output similar to the following. Note that GPU-Util shows 0% unless you are currently running a GPU workload on the VM. Your driver version and GPU details may be different from the ones shown.

```

Tue Oct 10 20:48:53 2017

```

## RDMA network connectivity

RDMA network connectivity can be enabled on RDMA-capable N-series VMs such as NC24r deployed in the same availability set or in a single placement group in a virtual machine (VM) scale set. The RDMA network supports Message Passing Interface (MPI) traffic for applications running with Intel MPI 5.x or a later version. Additional requirements follow:

### Distributions

Deploy RDMA-capable N-series VMs from one of the images in the Azure Marketplace that supports RDMA connectivity on N-series VMs:

- **Ubuntu 16.04 LTS** - Configure RDMA drivers on the VM and register with Intel to download Intel MPI:

1. Install dapl, rdmacm, ibverbs, and mlx4

```

sudo apt-get update

sudo apt-get install libdap12 libmlx4-1

```

2. In /etc/waagent.conf, enable RDMA by uncommenting the following configuration lines. You need root access to edit this file.

```

OS.EnableRDMA=y

OS.UpdateRdmaDriver=y

```

3. Add or change the following memory settings in KB in the /etc/security/limits.conf file. You need root access to edit this file. For testing purposes you can set memlock to unlimited. For example:

```
<User or group name> hard memlock unlimited.
```

```

<User or group name> hard    memlock <memory required for your application in KB>

<User or group name> soft    memlock <memory required for your application in KB>

```

4. Install Intel MPI Library. Either [purchase and download](#) the library from Intel or download the [free evaluation version](#).

```
wget http://registrationcenter-download.intel.com/akdlm/irc_nas/tec/9278/l_mpi_p_5.1.3.223.tgz
```

Only Intel MPI 5.x runtimes are supported.

For installation steps, see the [Intel MPI Library Installation Guide](#).

5. Enable ptrace for non-root non-debugger processes (needed for the most recent versions of Intel MPI).

```
echo 0 | sudo tee /proc/sys/kernel/yama/ptrace_scope
```

- **CentOS-based 7.4 HPC** - RDMA drivers and Intel MPI 5.1 are installed on the VM.
- **CentOS-based HPC** - CentOS-HPC 7.6 and later (for SKUs where InfiniBand is supported over SR-IOV). These images have Mellanox OFED and MPI libraries pre-installed.

#### NOTE

CX3-Pro cards are supported only through LTS versions of Mellanox OFED. Use LTS Mellanox OFED version (4.9-0.1.7.0) on the N-series VMs with ConnectX3-Pro cards. For more information, see [Linux Drivers](#).

Also, some of the latest Azure Marketplace HPC images have Mellanox OFED 5.1 and later, which don't support ConnectX3-Pro cards. Check the Mellanox OFED version in the HPC image before using it on VMs with ConnectX3-Pro cards.

The following images are the latest CentOS-HPC images that support ConnectX3-Pro cards:

- OpenLogic:CentOS-HPC:7.6:7.6.2020062900
- OpenLogic:CentOS-HPC:7\_6gen2:7.6.2020062901
- OpenLogic:CentOS-HPC:7.7:7.7.2020062600
- OpenLogic:CentOS-HPC:7\_7-gen2:7.7.2020062601
- OpenLogic:CentOS-HPC:8\_1:8.1.2020062400
- OpenLogic:CentOS-HPC:8\_1-gen2:8.1.2020062401

## Install GRID drivers on NV or NVv3-series VMs

To install NVIDIA GRID drivers on NV or NVv3-series VMs, make an SSH connection to each VM and follow the steps for your Linux distribution.

#### Ubuntu

1. Run the `lspci` command. Verify that the NVIDIA M60 card or cards are visible as PCI devices.
2. Install updates.

```
sudo apt-get update
sudo apt-get upgrade -y
sudo apt-get dist-upgrade -y
sudo apt-get install build-essential ubuntu-desktop -y
sudo apt-get install linux-azure -y
```

3. Disable the Nouveau kernel driver, which is incompatible with the NVIDIA driver. (Only use the NVIDIA driver on NV or NVv2 VMs.) To do this, create a file in `/etc/modprobe.d` named `nouveau.conf` with the following contents:

```
blacklist nouveau
blacklist lbm-nouveau
```

4. Reboot the VM and reconnect. Exit X server:

```
sudo systemctl stop lightdm.service
```

5. Download and install the GRID driver:

```
wget -O NVIDIA-Linux-x86_64-grid.run https://go.microsoft.com/fwlink/?LinkId=874272  
chmod +x NVIDIA-Linux-x86_64-grid.run  
sudo ./NVIDIA-Linux-x86_64-grid.run
```

6. When you're asked whether you want to run the nvidia-xconfig utility to update your X configuration file, select **Yes**.

7. After installation completes, copy /etc/nvidia/gridd.conf.template to a new file gridd.conf at location /etc/nvidia/

```
sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

8. Add the following to `/etc/nvidia/gridd.conf`:

```
IgnoreSP=False  
EnableUI=False
```

9. Remove the following from `/etc/nvidia/gridd.conf` if it is present:

```
FeatureType=0
```

10. Reboot the VM and proceed to verify the installation.

### **CentOS or Red Hat Enterprise Linux**

1. Update the kernel and DKMS (recommended). If you choose not to update the kernel, ensure that the versions of `kernel-devel` and `dkms` are appropriate for your kernel.

```
sudo yum update  
sudo yum install kernel-devel  
sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm  
sudo yum install dkms  
sudo yum install hyperv-daemons
```

2. Disable the Nouveau kernel driver, which is incompatible with the NVIDIA driver. (Only use the NVIDIA driver on NV or NV3 VMs.) To do this, create a file in `/etc/modprobe.d` named `nouveau.conf` with the following contents:

```
blacklist nouveau  
blacklist lbm-nouveau
```

3. Reboot the VM, reconnect, and install the latest [Linux Integration Services for Hyper-V and Azure](#). Check if LIS is required by verifying the results of `lspci`. If all GPU devices are listed as expected (and documented above), installing LIS is not required.

Skip this step if you plan to use CentOS/RHEL 7.8 (or higher versions) as LIS is no longer required for these versions.

```
wget https://aka.ms/lis
tar xvzf lis
cd LISISO

sudo ./install.sh
sudo reboot
```

4. Reconnect to the VM and run the `lspci` command. Verify that the NVIDIA M60 card or cards are visible as PCI devices.

5. Download and install the GRID driver:

```
wget -O NVIDIA-Linux-x86_64-grid.run https://go.microsoft.com/fwlink/?linkid=874272
chmod +x NVIDIA-Linux-x86_64-grid.run

sudo ./NVIDIA-Linux-x86_64-grid.run
```

6. When you're asked whether you want to run the nvidia-xconfig utility to update your X configuration file, select **Yes**.

7. After installation completes, copy `/etc/nvidia/gridd.conf.template` to a new file `gridd.conf` at location `/etc/nvidia/`

```
sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

8. Add the following to `/etc/nvidia/gridd.conf`:

```
IgnoreSP=False
EnableUI=False
```

9. Remove the following from `/etc/nvidia/gridd.conf` if it is present:

```
FeatureType=0
```

10. Reboot the VM and proceed to verify the installation.

### Verify driver installation

To query the GPU device state, SSH to the VM and run the `nvidia-smi` command-line utility installed with the driver.

If the driver is installed, you will see output similar to the following. Note that **GPU-Util** shows 0% unless you are currently running a GPU workload on the VM. Your driver version and GPU details may be different from the ones shown.

```
[azureuser@dan lepnvr3 nvidia]$ nvidia-smi
Wed May 24 00:19:43 2017
+-----+
| NVIDIA-SMI 367.92                    Driver Version: 367.92 |
+-----+
| GPU  Name      Persistence-M | Bus-Id     Disp.A  | Volatile Uncorr. ECC |
| Fan  Temp  Perf  Pwr:Usage/Cap | Memory-Usage | GPU-Util Compute M. |
|=====+=====+=====+=====+=====+=====+=====+=====|
| 0   Tesla M60        off    | 8342:00:00.0  Off    | 0%          off      |
| N/A   31C   P0    39W / 150W | 0MiB /  8123MiB |           Default |
+-----+
+-----+
| Processes:                               GPU Memory |
| GPU     PID  Type  Process name        Usage      |
|=====+=====+=====+=====
| No running processes found            |
+-----+
```

## X11 server

If you need an X11 server for remote connections to an NV or NVv2 VM, [x11vnc](#) is recommended because it allows hardware acceleration of graphics. The BusID of the M60 device must be manually added to the X11 configuration file (usually, `/etc/X11/xorg.conf`). Add a `"Device"` section similar to the following:

```
Section "Device"
    Identifier      "Device0"
    Driver         "nvidia"
    VendorName    "NVIDIA Corporation"
    BoardName     "Tesla M60"
    BusID          "PCI:0@your-BusID:0:0"
EndSection
```

Additionally, update your `"Screen"` section to use this device.

The decimal BusID can be found by running

```
nvidia-xconfig --query-gpu-info | awk '/PCI BusID/{print $4}'
```

The BusID can change when a VM gets reallocated or rebooted. Therefore, you may want to create a script to update the BusID in the X11 configuration when a VM is rebooted. For example, create a script named `busidupdate.sh` (or another name you choose) with contents similar to the following:

```
#!/bin/bash
XCONFIG="/etc/X11/xorg.conf"
OLDBUSID=`awk '/BusID/{gsub(/\//, "", $2); print $2}' ${XCONFIG}`
NEWBUSID=`nvidia-xconfig --query-gpu-info | awk '/PCI BusID/{print $4}`

if [[ "${OLDBUSID}" == "${NEWBUSID}" ]] ; then
    echo "NVIDIA BusID not changed - nothing to do"
else
    echo "NVIDIA BusID changed from \"${OLDBUSID}\" to \"${NEWBUSID}\": Updating ${XCONFIG}"
    sed -e 's|BusID.*|BusID      '\"${NEWBUSID}''|' -i ${XCONFIG}
fi
```

Then, create an entry for your update script in `/etc/rc.d/rc3.d` so the script is invoked as root on boot.

## Troubleshooting

- You can set persistence mode using `nvidia-smi` so the output of the command is faster when you need to query cards. To set persistence mode, execute `nvidia-smi -pm 1`. Note that if the VM is restarted, the mode setting goes away. You can always script the mode setting to execute upon startup.

- If you updated the NVIDIA CUDA drivers to the latest version and find RDMA connectivity is no longer working, [reinstall the RDMA drivers](#) to reestablish that connectivity.
- During installation of LIS, if a certain CentOS/RHEL OS version (or kernel) is not supported for LIS, an error “Unsupported kernel version” is thrown. Please report this error along with the OS and kernel versions.
- If jobs are interrupted by ECC errors on the GPU (either correctable or uncorrectable), first check to see if the GPU meets any of Nvidia's [RMA criteria for ECC errors](#). If the GPU is eligible for RMA, please contact support about getting it serviced; otherwise, reboot your VM to reattach the GPU as described [here](#). Note that less invasive methods such as `nvidia-smi -r` do not work with the virtualization solution deployed in Azure.

## Next steps

- To capture a Linux VM image with your installed NVIDIA drivers, see [How to generalize and capture a Linux virtual machine](#).

# Install NVIDIA GPU drivers on N-series VMs running Windows

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

To take advantage of the GPU capabilities of Azure N-series VMs backed by NVIDIA GPUs, you must install NVIDIA GPU drivers. The [NVIDIA GPU Driver Extension](#) installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the [NVIDIA GPU Driver Extension documentation](#) for supported operating systems and deployment steps.

If you choose to install NVIDIA GPU drivers manually, this article provides supported operating systems, drivers, and installation and verification steps. Manual driver setup information is also available for [Linux VMs](#).

For basic specs, storage capacities, and disk details, see [GPU Windows VM sizes](#).

## Supported operating systems and drivers

### NVIDIA Tesla (CUDA) drivers

NVIDIA Tesla (CUDA) drivers for NC, NCv2, NCv3, NCasT4\_v3, ND, and NDv2-series VMs (optional for NV-series) are tested on the operating systems listed in the following table. CUDA driver is generic and not Azure specific. For the latest drivers, visit the [NVIDIA](#) website.

#### TIP

As an alternative to manual CUDA driver installation on a Windows Server VM, you can deploy an Azure [Data Science Virtual Machine](#) image. The DSVM editions for Windows Server 2016 pre-install NVIDIA CUDA drivers, the CUDA Deep Neural Network Library, and other tools.

OS	Driver
Windows Server 2019	<a href="#">451.82 (.exe)</a>
Windows Server 2016	<a href="#">451.82 (.exe)</a>

### NVIDIA GRID drivers

Microsoft redistributes NVIDIA GRID driver installers for NV and NVv3-series VMs used as virtual workstations or for virtual applications. Install only these GRID drivers on Azure NV-series VMs, only on the operating systems listed in the following table. These drivers include licensing for GRID Virtual GPU Software in Azure. You do not need to set up a NVIDIA vGPU software license server.

The GRID drivers redistributed by Azure do not work on non-NV series VMs like NCv2, NCv3, ND, and NDv2-series VMs. The one exception is the NCas\_T4\_V3 VM series where the GRID drivers will enable the graphics functionalities similar to NV-series.

The NC-Series with Nvidia K80 GPUs do not support GRID/graphics applications.

The Nvidia extension always installs the latest driver. The following links to previous versions are provided to support dependencies on older driver versions.

For Windows Server 2022, Windows Server 2019, Windows Server 2016 1607, 1709, Windows 10 and Windows 11:

- [GRID 14.1 \(512.78\) \(.exe\)](#)
- [GRID 13.1 \(472.39\) \(.exe\)](#)

For Windows Server 2012 R2:

- [GRID 13.1 \(472.39\) \(.exe\)](#)
- [GRID 13 \(471.68\) \(.exe\)](#)

**NOTE**

The Azure NVads A10 v5 VMs only support GRID 14.1(512.78) or higher driver versions.

For links to all previous Nvidia GRID driver versions, visit [GitHub](#).

## Driver installation

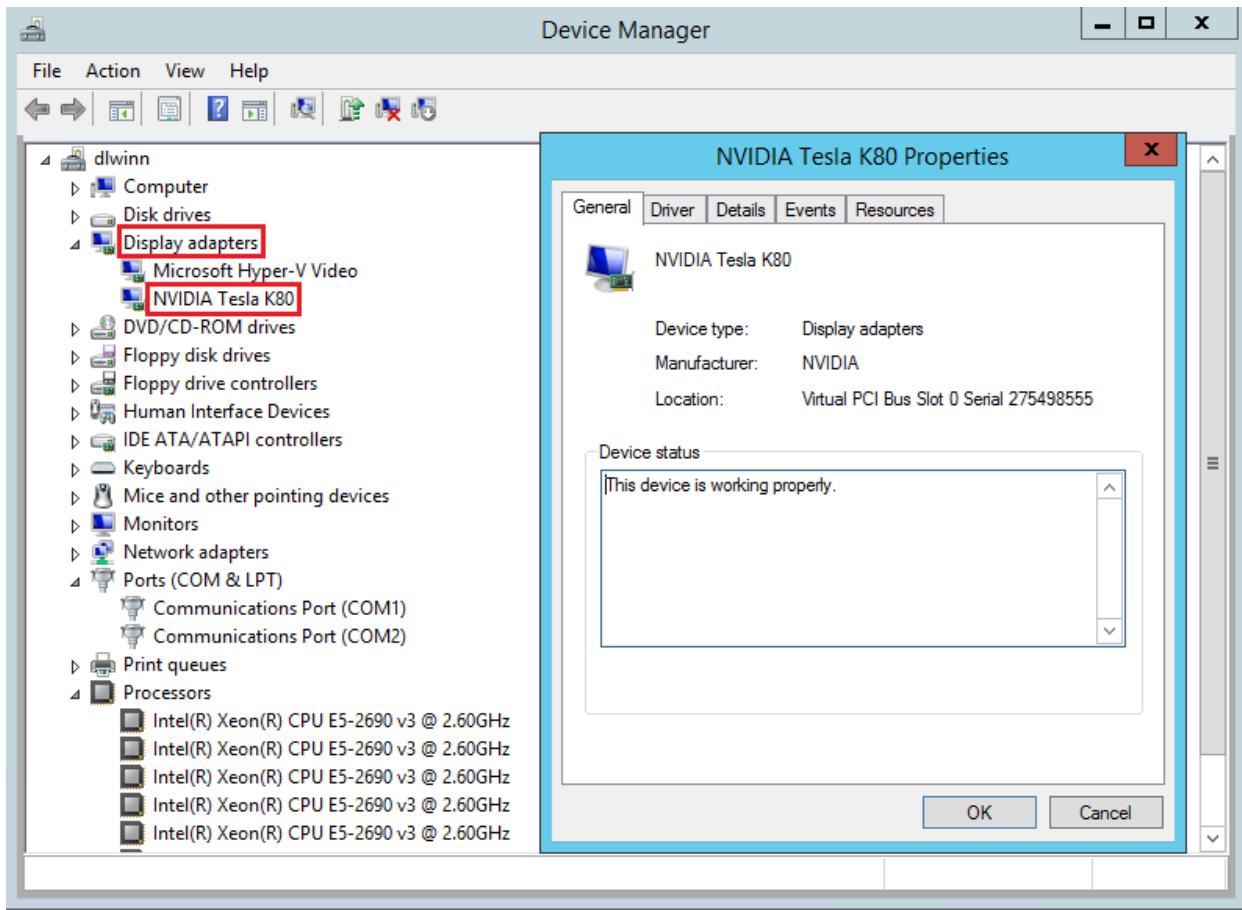

1. Connect by Remote Desktop to each N-series VM.
2. Download, extract, and install the supported driver for your Windows operating system.

After GRID driver installation on a VM, a restart is required. After CUDA driver installation, a restart is not required.

## Verify driver installation

Please note that the Nvidia Control panel is only accessible with the GRID driver installation. If you have installed CUDA drivers then the Nvidia control panel will not be visible.

You can verify driver installation in Device Manager. The following example shows successful configuration of the Tesla K80 card on an Azure NC VM.

To query the GPU device state, run the `nvidia-smi` command-line utility installed with the driver.

1. Open a command prompt and change to the `C:\Program Files\NVIDIA Corporation\NVSMI` directory.
2. Run `nvidia-smi`. If the driver is installed, you will see output similar to the following. The **GPU-Util** shows 0% unless you are currently running a GPU workload on the VM. Your driver version and GPU details may be different from the ones shown.

```
C:\Program Files\NVIDIA Corporation\NVSMI>nvidia-smi
Wed Nov 23 20:49:33 2016
+-----+
| NVIDIA-SMI 369.73       Driver Version: 369.73 |
+-----+
| GPU  Name        TCC/WDDM | Bus-Id      Disp.A  | Volatile Uncorr. ECC |
| Fan  Temp  Perf  Pwr:Usage/Cap| Memory-Usage | GPU-Util  Compute M. |
|-----+
|   0  Tesla K80        TCC | B794:00:00.0    Off  |          0%          Default |
| N/A   56C   P8    28W / 149W |     0MiB / 11423MiB |          0%          Default |
+-----+
+-----+
| Processes:                               GPU Memory |
| GPU  PID  Type  Process name             Usage      |
|-----+
| No running processes found               0MiB      |
+-----+
```

## RDMA network connectivity

RDMA network connectivity can be enabled on RDMA-capable N-series VMs such as NC24r deployed in the same availability set or in a single placement group in a virtual machine scale set. The HpcVmDrivers extension must be added to install Windows network device drivers that enable RDMA connectivity. To add the VM extension to an RDMA-enabled N-series VM, use [Azure PowerShell](#) cmdlets for Azure Resource Manager.

To install the latest version 1.1 HpcVMDrivers extension on an existing RDMA-capable VM named myVM in the West US region:

```
Set-AzVMExtension -ResourceGroupName "myResourceGroup" -Location "westus" -VMName "myVM" -ExtensionName "HpcVmDrivers" -Publisher "Microsoft.HpcCompute" -Type "HpcVmDrivers" -TypeHandlerVersion "1.1"
```

For more information, see [Virtual machine extensions and features for Windows](#).

The RDMA network supports Message Passing Interface (MPI) traffic for applications running with [Microsoft MPI](#) or Intel MPI 5.x.

## Next steps

- Developers building GPU-accelerated applications for the NVIDIA Tesla GPUs can also download and install the latest [CUDA Toolkit](#). For more information, see the [CUDA Installation Guide](#).

# Install AMD GPU drivers on N-series VMs running Windows

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: Windows VMs ✓ Flexible scale sets

To take advantage of the GPU capabilities of the new Azure NVv4 series VMs running Windows, AMD GPU drivers must be installed. The [AMD GPU Driver Extension](#) installs AMD GPU drivers on a NVv4-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the [AMD GPU Driver Extension documentation](#) for supported operating systems and deployment steps.

If you choose to install AMD GPU drivers manually, this article provides supported operating systems, drivers, and installation and verification steps.

Only GPU drivers published by Microsoft are supported on NVv4 VMs. Please DO NOT install GPU drivers from any other source.

For basic specs, storage capacities, and disk details, see [GPU Windows VM sizes](#).

## Supported operating systems and drivers

os	DRIVER
Windows 10 - Build 2009, 2004, 1909	<a href="#">21.Q2-1 (.exe)</a>
Windows 10 Enterprise multi-session - Build 2009, 2004, 1909	
Windows Server 2016 (version 1607)	
Windows Server 2019 (version 1909)	

Previous supported driver version for Windows builds up to 1909 is [20.Q4-1 \(.exe\)](#)

### NOTE

If you use build 1903/1909 then you may need to update the following group policy for optimal performance. These changes are not needed for any other Windows builds.

[Computer Configuration->Policies->Windows Settings->Administrative Templates->Windows Components->Remote Desktop Services->Remote Desktop Session Host->Remote Session Environment], set the Policy [Use WDDM graphics display driver for Remote Desktop Connections] to Disabled.

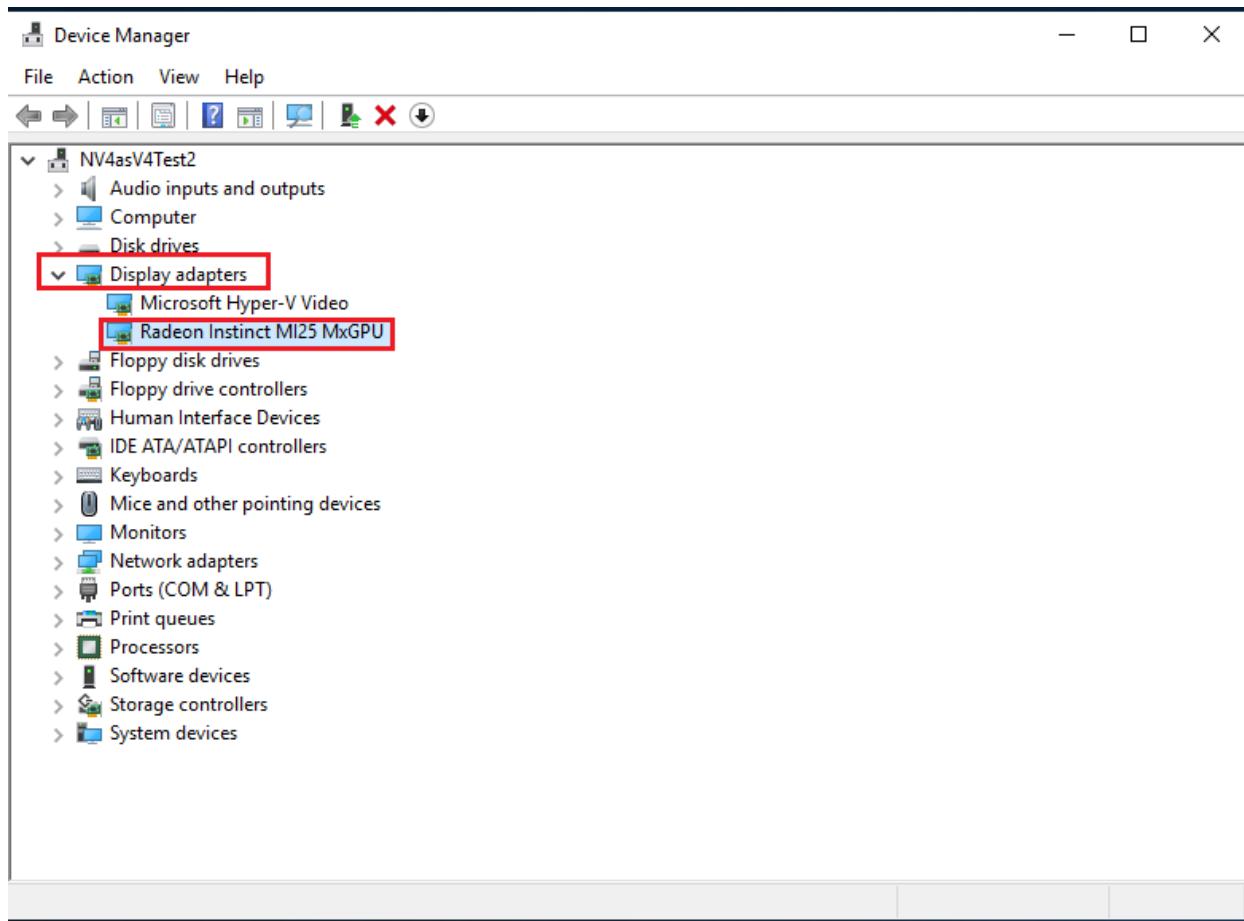

## Driver installation

1. Connect by Remote Desktop to each NVv4-series VM.
2. If you need to uninstall the previous driver version then download the [AMD cleanup utility](#). Please do not use the utility that comes with the previous version of the driver.
3. Download and install the latest driver.

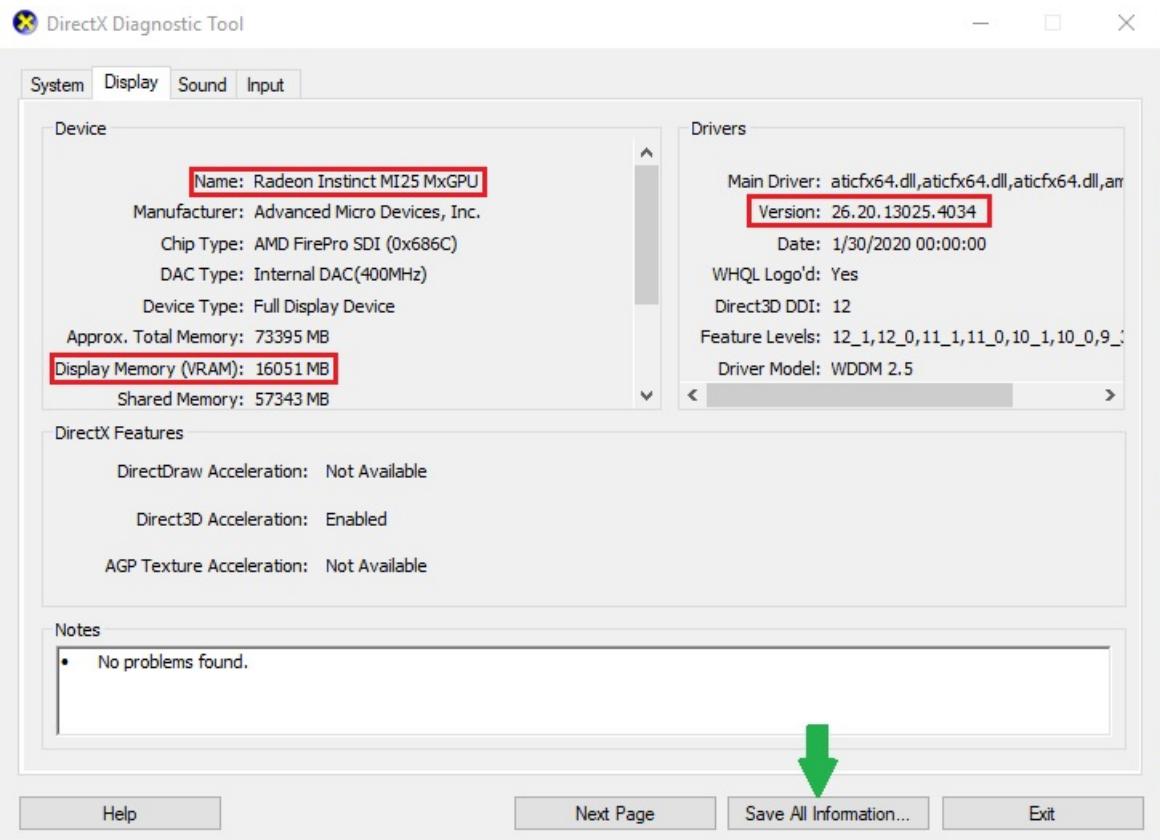

4. Reboot the VM.

## Verify driver installation

You can verify driver installation in Device Manager. The following example shows successful configuration of the Radeon Instinct MI25 card on an Azure NVv4 VM.

You can use dxdiag to verify the GPU display properties including the video RAM. The following example shows a 1/2 partition of the Radeon Instinct MI25 card on an Azure NVv4 VM.

If you are running Windows 10 build 1903 or higher then dxdiag will show no information in the 'Display' tab. Please use the 'Save All Information' option at the bottom and the output file will show the information related to AMD MI25 GPU.

# Migrate your NC and NC\_Promo series virtual machines by August 31, 2023

9/21/2022 • 2 minutes to read • [Edit Online](#)

Based on feedback we've received from customers we're happy to announce that we are extending the retirement date by 1 year to 31 August 2023, for the Azure NC-Series virtual machine to give you more time to plan your migration.

As we continue to bring modern and optimized virtual machine instances to Azure leveraging the latest innovations in datacenter technologies, we thoughtfully plan how we retire aging hardware. With this in mind, we are retiring our NC (v1) GPU VM sizes, powered by NVIDIA Tesla K80 GPUs on 31 August 2023.

## How does the NC-series migration affect me?

After 31 August 2023, any remaining NC size virtual machines remaining in your subscription will be set to a deallocated state. These virtual machines will be stopped and removed from the host. These virtual machines will no longer be billed in the deallocated state.

This VM size retirement only impacts the VM sizes in the [NC-series](#). This does not impact the newer [NCv3](#), [NC T4 v3](#), and [ND v2](#) series virtual machines.

## What actions should I take?

You will need to resize or deallocate your NC virtual machines. We recommend moving your GPU workloads to another GPU Virtual Machine size. Learn more about migrating your workloads to another [GPU Accelerated Virtual Machine size](#).

# Migrate your NCv2 series virtual machines by August 31, 2023

9/21/2022 • 2 minutes to read • [Edit Online](#)

Based on feedback we've received from customers we're happy to announce that we are extending the retirement date by 1 year to August 31, 2023, for the Azure NCv2-Series virtual machine to give you more time to plan your migration.

As we continue to bring modern and optimized virtual machine instances to Azure leveraging the latest innovations in datacenter technologies, we thoughtfully plan how we retire aging hardware. With this in mind, we are retiring our NC (v2) GPU VM sizes, powered by NVIDIA Tesla P100 GPUs on 31 August 2023.

## How does the NCv2-series migration affect me?

After 31 August 2023, any remaining NCv2 size virtual machines remaining in your subscription will be set to a deallocated state. These virtual machines will be stopped and removed from the host. These virtual machines will no longer be billed in the deallocated state.

This VM size retirement only impacts the VM sizes in the [NCv2-series](#). This does not impact the newer [NCv3](#), [NC T4 v3](#), and [ND v2](#) series virtual machines.

## What actions should I take?

You will need to resize or deallocate your NC virtual machines. We recommend moving your GPU workloads to another GPU Virtual Machine size. Learn more about migrating your workloads to another [GPU Accelerated Virtual Machine size](#).

## Next steps

# Migration Guide for GPU Compute Workloads in Azure

9/21/2022 • 10 minutes to read • [Edit Online](#)

As more powerful GPUs become available in the marketplace and in Microsoft Azure datacenters, we recommend re-assessing the performance of your workloads and considering migrating to newer GPUs.

For the same reason, as well as to maintain a high-quality and reliable service offering, Azure periodically retires the hardware that powers older VM sizes. The first group of GPU products to be retired in Azure are the original NC, NC v2 and ND-series VMs, powered by NVIDIA Tesla K80, P100, and P40 datacenter GPU accelerators respectively. These products will be retired on August 31st 2023, and the oldest VMs in this series launched in 2016.

Since then, GPUs have made incredible strides alongside the entire deep learning and HPC industry, typically exceeding a doubling in performance between generations. Since the launch of NVIDIA K80, P40, and P100 GPUs, Azure has shipped multiple newer generations and categories of VM products geared at GPU-accelerated compute and AI, based around NVIDIA's T4, V100, and A100 GPUs, and differentiated by optional features such as InfiniBand-based interconnect fabrics. These are all options we encourage customers to explore as migration paths.

In most cases, the dramatic increase in performance offered by newer generations of GPUs lowers overall TCO by decreasing the duration of job, for burstable jobs- or reducing the quantity of overall GPU-enabled VMs required to cover a fixed-size demand for compute resources, even though costs per GPU-hour may vary. In addition to these benefits, customers may improve Time-to-Solution via higher-performing VMs, and improve the health and supportability of their solution by adopting newer software, CUDA runtime, and driver versions.

## Migration vs. Optimization

Azure recognizes that customers have a multitude of requirements that may dictate the selection of a specific GPU VM product, including GPU architectural considerations, interconnects, TCO, Time to Solution, and regional availability based on compliance locality or latency requirements- and some of these even change over time.

At the same time, GPU acceleration is a new and rapidly evolving area.

Thus, there is no true one-size fits-all guidance for this product area, and a migration is a perfect time to re-evaluate potentially dramatic changes to a workload- like moving from a clustered deployment model to a single large 8-GPU VM or vice versa, leveraging reduced precision datatypes, adopting features like Multi-Instance GPU, and much more.

These sorts of considerations- when made the context of already dramatic per-generation GPU performance increases, where a feature such as the addition of TensorCores can increase performance by an order of magnitude, are extremely workload-specific.

Combining migration with application re-architecture can yield immense value and improvement in cost and time-to-solution.

However, these sorts of improvements are beyond the scope of this document, which aims to focus on direct equivalency classes for generalized workloads that may be run by customers today, to identify the most similar VM options in both price *and* performance per GPU to existing VM families undergoing retirement.

Thus, this document assumes that the user may not have any insight or control over workload-specific properties like the number of required VM instances, GPUs, interconnects, and more.

# Recommended Upgrade Paths

## NC-Series VMs featuring NVIDIA K80 GPUs

The [NC \(v1\)-Series](#) VMs are Azure's oldest GPU-accelerated compute VM type, powered by 1 to 4 NVIDIA Tesla K80 datacenter GPU accelerators paired with Intel Xeon E5-2690 v3 (Haswell) processors. Once a flagship VM type for demanding AI, ML, and HPC applications, they remained a popular choice late into the product lifecycle (particularly via NC-series promotional pricing) for users who valued having a very low absolute cost per GPU-hour over GPUs with higher throughput-per-dollar.

Today, given the relatively low compute performance of the aging NVIDIA K80 GPU platform, in comparison to VM series featuring newer GPUs, a popular use case for the NC-series is real-time inference and analytics workloads, where an accelerated VM must be available in a steady state to serve request from applications as they arrive. In these cases the volume or batch size of requests may be insufficient to benefit from more performant GPUs. NC VMs are also popular for developers and students learning about, developing for, or experimenting with GPU acceleration, who need an inexpensive cloud-based CUDA deployment target upon which to iterate that doesn't need to perform to production levels.

In general, NC-Series customers should consider moving directly across from NC sizes to [NC T4 v3](#) sizes, Azure's new GPU-accelerated platform for light workloads powered by NVIDIA Tesla T4 GPUs, although other VM SKUs should be considered for workloads running on InfiniBand-enabled NC-Series sizes.

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_NC6 Standard_NC6_Promo	Standard_NC4as_T4_v3 or Standard_NC8as_T4	CPU: Intel Haswell vs AMD Rome GPU count: 1 (same) GPU generation: NVIDIA Kepler vs. Turing (+2 generations, ~2x FP32 FLOPs) GPU memory (GiB per GPU): 16 (+4) vCPU: 4 (-2) or 8 (+2) Memory GiB: 16 (-40) or 56 (same) Temp Storage (SSD) GiB: 180 (-160) or 360 (+20) Max data disks: 8 (-4) or 16 (+4) Accelerated Networking: Yes (+) Premium Storage: Yes (+)

### ND-Series VMs featuring NVIDIA Tesla P40 GPUs

The ND-series virtual machines are a midrange platform originally designed for AI and Deep Learning workloads. They offered excellent performance for batch inferencing via improved single-precision floating point operations over their predecessors and are powered by NVIDIA Tesla P40 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and NC v2-Series, the ND-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_ND6	Standard_NC4as_T4_v3 or Standard_NC8as_T4	CPU: Intel Broadwell vs AMD Rome GPU count: 1 (same) GPU generation: NVIDIA Pascal vs. Turing (+1 generation) GPU memory (GiB per GPU): 16 (-8) vCPU: 4 (-2) or 8 (+2) Memory GiB: 16 (-40) or 56 (-56) Temp Storage (SSD) GiB: 180 (-552) or 360 (-372) Max data disks: 8 (-4) or 16 (+4) Accelerated Networking: Yes (+) Premium Storage: Yes (+)

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_ND12	Standard_NC16as_T4_v3	CPU: Intel Broadwell vs AMD Rome GPU count: 1 (-1) GPU generation: NVIDIA Pascal vs. Turing (+1 generations) GPU memory (GiB per GPU): 16 (-8) vCPU: 16 (+4) Memory GiB: 110 (-114) Temp Storage (SSD) GiB: 360 (-1,114) Max data disks: 48 (+16) Accelerated Networking: Yes (+) Premium Storage: Yes (+)

Standard_ND24r	Standard_NC24rs_v3*	CPU: Intel Broadwell (Same) GPU count: 4 (same) GPU generation: NVIDIA Pascal vs. Volta (+1 generation) GPU memory (GiB per GPU): 16 (-8) vCPU: 24 (+0) Memory GiB: 448 (same) Temp Storage (SSD) GiB: 2948 (same) Max data disks: 32 (same) Accelerated Networking: No (Same) Premium Storage: Yes (+) InfiniBand interconnect: Yes (Same)

### NC v2-Series VMs featuring NVIDIA Tesla P100 GPUs

The NC v2-series virtual machines are a flagship platform originally designed for AI and Deep Learning workloads. They offered excellent performance for Deep Learning training, with per-GPU performance roughly 2x that of the original NC-Series and are powered by NVIDIA Tesla P100 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and ND -Series, the NC v2-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
-----------------	----------------	-----------------------------

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_NC6s_v2	Standard_NC6s_v3	CPU: Intel Broadwell (Same) GPU count: 1 (same) GPU generation: NVIDIA Pascal vs. Volta (+1 generation) GPU memory (GiB per GPU): 16 (same) vCPU: 6 (same) Memory GiB: 112 (same) Temp Storage (SSD) GiB: 736 (same) Max data disks: 12 (same) Accelerated Networking: No (same) Premium Storage: Yes (+)
Standard_NC12s_v2	Standard_NC12s_v3	CPU: Intel Broadwell (Same) GPU count: 2 (same) GPU generation: NVIDIA Pascal vs. Volta (+1 generations) GPU memory (GiB per GPU): 16 (same) vCPU: 12 (same) Memory GiB: 112 (same) Temp Storage (SSD) GiB: 1474 (same) Max data disks: 24 (same) Accelerated Networking: No (same) Premium Storage: Yes (+)

## Migration Steps

### General Changes

1. Choose a series and size for migration. Leverage the [pricing calculator](#) for further insights.
2. Get quota for the target VM series

3. Resize the current N\* series VM size to the target size. This may also be a good time to update the operating system used by your Virtual Machine image, or adopt one of the HPC images with drivers pre-installed as your starting point.

#### **IMPORTANT**

Your VM image may have been produced with an older version of the CUDA runtime, NVIDIA driver, and (if applicable, for RDMA-enabled sizes only) Mellanox OFED drivers than your new GPU VM series requires, which can be updated by [following the instructions in the Azure Documentation](#).

## **Breaking Changes**

### **Select target size for migration**

After assessing your current usage, decide what type of GPU VM you need. Depending on the workload requirements you have few different choices.

#### **NOTE**

A best practice is to select a VM size based on both cost and performance. The recommendations in this guide are based on a general-purpose, one-to-one comparison of performance metrics and the nearest match in another VM series. Before deciding on the right size, get a cost comparison using the [Azure Pricing Calculator](#).

#### **IMPORTANT**

All legacy NC, NC v2 and ND-Series sizes are available in multi-GPU sizes, including 4-GPU sizes with and without InfiniBand interconnect for scale-out, tightly-coupled workloads that demand more compute power than a single 4-GPU VM, or a single K80, P40, or P100 GPU can supply respectively. Although the recommendations above offer a straightforward path forward, users of these sizes should consider achieving their performance goals with more powerful NVIDIA V100 GPU-based VM series like the [NC v3-Series](#) and [ND v2-series](#), which typically enable the same level of workload performance at lower costs and with improved manageability by providing considerably greater performance per GPU and per VM before multi-GPU and multi-node configurations are required, respectively.

### **Get quota for the target VM family**

Follow the guide to [request an increase in vCPU quota by VM family](#). Select the target VM size you have selected for migration.

### **Resize the current virtual machine**

You can [resize the virtual machine](#).

## **Next steps**

For a full list of GPU enabled virtual machine sizes, see [GPU - accelerated compute overview](#)

# Migrate your NV and NV\_Promo series virtual machines by August 31, 2023

9/21/2022 • 2 minutes to read • [Edit Online](#)

Based on feedback we've received from customers we're happy to announce that we are extending the retirement date by 1 year to August 31, 2023, for the Azure NV-Series and NV\_Promo Series virtual machine to give you more time to plan your migration.

We continue to bring modern and optimized virtual machine (VM) instances to Azure by using the latest innovations in datacenter technologies. As we innovate, we also thoughtfully plan how we retire aging hardware. With this context in mind, we're retiring our NV-series Azure VM sizes on August 31, 2023.

## How does the NV series migration affect me?

After August 31, 2023, any remaining NV and NV\_Promo-size VMs remaining in your subscription will be set to a deallocated state. These VMs will be stopped and removed from the host. These VMs will no longer be billed in the deallocated state.

The current VM size retirement only affects the VM sizes in the [NV series](#). This retirement doesn't affect the [NVv3](#) and [NVv4](#) series VMs.

## What actions should I take?

You'll need to resize or deallocate your NV VMs. We recommend moving your GPU visualizations or graphics workloads to another [GPU accelerated VM size](#).

[Learn more](#) about migrating your workloads to other GPU Azure VM sizes.

If you have questions, contact us through customer support.

# NV series migration guide

9/21/2022 • 4 minutes to read • [Edit Online](#)

As more powerful GPU VM sizes become available in Azure datacenters, assess your workloads and migrate virtual machines (VMs) in the NV and NV\_Promo series. These legacy VMs can be migrated into new VM series, such as NVsv3 and NVasv4, for better performance with reduced cost. The NVsv3 VM series is powered by Nvidia M60 GPUs. The NVasv4 series is powered by AMD Radeon Instinct MI25 GPUs.

The main differences between the NV and NV\_Promo series and the newer NVsv3 and NVasv4 series are:

- Improved performance.
- Support for Premium storage.
- The option to choose from a fractional GPU size to multi-GPU configurations.

Both the NVsv3 and NVasv4 series have more modern cores and greater capacity.

The following section summarizes the differences between the legacy NV series and the NVsv3 and NVv4 series.

## NVsv3 series

The NVv3-series VMs are powered by NVIDIA Tesla M60 GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These VMs are targeted for GPU accelerated graphics applications and virtual desktops where customers want to:

- Visualize their data.
- Simulate results to view.
- Work on CAD.
- Render and stream content.

These VMs can also run single precision workloads, such as encoding and rendering.

NVv3 VMs support Premium storage and come with twice the system memory (RAM) when compared with the NV series. For the most up-to-date specifications, see [GPU accelerated compute VM sizes: NVsv3 series](#).

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_NV6 Standard_NV6_Promo	Standard_NV12s_v3	vCPU: 12 (+6) Memory: GiB 112 (+56) Temp storage (SSD) GiB: 320 (-20) Max data disks: 12 (-12) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV24s_v3	vCPU: 24 (+12) Memory: GiB 224 (+112) Temp storage (SSD) GiB: 640 (-40) Max data disks: 24 (-24) Accelerated networking: Yes Premium storage: Yes

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_NV24 Standard_NV24_Promo	Standard_NV48s_v3	vCPU: 48 (+24) Memory: GiB 448 (+224) Temp storage (SSD) GiB: 1280 (-160) Max data disks: 32 (-32) Accelerated networking: Yes Premium storage: Yes

## NVv4 series

NVv4-series VMs are powered by AMD Radeon Instinct MI25 GPUs and AMD EPYC 7V12 (Rome) CPUs. With the NVv4 series, Azure introduces VMs with partial GPUs. Choose the right size VM for GPU accelerated graphics applications and virtual desktops that start at one-eighth of a GPU with a 2-GiB frame buffer to a full GPU with a 16-GiB frame buffer.

NVv4 VMs currently support only the Windows guest operating system. For the most up-to-date specifications, see [GPU accelerated compute VM sizes: NVv4 series](#).

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_NV6 Standard_NV6_Promo	Standard_NV16as_v4	vCPU: 16 (+10) Memory: GiB 56 Temp storage (SSD) GiB: 352 (+12) Max data disks: 16 (-8) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV32as_v4	vCPU: 32 (+20) Memory: GiB 112 Temp storage (SSD) GiB: 704 (+24) Max data disks: 32 (+16) Accelerated networking: Yes Premium storage: Yes
Standard_NV24 Standard_NV24_Promo	N/A	N/A

## Migration steps for general changes

To deal with general changes:

1. Choose a series and size for migration.
2. Get a quota for the target VM series.
3. Resize the current NV-series VM size to the target size.

If the target size is NVv4, make sure to remove the Nvidia GPU driver and install the AMD GPU driver.

## Migration steps for breaking changes

To deal with breaking changes, follow the steps in the next sections.

### Select a target size for migration

After you assess your current usage, decide what type of GPU VM you need. Depending on the workload requirements, you have a few different choices. Here's how to choose:

- If the workload is graphics or visualizations and has a hard dependency on using the Nvidia GPU, migrate to the NVsv3 series.
- If the workload is graphics or visualizations and has no hard dependency on a specific type of GPU, migrate to the NVsv3 or NVVasv4 series.

#### NOTE

A best practice is to select a VM size based on both cost and performance. The recommendations in this article are based on a one-to-one comparison of performance metrics for the NV and NV\_Promo sizes and the nearest match in another VM series. Before you decide on the right size, get a cost comparison by using the Azure Pricing Calculator.

### Get a quota for the target VM family

Follow the guide to [request an increase in vCPU quota by VM family](#). Select the NVSv3 series or NVv4 series as the VM family name depending on the target VM size you selected for migration.

### Resize the current VM

You can [resize the VM](#).

## FAQ

**Q:** Which GPU driver should I use for the target VM size?

**A:** For the NVsv3 series, use the [Nvidia GRID driver](#). For NVv4, use the [AMD GPU drivers](#).

**Q:** I use the Nvidia GPU driver extension today. Will it work for the target VM size?

**A:** The current [Nvidia driver extension](#) will work for NVsv3. Use the [AMD GPU driver extensions](#) if the target VM size is NVv4.

**Q:** Which target VM series should I use if I have dependency on CUDA?

**A:** NVv3 supports CUDA. The NVv4 VM series with the AMD GPUs doesn't support CUDA.

# FPGA optimized virtual machine sizes

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

FPGA optimized VM sizes are specialized virtual machines available with single or multiple FPGAs. These sizes are designed for compute-intensive workloads. This article provides information about the number and type of FPGAs, vCPUs, data disks, and NICs. Storage throughput and network bandwidth are also included for each size in this grouping.

- The [NP-series](#) sizes are optimized for workloads including machine learning inference, video transcoding, and database search & analytics. The NP-series are powered by Xilinx U250 accelerators.

## Deployment considerations

- For availability of N-series VMs, see [Products available by region](#).
- N-series VMs can only be deployed in the Resource Manager deployment model.
- If you want to deploy more than a few N-series VMs, consider a pay-as-you-go subscription or other purchase options. If you're using an [Azure free account](#), you can use only a limited number of Azure compute cores.
- You might need to increase the cores quota (per region) in your Azure subscription, and increase the separate quota for NP cores. To request a quota increase, [open an online customer support request](#) at no charge. Default limits may vary depending on your subscription category.

## Other sizes

- [General purpose](#)
- [Compute optimized](#)
- [GPU accelerated compute](#)
- [High performance compute](#)
- [Memory optimized](#)
- [Storage optimized](#)
- [Previous generations](#)

## Next steps

Learn more about how [Azure compute units \(ACU\)](#) can help you compare compute performance across Azure SKUs.

# NP-series

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The NP-series virtual machines are powered by [Xilinx U250](#) FPGAs for accelerating workloads including machine learning inference, video transcoding, and database search & analytics. NP-series VMs are also powered by Intel Xeon 8171M (Skylake) CPUs with all core turbo clock speed of 3.2 GHz.

[Premium Storage](#): Supported

[Premium Storage caching](#): Supported

[Live Migration](#): Not Supported

[Memory Preserving Updates](#): Not Supported

[VM Generation Support](#): Generation 1

[Accelerated Networking](#): Supported

[Ephemeral OS Disks](#): Supported

[Nested Virtualization](#): Not Supported

SIZE	VCPU	MEMORY: GIB	TEMP STORAGE (SSD) GIB	FPGA	FPGA MEMORY: GIB	MAX DATA DISKS	MAX NICs/EXPECTED NETWORK BANDWIDTH (MBPS)
Standard_N_P10s	10	168	736	1	64	8	1 / 7500
Standard_N_P20s	20	336	1474	2	128	16	2 / 15000
Standard_N_P40s	40	672	2948	4	256	32	4 / 30000

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended

application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

## Frequently asked questions

**Q:** How to request quota for NP VMs?

**A:** Please follow this page [Increase limits by VM series](#). NP VMs are available in East US, West US2, West Europe, SouthEast Asia, and SouthCentral US.

**Q:** What version of Vitis should I use?

**A:** Xilinx recommends [Vitis 2021.1](#), you can also use the Development VM marketplace options (Vitis 2021.1 Development VM for Ubuntu 18.04, Ubuntu 20.04, and CentOS 7.8)

**Q:** Do I need to use NP VMs to develop my solution?

**A:** No, you can develop on-premises and deploy to the cloud. Please make sure to follow the [attestation documentation](#) to deploy on NP VMs.

**Q:** Which file returned from attestation should I use when programming my FPGA in an NP VM?

**A:** Attestation returns two xclbins, **design.bit.xclbin** and **design.azure.xclbin**. Please use **design.azure.xclbin**.

**Q:** Where should I get all the XRT / Platform files?

**A:** Please visit Xilinx's [Microsoft-Azure](#) site for all files.

**Q:** What Version of XRT should I use?

**A:** xrt\_202110.2.11.680

**Q:** What is the target deployment platform?

**A:** Use the following platforms.

- xilinx-u250-gen3x16-xdma-platform-2.1-3\_all
- xilinx-u250-gen3x16-xdma-validate\_2.1-3005608.1

**Q:** Which platform should I target for development?

**A:** xilinx-u250-gen3x16-xdma-2.1-202010-1-dev\_1-2954688\_all

**Q:** What are the supported Operating Systems?

**A:** Xilinx and Microsoft have validated Ubuntu 18.04 LTS, Ubuntu 20.04 LTS, and CentOS 7.8.

Xilinx has created the following marketplace images to simplify the deployment of these VMs.

Xilinx Alveo U250 2021.1 Deployment VM – Ubuntu18.04

Xilinx Alveo U250 2021.1 Deployment VM – Ubuntu20.04

Xilinx Alveo U250 2021.1 Deployment VM – CentOS7.8

**Q:** Can I deploy my Own Ubuntu / CentOS VMs and install XRT / Deployment Target Platform?

**A:** Yes.

Q: If I deploy my own Ubuntu18.04 VM then what are the required packages and steps?

A: Use Kernel 4.15 per [Xilinx XRT documentation](#)

Install the following packages.

- xrt\_202110.2.11.680\_18.04-amd64-xrt.deb
- xrt\_202110.2.11.680\_18.04-amd64-azure.deb
- xilinx-u250-gen3x16-xdma-platform-2.1-3\_all\_18.04.deb.tar.gz
- xilinx-u250-gen3x16-xdma-validate\_2.1-3005608.1\_all.deb

Q: On Ubuntu, after rebooting my VM I can't find my FPGA(s):

A: Please verify that your kernel hasn't been upgraded (uname -a). If so, please downgrade to kernel 4.1X.

Q: If I deploy my own Ubuntu20.04 VM then what are the required packages and steps?

A: Use Kernel 5.4 per [Xilinx XRT documentation](#)

Install the following packages.

- xrt\_202110.2.11.680\_20.04-amd64-xrt.deb
- xrt\_202110.2.11.680\_20.04-amd64-azure.deb
- xilinx-u250-gen3x16-xdma-platform-2.1-3\_all\_18.04.deb.tar.gz
- xilinx-u250-gen3x16-xdma-validate\_2.1-3005608.1\_all.deb

Q: If I deploy my own CentOS7.8 VM then what are the required packages and steps?

A: Use Kernel version: 3.10.0-1160.15.2.el7.x86\_64

Install the following packages.

- xrt\_202110.2.11.680\_7.8.2003-x86\_64-xrt.rpm
- xrt\_202110.2.11.680\_7.8.2003-x86\_64-azure.rpm
- xilinx-u250-gen3x16-xdma-platform-2.1-3.noarch.rpm.tar.gz
- xilinx-u250-gen3x16-xdma-validate-2.1-3005608.1.noarch.rpm

Q: What are the differences between OnPrem and NP VMs?

A:

- **Regarding XOCL/XCLMGMT:**

On Azure NP VMs, only the role endpoint (Device ID 5005), which uses the XOCL driver, is present.

OnPrem FPGA, both the management endpoint (Device ID 5004) and role endpoint (Device ID 5005), which use the XCLMGMT and XOCL drivers respectively, are present.

- **Regarding XRT:**

On Azure NP VMs, the XDMA 2.1 platform only supports Host\_Mem(SB) and DDR data retention features.

To enable Host\_Mem(SB) (up to 1 Gb RAM): sudo xbutil host\_mem --enable --size 1g

To disable Host\_Mem(SB): sudo xbutil host\_mem --disable

Starting on XRT2021.1:

OnPrem FPGA in Linux exposes [M2M data transfer](#).

This feature is not supported in Azure NP VMs.

Q: Can I run xbmgmt commands?

A: No, on Azure VMs there's no management support directly from the Azure VM.

Q: Do I need to load a PLP?

A: No, the PLP is loaded automatically for you, so there's no need to load via xbmgmt commands.

Q: Does Azure support different PLPs?

A: Not at this time. We only support the PLP provided in the deployment platform packages.

Q: How can I query the PLP information?

A: Need to run xbutil query and look at the lower portion.

# FPGA attestation for Azure NP-Series VMs (Preview)

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The FPGA Attestation service performs a series of validations on a design checkpoint file (called a "netlist") generated by the Xilinx toolset and produces a file that contains the validated image (called a "bitstream") that can be loaded onto the Xilinx U250 FPGA card in an NP series VM.

## News

The current attestation service is using Vitis 2020.2 from Xilinx, on Jan 17th 2022, we'll be moving to Vitis 2021.1, the change should be transparent to most users. Once your designs are "attested" using Vitis 2021.1, you should be moving to XRT2021.1. Xilinx will publish new marketplace images based on XRT 2021.1. Please note that current designs already attested on Vitis 2020.2, will work on the current deployment marketplace images as well as new images based on XRT2021.1.

As part of the move to 2021.1, Xilinx introduced a new DRC that might affect some designs previously working on Vitis 2020.2 regarding BUFCE\_LEAF failing attestation, for more details here: [Xilinx AR 75980 UltraScale/UltraScale+ BRAM: CLOCK\\_DOMAIN = Common Mode skew checks](#).

## Prerequisites

You will need an Azure subscription and an Azure Storage account. The subscription gives you access to Azure and the storage account is used to hold your netlist and output files of the attestation service.

We provide PowerShell and Bash scripts to submit attestation requests. The scripts use Azure CLI, which can run on Windows and Linux. PowerShell can run on Windows, Linux, and macOS.

[Azure CLI download \(required\)](#)

[PowerShell for Windows, Linux, and macOS download \(only for PowerShell scripts\)](#)

You will need to have your tenant and subscription ID authorized to submit to the attestation service. Visit <https://aka.ms/AzureFPGAAttestationPreview> to request access.

## Building your design for attestation

The preferred Xilinx toolset for building designs is Vitis 2020.2. Netlist files that were created with an earlier version of the toolset and are still compatible with 2020.2 can be used. Make sure you have loaded the correct shell to build against. The currently supported version is `xilinx_u250_gen3x16_xdma_2_1_202010_1`. The support files can be downloaded from the Xilinx Alveo lounge.

You must include the following argument to Vitis (v++ cmd line) to build an `xclbin` file that contains a netlist instead of a bitstream.

```
--advanced.param compiler.acceleratorBinaryContent=dcp
```

## Logging into Azure

Prior to performing any operations with Azure, you must log into Azure and set the subscription that is

authorized to call the service. Use the `az login` and `az account set -s <Sub ID or Name>` commands for this purpose. Further information about this process is documented here: [Sign in with Azure CLI](#). Use either the `sign in interactively` or `sign in with credentials` option on the command line.

## Creating a storage account and blob container

Your netlist file must be uploaded to an Azure storage blob container for access by the attestation service.

For more information on creating the account, a container, and uploading your netlist as a blob to that container, see [Quickstart: Create, download, and list blobs with Azure CLI](#).

You can also use the Azure portal for this as well.

## Upload your netlist file to Azure blob storage

There are several ways to copy the file; an example using the `az storage upload` cmdlet is shown below. The `az` commands run on both Linux and Windows. You can choose any name for the "blob" name but make sure to retain the `xclbin` extension.

```
az storage blob upload --account-name <storage account to receive netlist> --container-name <blob container name> --name <blob filename> --file <local file with netlist>
```

## Download the attestation scripts

The Validation scripts can be downloaded from the following Azure storage blob container:

<https://fpgaattestation.blob.core.windows.net/validationscripts/validate.zip>

The zip file has two PowerShell scripts, one to submit and the other to monitor while the third file is a bash script which performs both functions.

## Running the attestation scripts

To run the scripts, you will need to provide the name of your storage account, the name of the blob container where the netlist file is stored and the name of the netlist file. You will also need to create a Service shared access signature (SAS) that grants read/write access to your container (not the netlist). This SAS is used by the attestation service to make a local copy of your netlist file and to write back the resulting output files of the validation process to your container.

An overview of shared access signatures is available here with specific information about the Service SAS available here. The Service SAS page includes an important caution about protecting the generated SAS. Read the caution to understand the need to keep the SAS protected from malicious or unintended use.

You can generate a SAS for your container using the `az storage container generate-sas` cmdlet. Specify an expiry time in UTC format that is at least a few hours past the time of submission; around 6 hours should be more than adequate.

If you wish to use virtual directories, you must include the directory hierarchy as part of the container argument. For example, if you have a container named "netlists" and have a virtual directory named "image1" that contains the netlist blob, you would specify "netlists/image1" as the container name. Append any additional directory names to specify a deeper hierarchy.

### PowerShell

```
$sas=$(az storage container generate-sas --account-name <storage acct name> --name <blob container name> --https-only --permissions rwc --expiry <e.g., 2021-01-07T17:00Z> --output tsv)

.\Validate-FPGAIImage.ps1 -StorageAccountName <storage acct name> -Container <blob container name> -BlobContainerSAS $sas -NetlistName <netlist blob filename>
```

## Bash

```
sas=az storage container generate-sas --account-name <storage acct name> --name <blob container name> --https-only --permissions rwc --expiry <2021-01-07T17:00Z> --output tsv

validate-fpgaimage.sh --storage-account <storage acct name> --container <blob container name> --netlist-name <netlist blob filename> --blob-container-sas $sas
```

## Checking on the status of your submission

The Attestation service will return the orchestration ID of your submission. The submission scripts automatically start monitoring the submission by polling for completion. The orchestration ID is the primary way for us to review what happened to your submission so please keep that in case you have an issue. As reference points, attestation takes about 30 minutes to complete for a small netlist file (300MB in size); a 1.6GB file took an hour.

You can call the Monitor-Validation.ps1 script at any time to get status and results of attestation, providing the orchestration ID as an argument:

```
.\Monitor-Validation.ps1 -OrchestrationId <orchestration ID>
```

Alternatively, you can submit HTTP post request to the attestation service endpoint:

```
https://fpga-attestation.azurewebsites.net/api/ComputeFPGA_HttpGetStatus
```

The request body should contain your Subscription ID, Tenant ID, and orchestration ID of your attestation request:

```
{
  "OrchestrationId": "<orchestration ID>",
  "ClientSubscriptionId": "<your subscription ID>",
  "ClientTenantId": "<your tenant ID>"
}
```

## Post validation steps

The service will write its output back to your container. If the validation pass succeeds, your container will have the original netlist file (abc.xclbin), a file with the bitstream (abc.bit.xclbin), a file that identifies the private location of your stored bitstream (abc.azure.xclbin) and four log files: one for the startup process (abc-log.txt) and one each for the three parallel phases that perform the validation. These are named \*logPhaseX.txt where X is a number for the phase. The azure.xclbin is used on your VM to signal the uploading of your validated image to the U250.

If validation failed, an error-\*.txt file is written indicating which step failed. Also check the log files if the error log indicates that attestation failed. When contacting us for support, please be sure to include all these files as part of the support request along with the orchestration ID.

You can use the Azure portal to create your container as well as uploading your netlist and downloading the bitstream and log files. Submitting an attestation request and monitoring its progress through the portal is not supported at this time and must be done through scripts as described above.

# High performance computing VM sizes

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

Azure H-series virtual machines (VMs) are designed to deliver leadership-class performance, scalability, and cost efficiency for various real-world HPC workloads.

**HBv3-series** VMs are optimized for HPC applications such as fluid dynamics, explicit and implicit finite element analysis, weather modeling, seismic processing, reservoir simulation, and RTL simulation. HBv3 VMs feature up to 120 AMD EPYC™ 7003-series (Milan) CPU cores, 448 GB of RAM, and no hyperthreading. HBv3-series VMs also provide 350 GB/sec of memory bandwidth, up to 32 MB of L3 cache per core, up to 7 GB/s of block device SSD performance, and clock frequencies up to 3.5 GHz.

All HBv3-series VMs feature 200 Gb/sec HDR InfiniBand from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. The HDR InfiniBand fabric also supports Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is strongly recommended.

**HBv2-series** VMs are optimized for applications driven by memory bandwidth, such as fluid dynamics, finite element analysis, and reservoir simulation. HBv2 VMs feature 120 AMD EPYC 7742 processor cores, 4 GB of RAM per CPU core, and no simultaneous multithreading. Each HBv2 VM provides up to 340 GB/sec of memory bandwidth, and up to 4 teraFLOPS of FP64 compute.

HBv2 VMs feature 200 Gb/sec Mellanox HDR InfiniBand, while both HB and HC-series VMs feature 100 Gb/sec Mellanox EDR InfiniBand. Each of these VM types is connected in a non-blocking fat tree for optimized and consistent RDMA performance. HBv2 VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is strongly recommended.

**HB-series** VMs are optimized for applications driven by memory bandwidth, such as fluid dynamics, explicit finite element analysis, and weather modeling. HB VMs feature 60 AMD EPYC 7551 processor cores, 4 GB of RAM per CPU core, and no hyperthreading. The AMD EPYC platform provides more than 260 GB/sec of memory bandwidth.

**HC-series** VMs are optimized for applications driven by dense computation, such as implicit finite element analysis, molecular dynamics, and computational chemistry. HC VMs feature 44 Intel Xeon Platinum 8168 processor cores, 8 GB of RAM per CPU core, and no hyperthreading. The Intel Xeon Platinum platform supports Intel's rich ecosystem of software tools such as the Intel Math Kernel Library.

**H-series** VMs are optimized for applications driven by high CPU frequencies or large memory per core requirements. H-series VMs feature 8 or 16 Intel Xeon E5 2667 v3 processor cores, 7 or 14 GB of RAM per CPU core, and no hyperthreading. H-series features 56 Gb/sec Mellanox FDR InfiniBand in a non-blocking fat tree configuration for consistent RDMA performance. H-series VMs support Intel MPI 5.x and MS-MPI.

**NOTE**

All HBv3, HBv2, HB, and HC-series VMs have exclusive access to the physical servers. There is only 1 VM per physical server and there is no shared multi-tenancy with any other VMs for these VM sizes.

**NOTE**

The [A8 – A11 VMs](#) are retired as of 3/2021. No new VM deployments of these sizes are now possible. If you have existing VMs, refer to emailed notifications for next steps including migrating to other VM sizes in [HPC Migration Guide](#).

## RDMA-capable instances

Most of the HPC VM sizes feature a network interface for remote direct memory access (RDMA) connectivity. Selected [N-series](#) sizes designated with 'r' are also RDMA-capable. This interface is in addition to the standard Azure Ethernet network interface available in the other VM sizes.

This secondary interface allows the RDMA-capable instances to communicate over an InfiniBand (IB) network, operating at HDR rates for HBv3, HBv2, EDR rates for HB, HC, NDv2, and FDR rates for H16r, H16mr, and other RDMA-capable N-series virtual machines. These RDMA capabilities can boost the scalability and performance of Message Passing Interface (MPI) based applications.

**NOTE**

**SR-IOV support:** In Azure HPC, currently there are two classes of VMs depending on whether they are SR-IOV enabled for InfiniBand. Currently, almost all the newer generation, RDMA-capable or InfiniBand enabled VMs on Azure are SR-IOV enabled except for H16r, H16mr, and NC24r. RDMA is only enabled over the InfiniBand (IB) network and is supported for all RDMA-capable VMs. IP over IB is only supported on the SR-IOV enabled VMs. RDMA is not enabled over the Ethernet network.

- **Operating System** - Linux distributions such as CentOS, RHEL, Ubuntu, SUSE are commonly used. Windows Server 2016 and newer versions are supported on all the HPC series VMs. Windows Server 2012 R2 and Windows Server 2012 are also supported on the non-SR-IOV enabled VMs. Note that [Windows Server 2012 R2 is not supported on HBv2 onwards as VM sizes with more than 64 \(virtual or physical\) cores](#). See [VM Images](#) for a list of supported VM Images on the Marketplace and how they can be configured appropriately. The respective VM size pages also list out the software stack support.
- **InfiniBand and Drivers** - On InfiniBand enabled VMs, the appropriate drivers are required to enable RDMA. See [VM Images](#) for a list of supported VM Images on the Marketplace and how they can be configured appropriately. Also see [enabling InfiniBand](#) to learn about VM extensions or manual installation of InfiniBand drivers.
- **MPI** - The SR-IOV enabled VM sizes on Azure allow almost any flavor of MPI to be used with Mellanox OFED. On non-SR-IOV enabled VMs, supported MPI implementations use the Microsoft Network Direct (ND) interface to communicate between VMs. Hence, only Intel MPI 5.x and Microsoft MPI (MS-MPI) 2012 R2 or later versions are supported. Later versions of the Intel MPI runtime library may or may not be compatible with the Azure RDMA drivers. See [Setup MPI for HPC](#) for more details on setting up MPI on HPC VMs on Azure.

#### NOTE

**RDMA network address space:** The RDMA network in Azure reserves the address space 172.16.0.0/16. To run MPI applications on instances deployed in an Azure virtual network, make sure that the virtual network address space does not overlap the RDMA network.

## Cluster configuration options

Azure provides several options to create clusters of HPC VMs that can communicate using the RDMA network, including:

- **Virtual machines** - Deploy the RDMA-capable HPC VMs in the same scale set or availability set (when you use the Azure Resource Manager deployment model). If you use the classic deployment model, deploy the VMs in the same cloud service.
- **Virtual machine scale sets** - In a virtual machine scale set, ensure that you limit the deployment to a single placement group for InfiniBand communication within the scale set. For example, in a Resource Manager template, set the `singlePlacementGroup` property to `true`. Note that the maximum scale set size that can be spun up with `singlePlacementGroup=true` is capped at 100 VMs by default. If your HPC job scale needs are higher than 100 VMs in a single tenant, you may request an increase, [open an online customer support request](#) at no charge. The limit on the number of VMs in a single scale set can be increased to 300. Note that when deploying VMs using Availability Sets the maximum limit is at 200 VMs per Availability Set.

#### NOTE

**MPI among virtual machines:** If RDMA (e.g. using MPI communication) is required between virtual machines (VMs), ensure that the VMs are in the same virtual machine scale set or availability set.

- **Azure CycleCloud** - Create an HPC cluster using [Azure CycleCloud](#) to run MPI jobs.
- **Azure Batch** - Create an [Azure Batch](#) pool to run MPI workloads. To use compute-intensive instances when running MPI applications with Azure Batch, see [Use multi-instance tasks to run Message Passing Interface \(MPI\) applications in Azure Batch](#).
- **Microsoft HPC Pack** - [HPC Pack](#) includes a runtime environment for MS-MPI that uses the Azure RDMA network when deployed on RDMA-capable Linux VMs. For example deployments, see [Set up a Linux RDMA cluster with HPC Pack to run MPI applications](#).

## Deployment considerations

- **Azure subscription** – To deploy more than a few compute-intensive instances, consider a pay-as-you-go subscription or other purchase options. If you're using an [Azure free account](#), you can use only a limited number of Azure compute cores.
- **Pricing and availability** - Check [VM pricing](#) and [availability](#) by Azure regions.
- **Cores quota** – You might need to increase the cores quota in your Azure subscription from the default value. Your subscription might also limit the number of cores you can deploy in certain VM size families, including the H-series. To request a quota increase, [open an online customer support request](#) at no charge. (Default limits may vary depending on your subscription category.)

#### NOTE

Contact Azure Support if you have large-scale capacity needs. Azure quotas are credit limits, not capacity guarantees. Regardless of your quota, you are only charged for cores that you use.

- **Virtual network** – An Azure [virtual network](#) is not required to use the compute-intensive instances. However, for many deployments you need at least a cloud-based Azure virtual network, or a site-to-site connection if you need to access on-premises resources. When needed, create a new virtual network to deploy the instances. Adding compute-intensive VMs to a virtual network in an affinity group is not supported.
- **Resizing** – Because of their specialized hardware, you can only resize compute-intensive instances within the same size family (H-series or N-series). For example, you can only resize an H-series VM from one H-series size to another. Additional considerations around InfiniBand driver support and NVMe disks may need to be considered for certain VMs.

<sup>1</sup> For MPI applications, dedicated RDMA backend network is enabled by FDR InfiniBand network.

#### NOTE

Among the [RDMA capable VMs](#), the H-series are not SR-IOV enabled. Therefore, the supported [VM Images](#), [InfiniBand driver](#) requirements and supported [MPI libraries](#) are different from the SR-IOV enabled VMs.

A quirk of the alternate NIC virtualization solution in place for the H-series is that the OS may occasionally report inaccurate link speeds for the synthetic NIC that is used for RDMA connections. This issue does not, however, impact actual performance experienced by jobs using the VM's RDMA capability, so outputs like the following are not a cause for concern.

```
$ ethtool eth1
Settings for eth1:
...
Speed: 10000Mb/s
```

## Software specifications

SOFTWARE SPECIFICATIONS	H-SERIES VM
Max MPI Job Size	4800 cores (300 VMs in a single virtual machine scale set with singlePlacementGroup=true)
MPI Support	Intel MPI 5.x, MS-MPI
OS Support for non-SRIOV RDMA	CentOS/RHEL 6.5 - 7.4, SLES 12 SP4+, WinServer 2012 - 2016
Orchestrator Support	CycleCloud, Batch, AKS

- [Enabling InfiniBand](#) with HPC VM images, VM extensions or manual installation.
- [Setting up MPI](#), including code snippets and recommendations.
- [Cluster configuration options](#).
- [Deployment considerations](#).

## Size table definitions

- Storage capacity is shown in units of GiB or  $1024^3$  bytes. When you compare disks measured in GB ( $1000^3$  bytes) to disks measured in GiB ( $1024^3$ ) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps =  $10^6$  bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see [Virtual machine and disk performance](#).
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see [Virtual machine network bandwidth](#).

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see [Optimize network throughput for Azure virtual machines](#). To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see [Bandwidth/Throughput testing \(NTTCP\)](#).

# HB-series

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

HB-series VMs are optimized for applications that are driven by memory bandwidth, such as fluid dynamics, explicit finite element analysis, and weather modeling. HB VMs feature 60 AMD EPYC 7551 processor cores, 4 GB of RAM per CPU core, and no simultaneous multithreading. An HB VM provides up to 260 GB/sec of memory bandwidth.

HB-series VMs feature 100 Gb/sec Mellanox EDR InfiniBand. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. These VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is recommended.

# HBv2-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

HBv2-series VMs are optimized for applications that are driven by memory bandwidth, such as fluid dynamics, finite element analysis, and reservoir simulation. HBv2 VMs feature 120 AMD EPYC 7742 processor cores, 4 GB of RAM per CPU core, and no simultaneous multithreading. Each HBv2 VM provides up to 340 GB/sec of memory bandwidth, and up to 4 teraFLOPS of FP64 compute.

HBv2-series VMs feature 200 Gb/sec Mellanox HDR InfiniBand. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. These VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is recommended.

# HBv3-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

HBv3-series VMs are optimized for HPC applications such as fluid dynamics, explicit and implicit finite element analysis, weather modeling, seismic processing, reservoir simulation, and RTL simulation. HBv3 VMs feature up to 120 AMD EPYC™ 7V73X (Milan-X) CPU cores, 448 GB of RAM, and no hyperthreading. HBv3-series VMs also provide 350 GB/sec of memory bandwidth (amplified up to 630 GB/s), up to 96 MB of L3 cache per core (1.536 GB total per VM), up to 7 GB/s of block device SSD performance, and clock frequencies up to 3.5 GHz.

All HBv3-series VMs feature 200 Gb/sec HDR InfiniBand from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. The HDR InfiniBand fabric also supports Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is strongly recommended.

# HC-series

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

HC-series VMs are optimized for applications driven by dense computation, such as implicit finite element analysis, molecular dynamics, and computational chemistry. HC VMs feature 44 Intel Xeon Platinum 8168 processor cores, 8 GB of RAM per CPU core, and no hyperthreading. The Intel Xeon Platinum platform supports Intel's rich ecosystem of software tools such as the Intel Math Kernel Library and advanced vector processing capabilities such as AVX-512.

HC-series VMs feature 100 Gb/sec Mellanox EDR InfiniBand. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. These VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is recommended.

# Migrate your H and H-series Promo virtual machines by August 31, 2022

9/21/2022 • 3 minutes to read • [Edit Online](#)

Microsoft Azure has introduced newer generations of high-performance computing (HPC), general purpose, and memory-optimized virtual machines (VMs). For this reason, we recommend that you migrate workloads from the original H-series and H-series Promo VMs to our newer offerings.

Azure [HC](#), [HBv2](#), [HBv3](#), [Dv4](#), [Dav4](#), [Ev4](#), and [Eav4](#) VMs have greater memory bandwidth, improved networking capabilities, and better cost and performance across various HPC workloads. On August 31, 2022, we're retiring the following H-series Azure VM sizes:

- H8
- H8m
- H16
- H16r
- H16m
- H16mr
- H8 Promo
- H8m Promo
- H16 Promo
- H16r Promo
- H16m Promo
- H16mr Promo

## How does the H-series migration affect me?

1-year and 3-year RI offerings for the VMs are no longer available; however, regular PAYGO offer can still be transacted until the official decommission date. After August 31, 2022, any remaining H-series VM subscriptions in the preceding list will be set to a deallocated state. They'll stop working and no longer incur billing charges. If you need RI, please refer to our migration documents to find the suitable VM offerings that have RI available.

You can either exchange/refund your existing reservations. If you choose not to, after the hardware is deprecated you won't be getting the reservation benefit but still be paying for it.

The current VM size retirement only affects the VM sizes in the [H series](#), which includes the H-series Promo.

## What actions should I take?

You'll need to resize or deallocate your H-series VMs. We recommend that you migrate workloads from the original H-series VMs and the H-series Promo VMs to our newer offerings.

**HPC workloads:** [HC](#), [HBv2](#), and [HBv3](#) VMs offer substantially higher levels of HPC workload performance and cost efficiency because of:

- Large improvements in CPU core architecture.
- Higher memory bandwidth.
- Larger L3 caches.
- Enhanced InfiniBand networking hardware and software support as compared to H series.

As a result, HC, HBv2, and HBv3 series will in general offer substantially better performance per unit of cost (maximizing performance for a fixed amount of spend) and cost per performance (minimizing cost for a fixed amount of performance).

**General purpose workloads:** [Dv4](#), [Dav4](#), and Dv5 VMs offer the same or better CPU performance at identical or larger core counts, a comparable amount of memory per physical CPU core, better Azure networking capabilities, and lower overall cost.

**Memory-optimized workloads:** [Ev4](#), [Eav4](#), and Ev5 VMs offer the same or better CPU performance at identical or larger core counts, a comparable amount of memory per physical CPU core, better Azure networking capabilities, and lower overall cost.

[H-series](#) and H-series Promo VMs won't be retired until September 2022. We're providing this guide in advance to give you a long window to assess, plan, and execute your migration.

## Migration steps

1. Choose a series and size for migration.
2. Get a quota for the target VM series.
3. Resize the current H-series VM size to the target size.

## Breaking changes

If you use H-series VM sizes that expose an InfiniBand networking interface, such as those sizes with an "r" in the VM size name, and you want your new VM sizes to also support InfiniBand networking, you'll no longer be able to use legacy OS images with built-in InfiniBand driver support (CentOS 7.4 and prior, Windows Server 2012).

Instead, use modern OS images such as those available in Azure Marketplace that support modern operating systems (CentOS 7.5 and newer, Windows Server 2016 and newer) and standard OFED drivers. See the [supported software stack](#), which includes the supported OS for the respective VM sizes.

## Get a quota for the target VM family

Follow the guide to [request an increase in vCPU quota by VM family](#).

## Resize the current VM

You can [resize the virtual machine](#).

# Migrate your HB-series virtual machines by August 31, 2024

9/21/2022 • 2 minutes to read • [Edit Online](#)

Microsoft Azure has introduced HBv2 and HBv3-series virtual machines (VMs) for high-performance computing (HPC). For this reason, we recommend that you migrate workloads from original HB-series VMs to our newer offerings.

Azure [HBv2](#) and [HBv3](#) VMs have greater memory bandwidth, improved remote direct memory access (RDMA) networking capabilities, larger and faster local solid-state drives, and better cost and performance across various HPC workloads. As a result, we're retiring our HB-series Azure VM sizes on August 31, 2024.

## How does the HB-series migration affect me?

After August 31, 2024, any remaining HB-size VM subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges.

### NOTE

This VM size retirement only affects the VM sizes in the HB series. This retirement announcement doesn't apply to the newer HBv2, HBv3, and HC-series VMs.

## What actions should I take?

You'll need to resize or deallocate your H-series VMs. We recommend that you migrate workloads from the original H-series VMs and the H-series Promo VMs to our newer offerings.

[HBv2](#) and [HBv3](#) VMs offer substantially higher levels of HPC workload performance and cost efficiency because of:

- Large improvements in CPU core architecture.
- Higher memory bandwidth.
- Larger L3 caches.
- Enhanced InfiniBand networking as compared to HB series.

As a result, HBv2 and HBv3 series will in general offer substantially better performance per unit of cost (maximizing performance for a fixed amount of spend) and cost per performance (minimizing cost for a fixed amount of performance).

All regions that contain HB-series VMs contain HBv2 and HBv3-series VMs. Existing workloads that run on HB-series VMs can be migrated without concern for geographic placement or for access to more services in those regions.

[HB-series](#) VMs won't be retired until September 2024. We're providing this guide in advance to give you a long window to assess, plan, and execute your migration.

### Recommendations for workload migration from HB-series VMs

CURRENT VM SIZE	TARGET VM SIZE	DIFFERENCE IN SPECIFICATION
Standard_HB60rs	Standard_HB120rs_v2 Standard_HB120rs_v3 Standard_HB120-64rs_v3	Newer CPU: AMD Rome and Milan (+20-30% IPC) Memory: Up to 2x more RAM Memory bandwidth: Up to 30% more memory bandwidth InfiniBand: 200 Gb HDR (2x higher bandwidth) Max data disks: Up to 32 (+8x)
Standard_HB60-45rs	Standard_HB120-96rs_v3 Standard_HB120-64rs_v3 Standard_HB120-32rs_v3	Newer CPU: AMD Rome and Milan (+20-30% IPC) Memory: Up to 2x more RAM Memory bandwidth: Up to 30% more memory bandwidth InfiniBand: 200 Gb HDR (2x higher bandwidth) Max data disks: Up to 32 (+8x)
Standard_HB60-30rs	Standard_HB120-32rs_v3 Standard_HB120-16rs_v3	Newer CPU: AMD Rome and Milan (+20-30% IPC) Memory: Up to 2x more RAM Memory bandwidth: Up to 30% more memory bandwidth InfiniBand: 200 Gb HDR (2x higher bandwidth) Max data disks: Up to 32 (+8x)
Standard_HB60-15rs	Standard_HB120-16rs_v3	Newer CPU: AMD Rome and Milan (+20-30% IPC) Memory: Up to 2x more RAM Memory bandwidth: Up to 30% more memory bandwidth InfiniBand: 200 Gb HDR (2x higher bandwidth) Max data disks: Up to 32 (+8x)

## Migration steps

1. Choose a series and size for migration.
2. Get a quota for the target VM series.
3. Resize the current HB-series VM size to the target size.

## Get a quota for the target VM family

Follow the guide to [request an increase in vCPU quota by VM family](#).

## Resize the current VM

You can [resize the virtual machine](#).

# Previous generations of virtual machine sizes

9/21/2022 • 15 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

## TIP

Try the [Virtual machines selector tool](#) to find other sizes that best fit your workload.

This section provides information on previous generations of virtual machine sizes. These sizes can still be used, but there are newer generations available.

## F-series

F-series is based on the 2.4 GHz Intel Xeon® E5-2673 v3 (Haswell) processor, which can achieve clock speeds as high as 3.1 GHz with the Intel Turbo Boost Technology 2.0. This is the same CPU performance as the Dv2-series of VMs.

F-series VMs are an excellent choice for workloads that demand faster CPUs but do not need as much memory or temporary storage per vCPU. Workloads such as analytics, gaming servers, web servers, and batch processing will benefit from the value of the F-series.

Standard_F2s	2	4	8	8	8000/64 (24)	6400/96	2/1500
Standard_F4s	4	8	16	16	16000/128 (48)	12800/192	4/3000
Standard_F8s	8	16	32	32	32000/256 (96)	25600/384	8/6000
Standard_F16s	16	32	64	64	64000/512 (192)	51200/768	8/12000

MBps =  $10^6$  bytes per second, and GiB =  $1024^3$  bytes.

<sup>1</sup> The maximum disk throughput (IOPS or MBps) possible with a Fs series VM may be limited by the number, size, and striping of the attached disk(s). For details, see [Design for high performance](#).

## NVv2-series

Newer size recommendation: [NVv3-series](#)

The NVv2-series virtual machines are powered by [NVIDIA Tesla M60](#) GPUs and NVIDIA GRID technology with Intel Broadwell CPUs. These virtual machines are targeted for GPU accelerated graphics applications and virtual desktops where customers want to visualize their data, simulate results to view, work on CAD, or render and stream content. Additionally, these virtual machines can run single precision workloads such as encoding and rendering. NVv2 virtual machines support Premium Storage and come with twice the system memory (RAM) when compared with its predecessor NV-series.

Each GPU in NVv2 instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

Ephemeral OS Disks: Supported

SIZE	VCPU	MEMORY: GIB	TEMP STORAGE (SSD) GIB	GPU	GPU MEMORY: GIB	MAX DATA DISKS	MAX NICS	VIRTUAL WORKSTATIONS	VIRTUAL APPLICATIONS
Standard_NV6s_v2	6	112	320	1	8	12	4	1	25
Standard_NV12s_v2	12	224	640	2	16	24	8	2	50
Standard_NV24s_v2	24	448	1280	4	32	32	8	4	100

## Older generations of virtual machine sizes

This section provides information on older generations of virtual machine sizes. These sizes are still supported but will not receive additional capacity. There are newer or alternative sizes that are generally available. Please refer to [Sizes virtual machines in Azure](#) to choose the VM sizes that will best fit your need.

For more information on resizing a Linux VM, see [Resize a VM](#).

### Basic A

Newer size recommendation: [Av2-series](#)

Premium Storage: Not Supported

Premium Storage caching: Not Supported

The basic tier sizes are primarily for development workloads and other applications that don't require load balancing, auto-scaling, or memory-intensive virtual machines.

SIZE - SIZE\NAME	VCPU	MEMORY	NICS (MAX)	MAX TEMPORARY DISK SIZE	MAX. DATA DISKS (1023 GB EACH)	MAX. IOPS (300 PER DISK)
A0\Basic_A0	1	768 MB	2	20 GB	1	1x300
A1\Basic_A1	1	1.75 GB	2	40 GB	2	2x300
A2\Basic_A2	2	3.5 GB	2	60 GB	4	4x300
A3\Basic_A3	4	7 GB	2	120 GB	8	8x300
A4\Basic_A4	8	14 GB	2	240 GB	16	16x300

### Standard A0 - A4 using CLI and PowerShell

In the classic deployment model, some VM size names are slightly different in CLI and PowerShell:

- Standard\_A0 is ExtraSmall

- Standard\_A1 is Small
- Standard\_A2 is Medium
- Standard\_A3 is Large
- Standard\_A4 is ExtraLarge

## A-series

Newer size recommendation: [Av2-series](#)

ACU: 50-100

Premium Storage: Not Supported

Premium Storage caching: Not Supported

SIZE	VCPU	MEMORY: GIB	TEMP STORAGE (HDD): GIB	MAX DATA DISKS	MAX DATA DISK THROUGHPUT: IOPS	MAX NICS/EXPECTED NETWORK BANDWIDTH (MBPS)
Standard_A0 <sup>1</sup>	1	0.768	20	1	1x500	2/100
Standard_A1	1	1.75	70	2	2x500	2/500
Standard_A2	2	3.5	135	4	4x500	2/500
Standard_A3	4	7	285	8	8x500	2/1000
Standard_A4	8	14	605	16	16x500	4/2000
Standard_A5	2	14	135	4	4x500	2/500
Standard_A6	4	28	285	8	8x500	2/1000
Standard_A7	8	56	605	16	16x500	4/2000

<sup>1</sup> The A0 size is over-subscribed on the physical hardware. For this specific size only, other customer deployments may impact the performance of your running workload. The relative performance is outlined below as the expected baseline, subject to an approximate variability of 15 percent.

## A-series - compute-intensive instances

Newer size recommendation: [Av2-series](#)

ACU: 225

Premium Storage: Not Supported

Premium Storage caching: Not Supported

The A8-A11 and H-series sizes are also known as *compute-intensive instances*. The hardware that runs these sizes is designed and optimized for compute-intensive and network-intensive applications, including high-performance computing (HPC) cluster applications, modeling, and simulations. The A8-A11 series uses Intel Xeon E5-2670 @ 2.6 GHZ and the H-series uses Intel Xeon E5-2667 v3 @ 3.2 GHz.

SIZE	VCPU	MEMORY: GIB	TEMP STORAGE (HDD): GIB	MAX DATA DISKS	MAX DATA DISK THROUGHPUT: IOPS	MAX NICs
Standard_A8 <sup>1</sup>	8	56	382	32	32x500	2
Standard_A9 <sup>1</sup>	16	112	382	64	64x500	4
Standard_A10	8	56	382	32	32x500	2
Standard_A11	16	112	382	64	64x500	4

<sup>1</sup> For MPI applications, dedicated RDMA backend network is enabled by FDR InfiniBand network, which delivers ultra-low-latency and high bandwidth.

#### NOTE

The A8 – A11 VMs are planned for retirement on 3/2021. We strongly recommend not creating any new A8 – A11 VMs. Please migrate any existing A8 – A11 VMs to newer and powerful high-performance computing VM sizes such as H, HB, HC, HBv2 as well as general purpose compute VM sizes such as D, E, and F for better price-performance. For more information, see [HPC Migration Guide](#).

## D-series

Newer size recommendation: [Dav4-series](#), [Dv4-series](#) and [Ddv4-series](#)

ACU: 160-250<sup>1</sup>

<sup>1</sup> The maximum disk throughput (IOPS or MBps) possible with a DS series VM may be limited by the number, size and striping of the attached disk(s). For details, see [Design for high performance](#). <sup>2</sup> VM Family can run on one of the following CPU's: 2.2 GHz Intel Xeon® E5-2660 v2, 2.4 GHz Intel Xeon® E5-2673 v3 (Haswell) or 2.3 GHz Intel XEON® E5-2673 v4 (Broadwell)

## Ls-series

Newer size recommendation: [Lsv2-series](#)

The Ls-series offers up to 32 vCPUs, using the Intel® Xeon® processor E5 v3 family. The Ls-series gets the same CPU performance as the G/GS-Series and comes with 8 GiB of memory per vCPU.

The Ls-series does not support the creation of a local cache to increase the IOPS achievable by durable data disks. The high throughput and IOPS of the local disk makes Ls-series VMs ideal for NoSQL stores such as Apache Cassandra and MongoDB which replicate data across multiple VMs to achieve persistence in the event of the failure of a single VM.

## NV-series

Newer size recommendation: [NVv3-series](#) and [NVv4-series](#)

The NV-series virtual machines are powered by [NVIDIA Tesla M60](#) GPUs and NVIDIA GRID technology for desktop accelerated applications and virtual desktops where customers are able to visualize their data or simulations. Users are able to visualize their graphics intensive workflows on the NV instances to get superior graphics capability and additionally run single precision workloads such as encoding and rendering. NV-series VMs are also powered by Intel Xeon E5-2690 v3 (Haswell) CPUs.

Each GPU in NV instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

\*RDMA capable

## NCv2 series

Newer size recommendation: [NC T4 v3-series](#) and [NC V100 v3-series](#)

NCv2-series VMs are powered by NVIDIA Tesla P100 GPUs. These GPUs can provide more than 2x the

computational performance of the NC-series. Customers can take advantage of these updated GPUs for traditional HPC workloads such as reservoir modeling, DNA sequencing, protein analysis, Monte Carlo simulations, and others. In addition to the GPUs, the NCv2-series VMs are also powered by Intel Xeon E5-2690 v4 (Broadwell) CPUs.

The NC24rs v2 configuration provides a low latency, high-throughput network interface optimized for tightly coupled parallel computing workloads.

## ND series

[Newer size recommendation: NDv2-series and NC V100 v3-series](#)

The ND-series virtual machines are a new addition to the GPU family designed for AI, and Deep Learning workloads. They offer excellent performance for training and inference. ND instances are powered by [NVIDIA Tesla P40](#) GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. These instances provide excellent performance for single-precision floating point operations, for AI workloads utilizing Microsoft Cognitive Toolkit, TensorFlow, Caffe, and other frameworks. The ND-series also offers a much larger GPU memory size (24 GB), enabling to fit much larger neural net models. Like the NC-series, the ND-series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

## Next steps

Learn more about how [Azure compute units \(ACU\)](#) can help you compare compute performance across Azure SKUs.

# Support for generation 2 VMs on Azure

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Support for generation 2 virtual machines (VMs) is now available on Azure. You can't change a virtual machine's generation after you've created it, so review the considerations on this page before you choose a generation.

Generation 2 VMs support key features that aren't supported in generation 1 VMs. These features include increased memory, Intel Software Guard Extensions (Intel SGX), and virtualized persistent memory (vPMEM). Generation 2 VMs running on-premises, have some features that aren't supported in Azure yet. For more information, see the [Features and capabilities](#) section.

Generation 2 VMs use the new UEFI-based boot architecture rather than the BIOS-based architecture used by generation 1 VMs. Compared to generation 1 VMs, generation 2 VMs might have improved boot and installation times. For an overview of generation 2 VMs and some of the differences between generation 1 and generation 2, see [Should I create a generation 1 or 2 virtual machine in Hyper-V?](#).

## Generation 2 VM sizes

Azure now offers generation 2 support for the following selected VM series:

<sup>1</sup> Mv2-series, DC-series, NDv2-series, Msv2 and Mds2-series Medium Memory do not support Generation 1 VM images and only support a subset of Generation 2 images. Please see [Mv2-series documentation](#), [DSv2-series](#), [ND A100 v4-series](#), [NDv2-series](#), and [Msv2 and Mds2 Medium Memory Series](#) for details.

## Generation 2 VM images in Azure Marketplace

Generation 2 VMs support the following Marketplace images:

- Windows Server 2022, 2019, 2016, 2012 R2, 2012
- Windows 11 Pro, Windows 11 Enterprise
- Windows 10 Pro, Windows 10 Enterprise
- SUSE Linux Enterprise Server 15 SP3, SP2
- SUSE Linux Enterprise Server 12 SP4
- Ubuntu Server 21.04 LTS, 20.04 LTS, 18.04 LTS, 16.04 LTS
- RHEL 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, 7.6, 7.5, 7.4, 7.0
- Cent OS 8.4, 8.3, 8.2, 8.1, 8.0, 7.7, 7.6, 7.5, 7.4
- Oracle Linux 8.4 LVM, 8.3 LVM, 8.2 LVM, 8.1, 7.9 LVM, 7.9, 7.8, 7.7

### NOTE

Specific Virtual machine sizes like Mv2-Series, DC-series, ND A100 v4-series, NDv2-series, Msv2 and Mds2-series may only support a subset of these images - please look at the relevant virtual machine size documentation for complete details.

## On-premises vs. Azure generation 2 VMs

Azure doesn't currently support some of the features that on-premises Hyper-V supports for generation 2 VMs.

GENERATION 2 FEATURE	ON-PREMISES HYPER-V	AZURE
Secure boot	✓	With <a href="#">trusted launch</a>
Shielded VM	✓	✗
vTPM	✓	With <a href="#">trusted launch</a>
Virtualization-based security (VBS)	✓	✓
VHDX format	✓	✗

For more information, see [Trusted launch](#).

## Features and capabilities

### Generation 1 vs. generation 2 features

FEATURE	GENERATION 1	GENERATION 2
Boot	PCAT	UEFI

## Creating a generation 2 VM

### Azure Resource Manager Template

To create a simple Windows Generation 2 VM, see [Create a Windows virtual machine from a Resource Manager template](#) To create a simple Linux Generation 2 VM, see [How to create a Linux virtual machine with Azure Resource Manager templates](#)

### Marketplace image

In the Azure portal or Azure CLI, you can create generation 2 VMs from a Marketplace image that supports UEFI boot.

#### Azure portal

Below are the steps to create a generation 2 (Gen2) VM in Azure portal.

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Search for **Virtual Machines**
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select **Add**, and then select **Virtual machine**.
5. Under **Project details**, make sure the correct subscription is selected.

6. Under **Resource group**, select **Create new** and type a name for your resource group or select an existing resource group from the dropdown.
7. Under **Instance details**, type a name for the virtual machine name and choose a region
8. Under **Image**, select a Gen2 image from the **Marketplace images to get started**

**TIP**

If you don't see the Gen 2 version of the image you want in the drop-down, select **See all images** and then change the **Image Type** filter to **Gen 2**.

9. Select a VM size that supports Gen2. See a list of [supported sizes](#).
10. Fill in the **Administrator account** information and then **Inbound port rules**
11. At the bottom of the page, select **Review + Create**
12. On the **Create a virtual machine** page, you can see the details about the VM you are about to deploy.  
Once validation shows as passed, select **Create**.

**PowerShell**

You can also use PowerShell to create a VM by directly referencing the generation 1 or generation 2 SKU.

For example, use the following PowerShell cmdlet to get a list of the SKUs in the **WindowsServer** offer.

```
Get-AzVMImageSku -Location westus2 -PublisherName MicrosoftWindowsServer -Offer WindowsServer
```

If you're creating a VM with Windows Server 2019 as the OS, then you can select a generation 2 (UEFI) image which looks like this:

```
2019-datacenter-gensecond
```

If you're creating a VM with Windows 10 as the OS, then you can select a generation 2 (UEFI) image which looks like this:

```
20H2-PRO-G2
```

See the [Features and capabilities](#) section for a current list of supported Marketplace images.

**Azure CLI**

Alternatively, you can use the Azure CLI to see any available generation 2 images, listed by **Publisher**.

```
az vm image list --publisher Canonical --sku gen2 --output table --all
```

**Managed image or managed disk**

You can create a generation 2 VM from a managed image or managed disk in the same way you would create a generation 1 VM.

**Virtual machine scale sets**

You can also create generation 2 VMs by using virtual machine scale sets. In the Azure CLI, use Azure scale sets to create generation 2 VMs.

## Frequently asked questions

- Are generation 2 VMs available in all Azure regions?

Yes. But not all [generation 2 VM sizes](#) are available in every region. The availability of the generation 2 VM depends on the availability of the VM size.

- **Is there a price difference between generation 1 and generation 2 VMs?**  
No.
- **I have a .vhf file from my on-premises generation 2 VM. Can I use that .vhf file to create a generation 2 VM in Azure?** Yes, you can bring your generation 2 .vhf file to Azure and use that to create a generation 2 VM. Use the following steps to do so:
  1. Upload the .vhf to a storage account in the same region where you'd like to create your VM.
  2. Create a managed disk from the .vhf file. Set the Hyper-V Generation property to V2. The following PowerShell commands set Hyper-V Generation property when creating managed disk.

```
$sourceUri = 'https://xyzstorage.blob.core.windows.net/vhd/abcd.vhd'. #<Provide location to  
your uploaded .vhf file>  
$osDiskName = 'gen2Diskfrmenvhd' #<Provide a name for your disk>  
$diskconfig = New-AzDiskConfig -Location '<location>' -DiskSizeGB 127 -AccountType  
Standard_LRS -OsType Windows -HyperVGeneration "V2" -SourceUri $sourceUri -CreateOption  
'Import'  
New-AzDisk -DiskName $osDiskName -ResourceGroupName '<Your Resource Group>' -Disk $diskconfig
```

- 3. Once the disk is available, create a VM by attaching this disk. The VM created will be a generation 2 VM. When the generation 2 VM is created, you can optionally generalize the image of this VM. By generalizing the image, you can use it to create multiple VMs.
- **How do I increase the OS disk size?**

OS disks larger than 2 TiB are new to generation 2 VMs. By default, OS disks are smaller than 2 TiB for generation 2 VMs. You can increase the disk size up to a recommended maximum of 4 TiB. Use the Azure CLI or the Azure portal to increase the OS disk size. For information about how to expand disks programmatically, see [Resize a disk](#) for [Windows](#) or [Linux](#).

To increase the OS disk size from the Azure portal:

1. In the Azure portal, go to the VM properties page.
2. To shut down and deallocate the VM, select the **Stop** button.
3. In the **Disk** section, select the OS disk you want to increase.
4. In the **Disk** section, select **Configuration**, and update the **Size** to the value you want.
5. Go back to the VM properties page and **Start** the VM.

You might see a warning for OS disks larger than 2 TiB. The warning doesn't apply to generation 2 VMs. However, OS disk sizes larger than 4 TiB are not supported.

- **Do generation 2 VMs support accelerated networking?**  
Yes. For more information, see [Create a VM with accelerated networking](#).
- **Do generation 2 VMs support Secure Boot or vTPM in Azure?** Both vTPM and Secure Boot are features of trusted launch for generation 2 VMs. For more information, see [Trusted launch](#).
- **Is VHDX supported on generation 2?**  
No, generation 2 VMs support only VHD.
- **Do generation 2 VMs support Azure Ultra Disk Storage?**  
Yes.
- **Can I migrate a VM from generation 1 to generation 2?**  
No, you can't change the generation of a VM after you create it. If you need to switch between VM

generations, create a new VM of a different generation.

- **Why is my VM size not enabled in the size selector when I try to create a Gen2 VM?**

This may be solved by doing the following:

1. Verify that the **VM generation** property is set to **Gen 2**.
2. Verify you are searching for a **VM size which supports Gen2 VMs**.

# Virtual machine isolation in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure Compute offers virtual machine sizes that are Isolated to a specific hardware type and dedicated to a single customer. The Isolated sizes live and operate on specific hardware generation and will be deprecated when the hardware generation is retired.

Isolated virtual machine sizes are best suited for workloads that require a high degree of isolation from other customers' workloads for reasons that include meeting compliance and regulatory requirements. Utilizing an isolated size guarantees that your virtual machine will be the only one running on that specific server instance.

Additionally, as the Isolated size VMs are large, customers may choose to subdivide the resources of these VMs by using [Azure support for nested virtual machines](#).

The current Isolated virtual machine offerings include:

- Standard\_E80ids\_v4
- Standard\_E80is\_v4
- Standard\_E104i\_v5
- Standard\_E104is\_v5
- Standard\_E104id\_v5
- Standard\_E104ids\_v5
- Standard\_M192is\_v2
- Standard\_M192ims\_v2
- Standard\_M192ids\_v2
- Standard\_M192idms\_v2
- Standard\_F72s\_v2
- Standard\_M128ms

## NOTE

Isolated VM Sizes have a hardware limited lifespan. Please see below for details

## Deprecation of Isolated VM Sizes

Isolated VM sizes have a hardware limited lifespan. Azure will issue reminders 12 months in advance of the official deprecation date of the sizes and will provide an updated isolated offering for your consideration.

SIZE	ISOLATION RETIREMENT DATE
Standard_DS15_v2	May 15, 2021
Standard_D15_v2	May 15, 2021
Standard_G5	February 15, 2022
Standard_GS5	February 15, 2022

SIZE	ISOLATION RETIREMENT DATE
Standard_E64i_v3	February 15, 2022
Standard_E64is_v3	February 15, 2022

## FAQ

**Q: Is the size going to get retired or only its "isolation" feature?**

A: Currently, only the isolation feature of the VM sizes is being retired. The deprecated isolated sizes will continue to exist in non-isolated state. If isolation is not needed, there is no action to be taken and the VM will continue to work as expected.

**Q: Is there a downtime when my vm lands on a non-isolated hardware?**

A: If there is no need of isolation, no action is needed and there will be no downtime. On contrary if isolation is required, our announcement will include the recommended replacement size. Selecting the replacement size will require our customers to resize their VMs.

**Q: Is there any cost delta for moving to a non-isolated virtual machine?**

A: No

**Q: When are the other isolated sizes going to retire?**

A: We will provide reminders 12 months in advance of the official deprecation of the isolated size. Our latest announcement includes isolation feature retirement of Standard\_G5, Standard\_GS5, Standard\_E64i\_v3 and Standard\_E64i\_v3.

**Q: I'm an Azure Service Fabric Customer relying on the Silver or Gold Durability Tiers. Does this change impact me?**

A: No. The guarantees provided by Service Fabric's [Durability Tiers](#) will continue to function even after this change. If you require physical hardware isolation for other reasons, you may still need to take one of the actions described above.

**Q: What are the milestones for D15\_v2 or DS15\_v2 isolation retirement?**

A:

DATE	ACTION
May 15, 2020 <sup>1</sup>	D/DS15_v2 isolation retirement announcement
May 15, 2021	D/DS15_v2 isolation guarantee removed

<sup>1</sup> Existing customer using these sizes will receive an announcement email with detailed instructions on the next steps.

**Q: What are the milestones for G5, Gs5, E64i\_v3 and E64is\_v3 isolation retirement?**

A:

DATE	ACTION
Feb 15, 2021 <sup>1</sup>	G5/GS5/E64i_v3/E64is_v3 isolation retirement announcement
Feb 28, 2022	G5/GS5/E64i_v3/E64is_v3 isolation guarantee removed

<sup>1</sup> Existing customer using these sizes will receive an announcement email with detailed instructions on the next steps.

## Next steps

Customers can also choose to further subdivide the resources of these Isolated virtual machines by using [Azure support for nested virtual machines](#).

# Azure compute unit (ACU)

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The concept of the Azure Compute Unit (ACU) provides a way of comparing compute (CPU) performance across Azure SKUs. This will help you easily identify which SKU is most likely to satisfy your performance needs. ACU is currently standardized on a Small (Standard\_A1) VM being 100 and all other SKUs then represent approximately how much faster that SKU can run a standard benchmark.

\*ACUs use Intel® Turbo technology to increase CPU frequency and provide a performance increase. The amount of the performance increase can vary based on the VM size, workload, and other workloads running on the same host.

\*\*ACUs use AMD® Boost technology to increase CPU frequency and provide a performance increase. The amount of the performance increase can vary based on the VM size, workload, and other workloads running on the same host.

\*\*\*Hyper-threaded and capable of running nested virtualization

\*\*\*\*AMD Simultaneous multithreading technology

## IMPORTANT

The ACU is only a guideline. The results for your workload may vary.

SKU FAMILY	ACU \ VCPU	VCPU: CORE
A1_v2 - A8_v2	100	1:1
A2m_v2 - A8m_v2	100	1:1
B	Varies	1:1

D1_v2 - D15_v2	210 - 250*	1:1
DS1 - DS14	160 - 250	1:1
DS1_v2 - DS15_v2	210 - 250*	1:1
D_v3	160 - 190*	2:1***
Ds_v3	160 - 190*	2:1***
Dav4	230 - 260**	2:1****
Dasv4	230 - 260**	2:1****

SKU FAMILY	ACU \ VCPU	VCPU: CORE
Dv4	195 - 210	2:1***
Dsv4	195 - 210	2:1***
Ddv4	195 -210*	2:1***
Ddsv4	195 - 210*	2:1***
E_v3	160 - 190*	2:1***
Es_v3	160 - 190*	2:1***
Eav4	230 - 260**	2:1****
Easv4	230 - 260**	2:1****
Ev4	195 - 210	2:1***
Esv4	195 - 210	2:1***
Edv4	195 - 210*	2:1***
Edsv4	195 - 210*	2:1***
F2s_v2 - F72s_v2	195 - 210*	2:1***
F1 - F16	210 - 250*	1:1
F1s - F16s	210 - 250*	1:1
FX4 - FX48	310 - 340*	2:1***
G1 - G5	180 - 240*	1:1
GS1 - GS5	180 - 240*	1:1
H	290 - 300*	1:1
HB	199 - 216**	1:1
HC	297 - 315*	1:1
L4s - L32s	180 - 240*	1:1
L8s_v2 - L80s_v2	150 - 175**	2:1****
M	160 - 180	2:1***
Mv2	240 - 280	2:1***

SKU FAMILY	ACU \ VCPU	VCPU: CORE
NVv4	230 - 260**	2:1****

Processor model information for each SKU is available in the SKU documentation (see links above). Optimal performance may require the latest VM images (OS and [VM generation](#)) to ensure the latest updates and fastest drivers.

## VM Series Retiring

The following VM series are retiring on or before August 31, 2024:

SKU FAMILY	ACU \ VCPU	VCPU: CORE	RETIREMENT DATE
H	290 - 300*	1:1	<a href="#">August 31, 2022</a>
HB	199 - 216**	1:1	<a href="#">August 31, 2024</a>
A0	50	1:1	<a href="#">August 31, 2024</a>
A1 - A4	100	1:1	<a href="#">August 31, 2024</a>
A5 - A7	100	1:1	<a href="#">August 31, 2024</a>
A8 - A11	225*	1:1	<a href="#">August 31, 2024</a>

The following GPU series are also retiring:

SKU FAMILY	RETIREMENT DATE
NC	<a href="#">August 31, 2023</a>
NCv2	<a href="#">August 31, 2023</a>
ND	<a href="#">August 31, 2023</a>
NV	<a href="#">August 31, 2023</a>

## Performance Consistency

We understand that Azure customers want the best possible consistent performance, they want to be able to count on getting the same performance from the same type of VM every time.

Azure VM sizes typically run with maximum performance on the hardware platform they are first released on. Azure may place controls on older Azure VMs when run on newer hardware to help maintain consistent performance for our customers even when the VMs run on different hardware. For example:

1. D, E, and F series VMs may have the processor frequency set to a lower level when running on newer hardware to help achieve better performance consistency across hardware updates. (The specific frequency setting varies based on the processor the VM series was first released on and the comparable performance of the current hardware.)
2. A series VMs use an older model based on time slicing newer hardware to deliver performance consistency across hardware versions.
3. B series VMs are burstable and use a credit system (described in their [documentation](#)) to achieve expected

performance.

These different processor settings for VMs are a key part of Azure's effort to provide consistent performance and minimize the impact of changes in underlying hardware platform outside of our customer's control.

## About CoreMark

CoreMark is a benchmark that tests the functionality of a microcontroller (MCU) or central processing unit (CPU). CoreMark is not system dependent, so it functions the same regardless of the platform (e.g. big or little endian, high-end or low-end processor).

Linux numbers were computed by running CoreMark on Ubuntu 18.04. CoreMark was configured with the

number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run.

## Running Coremark on Azure VMs

### Download:

CoreMark is an open source tool that can be downloaded from [GitHub](#).

### Building and Running:

To build and run the benchmark, type:

```
> make
```

Full results are available in the files `run1.log` and `run2.log`. `run1.log` contains CoreMark results. These are the benchmark results with performance parameters. `run2.log` contains benchmark results with validation parameters.

### Run Time:

By default, the benchmark will run between 10-100 seconds. To override, use `ITERATIONS=N`

```
% make ITERATIONS=10
```

above flag will run the benchmark for 10 iterations. **Results are only valid for reporting if the benchmark ran for at least 10 seconds!**

### Parallel Execution:

Use `XCFLAGS=-DMULTITHREAD=N` where N is number of threads to run in parallel. Several implementations are available to execute in multiple contexts.

```
% make XCFLAGS="-DMULTITHREAD=4 -DUSE_PTHREAD"
```

The above will compile the benchmark for execution on 4 cores.

### Recommendations for best results

- The benchmark needs to run for at least 10 seconds, probably longer on larger systems.
- All source files must be compiled with same flags.
- Do not change source files other than `core_portme*` (use `make check` to validate)
- Multiple runs are suggested for best results.

## Coverage

Older end-of-life series may not be shown. N series not shown as they are GPU centric and Coremark doesn't measure GPU performance. Newer series may not have been benchmarked yet. Previous versions of this document cited benchmark runs from Ubuntu 16.04 which resulted in slightly lower performance than the current benchmarks running on Ubuntu 18.04.

## GPU Series

Performance of GPU based VM series is best understood by using GPU appropriate benchmarks and running at the scale required for your workloads. Azure ranks among the best there:

- Top 10 Supercomputer: [November 2021 | TOP500](#) (Azure powered #10: Voyager-EUS2)

- Machine Learning: MLCommons Training: [v1.1 Results](#) | [MLCommons](#) (2 highest at scale and largest in the cloud)

## Next steps

- For storage capacities, disk details, and additional considerations for choosing among VM sizes, see [Sizes for virtual machines](#).

# Compute benchmark scores for Windows VMs

9/21/2022 • 40 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

The following CoreMark benchmark scores show compute performance for select Azure VMs running Windows Server 2019. Compute benchmark scores are also available for [Linux VMs](#).

TYPE	FAMILIES
Compute optimized	Fsv2, Fs, F, GS, G

## About CoreMark

[CoreMark](#) is a benchmark that tests the functionality of a microcontroller (MCU) or central processing unit (CPU). CoreMark isn't system dependent, so it functions the same regardless of the platform (for example, big or little endian, high-end or low-end processor).

Windows numbers were computed by running CoreMark on Windows Server 2019. CoreMark was configured with the number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run.

Windows numbers were computed by running CoreMark on Windows Server 2019. CoreMark was configured with the number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target

number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run. (Coremark doesn't properly support more than 64 vCPUs on Windows, therefore SKUs with > 64 vCPUs have been marked as N/A.)

## Running Coremark on Azure VMs

### Download:

CoreMark is an open source tool that can be downloaded from [GitHub](#).

### Building and Running:

To build and run the benchmark, type:

```
> make
```

Full results are available in the files `run1.log` and `run2.log`. `run1.log` contains CoreMark results with performance parameters. `run2.log` contains benchmark results with validation parameters.

### Run Time:

By default, the benchmark will run between 10-100 seconds. To override, use `ITERATIONS=N`

```
% make ITERATIONS=10
```

above flag will run the benchmark for 10 iterations. **Results are only valid for reporting if the benchmark ran for at least 10 seconds!**

### Parallel Execution:

Use `XCFLAGS=-DMULTITHREAD=N` where N is number of threads to run in parallel. Several implementations are available to execute in multiple contexts.

```
% make XCFLAGS="-DMULTITHREAD=4 -DUSE_PTHREAD"
```

The above will compile the benchmark for execution on 4 cores.

### Recommendations for best results

- The benchmark needs to run for at least 10 seconds, probably longer on larger systems.
- All source files must be compiled with same flags.
- Don't change source files other than `core_portme*` (use `make check` to validate)
- Multiple runs are suggested for best results.

## GPU Series

Performance of GPU based VM series is best understood by using GPU appropriate benchmarks and running at the scale required for your workloads. Azure ranks among the best there:

- Top 10 Supercomputer: [November 2021 | TOP500](#) (Azure powered #10: Voyager-EUS2)
- Machine Learning: MLCommons Training: [v1.1 Results | MLCommons](#) (2 highest at scale and largest in the cloud)

## Next steps

- For storage capacities, disk details, and other considerations for choosing among VM sizes, see [Sizes for virtual machines](#).

# Check vCPU quotas using the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

The vCPU quotas for virtual machines and virtual machine scale sets are arranged in two tiers for each subscription, in each region. The first tier is the Total Regional vCPUs, and the second tier is the various VM size family cores such as the D-series vCPUs. Any time a new VM is deployed the vCPUs for the VM must not exceed the vCPU quota for the VM size family or the total regional vCPU quota. If either of those quotas are exceeded, the VM deployment will not be allowed. There is also a quota for the overall number of virtual machines in the region. The details on each of these quotas can be seen in the **Usage + quotas** section of the **Subscription** page in the [Azure portal](#), or you can query for the values using the Azure CLI.

## NOTE

Quota is calculated based on the total number of cores in use both allocated and deallocated. If you need additional cores, [request a quota increase](#) or delete VMs that are no longer needed.

## Check usage

You can check your quota usage using [az vm list-usage](#).

```
az vm list-usage --location "East US" -o table
```

The output should look something like this:

Name	CurrentValue	Limit
Availability Sets	0	2000
Total Regional vCPUs	29	100
Virtual Machines	7	10000
Virtual Machine Scale Sets	0	2000
Standard DSv3 Family vCPUs	8	100
Standard DSv2 Family vCPUs	3	100
Standard Dv3 Family vCPUs	2	100
Standard D Family vCPUs	8	100
Standard Dv2 Family vCPUs	8	100
Basic A Family vCPUs	0	100
Standard A0-A7 Family vCPUs	0	100
Standard A8-A11 Family vCPUs	0	100
Standard DS Family vCPUs	0	100
Standard G Family vCPUs	0	100
Standard GS Family vCPUs	0	100
Standard F Family vCPUs	0	100
Standard FS Family vCPUs	0	100
Standard Storage Managed Disks	5	10000
Premium Storage Managed Disks	5	10000

## Reserved VM Instances

Reserved VM Instances, which are scoped to a single subscription without VM size flexibility, will add a new aspect to the vCPU quotas. These values describe the number of instances of the stated size that must be

deployable in the subscription. They work as a placeholder in the quota system to ensure that quota is reserved to ensure Azure reservations are deployable in the subscription. For example, if a specific subscription has 10 Standard\_D1 reservations the usages limit for Standard\_D1 reservations will be 10. This will cause Azure to ensure that there are always at least 10 vCPUs available in the Total Regional vCPUs quota to be used for Standard\_D1 instances and there are at least 10 vCPUs available in the Standard D Family vCPU quota to be used for Standard\_D1 instances.

If a quota increase is required to either purchase a Single Subscription RI, you can [request a quota increase on your subscription](#).

## Next steps

For more information about billing and quotas, see [Azure subscription and service limits, quotas, and constraints](#).

# Check vCPU quotas using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

The vCPU quotas for virtual machines and virtual machine scale sets are arranged in two tiers for each subscription, in each region. The first tier is the Total Regional vCPUs, and the second tier is the various VM size family cores such as the D-series vCPUs. Any time a new VM is deployed the vCPUs for the VM must not exceed the vCPU quota for the VM size family or the total regional vCPU quota. If either of those quotas are exceeded, the VM deployment will not be allowed. There is also a quota for the overall number of virtual machines in the region. The details on each of these quotas can be seen in the **Usage + quotas** section of the **Subscription** page in the [Azure portal](#), or you can query for the values using PowerShell.

## NOTE

Quota is calculated based on the total number of cores in use both allocated and deallocated. If you need additional cores, [request a quota increase](#) or delete VMs that are no longer needed.

## Check usage

You can use the [Get-AzVMUsage](#) cmdlet to check on your quota usage.

```
Get-AzVMUsage -Location "East US"
```

The output will look similar to this:

Name	Current Value	Limit	Unit
---	-----	-----	-----
Availability Sets	0	2000	Count
Total Regional vCPUs	4	260	Count
Virtual Machines	4	10000	Count
Virtual Machine Scale Sets	1	2000	Count
Standard B Family vCPUs	1	10	Count
Standard DSv2 Family vCPUs	1	100	Count
Standard Dv2 Family vCPUs	2	100	Count
Basic A Family vCPUs	0	100	Count
Standard A0-A7 Family vCPUs	0	250	Count
Standard A8-A11 Family vCPUs	0	100	Count
Standard D Family vCPUs	0	100	Count

Standard DS Family vCPUs	0	100	Count
Standard GS Family vCPUs	0	100	Count
Standard F Family vCPUs	0	100	Count
Standard FS Family vCPUs	0	100	Count
Standard NV Family vCPUs	0	24	Count
Standard NC Family vCPUs	0	48	Count
Standard H Family vCPUs	0	8	Count
Standard Av2 Family vCPUs	0	100	Count
Standard LS Family vCPUs	0	100	Count
Standard Dv2 Promo Family vCPUs	0	100	Count
Standard DSv2 Promo Family vCPUs	0	100	Count
Standard MS Family vCPUs	0	0	Count
Standard Dv3 Family vCPUs	0	100	Count
Standard DSv3 Family vCPUs	0	100	Count
Standard Ev3 Family vCPUs	0	100	Count
Standard ESv3 Family vCPUs	0	100	Count
Standard FSv2 Family vCPUs	0	100	Count
Standard ND Family vCPUs	0	0	Count
Standard NCv2 Family vCPUs	0	0	Count
Standard NCv3 Family vCPUs	0	0	Count
Standard LSv2 Family vCPUs	0	0	Count
Standard Storage Managed Disks	2	10000	Count
Premium Storage Managed Disks	1	10000	Count

## Reserved VM Instances

Reserved VM Instances, which are scoped to a single subscription without VM size flexibility, will add a new aspect to the vCPU quotas. These values describe the number of instances of the stated size that must be deployable in the subscription. They work as a placeholder in the quota system to ensure that quota is reserved to ensure reserved VM instances are deployable in the subscription. For example, if a specific subscription has 10 Standard\_D1 reserved VM instances the usages limit for Standard\_D1 reserved VM instances will be 10. This will cause Azure to ensure that there are always at least 10 vCPUs available in the Total Regional vCPUs quota to be used for Standard\_D1 instances and there are at least 10 vCPUs available in the Standard D Family vCPU quota to be used for Standard\_D1 instances.

If a quota increase is required to purchase a Single Subscription RI, you can [request a quota increase](#) on your subscription.

## Next steps

For more information about billing and quotas, see [Azure subscription and service limits, quotas, and constraints](#).

# Change the size of a virtual machine

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article shows you how to move a VM to a different [VM size](#).

After you create a virtual machine (VM), you can scale the VM up or down by changing the VM size. In some cases, you must deallocate the VM first. This can happen if the new size is not available on the hardware cluster that is currently hosting the VM.

If your VM uses Premium Storage, make sure that you choose an s version of the size to get Premium Storage support. For example, choose Standard\_E4s\_v3 instead of Standard\_E4\_v3.

## Change the VM size

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Open the [Azure portal](#).
2. Open the page for the virtual machine.
3. In the left menu, select **Size**.
4. Pick a new size from the list of available sizes and then select **Resize**.

If the virtual machine is currently running, changing its size will cause it to be restarted.

If your VM is still running and you don't see the size you want in the list, stopping the virtual machine may reveal more sizes.

### WARNING

Deallocating the VM also releases any dynamic IP addresses assigned to the VM. The OS and data disks are not affected.

If you are resizing a production VM, consider using [Azure Capacity Reservations](#) to reserve Compute capacity in the region.

## Next steps

For additional scalability, run multiple VM instances and scale out. For more information, see [Automatically scale machines in a Virtual Machine Scale Set](#).

# States and billing status of Azure Virtual Machines

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure Virtual Machines (VM) instances go through different states. There are *provisioning* and *power* states. This article describes these states and highlights when customers are billed for instance usage.

## Get states using Instance View

The instance view API provides VM running-state information. For more information, see [Virtual Machines - Instance View](#).

Azure Resources Explorer provides a simple UI for viewing the VM running state: [Resource Explorer](#).

The VM provisioning state is available, in slightly different forms, from within the VM properties `provisioningState` and the `InstanceView`. In the VM `InstanceView`, there's an element within the `status` array in the form of `ProvisioningState/<state>[/<errorCode>]`.

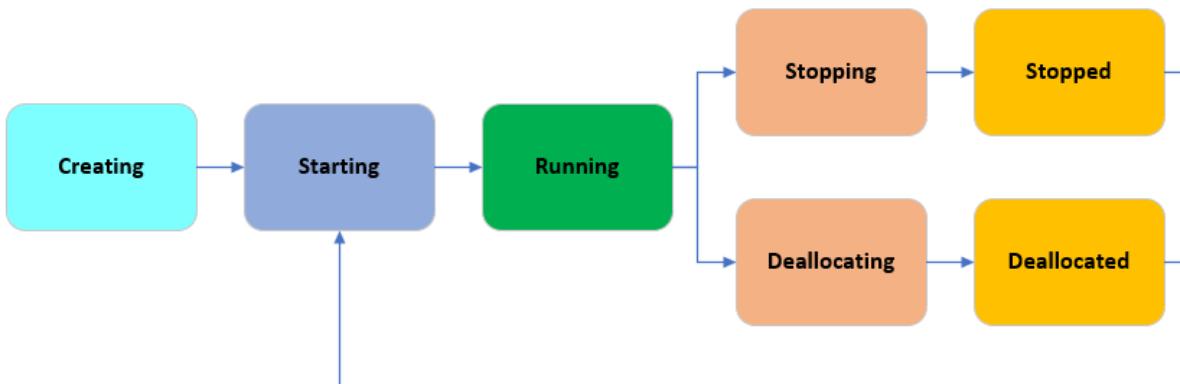

To retrieve the power state of all the VMs in your subscription, use the [Virtual Machines - List All API](#) with parameter `statusOnly` set to `true`.

### NOTE

[Virtual Machines - List All API](#) with parameter `statusOnly` set to `true` retrieves the power states of all VMs in a subscription. However, in some rare situations, the power state may not be available due to intermittent issues in the retrieval process. In such situations, we recommend retrying using the same API or using [Azure Resource Health](#) to check the power state of your VMs.

## Power states and billing

The power state represents the last known state of the VM.

The following table provides a description of each instance state and indicates whether that state is billed for instance usage.

POWER STATE	DESCRIPTION	BILLING
Creating	Virtual machine is allocating resources.	Not Billed*

POWER STATE	DESCRIPTION	BILLING
Starting	Virtual machine is powering up.	Billed
Running	Virtual machine is fully up. This state is the standard working state.	Billed
Stopping	This state is transitional between running and stopped.	Billed
Stopped	The virtual machine is allocated on a host but not running. Also called <i>PoweredOff</i> state or <i>Stopped (Allocated)</i> . This state can be result of invoking the <code>Poweroff</code> API operation or invoking shutdown from within the guest OS. The <i>Stopped</i> state may also be observed briefly during VM creation or while starting a VM from <i>Deallocated</i> state.	Billed
Deallocating	This state is transitional between <i>Running</i> and <i>Deallocated</i> .	Not billed*
Deallocated	The virtual machine has released the lease on the underlying hardware and is powered off. This state is also referred to as <i>Stopped (Deallocated)</i> .	Not billed*

\* Some Azure resources, such as [Disks](#) and [Networking](#) continue to incur charges.

Example of PowerState in JSON:

```
{
  "code": "PowerState/running",
  "level": "Info",
  "displayStatus": "VM running"
}
```

## Provisioning states

The provisioning state is the status of a user-initiated, control-plane operation on the VM. These states are separate from the power state of a VM.

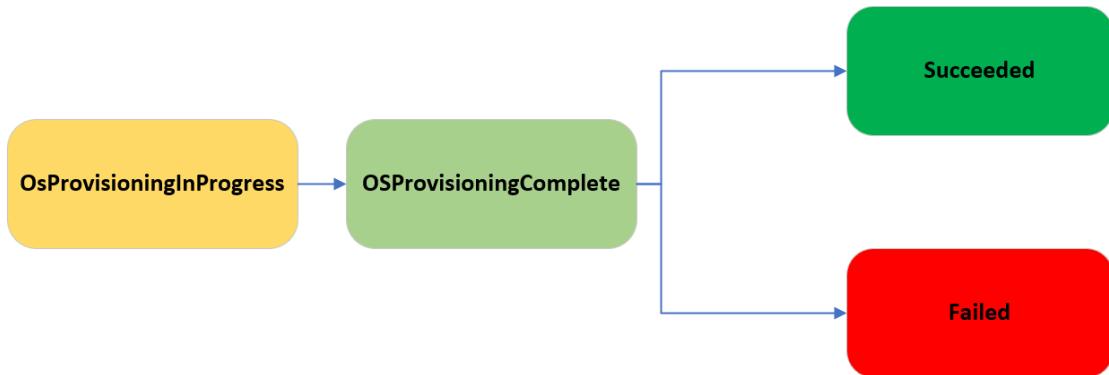

PROVISIONING STATE	DESCRIPTION
Creating	Virtual machine is being created.
Updating	Virtual machine is updating to the latest model. Some non-model changes to a virtual machine such as start and restart fall under the updating state.
Failed	Last operation on the virtual machine resource was unsuccessful.

PROVISIONING STATE	DESCRIPTION
Succeeded	Last operation on the virtual machine resource was successful.
Deleting	Virtual machine is being deleted.
Migrating	Seen when migrating from Azure Service Manager to Azure Resource Manager.

## OS Provisioning states

OS Provisioning states only apply to virtual machines created with a [generalized](#) OS image. [Specialized](#) images and disks attached as OS disk don't display these states. The OS provisioning state isn't shown separately. It's a substate of the Provisioning State in the VM InstanceView. For example,

```
ProvisioningState/creating/osProvisioningComplete .
```

OS PROVISIONING STATE	DESCRIPTION
OSProvisioningInProgress	The VM is running and the initialization (setup) of the Guest OS is in progress.
OSProvisioningComplete	This state is a short-lived state. The virtual machine quickly transitions from this state to <i>Success</i> . If extensions are still being installed, you continue to see this state until installation is complete.
Succeeded	The user-initiated actions have completed.
Failed	Represents a failed operation. For more information and possible solutions, see the error code.

## Troubleshooting VM states

To troubleshoot specific VM state issues, see [Troubleshoot Windows VM deployments](#) and [Troubleshoot Linux VM deployments](#).

For other troubleshooting help visit [Azure Virtual Machines troubleshooting documentation](#).

## Next steps

- Review the [Azure Cost Management and Billing documentation](#)
- Use the [Azure Pricing calculator](#) to plan your deployments.
- Learn more about monitoring your VM, see [Monitor virtual machines in Azure](#).

# Azure virtual machine sizes naming conventions

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This page outlines the naming conventions used for Azure VMs. VMs use these naming conventions to denote varying features and specifications.

## Naming convention explanation

[Family] + [Sub-family]\* + [# of vCPUs] + [Constrained vCPUs]\* + [Additive Features] + [Accelerator Type]\* + [Version]

VALUE	EXPLANATION
Family	Indicates the VM Family Series
*Sub-family	Used for specialized VM differentiations only
# of vCPUs	Denotes the number of vCPUs of the VM
*Constrained vCPUs	Used for certain VM sizes only. Denotes the number of vCPUs for the <a href="#">constrained vCPU capable size</a>
Additive Features	One or more lower case letters denote additive features, such as: a = AMD-based processor b = Block Storage performance c = confidential d = diskful (i.e., a local temp disk is present); this is for newer Azure VMs, see <a href="#">Ddv4 and Ddsv4-series</a> i = isolated size l = low memory; a lower amount of memory than the memory intensive size m = memory intensive; the most amount of memory in a particular size t = tiny memory; the smallest amount of memory in a particular size s = Premium Storage capable, including possible use of <a href="#">Ultra SSD</a> (Note: some newer sizes without the attribute of s can still support Premium Storage e.g. M128, M64, etc.) NP = node packing P = ARM Cpu
*Accelerator Type	Denotes the type of hardware accelerator in the specialized/GPU SKUs. Only the new specialized/GPU SKUs launched from Q3 2020 will have the hardware accelerator in the name.
Version	Denotes the version of the VM Family Series

## Example breakdown

[Family] + [Sub-family]\* + [# of vCPUs] + [Additive Features] + [Accelerator Type]\* + [Version]

**Example 1: M416ms\_v2**

VALUE	EXPLANATION
Family	M
# of vCPUs	416
Additive Features	m = memory intensive s = Premium Storage capable
Version	v2

**Example 2: NV16as\_v4**

VALUE	EXPLANATION
Family	N
Sub-family	V
# of vCPUs	16
Additive Features	a = AMD-based processor s = Premium Storage capable
Version	v4

**Example 3: NC4as\_T4\_v3**

VALUE	EXPLANATION
Family	N
Sub-family	C
# of vCPUs	4
Additive Features	a = AMD-based processor s = Premium Storage capable
Accelerator Type	T4
Version	v3

**Example 4: M8-2ms\_v2 (Constrained vCPU)**

VALUE	EXPLANATION
Family	M

# Store and share resources in an Azure Compute Gallery

9/21/2022 • 15 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

An Azure Compute Gallery helps you build structure and organization around your Azure resources, like images and [applications](#). An Azure Compute Gallery provides:

- Global replication.<sup>1</sup>
- Versioning and grouping of resources for easier management.
- Highly available resources with Zone Redundant Storage (ZRS) accounts in regions that support Availability Zones. ZRS offers better resilience against zonal failures.
- Premium storage support (Premium\_LRS).
- Sharing to the community, across subscriptions, and between Active Directory (AD) tenants.
- Scaling your deployments with resource replicas in each region.

With a gallery, you can share your resources to everyone, or limit sharing to different users, service principals, or AD groups within your organization. Resources can be replicated to multiple regions, for quicker scaling of your deployments.

<sup>1</sup> The Azure Compute Gallery service is not a global resource. For disaster recovery scenarios, it is a best practice is to have at least two galleries, in different regions.

## Images

For more information about storing images in an Azure Compute Gallery, see [Store and share images in an Azure Compute Gallery](#).

## VM apps

While you can create an image of a VM with apps pre-installed, you would need to update your image each time you have application changes. Separating your application installation from your VM images means there's no need to publish a new image for every line of code change.

For more information about storing applications in an Azure Compute Gallery, see [VM Applications](#).

## Regional Support

All public regions can be target regions, but certain regions require that customers go through a request process in order to gain access. To request that a subscription is added to the allowlist for a region such as Australia Central or Australia Central 2, submit [an access request](#)

## Limits

There are limits, per subscription, for deploying resources using Azure Compute Galleries:

- 100 galleries, per subscription, per region
- 1,000 image definitions, per subscription, per region
- 10,000 image versions, per subscription, per region

- 100 image version replicas, per subscription, per region however 50 replicas should be sufficient for most use cases
- Any disk attached to the image must be less than or equal to 1TB in size

For more information, see [Check resource usage against limits](#) for examples on how to check your current usage.

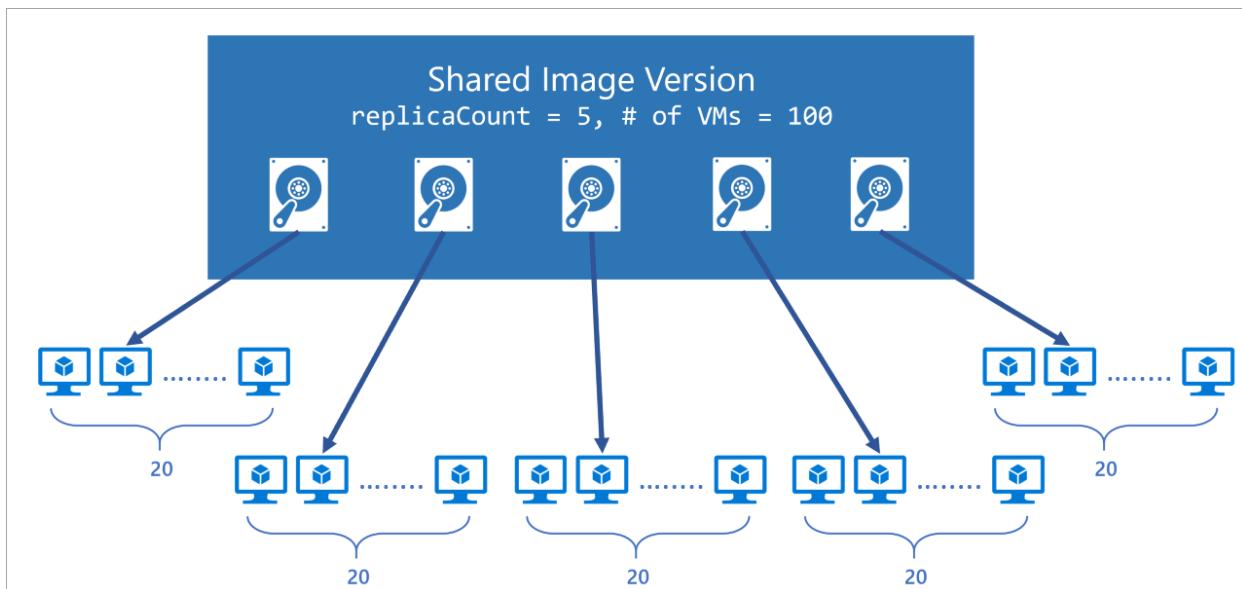

## Scaling

Azure Compute Gallery allows you to specify the number of replicas you want to keep. This helps in multi-VM deployment scenarios as the VM deployments can be spread to different replicas reducing the chance of instance creation processing being throttled due to overloading of a single replica.

With Azure Compute Gallery, you can deploy up to a 1,000 VM instances in a virtual machine scale set. You can set a different replica count in each target region, based on the scale needs for the region. Since each replica is a copy of your resource, this helps scale your deployments linearly with each extra replica. While we understand no two resources or regions are the same, here's our general guideline on how to use replicas in a region:

- For every 20 VMs that you create concurrently, we recommend you keep one replica. For example, if you are creating 120 VMs concurrently using the same image in a region, we suggest you keep at least 6 replicas of your image.
- For each scale set you create concurrently, we recommend you keep one replica.

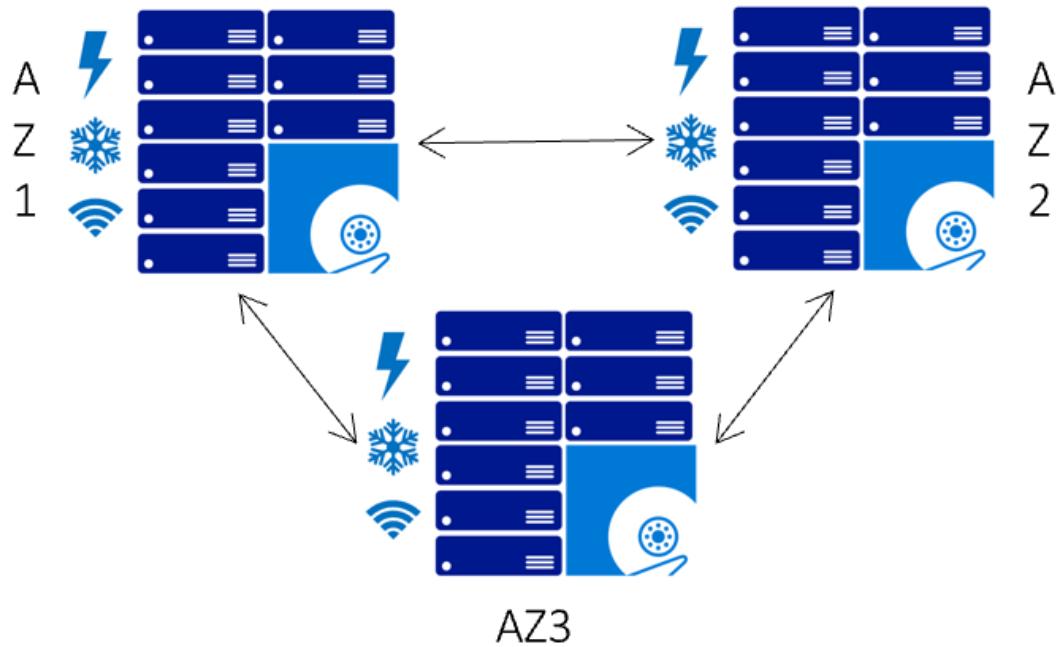

We always recommend that to over-provision the number of replicas due to factors like resource size, content and OS type.

## High availability

[Azure Zone Redundant Storage \(ZRS\)](#) provides resilience against an Availability Zone failure in the region. With the general availability of Azure Compute Gallery, you can choose to store your images in ZRS accounts in regions with Availability Zones.

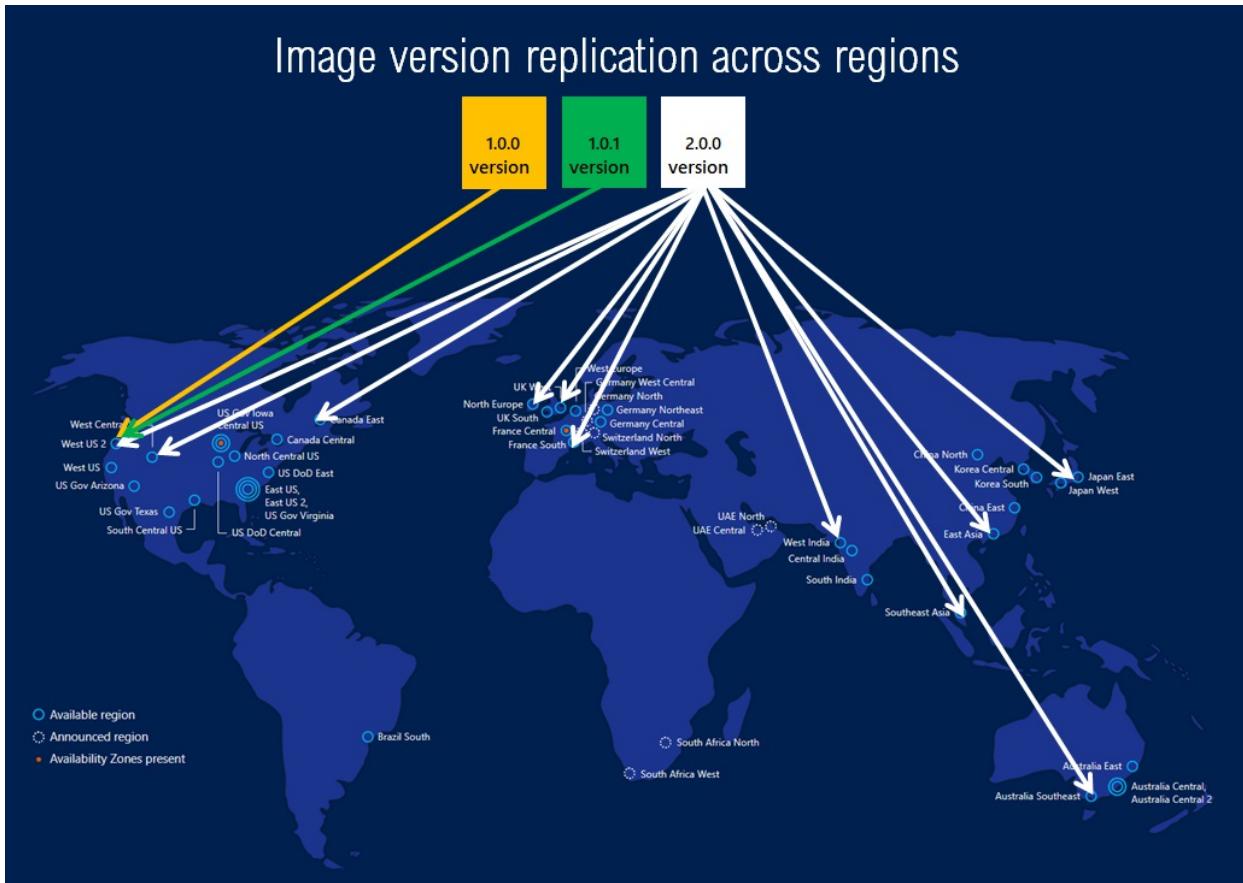

You can also choose the account type for each of the target regions. The default storage account type is Standard\_LRS, but you can choose Standard\_ZRS for regions with Availability Zones. For more information on regional availability of ZRS, see [Data redundancy](#).

## Replication

Azure Compute Gallery also allows you to replicate your resources to other Azure regions automatically. Each image version can be replicated to different regions depending on what makes sense for your organization. One example is to always replicate the latest image in multi-regions while all older image versions are only available in 1 region. This can help save on storage costs.

The regions that a resource is replicated to can be updated after creation time. The time it takes to replicate to different regions depends on the amount of data being copied and the number of regions the version is replicated to. This can take a few hours in some cases. While the replication is happening, you can view the status of replication per region. Once the image replication is complete in a region, you can then deploy a VM or scale-set using that resource in the region.

## Sharing

There are three main ways to share images in an Azure Compute Gallery, depending on who you want to share with:

SHARE WITH:	OPTION
Specific people, groups, or service principals	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
Subscriptions or tenants	Direct shared gallery (preview) lets you share to everyone in a subscription or tenant.
Everyone	Community gallery (preview) lets you share your entire gallery publicly, to all Azure users.

### RBAC

As the Azure Compute Gallery, definition, and version are all resources, they can be shared using the built-in native Azure Roles-based Access Control (RBAC) roles. Using Azure RBAC roles you can share these resources to other users, service principals, and groups. You can even share access to individuals outside of the tenant they were created within. Once a user has access to the resource version, they can use it to deploy a VM or a Virtual Machine Scale Set. Here is the sharing matrix that helps understand what the user gets access to:

SHARED WITH USER	AZURE COMPUTE GALLERY	IMAGE DEFINITION	IMAGE VERSION
Azure Compute Gallery	Yes	Yes	Yes
Image Definition	No	Yes	Yes

We recommend sharing at the Gallery level for the best experience. We do not recommend sharing individual image versions. For more information about Azure RBAC, see [Assign Azure roles](#).

For more information, see [Share using RBAC](#).

### Shared directly to a tenant or subscription

Give specific subscriptions or tenants access to a direct shared Azure Compute Gallery. Sharing a gallery with tenants and subscriptions give them read-only access to your gallery. For more information, see [Share a gallery with subscriptions or tenants](#).

#### IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

To publish images to a direct shared gallery during the preview, you need to register at <https://aka.ms/directsharedgallery-preview>. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

You can't currently create a Flexible virtual machine scale set from an image shared to you by another tenant.

#### Limitations

During the preview:

- You can only share to subscriptions that are also in the preview.
- You can only share to 30 subscriptions and 5 tenants.
- A direct shared gallery cannot contain encrypted image versions. Encrypted images cannot be created within a gallery that is directly shared.
- Only the owner of a subscription, or a user or service principal assigned to the `Compute Gallery Sharing Admin` role at the subscription or gallery level will be able to enable group-based sharing.
- You need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

### Community gallery

To share a gallery with all Azure users, you can create a community gallery (preview). Community galleries can be used by anyone with an Azure subscription. Someone creating a VM can browse images shared with the community using the portal, REST, or the Azure CLI.

Sharing images to the community is a new capability in [Azure Compute Gallery](#). In the preview, you can make your image galleries public, and share them to all Azure customers. When a gallery is marked as a community gallery, all images under the gallery become available to all Azure customers as a new resource type under `Microsoft.Compute/communityGalleries`. All Azure customers can see the galleries and use them to create VMs. Your original resources of the type `Microsoft.Compute/galleries` are still under your subscription, and private.

For more information, see [Share images using a community gallery](#).

## IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

To publish a community gallery, you need to register for the preview at <https://aka.ms/communitygallery-preview>. Creating VMs from the community gallery is open to all Azure users.

During the preview, the gallery must be created as a community gallery (for CLI, this means using the `--permissions community` parameter) you currently can't migrate a regular gallery to a community gallery.

You can't currently create a Flexible virtual machine scale set from an image shared by another tenant.

## Why share to the community?

As a content publisher, you might want to share a gallery to the community:

- If you have non-commercial, non-proprietary content to share widely on Azure.
- You want greater control over the number of versions, regions, and the duration of image availability.
- You want to quickly share daily or nightly builds with your customers.
- You don't want to deal with the complexity of multi-tenant authentication when sharing with multiple tenants on Azure.

## How sharing with the community works

You [create a gallery resource](#) under `Microsoft.Compute/Galleries` and choose `community` as a sharing option.

When you are ready, you flag your gallery as ready to be shared publicly. Only the owner of a subscription, or a user or service principal with the `Compute Gallery Sharing Admin` role at the subscription or gallery level, can enable a gallery to go public to the community. At this point, the Azure infrastructure creates proxy read-only regional resources, under `Microsoft.Compute/CommunityGalleries`, which are public.

The end-users can only interact with the proxy resources, they never interact with your private resources. As the publisher of the private resource, you should consider the private resource as your handle to the public proxy resources. The `prefix` you provide when you create the gallery will be used, along with a unique GUID, to create the public facing name for your gallery.

Azure users can see the latest image versions shared to the community in the portal, or query for them using the CLI. Only the latest version of an image is listed in the community gallery.

When creating a community gallery, you will need to provide contact information for your images. This information will be shown **publicly**, so be careful when providing it:

- Community gallery prefix
- Publisher support email
- Publisher URL
- Legal agreement URL

Information from your image definitions will also be publicly available, like what you provide for **Publisher**, **Offer**, and **SKU**.

## WARNING

If you want to stop sharing a gallery publicly, you can update the gallery to stop sharing, but making the gallery private will prevent existing virtual machine scale set users from scaling their resources.

If you stop sharing your gallery during the preview, you won't be able to re-share it.

## Limitations for images shared to the community

There are some limitations for sharing your gallery to the community:

- Encrypted images aren't supported.
- For the preview, image resources need to be created in the same region as the gallery. For example, if you create a gallery in West US, the image definitions and image versions should be created in West US if you want to make them available during the public preview.
- For the preview, you can't share [VM Applications](#) to the community.
- The gallery must be created as a community gallery. For the preview, there is no way to migrate an existing gallery to be a community gallery.
- To find images shared to the community from the Azure portal, you need to go through the VM create or scale set creation pages. You can't search the portal or Azure Marketplace for the images.

### IMPORTANT

Microsoft does not provide support for images you share to the community.

## Community-shared images FAQ

### Q: What are the charges for using a gallery that is shared to the community?

A: There are no charges for using the service itself. However, content publishers would be charged for the following:

- Storage charges for application versions and replicas in each of the regions (source and target). These charges are based on the storage account type chosen.
- Network egress charges for replication across regions.

### Q: Is it safe to use images shared to the community?

A: Users should exercise caution while using images from non-verified sources, since these images are not subject to Azure certification.

### Q: If an image that is shared to the community doesn't work, who do I contact for support?

A: Azure is not responsible for any issues users might encounter with community-shared images. The support is provided by the image publisher. Please look up the publisher contact information for the image and reach out to them for any support.

### Q: I have concerns about an image, who do I contact?

A: For issues with images shared to the community:

- To report malicious images, contact [Abuse Report](#).
- To report images that potentially violate intellectual property rights, contact [Infringement Report](#).

### Q: How do I request that an image shared to the community be replicated to a specific region?

A: Only the content publishers have control over the regions their images are available in. If you don't find an image in a specific region, reach out to the publisher directly.

## Activity Log

The [Activity log](#) displays recent activity on the gallery, image, or version including any configuration changes and when it was created and deleted. View the activity log in the Azure portal, or create a [diagnostic setting to send it to a Log Analytics workspace](#), where you can view events over time or analyze them with other collected data.

The following table lists a few example operations that relate to gallery operations in the activity log. For a complete list of possible log entries, see [Microsoft.Compute Resource Provider options](#)

OPERATION	DESCRIPTION
Microsoft.Compute/galleries/write	Creates a new Gallery or updates an existing one
Microsoft.Compute/galleries/delete	Deletes the Gallery
Microsoft.Compute/galleries/share/action	Shares a Gallery to different scopes
Microsoft.Compute/galleries/images/read	Gets the properties of Gallery Image
Microsoft.Compute/galleries/images/write	Creates a new Gallery Image or updates an existing one
Microsoft.Compute/galleries/images/versions/read	Gets the properties of Gallery Image Version

## Billing

There is no extra charge for using the Azure Compute Gallery service. You will be charged for the following resources:

- Storage costs of storing each replica. For images, the storage cost is charged as a snapshot and is based on the occupied size of the image version, the number of replicas of the image version and the number of regions the version is replicated to.
- Network egress charges for replication of the first resource version from the source region to the replicated regions. Subsequent replicas are handled within the region, so there are no additional charges.

For example, let's say you have an image of a 127 GB OS disk, that only occupies 10GB of storage, and one empty 32 GB data disk. The occupied size of each image would only be 10 GB. The image is replicated to 3 regions and each region has two replicas. There will be six total snapshots, each using 10GB. You will be charged the storage cost for each snapshot based on the occupied size of 10 GB. You will pay network egress charges for the first replica to be copied to the additional two regions. For more information on the pricing of snapshots in each region, see [Managed disks pricing](#). For more information on network egress, see [Bandwidth pricing](#).

## Best practices

- To prevent images from being accidentally deleted, use resource locks at the Gallery level. For more information, see [Protect your Azure resources with a lock](#).
- Use ZRS wherever available for high availability. You can configure ZRS in the replication tab when you create the a version of the image or VM application. For more information about which regions support ZRS, see [Azure regions with availability zones](#).
- Keep a minimum of 3 replicas for production images. For every 20 VMs that you create concurrently, we recommend you keep one replica. For example, if you create 1000 VM's concurrently, you should keep 50 replicas (you can have a maximum of 50 replicas per region). To update the replica count, please go to the gallery -> Image Definition -> Image Version -> Update replication.
- Maintain separate galleries for production and test images, don't put them in a single gallery.
- When creating an image definition, keep the Publisher/Offer/SKU consistent with Marketplace images to easily identify OS versions. For example, if you are customizing a Windows server 2019 image from Marketplace and store it as a Compute gallery image, please use the same Publisher/Offer/SKU that is used in the Marketplace image in your compute gallery image.

- Use `excludeFromLatest` when publishing images if you want to exclude a specific image version during VM or scale set creation. [Gallery Image Versions - Create Or Update](#).

If you want to exclude a version in a specific region, use `regionalExcludeFromLatest` instead of the global `excludeFromLatest`. You can set both global and regional `excludeFromLatest` flag, but the regional flag will take precedence when both are specified.

```
"publishingProfile": {
  "targetRegions": [
    {
      "name": "brazilsouth",
      "regionalReplicaCount": 1,
      "regionalExcludeFromLatest": false,
      "storageAccountType": "Standard_LRS"
    },
    {
      "name": "canadacentral",
      "regionalReplicaCount": 1,
      "regionalExcludeFromLatest": true,
      "storageAccountType": "Standard_LRS"
    }
  ],
  "replicaCount": 1,
  "excludeFromLatest": true,
  "storageAccountType": "Standard_LRS"
}
```

- For disaster recovery scenarios, it is a best practice is to have at least two galleries, in different regions. You can still use image versions in other regions, but if the region your gallery is in goes down, you can't create new gallery resources or update existing ones.

## SDK support

The following SDKs support creating Azure Compute Galleries:

- [.NET](#)
- [Java](#)
- [Node.js](#)
- [Python](#)
- [Go](#)

## Templates

You can create Azure Compute Gallery resource using templates. There are several quickstart templates available:

- [Create a gallery](#)
- [Create an image definition in a gallery](#)
- [Create an image version in a gallery](#)

## Next steps

Learn how to deploy [images](#) and [VM apps](#) using an Azure Compute Gallery.

# Create a gallery for storing and sharing resources

9/21/2022 • 7 minutes to read • [Edit Online](#)

An [Azure Compute Gallery](#) (formerly known as Shared Image Gallery) simplifies sharing resources, like images and application packages, across your organization.

The Azure Compute Gallery lets you share custom VM images and application packages with others in your organization, within or across regions, within a tenant. Choose what you want to share, which regions you want to make them available in, and who you want to share them with. You can create multiple galleries so that you can logically group resources.

The gallery is a top-level resource that can be shared in multiple ways:

SHARE WITH:	OPTION
<a href="#">Specific people, groups, or service principals</a>	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
<a href="#">Subscriptions or tenants</a>	Direct shared gallery (preview) lets you share to everyone in a subscription or tenant.
<a href="#">Everyone</a>	Community gallery (preview) lets you share your entire gallery publicly, to all Azure users.

## Naming

Allowed characters for gallery name are uppercase or lowercase letters, digits, dots, and periods. The gallery name can't contain dashes. Gallery names must be unique within your subscription.

## Create a private gallery

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Type **Azure Compute Gallery** in the search box and select **Azure Compute Gallery** in the results.
3. In the Azure Compute Gallery page, click **Add**.
4. On the **Create Azure Compute Gallery** page, select the correct subscription.
5. In **Resource group**, select a resource group from the drop-down or select **Create new** and type a name for the new resource group.
6. In **Name**, type a name for the name of the gallery.
7. Select a **Region** from the drop-down.
8. You can type a short description of the gallery, like *My gallery for testing.* and then click **Review + create**.
9. After validation passes, select **Create**.
10. When the deployment is finished, select **Go to resource**.

# Create a direct shared gallery

## IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

You can't currently create a Flexible virtual machine scale set from an image shared to you by another tenant.

- [Portal](#)
- [CLI](#)
- [REST](#)

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Type **Azure Compute Gallery** in the search box and select **Azure Compute Gallery** in the results.
3. In the **Azure Compute Gallery** page, click **Add**.
4. On the **Create Azure Compute Gallery** page, select the correct subscription.
5. Complete all of the details on the page.
6. At the bottom of the page, select **Next: Sharing method**.

[Home](#) > [Azure compute galleries](#) >

## Create Azure compute gallery

[Basics](#)   [Sharing](#)   [Tags](#)   [Review + create](#)

Azure compute galleries allow you to share images with users or user groups across subscriptions in your organization. Images are published to Azure compute gallery that will be available within Azure Marketplace.

[Learn more about Azure compute galleries](#)

7. On the **Sharing** tab, select **RBAC + share directly**.

## Create Azure compute gallery

...

Basics    **Sharing**    Tags    Review + create

In addition to role based sharing through Identity Access control, you're able to share the compute gallery using the methods below.

The Azure Compute Gallery - Direct Shared Gallery/Direct shared images (the "PREVIEW") subject to the [Preview Terms for Azure Compute Gallery - Direct Shared Gallery](#).

If you do not agree to these terms, do not use the PREVIEW

Sharing method 

- Role based access control (RBAC)  
Role based sharing through Identity Access control. Share based on permissions assigned to users, groups, and applications at a certain scope. [Learn more](#)
- RBAC + share directly  
Share resources with all users in the same subscription, same tenant, different subscriptions, and different tenants. All users in the subscription or tenant will have read access to the gallery and all the resources within it. [Learn more](#)
- RBAC + share to public community gallery (PREVIEW)  
Publish your Azure compute gallery to the community gallery. Your gallery will be shared with anyone using Azure, including users outside of your organization. [Learn more](#)

[Review + create](#)

[< Previous](#)

[Next : Tags >](#)

8. When you are done, select **Review + create**.

9. After validation passes, select **Create**.

10. When the deployment is finished, select **Go to resource**.

To start sharing the gallery with a subscription or tenant, see [Share a gallery with a subscription or tenant](#).

To start sharing the gallery with a subscription or tenant, use see [Share a gallery with a subscription or tenant](#).

## Create a community gallery

A [community gallery](#) is shared publicly with everyone. To create a community gallery, you create the gallery first, then enable it for sharing. The name of public instance of your gallery will be the prefix you provide, plus a unique GUID.

During the preview, make sure that you create your gallery, image definitions, and image versions in the same region in order to share your gallery publicly.

### IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

To publish a community gallery, you need to register for the preview at <https://aka.ms/communitygallery-preview>. Creating VMs from the community gallery is open to all Azure users.

When creating an image to share with the community, you'll need to provide contact information. This information will be shown **publicly**, so be careful when providing:

- Community gallery prefix
- Publisher support email
- Publisher URL

- Legal agreement URL

Information from your image definitions will also be publicly available, like what you provide for **Publisher**, **Offer**, and **SKU**.

## Prerequisites

Only the owner of a subscription, or a user or service principal assigned to the **Compute Gallery Sharing Admin** role at the subscription or gallery level, can enable a gallery to go public to the community. To assign a role to a user, group, service principal or managed identity, see [Steps to assign an Azure role](#).

- [CLI](#)
- [REST](#)
- [Portal](#)

The `--public-name-prefix` value is used to create a name for the public version of your gallery. The `--public-name-prefix` will be the first part of the public name, and the last part will be a GUID, created by the platform, that is unique to your gallery.

```
location=westus
galleryName=contosoGallery
resourceGroup=myCGRG
publisherUri=https://www.contoso.com
publisherEmail=support@contoso.com
eulaLink=https://www.contoso.com/eula
prefix=ContosoImages

az group create --name $resourceGroup --location $location

az sig create \
  --gallery-name $galleryName \
  --permissions community \
  --resource-group $resourceGroup \
  --publisher-uri $publisherUri \
  --publisher-email $publisherEmail \
  --eula $eulaLink \
  --public-name-prefix $prefix
```

The output of this command will give you the public name for your community gallery in the `sharingProfile` section, under `publicNames`.

To start sharing the gallery to all Azure users, see [Share images using a community gallery](#).

## Next steps

- Create an [image definition and an image version](#).
- [Create a VM application](#) in your gallery.

# Share gallery resources

9/21/2022 • 2 minutes to read • [Edit Online](#)

As the Azure Compute Gallery, definition, and version are all resources, they can be shared using the built-in native Azure Roles-based Access Control (RBAC) roles. Using Azure RBAC roles you can share these resources to other users, service principals, and groups. You can even share access to individuals outside of the tenant they were created within. Once a user has access, they can use the gallery resources to deploy a VM or a Virtual Machine Scale Set. Here's the sharing matrix that helps understand what the user gets access to:

SHARED WITH USER	AZURE COMPUTE GALLERY	IMAGE DEFINITION	IMAGE VERSION
Azure Compute Gallery	Yes	Yes	Yes
Image Definition	No	Yes	Yes

We recommend sharing at the Gallery level for the best experience. We don't recommend sharing individual image versions. For more information about Azure RBAC, see [Assign Azure roles](#).

There are three main ways to share images in an Azure Compute Gallery, depending on who you want to share with:

SHARE WITH:	OPTION
Specific people, groups, or service principals (described in this article)	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
<a href="#">Subscriptions or tenants</a>	A direct shared gallery lets you share to everyone in a subscription or tenant.
<a href="#">Everyone</a>	Community gallery lets you share your entire gallery publicly, to all Azure users.

## Share using RBAC

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. On the page for your gallery, in the menu on the left, select **Access control (IAM)**.
2. Under **Add a role assignment**, select **Add**. The **Add a role assignment** pane will open.
3. Under **Role**, select **Reader**.
4. Under **assign access to**, leave the default of **Azure AD user, group, or service principal**.
5. Under **Select**, type in the email address of the person that you would like to invite.
6. If the user is outside of your organization, you'll see the message **This user will be sent an email that enables them to collaborate with Microsoft**. Select the user with the email address and then click **Save**.

## Next steps

- Create an [image definition](#) and an [image version](#).
- Create a VM from a [generalized](#) or [specialized](#) private gallery.

# Share a gallery with subscriptions or tenants (preview)

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article covers how to share an Azure Compute Gallery with specific subscriptions or tenants using a direct shared gallery. Sharing a gallery with tenants and subscriptions give them read-only access to your gallery.

## IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

To publish images to a direct shared gallery during the preview, you need to register at <https://aka.ms/directsharedgallery-preview>. We will follow up within 5 business days after submitting the form. No additional access required to consume images, Creating VMs from a direct shared gallery is open to all Azure users in the target subscription or tenant the gallery is shared with.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

There are three main ways to share images in an Azure Compute Gallery, depending on who you want to share with:

SHARE WITH:	OPTION
<a href="#">Specific people, groups, or service principals</a>	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
[Subscriptions or tenants](explained in this article)	Direct shared gallery lets you share to everyone in a subscription or tenant (all users, service principals and managed identities)
<a href="#">Everyone</a>	Community gallery lets you share your entire gallery publicly, to all Azure users.

## Limitations

During the preview:

- You can only share to 30 subscriptions and 5 tenants.
- Only images can be shared. You can't directly share a [VM application](#) during the preview.
- A direct shared gallery can't contain encrypted image versions. Encrypted images can't be created within a gallery that is directly shared.
- Only the owner of a subscription, or a user or service principal assigned to the `Compute Gallery Sharing Admin` role at the subscription or gallery level will be able to enable group-based sharing.
- You need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the

property can't currently be updated.

- TrustedLaunch and ConfidentialVM are not supported
- PowerShell, Ansible, and Terraform aren't supported at this time.
- Not available in Government clouds
- For consuming direct shared images in target subscription, Direct shared images can be found from VM/VMSS creation blade only.
- **Known issue:** When creating a VM from a direct shared image using the Azure portal, if you select a region, select an image, then change the region, you will get an error message: "You can only create VM in the replication regions of this image" even when the image is replicated to that region. To get rid of the error, select a different region, then switch back to the region you want. If the image is available, it should clear the error message.

## Prerequisites

You need to create a [new direct shared gallery](#). A direct shared gallery has the `sharingProfile.permissions` property set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

## How sharing with direct shared gallery works

First you create a gallery under `Microsoft.Compute/Galleries` and choose `groups` as a sharing option.

When you are ready, you share your gallery with subscriptions and tenants. Only the owner of a subscription, or a user or service principal with the `Compute Gallery Sharing Admin` role at the subscription or gallery level, can share the gallery. At this point, the Azure infrastructure creates proxy read-only regional resources, under `Microsoft.Compute/SharedGalleries`. Only subscriptions and tenants you have shared with can interact with the proxy resources, they never interact with your private resources. As the publisher of the private resource, you should consider the private resource as your handle to the public proxy resources. The subscriptions and tenants you have shared your gallery with will see the gallery name as the subscription ID where the gallery was created, followed by the gallery name.

- [Portal](#)
- [CLI](#)
- [REST](#)

### NOTE

**Known issue:** In the Azure portal, If you get an error "Failed to update Azure compute gallery", please verify if you have owner (or) compute gallery sharing admin permission on the gallery.

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Type **Azure Compute Gallery** in the search box and select **Azure Compute Gallery** in the results.
3. In the **Azure Compute Gallery** page, click **Add**.
4. On the **Create Azure Compute Gallery** page, select the correct subscription.
5. Complete all of the details on the page.
6. At the bottom of the page, select **Next: Sharing method**.

## Create Azure compute gallery

...

[Basics](#) [Sharing](#) [Tags](#) [Review + create](#)

Azure compute galleries allow you to share images with users or user groups across subscriptions in your organization. Images are published to Azure compute gallery that will be available within Azure Marketplace.

### Instance details

Name \* ⓘ

myCommunityGallery

Region \* ⓘ

(US) West US

Description ⓘ

Azure Compute Gallery for sharing images publicly.

[Review + create](#)
[< Previous](#)
[Next : Sharing method >](#)

7. On the **Sharing** tab, select **RBAC + share directly**.

## Create Azure compute gallery

...

[Basics](#) [Sharing](#) [Tags](#) [Review + create](#)

In addition to role based sharing through Identity Access control, you're able to share the compute gallery using the methods below.

The Azure Compute Gallery - Direct Shared Gallery/Direct shared images (the "PREVIEW") subject to the [Preview Terms for Azure Compute Gallery - Direct Shared Gallery](#).

If you do not agree to these terms, do not use the PREVIEW

Sharing method ⓘ

 Role based access control (RBAC)

Role based sharing through Identity Access control. Share based on permissions assigned to users, groups, and applications at a certain scope. [Learn more](#)

 RBAC + share directly

Share resources with all users in the same subscription, same tenant, different subscriptions, and different tenants. All users in the subscription or tenant will have read access to the gallery and all the resources within it. [Learn more](#)

 RBAC + share to public community gallery (PREVIEW)

Publish your Azure compute gallery to the community gallery. Your gallery will be shared with anyone using Azure, including users outside of your organization. [Learn more](#)

[Review + create](#)
[< Previous](#)
[Next : Tags >](#)

8. When you are done, select **Review + create**.

9. After validation passes, select **Create**.

10. When the deployment is finished, select **Go to resource**.

To share the gallery:

1. On the page for the gallery, select **Sharing** from the left menu.

2. Under **Direct sharing settings**, select **Add**.

The screenshot shows the 'Sharing' page with the following interface elements:

- Top navigation: Share, Stop sharing, Refresh.
- Text: In addition to role based sharing through Identity Access control, you're able to share the compute gallery using the methods below.
- Sharing dropdown: RBAC + share directly (PREVIEW).
- Section: Direct sharing settings.
- Buttons: + Add (highlighted with a red box), Delete.
- Inputs: Type (checkbox) and Tenants and subscriptions (dropdown).
- Buttons at the bottom: Save (blue), Cancel.

3. If you would like to share with someone within your organization, for **Type** select *Subscription* or *Tenant* and choose the appropriate item from the **Tenants and subscriptions** drop-down. If you want to share with someone outside of your organization, select either *Subscription outside of my organization* or *Tenant outside of my organization* and then paste or type the ID into the text box.

4. When you are done adding items, select **Save**.

## Next steps

- Create an [image definition and an image version](#).
- Create a VM from a [generalized](#) or [specialized](#) image from a direct shared image in the target subscription or tenant.

# Share images using a community gallery (preview)

9/21/2022 • 5 minutes to read • [Edit Online](#)

To share a gallery with all Azure users, you can create a community gallery (preview). Community galleries can be used by anyone with an Azure subscription. Someone creating a VM can browse images shared with the community using the portal, REST, or the Azure CLI.

Sharing images to the community is a new capability in [Azure Compute Gallery](#). In the preview, you can make your image galleries public, and share them to all Azure customers. When a gallery is marked as a community gallery, all images under the gallery become available to all Azure customers as a new resource type under Microsoft.Compute/communityGalleries. All Azure customers can see the galleries and use them to create VMs. Your original resources of the type `Microsoft.Compute/galleries` are still under your subscription, and private.

## IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

To publish a community gallery, you need to register for the preview at <https://aka.ms/communitygallery-preview>. We will follow up within 5 business days after submitting the form. Creating VMs from the community gallery is open to all Azure users.

During the preview, the gallery must be created as a community gallery (for CLI, this means using the `--permissions community` parameter) you currently can't migrate a regular gallery to a community gallery.

You can't currently create a Flexible virtual machine scale set from an image shared by another tenant.

There are three main ways to share images in an Azure Compute Gallery, depending on who you want to share with:

SHARE WITH:	OPTION
<a href="#">Specific people, groups, or service principals</a>	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
<a href="#">Subscriptions or tenants</a>	Direct shared gallery lets you share to everyone in a subscription or tenant.
<a href="#">Everyone (described in this article)</a>	Community gallery lets you share your entire gallery publicly, to all Azure users.

## Limitations for images shared to the community

There are some limitations for sharing your gallery to the community:

- Encrypted images aren't supported.
- For the preview, image resources need to be created in the same region as the gallery. For example, if you create a gallery in West US, the image definitions and image versions should be created in West US if you want to make them available during the public preview.
- For the preview, you can't share [VM Applications](#) to the community.
- The gallery must be created as a community gallery. For the preview, there is no way to migrate an existing

gallery to be a community gallery.

- To find images shared to the community from the Azure portal, you need to go through the VM create or scale set creation pages. You can't search the portal or Azure Marketplace for the images.

#### IMPORTANT

Microsoft does not provide support for images you share to the community.

## How sharing with the community works

You [create a gallery resource](#) under `Microsoft.Compute/Galleries` and choose `community` as a sharing option.

When you are ready, you flag your gallery as ready to be shared publicly. Only the owner of a subscription, or a user or service principal with the `Compute Gallery Sharing Admin` role at the subscription or gallery level, can enable a gallery to go public to the community. At this point, the Azure infrastructure creates proxy read-only regional resources, under `Microsoft.Compute/CommunityGalleries`, which are public.

The end-users can only interact with the proxy resources, they never interact with your private resources. As the publisher of the private resource, you should consider the private resource as your handle to the public proxy resources. The `prefix` you provide when you create the gallery will be used, along with a unique GUID, to create the public facing name for your gallery.

Azure users can see the latest image versions shared to the community in the portal, or query for them using the CLI. Only the latest version of an image is listed in the community gallery.

When creating a community gallery, you will need to provide contact information for your images. This information will be shown **publicly**, so be careful when providing it:

- Community gallery prefix
- Publisher support email
- Publisher URL
- Legal agreement URL

Information from your image definitions will also be publicly available, like what you provide for **Publisher**, **Offer**, and **SKU**.

#### WARNING

If you want to stop sharing a gallery publicly, you can update the gallery to stop sharing, but making the gallery private will prevent existing virtual machine scale set users from scaling their resources.

If you stop sharing your gallery during the preview, you won't be able to re-share it.

## Start sharing publicly

In order to share a gallery publicly, it needs to be created as a community gallery. For more information, see [Create a community gallery](#)

- [CLI](#)
- [REST](#)
- [Portal](#)

Once you are ready to make the gallery available to the public, enable the community gallery using [az sig share enable-community](#). Only a user in the `Owner` role definition can enable a gallery for community sharing.

```
az sig share enable-community \
--gallery-name $galleryName \
--resource-group $resourceGroup
```

To go back to only RBAC based sharing, use the [az sig share reset](#) command.

To delete a gallery shared to community, you must first run [az sig share reset](#) to stop sharing, then delete the gallery.

#### IMPORTANT

If you are listed as the owner of your subscription, but you are having trouble sharing the gallery publicly, you may need to explicitly [add yourself as owner again](#).

To go back to only RBAC based sharing, use the [az sig share reset](#) command.

To delete a gallery shared to community, you must first run [az sig share reset](#) to stop sharing, then delete the gallery.

## Next steps

Create an [image definition and an image version](#).

Create a VM from a [generalized](#) or [specialized](#) image in a community gallery.

# Store and share images in an Azure Compute Gallery

9/21/2022 • 14 minutes to read • [Edit Online](#)

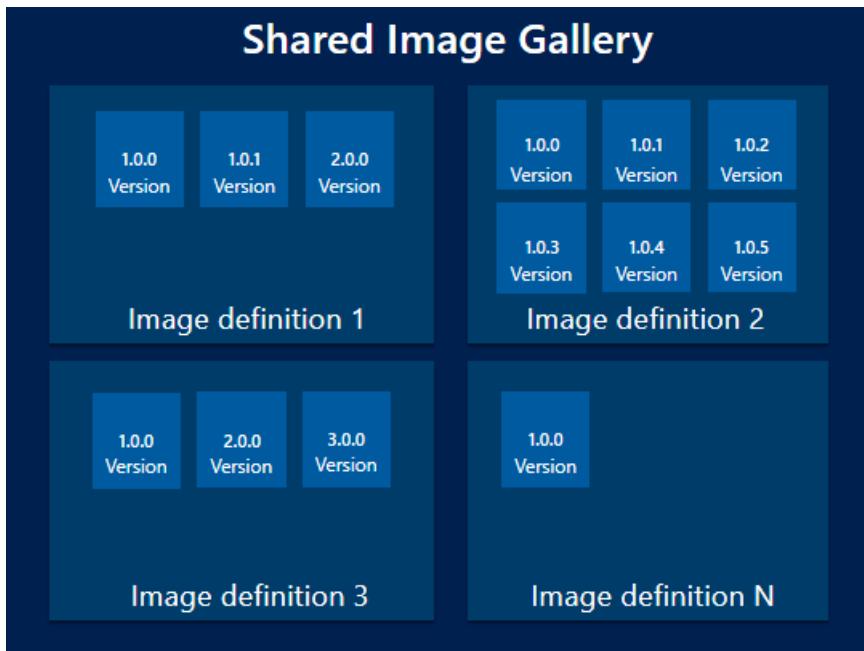

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

An image is a copy of either a full VM (including any attached data disks) or just the OS disk, depending on how it is created. When you create a VM from the image, a copy of the VHDs in the image are used to create the disks for the new VM. The image remains in storage and can be used over and over again to create new VMs.

If you have a large number of images that you need to maintain, and would like to make them available throughout your company, you can use an [Azure Compute Gallery](#) as a repository.

When you use a gallery to store images, multiple resource types are created:

RESOURCE	DESCRIPTION
<b>Image source</b>	This is a resource that can be used to create an <b>image version</b> in a gallery. An image source can be an existing Azure VM that is either <a href="#">generalized or specialized</a> , a managed image, a snapshot, a VHD or an image version in another gallery.
<b>Gallery</b>	Like the Azure Marketplace, a <b>gallery</b> is a repository for managing and sharing images and other resources, but you control who has access.
<b>Image definition</b>	Image definitions are created within a gallery and they carry information about the image and any requirements for using it to create VMs. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
<b>Image version</b>	An <b>image version</b> is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an <b>image version</b> to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

## Image definitions

Image definitions are a logical grouping for versions of an image. The image definition holds information about why the image was created, what OS it is for, and other information about using the image. An image definition is like a plan for all of the details around creating a specific image. You don't deploy a VM from an image definition, but from the image versions created from the definition.

There are three parameters for each image definition that are used in combination - **Publisher**, **Offer** and **SKU**. These are used to find a specific image definition. You can have image versions that share one or two, but not all three values. For example, here are three image definitions and their values:

IMAGE DEFINITION	PUBLISHER	OFFER	SKU
myImage1	Contoso	Finance	Backend
myImage2	Contoso	Finance	Frontend
myImage3	Testing	Finance	Frontend

All three of these have unique sets of values. The format is similar to how you can currently specify publisher, offer, and SKU for [Azure Marketplace images](#) in Azure PowerShell to get the latest version of a Marketplace image. Each image definition needs to have a unique set of these values.

The following parameters determine which types of image versions they can contain:

- Operating system state - You can set the OS state to [generalized or specialized](#). This field is required.
- Operating system - can be either Windows or Linux. This field is required.
- Hyper-V generation - specify whether the image was created from a generation 1 or [generation 2](#) Hyper-V VHD. Default is generation 1.

The following are other parameters that can be set on your image definition so that you can more easily track your resources:

- Description - use description to give more detailed information on why the image definition exists. For example, you might have an image definition for your front-end server that has the application pre-installed.
- EULA - can be used to point to an end-user license agreement specific to the image definition.
- Privacy Statement and Release notes - store release notes and privacy statements in Azure storage and

provide a URI for accessing them as part of the image definition.

- End-of-life date - establish a default date after which the image shouldn't be used, for all image versions in the image definition. End-of-life dates are informational; users will still be able to create VMs from images and versions past the end-of-life date.
- Tag - you can add tags when you create your image definition. For more information about tags, see [Using tags to organize your resources](#)
- Minimum and maximum vCPU and memory recommendations - if your image has vCPU and memory recommendations, you can attach that information to your image definition.
- Disallowed disk types - you can provide information about the storage needs for your VM. For example, if the image isn't suited for standard HDD disks, you add them to the disallow list.
- Purchase plan information for Marketplace images - `-PurchasePlanPublisher`, `-PurchasePlanName`, and `-PurchasePlanProduct`. For more information about purchase plan information, see [Find images in the Azure Marketplace](#) and [Supply Azure Marketplace purchase plan information when creating images](#).

## Image versions

An **image version** is what you use to create a VM. You can have multiple versions of an image as needed for your environment. When you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

The properties of an image version are:

- Version number. This is used as the name of the image version. It is always in the format: MajorVersion.MinorVersion.Patch. When you specify to use **latest** when creating a VM, the latest image is chosen based on the highest MajorVersion, then MinorVersion, then Patch.
- Source. The source can be a VM, managed disk, snapshot, managed image, or another image version.
- Exclude from latest. You can keep a version from being used as the latest image version.
- End of life date. Indicate the end-of-life date for the image version. End-of-life dates are informational; users will still be able to create VMs from versions past the end-of-life date.

## Generalized and specialized images

There are two operating system states supported by Azure Compute Gallery. Typically images require that the VM used to create the image has been **generalized** before taking the image. Generalizing is a process that removes machine and user specific information from the VM. For Linux, you can use `waagent -deprovision` or `-deprovision+user` parameters. For Windows, the Sysprep tool is used.

Specialized VMs have not been through a process to remove machine specific information and accounts. Also, VMs created from specialized images do not have an `osProfile` associated with them. This means that specialized images will have some limitations in addition to some benefits.

- VMs and scale sets created from specialized images can be up and running quicker. Because they are created from a source that has already been through first boot, VMs created from these images boot faster.
- Accounts that could be used to log into the VM can also be used on any VM created using the specialized image that is created from that VM.
- VMs will have the **Computer name** of the VM the image was taken from. You should change the computer name to avoid collisions.
- The `osProfile` is how some sensitive information is passed to the VM, using `secrets`. This may cause issues using KeyVault, WinRM and other functionality that uses `secrets` in the `osProfile`. In some cases, you can use managed service identities (MSI) to work around these limitations.

## Updating resources

Once created, you can make some changes to the gallery resources. These are limited to:

Azure Compute Gallery:

- Description

Image definition:

- Recommended vCPUs
- Recommended memory
- Description
- End of life date

Image version:

- Regional replica count
- Target regions
- Exclude from latest
- End of life date

## Sharing

There are three main ways to share an Azure Compute Gallery, depending on who you want to share with:

SHARE WITH:	OPTION
Specific people, groups, or service principals	Role-based access control (RBAC) lets you share resources to specific people, groups, or service principals on a granular level.
Subscriptions or tenants	A direct shared gallery (preview) lets you share to everyone in a subscription or tenant.
Everyone	Community gallery (preview) lets you share your entire gallery publicly, to all Azure users.

## Shallow replication

When you create an image version, you can set the replication mode to shallow for development and test.

Shallow replication skips copying the image, so the image version is ready much faster. But, it also means you can't deploy a large number of VMs from that image version. This is similar to the way that the older managed images worked.

Shallow replication can also be useful if you have very large images (up to 32TB) that aren't frequently deployed. Because the source image isn't copied, larger disks can be used. But, they also can't be used for deploying large numbers of VMs concurrently.

To set an image for shallow replication, use `--replication-mode Shallow` with the Azure CLI.

## SDK support

The following SDKs support creating Azure Compute Galleries:

- [.NET](#)
- [Java](#)
- [Node.js](#)

- [Python](#)
- [Go](#)

## Templates

You can create Azure Compute Gallery resource using templates. There are several quickstart templates available:

- [Create a gallery](#)
- [Create an image definition in a gallery](#)
- [Create an image version in a gallery](#)

## Frequently asked questions

- [How can I list all the Azure Compute Gallery resources across subscriptions?](#)
- [Can I move my existing image to an Azure Compute Gallery?](#)
- [Can I create an image version from a specialized disk?](#)
- [Can I move the Azure Compute Gallery resource to a different subscription after it has been created?](#)
- [Can I replicate my image versions across clouds such as Azure China 21Vianet, Azure Germany, or Azure Government Cloud?](#)
- [Can I replicate my image versions across subscriptions?](#)
- [Can I share image versions across Azure AD tenants?](#)
- [How long does it take to replicate image versions across the target regions?](#)
- [What is the difference between source region and target region?](#)
- [How do I specify the source region while creating the image version?](#)
- [How do I specify the number of image version replicas to be created in each region?](#)
- [Can I create the gallery in a different location than the one for the image definition and image version?](#)
- [What are the charges for using an Azure Compute Gallery?](#)
- [What API version should I use when creating images?](#)
- [What API version should I use to create a VM or Virtual Machine Scale Set out of the image version?](#)
- [Can I update my Virtual Machine Scale Set created using managed image to use Azure Compute Gallery images?](#)

### How can I list all the Azure Compute Gallery resources across subscriptions?

To list all the Azure Compute Gallery resources across subscriptions that you have access to on the Azure portal, follow the steps below:

1. Open the [Azure portal](#).
  2. Scroll down the page and select **All resources**.
  3. Select all the subscriptions under which you'd like to list all the resources.
  4. Look for resources of the **Azure Compute Gallery** type.
- [Azure CLI](#)
  - [Azure PowerShell](#)

To list all the Azure Compute Gallery resources, across subscriptions that you have permissions to, use the following command in the Azure CLI:

```
az account list -otsv --query "[].id" | xargs -n 1 az sig list --subscription
```

For more information, see [List, update, and delete image resources](#).

## **Can I move my existing image to an Azure Compute Gallery?**

Yes. There are 3 scenarios based on the types of images you may have.

Scenario 1: If you have a managed image, then you can create an image definition and image version from it. For more information, see [Create and image definition and an image version](#).

Scenario 2: If you have an unmanaged image, you can create a managed image from it, and then create an image definition and image version from it.

Scenario 3: If you have a VHD in your local file system, then you need to upload the VHD to a managed image, then you can create an image definition and image version from it.

- If the VHD is of a Windows VM, see [Upload a VHD](#).
- If the VHD is for a Linux VM, see [Upload a VHD](#)

## **Can I create an image version from a specialized disk?**

Yes, you can create a VM from a [specialized image](#).

## **Can I move the Azure Compute Gallery resource to a different subscription after it has been created?**

No, you can't move the gallery image resource to a different subscription. You can replicate the image versions in the gallery to other regions or copy an [image from another gallery](#).

## **Can I replicate my image versions across clouds such as Azure China 21Vianet or Azure Germany or Azure Government Cloud?**

No, you cannot replicate image versions across clouds.

## **Can I replicate my image versions across subscriptions?**

No, you may replicate the image versions across regions in a subscription and use it in other subscriptions through RBAC.

## **Can I share image versions across Azure AD tenants?**

Yes, you can use RBAC to share to individuals across tenants. But, to share at scale, see "Share gallery images across Azure tenants" using [PowerShell](#) or [CLI](#).

## **How long does it take to replicate image versions across the target regions?**

The image version replication time is entirely dependent on the size of the image and the number of regions it is being replicated to. However, as a best practice, it is recommended that you keep the image small, and the source and target regions close for best results. You can check the status of the replication using the -ReplicationStatus flag.

## **What is the difference between source region and target region?**

Source region is the region in which your image version will be created, and target regions are the regions in which a copy of your image version will be stored. For each image version, you can only have one source region. Also, make sure that you pass the source region location as one of the target regions when you create an image version.

## **How do I specify the source region while creating the image version?**

While creating an image version, you can use the `--location` argument in CLI and the `-Location` parameter in PowerShell to specify the source region. Please ensure the managed image that you are using as the base image to create the image version is in the same location as the location in which you intend to create the image version. Also, make sure that you pass the source region location as one of the target regions when you create an image version.

## **How do I specify the number of image version replicas to be created in each region?**

There are two ways you can specify the number of image version replicas to be created in each region:

1. The regional replica count which specifies the number of replicas you want to create per region.
  2. The common replica count which is the default per region count in case regional replica count is not specified.
- [Azure CLI](#)
  - [Azure PowerShell](#)

To specify the regional replica count, pass the location along with the number of replicas you want to create in that region: "South Central US=2".

If regional replica count is not specified with each location, then the default number of replicas will be the common replica count that you specified.

To specify the common replica count in Azure CLI, use the `--replica-count` argument in the `az sig image-version create` command.

#### **Can I create the gallery in a different location than the one for the image definition and image version?**

Yes, it is possible. But, as a best practice, we encourage you to keep the resource group, gallery, image definition, and image version in the same location.

#### **What are the charges for using an Azure Compute Gallery?**

There are no charges for using an Azure Compute Gallery, except the storage charges for storing the image versions and network egress charges for replicating the image versions from source region to target regions.

#### **What API version should I use when creating images?**

To work with galleries, image definitions, and image versions, we recommend you use API version 2018-06-01. Zone Redundant Storage (ZRS) requires version 2019-03-01 or later.

#### **What API version should I use to create a VM or Virtual Machine Scale Set out of the image version?**

For VM and Virtual Machine Scale Set deployments using an image version, we recommend you use API version 2018-04-01 or higher.

#### **Can I update my Virtual Machine Scale Set created using managed image to use Azure Compute Gallery images?**

Yes, you can update the scale set image reference from a managed image to an Azure Compute Gallery image, as long as the OS type, Hyper-V generation, and the data disk layout matches between the images.

## Troubleshoot

If you have issues with performing any operations on the gallery resources, consult the list of common errors in the [troubleshooting guide](#).

In addition, you can post and tag your question with `azure-virtual-machines-images` at [Q&A](#).

## Next steps

Learn how to deploy images using the [Azure Compute Gallery](#).

# Create an image of a VM in the portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

An image can be created from a VM and then used to create multiple VMs.

For images stored in an Azure Compute Gallery (formerly known as Shared Image Gallery), you can use VMs that already have accounts created on them (specialized) or you can generalize the VM before creating the image to remove machine accounts and other machine specific information. To generalize a VM, see [Generalized a Windows VM](#). For more information, see [Generalized and specialized images](#).

## Capture a VM in the portal

1. Go to the [Azure portal](#), then search for and select **Virtual machines**.
2. Select your VM from the list.
3. On the page for the VM, on the upper menu, select **Capture**.

The **Create an image** page appears.

4. For **Resource group**, either select **Create new** and enter a name, or select a resource group to use from the drop-down list. If you want to use an existing gallery, select the resource group for the gallery you want to use.
5. To create the image in a gallery, select **Yes, share it to a gallery as an image version**.

To only create a managed image, select **No, capture only a managed image**. The VM must have been generalized to create a managed image. The only other required information is a name for the image.

6. If you want to delete the source VM after the image has been created, select **Automatically delete this virtual machine after creating the image**. This is not recommended.
7. For **Gallery details**, select the gallery or create a new gallery by selecting **Create new**.
8. In **Operating system state** select generalized or specialized. For more information, see [Generalized and specialized images](#).
9. Select an image definition or select **create new** and provide a name and information for a new [Image definition](#).
10. Enter an [image version](#) number. If this is the first version of this image, type **1.0.0**.
11. If you want this version to be included when you specify **latest** for the image version, then leave **Exclude from latest** unchecked.
12. Select an **End of life** date. This date can be used to track when older images need to be retired.
13. Under **Replication**, select a default replica count and then select any additional regions where you would like your image replicated.
14. When you are done, select **Review + create**.
15. After validation passes, select **Create** to create the image.

## Next steps

- Azure Compute Galleries overview

# Create an image definition and an image version

9/21/2022 • 12 minutes to read • [Edit Online](#)

A [Azure Compute Gallery](#) (formerly known as Shared Image Gallery) simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Images can be created from a VM, VHD, snapshot, managed image, or another image version.

The Azure Compute Gallery lets you share your custom VM images with others in your organization, within or across regions, within an Azure AD tenant, or publicly using a [community gallery \(preview\)](#). Choose which images you want to share, which regions you want to make them available in, and who you want to share them with. You can create multiple galleries so that you can logically group images.

The Azure Compute Gallery feature has multiple resource types:

RESOURCE	DESCRIPTION
Image source	This is a resource that can be used to create an <b>image version</b> in a gallery. An image source can be an existing Azure VM that is either <a href="#">generalized or specialized</a> , a managed image, a snapshot, or an image version in another gallery.
Gallery	Like the Azure Marketplace, a <b>gallery</b> is a repository for managing and sharing images and <a href="#">VM applications</a> , but you control who has access.
Image definition	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
Image version	An <b>image version</b> is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an <b>image version</b> to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

## Before you begin

To complete this article, you must have an existing Azure Compute Gallery, and a source for your image available in Azure. Image sources can be:

- A VM in your subscription. You can capture an image from both [specialized and generalized](#) VMs.
- A Managed image,
- Managed OS and data disks.
- OS and data disks as VHDs in a storage account.
- Other image versions either in the same gallery or another gallery in the same subscription.

If the image will contain data disks, the data disk size cannot be more than 1 TB.

Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes and periods. For

more information about the values you can specify for an image definition, see [Image definitions](#).

Allowed characters for the image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion.MinorVersion.Patch*.

When working through this article, replace the resource names where needed.

For [generalized](#) images, see the OS specific guidance before capturing the image:

- **Linux**

- [Generic steps](#)
- [CentOS](#)
- [Debian](#)
- [Flatcar](#)
- [FreeBSD](#)
- [Oracle Linux](#)
- [OpenBSD](#)
- [Red Hat](#)
- [SUSE](#)
- [Ubuntu](#)

- **Windows**

If you plan to run Sysprep before uploading your virtual hard disk (VHD) to Azure for the first time, make sure you have [prepared your VM](#).

## Community gallery (preview)

### IMPORTANT

Azure Compute Gallery – community gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

To share images in the community gallery, you need to register for the preview at <https://aka.ms/communitygallery-preview>. Creating VMs and scale sets from images shared the community gallery is open to all Azure users.

Information from your image definitions will be publicly available, like what you provide for **Publish**, **Offer**, and **SKU**.

If you will be sharing your images using a [community gallery \(preview\)](#), make sure that you create your gallery, image definitions, and image versions in the same region.

When users search for community gallery images, only the latest version of an image is shown.

## Create an image

Choose an option below for creating your image definition and image version:

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

To create an image from a VM in the portal, see [Capture an image of a VM](#).

To create an image using a source other than a VM, follow these steps.

1. Go to the [Azure portal](#), then search for and select **Azure Compute Gallery**.
2. Select the gallery you want to use from the list.
3. On the page for your gallery, select **Add** from the top of the page and then select **VM image definition** from the drop-down.
4. on the **Add new image definition to Azure Compute Gallery** page, in the **Basics** tab, select a **Region**.
5. For **Image definition name**, type a name like *myImageDefinition*.
6. For **Operating system**, select the correct option based on your source.
7. For **VM generation**, select the option based on your source. In most cases, this will be *Gen 1*. For more information, see [Support for generation 2 VMs](#).
8. For **Operating system state**, select the option based on your source. For more information, see [Generalized and specialized](#).
9. For **Publisher**, type a unique name like *myPublisher*.
10. For **Offer**, type a unique name like *myOffer*.
11. For **SKU**, type a unique name like *mySKU*.
12. At the bottom of the page, select **Review + create**.
13. After the image definition passes validation, select **Create**.
14. When the deployment is finished, select **Go to resource**.
15. In the page for your image definition, on the **Get started** tab, select **Create a version**.
16. In **Region**, select the region where you want the image created. In some cases, the source must be in the same region where the image is created. If you aren't seeing your source listed in later drop-downs, try changing the region for the image. You can always replicate the image to other regions later.
17. For **Version number**, type a number like *1.0.0*. The image version name should follow *major.minor.patch* format using integers.
18. In **Source**, select the type of file you are using for your source from the drop-down. See the table below for specific details for each source type.

SOURCE	OTHER FIELDS
Disks or snapshots	<ul style="list-style-type: none"> <li>- For <b>OS disk</b> select the disk or snapshot from the drop-down.</li> <li>- To add a data disk, type the LUN number and then select the data disk from the drop-down.</li> </ul>
Image version	<ul style="list-style-type: none"> <li>- Select the <b>Source gallery</b> from the drop-down.</li> <li>- Select the correct image definition from the drop-down.</li> <li>- Select the existing image version that you want to use from the drop-down.</li> </ul>
Managed image	Select the <b>Source image</b> from the drop-down. The managed image must be in the same region that you chose in <b>Instance details</b> .

SOURCE	OTHER FIELDS
VHD in a storage account	Select <b>Browse</b> to choose the storage account for the VHD.

19. In **Exclude from latest**, leave the default value of *No* unless you don't want this version used when creating a VM using `latest` instead of a version number.
20. For **End of life date**, select a date from the calendar for when you think this version should stop being used.
21. In the **Replication** tab, select the storage type from the drop-down.
22. Set the **Default replica count**, you can override this for each region you add.
23. You need to replicate to the source region, so the first replica in the list will be in the region where you created the image. You can add more replicas by selecting the region from the drop-down and adjusting the replica count as necessary.
24. When you are done, select **Review + create**. Azure will validate the configuration.
25. When image version passes validation, select **Create**.
26. When the deployment is finished, select **Go to resource**.

It can take a while to replicate the image to all of the target regions.

You can also capture an existing VM as an image, from the portal. For more information, see [Create an image of a VM in the portal](#).

## New Features

Many new features like ARM64, Accelerated Networking, TrustedVMSupported etc. are only supported through Azure Compute Gallery and not available for 'Managed images'. For a complete list of new features available through Azure Compute Gallery, please refer <https://learn.microsoft.com/cli/azure/sig/image-version?view=azure-cli-latest#az-sig-image-version-create>

## Next steps

For information about how to supply purchase plan information, see [Supply Azure Marketplace purchase plan information when creating images](#).

# Create a VM from a generalized image version

9/21/2022 • 13 minutes to read • [Edit Online](#)

Create a VM from a [generalized image version](#) stored in an Azure Compute Gallery (formerly known as Shared Image Gallery). If you want to create a VM using a specialized image, see [Create a VM from a specialized image](#).

This article shows how to create a VM from a generalized image:

- [In your own gallery](#)
- Shared to a [community gallery](#)
- [Directly shared to your subscription or tenant](#)

## Create a VM from your gallery

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

Now you can create one or more new VMs. This example creates a VM named *myVM*, in the *myResourceGroup*, in the *East US* datacenter.

1. Go to your image definition. You can use the resource filter to show all image definitions available.
2. On the page for your image definition, select **Create VM** from the menu at the top of the page.
3. For **Resource group**, select **Create new** and type *myResourceGroup* for the name.
4. In **Virtual machine name**, type *myVM*.
5. For **Region**, select *East US*.
6. For **Availability options**, leave the default of *No infrastructure redundancy required*.
7. The value for **Image** is automatically filled with the **latest** image version if you started from the page for the image definition.
8. For **Size**, choose a VM size from the list of available sizes and then choose **Select**.
9. Under **Administrator account**, you need to provide a username, such as *azureuser* and a password or SSH key. The password must be at least 12 characters long and meet the [defined complexity requirements](#).
10. If you want to allow remote access to the VM, under **Public inbound ports**, choose **Allow selected ports** and then select **SSH (22)** or **RDP (3389)** from the drop-down. If you don't want to allow remote access to the VM, leave **None** selected for **Public inbound ports**.
11. When you are finished, select the **Review + create** button at the bottom of the page.
12. After the VM passes validation, select **Create** at the bottom of the page to start the deployment.

## Create a VM from a community gallery image

### IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

Microsoft does not provide support for images in the [community gallery](#).

- [CLI](#)
- [Portal](#)
- [REST](#)

To create a VM using an image shared to a community gallery, use the unique ID of the image for the `--image` which will be in the following format:

```
/CommunityGalleries/<community gallery name, like: ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f>/Images/<image name>/Versions/latest
```

As an end user, to get the public name of a community gallery, you need to use the portal. Go to **Virtual machines > Create > Azure virtual machine > Image > See all images > Community Images > Public gallery name.**

In this example, we are creating a VM from a Linux image and creating SSH keys for authentication.

```
imgDef="/CommunityGalleries/ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f/Images/myLinuxImage/Versions/latest"
vmResourceGroup=myResourceGroup
location=eastus
vmName=myVM
adminUsername=azureuser

az group create --name $vmResourceGroup --location $location

az vm create \
--resource-group $vmResourceGroup \
--name $vmName \
--image $imgDef \
--admin-username $adminUsername \
--generate-ssh-keys
```

When using a community image, you'll be prompted to accept the legal terms. The message will look like this:

To create the VM from community gallery image, you must accept the license agreement and privacy statement:  
<http://contoso.com>. (If you want to accept the legal terms by default, please use the option '--accept-term' when creating VM/VMSS) (Y/n):

## Create a VM from a gallery shared with your subscription or tenant

### IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

To publish images to a direct shared gallery during the preview, you need to register at <https://aka.ms/directsharedgallery-preview>. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

- [CLI](#)
- [Portal](#)
- [REST](#)

To create a VM using an image shared to your subscription or tenant, you need the unique ID of the image in the following format:

```
/SharedGalleries/<uniqueID>/Images/<image name>/Versions/latest
```

To find the `uniqueID` of a gallery that is shared with you, use [az sig list-shared](#). In this example, we are looking for galleries in the West US region.

```
region=westus
az sig list-shared --location $region --query "[].name" -o tsv
```

Use the gallery name to find the images that are available. In this example, we list all of the images in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

```
galleryName="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
az sig image-definition list-shared \
--gallery-unique-name $galleryName \
--location $region \
--query [*].{"Name:name,ID:uniqueId,OS:osType,State:osState}" -o table
```

Make sure the state of the image is `Generalized`. If you want to use an image with the `Specialized` state, see [Create a VM from a specialized image version](#).

Use the `Id` from the output, appended with `/Versions/latest` to use the latest version, as the value for `--image` to create a VM. In this example, we are creating a VM from a Linux image that is directly shared to us, and creating SSH keys for authentication.

```
imgDef="/SharedGalleries/1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-
MYDIRECTSHARED/Images/myDirectDefinition/Versions/latest"
vmResourceGroup=myResourceGroup
location=westus
vmName=myVM
adminUsername=azureuser

az group create --name $vmResourceGroup --location $location

az vm create\
--resource-group $vmResourceGroup \
--name $vmName \
--image $imgDef \
--admin-username $adminUsername \
--generate-ssh-keys
```

## Next steps

- [Create an Azure Compute Gallery](#)
- [Create an image in an Azure Compute Gallery](#)

# Create a VM using a specialized image version

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

Create a VM from a [specialized image version](#) stored in an Azure Compute Gallery (formerly known as Shared Image Gallery). If you want to create a VM using a generalized image version, see [Create a VM from a generalized image version](#).

This article shows how to create a VM from a specialized image:

- [In your own gallery](#)
- Shared to a [community gallery](#)
- [Directly shared to your subscription or tenant](#)

## IMPORTANT

When you create a new VM from a specialized image, the new VM retains the computer name of the original VM. Other computer-specific information, like the CMID, is also kept. This duplicate information can cause issues. When copying a VM, be aware of what types of computer-specific information your applications rely on.

## Create a VM from your gallery

- [CLI](#)
- [PowerShell](#)
- [Portal](#)

List the image definitions in a gallery using [az sig image-definition list](#) to see the name and ID of the definitions.

```
resourceGroup=myGalleryRG
gallery=myGallery
az sig image-definition list \
--resource-group $resourceGroup \
--gallery-name $gallery \
--query "[].[name, id]" \
--output tsv
```

Create the VM using [az vm create](#) using the --specialized parameter to indicate that the image is a specialized image.

Use the image definition ID for `--image` to create the VM from the latest version of the image that is available. You can also create the VM from a specific version by supplying the image version ID for `--image`.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
--name myVM \
--image "/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myGallery/images/myImageDefinition" \
--specialized
```

# Create a VM from a community gallery image

## IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

Microsoft does not provide support for images in the [community gallery](#).

- [CLI](#)
- [Portal](#)

To create a VM using an image shared to a community gallery, use the unique ID of the image for the `--image`, which will be in the following format:

```
/CommunityGalleries/<community gallery name, like: ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f>/Images/<image name>/Versions/latest
```

As an end user, to get the public name of a community gallery, you need to use the portal. Go to **Virtual machines > Create > Azure virtual machine > Image > See all images > Community Images > Public gallery name**.

List all of the image definitions that are available in a community gallery using [az sig image-definition list-community](#). In this example, we list all of the images in the *ContosoImage* gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

```
az sig image-definition list-community \
--public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f" \
--location westus \
--query [*].{"Name:name, ID:uniqueId, OS:osType, State:osState}" -o table
```

To create a VM from a generalized image in a community gallery, see [Create a VM from a generalized image version](#).

Create the VM using `az vm create` using the `--specialized` parameter to indicate that the image is a specialized image.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
--name myVM \
--image "/CommunityGalleries/ContosoImages-f61bb1d9-3c5a-4ad2-99b5-744030225de6/Images/LinuxSpecializedVersions/latest" \
--specialized
```

When using a community image, you'll be prompted to accept the legal terms. The message will look like this:

```
To create the VM from community gallery image, you must accept the license agreement and privacy statement:
http://contoso.com. (If you want to accept the legal terms by default, please use the option '--accept-term' when creating VM/VMSS) (Y/n):
```

## Create a VM from a gallery shared with your subscription or tenant

## IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

To publish images to a direct shared gallery during the preview, you need to register at <https://aka.ms/directsharedgallery-preview>. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

- [CLI](#)
- [Portal](#)

To create a VM using the latest version of an image shared to your subscription or tenant, you need the ID of the image in the following format:

```
/SharedGalleries/<uniqueID>/Images/<image name>/Versions/latest
```

To find the `uniqueID` of a gallery that is shared with you, use [az sig list-shared](#). In this example, we're looking for galleries in the West US region.

```
region=westus
az sig list-shared --location $region --query "[]?.name" -o tsv
```

Use the gallery name to find all of the images that are available. In this example, we list all of the images in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

```
galleryName="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
az sig image-definition list-shared \
--gallery-unique-name $galleryName \
--location $region \
--query "[*].'{Name:name, ID:uniqueId, OS:osType, State:osState}" -o table
```

Make sure the state of the image is `Specialized`. If you want to use an image with the `Generalized` state, see [Create a VM from a generalized image version](#).

Create the VM using [az vm create](#) using the `--specialized` parameter to indicate that the image is a specialized image.

Use the `Id`, appended with `/Versions/latest` to use the latest version, as the value for `--image` to create a VM.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

```
imgDef="/SharedGalleries/1a2b3c4d-1234-abcd-1a2b3c4d5e6f-  
MYDIRECTSHARED/Images/myDirectDefinition/Versions/latest"  
vmResourceGroup=myResourceGroup  
location=westus  
vmName=myVM  
  
az group create --name $vmResourceGroup --location $location  
  
az vm create\  
  --resource-group $vmResourceGroup \  
  --name $vmName \  
  --image $imgDef \  
  --specialized
```

## Next steps

- [Create an Azure Compute Gallery](#)
- [Create an image in an Azure Compute Gallery](#)

# List, update, and delete gallery resources

9/21/2022 • 6 minutes to read • [Edit Online](#)

You can manage your Azure Compute Gallery (formerly known as Shared Image Gallery) resources using the Azure CLI or Azure PowerShell.

## List galleries shared with you

- [CLI](#)
- [REST](#)
- [PowerShell](#)

List Galleries shared with your subscription.

```
region=westus
az sig list-shared --location $region
```

List Galleries shared with your tenant.

```
region=westus
az sig list-shared --location $region --shared-to tenant
```

The output will contain the public `name` and `uniqueID` of the gallery that is shared with you. You can use the name of the gallery to query for images that are available through the gallery.

Here is example output:

```
[  
 {  
   "location": "westus",  
   "name": "1231b567-8a99-1a2b-1a23-123456789abc-MYDIRECTSHARED",  
   "uniqueId": "/SharedGalleries/1231b567-8a99-1a2b-1a23-123456789abc-MYDIRECTSHARED"  
 }  
]
```

## Update resources

There are some limitations on what can be updated. The following items can be updated:

Azure Compute Gallery:

- Description

Image definition:

- Recommended vCPUs
- Recommended memory
- Description
- End of life date

Image version:

- Regional replica count
- Target regions
- Exclusion from latest
- End of life date

If you plan on adding replica regions, don't delete the source managed image. The source managed image is needed for replicating the image version to additional regions.

- [CLI](#)
- [PowerShell](#)

Update the description of a gallery using [az sig update](#).

```
az sig update \
--gallery-name myGallery \
--resource-group myGalleryRG \
--set description="My updated description."
```

Update the description of an image definition using [az sig image-definition update](#).

```
az sig image-definition update \
--gallery-name myGallery\
--resource-group myGalleryRG \
--gallery-image-definition myImageDefinition \
--set description="My updated description."
```

Update an image version to add a region to replicate to using [az sig image-version update](#). This change will take a while as the image gets replicated to the new region.

```
az sig image-version update \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--gallery-image-version 1.0.0 \
--add publishingProfile.targetRegions name=eastus
```

This example shows how to use [az sig image-version update](#) to exclude this image version from being used as the *latest* image.

```
az sig image-version update \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--gallery-image-version 1.0.0 \
--set publishingProfile.excludeFromLatest=true
```

This example shows how to use [az sig image-version update](#) to include this image version in being considered for *latest* image.

```
az sig image-version update \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--gallery-image-version 1.0.0 \
--set publishingProfile.excludeFromLatest=false
```

## Delete resources

You have to delete resources in reverse order, by deleting the image version first. After you delete all of the image versions, you can delete the image definition. After you delete all image definitions, you can delete the gallery.

- [CLI](#)
- [PowerShell](#)

Before you can delete a community shared gallery, you need to use [az sig share reset](#) to stop sharing the gallery publicly.

Delete an image version using [az sig image-version delete](#).

```
az sig image-version delete \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
--gallery-image-version 1.0.0
```

Delete an image definition using [az sig image-definition delete](#).

```
az sig image-definition delete \
--resource-group myGalleryRG \
--gallery-name myGallery \
--gallery-image-definition myImageDefinition
```

Delete a gallery using [az sig delete](#).

```
az sig delete \
--resource-group myGalleryRG \
--gallery-name myGallery
```

## Community galleries

### IMPORTANT

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery - community gallery](#).

To list your own galleries, and output the public names for your community galleries:

```
az sig list --query [*].{Name:name,PublicName:sharingProfile.communityGalleryInfo.publicNames}"
```

### NOTE

As an end user, to get the public name of a community gallery, you currently need to use the portal. Go to **Virtual machines > Create > Azure virtual machine > Image > See all images > Community Images > Public gallery name**.

List all of the image definitions that are available in a community gallery using [az sig image-definition list-community](#).

In this example, we list all of the images in the *ContosoImage* gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

```
az sig image-definition list-community \
--public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f" \
--location westus \
--query [*].{"Name:name, ID:uniqueId, OS:osType, State:osState}" -o table
```

List image versions shared in a community gallery using [az sig image-version list-community](#):

```
az sig image-version list-community \
--location westus \
--public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f" \
--gallery-image-definition myImageDefinition \
--query [*].{"Name:name, UniqueId:uniqueId}" \
-o table
```

## Direct shared galleries

### IMPORTANT

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the [Preview Terms for Azure Compute Gallery](#).

To publish images to a direct shared gallery during the preview, you need to register at <https://aka.ms/directsharedgallery-preview>. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

To find the `uniqueID` of a gallery that is shared with you, use [az sig list-shared](#). In this example, we are looking for galleries in the West US region.

```
region=westus
az sig list-shared --location $region --query "[].uniqueId" -o tsv
```

List all of the image definitions that are shared directly with you, use [az sig image-definition list-shared](#).

In this example, we list all of the images in the gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

```
name="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
az sig image-definition list-shared \
--gallery-unique-name $name
--location $region \
--query [*].{"Name:name, ID:uniqueId, OS:osType, State:osState}" -o table
```

List image versions directly shared to you using [az sig image-version list-shared](#):

```
imgDef="myImageDefinition"
az sig image-version list-shared \
--location $region \
--public-gallery-name $name \
--gallery-image-definition $imgDef \
--query "[*].\"{Name:name,UniqueId:uniqueId}\"" \
-o table
```

## Next steps

- Create an [image definition and an image version](#).
- Create a VM from a [generalized](#) or [specialized](#) image in a direct shared gallery.

# Troubleshoot images in an Azure Compute Gallery

9/21/2022 • 21 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

If you have problems performing any operations on Azure Compute Gallery (formerly known as Shared Image Gallery) resources, like galleries, image definitions, and image versions, run the failing command again in debug mode. You activate debug mode by passing the `--debug` switch with the Azure CLI and the `-Debug` switch with PowerShell. After you've located the error, follow this article to troubleshoot it.

## Creating or modifying a gallery

Error message	Cause	Mitigation
Gallery name is invalid. Allowed characters are English alphanumeric characters, with underscores, and periods allowed in the middle, up to 80 characters total. All other special characters, including dashes, are disallowed.	The name for the gallery does not meet the naming requirements	Choose a name that meets the following conditions: <ul style="list-style-type: none"><li>• Has an 80-character limit</li><li>• Contains only English letters, numbers, underscores, and periods</li><li>• Starts and ends with English letters or numbers</li></ul>
The provided resource name <galleryName> has these invalid trailing characters: <character>. The name can not end with characters: <character>	The name for the gallery ends with a period or underscore	Choose a name for the gallery that meets the following conditions: <ul style="list-style-type: none"><li>• Has an 80-character limit</li><li>• Contains only English letters, numbers, underscores, and periods</li><li>• Starts and ends with English letters or numbers</li></ul>
The provided location <region> is not available for resource type 'Microsoft.Compute/galleries'. List of available regions for the resource type is ...	The region specified for the gallery is incorrect or requires an access request	Check that the region name is correct. If the region name is correct, submit <a href="#">an access request</a> for the region
Can not delete resource before nested resources are deleted	You've tried to delete a gallery that contains at least one existing image definition. A gallery must be empty before it can be deleted	Delete all image definitions inside the gallery and then proceed to delete the gallery. If the image definition contains image versions, you must delete the image versions before you delete the image definitions
The gallery name <galleryName> is not unique within the subscription <subscriptionID>. Please pick another gallery name	You have an existing gallery with the same name and have tried to create another gallery with the same name	Choose a different name for the gallery
The resource <galleryName> already exists in location <region_1> in resource group <resourceGroup>. A resource with the same name cannot be created in location <region_2>. Please select a new resource name	You have an existing gallery with the same name and have tried to create another gallery with the same name	Choose a different name for the gallery

## Creating or modifying image definitions

Error message	Cause	Mitigation
Changing property 'galleryImage.properties.<property>' is not allowed	You tried to change the OS type, OS state, Hyper-V generation, offer, publisher, or SKU. Changing any of these properties is not permitted	Create a new image definition instead
The resource <galleryName/imageDefinitionName> already exists in location <region_1> in resource group <resourceGroup>. A resource with the same name cannot be created in location <region_2>. Please select a new resource name.	You have an existing image definition in the same gallery and resource group with the same name. You've tried to create another image definition with the same name and in the same gallery but in a different region.	Use a different name for the image definition, or put the image definition in a different gallery or resource group
The provided resource name <galleryName>/<imageDefinitionName> has these invalid trailing characters: <character>. The name can not end with characters: <character>	The <imageDefinitionName> name ends with a period or underscore.	Choose a name for the image definition that meets the following conditions: <ul style="list-style-type: none"> <li>Has an 80-character limit</li> <li>Contains only English letters, numbers, underscores, hyphens and periods</li> <li>Starts and ends with English letters or numbers</li> </ul>
The entity name <imageDefinitionName> is invalid according to its validation rule: ^[^\W][\w-_]{0,79}(?![.-])\$^*	The <imageDefinitionName> name ends with a period or underscore.	Choose a name for the image definition that meets the following conditions: <ul style="list-style-type: none"> <li>Has an 80-character limit</li> <li>Contains only English letters, numbers, underscores, hyphens, and periods</li> <li>Starts and ends with English letters or numbers</li> </ul>
Asset name galleryImage.properties.identifier. <property> is not valid. It cannot be empty. Allowed characters are uppercase or lowercase letters, digits, hyphen(-), period (), underscore (_). Names are not allowed to end with period(.). The length of the name cannot exceed <number> characters.	The publisher, offer, or SKU value does not meet the naming requirements.	Choose a value that meets the following conditions: <ul style="list-style-type: none"> <li>Has a 128-character limit for publisher or 64-character limit for offer and SKU</li> <li>Contains only English letters, numbers, hyphens, underscores, and periods</li> <li>Does not end with a period</li> </ul>
Can not perform requested operation on nested resource. Parent resource <galleryName> not found.	There is no gallery with the name <galleryName> in the current subscription and resource group.	Check that the names of the gallery, subscription, and resource group are correct. Otherwise, create a new gallery named <galleryName>
The provided location <region> is not available for resource type 'Microsoft.Compute/galleries'. List of available regions for the resource type is ...	The <region> name is incorrect or requires an access request.	Check that the region name is spelled correctly. You can run this command to see what regions you have access to. If the region is not in the list, submit <a href="#">an access request</a> .

ERROR MESSAGE	CAUSE	MITIGATION
Unable to serialize value: <value> as type: 'iso-8601', ISO8601Error: ISO 8601 time designator 'T' missing. Unable to parse datetime string <value>	The value provided to the property is not properly formatted as a date.	Provide a date in the yyyy-MM-dd, yyyy-MM-dd'T'HH:mm:sszzz, or <a href="#">ISO 8601</a> -valid format.
Could not convert string to DateTimeOffset: <value>. Path 'properties.<property>'	The value provided to the property is not properly formatted as a date.	Provide a date in the yyyy-MM-dd, yyyy-MM-dd'T'HH:mm:sszzz, or <a href="#">ISO 8601</a> -valid format
EndOfLifeDate must be set to a future date.	The end-of-life date property is not properly formatted as a date that's after today's date.	Provide a date in the yyyy-MM-dd, yyyy-MM-dd'T'HH:mm:sszzz, or <a href="#">ISO 8601</a> -valid format
<i>argument --&lt;property&gt;: invalid int value: &lt;value&gt;</i>	<property> accepts only integer values, and <value> is not an integer.	Choose an integer value.
The minimum value of <property> must not be greater than the maximum value of <property>.	The minimum value provided for <property> is higher than the maximum value provided for <property>.	Change the values so that the minimum is less than or equal to the maximum.
Gallery image: <imageDefinitionName> identified by (publisher:<Publisher>, offer:<Offer>, sku:<SKU>) already exists. Choose a different publisher, offer, sku combination.	You've tried to create a new image definition with the same publisher, offer, and SKU triplet as an existing image definition in the same gallery.	Within a gallery, all image definitions must have a unique combination of publisher, offer, and SKU. Choose a unique combination, or choose a new gallery and create the image definition again
Can not delete resource before nested resources are deleted.	You've tried to delete an image definition that contains image versions. An image definition must be empty before it can be deleted.	Delete all image versions inside the image definition and then proceed to delete the image definition
Cannot bind parameter <property>. Cannot convert value <value> to type <propertyType>. Unable to match the identifier name <value> to a valid enumerator name. Specify one of the following enumerator names and try again: <choice_1>, <choice_2>, ...	The property has a restricted list of possible values, and <value> is not one of them	Choose one of the possible <choice> values
Cannot bind parameter <property>. Cannot convert value <value> to type "System.DateTime"	The value provided to the property is not properly formatted as a date.	Provide a date in the yyyy-MM-dd, yyyy-MM-dd'T'HH:mm:sszzz, or <a href="#">ISO 8601</a> -valid format
Cannot bind parameter <property>. Cannot convert value <value> to type "System.Int32"	<property> accepts only integer values, and <value> is not an integer.	Choose an integer value
ZRS storage account type is not supported in this region.	You've chosen standard zone-redundant storage (ZRS) in a region that does not yet support it	Change the storage account type to <a href="#">Premium_LRS</a> or <a href="#">Standard_LRS</a> . Check our documentation for the latest <a href="#">list of regions</a> with ZRS preview enabled

## Creating or updating image versions

The source id: <resourceID> must either be a managed image, virtual machine or another gallery image version	The <resourceID> value is incorrectly formatted	If you're using a VM, managed image, or gallery image version as the source image, check that the resource ID of the VM, managed image, or gallery image version is correct
The source id: <resourceID> must be a managed disk or snapshot	The <resourceID> value is incorrectly formatted	If you're using disks and/or disk snapshots as sources for the image version, check that the resource IDs of the disks and/or disk snapshots are correct
Cannot create Gallery Image Version from: <resourceID> since the OS State in the parent gallery image (<OsState_1>) is not <OsState_2>	The operating system state (Generalized or Specialized) does not match the operating system state specified in the image definition	Either choose a source based on a VM with the operating system state of <OsState_1> or create a new image definition for VMs based on <OsState_2>
The resource with id '<resourceID>' has a different Hypervisor generation ['<V#_1>'] than the parent gallery image Hypervisor generation ['<V#_2>']	The hypervisor generation of the image version does not match the hypervisor generation specified in the image definition. The image definition operating system is <V#_1>, and the image version operating system is <V#_2>	Either choose a source with the same hypervisor generation as the image definition or create/choose a new image definition that has the same hypervisor generation as the image version
The resource with id '<resourceID>' has a different OS type ['<OsType_1>'] than the parent gallery image OS type generation ['<OsType_2>']	The hypervisor generation of the image version does not match the hypervisor generation specified in the image definition. The image definition operating system is <OsType_1>, and the image version operating system is <OsType_2>	Either choose a source with the same operating system (Linux/Windows) as the image definition or create/choose a new image definition that has the same operating system generation as the image version
Source virtual machine <resourceID> cannot contain an ephemeral OS disk	The source at <resourceID> contains an ephemeral OS disk. The Azure Compute Gallery does not currently support ephemeral OS disks	Choose a different source based on a VM that does not use an ephemeral OS disk
Source virtual machine <resourceID> cannot contain disk ['<diskID>'] stored in an UltraSSD account type	The disk <diskID> is an Ultra SSD disk. The Azure Compute Gallery does not currently support Ultra SSD disks	Use a source that contains only Premium SSD, Standard SSD, and/or Standard HDD managed disks
Source virtual machine <resourceID> must be created from Managed Disks	The virtual machine in <resourceID> uses unmanaged disks	Use a source based on a VM that contains only Premium SSD, Standard SSD, and/or Standard HDD managed disks

ERROR MESSAGE	CAUSE	MITIGATION
Too many requests on source '<resourceID>'. Please reduce the number of requests on the source or wait some time before retrying	The source for this image version is currently being throttled because of too many requests	Try to create the image version later
The disk encryption set '<diskEncryptionSetID>' must be in the same subscription '<subscriptionID>' as the gallery resource	Disk encryption sets can be used only in the same subscription and region in which they were created	Create or use an encryption set in the same subscription and region as the image version
Encrypted source: '<resourceID>' is in a different subscription ID than the current gallery image version subscription '<subscriptionID_1>'. Please retry with an unencrypted source(s) or use the source's subscription '<subscriptionID_2>' to create the gallery image version	The Azure Compute Gallery does not currently support creating image versions in another subscription from another source image if the source image is encrypted	Use an unencrypted source or create the image version in the same subscription as the source
The disk encryption set <diskEncryptionSetID> was not found	The disk encryption might be incorrect	Check that the resource ID of the disk encryption set is correct
The image version name is invalid. The image version name should follow Major(int).Minor(int).Patch(int) format, for e.g: 1.0.0, 2018.12.1 etc	The valid format for an image version is three integers separated by a period. The image version name did not meet the valid format	Use an image version name that follows the format Major(int).Minor(int).Patch(int). For example: 1.0.0. or 2018.12.1
The value of parameter galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.dataDiskImages.diskEncryptionSetId is invalid	The resource ID of the disk encryption set used on a data disk image uses an invalid format	Ensure that the resource ID of the disk encryption set follows the format /subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/<diskEncryptionSetName>
The value of parameter galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.osDiskImage.diskEncryptionSetId is invalid	The resource ID of the disk encryption set used on the OS disk image uses an invalid format	Ensure that the resource ID of the disk encryption set follows the format /subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/<diskEncryptionSetName>
Cannot specify new data disk image encryption lun [<number>] with a disk encryption set in region [<region>] for update gallery image version request. To update this version, remove the new lun. If you need to change the data disk image encryption settings, you must create a new gallery image version with the correct settings.	You added encryption to the data disk of an existing image version. You can't add encryption to an existing image version	Create a new gallery image version or remove the added encryption settings
The gallery artifact version source can only be specified either directly under storageProfile or within individual OS or data disks. One and only one source type (user image, snapshot, disk, virtual machine) can be provided	The source ID is missing	Ensure that the source ID of the source is present

ERROR MESSAGE	CAUSE	MITIGATION
Source was not found: <resourceID>. Please make sure the source exists	The resource ID of the source might be incorrect	Ensure that the resource ID of the source is correct
A disk encryption set is required for disk 'galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.osDiskImage.diskEncryptionSetId' in target region '<region_1>' since disk encryption set '<diskEncryptionSetID>' is used for the corresponding disk in region '<region_2>'	Encryption has been used on the OS disk in <region_2>, but not in <region_1>	If you're using encryption on the OS disk, use encryption in all regions
A disk encryption set is required for disk 'LUN <number>' in target region '<region_1>' since disk encryption set '<diskEncryptionSetID>' is used for the corresponding disk in region '<region_2>'	Encryption has been used on the data disk at LUN <number> in <region_2>, but not in <region_1>	If you're using encryption on a data disk, use encryption in all regions
An invalid lun [<number>] was specified in encryption.dataDiskImages. The lun must be one of the following values ['0,9']	The LUN specified for the encryption does not match any of the LUNs for disks attached to the VM	Change the LUN in the encryption to the LUN of a data disk present in the VM
Duplicate luns '<number>' were specified in target region '<region>' encryption.dataDiskImages	The encryption settings used in <region> specified a LUN at least twice	Change the LUN in <region> to make sure that all the LUNs are unique in <region>
OSDiskImage and DataDiskImage cannot point to same blob <sourceID>	The sources for the OS disk and at least one data disk are not unique	Change the source for the OS disk and/or data disks to ensure that the OS disk as well as each data disk is unique
Duplicate regions are not allowed in target publishing regions	A region is listed among the publishing regions more than once	Remove the duplicate region
Adding new Data Disks or changing the LUN of a Data Disk in an existing Image is not allowed	An update call to the image version either contains a new data disk or has a new LUN for a disk	Use the LUNs and data disks of the existing image version
The disk encryption set <diskEncryptionSetID> must be in the same subscription <subscriptionID> as the gallery resource	The Azure Compute Gallery does not currently support using a disk encryption set in a different subscription	Create the image version and disk encryption set in the same subscription
Replication failed in this region due to 'The GalleryImageVersion source resource size 2048 exceeds the max size 1024 supported	A data disk in the source is greater than 1TB	Resize the data disk to under 1 TB

ERROR MESSAGE	CAUSE	MITIGATION
Operation 'Update Gallery Image Version' is not allowed on <versionNumber>; since it is marked for deletion. You can only retry the Delete operation (or wait for an ongoing one to complete)	You attempted to update a gallery image version that is in the process of being deleted	Wait for the deletion event to complete and recreate the image version again
Encryption is not supported for source resource '<sourceID>'. Please use a different source resource type which supports encryption or remove encryption properties	Currently the Azure Compute Gallery only supports encryption for VMs, disks, snapshots and managed images. One of the sources provided for the image version is not in the previous list of sources that support encryption	Remove the disk encryption set from the image version and contact the support team.

## Creating or updating a VM or scale sets from an image version

ERROR MESSAGE	CAUSE	MITIGATION
There is no latest image version exists for "<imageDefinitionResourceId>"	The image definition you used to deploy the virtual machine does not contain any image versions that are included in latest	Ensure that there is at least one image version that has 'Exclude from latest' set to False
The gallery image /subscriptions/<subscriptionID>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageName>/versions/<versionNumber> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region.	The version selected for deployment does not exist or does not have a replica in the indicated region	Ensure that the name of the image resource is correct and that there is at least one replica in the indicated region
The gallery image /subscriptions/<subscriptionID>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageName> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region	The image definition selected for deployment does not have any image versions that are included in latest and also in the indicated region	Ensure that there is at least one image version in the region that has 'Exclude from latest' set to False
The client has permission to perform action 'Microsoft.Compute/galleries/images/versions/read' on scope <resourceID>, however the current tenant <tenantID> is not authorized to access linked subscription <subscriptionID>	The virtual machine or scale set was created through a gallery image in another tenant. You've tried to make a change to the virtual machine or scale set, but you don't have access to the subscription that owns the image	Contact the owner of the subscription of the image version to grant read access to the image version

ERROR MESSAGE	CAUSE	MITIGATION
The gallery image <resourceID> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region.	The VM is being created in a region that's not among the list of published regions for the gallery image.	Either replicate the image to the region or create a VM in one of the regions in the gallery image's publishing regions
Parameter 'osProfile' is not allowed	Admin username, password, or SSH keys were provided for a VM that was created from a specialized image version	Don't include the admin username, password, or SSH keys if you intend to create a VM from that image. Otherwise, use a generalized image version and supply the admin username, password, or SSH keys
Required parameter 'osProfile' is missing (null)	The VM is created from a generalized image, and it's missing the admin username, password, or SSH keys. Because generalized images don't retain the admin username, password, or SSH keys, these fields must be specified during creation of a VM or scale set	Specify the admin username, password, or SSH keys, or use a specialized image version
Cannot update Virtual Machine Scale Set <vmssName> as the current OS state of the VM Scale Set is Generalized which is different from the updated gallery image OS state which is Specialized	The current source image for the scale set is a generalized source image, but it's being updated with a source image that is specialized. The current source image and the new source image for a scale set must be of the same state	To update the scale set, use a generalized image version
Disk encryption set <diskEncryptionSetID> in Azure Compute Gallery <versionID> belongs to subscription <subscriptionID_1> and cannot be used with resource " in subscription <subscriptionID_2>	The disk encryption set used to encrypt the image version resides in a different subscription than the subscription to host the image version	Use the same subscription for the image version and disk encryption set
The resource with id <vmID> has a different plan [{"name": " <name>","publisher": " <publisher>","product": " <product>","promotionCode": " <promotionCode>"}] than the parent gallery image plan [null]	The parent image definition for the image version being deployed does not have a purchase plan information	Create an image definition with the same purchase plan details from the error message and create the image version within the image definition
The VM or virtual machine scale set creation takes a long time	NA	Verify that the <b>OSType</b> of the image version that you're trying to create the VM or virtual machine scale set from has the same <b>OSType</b> of the source that you used to create the image version

## Creating a disk from an image version

ERROR MESSAGE	CAUSE	MITIGATION
The value of parameter imageReference is invalid.	You've tried to export from a gallery Image version to a disk but used a LUN position that does not exist on the image.	Check the image version to see what LUN positions are in use

## Sharing resources

The sharing of gallery, image definition, and image version resources across subscriptions is enabled using [Azure role-based access control \(Azure RBAC\)](#).

## Replication speed

Use the `--expand ReplicationStatus` flag to check if the replication to all the specified target regions has finished. If not, wait for up to six hours for the job to finish. If it fails, trigger the command again to create and replicate the image version. If there are many target regions that the image version is being replicated to, consider doing the replication in phases.

## Azure limits and quotas

[Azure limits and quotas](#) apply to all Azure Compute Gallery, image definition, and image version resources. Make sure you're within the limits for your subscriptions.

# Use customer-managed keys for encrypting images

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Images in an Azure Compute Gallery (formerly known as Shared Image Gallery) are stored as snapshots, so they're automatically encrypted through server-side encryption. Server-side encryption uses 256-bit [AES encryption](#), one of the strongest block ciphers available. Server-side encryption is also FIPS 140-2 compliant. For more information about the cryptographic modules underlying Azure managed disks, see [Cryptography API: Next Generation](#).

You can rely on platform-managed keys for the encryption of your images, or use your own keys. You can also use both together, for double encryption. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all disks in your images.

Server-side encryption through customer-managed keys uses Azure Key Vault. You can either import [your RSA keys](#) to your key vault or generate new RSA keys in Azure Key Vault.

## Prerequisites

This article requires you to already have a disk encryption set in each region where you want to replicate your image:

- To use only a customer-managed key, see the articles about enabling customer-managed keys with server-side encryption by using the [Azure portal](#) or [PowerShell](#).
- To use both platform-managed and customer-managed keys (for double encryption), see the articles about enabling double encryption at rest by using the [Azure portal](#) or [PowerShell](#).

### IMPORTANT

You must use the link <https://aka.ms/diskencryptionupdates> to access the Azure portal. Double encryption at rest is not currently visible in the public Azure portal unless you use that link.

## Limitations

When you're using customer-managed keys for encrypting images in an Azure Compute Gallery, these limitations apply:

- Encryption key sets must be in the same subscription as your image.
- Encryption key sets are regional resources, so each region requires a different encryption key set.
- You can't copy or share images that use customer-managed keys.
- After you've used your own keys to encrypt a disk or image, you can't go back to using platform-managed keys for encrypting those disks or images.

## PowerShell

To specify a disk encryption set for an image version, use `New-AzGalleryImageVersion` with the `-TargetRegion` parameter:

```

```

## Create a VM

You can create a virtual machine (VM) from an Azure Compute Gallery and use customer-managed keys to encrypt the disks. The syntax is the same as creating a [generalized](#) or [specialized](#) VM from an image. Use the extended parameter set and add

```
Set-AzVMOSDisk -Name $($vmName +"_OSDisk") -DiskEncryptionSetId $diskEncryptionSet.Id -CreateOption FromImage
```

to the VM configuration.

For data disks, add the `-DiskEncryptionSetId $setID` parameter when you use [Add-AzVMDataDisk](#).

## CLI

To specify a disk encryption set for an image version, use [az image gallery create-image-version](#) with the `--target-region-encryption` parameter. The format for `--target-region-encryption` is a comma-separated list of keys for encrypting the OS and data disks. It should look like this:

```
<encryption set for the OS disk>,<Lun number of the data disk>,<encryption set for the data disk>,<Lun number for the second data disk>,<encryption set for the second data disk>
```

If the source for the OS disk is a managed disk or a VM, use `--managed-image` to specify the source for the image version. In this example, the source is a managed image that has an OS disk and a data disk at LUN 0. The OS disk will be encrypted with DiskEncryptionSet1, and the data disk will be encrypted with DiskEncryptionSet2.

```
az sig image-version create \
-g MyResourceGroup \
--gallery-image-version 1.0.0 \
--location westus \
--target-regions westus=2=standard_lrs eastus2 \
--target-region-encryption WestUSDiskEncryptionSet1,0,WestUSDiskEncryptionSet2
EastUS2DiskEncryptionSet1,0,EastUS2DiskEncryptionSet2 \
--gallery-name MyGallery \
--gallery-image-definition MyImage \
--managed-image "/subscriptions/<subscription
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/images/myImage"
```

If the source for the OS disk is a snapshot, use `--os-snapshot` to specify the OS disk. If there are data disk snapshots that should also be part of the image version, add those. Use `--data-snapshot-luns` to specify the LUN, and use `--data-snapshots` to specify the snapshots.

In this example, the sources are disk snapshots. There's an OS disk and a data disk at LUN 0. The OS disk will be encrypted with DiskEncryptionSet1, and the data disk will be encrypted with DiskEncryptionSet2.

```
az sig image-version create \
-g MyResourceGroup \
--gallery-image-version 1.0.0 \
--location westus \
--target-regions westus=2=standard_lrs eastus \
--target-region-encryption WestUSDiskEncryptionSet1,0,WestUSDiskEncryptionSet2
EastUS2DiskEncryptionSet1,0,EastUS2DiskEncryptionSet2 \
--os-snapshot "/subscriptions/<subscription
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/snapshots/myOSSnapshot" \
--data-snapshot-luns 0 \
--data-snapshots "/subscriptions/<subscription
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/snapshots/myDDSnapshot" \
--gallery-name MyGallery \
--gallery-image-definition MyImage
```

## Create the VM

You can create a VM from an Azure Compute Gallery and use customer-managed keys to encrypt the disks. The syntax is the same as creating a [generalized](#) or [specialized](#) VM from an image. Just add the `--os-disk-encryption-set` parameter with the ID of the encryption set. For data disks, add `--data-disk-encryption-sets` with a space-delimited list of the disk encryption sets for the data disks.

## Portal

When you create your image version in the portal, you can use the **Encryption** tab to apply your storage encryption sets.

1. On the [Create an image version](#) page, select the **Encryption** tab.
2. In **Encryption type**, select **Encryption at-rest with a customer-managed key** or **Double encryption with platform-managed and customer-managed keys**.
3. For each disk in the image, select an encryption set from the **Disk encryption set** drop-down list.

## Create the VM

You can create a VM from an image version and use customer-managed keys to encrypt the disks. When you create the VM in the portal, on the **Disks** tab, select **Encryption at-rest with customer-managed keys** or **Double encryption with platform-managed and customer-managed keys** for **Encryption type**. You can then select the encryption set from the drop-down list.

## Next steps

Learn more about [server-side disk encryption](#).

For information about how to supply purchase plan information, see [Supply Azure Marketplace purchase plan information when creating images](#).

# Export an image version to a managed disk

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can export the OS or a single data disk from an image version as a managed disk from an image version stored in an Azure Compute Gallery (formerly known as Shared Image Gallery).

## CLI

List the image versions in a gallery using [az sig image-version list](#). In this example, we are looking for all of the image versions that are part of the *myImageDefinition* image definition in the *myGallery* gallery.

```
az sig image-version list \
--resource-group myResourceGroup\
--gallery-name myGallery \
--gallery-image-definition myImageDefinition \
-o table
```

Set the `source` variable to the ID of the image version, then use [az disk create](#) to create the managed disk.

In this example, we export the OS disk of the image version to create a managed disk named *myManagedOSDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

```
source="/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<galleryImageDefinition>/versions/<imageVersion>"  
  
az disk create --resource-group myResourceGroup --location EastUS --name myManagedOSDisk --gallery-image-reference $source
```

If you want to export a data disk from the image version, add `--gallery-image-reference-lun` to specify the LUN location of the data disk to export.

In this example, we export the data disk located at LUN 0 of the image version to create a managed disk named *myManagedDataDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

```
source="/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<galleryImageDefinition>/versions/<imageVersion>"  
  
az disk create --resource-group myResourceGroup --location EastUS --name myManagedDataDisk --gallery-image-reference $source --gallery-image-reference-lun 0
```

## PowerShell

List the image versions in a gallery using [Get-AzResource](#).

```
Get-AzResource `
-ResourceType Microsoft.Compute/galleries/images/versions | `
Format-Table -Property Name,ResourceId,ResourceGroupName
```

Once you have all of the information you need, you can use [Get-AzGalleryImageVersion](#) to get the source image

version you want to use and assign it to a variable. In this example, we are getting the `1.0.0` image version, of the `myImageDefinition` definition, in the `myGallery` source gallery, in the `myResourceGroup` resource group.

```
$sourceImgVer = Get-AzGalleryImageVersion `  
    -GalleryImageDefinitionName myImageDefinition `  
    -GalleryName myGallery `  
    -ResourceGroupName myResourceGroup `  
    -Name 1.0.0
```

After setting the `source` variable to the ID of the image version, use [New-AzDiskConfig](#) to create a disk configuration and [New-AzDisk](#) to create the disk.

In this example, we export the OS disk of the image version to create a managed disk named `myManagedOSDisk`, in the `EastUS` region, in a resource group named `myResourceGroup`.

Create a disk configuration.

```
$diskConfig = New-AzDiskConfig `  
    -Location EastUS `  
    -CreateOption FromImage `  
    -GalleryImageReference @{Id = $sourceImgVer.Id}
```

Create the disk.

```
New-AzDisk -Disk $diskConfig `  
    -ResourceGroupName myResourceGroup `  
    -DiskName myManagedOSDisk
```

If you want to export a data disk on the image version, add a LUN ID to the disk configuration to specify the LUN location of the data disk to export.

In this example, we export the data disk located at LUN 0 of the image version to create a managed disk named `myManagedDataDisk`, in the `EastUS` region, in a resource group named `myResourceGroup`.

Create a disk configuration.

```
$diskConfig = New-AzDiskConfig `  
    -Location EastUS `  
    -CreateOption FromImage `  
    -GalleryImageReference @{Id = $sourceImgVer.Id; Lun=0}
```

Create the disk.

```
New-AzDisk -Disk $diskConfig `  
    -ResourceGroupName myResourceGroup `  
    -DiskName myManagedDataDisk
```

## Next steps

You can also create an [image version](#) from a managed disk.

# Supply Azure Marketplace purchase plan information when creating images

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

If you are creating an image in a shared gallery, using a source that was originally created from an Azure Marketplace image, you may need to keep track of purchase plan information. This article shows how to find purchase plan information for a VM, then use that information when creating an image definition. We also cover using the information from the image definition to simplify supplying the purchase plan information when creating a VM for an image.

For more information about finding and using Marketplace images, see [Find and use Azure Marketplace images](#).

## Get the source VM information

If you still have the original VM, you can get the plan name, publisher, and product information from it using `Get-AzVM`. This example gets a VM named `myVM` in the `myResourceGroup` resource group and then displays the purchase plan information for the VM.

```
$vm = Get-AzVM `  
-ResourceGroupName myResourceGroup `  
-Name myVM  
$vm.Plan
```

## Create the image definition

Get the gallery you want to use to store the image. You can list all of the galleries first.

```
Get-AzResource -ResourceType Microsoft.Compute/galleries | Format-Table
```

Then create variables for the gallery you want to use. In this example, we are creating a variable named `$gallery` for `myGallery` in the `myGalleryRG` resource group.

```
$gallery = Get-AzGallery `  
-Name myGallery `  
-ResourceGroupName myGalleryRG
```

Create the image definition, using the `-PurchasePlanPublisher`, `-PurchasePlanProduct`, and `-PurchasePlanName` parameters.

```
$imageDefinition = New-AzGalleryImageDefinition `  
    -GalleryName $gallery.Name `  
    -ResourceGroupName $gallery.ResourceGroupName `  
    -Location $gallery.Location `  
    -Name 'myImageDefinition' `  
    -OsState specialized `  
    -OsType Linux `  
    -Publisher 'myPublisher' `  
    -Offer 'myOffer' `  
    -Sku 'mySKU' `  
    -PurchasePlanPublisher $vm.Plan.Publisher `  
    -PurchasePlanProduct $vm.Plan.Product `  
    -PurchasePlanName $vm.Plan.Name
```

Then create your [image version](#) using [New-AzGalleryImageVersion](#).

## Create the VM

When you go to create a VM from the image, you can use the information from the image definition to pass in the publisher information using [Set-AzVMPlan](#).

```

# Create some variables for the new VM.
$resourceGroup = "mySIGPubVM"
$location = "West Central US"
$vmName = "mySIGPubVM"

# Create a resource group
New-AzResourceGroup -Name $resourceGroup -Location $location

# Create the network resources.
$subnetConfig = New-AzVirtualNetworkSubnetConfig `

    -Name mySubnet `

    -AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork `

    -ResourceGroupName $resourceGroup `

    -Location $location `

    -Name MYvNET `

    -AddressPrefix 192.168.0.0/16 `

    -Subnet $subnetConfig
$pip = New-AzPublicIpAddress `

    -ResourceGroupName $resourceGroup `

    -Location $location `

    -Name "mynpublicdns$(Get-Random)" `

    -AllocationMethod Static `

    -IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig `

    -Name myNetworkSecurityGroupRuleRDP `

    -Protocol Tcp `

    -Direction Inbound `

    -Priority 1000 `

    -SourceAddressPrefix * `

    -SourcePortRange * `

    -DestinationAddressPrefix * `

    -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup `

    -ResourceGroupName $resourceGroup `

    -Location $location `

    -Name myNetworkSecurityGroup `

    -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface `

    -Name $vmName `

    -ResourceGroupName $resourceGroup `

    -Location $location `

    -SubnetId $vnet.Subnets[0].Id `

    -PublicIpAddressId $pip.Id `

    -NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration using Set-AzVMSourceImage -Id $imageDefinition.Id to use the latest
available image version. Set-AZVMPlan is used to pass the plan information in for the VM.

$vmConfig = New-AzVMConfig `

    -VMName $vmName `

    -VMSize Standard_D1_v2 | `

Set-AzVMSourceImage -Id $imageDefinition.Id | `

Set-AzVMPlan `

    -Publisher $imageDefinition.PurchasePlan.Publisher `

    -Product $imageDefinition.PurchasePlan.Product `

    -Name $imageDefinition.PurchasePlan.Name | `

Add-AzVMNetworkInterface -Id $nic.Id

# Create the virtual machine
New-AzVM `

    -ResourceGroupName $resourceGroup `

    -Location $location `

    -VM $vmConfig

```

## Next steps

For more information about finding and using Marketplace images, see [Find and use Azure Marketplace images](#).

# VM Applications overview

9/21/2022 • 14 minutes to read • [Edit Online](#)

VM Applications are a resource type in Azure Compute Gallery (formerly known as Shared Image Gallery) that simplifies management, sharing, and global distribution of applications for your virtual machines.

## IMPORTANT

Deploying VM applications in Azure Compute Gallery **do not currently support using Azure policies**.

While you can create an image of a VM with apps pre-installed, you would need to update your image each time you have application changes. Separating your application installation from your VM images means there's no need to publish a new image for every line of code change.

Application packages provide benefits over other deployment and packaging methods:

- Grouping and versioning of your packages
- VM applications can be globally replicated to be closer to your infrastructure, so you don't need to use AzCopy or other storage copy mechanisms to copy the bits across Azure regions.
- Sharing with other users through Azure Role Based Access Control (RBAC)
- Support for virtual machines, and both flexible and uniform scale sets
- If you have Network Security Group (NSG) rules applied on your VM or scale set, downloading the packages from an internet repository might not be possible. And with storage accounts, downloading packages onto locked-down VMs would require setting up private links.

## What are VM app packages?

The VM application packages use multiple resource types:

RESOURCE	DESCRIPTION
Azure compute gallery	A gallery is a repository for managing and sharing application packages. Users can share the gallery resource and all the child resources will be shared automatically. The gallery name must be unique per subscription. For example, you may have one gallery to store all your OS images and another gallery to store all your VM applications.
VM application	The definition of your VM application. It's a <i>logical</i> resource that stores the common metadata for all the versions under it. For example, you may have an application definition for Apache Tomcat and have multiple versions within it.
VM Application version	The deployable resource. You can globally replicate your VM application versions to target regions closer to your VM infrastructure. The VM Application Version must be replicated to a region before it may be deployed on a VM in that region.

## Limitations

- **No more than 3 replicas per region:** When creating a VM Application version, the maximum number of replicas per region is three.
- **Retrying failed installations:** Currently, the only way to retry a failed installation is to remove the application from the profile, then add it back.
- **Only 5 applications per VM:** No more than five applications may be deployed to a VM at any point.
- **1GB application size:** The maximum file size of an application version is 1 GB.
- **No guarantees on reboots in your script:** If your script requires a reboot, the recommendation is to place that application last during deployment. While the code attempts to handle reboots, it may fail.
- **Requires a VM Agent:** The VM agent must exist on the VM and be able to receive goal states.
- **Multiple versions of same application on the same VM:** You can't have multiple versions of the same application on a VM.
- **Move operations currently not supported:** Moving VMs with VM Apps to other resource groups are not supported at this time.

## Cost

There's no extra charge for using VM Application Packages, but you'll be charged for the following resources:

- Storage costs of storing each package and any replicas.
- Network egress charges for replication of the first image version from the source region to the replicated regions. Subsequent replicas are handled within the region, so there are no extra charges.

For more information on network egress, see [Bandwidth pricing](#).

## VM applications

The VM application resource defines the following about your VM application:

- Azure Compute Gallery where the VM application is stored
- Name of the application
- Supported OS type like Linux or Windows
- A description of the VM application

## VM application versions

VM application versions are the deployable resource. Versions are defined with the following properties:

- Version number
- Link to the application package file in a storage account
- Install string for installing the application
- Remove string to show how to properly remove the app
- Package file name to use when it's downloaded to the VM
- Configuration file name to be used to configure the app on the VM
- A link to the configuration file for the VM application, which you can include license files
- Update string for how to update the VM application to a newer version
- End-of-life date. End-of-life dates are informational; you'll still be able to deploy VM application versions past the end-of-life date.

- Exclude from latest. You can keep a version from being used as the latest version of the application.
- Target regions for replication
- Replica count per region

## Download directory

The download location of the application package and the configuration files are:

- Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<appname>/<app version>`
- Windows:
 

```
C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.4\Downloads\<appname>\<app version>
```

The install/update/remove commands should be written assuming the application package and the configuration file are in the current directory.

## File naming

When the application file gets downloaded to the VM, the file name is the same as the name you use when you create the VM application. For example, if I name my VM application `myApp`, the file that will be downloaded to the VM will also be named `myApp`, regardless of what the file name is used in the storage account. If your VM application also has a configuration file, that file is the name of the application with `_config` appended. If `myApp` has a configuration file, it will be named `myApp_config`.

For example, if I name my VM application `myApp` when I create it in the Gallery, but it's stored as `myApplication.exe` in the storage account, when it gets downloaded to the VM the file name will be `myApp`. My install string should start by renaming the file to be whatever it needs to be to run on the VM (like `myApp.exe`).

The install, update, and remove commands must be written with file naming in mind. The `configFileName` is assigned to the config file for the VM and `packageFileName` is the name assigned downloaded package on the VM. For more information regarding these additional VM settings, refer to [UserArtifactSettings](#) in our API docs.

## Command interpreter

The default command interpreters are:

- Linux: `/bin/sh`
- Windows: `cmd.exe`

It's possible to use a different interpreter like Chocolatey or PowerShell, as long as it's installed on the machine, by calling the executable and passing the command to it. For example, to have your command run in PowerShell on Windows instead of cmd, you can pass `powershell.exe -Command '<powershell command>'`

## How updates are handled

When you update an application version on a VM or VMSS, the update command you provided during deployment will be used. If the updated version doesn't have an update command, then the current version will be removed and the new version will be installed.

Update commands should be written with the expectation that it could be updating from any older version of the VM application.

## Tips for creating VM Applications on Linux

Third party applications for Linux can be packaged in a few ways. Let's explore how to handle creating the install

commands for some of the most common.

### .tar and .gz files

These are compressed archives and can be extracted to a desired location. Check the installation instructions for the original package to see if they need to be extracted to a specific location. If .tar.gz file contains source code, refer to the instructions for the package for how to install from source.

Example to install command to install `golang` on a Linux machine:

```
tar -C /usr/local -xzf go_linux
```

Example remove command:

```
rm -rf /usr/local/go
```

### .deb, .rpm, and other platform specific packages

You can download individual packages for platform specific package managers, but they usually don't contain all the dependencies. For these files, you must also include all dependencies in the application package, or have the system package manager download the dependencies through the repositories that are available to the VM. If you're working with a VM with restricted internet access, you must package all the dependencies yourself.

Figuring out the dependencies can be a bit tricky. There are third party tools that can show you the entire dependency tree.

On Ubuntu, you can run `apt-get install <name> --simulate` to show all the packages that will be installed for the `apt-get install <name>` command. Then you can use that output to download all .deb files to create an archive that can be used as the application package. The downside to this method is that it doesn't show the dependencies that are already installed on the VM.

Example, to create a VM application package to install PowerShell for Ubuntu, run the command

`apt-get install powershell --simulate` on a new Ubuntu VM. Check the output of the line **The following NEW packages will be installed** which lists the following packages:

- `liblttng-ust-ctl14`
- `liblttng-ust0`
- `liburcu6`
- `powershell`.

Download these files using `apt-get download` and create a tar archive with all files at the root level. This tar archive will be the application package file. The install command in this case is:

```
tar -xf powershell && dpkg -i ./liblttng-ust-ctl14_2.10.1-1_amd64.deb ./liburcu6_0.10.1-1ubuntu1_amd64.deb  
./liblttng-ust0_2.10.1-1_amd64.deb ./powershell_7.1.2-1.ubuntu.18.04_amd64.deb
```

And the remove command is:

```
dpkg -r powershell && apt autoremove
```

Use `apt autoremove` instead of explicitly trying to remove all the dependencies. You may have installed other applications with overlapping dependencies, and in that case, an explicit remove command would fail.

In case you don't want to resolve the dependencies yourself and apt/rpm is able to connect to the repositories, you can install an application with just one .deb/.rpm file and let apt/rpm handle the dependencies.

Example install command:

```
dpkg -i <appname> || apt --fix-broken install -y
```

## Tips for creating VM Applications on Windows

Most third party applications in Windows are available as .exe or .msi installers. Some are also available as extract and run zip files. Let us look at the best practices for each of them.

### .exe installer

Installer executables typically launch a user interface (UI) and require someone to select through the UI. If the installer supports a silent mode parameter, it should be included in your installation string.

Cmd.exe also expects executable files to have the extension .exe, so you need to rename the file to have the .exe extension.

If I wanted to create a VM application package for myApp.exe, which ships as an executable, my VM Application is called 'myApp', so I write the command assuming that the application package is in the current directory:

```
"move .\\myApp .\\myApp.exe & myApp.exe /S -config myApp_config"
```

If the installer executable file doesn't support an uninstall parameter, you can sometimes look up the registry on a test machine to know here the uninstaller is located.

In the registry, the uninstall string is stored in

```
Computer\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\<installed application name>\UninstallString
```

so I would use the contents as my remove command:

```
'\"C:\\Program Files\\myApp\\uninstall\\helper.exe\" /S'
```

### .msi installer

For command line execution of .msi installers, the commands to install or remove an application should use msieexec. Typically, msieexec runs as its own separate process and cmd doesn't wait for it to complete, which can lead to problems when installing more than one VM application. The start command can be used with msieexec to ensure that the installation completes before the command returns. For example:

```
start /wait %windir%\system32\msieexec.exe /i myapp /quiet /forcerestart /log myapp_install.log
```

Example remove command:

```
start /wait %windir%\system32\msieexec.exe /x $appname /quiet /forcerestart /log ${appname}_uninstall.log
```

### Zipped files

For .zip or other zipped files, rename and unzip the contents of the application package to the desired destination.

Example install command:

```
rename myapp myapp.zip && mkdir C:\\myapp && powershell.exe -Command "Expand-Archive -path myapp.zip -destinationpath C:\\myapp"
```

Example remove command:

```
rmdir /S /Q C:\\myapp
```

## Treat failure as deployment failure

The VM application extension always returns a *success* regardless of whether any VM app failed while being installed/updated/removed. The VM Application extension will only report the extension status as failure when there's a problem with the extension or the underlying infrastructure. This is triggered by the "treat failure as deployment failure" flag which is set to `$false` by default and can be changed to `$true`. The failure flag can be configured in [PowerShell](#) or [CLI](#).

## Troubleshooting VM Applications

To know whether a particular VM application was successfully added to the VM instance, check the message of the VM Application extension.

To learn more about getting the status of VM extensions, see [Virtual machine extensions and features for Linux](#) and [Virtual machine extensions and features for Windows](#).

To get status of VM extensions, use [Get-AzVM](#):

```
Get-AzVM -name <VM name> -ResourceGroupName <resource group name> -Status | convertto-json -Depth 10
```

To get status of scale set extensions, use [Get-AzVMSS](#):

```
$result = Get-AzVmssVM -ResourceGroupName $rgName -VMScaleSetName $vmssName -InstanceView
$resultSummary = New-Object System.Collections.ArrayList
$result | ForEach-Object {
    $res = @{
        instanceId = $_.InstanceId;
        vmappStatus = $_.InstanceView.Extensions | Where-Object {$_._Name -eq "VMAppExtension"}
    }
    $resultSummary.Add($res) | Out-Null
}
$resultSummary | convertto-json -depth 5
```

## Error messages

MESSAGE	DESCRIPTION
Current VM Application Version {name} was deprecated at {date}.	You tried to deploy a VM Application version that has already been deprecated. Try using <code>latest</code> instead of specifying a specific version.
Current VM Application Version {name} supports OS {OS}, while current OSDisk's OS is {OS}.	You tried to deploy a Linux application to Windows instance or vice versa.
The maximum number of VM applications (max=5, current={count}) has been exceeded. Use fewer applications and retry the request.	We currently only support five VM applications per VM or scale set.
More than one VM Application was specified with the same packageReferenceld.	The same application was specified more than once.

MESSAGE	DESCRIPTION
Subscription not authorized to access this image.	The subscription doesn't have access to this application version.
Storage account in the arguments doesn't exist.	There are no applications for this subscription.
The platform image {image} isn't available. Verify that all fields in the storage profile are correct. For more details about storage profile information, please refer to <a href="https://aka.ms/storageprofile">https://aka.ms/storageprofile</a> .	The application doesn't exist.
The gallery image {image} is not available in {region} region. Please contact image owner to replicate to this region, or change your requested region.	The gallery application version exists, but it was not replicated to this region.
The SAS is not valid for source uri {uri}.	A <code>Forbidden</code> error was received from storage when attempting to retrieve information about the url (either mediaLink or defaultConfigurationLink).
The blob referenced by source uri {uri} doesn't exist.	The blob provided for the mediaLink or defaultConfigurationLink properties doesn't exist.
The gallery application version url {url} cannot be accessed due to the following error: remote name not found. Ensure that the blob exists and that it's either publicly accessible or is a SAS url with read privileges.	The most likely case is that a SAS uri with read privileges was not provided.
The gallery application version url {url} cannot be accessed due to the following error: {error description}. Ensure that the blob exists and that it's either publicly accessible or is a SAS url with read privileges.	There was an issue with the storage blob provided. The error description will provide more information.
Operation {operationName} is not allowed on {application} since it is marked for deletion. You can only retry the Delete operation (or wait for an ongoing one to complete).	Attempt to update an application that's currently being deleted.
The value {value} of parameter 'galleryApplicationVersion.properties.publishingProfile.replicaCount' is out of range. The value must be between 1 and 3, inclusive.	Only between 1 and 3 replicas are allowed for VM Application versions.
Changing property 'galleryApplicationVersion.properties.publishingProfile.manageActions.install' is not allowed. (or update, delete)	It is not possible to change any of the manage actions on an existing VmApplication. A new VmApplication version must be created.
Changing property 'galleryApplicationVersion.properties.publishingProfile.settings.packageFileName' is not allowed. (or configFileName)	It is not possible to change any of the settings, such as the package file name or config file name. A new VmApplication version must be created.
The blob referenced by source uri {uri} is too big: size = {size}. The maximum blob size allowed is '1 GB'.	The maximum size for a blob referred to by mediaLink or defaultConfigurationLink is currently 1 GB.
The blob referenced by source uri {uri} is empty.	An empty blob was referenced.
{type} blob type is not supported for {operation} operation. Only page blobs and block blobs are supported.	VmApplications only supports page blobs and block blobs.

MESSAGE	DESCRIPTION
The SAS is not valid for source uri {uri}.	The SAS uri supplied for mediaLink or defaultConfigurationLink is not a valid SAS uri.
Cannot specify {region} in target regions because the subscription is missing required feature {featureName}. Either register your subscription with the required feature or remove the region from the target region list.	To use VmApplications in certain restricted regions, one must have the feature flag registered for that subscription.
Gallery image version publishing profile regions {regions} must contain the location of image version {location}.	The list of regions for replication must contain the location where the application version is.
Duplicate regions are not allowed in target publishing regions.	The publishing regions may not have duplicates.
Gallery application version resources currently do not support encryption.	The encryption property for target regions is not supported for VM Applications
Entity name doesn't match the name in the request URL.	The gallery application version specified in the request url doesn't match the one specified in the request body.
The gallery application version name is invalid. The application version name should follow Major(int32).Minor(int32).Patch(int32) format, where int is between 0 and 2,147,483,647 (inclusive). e.g. 1.0.0, 2018.12.1 etc.	The gallery application version must follow the format specified.

- Learn how to [create and deploy VM application packages](#).

# Create and deploy VM Applications

9/21/2022 • 12 minutes to read • [Edit Online](#)

VM Applications are a resource type in Azure Compute Gallery (formerly known as Shared Image Gallery) that simplifies management, sharing and global distribution of applications for your virtual machines.

## IMPORTANT

Deploying VM applications in Azure Compute Gallery **do not currently support using Azure policies**.

## Prerequisites

Before you get started, make sure you have the following:

This article assumes you already have an Azure Compute Gallery. If you don't already have a gallery, create one first. To learn more, see [Create a gallery for storing and sharing resources](#).

You should have uploaded your application to a container in an [Azure storage account](#). Your application can be stored in a block or page blob. If you choose to use a page blob, you need to byte align the files before you upload them. Here's a sample that will byte align your file:

```
$inputFile = <the file you want to pad>

$fileInfo = Get-Item -Path $inputFile

$remainder = $ fileInfo.Length % 512

if ($remainder -ne 0){

    $difference = 512 - $remainder

    $bytesToPad = [System.Byte[]]::CreateInstance([System.Byte], $difference)

    Add-Content -Path $inputFile -Value $bytesToPad -Encoding Byte
}
```

You need to make sure the files are publicly available, or you'll need the SAS URI for the files in your storage account. You can use [Storage Explorer](#) to quickly create a SAS URI if you don't already have one.

If you're using PowerShell, you need to be using version 3.11.0 of the Az.Storage module.

To learn more about the installation mechanism, see the [command interpreter](#).

## Create the VM application

Choose an option below for creating your VM application definition and version:

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

1. Go to the [Azure portal](#), then search for and select **Azure Compute Gallery**.

2. Select the gallery you want to use from the list.
3. On the page for your gallery, select **Add** from the top of the page and then select **VM application definition** from the drop-down. The **Create a VM application definition** page will open.
4. In the **Basics** tab, enter a name for your application and choose whether the application is for VMs running Linux or Windows.
5. Select the **Publishing options** tab if you want to specify any of the following optional settings for your VM application definition:
  - A description of the VM application definition.
  - End of life date
  - Link to a Eula
  - URI of a privacy statement
  - URI for release notes
6. When you're done, select **Review + create**.
7. When validation completes, select **Create** to have the definition deployed.
8. Once the deployment is complete, select **Go to resource**.
9. On the page for the application, select **Create a VM application version**. The **Create a VM Application Version** page will open.
10. Enter a version number like 1.0.0.
11. Select the region where you've uploaded your application package.
12. Under **Source application package**, select **Browse**. Select the storage account, then the container where your package is located. Select the package from the list and then click **Select** when you're done.  
Alternatively, you can paste the SAS URI in this field if preferred.
13. Type in the **Install script**. You can also provide the **Uninstall script** and **Update script**. See the [Overview](#) for information on how to create the scripts.
14. If you have a default configuration file uploaded to a storage account, you can select it in **Default configuration**.
15. Select **Exclude from latest** if you don't want this version to appear as the latest version when you create a VM.
16. For **End of life date**, choose a date in the future to track when this version should be retired. It isn't deleted or removed automatically, it's only for your own tracking.
17. To replicate this version to other regions, select the **Replication** tab and add more regions and make changes to the number of replicas per region. The original region where your version was created must be in the list and can't be removed.
18. When you're done making changes, select **Review + create** at the bottom of the page.
19. When validation shows as passed, select **Create** to deploy your VM application version.

Now you can create a VM and deploy the VM application to it using the portal. Just create the VM as usual, and under the **Advanced** tab, choose **Select a VM application to install**.

Add additional configuration, agents, scripts or applications via virtual machine extensions or cloud-init.

## Extensions

Extensions provide post-deployment configuration and automation.

Extensions [\(1\)](#)

Select an extension to install

## VM applications (preview)

VM applications contain application files that are securely and reliably downloaded on your VM after deployment. In addition to the application files, an install and uninstall script are included in the application. You can easily add or remove applications on your VM after create. [Learn more ↗](#)

Select a VM application to install

Select the VM application from the list, and then select **Save** at the bottom of the page.

The screenshot shows a 'Select VM applications' dialog box. At the top, there's a search bar and a 'Showing 1 application' message. Below is a table with columns: Application name, Description, Gallery name, Resource group, Operating system type, and Version. One row is visible for 'myApp' from 'myGallery' with version 1.0.0. A red box highlights the checkbox next to 'myApp'. At the bottom are 'Save' and 'Cancel' buttons.

If you've more than one VM application to install, you can set the install order for each VM application back on the **Advanced** tab.

You can also deploy the VM application to currently running VMs. Select the **Extensions + applications** option under **Settings** in the left menu when viewing the VM details in the portal.

Choose **VM applications** and then select **Add application** to add your VM application.

Home > myVM >

The screenshot shows the 'myVM | Extensions + applications' settings page. The 'VM Applications' tab is active. On the right, there's a table with 'Install order' and 'Application name' columns. A new row is being added with a grey placeholder bar. On the left, a sidebar lists various settings: Networking, Connect, Disks, Size, Security, Advisor recommendations, Extensions + applications (selected), and Continuous delivery. A search bar is at the top left.

Select the VM application from the list, and then select **Save** at the bottom of the page.

To show the VM application status, go to the Extensions + applications tab/settings and check the status of the VMAppExtension:

To show the VM application status for VMSS, go to the VMSS page, Instances, select one of them, then go to VMAppExtension:

# Find Azure Marketplace image information using the Azure CLI

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This topic describes how to use the Azure CLI to find VM images in the Azure Marketplace. Use this information to specify a Marketplace image when you create a VM programmatically with the CLI, Resource Manager templates, or other tools.

You can also browse available images and offers using the [Azure Marketplace](#) or [Azure PowerShell](#).

## Terminology

A Marketplace image in Azure has the following attributes:

- **Publisher:** The organization that created the image. Examples: Canonical, MicrosoftWindowsServer
- **Offer:** The name of a group of related images created by a publisher. Examples: UbuntuServer, WindowsServer
- **SKU:** An instance of an offer, such as a major release of a distribution. Examples: 18.04-LTS, 2019-Datacenter
- **Version:** The version number of an image SKU.

These values can be passed individually or as an image *URN*, combining the values separated by the colon (:). For example: *Publisher.Offer.Sku.Version*. You can replace the version number in the URN with `latest` to use the latest version of the image.

If the image publisher provides additional license and purchase terms, then you must accept those before you can use the image. For more information, see [Check the purchase plan information](#).

## List popular images

Run the `az vm image list` command, without the `--all` option, to see a list of popular VM images in the Azure Marketplace. For example, run the following command to display a cached list of popular images in table format:

```
az vm image list --output table
```

The output includes the image URN. You can also use the *UrnAlias* which is a shortened version created for popular images like *UbuntuLTS*.

Offer UrnAlias	Publisher Version	Sku	Urn
CentOS	OpenLogic	7.5	OpenLogic:CentOS:7.5:latest
CentOS		latest	
CoreOS	CoreOS	Stable	CoreOS:CoreOS:Stable:latest
CoreOS		latest	
debian-10	Debian	10	Debian:debian-10:10:latest
Debian		latest	
openSUSE-Leap	SUSE	42.3	SUSE:openSUSE-Leap:42.3:latest
openSUSE-Leap		latest	
RHEL	RedHat	7-LVM	RedHat:RHEL:7-LVM:latest
RHEL		latest	
SLES	SUSE	15	SUSE:SLES:15:latest
SLES		latest	
UbuntuServer	Canonical	18.04-LTS	Canonical:UbuntuServer:18.04-LTS:latest
UbuntuLTS		latest	
WindowsServer	MicrosoftWindowsServer	2019-Datacenter	MicrosoftWindowsServer:WindowsServer:2019-
Datacenter:latest	Win2019Datacenter	latest	
WindowsServer	MicrosoftWindowsServer	2016-Datacenter	MicrosoftWindowsServer:WindowsServer:2016-
Datacenter:latest	Win2016Datacenter	latest	
WindowsServer	MicrosoftWindowsServer	2012-R2-Datacenter	MicrosoftWindowsServer:WindowsServer:2012-R2-
Datacenter:latest	Win2012R2Datacenter	latest	
WindowsServer	MicrosoftWindowsServer	2012-Datacenter	MicrosoftWindowsServer:WindowsServer:2012-
Datacenter:latest	Win2012Datacenter	latest	
WindowsServer	MicrosoftWindowsServer	2008-R2-SP1	MicrosoftWindowsServer:WindowsServer:2008-R2-
SP1:latest	Win2008R2SP1	latest	

## Find specific images

To find a specific VM image in the Marketplace, use the `az vm image list` command with the `--all` option. This version of the command takes some time to complete and can return lengthy output, so you usually filter the list by `--publisher` or another parameter.

For example, the following command displays all Debian offers (remember that without the `--all` switch, it only searches the local cache of common images):

```
az vm image list --offer Debian --all --output table
```

Partial output:

Offer	Publisher	SKU
Urn		
Version		
-----	-----	-----
-----	-----	-----

## Look at all available images

Another way to find an image in a location is to run the [az vm image list-publishers](#), [az vm image list-offers](#), and [az vm image list-skus](#) commands in sequence. With these commands, you determine these values:

1. List the image publishers for a location. In this example, we are looking at the *West US* region.

```
az vm image list-publishers --location westus --output table
```

2. For a given publisher, list their offers. In this example, we add *Canonical* as the publisher.

```
az vm image list-offers --location westus --publisher Canonical --output table
```

3. For a given offer, list their SKUs. In this example, we add *UbuntuServer* as the offer.

```
az vm image list-skus --location westus --publisher Canonical --offer UbuntuServer --output table
```

4. For a given publisher, offer, and SKU, show all of the versions of the image. In this example, we add *18.04-LTS* as the SKU.

```
az vm image list \
--location westus \
--publisher Canonical \
--offer UbuntuServer \
--sku 18.04-LTS \
--all --output table
```

Pass this value of the URN column with the `--image` parameter when you create a VM with the [az vm create](#) command. You can also replace the version number in the URN with "latest", to simply use the latest version of the image.

If you deploy a VM with a Resource Manager template, you set the image parameters individually in the `imageReference` properties. See the [template reference](#).

## Check the purchase plan information

Some VM images in the Azure Marketplace have additional license and purchase terms that you must accept before you can deploy them programmatically.

To deploy a VM from such an image, you'll need to accept the image's terms the first time you use it, once per subscription. You'll also need to specify *purchase plan* parameters to deploy a VM from that image.

To view an image's purchase plan information, run the [az vm image show](#) command with the URN of the image. If the `plan` property in the output is not `null`, the image has terms you need to accept before programmatic deployment.

For example, the Canonical Ubuntu Server 18.04 LTS image doesn't have additional terms, because the `plan` information is `null`:

```
az vm image show --location westus --urn Canonical:UbuntuServer:18.04-LTS:latest
```

Output:

```
{
  "dataDiskImages": [],
  "id": "/Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/Canonical/ArtifactTypes/VMImage/Offers/
UbuntuServer/Skus/18.04-LTS/Versions/18.04.201901220",
  "location": "westus",
  "name": "18.04.201901220",
  "osDiskImage": {
    "operatingSystem": "Linux"
  },
  "plan": null,
  "tags": null
}
```

Running a similar command for the RabbitMQ Certified by Bitnami image shows the following `plan` properties: `name`, `product`, and `publisher`. (Some images also have a `promotion code` property.)

```
az vm image show --location westus --urn bitnami:rabbitmq:rabbitmq:latest
```

Output:

```
{  
    "dataDiskImages": [],  
    "id": "/Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-  
xxxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/bitnami/ArtifactTypes/VMImage/Offers/ra  
bbitmq/Skus/rabbitmq/Versions/3.7.1901151016",  
    "location": "westus",  
    "name": "3.7.1901151016",  
    "osDiskImage": {  
        "operatingSystem": "Linux"  
    },  
    "plan": {  
        "name": "rabbitmq",  
        "product": "rabbitmq",  
        "publisher": "bitnami"  
    },  
    "tags": null  
}
```

To deploy this image, you need to accept the terms and provide the purchase plan parameters when you deploy a VM using that image.

## Accept the terms

To view and accept the license terms, use the [az vm image terms](#) command. When you accept the terms, you enable programmatic deployment in your subscription. You only need to accept terms once per subscription for the image. For example:

```
az vm image terms show --urn bitnami:rabbitmq:rabbitmq:latest
```

The output includes a `licenseTextLink` to the license terms, and indicates that the value of `accepted` is `true`:

```
{  
    "accepted": true,  
    "additionalProperties": {},  
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-  
xxxxxxxxxxxx/providers/Microsoft.MarketplaceOrdering/offertypes/bitnami/offers/rabbitmq/plans/rabbitmq",  
    "licenseTextLink":  
        "https://storelegalterms.blob.core.windows.net/legalterms/3E5ED_legalterms_BITNAMI%253a24RABBITMQ%253a24RABB  
ITMQ%253a24IGRT7HHPIFOBV3IQYJHEN202FGUVXXZ3WUYIMEIVF3KCUNJ7GTVXNNM23I567GBMNDWRFOY4WXJPNSPUYXNKB2QLAKCHP4IE5  
GO3B2I.txt",  
    "name": "rabbitmq",  
    "plan": "rabbitmq",  
    "privacyPolicyLink": "https://bitnami.com/privacy",  
    "product": "rabbitmq",  
    "publisher": "bitnami",  
    "retrieveDatetime": "2019-01-25T20:37:49.937096Z",  
    "signature":  
        "XXXXXXXXLAZIK7ZL2YRV5JYQXONPV76NQJW3FKMDZYCRGXZYVDGX6BVY45J03BXVMNA2COBOEYG2N0760NORU7ITTRHGZDYNJNXXXXXX",  
    "type": "Microsoft.MarketplaceOrdering/offertypes"  
}
```

To accept the terms, type:

```
az vm image terms accept --urn bitnami:rabbitmq:rabbitmq:latest
```

## Deploy a new VM using the image parameters

With information about the image, you can deploy it using the `az vm create` command.

To deploy an image that does not have plan information, like the latest Ubuntu Server 18.04 image from Canonical, pass the URN for `--image`:

```
az group create --name myURNVM --location westus
az vm create \
    --resource-group myURNVM \
    --name myVM \
    --admin-username azureuser \
    --generate-ssh-keys \
    --image Canonical:UbuntuServer:18.04-LTS:latest
```

For an image with purchase plan parameters, like the RabbitMQ Certified by Bitnami image, you pass the URN for `--image` and also provide the purchase plan parameters:

```
az group create --name myPurchasePlanRG --location westus

az vm create \
    --resource-group myPurchasePlanRG \
    --name myVM \
    --admin-username azureuser \
    --generate-ssh-keys \
    --image bitnami:rabbitmq:rabbitmq:latest \
    --plan-name rabbitmq \
    --plan-product rabbitmq \
    --plan-publisher bitnami
```

If you get a message about accepting the terms of the image, review section [Accept the terms](#). Make sure the output of `az vm image accept-terms` returns the value `"accepted": true,` showing that you have accepted the terms of the image.

## Using an existing VHD with purchase plan information

If you have an existing VHD from a VM that was created using a paid Azure Marketplace image, you might need to supply the purchase plan information when you create a new VM from that VHD.

If you still have the original VM, or another VM created using the same marketplace image, you can get the plan name, publisher, and product information from it using `az vm get-instance-view`. This example gets a VM named `myVM` in the `myResourceGroup` resource group and then displays the purchase plan information.

```
az vm get-instance-view -g myResourceGroup -n myVM --query plan
```

If you didn't get the plan information before the original VM was deleted, you can file a [support request](#). They will need the VM name, subscription ID and the time stamp of the delete operation.

Once you have the plan information, you can create the new VM using the `--attach-os-disk` parameter to specify the VHD.

```
az vm create \
--resource-group myResourceGroup \
--name myNewVM \
--nics myNic \
--size Standard_DS1_v2 --os-type Linux \
--attach-os-disk myVHD \
--plan-name planName \
--plan-publisher planPublisher \
--plan-product planProduct
```

## Next steps

To create a virtual machine quickly by using the image information, see [Create and Manage Linux VMs with the Azure CLI](#).

# Find and use Azure Marketplace VM images with Azure PowerShell

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes how to use Azure PowerShell to find VM images in the Azure Marketplace. You can then specify a Marketplace image and plan information when you create a VM.

You can also browse available images and offers using the [Azure Marketplace](#) or the [Azure CLI](#).

## Terminology

A Marketplace image in Azure has the following attributes:

- **Publisher:** The organization that created the image. Examples: Canonical, MicrosoftWindowsServer
- **Offer:** The name of a group of related images created by a publisher. Examples: UbuntuServer, WindowsServer
- **SKU:** An instance of an offer, such as a major release of a distribution. Examples: 18.04-LTS, 2019-Datacenter
- **Version:** The version number of an image SKU.

These values can be passed individually or as an image *URN*, combining the values separated by the colon (:). For example: *Publisher.Offer.Sku.Version*. You can replace the version number in the URN with `latest` to use the latest version of the image.

If the image publisher provides additional license and purchase terms, then you must accept those before you can use the image. For more information, see [Accept purchase plan terms](#).

## List images

You can use PowerShell to narrow down a list of images. Replace the values of the variables to meet your needs.

1. List the image publishers using [Get-AzVMImagePublisher](#).

```
$locName=<location>
Get-AzVMImagePublisher -Location $locName | Select PublisherName
```

2. For a given publisher, list their offers using [Get-AzVMImageOffer](#).

```
$pubName=<publisher>
Get-AzVMImageOffer -Location $locName -PublisherName $pubName | Select Offer
```

3. For a given publisher and offer, list the SKUs available using [Get-AzVMImageSku](#).

```
$offerName=<offer>
Get-AzVMImageSku -Location $locName -PublisherName $pubName -Offer $offerName | Select Skus
```

4. For a SKU, list the versions of the image using [Get-AzVMImage](#).

```
$skuName="<SKU>"  
Get-AzVMImage -Location $locName -PublisherName $pubName -Offer $offerName -Sku $skuName | Select  
Version
```

You can also use `latest` if you want to use the latest image and not a specific older version.

Now you can combine the selected publisher, offer, SKU, and version into a URN (values separated by `:`). Pass this URN with the `-Image` parameter when you create a VM with the [New-AzVM](#) cmdlet. You can also replace the version number in the URN with `latest` to get the latest version of the image.

If you deploy a VM with a Resource Manager template, then you'll set the image parameters individually in the `imageReference` properties. See the [template reference](#).

## View purchase plan properties

Some VM images in the Azure Marketplace have additional license and purchase terms that you must accept before you can deploy them programmatically. You'll need to accept the image's terms once per subscription.

To view an image's purchase plan information, run the `Get-AzVMImage` cmdlet. If the `PurchasePlan` property in the output is not `null`, the image has terms you need to accept before programmatic deployment.

For example, the *Windows Server 2016 Datacenter* image doesn't have additional terms, so the `PurchasePlan` information is `null`:

```
$version = "2016.127.20170406"  
Get-AzVMImage -Location $locName -PublisherName $pubName -Offer $offerName -Skus $skuName -Version $version
```

The output will look similar to the following:

```
Id : /Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/MicrosoftWindowsServer/ArtifactTypes/VM  
Image/Offers/WindowsServer/Skus/2016-Datacenter/Versions/2019.0.20190115  
Location : westus  
PublisherName : MicrosoftWindowsServer  
Offer : WindowsServer  
Skus : 2019-Datacenter  
Version : 2019.0.20190115  
FilterExpression :  
Name : 2019.0.20190115  
OSDiskImage : {  
    "operatingSystem": "Windows"  
}  
PurchasePlan : null  
DataDiskImages : []
```

The example below shows a similar command for the *Data Science Virtual Machine - Windows 2016* image, which has the following `PurchasePlan` properties: `name`, `product`, and `publisher`. Some images also have a `promotion code` property. To deploy this image, see the following sections to accept the terms and to enable programmatic deployment.

```
Get-AzVMImage -Location "westus" -PublisherName "microsoft-ads" -Offer "windows-data-science-vm" -Skus  
"windows2016" -Version "0.2.02"
```

The output will look similar to the following:

```

Id          : /Subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxxx/Providers/Microsoft.Compute/Locations/westus/Publishers/microsoft-
ads/ArtifactTypes/VMImage/Offers/windows-data-science-vm/Skus/windows2016/Versions/19.01.14
Location    : westus
PublisherName : microsoft-ads
Offer        : windows-data-science-vm
Skus         : windows2016
Version      : 19.01.14
FilterExpression :
Name         : 19.01.14
OSDiskImage   : {
                  "operatingSystem": "Windows"
                }
PurchasePlan   : {
                  "publisher": "microsoft-ads",
                  "name": "windows2016",
                  "product": "windows-data-science-vm"
                }
DataDiskImages : []

```

To view the license terms, use the [Get-AzMarketplaceterms](#) cmdlet and pass in the purchase plan parameters. The output provides a link to the terms for the Marketplace image and shows whether you previously accepted the terms. Be sure to use all lowercase letters in the parameter values.

```
Get-AzMarketplaceterms -Publisher "microsoft-ads" -Product "windows-data-science-vm" -Name "windows2016"
```

The output will look similar to the following:

```

Publisher      : microsoft-ads
Product        : windows-data-science-vm
Plan           : windows2016
LicenseTextLink :

Accepted       : False
Signdate       : 1/25/2019 7:43:00 PM

```

## Accept purchase plan terms

Use the [Set-AzMarketplaceterms](#) cmdlet to accept or reject the terms. You only need to accept terms once per subscription for the image. Be sure to use all lowercase letters in the parameter values.

```

$agreementTerms=Get-AzMarketplaceterms -Publisher "microsoft-ads" -Product "windows-data-science-vm" -Name
"windows2016"

Set-AzMarketplaceTerms -Publisher "microsoft-ads" -Product "windows-data-science-vm" -Name "windows2016" -
Terms $agreementTerms -Accept

```

```
Publisher      : microsoft-ads
Product       : windows-data-science-vm
Plan          : windows2016

## Create a new VM from a marketplace image

If you already have the information about what image you want to use, you can pass that information into [Set-AzVMSourceImage](#) cmdlet to add image information to the VM configuration. See the next sections for searching and listing the images available in the marketplace.

Some paid images also require that you provide purchase plan information using the [Set-AzVMPlan](#).

```
...

$vmConfig = New-AzVMConfig -VMName "myVM" -VMSize Standard_D1

# Set the Marketplace image
$offerName = "windows-data-science-vm"
$skuName = "windows2016"
$version = "19.01.14"
$vmConfig = Set-AzVMSourceImage -VM $vmConfig -PublisherName $publisherName -Offer $offerName -Skus $skuName
-Version $version

# Set the Marketplace plan information, if needed
$publisherName = "microsoft-ads"
$productName = "windows-data-science-vm"
$planName = "windows2016"
$vmConfig = Set-AzVMPlan -VM $vmConfig -Publisher $publisherName -Product $productName -Name $planName

...
```

You'll then pass the VM configuration along with the other configuration objects to the [New-AzVM](#) cmdlet. For a detailed example of using a VM configuration with PowerShell, see this [script](#).

If you get a message about accepting the terms of the image, see the earlier section [Accept purchase plan terms](#).

## Create a new VM from a VHD with purchase plan information

If you have an existing VHD that was created using an Azure Marketplace image, you might need to supply the purchase plan information when you create a new VM from that VHD.

If you still have the original VM, or another VM created from the same image, you can get the plan name, publisher, and product information from it using Get-AzVM. This example gets a VM named *myVM* in the *myResourceGroup* resource group and then displays the purchase plan information.

```
$vm = Get-azvm ` 
    -ResourceGroupName myResourceGroup ` 
    -Name myVM
$vm.Plan
```

If you didn't get the plan information before the original VM was deleted, you can file a [support request](#). They will need the VM name, subscription ID and the time stamp of the delete operation.

To create a VM using a VHD, refer to this article [Create a VM from a specialized VHD](#) and add in a line to add the plan information to the VM configuration using [Set-AzVMPlan](#) similar to the following:

```
$vmConfig = Set-AzVMPlan ` 
    -VM $vmConfig ` 
    -Publisher "publisherName" ` 
    -Product "productName" ` 
    -Name "planName"
```

## Next steps

To create a virtual machine quickly with the `New-AzVM` cmdlet by using basic image information, see [Create a Windows virtual machine with PowerShell](#).

For more information on using Azure Marketplace images to create custom images in an Azure Compute Gallery (formerly known as Shared Image Gallery), see [Supply Azure Marketplace purchase plan information when creating images](#).

# Use Windows client in Azure for dev/test scenarios

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

You can use Windows 7, Windows 8, or Windows 10 Enterprise (x64) in Azure for dev/test scenarios provided you have an appropriate Visual Studio (formerly MSDN) subscription.

To run Windows 10 in a production environment see, [How to deploy Windows 10 on Azure with Multitenant Hosting Rights](#).

## Subscription eligibility

Active Visual Studio subscribers (people who have acquired a Visual Studio subscription license) can use Windows client images for development and testing purposes. Windows client images can be used on your own hardware or on Azure virtual machines.

Certain Windows client images are available from the Azure Marketplace. Visual Studio subscribers within any type of offer can also [prepare and create](#) 64-bit Windows 7, Windows 8, or Windows 10 images and then [upload to Azure](#).

## Eligible offers and client images

The following table details the offer IDs that are eligible to deploy Windows client images through the Azure Marketplace. The Windows client images are only visible to the following offers.

### NOTE

Image offers are under **Windows Client** in the Azure Marketplace. Use **Windows Client** when searching for client images available to Visual Studio subscribers. If you need to purchase a Visual Studio subscription, see the various options at [Buy Visual Studio](#)

OFFER NAME	OFFER NUMBER	AVAILABLE CLIENT IMAGES
<a href="#">Pay-As-You-Go Dev/Test</a>	0023P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)
<a href="#">Visual Studio Enterprise (MPN) subscribers</a>	0029P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)
<a href="#">Visual Studio Professional subscribers</a>	0059P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)
<a href="#">Visual Studio Test Professional subscribers</a>	0060P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)

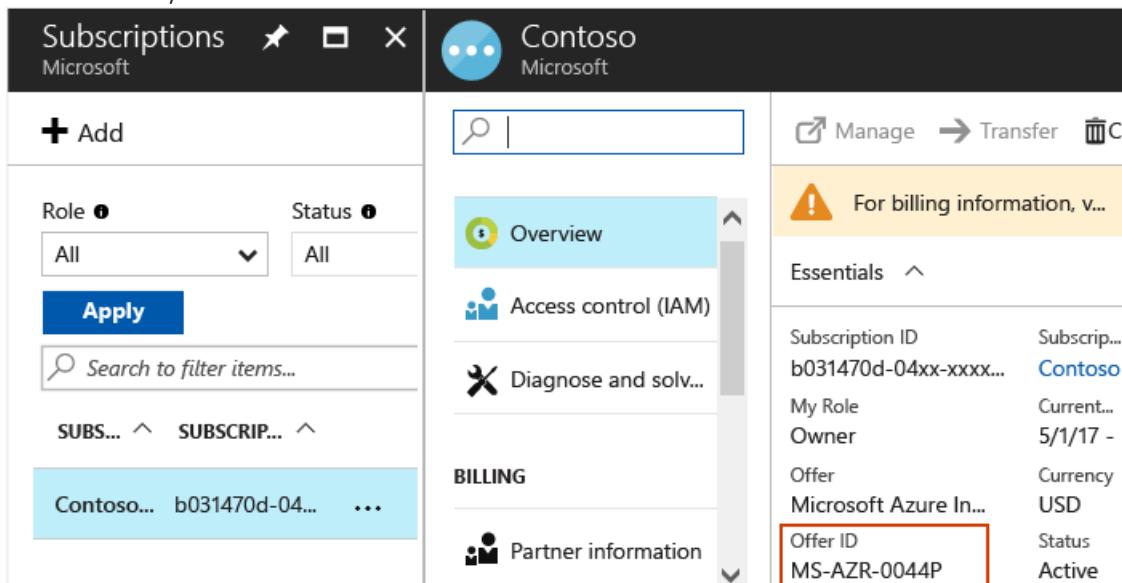

OFFER NAME	OFFER NUMBER	AVAILABLE CLIENT IMAGES
Visual Studio Enterprise subscribers	0063P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)
Visual Studio Enterprise (BizSpark) subscribers	0064P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)
Enterprise Dev/Test	0148P	Windows 10 Enterprise N (x64) Windows 8.1 Enterprise N (x64) Windows 7 Enterprise N with SP1 (x64)

For more information, see [Understand Microsoft offer types](#)

## Check your Azure subscription

If you do not know your offer ID, you can obtain it through the Azure portal.

- On the *Subscriptions* window:

The screenshot shows the Azure Subscriptions window for the Contoso Microsoft account. The left sidebar has filters for Role (All) and Status (All), with an 'Apply' button. Below that are 'SUBS...' and 'SUBSCRIP...' dropdowns, and a list item for 'Contoso... b031470d-04... ...'. The main area has tabs for 'Overview' (which is selected and highlighted in blue), 'Access control (IAM)', 'Diagnose and solv...', 'BILLING', and 'Partner information'. The 'BILLING' tab is expanded, showing a table with columns for Subscription ID, Offer, and Partner information. The 'Offer ID' row is highlighted with a red box, showing the value 'MS-AZR-0044P'.

Subscription ID	Offer	Partner information
b031470d-04xx-xxxx...	Microsoft Azure In...	MS-AZR-0044P

- Or, click **Billing** and then click your subscription ID. The offer ID appears in the *Billing* window.
- You can also view the offer ID from the '[Subscriptions](#)' tab of the Azure Account portal:

**ACCOUNT ADMINISTRATOR**

**SUBSCRIPTION ID**

**ORDER ID**

**OFFER**

Visual Studio Enterprise

**OFFER ID**

MS-AZR-0063P

**CURRENCY**

USD

**STATUS**

Active

## Next steps

You can now deploy your VMs using [PowerShell](#), [Resource Manager templates](#), or [Visual Studio](#).

# How to deploy Windows 10 on Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

For customers with Windows 10 Enterprise E3/E5 per user or Azure Virtual Desktop Access per user (User Subscription Licenses or Add-on User Subscription Licenses), Multitenant Hosting Rights for Windows 10 allows you to bring your Windows 10 Licenses to the cloud and run Windows 10 Virtual Machines on Azure without paying for another license. Multitenant Hosting Rights are only available for Windows 10 (version 1703 or later).

For more information, see [Multitenant Hosting for Windows 10](#).

## NOTE

- To use Windows 7, 8.1 and 10 images for development or testing see [Windows client in Azure for dev/test scenarios](#)
- For Windows Server licensing benefits, please refer to [Azure Hybrid use benefits for Windows Server images](#).

## Subscription Licenses that qualify for Multitenant Hosting Rights

For more details about subscription licenses that qualify to run Windows 10 on Azure, download the [Windows 10 licensing brief for Virtual Desktops](#)

## IMPORTANT

Users **must** have one of the below subscription licenses in order to use Windows 10 images in Azure for any production workload. If you do not have one of these subscription licenses, they can be purchased through your [Cloud Service Partner](#) or directly through [Microsoft](#).

## Operating systems and licenses

You have a choice of operating systems that you can use for session hosts to provide virtual desktops and remote apps. You can use different operating systems with different host pools to provide flexibility to your users. Supported dates are inline with the [Microsoft Lifecycle Policy](#). We support the following 64-bit versions of these operating systems:

### Operating system licenses

- Windows 11 Enterprise multi-session
- Windows 11 Enterprise
- Windows 10 Enterprise, version 1909 and later

### License entitlement

- Microsoft 365 E3, E5, A3, A5, F3, Business Premium, Student Use Benefit
- Windows Enterprise E3, E5
- Windows VDA E3, E5
- Windows Education A3, A5

External users can use [per-user access pricing](#) instead of license entitlement.

## Deploying Windows 10 Image from Azure Marketplace

For PowerShell, CLI and Azure Resource Manager template deployments, Windows 10 images can be found using the `PublisherName: MicrosoftWindowsDesktop` and `Offer: Windows-10`. Windows 10 version Creators Update (1809) or later is supported for Multitenant Hosting Rights.

```
Get-AzVmImageSku -Location '$location' -PublisherName 'MicrosoftWindowsDesktop' -Offer 'Windows-10'

Skus          Offer      PublisherName      Location
----          -----      -----            -----
rs4-pro       Windows-10 MicrosoftWindowsDesktop eastus
rs4-pron      Windows-10 MicrosoftWindowsDesktop eastus
rs5-enterprise Windows-10 MicrosoftWindowsDesktop eastus
rs5-enterprisen Windows-10 MicrosoftWindowsDesktop eastus
rs5-pron      Windows-10 MicrosoftWindowsDesktop eastus
```

For more information on available images see [Find and use Azure Marketplace VM images with Azure PowerShell](#)

## Uploading Windows 10 VHD to Azure

If you are uploading a generalized Windows 10 VHD, please note Windows 10 does not have built-in administrator account enabled by default. To enable the built-in administrator account, include the following command as part of the Custom Script extension.

```
Net user <username> /active:yes
```

The following PowerShell snippet is to mark all administrator accounts as active, including the built-in administrator. This example is useful if the built-in administrator username is unknown.

```
$adminAccount = Get-WmiObject Win32_UserAccount -filter "LocalAccount=True" | ? {$_.SID -Like "S-1-5-21-*-500"}
if($adminAccount.Disabled)
{
    $adminAccount.Disabled = $false
    $adminAccount.Put()
}
```

For more information:

- [How to upload VHD to Azure](#)
- [How to prepare a Windows VHD to upload to Azure](#)

## Deploying Windows 10 with Multitenant Hosting Rights

Make sure you have [installed and configured the latest Azure PowerShell](#). Once you have prepared your VHD, upload the VHD to your Azure Storage account using the `Add-AzVhd` cmdlet as follows:

```
Add-AzVhd -ResourceGroupName "myResourceGroup" -LocalFilePath "C:\Path\To\myvhd.vhd" ` 
-Destination "https://mystorageaccount.blob.core.windows.net/vhds/myvhd.vhd"
```

**Deploy using Azure Resource Manager Template Deployment** Within your Resource Manager templates, an additional parameter for `licenseType` can be specified. You can read more about [authoring Azure Resource Manager templates](#). Once you have your VHD uploaded to Azure, edit your Resource Manager template to include the license type as part of the compute provider and deploy your template as normal:

```
"properties": {  
    "licenseType": "Windows_Client",  
    "hardwareProfile": {  
        "vmSize": "[variables('vmSize')]"  
    }  
}
```

**Deploy via PowerShell** When deploying your Windows Server VM via PowerShell, you have an additional parameter for `-LicenseType`. Once you have your VHD uploaded to Azure, you create a VM using `New-AzVM` and specify the licensing type as follows:

```
New-AzVM -ResourceGroupName "myResourceGroup" -Location "West US" -VM $vm -LicenseType "Windows_Client"
```

## Verify your VM is utilizing the licensing benefit

Once you have deployed your VM through either the PowerShell or Resource Manager deployment method, verify the license type with `Get-AzVM` as follows:

```
Get-AzVM -ResourceGroup "myResourceGroup" -Name "myVM"
```

The output is similar to the following example for Windows 10 with correct license type:

```
Type          : Microsoft.Compute/virtualMachines  
Location     : westus  
LicenseType  : Windows_Client
```

This output contrasts with the following VM deployed without Azure Hybrid Use Benefit licensing, such as a VM deployed straight from the Azure Gallery:

```
Type          : Microsoft.Compute/virtualMachines  
Location     : westus  
LicenseType  :
```

## Additional Information about joining Azure Active Directory

Azure provisions all Windows VMs with built-in administrator account, which cannot be used to join Azure Active Directory. For example, *Settings > Account > Access Work or School > +Connect* will not work. You must create and log on as a second administrator account to join Azure AD manually. You can also configure Azure AD using a provisioning package, use the link in the *Next Steps* section to learn more.

# Bringing and creating Linux images in Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

This overview covers the basic concepts around imaging and how to successfully build and use Linux images in Azure. Before you bring a custom image to Azure, you need to be aware of the types and options available to you.

This article will talk through the image decision points and requirements as well as explain key concepts so that you can follow this and be able to create your own custom images to your specification.

## Difference between managed disks and images

Azure allows you to bring a VHD to the platform to use as a [Managed Disk](#) or as a source for an image.

An Azure managed disk is a single VHD. You can either take an existing VHD and create a managed disk from it, or create an empty managed disk from scratch. You can create VMs from managed disks by attaching the disk to the VM, but you can only use a VHD with one VM. You won't be able to modify any OS properties as Azure will just try to turn on the VM and start up using that disk.

Azure images can be made up of multiple OS disks and data disks. When you use a managed image to create a VM, the platform makes a copy of the image and uses that to create the VM. This allows managed images to support reusing the same image for multiple VMs. Azure also provides advanced management capabilities for images, like global replication and versioning through [Azure Compute Gallery](#) (formerly known as Shared Image Gallery).

## Generalized and specialized

Azure offers two main image types, generalized and specialized. The terms generalized and specialized are originally Windows terms which migrated in to Azure. These types define how the platform will handle the VM when it turns it on. Both types have advantages, disadvantages, and prerequisites. Before you get started, you need to know what image type you will need. Below summarizes the scenarios and type you would need to choose:

SCENARIO	IMAGE TYPE	STORAGE OPTIONS
Create an image that can be configured for use by multiple VMs. You can set the hostname, add an admin user, and perform other tasks during first boot.	Generalized	Azure Compute Gallery or stand-alone managed images
Create an image from a VM snapshot or a backup.	Specialized	Azure Compute Gallery or a managed disk
Quickly create an image that does not need any configuration for creating multiple VMs.	Specialized	Azure Compute Gallery

### Generalized images

A generalized image is an image that requires setup to be completed on first boot. For example, on first boot

you set the hostname, admin user, and other VM-specific configurations. This is useful when you want the image to be reused multiple times and when you want to pass in parameters during creation. If the generalized image contains the Azure agent, the agent will process the parameters and signal back to the platform that the initial configuration has completed. This process is called [provisioning](#).

Provisioning requires that a provisioner is included in the image. There are two provisioners:

- [Azure Linux Agent](#)
- [cloud-init](#)

These are [prerequisites](#) for creating an image.

### Specialized images

These are images that are completely configured and do not require VM or special parameters. The platform will just turn the VM on and you will need to handle uniqueness within the VM, like setting a hostname, to avoid DNS conflicts on the same VNET.

Provisioning agents are not required for these images, however you may want to have extension handling capabilities. You can install the Linux Agent but disable the provisioning option. Even though you do not need a provisioning agent, the image must fulfill [prerequisites](#) for Azure Images.

## Image storage options

When bringing your Linux image you have two options:

- Managed images for simple VM creation in a development and test environment.
- [Azure Compute Gallery](#) for creating and sharing images at-scale.

### Managed images

Managed images can be used to create multiple VMs, but they have a lot of limitations. Managed images can only be created from a generalized source (VM or VHD). They can only be used to create VMs in the same region and they can't be shared across subscriptions and tenants.

Managed images can be used for development and test environments, where you need a couple of simple generalized images to use within single region and subscription.

### Azure Compute Gallery

[Azure Compute Gallery](#) (formerly known as Shared Image Gallery) is recommended for creating, managing, and sharing images at scale. Azure Compute Gallery helps you build structure and organization around your images.

- Support for both generalized and specialized images.
- Support for image both generation 1 and 2 images.
- Global replication of images.
- Versioning and grouping of images for easier management.
- Highly available images with Zone Redundant Storage (ZRS) in regions that support Availability Zones. ZRS offers better resilience against zonal failures.
- Sharing across subscriptions and even between Active Directory (AD) tenants using Azure RBAC.
- Scaling your deployments with image replicas in each region.

At a high level, you create a gallery and it is made up of:

- Image Definitions - These are containers that hold groups of images.
- Image Versions - These are the actual images.

## Hyper-V generation

Azure supports Hyper-V Generation 1 (Gen1) and Generation 2 (Gen2). Gen2 is the latest generation and offers additional functionality over Gen1. For example: increased memory, Intel Software Guard Extensions (Intel SGX), and virtualized persistent memory (vPMEM). Generation 2 VMs running on-premises have some features that aren't supported in Azure yet. For more information, see the Features and capabilities section in this [article](#). Create Gen2 images if you require the additional functionality.

If you still need to create your own image, ensure it meets the [image prerequisites](#) and upload to Azure.

Distribution specific requirements:

- [CentOS-based Distributions](#)
- [Debian Linux](#)
- [Flatcar Container Linux](#)
- [Oracle Linux](#)
- [Red Hat Enterprise Linux](#)
- [SLES & openSUSE](#)
- [Ubuntu](#)

## Next steps

Learn how to create an [Azure Compute Gallery](#).

# Azure Linux VM provisioning

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you create a VM from a generalized image (Azure Compute Gallery or Managed Image), the control plane will allow you to create a VM, and pass parameters and settings to the VM. This is called *VM provisioning*.

During provisioning, the platform makes required VM Create parameter values (hostname, username, password, SSH keys, customData) available to the VM as it boots.

A provisioning agent baked inside the image will interface with the platform, connecting up to multiple independent provisioning interfaces), set the properties and signal to the platform it has completed.

The provisioning agents can be the [Azure Linux Agent](#), or [cloud-init](#). These are [prerequisites](#) of creating generalized images.

The provisioning agents, provide support for all endorsed [Azure Linux distributions](#), and you will find the endorsed distro images in many cases will ship with both cloud-init and the Linux Agent. This gives you the option to have cloud-init to handle the provisioning, then the Linux Agent will provide support to handle [Azure Extensions](#). Providing support for extensions means the VM will then be eligible to support additional Azure services, such as VM Password Reset, Azure Monitoring, Azure Backup, Azure Disk encryption etc.

After provisioning completes, cloud-init will run on each boot. Cloud-init will monitor for changes to the VM, like networking changes, mounting, and formatting the ephemeral disk, and starting the Linux Agent. The Linux Agent continually runs on the server, seeking a 'goal state' (new configuration) from the Azure platform, so whenever you install extensions, the agent will be able to process them.

Whilst there are currently two provisioning agents, cloud-init should be the provisioning agent you choose, and the Linux Agent should be installed for extension support. This allows you to take advantage of platform optimizations, and allows you to disable/remove the Linux Agent, for more details on how to create images without the agent, and how to remove it, please review this [documentation](#).

If you have a Linux kernel that cannot support running either agent, but wish to set some of the VM Create properties, such as hostname, customData, userName, password, ssh keys, then in this document discusses how you can [create generalized images without an agent](#), and meet platform requirements.

## Provisioning agent responsibilities

### Image provisioning

- Creation of a user account
- Configuring SSH authentication types
- Deployment of SSH public keys and key pairs
- Setting the host name
- Publishing the host name to the platform DNS
- Reporting SSH host key fingerprint to the platform
- Resource Disk Management
- Formatting and mounting the resource disk
- Consuming and processing `customData`

### Networking

- Manages routes to improve compatibility with platform DHCP servers
- Ensures the stability of the network interface name

## Kernel

- Configures virtual NUMA (disable for kernel < 2.6.37 )
- Consumes Hyper-V entropy for /dev/random
- Configures SCSI timeouts for the root device (which could be remote)

## Diagnostics

- Console redirection to the serial port

# Communication

The information flow from the platform to the agent occurs via two channels:

- A boot-time attached DVD for IaaS deployments. The DVD includes an OVF-compliant configuration file that includes all provisioning information, other than the actual SSH key pairs.
- A TCP endpoint exposing a REST API used to obtain deployment, and topology configuration.

# Azure provisioning agent requirements

The Linux Agent, and cloud-init, depend on some system packages in order to function properly:

- Python 2.6+
- OpenSSL 1.0+
- OpenSSH 5.3+
- Filesystem utilities: sfdisk , fdisk , mkfs , parted
- Password tools: chpasswd, sudo
- Text processing tools: sed, grep
- Network tools: ip-route
- Kernel support for mounting UDF filesystems.

# Next steps

If you need to, you can [disable provisioning and remove the Linux agent](#).

# Endorsed Linux distributions on Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

Partners provide Linux images in Azure Marketplace. Microsoft works with various Linux communities to add even more flavors to the Endorsed Distribution list. For distributions that are not available from the Marketplace, you can always bring your own Linux by following the guidelines at [Create and upload a virtual hard disk that contains the Linux operating system](#).

## Supported distributions and versions

The following table lists the Linux distributions and versions that are supported on Azure. For more information, see [Support for Linux images in Microsoft Azure](#).

The Linux Integration Services (LIS) drivers for Hyper-V and Azure are kernel modules that Microsoft contributes directly to the upstream Linux kernel. Some LIS drivers are built into the distribution's kernel by default. Older distributions that are based on Red Hat Enterprise (RHEL)/CentOS are available as a separate download at [Linux Integration Services Version 4.2 for Hyper-V and Azure](#). For more information, see [Linux kernel requirements](#).

The Azure Linux Agent is already pre-installed on Azure Marketplace images and is typically available from the distribution's package repository. Source code can be found on [GitHub](#).

DISTRIBUTION	VERSION	DRIVERS	AGENT
CentOS by Rogue Wave Software (formerly known as OpenLogic)	CentOS 6.x, 7.x, 8.x	CentOS 6.3: <a href="#">LIS download</a> CentOS 6.4+: In kernel	Package: In <a href="#">repo</a> under "WALinuxAgent" Source code: <a href="#">GitHub</a>
<a href="#">CoreOS</a> CoreOS is now <a href="#">end of life</a> as of May 26, 2020.	No Longer Available		
Debian by credativ	9.x (LTS), 10.x, 11.x	In kernel	Package: In repo under "waagent" Source code: <a href="#">GitHub</a>
Flatcar Container Linux by Kinvolk	Pro, Stable, Beta	In kernel	wa-linux-agent is installed already in /usr/share/oem/bin/waagent
Oracle Linux by Oracle	6.x, 7.x, 8.x	In kernel	Package: In repo under "WALinuxAgent" Source code: <a href="#">GitHub</a>
<a href="#">Red Hat Enterprise Linux by Red Hat</a>	7.x, 8.x	In kernel	Package: In repo under "WALinuxAgent" Source code: <a href="#">GitHub</a>

DISTRIBUTION	VERSION	DRIVERS	AGENT
SUSE Linux Enterprise by SUSE	SLES/SLES for SAP 11.x, 12.x, 15.x <a href="#">SUSE Public Cloud Image Lifecycle</a>	In kernel	Package: for 11 in <a href="#">Cloud:Tools</a> repo for 12 included in "Public Cloud" Module under "python-azure-agent" Source code: <a href="#">GitHub</a>
openSUSE by SUSE	openSUSE Leap 15.x	In kernel	Package: In <a href="#">Cloud:Tools</a> repo under "python-azure-agent" Source code: <a href="#">GitHub</a>
Ubuntu by Canonical	Ubuntu Server and Pro. 18.x, 20.x 22.x Information about extended support for Ubuntu 14.04 pro and 16.04 pro can be found here: <a href="#">Ubuntu Extended Security Maintenance</a> .	In kernel	Package: In repo under "walinuxagent" Source code: <a href="#">GitHub</a>

## Image update cadence

Azure requires that the publishers of the endorsed Linux distributions regularly update their images in Azure Marketplace with the latest patches and security fixes, at a quarterly or faster cadence. Updated images in the Marketplace are available automatically to customers as new versions of an image SKU. More information about how to find Linux images: [Find Linux VM images in Azure Marketplace](#).

## Azure-tuned kernels

Azure works closely with various endorsed Linux distributions to optimize the images that they published to Azure Marketplace. One aspect of this collaboration is the development of "tuned" Linux kernels that are optimized for the Azure platform and delivered as fully supported components of the Linux distribution. The Azure-Tuned kernels incorporate new features and performance improvements, and at a faster (typically quarterly) cadence compared to the default or generic kernels that are available from the distribution.

In most cases, you will find these kernels pre-installed on the default images in Azure Marketplace so customers will immediately get the benefit of these optimized kernels. More information about these Azure-Tuned kernels can be found in the following links:

- [CentOS Azure-Tuned Kernel - Available via the CentOS Virtualization SIG](#)
- [Debian Cloud Kernel - Available with the Debian 10 and Debian 9 "backports" image on Azure](#)
- [SLES Azure-Tuned Kernel](#)
- [Ubuntu Azure-Tuned Kernel](#)
- [Flatcar Container Linux Pro](#)

## Partners

### CoreOS

CoreOS is scheduled to be [end of life](#) by May 26, 2020. Microsoft has two (2) channels of migration for CoreOS

users.

- Flatcar by Kinvolk (see the "Flatcar Container Linux by Kinvolk" entry.)
- [Fedora Core OS](#) (customers must upload their own image. Here is the [migration documentation](#)).

## **credativ**

<https://www.creativ.de/en/portfolio/support/open-source-support-center/>

credativ is an independent consulting and services company that specializes in the development and implementation of professional solutions by using free software. As leading open-source specialists, creditativ has international recognition with many IT departments that use their support. In conjunction with Microsoft, creditativ is preparing Debian images. The images are specially designed to run on Azure and can be easily managed via the platform. creditativ will also support the long-term maintenance and updating of the Debian images for Azure through its Open Source Support Centers.

## **Kinvolk**

<https://www.flatcar-linux.org/>

Kinvolk is the team behind Flatcar Container Linux, continuing the original CoreOS vision for a minimal, immutable, and auto-updating foundation for containerized applications. As a minimal distro, Flatcar contains just those packages required for deploying containers. Its immutable file system guarantees consistency and security, while its auto-update capabilities, enable you to be always up-to-date with the latest security fixes. Kinvolk was [acquired by Microsoft](#) in April 2021 and, post-acquisition, continues its mission to support the Flatcar Container Linux community.

## **Oracle**

<https://www.oracle.com/technetwork/topics/cloud/faq-1963009.html>

Oracle's strategy is to offer a broad portfolio of solutions for public and private clouds. The strategy gives customers choice and flexibility in how they deploy Oracle software in Oracle clouds and other clouds. Oracle's partnership with Microsoft enables customers to deploy Oracle software in Microsoft public and private clouds with the confidence of certification and support from Oracle. Oracle's commitment and investment in Oracle public and private cloud solutions is unchanged.

## **Red Hat**

<https://www.redhat.com/en/partners/strategic-alliance/microsoft>

The world's leading provider of open-source solutions, Red Hat helps more than 90% of Fortune 500 companies solve business challenges, align their IT and business strategies, and prepare for the future of technology. Red Hat achieves this by providing secure solutions through an open business model and an affordable, predictable subscription model.

## **SUSE**

<https://www.suse.com/suse-linux-enterprise-server-on-azure>

SUSE Linux Enterprise Server on Azure is a proven platform that provides superior reliability and security for cloud computing. SUSE's versatile Linux platform seamlessly integrates with Azure cloud services to deliver an easily manageable cloud environment. With more than 9,200 certified applications from more than 1,800 independent software vendors for SUSE Linux Enterprise Server, SUSE ensures that workloads running supported in the data center can be confidently deployed on Azure.

## **Canonical**

<https://www.ubuntu.com/cloud/azure>

Canonical engineering and open community governance drive Ubuntu's success in client, server, and cloud computing, which includes personal cloud services for consumers. Canonical's vision of a unified, free platform

in Ubuntu, from phone to cloud, provides a family of coherent interfaces for the phone, tablet, TV, and desktop. This vision makes Ubuntu the first choice for diverse institutions from public cloud providers to the makers of consumer electronics and a favorite among individual technologists.

With developers and engineering centers around the world, Canonical is uniquely positioned to partner with hardware makers, content providers, and software developers to bring Ubuntu solutions to market for PCs, servers, and handheld devices.

# Information for community supported and non-endorsed distributions

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The Azure platform SLA applies to virtual machines running the Linux OS only when one of the [endorsed distributions](#) is used. For these endorsed distributions, pre-configured Linux images are provided in the Azure Marketplace.

- [Linux on Azure - Endorsed Distributions](#)
- [Support for Linux images in Microsoft Azure](#)

All other, non-Azure Marketplace, distributions running on Azure have a number of prerequisites. This article can't be comprehensive, as every distribution is different. Even if you meet all the criteria below, you may need to significantly tweak your Linux system for it to run properly.

This article focuses on general guidance for running your Linux distribution on Azure.

## General Linux Installation Notes

1. The Hyper-V virtual hard disk (VHDX) format isn't supported in Azure, only *fixed VHD*. You can convert the disk to VHD format using Hyper-V Manager or the [Convert-VHD](#) cmdlet. If you're using VirtualBox, select **Fixed size** rather than the default (dynamically allocated) when creating the disk.
2. Azure supports Gen1 (BIOS boot) & Gen2 (UEFI boot) Virtual machines.
3. The maximum size allowed for the VHD is 1,023 GB.
4. When installing the Linux system we recommend that you use standard partitions, rather than Logical Volume Manager (LVM) which is the default for many installations. Using standard partitions will avoid LVM name conflicts with cloned VMs, particularly if an OS disk is ever attached to another identical VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks.
5. Kernel support for mounting UDF file systems is necessary. At first boot on Azure the provisioning configuration is passed to the Linux VM by using UDF-formatted media that is attached to the guest. The Azure Linux agent must mount the UDF file system to read its configuration and provision the VM.
6. Linux kernel versions earlier than 2.6.37 don't support NUMA on Hyper-V with larger VM sizes. This issue primarily impacts older distributions using the upstream Red Hat 2.6.32 kernel, and was fixed in Red Hat Enterprise Linux (RHEL) 6.6 (kernel-2.6.32-504). Systems running custom kernels older than 2.6.37, or RHEL-based kernels older than 2.6.32-504 must set the boot parameter `numa=off` on the kernel command line in grub.conf. For more information, see [Red Hat KB 436883](#).
7. Don't configure a swap partition on the OS disk. The Linux agent can be configured to create a swap file on the temporary resource disk, as described in the following steps.
8. All VHDs on Azure must have a virtual size aligned to 1 MB ( $1024 \times 1024$  bytes). When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1 MB before conversion, as described in the following steps.
9. Use the most up-to-date distribution version, packages, and software.

10. Remove users and system accounts, public keys, sensitive data, unnecessary software and application.

## Installing kernel modules without Hyper-V

Azure runs on the Hyper-V hypervisor, so Linux requires certain kernel modules to run in Azure. If you have a VM that was created outside of Hyper-V, the Linux installers may not include the drivers for Hyper-V in the initial ramdisk (initrd or initramfs), unless the VM detects that it's running on a Hyper-V environment. When using a different virtualization system (such as VirtualBox, KVM, and so on) to prepare your Linux image, you may need to rebuild the initrd so that at least the hv\_vmbus and hv\_storvsc kernel modules are available on the initial ramdisk. This known issue is for systems based on the upstream Red Hat distribution, and possibly others.

The mechanism for rebuilding the initrd or initramfs image may vary depending on the distribution. Consult your distribution's documentation or support for the proper procedure. Here is one example for rebuilding the initrd by using the `mkinitrd` utility:

1. Back up the existing initrd image:

```
cd /boot  
sudo cp initrd-`uname -r`.img initrd-`uname -r`.img.bak
```

2. Rebuild the `initrd` with the `hv_vmbus` and `hv_storvsc` kernel modules:

```
sudo mkinitrd --preload=hv_storvsc --preload=hv_vmbus -v -f initrd-`uname -r`.img `uname -r`
```

## Resizing VHDs

VHD images on Azure must have a virtual size aligned to 1 MB. Typically, VHDs created using Hyper-V are aligned correctly. If the VHD isn't aligned correctly, you may receive an error message similar to the following when you try to create an image from your VHD.

```
The VHD http://<mystorageaccount>.blob.core.windows.net/vhds/MyLinuxVM.vhd has an unsupported virtual size of 21475270656 bytes. The size must be a whole number (in MBs).
```

In this case, resize the VM using either the Hyper-V Manager console or the [Resize-VHD](#) PowerShell cmdlet. If you aren't running in a Windows environment, we recommend using `qemu-img` to convert (if needed) and resize the VHD.

### NOTE

There is a [known bug in qemu-img](#) versions >=2.2.1 that results in an improperly formatted VHD. The issue has been fixed in QEMU 2.6. We recommend using either `qemu-img` 2.2.0 or lower, or 2.6 or higher.

1. Resizing the VHD directly using tools such as `qemu-img` or `vbox-manage` may result in an unbootable VHD. We recommend first converting the VHD to a RAW disk image. If the VM image was created as a RAW disk image (the default for some hypervisors such as KVM), then you may skip this step.

```
qemu-img convert -f vpc -O raw MyLinuxVM.vhd MyLinuxVM.raw
```

2. Calculate the required size of the disk image so that the virtual size is aligned to 1 MB. The following bash shell script uses `qemu-img info` to determine the virtual size of the disk image, and then calculates the size to the next 1 MB.

```

rawdisk="MyLinuxVM.raw"
vhddisk="MyLinuxVM.vhd"

MB=$((1024*1024))
size=$(qemu-img info -f raw --output json "$rawdisk" | \
gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

rounded_size=$((($size+$MB-1)/$MB)*$MB)

echo "Rounded Size = $rounded_size"

```

3. Resize the raw disk using `$rounded_size` as set above.

```
qemu-img resize MyLinuxVM.raw $rounded_size
```

4. Now, convert the RAW disk back to a fixed-size VHD.

```
qemu-img convert -f raw -o subformat=fixed -O vpc MyLinuxVM.raw MyLinuxVM.vhd
```

Or, with qemu version 2.6+, include the `force_size` option.

```
qemu-img convert -f raw -o subformat=fixed,force_size -O vpc MyLinuxVM.raw MyLinuxVM.vhd
```

## Linux Kernel Requirements

The Linux Integration Services (LIS) drivers for Hyper-V and Azure are contributed directly to the upstream Linux kernel. Many distributions that include a recent Linux kernel version (such as 3.x) have these drivers available already, or otherwise provide backported versions of these drivers with their kernels. These drivers are constantly being updated in the upstream kernel with new fixes and features, so when possible we recommend running an [endorsed distribution](#) that includes these fixes and updates.

If you're running a variant of Red Hat Enterprise Linux versions 6.0 to 6.3, then you'll need to install the [latest LIS drivers for Hyper-V](#). Beginning with RHEL 6.4+ (and derivatives) the LIS drivers are already included with the kernel and so no additional installation packages are needed.

If a custom kernel is required, we recommend a recent kernel version (such as 3.8+). For distributions or vendors who maintain their own kernel, you'll need to regularly backport the LIS drivers from the upstream kernel to your custom kernel. Even if you're already running a relatively recent kernel version, we highly recommend keeping track of any upstream fixes in the LIS drivers and backport them as needed. The locations of the LIS driver source files are specified in the [MAINTAINERS](#) file in the Linux kernel source tree:

```

F:    arch/x86/include/asm/mshyperv.h
F:    arch/x86/include/uapi/asm/hyperv.h
F:    arch/x86/kernel/cpu/mshyperv.c
F:    drivers/hid/hid-hyperv.c
F:    drivers/hv/
F:    drivers/input/serio/hyperv-keyboard.c
F:    drivers/net/hyperv/
F:    drivers/scsi/storvsc_drv.c
F:    drivers/video/fbdev/hyperv_fb.c
F:    include/linux/hyperv.h
F:    tools/hv/

```

The following patches must be included in the kernel. This list can't be complete for all distributions.

- [ata\\_piix](#): defer disks to the Hyper-V drivers by default
- [storvsc](#): Account for in-transit packets in the RESET path
- [storvsc](#): avoid usage of WRITE\_SAME
- [storvsc](#): Disable WRITE SAME for RAID and virtual host adapter drivers
- [storvsc](#): NULL pointer dereference fix
- [storvsc](#): ring buffer failures may result in I/O freeze
- [scsi\\_sysfs](#): protect against double execution of \_\_scsi\_remove\_device

## The Azure Linux Agent

The [Azure Linux Agent](#) `waagent` provisions a Linux virtual machine in Azure. You can get the latest version, file issues, or submit pull requests at the [Linux Agent GitHub repo](#).

- The Linux agent is released under the Apache 2.0 license. Many distributions already provide RPM or .deb packages for the agent, and these packages can easily be installed and updated.
- The Azure Linux Agent requires Python v2.6+.
- The agent also requires the `python-pyasn1` module. Most distributions provide this module as a separate package to be installed.
- In some cases, the Azure Linux Agent may not be compatible with NetworkManager. Many of the RPM/deb packages provided by distributions configure NetworkManager as a conflict to the `waagent` package. In these cases, it will uninstall NetworkManager when you install the Linux agent package.
- The Azure Linux Agent must be at or above the [minimum supported version](#).

### NOTE

Make sure '`udf`' (cloud-init >= 21.2) and '`vfat`' modules are enable. Blocklisting the `udf` module will cause a provisioning failure and backlisting `vfat` module will cause both provisioning and boot failures. *Cloud-init < 21.2 are not affected and does not require this change.*

## General Linux System Requirements

1. Modify the kernel boot line in GRUB or GRUB2 to include the following parameters, so that all console messages are sent to the first serial port. These messages can assist Azure support with debugging any issues.

```
GRUB_CMDLINE_LINUX="rootdelay=300 console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

We also recommend *removing* the following parameters if they exist.

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot isn't useful in a cloud environment, where we want all logs sent to the serial port. The `crashkernel` option may be left configured if needed, but note that this parameter reduces the amount of available memory in the VM by at least 128 MB, which may be problematic for smaller VM sizes.

2. After you are done editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

3. Add Hyper-V modules both initrd and initramfs instructions (Dracut).

4. Rebuild initrd or initramfs **Initramfs**

```
cp /boot/initramfs-$(uname -r).img /boot/initramfs-[latest kernel version ].img.bak  
dracut -f -v /boot/initramfs-[latest kernel version ].img [depending on the version of grub]  
grub-mkconfig -o /boot/grub/grub.cfg  
grub2-mkconfig -o /boot/grub2/grub.cfg
```

## Initrd

```
mv /boot/[initrd kernel] /boot/[initrd kernel]-old  
mkinitrd /boot/initrd.img-[initrd kernel]-generic /boot/[initrd kernel]-generic-old  
update-initramfs -c -k [initrd kernel]  
update-grub
```

5. Ensure that the SSH server is installed, and configured to start at boot time. This configuration is usually the default.

6. Install the Azure Linux Agent. The Azure Linux Agent is required for provisioning a Linux image on Azure. Many distributions provide the agent as an RPM or .deb package (the package is typically called WALinuxAgent or walinuagent). The agent can also be installed manually by following the steps in the [Linux Agent Guide](#).

Install the Azure Linux Agent, cloud-init and other necessary utilities by running the following command:

### Redhat/Centos

```
sudo yum install -y [waagent] cloud-init cloud-utils-growpart gdisk hyperv-daemons
```

### Ubuntu/Debian

```
sudo apt install walinuagent cloud-init cloud-utils-growpart gdisk hyperv-daemons
```

### Suse

```
sudo zypper install python-azure-agent cloud-init cloud-utils-growpart gdisk hyperv-daemons
```

Then enable the agent and cloud-init on all distributions using:

```
sudo systemctl enable waagent.service  
sudo systemctl enable cloud-init.service
```

7. Don't create swap space on the OS disk. The Azure Linux Agent can automatically configure swap space using the local resource disk that is attached to the VM after provisioning on Azure. The local resource disk is a temporary disk, and might be emptied when the VM is deprovisioned. After installing the Azure Linux Agent, modify the following parameters in /etc/waagent.conf as needed.

```
ResourceDisk.Format=  
ResourceDisk.Filesystem=ext4  
ResourceDisk.MountPoint=/mnt/resource  
ResourceDisk.EnableSwap=  
ResourceDisk.SwapSizeMB=2048 ## NOTE: Set this to your desired size.
```

8. Configure cloud-init to handle the provisioning:

a. Configure waagent for cloud-init:

```
sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g' /etc/waagent.conf
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
```

If you are migrating a specific virtual machine and do not wish to create a generalized image, set

`Provisioning.Agent=disabled` in the `/etc/waagent.conf` config.

b. Configure mounts:

```
echo "Adding mounts and disk_setup to init stage"
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

c. Configure Azure datasource:

```
echo "Allow only Azure datasource, disable fetching network setting via IMDS"
cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
  Azure:
    apply_network_config: False
EOF
```

d. If configured, remove existing swapfile:

```
if [[ -f /mnt/resource/swapfile ]]; then
echo "Removing swapfile" #RHEL uses a swapfile by default
swapoff /mnt/resource/swapfile
rm /mnt/resource/swapfile -f
fi
```

9. Configure cloud-init logging:

```
echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

10. Swap configuration. Do not create swap space on the operating system disk. Previously, the Azure Linux Agent automatically configured swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However, this is now handled by cloud-init, you must not use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=n
ResourceDisk.EnableSwap=n
```

If you want to mount, format and create swap you can either: 1. Pass this in as a cloud-init config every time you create a VM through `customdata`. This is the recommended method. 2. Use a cloud-init directive baked into the image that will do this every time the VM is created.

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
ephemeral0:
  table_type: mbr
  layout: [66, [33, 82]]
  overwrite: True
fs_setup:
- device: ephemeral0.1
  filesystem: ext4
- device: ephemeral0.2
  filesystem: swap
mounts:
- ["ephemeral0.1", "/mnt"]
- ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-
systemd.device-timeout=2", "0", "0"]
EOF
```

```

## 11. Deprovision.

### Caution

If you are migrating a specific virtual machine and do not wish to create a generalized image, skip the deprovision step. Running the command `waagent -force -deprovision+user` will render the source machine unusable, this step is intended only to create a generalized image.

Run the following commands to deprovision the virtual machine.

```
# sudo rm -f /var/log/waagent.log
# sudo cloud-init clean
# waagent -force -deprovision+user
# rm -f ~/.bash_history
# export HISTSIZE=0
# logout
```

### NOTE

On Virtualbox you may see the following error after running `waagent -force -deprovision` that says `[Errno 5] Input/output error`. This error message is not critical and can be ignored.

## 12. Shut down the virtual machine and upload the VHD to Azure.

# Next Steps

[Create a Linux VM from a custom disk with the Azure CLI.](#)

# Prepare a CentOS-based virtual machine for Azure

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Learn to create and upload an Azure virtual hard disk (VHD) that contains a CentOS-based Linux operating system.

- [Prepare a CentOS 6.x virtual machine for Azure](#)
- [Prepare a CentOS 7.0+ virtual machine for Azure](#)

## Prerequisites

This article assumes that you have already installed a CentOS (or similar derivative) Linux operating system to a virtual hard disk. Multiple tools exist to create .vhd files, for example a virtualization solution such as Hyper-V. For instructions, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

### CentOS installation notes

- Please see also [General Linux Installation Notes](#) for more tips on preparing Linux for Azure.
- The VHDX format is not supported in Azure, only **fixed VHD**. You can convert the disk to VHD format using Hyper-V Manager or the convert-vhd cmdlet. If you are using VirtualBox this means selecting **Fixed size** as opposed to the default dynamically allocated when creating the disk.
- When installing the Linux system it is *recommended* that you use standard partitions rather than LVM (often the default for many installations). This will avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another identical VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks.
- **Kernel support for mounting UDF file systems is required.** At first boot on Azure the provisioning configuration is passed to the Linux VM via UDF-formatted media that is attached to the guest. The Azure Linux agent must be able to mount the UDF file system to read its configuration and provision the VM.
- Linux kernel versions below 2.6.37 do not support NUMA on Hyper-V with larger VM sizes. This issue primarily impacts older distributions using the upstream Red Hat 2.6.32 kernel, and was fixed in RHEL 6.6 (kernel-2.6.32-504). Systems running custom kernels older than 2.6.37, or RHEL-based kernels older than 2.6.32-504 must set the boot parameter `numa=off` on the kernel command-line in grub.conf. For more information see Red Hat [KB 436883](#).
- Do not configure a swap partition on the OS disk. More information about this can be found in the steps below.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1MB before conversion. See [Linux Installation Notes](#) for more information.

## CentOS 6.x

1. In Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open a console window for the virtual machine.
3. In CentOS 6, NetworkManager can interfere with the Azure Linux agent. Uninstall this package by running the following command:

```
sudo rpm -e --nodeps NetworkManager
```

4. Create or edit the file `/etc/sysconfig/network` and add the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

5. Create or edit the file `/etc/sysconfig/network-scripts/ifcfg-eth0` and add the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no
```

6. Modify udev rules to avoid generating static rules for the Ethernet interface(s). These rules can cause problems when cloning a virtual machine in Microsoft Azure or Hyper-V:

```
sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules  
sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure the network service will start at boot time by running the following command:

```
sudo chkconfig network on
```

8. If you would like to use the OpenLogic mirrors that are hosted within the Azure datacenters, then replace the `/etc/yum.repos.d/CentOS-Base.repo` file with the following repositories. This will also add the `[openlogic]` repository that includes additional packages such as the Azure Linux agent:

```

[openlogic]
name=CentOS-$releasever - openlogic packages for $basearch
baseurl=http://olcentgbl.trafficmanager.net/openlogic/$releasever/openlogic/$basearch/
enabled=1
gpgcheck=0

[base]
name=CentOS-$releasever - Base
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/os/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#released updates
[updates]
name=CentOS-$releasever - Updates
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=updates&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/updates/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#additional packages that may be useful
[extras]
name=CentOS-$releasever - Extras
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=extras&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/extras/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#additional packages that extend functionality of existing packages
[centosplus]
name=CentOS-$releasever - Plus
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=centosplus&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/centosplus/$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

#contrib - packages by Centos Users
[contrib]
name=CentOS-$releasever - Contrib
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=contrib&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/contrib/$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

```

#### NOTE

The rest of this guide will assume you are using at least the `[openlogic]` repo, which will be used to install the Azure Linux agent below.

- Add the following line to `/etc/yum.conf`:

```
http_caching=packages
```

- Run the following command to clear the current yum metadata and update the system with the latest packages:

```
yum clean all
```

Unless you are creating an image for an older version of CentOS, it is recommended to update all the packages to the latest:

```
sudo yum -y update
```

A reboot may be required after running this command.

11. (Optional) Install the drivers for the Linux Integration Services (LIS).

**IMPORTANT**

The step is **required** for CentOS 6.3 and earlier, and optional for later releases.

```
sudo rpm -e hypervkvpd ## (may return error if not installed, that's OK)
sudo yum install microsoft-hyper-v
```

Alternatively, you can follow the manual installation instructions on the [LIS download page](#) to install the RPM onto your VM.

12. Install the Azure Linux Agent and dependencies. Start and enable waagent service:

```
sudo yum install python-pyasn1 WALinuxAgent
sudo service waagent start
sudo chkconfig waagent on
```

The WALinuxAgent package will remove the NetworkManager and NetworkManager-gnome packages if they were not already removed as described in step 3.

13. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure.

To do this, open `/boot/grub/menu.lst` in a text editor and ensure that the default kernel includes the following parameters:

```
console=ttyS0 earlyprintk=ttyS0 rootdelay=300
```

This will also ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

In addition to the above, it is recommended to *remove* the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. The `crashkernel` option may be left configured if desired, but note that this parameter will reduce the amount of available memory in the VM by 128MB or more, which may be problematic on the smaller VM sizes.

**IMPORTANT**

CentOS 6.5 and earlier must also set the kernel parameter `numa=off`. See Red Hat [KB 436883](#).

14. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.

15. Do not create swap space on the OS disk.

The Azure Linux Agent can automatically configure swap space using the local resource disk that is attached to the VM after provisioning on Azure. Note that the local resource disk is a *temporary* disk, and might be emptied when the VM is deprovisioned. After installing the Azure Linux Agent (see previous step), modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.EnableSwap=y
ResourceDisk.SwapSizeMB=2048 ## NOTE: set this to whatever you need it to be.
```

16. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
sudo waagent -force -deprovision+user
export HISTSIZE=0
logout
```

17. Click **Action** -> **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## CentOS 7.0+

### Changes in CentOS 7 (and similar derivatives)

Preparing a CentOS 7 virtual machine for Azure is very similar to CentOS 6, however there are several important differences worth noting:

- The NetworkManager package no longer conflicts with the Azure Linux agent. This package is installed by default and we recommend that it is not removed.
- GRUB2 is now used as the default bootloader, so the procedure for editing kernel parameters has changed (see below).
- XFS is now the default file system. The ext4 file system can still be used if desired.
- Since CentOS 8 Stream and newer no longer include `network.service` by default, you will need to install it manually:

```
sudo yum install network-scripts
sudo systemctl enable network.service
```

### Configuration Steps

1. In Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open a console window for the virtual machine.
3. Create or edit the file `/etc/sysconfig/network` and add the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

4. Create or edit the file `/etc/sysconfig/network-scripts/ifcfg-eth0` and add the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no  
NM_CONTROLLED=no
```

5. Modify udev rules to avoid generating static rules for the Ethernet interface(s). These rules can cause problems when cloning a virtual machine in Microsoft Azure or Hyper-V:

```
sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
```

6. If you would like to use the OpenLogic mirrors that are hosted within the Azure datacenters, then replace the `/etc/yum.repos.d/CentOS-Base.repo` file with the following repositories. This will also add the `[openlogic]` repository that includes packages for the Azure Linux agent:

```

[openlogic]
name=CentOS-$releasever - openlogic packages for $basearch
baseurl=http://olcentgbl.trafficmanager.net/openlogic/$releasever/openlogic/$basearch/
enabled=1
gpgcheck=0

[base]
name=CentOS-$releasever - Base
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/os/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#released updates
[updates]
name=CentOS-$releasever - Updates
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=updates&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/updates/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#additional packages that may be useful
[extras]
name=CentOS-$releasever - Extras
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=extras&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/extras/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

#additional packages that extend functionality of existing packages
[centosplus]
name=CentOS-$releasever - Plus
#mirrorlist=http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=centosplus&infra=$infra
baseurl=http://olcentgbl.trafficmanager.net/centos/$releasever/centosplus/$basearch/
gpgcheck=1
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7

```

#### NOTE

The rest of this guide will assume you are using at least the `[openlogic]` repo, which will be used to install the Azure Linux agent below.

- Run the following command to clear the current yum metadata and install any updates:

```
sudo yum clean all
```

Unless you are creating an image for an older version of CentOS, it is recommended to update all the packages to the latest:

```
sudo yum -y update
```

A reboot maybe required after running this command.

- Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this, open `/etc/default/grub` in a text editor and edit the `GRUB_CMDLINE_LINUX` parameter, for example:

```
GRUB_CMDLINE_LINUX="rootdelay=300 console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

This will also ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues. It also turns off the new CentOS 7 naming conventions for NICs. In addition to the above, it is recommended to *remove* the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. The `crashkernel` option may be left configured if desired, but note that this parameter will reduce the amount of available memory in the VM by 128MB or more, which may be problematic on the smaller VM sizes.

- Once you are done editing `/etc/default/grub` per above, run the following command to rebuild the grub configuration:

```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

- If building the image from **VMware**, **VirtualBox** or **KVM**: Ensure the Hyper-V drivers are included in the initramfs:

Edit `/etc/dracut.conf`, add content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild the initramfs:

```
sudo dracut -f -v
```

- Install the Azure Linux Agent and dependencies for Azure VM Extensions:

```
sudo yum install python-pyasn1 WALinuxAgent
sudo systemctl enable waagent
```

- Install cloud-init to handle the provisioning

```

yum install -y cloud-init cloud-utils-growpart gdisk hyperv-daemons

# Configure waagent for cloud-init
sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g' /etc/waagent.conf
sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g' /etc/waagent.conf

echo "Adding mounts and disk_setup to init stage"
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg

echo "Allow only Azure datasource, disable fetching network setting via IMDS"
cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
  Azure:
    apply_network_config: False
EOF

if [[ -f /mnt/resource/swapfile ]]; then
echo Removing swapfile - RHEL uses a swapfile by default
swapoff /mnt/resource/swapfile
rm /mnt/resource/swapfile -f
fi

echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF

```

### 13. Swap configuration Do not create swap space on the operating system disk.

Previously, the Azure Linux Agent was used automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However this is now handled by cloud-init you **must not** use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```

sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf

```

If you want mount, format and create swap you can either:

- Pass this in as a cloud-init config every time you create a VM
- Use a cloud-init directive baked into the image that will do this every time the VM is created:

```

echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
ephemeral0:
  table_type: mbr
  layout: [66, [33, 82]]
  overwrite: True
fs_setup:
- device: ephemeral0.1
  filesystem: ext4
- device: ephemeral0.2
  filesystem: swap
mounts:
- ["ephemeral0.1", "/mnt"]
- ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-
systemd.device-timeout=2", "0", "0"]
EOF

```

14. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

**Note:** if you are migrating a specific virtual machine and do not wish to create a generalized image, skip the deprovision step

```

# sudo rm -f /var/log/waagent.log
# sudo cloud-init clean
# waagent -force -deprovision+user
# rm -f ~/.bash_history
# export HISTSIZE=0
# logout

```

15. Click Action -> **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## Next steps

You're now ready to use your CentOS Linux virtual hard disk to create new virtual machines in Azure. If this is the first time that you're uploading the .vhd file to Azure, see [Create a Linux VM from a custom disk](#).

# Prepare a Debian VHD for Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

## Prerequisites

This section assumes that you have already installed a Debian Linux operating system from an .iso file downloaded from the [Debian website](#) to a virtual hard disk. Multiple tools exist to create .vhd files; Hyper-V is only one example. For instructions using Hyper-V, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

## Installation notes

- See also [General Linux Installation Notes](#) for more tips on preparing Linux for Azure.
- The newer VHDX format is not supported in Azure. You can convert the disk to VHD format using Hyper-V Manager or the `convert-vhd` cmdlet.
- When installing the Linux system, it is recommended that you use standard partitions rather than LVM (often the default for many installations). This will avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks if preferred.
- Do not configure a swap partition on the OS disk. The Azure Linux agent can be configured to create a swap file on the temporary resource disk. More information can be found in the steps below.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD, you must ensure that the raw disk size is a multiple of 1MB before conversion. For more information, see [Linux Installation Notes](#).

## Use Azure-Manage to create Debian VHDs

There are tools available for generating Debian VHDs for Azure, such as the `azure-manage` scripts from [Credativ](#). This is the recommended approach versus creating an image from scratch. For example, to create a Debian 8 VHD run the following commands to download the `azure-manage` utility (and dependencies) and run the `azure_build_image` script:

```
# sudo apt-get update
# sudo apt-get install git qemu-utils mbr kpartx debootstrap

# sudo apt-get install python3-pip python3-dateutil python3-cryptography
# sudo pip3 install azure-storage azure-servicemanagement-legacy azure-common pytest pyyaml
# git clone https://github.com/credativ/azure-manage.git
# cd azure-manage
# sudo pip3 install .

# sudo azure_build_image --option release=jessie --option image_size_gb=30 --option image_prefix=debian-jessie-azure section
```

## Prepare a Debian image for Azure

You can create the base Azure Debian Cloud image with the [FAI cloud image builder](#).

(The following git clone and apt install commands were pulled from the Debian Cloud Images repo) Start by cloning the repo and installing dependencies:

```
$ git clone https://salsa.debian.org/cloud-team/debian-cloud-images.git
$ sudo apt install --no-install-recommends ca-certificates debsums dosfstools \
    fai-server fai-setup-storage make python3 python3-libcloud python3-marshmallow \
    python3-pytest python3-yaml qemu-utils udev
$ cd ./debian-cloud-images
```

(Optional) Customize the build by adding scripts (e.g. shell scripts) to `./config_space/scripts/AZURE`.

An example of a script to customize the image is:

```
$ mkdir -p ./config_space/scripts/AZURE
$ cat > ./config_space/scripts/AZURE/10-custom <<EOF
#!/bin/bash

\$ROOTCMD bash -c "echo test > /usr/local/share/testing"
EOF
$ sudo chmod 755 ./config_space/scripts/AZURE/10-custom
```

Note that it is important to prefix any commands you want to have customizing the image with `\$ROOTCMD` as this is aliased as `chroot $target`.

Build the Azure Debian 10 image:

```
$ make image_buster_azure_amd64
```

This will output a handful of files in the current directory, most notably the `image_buster_azure_amd64.raw` image file.

To convert the raw image to VHD for Azure, you can do the following:

```
rawdisk="image_buster_azure_amd64.raw"
vhddisk="image_buster_azure_amd64.vhd"

MB=$((1024*1024))
size=$(qemu-img info -f raw --output json "$rawdisk" | \
gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

rounded_size=$(((($size+$MB-1)/$MB)*$MB))
rounded_size_adjusted=$((rounded_size + 512))

echo "Rounded Size Adjusted = $rounded_size_adjusted"

sudo qemu-img resize "$rawdisk" $rounded_size
qemu-img convert -f raw -o subformat=fixed,force_size -O vpc "$rawdisk" "$vhddisk"
```

This creates a VHD `image_buster_azure_amd64.vhd` with a rounded size to be able to copy it successfully to an Azure Disk.

Now we need to create the Azure resources for this image (this uses the `$rounded_size_adjusted` variable, so it should be from within the same shell process from above).

```

az group create -l $LOCATION -n $RG

az disk create \
    -n $DISK \
    -g $RG \
    -l $LOCATION \
    --for-upload --upload-size-bytes "$rounded_size_adjusted" \
    --sku standard_lrs --hyper-v-generation V1

ACCESS=$(az disk grant-access \
    -n $DISK -g $RG \
    --access-level write \
    --duration-in-seconds 86400 \
    --query accessSas -o tsv)

azcopy copy "$vhddisk" "$ACCESS" --blob-type PageBlob

az disk revoke-access -n $DISK -g $RG
az image create \
    -g $RG \
    -n $IMAGE \
    --os-type linux \
    --source $(az disk show \
        -g $RG \
        -n $DISK \
        --query id -o tsv)
az vm create \
    -g $RG \
    -n $VM \
    --ssh-key-value $SSH_KEY_VALUE \
    --public-ip-address-dns-name $VM \
    --image $(az image show \
        -g $RG \
        -n $IMAGE \
        --query id -o tsv)

```

#### NOTE

If the bandwidth from your local machine to the Azure Disk is causing a long time to process the upload with azcopy, you can use an Azure VM jumpbox to speed up the process. Here's how this can be done:

1. Create a tarball of the VHD on your local machine:

```
tar -czvf ./image_buster_azure_amd64.vhd.tar.gz ./image_buster_azure_amd64.vhd .
```

2. Create an Azure Linux VM (distro of your choice). Make sure that you create it with a large enough disk to hold the extracted VHD!
3. Download the azcopy utility to the Azure Linux VM. It can be retrieved from [here](#).
4. Copy the tarball to the VM: 

```
scp ./image_buster_azure_amd64.vhd.tar.gz <vm>:~ .
```
5. On the VM, extract the VHD: 

```
tar -xf ./image_buster_azure_amd64.vhd.tar.gz
```

 (this will take a bit of time given the size of the file).
6. Finally on the VM, copy the VHD to the Azure Disk with `azcopy` (the command from above).

**Next steps:** You're now ready to use your Debian Linux virtual hard disk to create new virtual machines in Azure. If this is the first time that you're uploading the .vhd file to Azure, see [Create a Linux VM from a custom disk](#).

# Using a prebuilt Flatcar image for Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You can download prebuilt Azure virtual hard disk images of Flatcar Container Linux for each of the Flatcar supported channels:

- [stable](#)
- [beta](#)
- [alpha](#)
- [LTS](#)

This image is already fully set up and optimized to run on Azure. You only need to decompress it.

## Building your own Flatcar-based virtual machine for Azure

Alternatively, you can choose to build your own Flatcar Container Linux image.

On any linux based machine, follow the instructions detailed in the [Flatcar Container Linux developer SDK guide](#).

When running the `image_to_vm.sh` script, make sure you pass `--format=azure` to create an Azure virtual hard disk.

## Next steps

Once you have the .vhd file, you can use the resulting file to create new virtual machines in Azure. If this is the first time that you're uploading a .vhd file to Azure, see [Create a Linux VM from a custom disk](#).

# Introduction to FreeBSD on Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article provides an overview of running a FreeBSD virtual machine in Azure.

## Overview

FreeBSD for Microsoft Azure is an advanced computer operating system used to power modern servers, desktops, and embedded platforms.

Microsoft Corporation is making images of FreeBSD available on Azure with the [Azure VM Guest Agent](#) pre-configured. Currently, the following FreeBSD versions are offered as images by Microsoft:

- FreeBSD 10.4 on the Azure Marketplace
- FreeBSD 11.2 on the Azure Marketplace
- FreeBSD 11.3 on the Azure Marketplace
- FreeBSD 12.0 on the Azure Marketplace

The following FreeBSD versions also include the [Azure VM Guest Agent](#), however, they are offered as images by the FreeBSD Foundation:

- FreeBSD 11.4 on the Azure Marketplace
- FreeBSD 12.2 on the Azure Marketplace
- FreeBSD 13.0 on the Azure Marketplace

The agent is responsible for communication between the FreeBSD VM and the Azure fabric for operations such as provisioning the VM on first use (user name, password or SSH key, host name, etc.) and enabling functionality for selective VM extensions.

As for future versions of FreeBSD, the strategy is to stay current and make the latest releases available shortly after they are published by the FreeBSD release engineering team.

### Create a FreeBSD VM through Azure CLI on FreeBSD

First you need to install [Azure CLI](#) though following command on a FreeBSD machine.

```
curl -L https://aka.ms/InstallAzureCli | bash
```

If bash is not installed on your FreeBSD machine, run following command before the installation.

```
sudo pkg install bash
```

If Python is not installed on your FreeBSD machine, run following commands before the installation.

```
sudo pkg install python38
cd /usr/local/bin
sudo rm /usr/local/bin/python
sudo ln -s /usr/local/bin/python3.8 /usr/local/bin/python
```

During the installation, you are asked

Modify profile to update your \$PATH and enable shell/tab completion now? (Y/n) . If you answer `y` and enter `/etc/rc.conf` as a path to an rc file to update , you may meet the problem

ERROR: [Errno 13] Permission denied . To resolve this problem, you should grant the write right to current user against the file `/etc/rc.conf` .

Now you can sign in to Azure and create your FreeBSD VM. Below is an example to create a FreeBSD 11.0 VM. You can also add the parameter `--public-ip-address-dns-name` with a globally unique DNS name for a newly created Public IP.

```
az login
az group create --name myResourceGroup --location eastus
az vm create --name myFreeBSD11 \
    --resource-group myResourceGroup \
    --image MicrosoftOSTC:FreeBSD:11.0:latest \
    --admin-username azureuser \
    --generate-ssh-keys
```

Then you can sign in to your FreeBSD VM through the ip address that printed in the output of above deployment.

```
ssh azureuser@xx.xx.xx.xx -i /etc/ssh/ssh_host_rsa_key
```

## VM extensions for FreeBSD

Following are supported VM extensions in FreeBSD.

### VMAccess

The [VMAccess](#) extension can:

- Reset the password of the original sudo user.
- Create a new sudo user with the password specified.
- Set the public host key with the key given.
- Reset the public host key provided during VM provisioning if the host key is not provided.
- Open the SSH port (22) and restore the `sshd_config` if `reset_ssh` is set to true.
- Remove the existing user.
- Check disks.
- Repair an added disk.

### CustomScript

The [CustomScript](#) extension can:

- If provided, download the customized scripts from Azure Storage or external public storage (for example, GitHub).
- Run the entry point script.
- Support inline commands.
- Convert Windows-style newline in shell and Python scripts automatically.
- Remove BOM in shell and Python scripts automatically.
- Protect sensitive data in `CommandToExecute`.

#### NOTE

FreeBSD VM only supports CustomScript version 1.x by now.

## Authentication: user names, passwords, and SSH keys

When you're creating a FreeBSD virtual machine by using the Azure portal, you must provide a user name, password, or SSH public key. User names for deploying a FreeBSD virtual machine on Azure must not match names of system accounts (UID < 100) already present in the virtual machine ("root", for example). Currently, only the RSA SSH key is supported. A multiline SSH key must begin with `----- BEGIN SSH2 PUBLIC KEY -----` and end with `----- END SSH2 PUBLIC KEY -----`.

## Obtaining superuser privileges

The user account that is specified during virtual machine instance deployment on Azure is a privileged account. The package of sudo was installed in the published FreeBSD image. After you're logged in through this user account, you can run commands as root by using the command syntax.

```
$ sudo <COMMAND>
```

You can optionally obtain a root shell by using `sudo -s`.

## Known issues

The [Azure VM Guest Agent](#) version 2.2.2 has a [known issue](#) that causes the provision failure for FreeBSD VM on Azure. The fix was captured by [Azure VM Guest Agent](#) version 2.2.3 and later releases.

## Next steps

- Go to [Azure Marketplace](#) to create a FreeBSD VM.

# Prepare an Oracle Linux virtual machine for Azure

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article assumes that you have already installed an Oracle Linux operating system to a virtual hard disk. Multiple tools exist to create .vhdx files, for example a virtualization solution such as Hyper-V. For instructions, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

## Oracle Linux installation notes

- Please see also [General Linux Installation Notes](#) for more tips on preparing Linux for Azure.
- Hyper-V and Azure support Oracle Linux with either the Unbreakable Enterprise Kernel (UEK) or the Red Hat Compatible Kernel.
- Oracle's UEK2 is not supported on Hyper-V and Azure as it does not include the required drivers.
- The VHDX format is not supported in Azure, only **fixed VHD**. You can convert the disk to VHD format using Hyper-V Manager or the convert-vhd cmdlet.
- **Kernel support for mounting UDF file systems is required.** At first boot on Azure the provisioning configuration is passed to the Linux VM via UDF-formatted media that is attached to the guest. The Azure Linux agent must be able to mount the UDF file system to read its configuration and provision the VM.
- When installing the Linux system it is recommended that you use standard partitions rather than LVM (often the default for many installations). This will avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks if preferred.
- Linux kernel versions earlier than 2.6.37 don't support NUMA on Hyper-V with larger VM sizes. This issue primarily impacts older distributions using the upstream Red Hat 2.6.32 kernel, and was fixed in Oracle Linux 6.6 and later
- Do not configure a swap partition on the OS disk. More information about this can be found in the steps below.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1MB before conversion. See [Linux Installation Notes](#) for more information.
- Make sure that the `Addons` repository is enabled. Edit the file `/etc/yum.repos.d/public-yum-ol6.repo` (Oracle Linux 6) or `/etc/yum.repos.d/public-yum-ol7.repo` (Oracle Linux 7), and change the line `enabled=0` to `enabled=1` under `[ol6_addons]` or `[ol7_addons]` in this file.

## Oracle Linux 6.4 and later

You must complete specific configuration steps in the operating system for the virtual machine to run in Azure.

1. In the center pane of Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open the window for the virtual machine.
3. Uninstall NetworkManager by running the following command:

```
# sudo rpm -e --nodeps NetworkManager
```

**Note:** If the package is not already installed, this command will fail with an error message. This is

expected.

4. Create a file named **network** in the `/etc/sysconfig/` directory that contains the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

5. Create a file named **ifcfg-eth0** in the `/etc/sysconfig/network-scripts/` directory that contains the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no
```

6. Modify udev rules to avoid generating static rules for the Ethernet interface(s). These rules can cause problems when cloning a virtual machine in Microsoft Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules  
# sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure the network service will start at boot time by running the following command:

```
# chkconfig network on
```

8. Install `python-pyasn1` by running the following command:

```
# sudo yum install python-pyasn1
```

9. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this open `/boot/grub/menu.lst` in a text editor and ensure that the kernel includes the following parameters:

```
console=ttyS0 earlyprintk=ttyS0
```

This will ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

In addition to the above, it is recommended to *remove* the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port.

The `crashkernel` option may be left configured if desired, but note that this parameter will reduce the amount of available memory in the VM by 128MB or more, which may be problematic on the smaller VM sizes.

10. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.

11. Install the Azure Linux Agent by running the following command. The latest version is 2.0.15.

```
# sudo yum install WALinuxAgent
```

Note that installing the WALinuxAgent package will remove the NetworkManager and NetworkManager-gnome packages if they were not already removed as described in step 2.

12. Do not create swap space on the OS disk.

The Azure Linux Agent can automatically configure swap space using the local resource disk that is attached to the VM after provisioning on Azure. Note that the local resource disk is a *temporary* disk, and might be emptied when the VM is deprovisioned. After installing the Azure Linux Agent (see previous step), modify the following parameters in /etc/waagent.conf appropriately:

```
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.EnableSwap=y
ResourceDisk.SwapSizeMB=2048    ## NOTE: set this to whatever you need it to be.
```

13. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# sudo waagent -force -deprovision
# export HISTSIZE=0
# logout
```

14. Click Action -> Shut Down in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## Oracle Linux 7.0 and later

### Changes in Oracle Linux 7

Preparing an Oracle Linux 7 virtual machine for Azure is very similar to Oracle Linux 6, however there are several important differences worth noting:

- Azure supports Oracle Linux with either the Unbreakable Enterprise Kernel (UEK) or the Red Hat Compatible Kernel. Oracle Linux with UEK is recommended.
- The NetworkManager package no longer conflicts with the Azure Linux agent. This package is installed by default and we recommend that it is not removed.
- GRUB2 is now used as the default bootloader, so the procedure for editing kernel parameters has changed (see below).
- XFS is now the default file system. The ext4 file system can still be used if desired.

### Configuration steps

1. In Hyper-V Manager, select the virtual machine.
2. Click Connect to open a console window for the virtual machine.
3. Create a file named **network** in the `/etc/sysconfig/` directory that contains the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

4. Create a file named `ifcfg-eth0` in the `/etc/sysconfig/network-scripts/` directory that contains the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no
```

5. Modify udev rules to avoid generating static rules for the Ethernet interface(s). These rules can cause problems when cloning a virtual machine in Microsoft Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
```

6. Ensure the network service will start at boot time by running the following command:

```
# sudo chkconfig network on
```

7. Install the `python-pyasn1` package by running the following command:

```
# sudo yum install python-pyasn1
```

8. Run the following command to clear the current yum metadata and install any updates:

```
# sudo yum clean all  
# sudo yum -y update
```

9. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this open `/etc/default/grub` in a text editor and edit the `GRUB_CMDLINE_LINUX` parameter, for example:

```
GRUB_CMDLINE_LINUX="console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

This will also ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues. It also turns off the naming conventions for NICs in Oracle Linux 7 with the Unbreakable Enterprise Kernel. In addition to the above, it is recommended to *remove* the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port.

The `crashkernel` option may be left configured if desired, but note that this parameter will reduce the amount of available memory in the VM by 128MB or more, which may be problematic on the smaller VM sizes.

10. Once you are done editing "/etc/default/grub" per above, run the following command to rebuild the grub configuration:

```
# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

11. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.

12. Install the Azure Linux Agent and dependencies:

```
sudo yum install WALinuxAgent  
sudo systemctl enable waagent
```

13. Install cloud-init to handle the provisioning

```
yum install -y cloud-init cloud-utils-growpart gdisk hyperv-daemons

# Configure waagent for cloud-init
sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g' /etc/waagent.conf
sed -i 's/Provisioning.Enabled=n/Provisioning.Enabled=y/g' /etc/waagent.conf

echo "Adding mounts and disk_setup to init stage"
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg

echo "Allow only Azure datasource, disable fetching network setting via IMDS"
cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
    Azure:
        apply_network_config: False
EOF

if [[ -f /mnt/resource/swapfile ]]; then
echo Removing swapfile - RHEL uses a swapfile by default
swapoff /mnt/resource/swapfile
rm /mnt/resource/swapfile -f
fi

echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

14. Swap configuration Do not create swap space on the operating system disk.

Previously, the Azure Linux Agent was used automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However this is now handled by cloud-init, you **must not** use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
```

If you want mount, format and create swap you can either:

- Pass this in as a cloud-init config every time you create a VM
- Use a cloud-init directive baked into the image that will do this every time the VM is created:

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-
systemd.device-timeout=2", "0", "0"]
EOF
```

15. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

**Note:** if you are migrating a specific virtual machine and do not wish to create a generalized image, skip the deprovision step

```
# sudo cloud-init clean
# sudo rm -f /var/log/waagent.log

# waagent -force -deprovision+user
# rm -f ~/.bash_history

# export HISTSIZE=0

# logout
```

16. Click Action -> **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## Next steps

You're now ready to use your Oracle Linux .vhd to create new virtual machines in Azure. If this is the first time that you're uploading the .vhd file to Azure, see [Create a Linux VM from a custom disk](#).

# Create and Upload an OpenBSD disk image to Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to create and upload a virtual hard disk (VHD) that contains the OpenBSD operating system. After you upload it, you can use it as your own image to create a virtual machine (VM) in Azure through Azure CLI.

## Prerequisites

This article assumes that you have the following items:

- **An Azure subscription** - If you don't have an account, you can create one in just a couple of minutes. If you have an MSDN subscription, see [Monthly Azure credit for Visual Studio subscribers](#). Otherwise, learn how to [create a free trial account](#).
- **Azure CLI** - Make sure you have the latest [Azure CLI](#) installed and logged in to your Azure account with [az login](#).
- **OpenBSD operating system installed in a .vhd file** - A supported OpenBSD operating system ([6.6 version AMD64](#)) must be installed to a virtual hard disk. Multiple tools exist to create .vhd files. For example, you can use a virtualization solution such as Hyper-V to create the .vhd file and install the operating system. For instructions about how to install and use Hyper-V, see [Install Hyper-V and create a virtual machine](#).

## Prepare OpenBSD image for Azure

On the VM where you installed the OpenBSD operating system 6.1, which added Hyper-V support, complete the following procedures:

1. If DHCP is not enabled during installation, enable the service as follows:

```
echo dhcp > /etc/hostname.hvn0
```

2. Set up a serial console as follows:

```
echo "stty com0 115200" >> /etc/boot.conf
echo "set tty com0" >> /etc/boot.conf
```

3. Configure Package installation as follows:

```
echo "https://ftp.openbsd.org/pub/OpenBSD" > /etc/installurl
```

4. By default, the `root` user is disabled on virtual machines in Azure. Users can run commands with elevated privileges by using the `doas` command on OpenBSD VM. Doas is enabled by default. For more information, see [doas.conf](#).
5. Install and configure prerequisites for the Azure Agent as follows:

```
pkg_add py-setuptools openssl git
ln -sf /usr/local/bin/python2.7 /usr/local/bin/python
ln -sf /usr/local/bin/python2.7-2to3 /usr/local/bin/2to3
ln -sf /usr/local/bin/python2.7-config /usr/local/bin/python-config
ln -sf /usr/local/bin/pydoc2.7 /usr/local/bin/pydoc
```

6. The latest release of the Azure agent can always be found on [GitHub](#). Install the agent as follows:

```
git clone https://github.com/Azure/WALinuxAgent
cd WALinuxAgent
python setup.py install
waagent -register-service
```

#### IMPORTANT

After you install Azure Agent, it's a good idea to verify that it's running as follows:

```
ps auxw | grep waagent
root      79309  0.0  1.5  9184 15356 p1  S      4:11PM   0:00.46 python /usr/local/sbin/waagent
-daemon (python2.7)
cat /var/log/waagent.log
```

7. Deprovision the system to clean it and make it suitable for reprovisioning. The following command also deletes the last provisioned user account and the associated data:

```
waagent -deprovision+user -force
```

Now you can shut down your VM.

## Prepare the VHD

The VHDX format is not supported in Azure, only **fixed VHD**. You can convert the disk to fixed VHD format using Hyper-V Manager or the PowerShell `convert-vhd` cmdlet. An example is as following.

```
Convert-VHD OpenBSD61.vhdx OpenBSD61.vhd -VHDTType Fixed
```

## Create storage resources and upload

First, create a resource group with `az group create`. The following example creates a resource group named `myResourceGroup` in the `eastus` location:

```
az group create --name myResourceGroup --location eastus
```

To upload your VHD, create a storage account with `az storage account create`. Storage account names must be unique, so provide your own name. The following example creates a storage account named `mystorageaccount`.

```
az storage account create --resource-group myResourceGroup \
--name mystorageaccount \
--location eastus \
--sku Premium_LRS
```

To control access to the storage account, obtain the storage key with [az storage account keys list](#) as follows:

```
STORAGE_KEY=$(az storage account keys list \
--resource-group myResourceGroup \
--account-name mystorageaccount \
--query "[?keyName=='key1'] | [0].value" -o tsv)
```

To logically separate the VHDs you upload, create a container within the storage account with [az storage container create](#):

```
az storage container create \
--name vhds \
--account-name mystorageaccount \
--account-key ${STORAGE_KEY}
```

Finally, upload your VHD with [az storage blob upload](#) as follows:

```
az storage blob upload \
--container-name vhds \
--file ./OpenBSD61.vhd \
--name OpenBSD61.vhd \
--account-name mystorageaccount \
--account-key ${STORAGE_KEY}
```

## Create VM from your VHD

You can create a VM with a [sample script](#) or directly with [az vm create](#). To specify the OpenBSD VHD you uploaded, use the `--image` parameter as follows:

```
az vm create \
--resource-group myResourceGroup \
--name myOpenBSD61 \
--image "https://mystorageaccount.blob.core.windows.net/vhds/OpenBSD61.vhd" \
--os-type linux \
--admin-username azureuser \
--ssh-key-value ~/.ssh/id_rsa.pub
```

Obtain the IP address for your OpenBSD VM with [az vm list-ip-addresses](#) as follows:

```
az vm list-ip-addresses --resource-group myResourceGroup --name myOpenBSD61
```

Now you can SSH to your OpenBSD VM as normal:

```
ssh azureuser@<ip address>
```

## Next steps

If you want to know more about Hyper-V support on OpenBSD6.1, read [OpenBSD 6.1](#) and [hyperv.4](#).

If you want to create a VM from managed disk, read [az disk](#).

# Prepare a Red Hat-based virtual machine for Azure

9/21/2022 • 32 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

In this article, you will learn how to prepare a Red Hat Enterprise Linux (RHEL) virtual machine for use in Azure. The versions of RHEL that are covered in this article are 6.7+ and 7.1+. The hypervisors for preparation that are covered in this article are Hyper-V, kernel-based virtual machine (KVM), and VMware. For more information about eligibility requirements for participating in Red Hat's Cloud Access program, see [Red Hat's Cloud Access website](#) and [Running RHEL on Azure](#). For ways to automate building RHEL images, see [Azure Image Builder](#).

## Hyper-V Manager

This section shows you how to prepare a [RHEL 6](#), [RHEL 7](#), or [RHEL 8](#) virtual machine using Hyper-V Manager.

### Prerequisites

This section assumes that you have already obtained an ISO file from the Red Hat website and installed the RHEL image to a virtual hard disk (VHD). For more details about how to use Hyper-V Manager to install an operating system image, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

### RHEL installation notes

- Azure does not support the VHDX format. Azure supports only fixed VHD. You can use Hyper-V Manager to convert the disk to VHD format, or you can use the convert-vhd cmdlet. If you use VirtualBox, select **Fixed size** as opposed to the default dynamically allocated option when you create the disk.
- Azure supports Gen1 (BIOS boot) & Gen2 (UEFI boot) Virtual machines.
- The maximum size that's allowed for the VHD is 1,023 GB.
- Logical Volume Manager (LVM) is supported and may be used on the OS disk or data disks in Azure virtual machines. However, in general it is recommended to use standard partitions on the OS disk rather than LVM. This practice will avoid LVM name conflicts with cloned virtual machines, particularly if you ever need to attach an operating system disk to another identical virtual machine for troubleshooting. See also [LVM](#) and [RAID](#) documentation.
- **Kernel support for mounting Universal Disk Format (UDF) file systems is required.** At first boot on Azure, the UDF-formatted media that is attached to the guest passes the provisioning configuration to the Linux virtual machine. The Azure Linux Agent must be able to mount the UDF file system to read its configuration and provision the virtual machine, without this, provisioning will fail!
- Do not configure a swap partition on the operating system disk. More information about this can be found in the following steps.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1MB before conversion. More details can be found in the steps below. See also [Linux Installation Notes](#) for more information.

### RHEL 6 using Hyper-V Manager

1. In Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open a console window for the virtual machine.
3. In RHEL 6, NetworkManager can interfere with the Azure Linux agent. Uninstall this package by running

the following command:

```
# sudo rpm -e --nodeps NetworkManager
```

4. Create or edit the `/etc/sysconfig/network` file, and add the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

5. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no
```

6. Move (or remove) the udev rules to avoid generating static rules for the Ethernet interface. These rules cause problems when you clone a virtual machine in Microsoft Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules  
  
# sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure that the network service will start at boot time by running the following command:

```
# sudo chkconfig network on
```

8. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# sudo subscription-manager register --auto-attach --username=XXX --password=XXX
```

9. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository. Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-6-server-extras-rpms
```

10. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this modification, open `/boot/grub/menu.lst` in a text editor, and ensure that the default kernel includes the following parameters:

```
console=ttyS0 earlyprintk=ttyS0
```

This will also ensure that all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

In addition, we recommended that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more. This configuration might be problematic on smaller virtual machine sizes.

11. Ensure that the secure shell (SSH) server is installed and configured to start at boot time, which is usually the default. Modify `/etc/ssh/sshd_config` to include the following line:

```
ClientAliveInterval 180
```

12. Install the Azure Linux Agent by running the following command:

```
# sudo yum install WALinuxAgent  
  
# sudo chkconfig waagent on
```

Installing the WALinuxAgent package removes the NetworkManager and NetworkManager-gnome packages if they were not already removed in step 3.

13. Do not create swap space on the operating system disk.

The Azure Linux Agent can automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. Note that the local resource disk is a temporary disk and that it might be emptied if the virtual machine is deprovisioned. After you install the Azure Linux Agent in the previous step, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=y  
ResourceDisk.Filesystem=ext4  
ResourceDisk.MountPoint=/mnt/resource  
ResourceDisk.EnableSwap=y  
ResourceDisk.SwapSizeMB=2048 ## NOTE: set this to whatever you need it to be.
```

14. Unregister the subscription (if necessary) by running the following command:

```
# sudo subscription-manager unregister
```

15. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# Note: if you are migrating a specific virtual machine and do not wish to create a generalized  
image,  
# skip the deprovision step  
# sudo waagent -force -deprovision  
  
# export HISTSIZE=0  
  
# logout
```

16. Click Action > **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## RHEL 7 using Hyper-V Manager

1. In Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open a console window for the virtual machine.
3. Create or edit the `/etc/sysconfig/network` file, and add the following text:

```
NETWORKING=yes  
HOSTNAME=localhost.localdomain
```

4. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0  
ONBOOT=yes  
BOOTPROTO=dhcp  
TYPE=Ethernet  
USERCTL=no  
PEERDNS=yes  
IPV6INIT=no  
PERSISTENT_DHCLIENT=yes  
NM_CONTROLLED=yes
```

5. Ensure that the network service will start at boot time by running the following command:

```
# sudo systemctl enable network
```

6. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# sudo subscription-manager register --auto-attach --username=XXX --password=XXX
```

7. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure.

To do this modification, open `/etc/default/grub` in a text editor, and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

```
GRUB_CMDLINE_LINUX="console=tty1 console=ttyS0,115200n8 earlyprintk=ttyS0,115200 earlyprintk=ttyS0  
net.ifnames=0"  
GRUB_TERMINAL_OUTPUT="serial console"  
GRUB_SERIAL_COMMAND="serial --speed=115200 --unit=0 --word=8 --parity=no --stop=1"
```

This will also ensure that all console messages are sent to the first serial port and enable interaction with the serial console, which can assist Azure support with debugging issues. This configuration also turns off the new RHEL 7 naming conventions for NICs.

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

8. After you are done editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```
# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

#### NOTE

If uploading an UEFI enabled VM, the command to update grub is

```
grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg .
```

9. Ensure that the SSH server is installed and configured to start at boot time, which is usually the default.

Modify `/etc/ssh/sshd_config` to include the following line:

```
ClientAliveInterval 180
```

10. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository.

Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-7-server-extras-rpms
```

11. Install the Azure Linux Agent, cloud-init and other necessary utilities by running the following command:

```
# sudo yum install -y WALinuxAgent cloud-init cloud-utils-growpart gdisk hyperv-daemons  
  
# sudo systemctl enable waagent.service  
# sudo systemctl enable cloud-init.service
```

12. Configure cloud-init to handle the provisioning:

- Configure waagent for cloud-init:

```
sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g' /etc/waagent.conf  
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf  
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
```

#### NOTE

If you are migrating a specific virtual machine and do not wish to create a generalized image, set

```
Provisioning.Agent=disabled
```

 on the `/etc/waagent.conf` config.

- Configure mounts:

```
echo "Adding mounts and disk_setup to init stage"  
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg  
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg  
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg  
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

- Configure Azure datasource:

```
echo "Allow only Azure datasource, disable fetching network setting via IMDS"
cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF
datasource_list: [ Azure ]
datasource:
  Azure:
    apply_network_config: False
EOF
```

- a. If configured, remove existing swapfile:

```
if [[ -f /mnt/resource/swapfile ]]; then
  echo "Removing swapfile" #RHEL uses a swapfile by default
  swapoff /mnt/resource/swapfile
  rm /mnt/resource/swapfile -f
fi
```

- a. Configure cloud-init logging:

```
echo "Add console log file"
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF

# This tells cloud-init to redirect its stdout and stderr to
# 'tee -a /var/log/cloud-init-output.log' so the user can see output
# there without needing to look on the console.
output: {all: '| tee -a /var/log/cloud-init-output.log'}
EOF
```

### 13. Swap configuration Do not create swap space on the operating system disk.

Previously, the Azure Linux Agent was used automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However this is now handled by cloud-init, you **must not** use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=n
ResourceDisk.EnableSwap=n
```

If you want mount, format and create swap you can either:

- Pass this in as a cloud-init config every time you create a VM through customdata. This is the recommended method.
- Use a cloud-init directive baked into the image that will do this every time the VM is created.

```

echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
  ephemeral0:
    table_type: mbr
    layout: [66, [33, 82]]
    overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-
systemd.device-timeout=2", "0", "0"]
EOF

```

14. If you want to unregister the subscription, run the following command:

```
# sudo subscription-manager unregister
```

15. Deprovision

Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

**Caution**

If you are migrating a specific virtual machine and do not wish to create a generalized image, skip the deprovision step. Running the command `waagent -force -deprovision+user` will render the source machine unusable, this step is intended only to create a generalized image.

```

# sudo rm -f /var/log/waagent.log
# sudo cloud-init clean
# waagent -force -deprovision+user
# rm -f ~/.bash_history
# export HISTSIZE=0
# logout

```

16. Click **Action > Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## RHEL 8 using Hyper-V Manager

- In Hyper-V Manager, select the virtual machine.
- Click **Connect** to open a console window for the virtual machine.
- Ensure that the Network Manager service will start at boot time by running the following command:

```
# sudo systemctl enable NetworkManager.service
```

- Configure the network interface to automatically start at boot and use DHCP:

```
# nmcli con mod eth0 connection.autoconnect yes ipv4.method auto
```

5. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# sudo subscription-manager register --auto-attach --username=XXX --password=XXX
```

6. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure and enable the serial console.

- a. Remove current GRUB parameters:

```
# grub2-editenv - unset kernelopts
```

- a. Edit `/etc/default/grub` in a text editor, and add the following parameters:

```
GRUB_CMDLINE_LINUX="console=tty1 console=ttyS0,115200n8 earlyprintk=ttyS0,115200 earlyprintk=ttyS0  
net.ifnames=0"  
GRUB_TERMINAL_OUTPUT="serial console"  
GRUB_SERIAL_COMMAND="serial --speed=115200 --unit=0 --word=8 --parity=no --stop=1"
```

This will also ensure that all console messages are sent to the first serial port and enable interaction with the serial console, which can assist Azure support with debugging issues. This configuration also turns off the new naming conventions for NICs.

- a. Additionally, we recommend that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

7. After you are done editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```
# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

And for an UEFI enabled VM, run the following command:

```
# sudo grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
```

8. Ensure that the SSH server is installed and configured to start at boot time, which is usually the default. Modify `/etc/ssh/sshd_config` to include the following line:

```
ClientAliveInterval 180
```

9. Install the Azure Linux Agent, cloud-init and other necessary utilities by running the following command:

```
# sudo yum install -y WALinuxAgent cloud-init cloud-utils-growpart gdisk hyperv-daemons  
  
# sudo systemctl enable waagent.service  
# sudo systemctl enable cloud-init.service
```

## 10. Configure cloud-init to handle the provisioning:

### a. Configure waagent for cloud-init:

```
sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g' /etc/waagent.conf  
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf  
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
```

#### NOTE

If you are migrating a specific virtual machine and do not wish to create a generalized image, set `Provisioning.Agent=disabled` on the `/etc/waagent.conf` config.

### a. Configure mounts:

```
echo "Adding mounts and disk_setup to init stage"  
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg  
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg  
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg  
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg
```

### a. Configure Azure datasource:

```
echo "Allow only Azure datasource, disable fetching network setting via IMDS"  
cat > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg <<EOF  
datasource_list: [ Azure ]  
datasource:  
    Azure:  
        apply_network_config: False  
EOF
```

### a. If configured, remove existing swapfile:

```
if [[ -f /mnt/resource/swapfile ]]; then  
    echo "Removing swapfile" #RHEL uses a swapfile by default  
    swapoff /mnt/resource/swapfile  
    rm /mnt/resource/swapfile -f  
fi
```

### a. Configure cloud-init logging:

```
echo "Add console log file"  
cat >> /etc/cloud/cloud.cfg.d/05_logging.cfg <<EOF  
  
# This tells cloud-init to redirect its stdout and stderr to  
# 'tee -a /var/log/cloud-init-output.log' so the user can see output  
# there without needing to look on the console.  
output: {all: '| tee -a /var/log/cloud-init-output.log'}  
EOF
```

## 11. Swap configuration

Do not create swap space on the operating system disk.

Previously, the Azure Linux Agent was used automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However this is now handled by cloud-init, you **must not** use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=n  
ResourceDisk.EnableSwap=n
```

- Pass this in as a cloud-init config every time you create a VM through customdata. This is the recommended method.
- Use a cloud-init directive baked into the image that will do this every time the VM is created.

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>  
/etc/systemd/system.conf  
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF  
#cloud-config  
# Generated by Azure cloud image build  
disk_setup:  
  ephemeral0:  
    table_type: mbr  
    layout: [66, [33, 82]]  
    overwrite: True  
fs_setup:  
  - device: ephemeral0.1  
    filesystem: ext4  
  - device: ephemeral0.2  
    filesystem: swap  
mounts:  
  - ["ephemeral0.1", "/mnt"]  
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.device-timeout=2,x-  
systemd.requires=cloud-init.service", "0", "0"]  
EOF
```

## 12. If you want to unregister the subscription, run the following command:

```
# sudo subscription-manager unregister
```

## 13. Deprovision

Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# sudo cloud-init clean  
# waagent -force -deprovision+user  
# rm -f ~/.bash_history  
# sudo rm -f /var/log/waagent.log  
# export HISTSIZE=0  
# logout
```

### Caution

If you are migrating a specific virtual machine and do not wish to create a generalized image, skip the deprovision step. Running the command `waagent -force -deprovision+user` will render the source machine unusable, this step is intended only to create a generalized image.

## 14. Click Action > Shut Down in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to](#)

## KVM

This section shows you how to use KVM to prepare a [RHEL 6](#) or [RHEL 7](#) distro to upload to Azure.

### RHEL 6 using KVM

1. Download the KVM image of RHEL 6 from the Red Hat website.
2. Set a root password.

Generate an encrypted password, and copy the output of the command:

```
# openssl passwd -1 changeme
```

Set a root password with guestfish:

```
# guestfish --rw -a <image-name>
> <fs> run
> <fs> list-filesystems
> <fs> mount /dev/sda1 /
> <fs> vi /etc/shadow
> <fs> exit
```

Change the second field of the root user from "!!" to the encrypted password.

3. Create a virtual machine in KVM from the qcow2 image. Set the disk type to **qcow2**, and set the virtual network interface device model to **virtio**. Then, start the virtual machine, and sign in as root.
4. Create or edit the `/etc/sysconfig/network` file, and add the following text:

```
NETWORKING=yes
HOSTNAME=localhost.localdomain
```

5. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
```

6. Move (or remove) the udev rules to avoid generating static rules for the Ethernet interface. These rules cause problems when you clone a virtual machine in Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
# sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

7. Ensure that the network service will start at boot time by running the following command:

```
# chkconfig network on
```

8. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# subscription-manager register --auto-attach --username=XXX --password=XXX
```

9. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this configuration, open `/boot/grub/menu.lst` in a text editor, and ensure that the default kernel includes the following parameters:

```
console=ttyS0 earlyprintk=ttyS0
```

This will also ensure that all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

In addition, we recommend that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

10. Add Hyper-V modules to initramfs:

Edit `/etc/dracut.conf`, and add the following content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild initramfs:

```
# dracut -f -v
```

11. Uninstall cloud-init:

```
# yum remove cloud-init
```

12. Ensure that the SSH server is installed and configured to start at boot time:

```
# chkconfig sshd on
```

Modify `/etc/ssh/sshd_config` to include the following lines:

```
PasswordAuthentication yes  
ClientAliveInterval 180
```

13. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository.

Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-6-server-extras-rpms
```

14. Install the Azure Linux Agent by running the following command:

```
# yum install WALinuxAgent  
# chkconfig waagent on
```

15. The Azure Linux Agent can automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. Note that the local resource disk is a temporary disk, and it might be emptied if the virtual machine is deprovisioned. After you install the Azure Linux Agent in the previous step, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=y  
ResourceDisk.Filesystem=ext4  
ResourceDisk.MountPoint=/mnt/resource  
ResourceDisk.EnableSwap=y  
ResourceDisk.SwapSizeMB=2048    ## NOTE: set this to whatever you need it to be.
```

16. Unregister the subscription (if necessary) by running the following command:

```
# subscription-manager unregister
```

17. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# Note: if you are migrating a specific virtual machine and do not wish to create a generalized image,  
# skip the deprovision step  
# sudo rm -rf /var/lib/waagent/  
# sudo rm -f /var/log/waagent.log  
  
# waagent -force -deprovision+user  
# rm -f ~/.bash_history  
  
# export HISTSIZE=0  
  
# logout
```

18. Shut down the virtual machine in KVM.

19. Convert the qcow2 image to the VHD format.

**NOTE**

There is a known bug in qemu-img versions  $\geq 2.2.1$  that results in an improperly formatted VHD. The issue has been fixed in QEMU 2.6. It is recommended to use either qemu-img 2.2.0 or lower, or update to 2.6 or higher. Reference: <https://bugs.launchpad.net/qemu/+bug/1490611>.

First convert the image to raw format:

```
# qemu-img convert -f qcow2 -O raw rhel-6.9.qcow2 rhel-6.9.raw
```

Make sure that the size of the raw image is aligned with 1 MB. Otherwise, round up the size to align with 1 MB:

```
# MB=$((1024*1024))
# size=$(qemu-img info -f raw --output json "rhel-6.9.raw" | \
#       gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')
#
# rounded_size=$(((size/$MB + 1)*$MB))
# qemu-img resize rhel-6.9.raw $rounded_size
```

Convert the raw disk to a fixed-sized VHD:

```
# qemu-img convert -f raw -o subformat=fixed -O vpc rhel-6.9.raw rhel-6.9.vhd
```

Or, with qemu version 2.6+ include the `force_size` option:

```
# qemu-img convert -f raw -o subformat=fixed,force_size -O vpc rhel-6.9.raw rhel-6.9.vhd
```

## RHEL 7 using KVM

1. Download the KVM image of RHEL 7 from the Red Hat website. This procedure uses RHEL 7 as the example.
2. Set a root password.

Generate an encrypted password, and copy the output of the command:

```
# openssl passwd -1 changeme
```

Set a root password with guestfish:

```
# guestfish --rw -a <image-name>
> <fs> run
> <fs> list/filesystems
> <fs> mount /dev/sda1 /
> <fs> vi /etc/shadow
> <fs> exit
```

Change the second field of root user from "!!" to the encrypted password.

3. Create a virtual machine in KVM from the qcow2 image. Set the disk type to **qcow2**, and set the virtual network interface device model to **virtio**. Then, start the virtual machine, and sign in as root.
4. Create or edit the `/etc/sysconfig/network` file, and add the following text:

```
NETWORKING=yes
HOSTNAME=localhost.localdomain
```

5. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
PERSISTENT_DHCLIENT=yes
NM_CONTROLLED=yes
```

6. Ensure that the network service will start at boot time by running the following command:

```
# sudo systemctl enable network
```

7. Register your Red Hat subscription to enable installation of packages from the RHEL repository by running the following command:

```
# subscription-manager register --auto-attach --username=XXX --password=XXX
```

8. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure.

To do this configuration, open `/etc/default/grub` in a text editor, and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

```
GRUB_CMDLINE_LINUX="console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

This command also ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. The command also turns off the new RHEL 7 naming conventions for NICs. In addition, we recommend that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

9. After you are done editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```
# grub2-mkconfig -o /boot/grub2/grub.cfg
```

10. Add Hyper-V modules into initramfs.

Edit `/etc/dracut.conf` and add content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild initramfs:

```
# dracut -f -v
```

11. Uninstall cloud-init:

```
# yum remove cloud-init
```

12. Ensure that the SSH server is installed and configured to start at boot time:

```
# systemctl enable sshd
```

Modify /etc/ssh/sshd\_config to include the following lines:

```
PasswordAuthentication yes  
ClientAliveInterval 180
```

13. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository.

Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-7-server-extras-rpms
```

14. Install the Azure Linux Agent by running the following command:

```
# yum install WALinuxAgent
```

Enable the waagent service:

```
# systemctl enable waagent.service
```

15. Install cloud-init Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 12, 'Install cloud-init to handle the provisioning.'

16. Swap configuration

Do not create swap space on the operating system disk. Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 13, 'Swap configuration'

17. Unregister the subscription (if necessary) by running the following command:

```
# subscription-manager unregister
```

18. Deprovision

Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 15, 'Deprovision'

19. Shut down the virtual machine in KVM.

20. Convert the qcow2 image to the VHD format.

**NOTE**

There is a known bug in qemu-img versions  $\geq 2.2.1$  that results in an improperly formatted VHD. The issue has been fixed in QEMU 2.6. It is recommended to use either qemu-img 2.2.0 or lower, or update to 2.6 or higher.

Reference: <https://bugs.launchpad.net/qemu/+bug/1490611>.

First convert the image to raw format:

```
# qemu-img convert -f qcow2 -O raw rhel-7.4.qcow2 rhel-7.4.raw
```

Make sure that the size of the raw image is aligned with 1 MB. Otherwise, round up the size to align with 1 MB:

```
# MB=$((1024*1024))
# size=$(qemu-img info -f raw --output json "rhel-7.4.raw" | \
gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

# rounded_size=$(((size/$MB + 1)*$MB))
# qemu-img resize rhel-7.4.raw $rounded_size
```

Convert the raw disk to a fixed-sized VHD:

```
# qemu-img convert -f raw -o subformat=fixed -O vpc rhel-7.4.raw rhel-7.4.vhd
```

Or, with qemu version 2.6+ include the `force_size` option:

```
# qemu-img convert -f raw -o subformat=fixed,force_size -O vpc rhel-7.4.raw rhel-7.4.vhd
```

## VMware

This section shows you how to prepare a [RHEL 6](#) or [RHEL 7](#) distro from VMware.

### Prerequisites

This section assumes that you have already installed a RHEL virtual machine in VMware. For details about how to install an operating system in VMware, see [VMware Guest Operating System Installation Guide](#).

- When you install the Linux operating system, we recommend that you use standard partitions rather than LVM, which is often the default for many installations. This will avoid LVM name conflicts with cloned virtual machine, particularly if an operating system disk ever needs to be attached to another virtual machine for troubleshooting. LVM or RAID can be used on data disks if preferred.
- Do not configure a swap partition on the operating system disk. You can configure the Linux agent to create a swap file on the temporary resource disk. You can find more information about this in the steps that follow.
- When you create the virtual hard disk, select **Store virtual disk as a single file**.

### RHEL 6 using VMware

1. In RHEL 6, NetworkManager can interfere with the Azure Linux agent. Uninstall this package by running the following command:

```
# sudo rpm -e --nodeps NetworkManager
```

2. Create a file named **network** in the `/etc/sysconfig/` directory that contains the following text:

```
NETWORKING=yes
HOSTNAME=localhost.localdomain
```

3. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
```

4. Move (or remove) the udev rules to avoid generating static rules for the Ethernet interface. These rules cause problems when you clone a virtual machine in Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
# sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

5. Ensure that the network service will start at boot time by running the following command:

```
# sudo chkconfig network on
```

6. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# sudo subscription-manager register --auto-attach --username=XXX --password=XXX
```

7. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository. Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-6-server-extras-rpms
```

8. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this, open `/etc/default/grub` in a text editor, and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

```
GRUB_CMDLINE_LINUX="console=ttyS0 earlyprintk=ttyS0"
```

This will also ensure that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. In addition, we recommend that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

9. Add Hyper-V modules to initramfs:

Edit `/etc/dracut.conf`, and add the following content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild initramfs:

```
# dracut -f -v
```

10. Ensure that the SSH server is installed and configured to start at boot time, which is usually the default.

Modify `/etc/ssh/sshd_config` to include the following line:

```
ClientAliveInterval 180
```

11. Install the Azure Linux Agent by running the following command:

```
# sudo yum install WALinuxAgent  
# sudo chkconfig waagent on
```

12. Do not create swap space on the operating system disk.

The Azure Linux Agent can automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. Note that the local resource disk is a temporary disk, and it might be emptied if the virtual machine is deprovisioned. After you install the Azure Linux Agent in the previous step, modify the following parameters in `/etc/waagent.conf` appropriately:

```
ResourceDisk.Format=y  
ResourceDisk.Filesystem=ext4  
ResourceDisk.MountPoint=/mnt/resource  
ResourceDisk.EnableSwap=y  
ResourceDisk.SwapSizeMB=2048    ## NOTE: set this to whatever you need it to be.
```

13. Unregister the subscription (if necessary) by running the following command:

```
# sudo subscription-manager unregister
```

14. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# Note: if you are migrating a specific virtual machine and do not wish to create a generalized image,  
# skip the deprovision step  
# sudo rm -rf /var/lib/waagent/  
# sudo rm -f /var/log/waagent.log  
  
# waagent -force -deprovision+user  
# rm -f ~/.bash_history  
  
# export HISTSIZE=0  
  
# logout
```

15. Shut down the virtual machine, and convert the VMDK file to a .vhdx file.

## NOTE

There is a known bug in qemu-img versions  $\geq 2.2.1$  that results in an improperly formatted VHD. The issue has been fixed in QEMU 2.6. It is recommended to use either qemu-img 2.2.0 or lower, or update to 2.6 or higher. Reference: <https://bugs.launchpad.net/qemu/+bug/1490611>.

First convert the image to raw format:

```
# qemu-img convert -f vmdk -O raw rhel-6.9.vmdk rhel-6.9.raw
```

Make sure that the size of the raw image is aligned with 1 MB. Otherwise, round up the size to align with 1 MB:

```
# MB=$((1024*1024))
# size=$(qemu-img info -f raw --output json "rhel-6.9.raw" | \
gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}')

# rounded_size=$(((size/$MB + 1)*$MB))
# qemu-img resize rhel-6.9.raw $rounded_size
```

Convert the raw disk to a fixed-sized VHD:

```
# qemu-img convert -f raw -o subformat=fixed -O vpc rhel-6.9.raw rhel-6.9.vhd
```

Or, with qemu version 2.6+ include the `force_size` option:

```
# qemu-img convert -f raw -o subformat=fixed,force_size -O vpc rhel-6.9.raw rhel-6.9.vhd
```

## RHEL 7 using VMware

1. Create or edit the `/etc/sysconfig/network` file, and add the following text:

```
NETWORKING=yes
HOSTNAME=localhost.localdomain
```

2. Create or edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file, and add the following text:

```
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
PERSISTENT_DHCLIENT=yes
NM_CONTROLLED=yes
```

3. Ensure that the network service will start at boot time by running the following command:

```
# sudo systemctl enable network
```

4. Register your Red Hat subscription to enable the installation of packages from the RHEL repository by running the following command:

```
# sudo subscription-manager register --auto-attach --username=XXX --password=XXX
```

5. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure.

To do this modification, open `/etc/default/grub` in a text editor, and edit the `GRUB_CMDLINE_LINUX` parameter. For example:

```
GRUB_CMDLINE_LINUX="console=ttyS0 earlyprintk=ttyS0 net.ifnames=0"
```

This configuration also ensures that all console messages are sent to the first serial port, which can assist Azure support with debugging issues. It also turns off the new RHEL 7 naming conventions for NICs. In addition, we recommend that you remove the following parameters:

```
rhgb quiet crashkernel=auto
```

Graphical and quiet boot are not useful in a cloud environment where we want all the logs to be sent to the serial port. You can leave the `crashkernel` option configured if desired. Note that this parameter reduces the amount of available memory in the virtual machine by 128 MB or more, which might be problematic on smaller virtual machine sizes.

6. After you are done editing `/etc/default/grub`, run the following command to rebuild the grub configuration:

```
# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. Add Hyper-V modules to initramfs.

Edit `/etc/dracut.conf`, add content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild initramfs:

```
# dracut -f -v
```

8. Ensure that the SSH server is installed and configured to start at boot time. This setting is usually the default. Modify `/etc/ssh/sshd_config` to include the following line:

```
ClientAliveInterval 180
```

9. The WALinuxAgent package, `WALinuxAgent-<version>`, has been pushed to the Red Hat extras repository. Enable the extras repository by running the following command:

```
# subscription-manager repos --enable=rhel-7-server-extras-rpms
```

10. Install the Azure Linux Agent by running the following command:

```
# sudo yum install WALinuxAgent  
# sudo systemctl enable waagent.service
```

## 11. Install cloud-init

Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 12, 'Install cloud-init to handle the provisioning.'

## 12. Swap configuration

Do not create swap space on the operating system disk. Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 13, 'Swap configuration'

## 13. If you want to unregister the subscription, run the following command:

```
# sudo subscription-manager unregister
```

## 14. Deprovision

Follow the steps in 'Prepare a RHEL 7 virtual machine from Hyper-V Manager', step 15, 'Deprovision'

## 15. Shut down the virtual machine, and convert the VMDK file to the VHD format.

### NOTE

There is a known bug in qemu-img versions >=2.2.1 that results in an improperly formatted VHD. The issue has been fixed in QEMU 2.6. It is recommended to use either qemu-img 2.2.0 or lower, or update to 2.6 or higher.

Reference: <https://bugs.launchpad.net/qemu/+bug/1490611>.

First convert the image to raw format:

```
# qemu-img convert -f vmdk -O raw rhel-7.4.vmdk rhel-7.4.raw
```

Make sure that the size of the raw image is aligned with 1 MB. Otherwise, round up the size to align with 1 MB:

```
# MB=$((1024*1024))  
# size=$(qemu-img info -f raw --output json "rhel-7.4.raw" | \  
# gawk 'match($0, /"virtual-size": ([0-9]+),/, val) {print val[1]}' )  
  
# rounded_size=$(((size/$MB + 1)*$MB))  
# qemu-img resize rhel-7.4.raw $rounded_size
```

Convert the raw disk to a fixed-sized VHD:

```
# qemu-img convert -f raw -O vpc rhel-7.4.raw rhel-7.4.vhd
```

Or, with qemu version 2.6+ include the `force_size` option:

```
# qemu-img convert -f raw -O vpc,force_size rhel-7.4.raw rhel-7.4.vhd
```

# Kickstart file

This section shows you how to prepare a RHEL 7 distro from an ISO using a kickstart file.

## RHEL 7 from a kickstart file

1. Create a kickstart file that includes the following content, and save the file. For details about kickstart installation, see the [Kickstart Installation Guide](#).

```
# Kickstart for provisioning a RHEL 7 Azure VM

# System authorization information
auth --enableshadow --passalgo=sha512

# Use graphical install
text

# Do not run the Setup Agent on first boot
firstboot --disable

# Keyboard layouts
keyboard --vckeymap=us --xlayouts='us'

# System language
lang en_US.UTF-8

# Network information
network --bootproto=dhcp

# Root password
rootpw --plaintext "to_be_disabled"

# System services
services --enabled="sshd,waagent,NetworkManager"

# System timezone
timezone Etc/UTC --isUtc --ntpservers
0.rhel.pool.ntp.org,1.rhel.pool.ntp.org,2.rhel.pool.ntp.org,3.rhel.pool.ntp.org

# Partition clearing information
clearpart --all --initlabel

# Clear the MBR
zerombr

# Disk partitioning information
part /boot --fstype="xfs" --size=500
part / --fstype="xfs" --size=1 --grow --asprimary

# System bootloader configuration
bootloader --location=mbr

# Firewall configuration
firewall --disabled

# Enable SELinux
selinux --enforcing

# Don't configure X
skipx

# Power down the machine after install
poweroff

%packages
@base
@console-internet
```

```

crony
sudo
parted
-dracut-config-rescue

%end

%post --log=/var/log/anaconda/post-install.log

#!/bin/bash

# Register Red Hat Subscription
subscription-manager register --username=XXX --password=XXX --auto-attach --force

# Install latest repo update
yum update -y

# Enable extras repo
subscription-manager repos --enable=rhel-7-server-extras-rpms

# Install WALinuxAgent
yum install -y WALinuxAgent

# Unregister Red Hat subscription
subscription-manager unregister

# Enable waaagent at boot-up
systemctl enable waagent

# Install cloud-init
yum install -y cloud-init cloud-utils-growpart gdisk hyperv-daemons

# Configure waagent for cloud-init
sed -i 's/Provisioning.Agent=auto/Provisioning.Agent=cloud-init/g' /etc/waagent.conf
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf

echo "Adding mounts and disk_setup to init stage"
sed -i '/ - mounts/d' /etc/cloud/cloud.cfg
sed -i '/ - disk_setup/d' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - mounts' /etc/cloud/cloud.cfg
sed -i '/cloud_init_modules/a\\ - disk_setup' /etc/cloud/cloud.cfg

# Disable the root account
usermod root -p '!!!

# Configure swap using cloud-init
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
ephemeral0:
  table_type: mbr
  layout: [66, [33, 82]]
  overwrite: True
fs_setup:
- device: ephemeral0.1
  filesystem: ext4
- device: ephemeral0.2
  filesystem: swap
mounts:
- ["ephemeral0.1", "/mnt"]
- ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.device-timeout=2,x-systemd.requires=cloud-init.service", "0", "0"]
EOF

# Set the cmdline

```

```

sed -i 's/^\\(GRUB_CMDLINE_LINUX\\)=.*"$\\1="console=tty1 console=ttyS0 earlyprintk=ttyS0"/g'
/etc/default/grub

# Enable SSH keepalive
sed -i 's/^#\\(ClientAliveInterval\\).*$\\1 180/g' /etc/ssh/sshd_config

# Build the grub cfg
grub2-mkconfig -o /boot/grub2/grub.cfg

# Configure network
cat << EOF > /etc/sysconfig/network-scripts/ifcfg-eth0
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp
TYPE=Ethernet
USERCTL=no
PEERDNS=yes
IPV6INIT=no
PERSISTENT_DHCLIENT=yes
NM_CONTROLLED=yes
EOF

# Deprovision and prepare for Azure if you are creating a generalized image
sudo cloud-init clean --logs --seed
sudo rm -rf /var/lib/cloud/
sudo rm -rf /var/lib/waagent/
sudo rm -f /var/log/waagent.log

sudo waagent -force -deprovision+user
rm -f ~/.bash_history
export HISTSIZE=0

%end

```

2. Place the kickstart file where the installation system can access it.
3. In Hyper-V Manager, create a new virtual machine. On the **Connect Virtual Hard Disk** page, select **Attach a virtual hard disk later**, and complete the New Virtual Machine Wizard.
4. Open the virtual machine settings:
  - a. Attach a new virtual hard disk to the virtual machine. Make sure to select **VHD Format** and **Fixed Size**.
  - b. Attach the installation ISO to the DVD drive.
  - c. Set the BIOS to boot from CD.
5. Start the virtual machine. When the installation guide appears, press **Tab** to configure the boot options.
6. Enter `inst.ks=<the location of the kickstart file>` at the end of the boot options, and press **Enter**.
7. Wait for the installation to finish. When it's finished, the virtual machine will be shut down automatically. Your Linux VHD is now ready to be uploaded to Azure.

## Known issues

### The Hyper-V driver could not be included in the initial RAM disk when using a non-Hyper-V hypervisor

In some cases, Linux installers might not include the drivers for Hyper-V in the initial RAM disk (initrd or initramfs) unless Linux detects that it is running in a Hyper-V environment.

When you're using a different virtualization system (that is, VirtualBox, Xen, etc.) to prepare your Linux image, you might need to rebuild initrd to ensure that at least the hv\_vmbus and hv\_storvsc kernel modules are available on the initial RAM disk. This is a known issue at least on systems that are based on the upstream Red

Hat distribution.

To resolve this issue, add Hyper-V modules to initramfs and rebuild it:

Edit `/etc/dracut.conf`, and add the following content:

```
add_drivers+=" hv_vmbus hv_netvsc hv_storvsc "
```

Rebuild initramfs:

```
# dracut -f -v
```

For more details, see the information about [rebuilding initramfs](#).

## Next steps

- You're now ready to use your Red Hat Enterprise Linux virtual hard disk to create new virtual machines in Azure. If this is the first time that you're uploading the .vhdx file to Azure, see [Create a Linux VM from a custom disk](#).
- For more details about the hypervisors that are certified to run Red Hat Enterprise Linux, see [the Red Hat website](#).
- To learn more about using production-ready RHEL BYOS images, go to the documentation page for [BYOS](#).

# Prepare a SLES or openSUSE Leap virtual machine for Azure

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets Applies to: ✓ Uniform scale sets

This article assumes that you have already installed a SUSE or openSUSE Leap Linux operating system to a virtual hard disk. Multiple tools exist to create .vhd files, for example a virtualization solution such as Hyper-V. For instructions, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

## SLES / openSUSE Leap installation notes

- Please see also [General Linux Installation Notes](#) for more tips on preparing Linux for Azure.
- The VHDX format is not supported in Azure, only **fixed VHD**. You can convert the disk to VHD format using Hyper-V Manager or the convert-vhd cmdlet.
- When installing the Linux system it is recommended that you use standard partitions rather than LVM (often the default for many installations). This will avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks if preferred.
- Do not configure a swap partition on the OS disk. The Linux agent can be configured to create a swap file on the temporary resource disk. More information about this can be found in the steps below.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1MB before conversion. See [Linux Installation Notes](#) for more information.

## Use SUSE Studio

[SUSE Studio](#) can easily create and manage your SLES and openSUSE Leap images for Azure and Hyper-V. This is the recommended approach for customizing your own SLES and openSUSE Leap images.

As an alternative to building your own VHD, SUSE also publishes BYOS (Bring Your Own Subscription) images for SLES at [VM Depot](#).

## Prepare SUSE Linux Enterprise Server for Azure

1. In the center pane of Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open the window for the virtual machine.
3. Register your SUSE Linux Enterprise system to allow it to download updates and install packages.
4. Update the system with the latest patches:

```
# sudo zypper update
```

5. Install Azure Linux Agent and cloud-init

```
# SUSEConnect -p sle-module-public-cloud/15.2/x86_64 (SLES 15 SP2)
# sudo zypper refresh
# sudo zypper install python-azure-agent
# sudo zypper install cloud-init
```

## 6. Enable waagent & cloud-init to start on boot

```
# sudo chkconfig waagent on
# systemctl enable cloud-init-local.service
# systemctl enable cloud-init.service
# systemctl enable cloud-config.service
# systemctl enable cloud-final.service
# systemctl daemon-reload
# cloud-init clean
```

## 7. Update waagent and cloud-init configuration

```
# sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g' /etc/waagent.conf
# sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g' /etc/waagent.conf

# sudo sh -c 'printf "datasource:\n Azure:" > /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg'
# sudo sh -c 'printf "reporting:\n logging:\n type: log\n telemetry:\n type: hyperv" >
/etc/cloud/cloud.cfg.d/10-azure-kvp.cfg'
```

## 8. Edit /etc/default/grub file to ensure console logs are sent to serial port and then update the main configuration file with grub2-mkconfig -o /boot/grub2/grub.cfg

```
console=ttyS0 earlyprintk=ttyS0
```

This will ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues.

## 9. Ensure /etc/fstab file reference the disk using its UUID (by-uuid)

## 10. Modify udev rules to avoid generating static rules for the Ethernet interface(s). These rules can cause problems when cloning a virtual machine in Microsoft Azure or Hyper-V:

```
# sudo ln -s /dev/null /etc/udev/rules.d/75-persistent-net-generator.rules
# sudo rm -f /etc/udev/rules.d/70-persistent-net.rules
```

## 11. It is recommended to edit the file "/etc/sysconfig/network/dhcp" and change the `DHCLIENT_SET_HOSTNAME` parameter to the following:

```
DHCLIENT_SET_HOSTNAME="no"
```

## 12. In "/etc/sudoers", comment out or remove the following lines if they exist:

```
Defaults targetpw  # ask for the password of the target user i.e. root
ALL      ALL=(ALL) ALL    # WARNING! Only use this together with 'Defaults targetpw'!
```

## 13. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.

## 14. Swap configuration

Do not create swap space on the operating system disk.

Previously, the Azure Linux Agent was used automatically configure swap space by using the local resource disk that is attached to the virtual machine after the virtual machine is provisioned on Azure. However this is now handled by cloud-init, you **must not** use the Linux Agent to format the resource disk create the swap file, modify the following parameters in `/etc/waagent.conf` appropriately:

```
# sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
# sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf
```

If you want mount, format and create swap you can either:

- Pass this in as a cloud-init config every time you create a VM.
- Use a cloud-init directive baked into the image that will do this every time the VM is created:

```
echo 'DefaultEnvironment="CLOUD_CFG=/etc/cloud/cloud.cfg.d/00-azure-swap.cfg"' >>
/etc/systemd/system.conf
cat > /etc/cloud/cloud.cfg.d/00-azure-swap.cfg << EOF
#cloud-config
# Generated by Azure cloud image build
disk_setup:
ephemeral0:
  table_type: mbr
  layout: [66, [33, 82]]
  overwrite: True
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service,x-
systemd.device-timeout=2", "0", "0"]
EOF
```

15. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# sudo rm -rf /var/lib/waagent/
# sudo rm -f /var/log/waagent.log

# waagent -force -deprovision+user
# rm -f ~/.bash_history

# export HISTSIZE=0

# logout
```

16. Click Action -> **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## Prepare openSUSE 15.2+

1. In the center pane of Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open the window for the virtual machine.

3. On the shell, run the command '`zypper lr`'. If this command returns output similar to the following, then the repositories are configured as expected--no adjustments are necessary (note that version numbers may vary):

| # | ALIAS                 | NAME                  | ENABLED | REFRESH |
|---|-----------------------|-----------------------|---------|---------|
| 1 | Cloud:Tools_15.2      | Cloud:Tools_15.2      | Yes     | Yes     |
| 2 | openSUSE_15.2_OS<br>S | openSUSE_15.2_OS<br>S | Yes     | Yes     |
| 3 | openSUSE_15.2_Updates | openSUSE_15.2_Updates | Yes     | Yes     |

If the command returns "No repositories defined..." then use the following commands to add these repos:

```
# sudo zypper ar -f http://download.opensuse.org/repositories/Cloud:Tools/openSUSE_15.2  
Cloud:Tools_15.2  
# sudo zypper ar -f https://download.opensuse.org/distribution/15.2/repo/oss openSUSE_15.2_OSS  
# sudo zypper ar -f http://download.opensuse.org/update/15.2 openSUSE_15.2_Updates
```

You can then verify the repositories have been added by running the command '`zypper lr`' again. In case one of the relevant update repositories is not enabled, enable it with following command:

```
# sudo zypper mr -e [NUMBER OF REPOSITORY]
```

4. Update the kernel to the latest available version:

```
# sudo zypper up kernel-default
```

Or to update the system with all the latest patches:

```
# sudo zypper update
```

5. Install the Azure Linux Agent.

```
# sudo zypper install WALinuxAgent
```

6. Modify the kernel boot line in your grub configuration to include additional kernel parameters for Azure. To do this, open "/boot/grub/menu.lst" in a text editor and ensure that the default kernel includes the following parameters:

```
console=ttyS0 earlyprintk=ttyS0
```

This will ensure all console messages are sent to the first serial port, which can assist Azure support with debugging issues. In addition, remove the following parameters from the kernel boot line if they exist:

```
libata.atapi_enabled=0 reserve=0x1f0,0x8
```

7. It is recommended to edit the file "/etc/sysconfig/network/dhcp" and change the `DHCLIENT_SET_HOSTNAME`

parameter to the following:

```
DHCLIENT_SET_HOSTNAME="no"
```

8. **Important:** In "/etc/sudoers", comment out or remove the following lines if they exist:

```
Defaults targetpw  # ask for the password of the target user i.e. root
ALL    ALL=(ALL) ALL  # WARNING! Only use this together with 'Defaults targetpw'!
```

9. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.

10. Do not create swap space on the OS disk.

The Azure Linux Agent can automatically configure swap space using the local resource disk that is attached to the VM after provisioning on Azure. Note that the local resource disk is a *temporary* disk, and might be emptied when the VM is deprovisioned. After installing the Azure Linux Agent (see previous step), modify the following parameters in /etc/waagent.conf appropriately:

```
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.EnableSwap=y
ResourceDisk.SwapSizeMB=2048    ## NOTE: set this to whatever you need it to be.
```

11. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

```
# sudo waagent -force -deprovision
# export HISTSIZE=0
# logout
```

12. Ensure the Azure Linux Agent runs at startup:

```
# sudo systemctl enable waagent.service
```

13. Click Action -> **Shut Down** in Hyper-V Manager. Your Linux VHD is now ready to be [uploaded to Azure](#).

## Next steps

You're now ready to use your SUSE Linux virtual hard disk to create new virtual machines in Azure. If this is the first time that you're uploading the .vhd file to Azure, see [Create a Linux VM from a custom disk](#).

# Prepare an Ubuntu virtual machine for Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Ubuntu now publishes official Azure VHDs for download at <https://cloud-images.ubuntu.com/>. If you need to build your own specialized Ubuntu image for Azure, rather than use the manual procedure below it is recommended to start with these known working VHDs and customize as needed. The latest image releases can always be found at the following locations:

- Ubuntu 18.04/Bionic: [bionic-server-cloudimg-amd64-azure.vhd.zip](#)
- Ubuntu 20.04/Focal: [focal-server-cloudimg-amd64-azure.vhd.zip](#)

## Prerequisites

This article assumes that you have already installed an Ubuntu Linux operating system to a virtual hard disk. Multiple tools exist to create .vhd files, for example a virtualization solution such as Hyper-V. For instructions, see [Install the Hyper-V Role and Configure a Virtual Machine](#).

### Ubuntu installation notes

- Please see also [General Linux Installation Notes](#) for more tips on preparing Linux for Azure.
- The VHDX format is not supported in Azure, only **fixed VHD**. You can convert the disk to VHD format using Hyper-V Manager or the `Convert-VHD` cmdlet.
- When installing the Linux system it is recommended that you use standard partitions rather than LVM (often the default for many installations). This will avoid LVM name conflicts with cloned VMs, particularly if an OS disk ever needs to be attached to another VM for troubleshooting. [LVM](#) or [RAID](#) may be used on data disks if preferred.
- Do not configure a swap partition or swapfile on the OS disk. The cloud-init provisioning agent can be configured to create a swap file or a swap partition on the temporary resource disk. More information about this can be found in the steps below.
- All VHDs on Azure must have a virtual size aligned to 1MB. When converting from a raw disk to VHD you must ensure that the raw disk size is a multiple of 1MB before conversion. See [Linux Installation Notes](#) for more information.

## Manual steps

### NOTE

Before attempting to create your own custom Ubuntu image for Azure, please consider using the pre-built and tested images from <https://cloud-images.ubuntu.com/> instead.

1. In the center pane of Hyper-V Manager, select the virtual machine.
2. Click **Connect** to open the window for the virtual machine.
3. Replace the current repositories in the image to use Ubuntu's Azure repository.

Before editing `/etc/apt/sources.list`, it is recommended to make a backup:

```
# sudo cp /etc/apt/sources.list /etc/apt/sources.list.bak
```

Ubuntu 18.04 and Ubuntu 20.04:

```
# sudo sed -i  
's/http://archive.ubuntu.com/ubuntu//http://azure.archive.ubuntu.com/ubuntu//g'  
/etc/apt/sources.list  
# sudo sed -i 's/http:///[a-z][a-  
z]archive.ubuntu.com/ubuntu//http://azure.archive.ubuntu.com/ubuntu//g'  
/etc/apt/sources.list  
# sudo apt-get update
```

4. The Ubuntu Azure images are now using the [Azure-tailored kernel](#). Update the operating system to the latest Azure-tailored kernel and install Azure Linux tools (including Hyper-V dependencies) by running the following commands:

Ubuntu 18.04 and Ubuntu 20.04:

```
# sudo apt update  
# sudo apt install linux-azure linux-image-azure linux-headers-azure linux-tools-common linux-cloud-  
tools-common linux-tools-azure linux-cloud-tools-azure  
(recommended) # sudo apt full-upgrade  
  
# sudo reboot
```

5. Modify the kernel boot line for Grub to include additional kernel parameters for Azure. To do this open `/etc/default/grub` in a text editor, find the variable called `GRUB_CMDLINE_LINUX_DEFAULT` (or add it if needed) and edit it to include the following parameters:

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0,115200n8 earlyprintk=ttyS0,115200  
rootdelay=300 quiet splash"
```

Save and close this file, and then run `sudo update-grub`. This will ensure all console messages are sent to the first serial port, which can assist Azure technical support with debugging issues.

6. Ensure that the SSH server is installed and configured to start at boot time. This is usually the default.
7. Install cloud-init (the provisioning agent) and the Azure Linux Agent (the guest extensions handler). Cloud-init uses `netplan` to configure the system network configuration (during provisioning and each subsequent boot) and `gdisk` to partition resource disks.

```
# sudo apt update  
# sudo apt install cloud-init gdisk netplan.io walinuagent && systemctl stop walinuagent
```

#### NOTE

The `walinuagent` package may remove the `NetworkManager` and `NetworkManager-gnome` packages, if they are installed.

8. Remove cloud-init default configs and leftover `netplan` artifacts that may conflict with cloud-init provisioning on Azure:

```
# rm -f /etc/cloud/cloud.cfg.d/50-curtin-networking.cfg /etc/cloud/cloud.cfg.d/curtin-preserve-sources.cfg /etc/cloud/cloud.cfg.d/99-installer.cfg /etc/cloud/cloud.cfg.d/subiquity-disable-cloudinit-networking.cfg
# rm -f /etc/cloud/ds-identify.cfg
# rm -f /etc/netplan/*.yaml
```

9. Configure cloud-init to provision the system using the Azure datasource:

```
# cat > /etc/cloud/cloud.cfg.d/90_dpkg.cfg << EOF
datasource_list: [ Azure ]
EOF

# cat > /etc/cloud/cloud.cfg.d/90-azure.cfg << EOF
system_info:
  package_mirrors:
    - arches: [i386, amd64]
      failsafe:
        primary: http://archive.ubuntu.com/ubuntu
        security: http://security.ubuntu.com/ubuntu
      search:
        primary:
          - http://azure.archive.ubuntu.com/ubuntu/
        security: []
    - arches: [armhf, armel, default]
      failsafe:
        primary: http://ports.ubuntu.com/ubuntu-ports
        security: http://ports.ubuntu.com/ubuntu-ports
EOF

# cat > /etc/cloud/cloud.cfg.d/10-azure-kvp.cfg << EOF
reporting:
  logging:
    type: log
  telemetry:
    type: hyperv
EOF
```

10. Configure the Azure Linux agent to rely on cloud-init to perform provisioning. Have a look at the [WALinuxAgent project](#) for more information on these options.

```
sed -i 's/Provisioning.Enabled=y/Provisioning.Enabled=n/g' /etc/waagent.conf
sed -i 's/Provisioning.UseCloudInit=n/Provisioning.UseCloudInit=y/g' /etc/waagent.conf
sed -i 's/ResourceDisk.Format=y/ResourceDisk.Format=n/g' /etc/waagent.conf
sed -i 's/ResourceDisk.EnableSwap=y/ResourceDisk.EnableSwap=n/g' /etc/waagent.conf

cat >> /etc/waagent.conf << EOF
# For Azure Linux agent version >= 2.2.45, this is the option to configure,
# enable, or disable the provisioning behavior of the Linux agent.
# Accepted values are auto (default), waagent, cloud-init, or disabled.
# A value of auto means that the agent will rely on cloud-init to handle
# provisioning if it is installed and enabled, which in this case it will.
Provisioning.Agent=auto
EOF
```

11. Clean cloud-init and Azure Linux agent runtime artifacts and logs:

```
# sudo cloud-init clean --logs --seed
# sudo rm -rf /var/lib/cloud/
# sudo systemctl stop walinuxagent.service
# sudo rm -rf /var/lib/waagent/
# sudo rm -f /var/log/waagent.log
```

12. Run the following commands to deprovision the virtual machine and prepare it for provisioning on Azure:

**NOTE**

The `sudo waagent -force -deprovision+user` command generalizes the image by attempting to clean the system and make it suitable for re-provisioning. The `+user` option deletes the last provisioned user account and associated data.

**WARNING**

Deprovisioning using the command above does not guarantee that the image is cleared of all sensitive information and is suitable for redistribution.

```
# sudo waagent -force -deprovision+user  
# rm -f ~/.bash_history  
# export HISTSIZE=0  
# logout
```

13. Click Action -> Shut Down in Hyper-V Manager.

14. Azure only accepts fixed-size VHDs. If the VM's OS disk is not a fixed-size VHD, use the `Convert-VHD` PowerShell cmdlet and specify the `-VHDTtype Fixed` option. Please have a look at the docs for `Convert-VHD` here: [Convert-VHD](#).

15. To bring a Generation 2 VM on Azure, follow these steps:

- a. Change directory to the boot EFI directory:

```
# cd /boot/efi/EFI
```

- b. Copy the ubuntu directory to a new directory named boot:

```
# sudo cp -r ubuntu/ boot
```

- c. Change directory to the newly created boot directory:

```
# cd boot
```

- d. Rename the shimx64.efi file:

```
# sudo mv shimx64.efi bootx64.efi
```

- e. Rename the grub.cfg file to bootx64.cfg:

```
# sudo mv grub.cfg bootx64.cfg
```

## Next steps

You're now ready to use your Ubuntu Linux virtual hard disk to create new virtual machines in Azure. If this is

the first time that you're uploading the .vhdx file to Azure, see [Create a Linux VM from a custom disk](#).

# cloud-init support for virtual machines in Azure

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article explains the support that exists for [cloud-init](#) to configure a virtual machine (VM) or virtual machine scale sets at provisioning time in Azure. These cloud-init configurations are run on first boot once the resources have been provisioned by Azure.

VM Provisioning is the process where the Azure will pass down your VM Create parameter values, such as hostname, username, password etc., and make them available to the VM as it boots up. A 'provisioning agent' will consume those values, configure the VM, and report back when completed.

Azure supports two provisioning agents [cloud-init](#), and the [Azure Linux Agent \(WALA\)](#).

## cloud-init overview

[cloud-init](#) is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. Because cloud-init is called during the initial boot process, there are no additional steps or required agents to apply your configuration. For more information on how to properly format your `#cloud-config` files or other inputs, see the [cloud-init documentation site](#). `#cloud-config` files are text files encoded in base64.

cloud-init also works across distributions. For example, you don't use `apt-get install` or `yum install` to install a package. Instead you can define a list of packages to install. cloud-init automatically uses the native package management tool for the distro you select.

We are actively working with our endorsed Linux distro partners in order to have cloud-init enabled images available in the Azure Marketplace. These images will make your cloud-init deployments and configurations work seamlessly with VMs and virtual machine scale sets. Initially we collaborate with the endorsed Linux distro partners and upstream to ensure cloud-init functions with the OS on Azure, then the packages are updated and made publicly available in the distro package repositories.

There are two stages to making cloud-init available to the endorsed Linux distro OS's on Azure, package support, and then image support:

- 'cloud-init package support on Azure' documents which cloud-init packages onwards are supported or in preview, so you can use these packages with the OS in a custom image.
- 'image cloud-init ready' documents if the image is already configured to use cloud-init.

### Canonical

| PUBLISHER / VERSION | OFFER        | SKU       | VERSION | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE |
|---------------------|--------------|-----------|---------|------------------------|-------------------------------------|
| Canonical 20.04     | UbuntuServer | 20.04-LTS | latest  | yes                    | yes                                 |
| Canonical 18.04     | UbuntuServer | 18.04-LTS | latest  | yes                    | yes                                 |

### RHEL

| PUBLISHER / VERSION | OFFER | SKU                | VERSION | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE |
|---------------------|-------|--------------------|---------|------------------------|-------------------------------------|
| RedHat 7            | RHEL  | 7.7, 7.8, 7_9      | latest  | yes                    | yes                                 |
| RedHat 8            | RHEL  | 8.1, 8.2, 8_3, 8_4 | latest  | yes                    | yes                                 |

- All other RedHat SKUs starting from RHEL 7 (version 7.7) and RHEL 8 (version 8.1) including both Gen1 and Gen2 images are provisioned using cloud-init. RHEL 6 images do not support cloud-init.

## CentOS

| PUBLISHER / VERSION | OFFER  | SKU           | VERSION | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE |
|---------------------|--------|---------------|---------|------------------------|-------------------------------------|
| OpenLogic 7         | CentOS | 7.7, 7.8, 7.9 | latest  | yes                    | yes                                 |
| OpenLogic 8         | CentOS | 8.1, 8.2, 8.3 | latest  | yes                    | yes                                 |

- All other CentOS SKUs starting from CentOS 7 (version 7.7) and CentOS 8 (version 8.1) including both Gen1 and Gen2 images are provisioned using cloud-init. CentOS 6.10, 7.4, 7.5, and 7.6 images do not support cloud-init.

### NOTE

OpenLogic is now Rogue Wave Software

## Oracle

| PUBLISHER / VERSION | OFFER        | SKU                          | VERSION | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE |
|---------------------|--------------|------------------------------|---------|------------------------|-------------------------------------|
| Oracle 7            | Oracle Linux | 77, 78, ol79                 | latest  | yes                    | yes                                 |
| Oracle 8            | Oracle Linux | 81, ol82, ol83-lvm, ol84-lvm | latest  | yes                    | yes                                 |

- All other Oracle SKUs starting from Oracle 7 (version 7.7) and Oracle 8 (version 8.1) including both Gen1 and Gen2 images are provisioned using cloud-init.

## SUSE SLES

| PUBLISHER / VERSION | OFFER                               | SKU           | VERSION | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE |
|---------------------|-------------------------------------|---------------|---------|------------------------|-------------------------------------|
| SUSE 15             | SLES (SUSE Linux Enterprise Server) | sp1, sp2, sp3 | latest  | yes                    | yes                                 |

## Debian

| PUBLISHER / VERSION | OFFER     | SKU               | VERSION           | IMAGE CLOUD-INIT READY | CLOUD-INIT PACKAGE SUPPORT ON AZURE                   |
|---------------------|-----------|-------------------|-------------------|------------------------|-------------------------------------------------------|
| debian (Gen1)       | debian-10 | 10-cloudinit      | 10:0.20201013.422 | yes                    | yes - support from package version:<br>20.2-2~deb10u1 |
| debian (Gen2)       | debian-10 | 10-cloudinit-gen2 | 0.20201013.422    | yes                    | yes - support from package version:<br>20.2-2~deb10u1 |

Currently Azure Stack will support the provisioning of cloud-init enabled images.

## What is the difference between cloud-init and the Linux Agent (WALA)?

WALA is an Azure platform-specific agent used to provision and configure VMs, and handle [Azure extensions](#).

We are enhancing the task of configuring VMs to use cloud-init instead of the Linux Agent in order to allow existing cloud-init customers to use their current cloud-init scripts, or new customers to take advantage of the

rich cloud-init configuration functionality. If you have existing investments in cloud-init scripts for configuring Linux systems, there are **no additional settings required** to enable cloud-init process them.

cloud-init cannot process Azure extensions, so WALA is still required in the image to process extensions, but will need to have its provisioning code disabled, for endorsed Linux distros images that are being converted to provision by cloud-init, they will have WALA installed, and setup correctly.

When creating a VM, if you do not include the Azure CLI `--custom-data` switch at provisioning time, cloud-init or WALA takes the minimal VM provisioning parameters required to provision the VM and complete the deployment with the defaults. If you reference the cloud-init configuration with the `--custom-data` switch, whatever is contained in your custom data will be available to cloud-init when the VM boots.

cloud-init configurations applied to VMs do not have time constraints and will not cause a deployment to fail by timing out. This is not true for WALA, if you change the WALA defaults to process custom-data, it cannot exceed the total VM provisioning time allowance of 40mins, if so, the VM Create will fail.

## cloud-init VM provisioning without a UDF driver

Beginning with cloud-init 21.2, you can use cloud-init to provision a VM in Azure without a UDF driver. If a UDF driver isn't available in the image, cloud-init uses the metadata that's available in the Azure Instance Metadata Service to provision the VM. Note that this option works only for SSH key and [user data](#). To pass in a password or custom data to a VM during provisioning, you must use a UDF driver.

## Deploying a cloud-init enabled Virtual Machine

Deploying a cloud-init enabled virtual machine is as simple as referencing a cloud-init enabled distribution during deployment. Linux distribution maintainers have to choose to enable and integrate cloud-init into their base Azure published images. Once you have confirmed the image you want to deploy is cloud-init enabled, you can use the Azure CLI to deploy the image.

The first step in deploying this image is to create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group named *myResourceGroup* in the *eastus* location.

```
az group create --name myResourceGroup --location eastus
```

The next step is to create a file in your current shell, named *cloud-init.txt* and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Enter `sensible-editor cloud-init.txt` to create the file and see a list of available editors. Choose #1 to use the `nano` editor. Make sure that the whole cloud-init file is copied correctly, especially the first line:

```
#cloud-config
package_upgrade: true
packages:
- httpd
```

### NOTE

cloud-init has multiple [input types](#), cloud-init will use first line of the customData/userData to indicate how it should process the input, for example `#cloud-config` indicates that the content should be processed as a cloud-init config.

Press `Ctrl + X` to exit the file, type `y` to save the file, and press `Enter` to confirm the file name on exit.

The final step is to create a VM with the [az vm create](#) command.

The following example creates a VM named `centos74` and creates SSH keys if they do not already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option. Use the `--custom-data` parameter to pass in your cloud-init config file. Provide the full path to the `cloud-init.txt` config if you saved the file outside of your present working directory.

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS-CI:7-CI:latest \
--custom-data cloud-init.txt \
--generate-ssh-keys
```

When the VM has been created, the Azure CLI shows information specific to your deployment. Take note of the `publicIpAddress`. This address is used to access the VM. It takes some time for the VM to be created, the packages to install, and the app to start. There are background tasks that continue to run after the Azure CLI returns you to the prompt. You can SSH into the VM and use the steps outlined in the Troubleshooting section to view the cloud-init logs.

You can also deploy a cloud-init enabled VM by passing the [parameters in ARM template](#).

## Troubleshooting cloud-init

Once the VM has been provisioned, cloud-init will run through all the modules and script defined in `--custom-data` in order to configure the VM. If you need to troubleshoot any errors or omissions from the configuration, you need to search for the module name (`disk_setup` or `runcmd` for example) in the cloud-init log - located in `/var/log/cloud-init.log`.

### NOTE

Not every module failure results in a fatal cloud-init overall configuration failure. For example, using the `runcmd` module, if the script fails, cloud-init will still report provisioning succeeded because the runcmd module executed.

For more details of cloud-init logging, refer to the [cloud-init documentation](#)

## Telemetry

cloud-init collects usage data and sends it to Microsoft to help improve our products and services. Telemetry is only collected during the provisioning process (first boot of the VM). The data collected helps us investigate provisioning failures and monitor performance and reliability. Data collected does not include any personally identifiable information. Read our [privacy statement](#) to learn more. Some examples of telemetry being collected are (this is not an exhaustive list): OS-related information (cloud-init version, distro version, kernel version), performance metrics of essential VM provisioning actions (time to obtain DHCP lease, time to retrieve metadata necessary to configure the VM, etc.), cloud-init log, and dmesg log.

Telemetry collection is currently enabled for a majority of our marketplace images that use cloud-init. It is enabled by specifying KVP telemetry reporter for cloud-init. In a majority of Azure marketplace images, this configuration can be found in the file `/etc/cloud/cloud.cfg.d/10-azure-kvp.cfg`. Removing this file during image preparation will disable telemetry collection for any VM created from this image.

Sample content of `10-azure-kvp.cfg`

```
reporting:  
  logging:  
    type: log  
  telemetry:  
    type: hyperv
```

## Next steps

[Troubleshoot issues with cloud-init.](#)

For cloud-init examples of configuration changes, see the following documents:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Diving deeper into cloud-init

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

To learn more about [cloud-init](#) or troubleshoot it at a deeper level, you need to understand how it works. This document highlights the important parts, and explains the Azure specifics.

When cloud-init is included in a generalized image, and a VM is created from that image, it will process configurations and run through 5 stages during the initial boot. These stages matter, as it shows you at what point cloud-init will apply configurations.

## Understand Cloud-Init configuration

Configuring a VM to run on a platform, means cloud-init needs to apply multiple configurations, as an image consumer, the main configurations you will be interacting with is `user data` (customData), which supports multiple formats. For more information, see [User-Data Formats & cloud-init 21.2 documentation](#). You also have the ability to add and run scripts (`/var/lib/cloud/scripts`) for additional configuration, below discusses this in more detail.

Some configurations are already baked into Azure Marketplace images that come with cloud-init, such as:

1. **Cloud data source** - cloud-init contains code that can interact with cloud platforms, these are called 'datasources'. When a VM is created from a cloud-init image in [Azure](#), cloud-init loads the Azure datasource, which will interact with the Azure metadata endpoints to get the VM specific configuration.
2. **Runtime config** (`/run/cloud-init`)
3. **Image config** (`/etc/cloud`), like `/etc/cloud/cloud.cfg`, `/etc/cloud/cloud.cfg.d/*.cfg`. An example of where this is used in Azure, it is common for the Linux OS images with cloud-init to have an Azure datasource directive, that tells cloud-init what datasource it should use, this saves cloud-init time:

```
/etc/cloud/cloud.cfg.d# cat 90_dpkg.cfg
# to update this file, run dpkg-reconfigure cloud-init
datasource_list: [ Azure ]
```

## Cloud-init boot stages (processing configuration)

When provisioning with cloud-init, there are 5 stages of boot, which process configuration, and shown in the logs.

1. **Generator Stage:** The cloud-init systemd generator starts, and determines that cloud-init should be included in the boot goals, and if so, it enables cloud-init.
2. **Cloud-init Local Stage:** Here cloud-init will look for the local "Azure" datasource, which will enable cloud-init to interface with Azure, and apply a networking configuration, including fallback.
3. **Cloud-init init Stage (Network):** Networking should be online, and the NIC and route table information should be generated. At this stage, the modules listed in `cloud_init_modules` in `/etc/cloud/cloud.cfg` will be run. The VM in Azure will be mounted, the ephemeral disk is formatted, the hostname is set, along with other tasks.

These are some of the `cloud_init_modules`:

```
- migrator
- seed_random
- bootcmd
- write-files
- growpart
- resizefs
- disk_setup
- mounts
- set_hostname
- update_hostname
- ssh
```

After this stage, cloud-init will signal to the Azure platform that the VM has been provisioned successfully. Some modules may have failed, not all module failures will result in a provisioning failure.

4. **Cloud-init Config Stage:** At this stage, the modules in `cloud_config_modules` defined and listed in `/etc/cloud/cloud.cfg` will be run.
5. **Cloud-init Final Stage:** At this final stage, the modules in `cloud_final_modules`, listed in `/etc/cloud/cloud.cfg`, will be run. Here modules that need to be run late in the boot process run, such as package installations and run scripts etc.
  - During this stage, you can run scripts by placing them in the directories under `/var/lib/cloud/scripts` :
    - `per-boot` - scripts within this directory, run on every reboot
    - `per-instance` - scripts within this directory run when a new instance is first booted
    - `per-once` - scripts within this directory run only once

## Next steps

[Troubleshooting cloud-init](#).

# Troubleshooting VM provisioning with cloud-init

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

If you have been creating generalized custom images, using cloud-init to do provisioning, but have found that VM did not create correctly, you will need to troubleshoot your custom images.

Some examples, of issues with provisioning:

- VM gets stuck at 'creating' for 40 minutes, and the VM creation is marked as failed
- `CustomData` does not get processed
- The ephemeral disk fails to mount
- Users do not get created, or there are user access issues
- Networking is not set up correctly
- Swap file or partition failures

This article steps you through how to troubleshoot cloud-init. For more in-depth details, see [cloud-init deep dive](#).

## Step 1: Test the deployment without `customData`

Cloud-init can accept `customData`, that is passed to it, when the VM is created. First you should ensure this is not causing any issues with deployments. Try to provisioning the VM without passing in any configuration. If you find the VM fails to provision, continue with the steps below, if you find the configuration you are passing is not being applied go [step 4](#).

## Step 2: Review image requirements

The primary cause of VM provisioning failure is the OS image doesn't satisfy the prerequisites for running on Azure. Make sure your images are properly prepared before attempting to provision them in Azure.

The following articles illustrate the steps to prepare various linux distributions that are supported in Azure:

- [CentOS-based Distributions](#)
- [Debian Linux](#)
- [Flatcar Container Linux](#)
- [Oracle Linux](#)
- [Red Hat Enterprise Linux](#)
- [SLES & openSUSE](#)
- [Ubuntu](#)
- [Others: Non-Endorsed Distributions](#)

For the [supported Azure cloud-init images](#), the Linux distributions already have all the required packages and configurations in place to correctly provision the image in Azure. If you find your VM is failing to create from your own curated image, try a supported Azure Marketplace image that already is configured for cloud-init, with your optional `customData`. If the `customData` works correctly with an Azure Marketplace image, then there is probably an issue with your curated image.

## Step 3: Collect & review VM logs

When the VM fails to provision, Azure will show 'creating' status, for 20 minutes, and then reboot the VM, and wait another 20 minutes before finally marking the VM deployment as failed, before finally marking it with an `OSProvisioningTimedOut` error.

While the VM is running, you will need the logs from the VM to understand why provisioning failed. To understand why VM provisioning failed, do not stop the VM. Keep the VM running. You will need to keep the failed VM in a running state in order to collect logs. To collect the logs, use one of the following methods:

- [Serial Console](#)
- [Enable Boot Diagnostics](#) before creating the VM and then [View](#) them during the boot.
- [Run AZ VM Repair](#) to attach and mount the OS disk, which will allow you to collect these logs:

```
/var/log/cloud-init*
/var/log/waagent*
/var/log/syslog*
/var/log/rsyslog*
/var/log/messages*
/var/log/kern*
/var/log/dmesg*
/var/log/boot*
```

To start initial troubleshooting, start with the cloud-init logs, and understand where the failure occurred, then use the other logs to deep dive, and provide additional insights.

- `/var/log/cloud-init.log`
- `/var/log/cloud-init-output.log`
- Serial/boot logs

In all logs, start searching for "Failed", "WARNING", "WARN", "err", "error", "ERROR". Setting configuration to ignore case-sensitive searches is recommended.

### TIP

If you are troubleshooting a custom image, you should consider adding a user during the image. If the provisioning fails to set the admin user, you can still log in to the OS.

## Analyzing the logs

Here are more details about what to look for in each cloud-init log.

### `/var/log/cloud-init.log`

By default, all cloud-init events with a priority of debug or higher, are written to `/var/log/cloud-init.log`. This provides verbose logs of every event that occurred during cloud-init initialization.

For example:

```
2019-10-10 04:51:25,321 - util.py[DEBUG]: Failed mount of '/dev/sr0' as 'auto': Unexpected error while running command.
Command: ['mount', '-o', 'ro,sync', '-t', 'auto', u'/dev/sr0', '/run/cloud-init/tmp/tmpLirklc']
Exit code: 32
Reason: -
Stdout:
Stderr: mount: unknown filesystem type 'udf'
2020-01-31 00:21:53,352 - DataSourceAzure.py[WARNING]: /dev/sr0 was not mountable
```

Once you have found an error or warning, read backwards in the cloud-init log to understand what cloud-init was attempting before it hit the error or warning. In many cases cloud-init will have run OS commands or performed provisioning operations prior to the error, which can provide insights as to why errors appeared in the logs. The following example shows that cloud-init attempted to mount a device right before it hit an error.

```
2019-10-10 04:51:24,010 - util.py[DEBUG]: Running command ['mount', '-o', 'ro,sync', '-t', 'auto', u'/dev/sr0', '/run/cloud-init/tmp/tmpXXXXX'] with allowed return codes [0] (shell=False, capture=True)
```

If you have access to the [Serial Console](#), you can try to rerun the command that cloud-init was trying to run.

The logging for `/var/log/cloud-init.log` can also be reconfigured within `/etc/cloud/cloud.cfg.d/05_logging.cfg`. For more details of cloud-init logging, refer to the [cloud-init documentation](#).

### /var/log/cloud-init-output.log

You can get information from the `stdout` and `stderr` during the [stages of cloud-init](#). This normally involves routing table information, networking information, ssh host key verification information, `stdout` and `stderr` for each stage of cloud-init, along with the timestamp for each stage. If desired, `stderr` and `stdout` logging can be reconfigured from `/etc/cloud/cloud.cfg.d/05_logging.cfg`.

### Serial/boot logs

Cloud-init has multiple dependencies, these are documented in required prerequisites for images on Azure, such as networking, storage, ability to mount an ISO, and mount and format the temporary disk. Any of these may throw errors and cause cloud-init to fail. For example, if the VM cannot get a DHCP lease, cloud-init will fail.

If you still cannot isolate why cloud-init failed to provision then you need to understand what cloud-init stages, and when modules run. See [Diving deeper into cloud-init](#) for more details.

## Step 4: Investigate why the configuration isn't being applied

Not every failure in cloud-init results in a fatal provisioning failure. For example, if you are using the `runcmd` module in a cloud-init config, a non-zero exit code from the command it is running will cause the VM provisioning to fail. This is because it runs after core provisioning functionality that happens in the first 3 stages of cloud-init. To troubleshoot why the configuration did not apply, review the logs in Step 3, and cloud-init modules manually. For example:

- `runcmd` - do the scripts run without errors? Run the configuration manually from the terminal to ensure they run as expected.
- Installing packages - does the VM have access to package repositories?
- You should also check the `customData` data configuration that was provided to the VM, this is located in `/var/lib/cloud/instances/<unique-instance-identifier>/user-data.txt`.

## Next steps

If you still cannot isolate why cloud-init did not run the configuration, you need to look more closely at what happens in each cloud-init stage, and when modules run. See [Diving deeper into cloud-init configuration](#) for

more information.

# Use cloud-init to set hostname for a Linux VM in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use [cloud-init](#) to configure a specific hostname on a virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see [cloud-init overview](#)

## Set the hostname with cloud-init

By default, the hostname is the same as the VM name when you create a new virtual machine in Azure. To run a cloud-init script to change this default hostname when you create a VM in Azure with [az vm create](#), specify the cloud-init file with the `--custom-data` switch.

To see upgrade process in action, create a file in your current shell named `cloud_init_hostname.txt` and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Enter `sensible-editor cloud_init_hostname.txt` to create the file and see a list of available editors. Choose #1 to use the `nano` editor. Make sure that the whole cloud-init file is copied correctly, especially the first line.

```
#cloud-config
fqdn: myhostname
```

Before deploying this image, you need to create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `myResourceGroup` in the `eastus` location.

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with [az vm create](#) and specify the cloud-init file with `--custom-data cloud_init_hostname.txt` as follows:

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS:7-CI:latest \
--custom-data cloud_init_hostname.txt \
--generate-ssh-keys
```

Once created, the Azure CLI shows information about the VM. Use the `publicIpAddress` to SSH to your VM. Enter your own address as follows:

```
ssh <publicIpAddress>
```

To see the VM name, use the `hostname` command as follows:

```
hostname
```

The VM should report the hostname as that value set in the cloud-init file, as shown in the following example output:

```
myhostname
```

## Next steps

For additional cloud-init examples of configuration changes, see the following:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Use cloud-init to update and install packages in a Linux VM in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use [cloud-init](#) to update packages on a Linux virtual machine (VM) or virtual machine scale sets at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see [cloud-init overview](#)

## Update a VM with cloud-init

For security purposes, you may want to configure a VM to apply the latest updates on first boot. As cloud-init works across different Linux distros, there is no need to specify `apt` or `yum` for the package manager. Instead, you define `package_upgrade` and let the cloud-init process determine the appropriate mechanism for the distro in use.

For this example, we will be using the Azure Cloud Shell. To see the upgrade process in action, create a file named `cloud_init_upgrade.txt` and paste the following configuration.

Select the Try it button on the code block below to open the Cloud Shell. To create the file and see a list of available editors in the Cloud Shell, type the following:

```
sensible-editor cloud_init_upgrade.txt
```

Copy the text below and paste it into the `cloud_init_upgrade.txt` file. Make sure that the whole cloud-init file is copied correctly, especially the first line.

```
#cloud-config
package_upgrade: true
packages:
- httpd
```

Before deploying, you need to create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `myResourceGroup` in the `eastus` location.

```
az group create --name myCentOSGroup --location eastus
```

Now, create a VM with [az vm create](#) and specify the cloud-init file with the `--custom-data` parameter as follows:

```
az vm create \
--resource-group myCentOSGroup \
--name centos83 \
--image OpenLogic:CentOS:8_3:latest \
--custom-data cloud_init_upgrade.txt \
--admin-username azureuser \
--generate-ssh-keys
```

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own `publicIpAddress` as follows:

```
ssh azureuser@<publicIpAddress>
```

Run the package management tool and check for updates.

```
sudo yum update
```

As cloud-init checked for and installed updates on boot, there should be no additional updates to apply. You see the update process, number of altered packages as well as the installation of `httpd` by running `yum history` and review the output similar to the one below.

| ID | Command line     | Date and time    | Action(s) | Altered |
|----|------------------|------------------|-----------|---------|
| 3  | -y install httpd | 2022-02-18 18:30 | Install   | 7       |
| 2  | -y upgrade       | 2022-02-18 18:23 | I, O, U   | 321 EE  |
| 1  |                  | 2021-02-04 19:20 | Install   | 496 EE  |

## Next steps

For additional cloud-init examples of configuration changes, see the following:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Use cloud-init to add a user to a Linux VM in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use [cloud-init](#) to add a user on a virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. This cloud-init script runs on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see [cloud-init overview](#).

## Add a user to a VM with cloud-init

One of the first tasks on any new Linux VM is to add an additional user for yourself to avoid the use of `root`. SSH keys are best practice for security and usability. Keys are added to the `~/.ssh/authorized_keys` file with this cloud-init script.

To add a user to a Linux VM, create a file in your current shell named `cloud_init_add_user.txt` and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Enter `sensible-editor cloud_init_add_user.txt` to create the file and see a list of available editors. Choose #1 to use the `nano` editor. Make sure that the whole cloud-init file is copied correctly, especially the first line. You need to provide your own public key (such as the contents of `~/.ssh/id_rsa.pub`) for the value of `ssh-authorized-keys:` - it has been shortened here to simplify the example.

```
#cloud-config
users:
  - default
  - name: myadminuser
    groups: sudo
    shell: /bin/bash
    sudo: ['ALL=(ALL) NOPASSWD:ALL']
    ssh-authorized-keys:
      - ssh-rsa AAAAB3<snip>
```

### NOTE

The `#cloud-config` file includes the `- default` parameter included. This will append the user, to the existing admin user created during provisioning. If you create a user without the `- default` parameter - the auto generated admin user created by the Azure platform would be overwritten.

Before deploying this image, you need to create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `myResourceGroup` in the `eastus` location.

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with [az vm create](#) and specify the cloud-init file with `--custom-data cloud_init_add_user.txt` as follows:

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS:7-CI:latest \
--custom-data cloud_init_add_user.txt \
--generate-ssh-keys
```

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own `publicIpAddress` as follows:

```
ssh <publicIpAddress>
```

To confirm your user was added to the VM and the specified groups, view the contents of the `/etc/group` file as follows:

```
cat /etc/group
```

The following example output shows the user from the `cloud_init_add_user.txt` file has been added to the VM and the appropriate group:

```
root:x:0:
<snip />
sudo:x:27:myadminuser
<snip />
myadminuser:x:1000:
```

## Next steps

For additional cloud-init examples of configuration changes, see the following:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Use cloud-init to configure a swap partition on a Linux VM

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use [cloud-init](#) to configure the swap partition on various Linux distributions. The swap partition was traditionally configured by the Linux Agent (WALA) based on which distributions required one. This document will outline the process for building the swap partition on demand during provisioning time using cloud-init. For more information about how cloud-init works natively in Azure and the supported Linux distros, see [cloud-init overview](#)

## Create swap partition for Ubuntu based images

By default on Azure, Ubuntu gallery images do not create swap partitions. To enable swap partition configuration during VM provisioning time using cloud-init - please see the [AzureSwapPartitions document](#) on the Ubuntu wiki.

## Create swap partition for Red Hat and CentOS based images

Create a file in your current shell named `cloud_init_swappart.txt` and paste the following configuration. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Enter `sensible-editor cloud_init_swappart.txt` to create the file and see a list of available editors. Choose #1 to use the `nano` editor. Make sure that the whole cloud-init file is copied correctly, especially the first line.

```
#cloud-config
disk_setup:
  ephemeral0:
    table_type: gpt
    layout: [66, [33,82]]
    overwrite: true
fs_setup:
  - device: ephemeral0.1
    filesystem: ext4
  - device: ephemeral0.2
    filesystem: swap
mounts:
  - ["ephemeral0.1", "/mnt"]
  - ["ephemeral0.2", "none", "swap", "sw,nofail,x-systemd.requires=cloud-init.service", "0", "0"]
```

The mount is created with the `nofail` option to ensure that the boot will continue even if the mount is not completed successfully.

Before deploying this image, you need to create a resource group with the `az group create` command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `myResourceGroup` in the `eastus` location.

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with `az vm create` and specify the cloud-init file with `--custom-data cloud_init_swappart.txt` as follows:

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS:7-CI:latest \
--custom-data cloud_init_swappart.txt \
--generate-ssh-keys
```

## Verify swap partition was created

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own **publicIpAddress** as follows:

```
ssh <publicIpAddress>
```

Once you have SSH'ed into the vm, check if the swap partition was created

```
swapon -s
```

The output from this command should look like this:

| Filename  | Type      | Size    | Used | Priority |
|-----------|-----------|---------|------|----------|
| /dev/sdb2 | partition | 2494440 | 0    | -1       |

### NOTE

If you have an existing Azure image that has a swap partition configured and you want to change the swap partition configuration for new images, you should remove the existing swap partition. Please see 'Customize Images to provision by cloud-init' document for more details.

## Next steps

For additional cloud-init examples of configuration changes, see the following:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Use cloud-init to run a bash script in a Linux VM in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use [cloud-init](#) to run an existing bash script on a Linux virtual machine (VM) or virtual machine scale sets (VMSS) at provisioning time in Azure. These cloud-init scripts run on first boot once the resources have been provisioned by Azure. For more information about how cloud-init works natively in Azure and the supported Linux distros, see [cloud-init overview](#)

## Run a bash script with cloud-init

With cloud-init you do not need to convert your existing scripts into a cloud-config, cloud-init accepts multiple input types, one of which is a bash script.

If you have been using the Linux Custom Script Azure Extension to run your scripts, you can migrate them to use cloud-init. However, Azure Extensions have integrated reporting to alert to script failures, a cloud-init image deployment will NOT fail if the script fails.

To see this functionality in action, create a simple bash script for testing. Like the cloud-init `#cloud-config` file, this script must be local to where you will be running the AzureCLI commands to provision your virtual machine. For this example, create the file in the Cloud Shell not on your local machine. You can use any editor you wish. Enter `sensible-editor simple_bash.sh` to create the file and see a list of available editors. Choose #1 to use the `nano` editor. Make sure that the whole cloud-init file is copied correctly, especially the first line.

```
#!/bin/sh
echo "this has been written via cloud-init" + $(date) >> /tmp/myScript.txt
```

Before deploying this image, you need to create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location.

```
az group create --name myResourceGroup --location eastus
```

Now, create a VM with [az vm create](#) and specify the bash script file with `--custom-data simple_bash.sh` as follows:

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS:7-CI:latest \
--custom-data simple_bash.sh \
--generate-ssh-keys
```

## Verify bash script has run

SSH to the public IP address of your VM shown in the output from the preceding command. Enter your own `publicIpAddress` as follows:

```
ssh <publicIpAddress>
```

Change to the **/tmp** directory and verify that myScript.txt file exists and has the appropriate text inside of it. If it does not, you can check the **/var/log/cloud-init.log** for more details. Search for the following entry:

```
Running config-scripts-user using lock Running command ['/var/lib/cloud/instance/scripts/part-001']
```

## Next steps

For additional cloud-init examples of configuration changes, see the following:

- [Add an additional Linux user to a VM](#)
- [Run a package manager to update existing packages on first boot](#)
- [Change VM local hostname](#)
- [Install an application package, update configuration files and inject keys](#)

# Creating generalized images without a provisioning agent

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Microsoft Azure provides provisioning agents for Linux VMs in the form of the [walinuxagent](#) or [cloud-init](#) (recommended). But there could be a scenario when you don't want to use either of these applications for your provisioning agent, such as:

- Your Linux distro/version does not support cloud-init/Linux Agent.
- You require specific VM properties to be set, such as hostname.

## NOTE

If you do not require any properties to be set or any form of provisioning to happen you should consider creating a specialized image.

This article shows how you can setup your VM image to satisfy the Azure platform requirements and set the hostname, without installing a provisioning agent.

## Networking and reporting ready

In order to have your Linux VM communicating with Azure components, you will require a DHCP client to retrieve a host IP from the virtual network, as well as DNS resolution and route management. Most distros ship with these utilities out-of-the-box. Tools that have been tested on Azure by Linux distro vendors include

`dhclient` , `network-manager` , `systemd-networkd` and others.

## NOTE

Currently creating generalized images without a provisioning agent only supports DHCP-enabled VMs.

After networking has been setup and configured, you must "report ready". This will tell Azure that the VM has been successfully provisioning.

## IMPORTANT

Failing to report ready to Azure will result in your VM being rebooted!

## Demo/sample

This demo will show how you can take an existing Marketplace image (in this case, a Debian Buster VM) and remove the Linux Agent (walinuxagent), but also creating the most basic process to report to Azure that the VM is "ready".

### Create the resource group and base VM:

```
$ az group create --location eastus --name demo1
```

Create the base VM:

```
$ az vm create \
--resource-group demo1 \
--name demo1 \
--location eastus \
--ssh-key-value <ssh_pub_key_path> \
--public-ip-address-dns-name demo1 \
--image "debian:debian-10:10:latest"
```

## Remove the image provisioning Agent

Once the VM is provisioning, you can SSH into it and remove the Linux Agent:

```
$ sudo apt purge -y waagent
$ sudo rm -rf /var/lib/waagent /etc/waagent.conf /var/log/waagent.log
```

## Add required code to the VM

Also inside the VM, because we've removed the Azure Linux Agent we need to provide a mechanism to report ready.

### Python script

```
import http.client
import sys
from xml.etree import ElementTree

wireserver_ip = '168.63.129.16'
wireserver_conn = http.client.HTTPConnection(wireserver_ip)

print('Retrieving goal state from the Wireserver')
wireserver_conn.request(
    'GET',
    '/machine?comp=goalstate',
    headers={'x-ms-version': '2012-11-30'}
)

resp = wireserver_conn.getresponse()

if resp.status != 200:
    print('Unable to connect with wireserver')
    sys.exit(1)

wireserver_goalstate = resp.read().decode('utf-8')

xml_el = ElementTree.fromstring(wireserver_goalstate)

container_id = xml_el.findtext('Container/ContainerId')
instance_id = xml_el.findtext('Container/RoleInstanceList/RoleInstance/InstanceId')
incarnation = xml_el.findtext('Incarnation')
print(f'ContainerId: {container_id}')
print(f'InstanceId: {instance_id}')
print(f'Incarnation: {incarnation}')

# Construct the XML response we need to send to Wireserver to report ready.
health = ElementTree.Element('Health')
goalstate_incarnation = ElementTree.SubElement(health, 'GoalStateIncarnation')
goalstate_incarnation.text = incarnation
container = ElementTree.SubElement(health, 'Container')
container_id_el = ElementTree.SubElement(container, 'ContainerId')
container_id_el.text = container_id
role_instance_list = ElementTree.SubElement(container, 'RoleInstanceList')
role = ElementTree.SubElement(role_instance_list, 'Role')
instance_id_el = ElementTree.SubElement(role, 'InstanceId')
```

```
instance_id_el.text = instance_id
health_second = ElementTree.SubElement(role, 'Health')
state = ElementTree.SubElement(health_second, 'State')
state.text = 'Ready'

out_xml = ElementTree.tostring(
    health,
    encoding='unicode',
    method='xml'
)
print('Sending the following data to Wireserver:')
print(out_xml)

wireserver_conn.request(
    'POST',
    '/machine?comp=health',
    headers={
        'x-ms-version': '2012-11-30',
        'Content-Type': 'text/xml; charset=utf-8',
        'x-ms-agent-name': 'custom-provisioning'
    },
    body=out_xml
)

resp = wireserver_conn.getresponse()
print(f'Response: {resp.status} {resp.reason}')

wireserver_conn.close()
```

### Bash script

```

#!/bin/bash

attempts=1
until [ "$attempts" -gt 5 ]
do
    echo "obtaining goal state - attempt $attempts"
    goalstate=$(curl --fail -v -X 'GET' -H "x-ms-agent-name: azure-vm-register" \
        -H "Content-Type: text/xml;charset=utf-8" \
        -H "x-ms-version: 2012-11-30" \
        "http://168.63.129.16/machine/?comp=goalstate")
    if [ $? -eq 0 ]
    then
        echo "successfully retrieved goal state"
        retrieved_goal_state=true
        break
    fi
    sleep 5
    attempts=$((attempts+1))
done

if [ "$retrieved_goal_state" != "true" ]
then
    echo "failed to obtain goal state - cannot register this VM"
    exit 1
fi

container_id=$(grep ContainerId <<< "$goalstate" | sed 's/\s*<\/\*ContainerId>//g' | sed 's/\r//')
instance_id=$(grep InstanceId <<< "$goalstate" | sed 's/\s*<\/\*InstanceId>//g' | sed 's/\r//')

ready_doc=$(cat << EOF
<?xml version="1.0" encoding="utf-8"?>
<Health xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <GoalStateIncarnation>1</GoalStateIncarnation>
    <Container>
        <ContainerId>$container_id</ContainerId>
        <RoleInstanceList>
            <Role>
                <InstanceId>$instance_id</InstanceId>
                <Health>
                    <State>Ready</State>
                </Health>
            </Role>
        </RoleInstanceList>
    </Container>
</Health>
EOF
)

attempts=1
until [ "$attempts" -gt 5 ]
do
    echo "registering with Azure - attempt $attempts"
    curl --fail -v -X 'POST' -H "x-ms-agent-name: azure-vm-register" \
        -H "Content-Type: text/xml;charset=utf-8" \
        -H "x-ms-version: 2012-11-30" \
        -d "$ready_doc" \
        "http://168.63.129.16/machine?comp=health"
    if [ $? -eq 0 ]
    then
        echo "successfully register with Azure"
        break
    fi
    sleep 5 # sleep to prevent throttling from wire server
done

```

#### Generic steps (if not using Python or Bash)

If your VM doesn't have Python installed or available, you can programmatically reproduce this above script logic with the following steps:

1. Retrieve the `ContainerId`, `InstanceId`, and `Incarnation` by parsing the response from the WireServer:

```
curl -X GET -H 'x-ms-version: 2012-11-30' http://168.63.129.16/machine?comp=goalstate .
```

2. Construct the following XML data, injecting the parsed `ContainerId`, `InstanceId`, and `Incarnation` from the above step:

```
<Health>
  <GoalStateIncarnation>INCARNATION</GoalStateIncarnation>
  <Container>
    <ContainerId>CONTAINER_ID</ContainerId>
    <RoleInstanceList>
      <Role>
        <InstanceId>INSTANCE_ID</InstanceId>
        <Health>
          <State>Ready</State>
        </Health>
      </Role>
    </RoleInstanceList>
  </Container>
</Health>
```

3. Post this data to WireServer:

```
curl -X POST -H 'x-ms-version: 2012-11-30' -H "x-ms-agent-name: WALinuxAgent" -H "Content-Type: text/xml; charset=utf-8" -d "$REPORT_READY_XML" http://168.63.129.16/machine?comp=health
```

## Automating running the code at first boot

This demo uses systemd, which is the most common init system in modern Linux distros. So the easiest and most native way to ensure this report ready mechanism runs at the right time is to create a systemd service unit. You can add the following unit file to `/etc/systemd/system` (this example names the unit file

```
azure-provisioning.service ):
```

```
[Unit]
Description=Azure Provisioning

[Service]
Type=oneshot
ExecStart=/usr/bin/python3 /usr/local/azure-provisioning.py
ExecStart=/bin/bash -c "hostnamectl set-hostname $(curl \
-H 'metadata: true' \
'http://169.254.169.254/metadata/instance/compute/name?api-version=2019-06-01&format=text')"
ExecStart=/usr/bin/systemctl disable azure-provisioning.service

[Install]
WantedBy=multi-user.target
```

This systemd service does three things for basic provisioning:

1. Reports ready to Azure (to indicate that it came up successfully).
2. Renames the VM based off of the user-supplied VM name by pulling this data from [Azure Instance Metadata Service \(IMDS\)](#). Note IMDS also provides other [instance metadata](#), such as SSH Public Keys, so you can set more than the hostname.
3. Disables itself so that it only runs on first boot and not on subsequent reboots.

With the unit on the filesystem, run the following to enable it:

```
$ sudo systemctl enable azure-provisioning.service
```

Now the VM is ready to be generalized and have an image created from it.

#### Completing the preparation of the image

Back on your development machine, run the following to prepare for image creation from the base VM:

```
$ az vm deallocate --resource-group demo1 --name demo1
$ az vm generalize --resource-group demo1 --name demo1
```

And create the image from this VM:

```
$ az image create \
--resource-group demo1 \
--source demo1 \
--location eastus \
--name demo1img
```

Now we are ready to create a new VM (or multiple VMs) from the image:

```
$ IMAGE_ID=$(az image show -g demo1 -n demo1img --query id -o tsv)
$ az vm create \
--resource-group demo12 \
--name demo12 \
--location eastus \
--ssh-key-value <ssh_pub_key_path> \
--public-ip-address-dns-name demo12 \
--image "$IMAGE_ID"
--enable-agent false
```

#### NOTE

It is important to set `--enable-agent` to `false` because walinuxagent doesn't exist on this VM that is going to be created from the image.

This VM should provisioning successfully. Logging into the newly-provisioning VM, you should be able to see the output of the report ready systemd service:

```
$ sudo journalctl -u azure-provisioning.service
-- Logs begin at Thu 2020-06-11 20:28:45 UTC, end at Thu 2020-06-11 20:31:24 UTC. --
Jun 11 20:28:49 thstringnopa systemd[1]: Starting Azure Provisioning...

```

## Support

If you implement your own provisioning code/agent, then you own the support of this code, Microsoft support will only investigate issues relating to the provisioning interfaces not being available. We are continually making improvements and changes in this area, so you must monitor for changes in cloud-init and Azure Linux Agent for provisioning API changes.

## Next steps

For more information, see [Linux provisioning](#).

# Disable or remove the Linux Agent from VMs and images

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Before removing the Linux Agent, you must understand of what VM will not be able to do after the Linux Agent is removed.

Azure virtual machine (VM) [extensions](#) are small applications that provide post-deployment configuration and automation tasks on Azure VMs, extensions are installed and managed by the Azure control plane. It is the job of the [Azure Linux Agent](#) to process the platform extension commands and ensure the correct state of the extension inside the VM.

The Azure platform hosts many extensions that range from VM configuration, monitoring, security, and utility applications. There is a large choice of first and third-party extensions, examples of key scenarios that extensions are used for:

- Supporting first party Azure services, such as Azure Backup, Monitoring, Disk Encryption, Security, Site Replication and others.
- SSH / Password resets
- VM configuration - Running custom scripts, installing Chef, Puppet agents etc..
- Third-party products, such as AV products, VM vulnerability tools, VM and App monitoring tooling.
- Extensions can be bundled with a new VM deployment. For example, they can be part of a larger deployment, configuring applications on VM provision, or run against any supported extension operated systems post deployment.

## Disabling extension processing

There are several ways to disable extension processing, depending on your needs, but before you continue, you **MUST** remove all extensions deployed to the VM, for example using the Azure CLI, you can [list](#) and [delete](#):

```
az vm extension delete -g MyResourceGroup --vm-name MyVm -n extension_name
```

### NOTE

If you do not do the above, the platform will try to send the extension configuration and timeout after 40min.

### Disable at the control plane

If you are not sure whether you will need extensions in the future, you can leave the Linux Agent installed on the VM, then disable extension processing capability from the platform. This is option is available in

`Microsoft.Compute` api version `2018-06-01` or higher, and does not have a dependency on the Linux Agent version installed.

```
az vm update -g <resourceGroup> -n <vmName> --set osProfile.allowExtensionOperations=false
```

You can easily reenable this extension processing from the platform, with the above command, but set it to 'true'.

# Remove the Linux Agent from a running VM

Ensure you have **removed** all existing extensions from the VM before, as per above.

## Step 1: Remove the Azure Linux Agent

If you just remove the Linux Agent, and not the associated configuration artifacts, you can reinstall at a later date. Run one of the following, as root, to remove the Azure Linux Agent:

### For Ubuntu >=18.04

```
apt -y remove walinuxagent
```

### For Redhat >= 7.7

```
yum -y remove WALinuxAgent
```

### For SUSE

```
zypper --non-interactive remove python-azure-agent
```

## Step 2: (Optional) Remove the Azure Linux Agent artifacts

### IMPORTANT

You can remove all associated artifacts of the Linux Agent, but this will mean you cannot reinstall it at a later date. Therefore, it is strongly recommended you consider disabling the Linux Agent first, removing the Linux Agent using the above only.

If you know you will not ever reinstall the Linux Agent again, then you can run the following:

### For Ubuntu >=18.04

```
apt -y purge walinuxagent
rm -rf /var/lib/waagent
rm -f /var/log/waagent.log
```

### For Redhat >= 7.7

```
yum -y remove WALinuxAgent
rm -f /etc/waagent.conf.rpmsave
rm -rf /var/lib/waagent
rm -f /var/log/waagent.log
```

### For SUSE

```
zypper --non-interactive remove python-azure-agent
rm -f /etc/waagent.conf.rpmsave
rm -rf /var/lib/waagent
rm -f /var/log/waagent.log
```

# Preparing an image without the Linux Agent

If you have an image that already contains cloud-init, and you want to remove the Linux agent, but still provision using cloud-init, run the steps in Step 2 (and optionally Step 3) as root to remove the Azure Linux Agent and

then the following will remove the cloud-init configuration and cached data, and prepare the VM to create a custom image.

```
cloud-init clean --logs --seed
```

## Deprovision and create an image

The Linux Agent has the ability to clean up some of the existing image metadata, with the step "waagent - deprovision+user", however, after it has been removed, you will need to perform actions such as the below, and remove any other sensitive data from it.

- Remove all existing ssh host keys

```
rm /etc/ssh/ssh_host_*key*
```

- Delete the admin account

```
touch /var/run/utmp
userdel -f -r <admin_user_account>
```

- Delete the root password

```
passwd -d root
```

Once you have completed the above, you can create the custom image using the Azure CLI.

### Create a regular managed image

```
az vm deallocate -g <resource_group> -n <vm_name>
az vm generalize -g <resource_group> -n <vm_name>
az image create -g <resource_group> -n <image_name> --source <vm_name>
```

### Create an image version in a Azure Compute Gallery

```
az sig image-version create \
-g $sigResourceGroup
--gallery-name $signName
--gallery-image-definition $imageDefName
--gallery-image-version 1.0.0
--managed-image /subscriptions/00000000-0000-0000-0000-
00000000xxxx/resourceGroups/imageGroups/providers/images/MyManagedImage
```

### Creating a VM from an image that does not contain a Linux Agent

When you create the VM from the image with no Linux Agent, you need to ensure the VM deployment configuration indicates extensions are not supported on this VM.

#### NOTE

If you do not do the above, the platform will try to send the extension configuration and timeout after 40min.

To deploy the VM with extensions disabled, you can use the Azure CLI with [--enable-agent](#).

```
az vm create \
--resource-group $resourceGroup \
--name $prodVmName \
--image RedHat:RHEL:8.1-ci:latest \
--admin-username azadmin \
--ssh-key-value "$sshPubkeyPath" \
--enable-agent false
```

Alternatively, you can do this using Azure Resource Manager (ARM) templates, by setting

```
"provisionVMAgent": false,
```

```
"osProfile": {
  "computerName": "[parameters('virtualMachineName')]",
  "adminUsername": "[parameters('adminUsername')]",
  "linuxConfiguration": {
    "disablePasswordAuthentication": "true",
    "provisionVMAgent": false,
    "ssh": {
      "publicKeys": [
        {
          "path": "[concat('/home/', parameters('adminUsername'), '/.ssh/authorized_keys')]",
          "keyData": "[parameters('adminPublicKey')]"
        }
      ]
    }
  }
}
```

## Next steps

For more information, see [Provisioning Linux](#).

# Prepare a Windows VHD or VHDX to upload to Azure

9/21/2022 • 20 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Before you upload a Windows virtual machine (VM) from on-premises to Azure, you must prepare the virtual hard disk (VHD or VHDX). Azure supports both generation 1 and generation 2 VMs that are in VHD file format and that have a fixed-size disk. The maximum size allowed for the OS VHD on a generation 1 VM is 2 TB.

You can convert a VHDX file to VHD, convert a dynamically expanding disk to a fixed-size disk, but you can't change a VM's generation. For more information, see [Should I create a generation 1 or 2 VM in Hyper-V?](#) and [Support for generation 2 VMs on Azure](#).

For information about the support policy for Azure VMs, see [Microsoft server software support for Azure VMs](#).

## NOTE

The instructions in this article apply to:

- The 64-bit version of Windows Server 2008 R2 and later Windows Server operating systems. For information about running a 32-bit operating system in Azure, see [Support for 32-bit operating systems in Azure VMs](#).
- If any Disaster Recovery tool will be used to migrate the workload, like Azure Site Recovery or Azure Migrate, this process is still required on the Guest OS to prepare the image before the migration.

## System File Checker

### Run Windows System File Checker utility before generalization of OS image

The System File Checker (SFC) is used to verify and replace Windows system files.

## IMPORTANT

Use an elevated PowerShell session to run the examples in this article.

Run the SFC command:

```
sfc.exe /scannow
```

```
Beginning system scan. This process will take some time.
```

```
Beginning verification phase of system scan.  
Verification 100% complete.
```

```
Windows Resource Protection did not find any integrity violations.
```

After the SFC scan completes, install Windows Updates and restart the computer.

## Set Windows configurations for Azure

#### NOTE

Azure platform mounts an ISO file to the DVD-ROM when a Windows VM is created from a generalized image. For this reason, the DVD-ROM must be enabled in the OS in the generalized image. If it is disabled, the Windows VM will be stuck at out-of-box experience (OOBE).

#### 1. Remove any static persistent routes in the routing table:

- To view the routing table, run `route.exe print`.
- Check the **Persistence Routes** section. If there's a persistent route, use the `route.exe delete` command to remove it.

#### 2. Remove the WinHTTP proxy:

```
netsh.exe winhttp reset proxy
```

If the VM needs to work with a specific proxy, add a proxy exception for the Azure IP address ([168.63.129.16](#)) so the VM can connect to Azure:

```
$proxyAddress='<your proxy server>'  
$proxyBypassList='<your list of bypasses>;168.63.129.16'  
netsh.exe winhttp set proxy $proxyAddress $proxyBypassList
```

#### 3. Open DiskPart:

```
diskpart.exe
```

Set the disk SAN policy to [Onlineall](#):

```
DISKPART> san policy=onlineall  
DISKPART> exit
```

#### 4. Set Coordinated Universal Time (UTC) time for Windows. Also, set the startup type of the Windows time service **w32time** to **Automatic**:

```
Set-ItemProperty -Path HKLM:\SYSTEM\CurrentControlSet\Control\TimeZoneInformation -Name  
RealTimeIsUniversal -Value 1 -Type DWord -Force  
Set-Service -Name w32time -StartupType Automatic
```

#### 5. Set the power profile to high performance:

```
powercfg.exe /setactive SCHEME_MIN  
powercfg /setacvalueindex SCHEME_CURRENT SUB_VIDEO VIDEOIDLE 0
```

#### 6. Make sure the environmental variables **TEMP** and **TMP** are set to their default values:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Environment' -Name  
TEMP -Value "%SystemRoot%\TEMP" -Type ExpandString -Force  
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Environment' -Name TMP  
-Value "%SystemRoot%\TEMP" -Type ExpandString -Force
```

#### 7. For VMs with legacy operating systems (Windows Server 2012 R2 or Windows 8.1 and below), make

sure the latest Hyper-V Integration Component Services are installed. For more information, see [Hyper-V integration components update for Windows VM](#).

#### NOTE

In a scenario where VMs are to be set up with a disaster recovery solution between the on-premises VMware server and Azure, the Hyper-V Integration Component Services can't be used. If that's the case, please contact the VMware support to migrate the VM to Azure and make it co-reside in VMware server.

## Check the Windows services

Make sure that each of the following Windows services is set to the Windows default value. These services are the minimum that must be configured to ensure VM connectivity. To set the startup settings, run the following example:

```
Get-Service -Name BFE, Dhcp, Dnscache, IKEEXT, iphlpsvc, nsi, mpssvc, RemoteRegistry |  
    Where-Object StartType -ne Automatic |  
        Set-Service -StartupType Automatic  
  
Get-Service -Name Netlogon, Netman, TermService |  
    Where-Object StartType -ne Manual |  
        Set-Service -StartupType Manual
```

## Update remote desktop registry settings

Make sure the following settings are configured correctly for remote access:

#### NOTE

If you receive an error message when running

```
Set-ItemProperty -Path 'HKLM:\SOFTWARE\ Policies\Microsoft\Windows NT\Terminal Services' -Name <string> -  
Value <object>
```

, you can safely ignore it. It means the domain isn't setting that configuration through a Group Policy Object.

1. Remote Desktop Protocol (RDP) is enabled:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server' -Name  
fDenyTSConnections -Value 0 -Type DWord -Force  
Set-ItemProperty -Path 'HKLM:\SOFTWARE\ Policies\Microsoft\Windows NT\Terminal Services' -Name  
fDenyTSConnections -Value 0 -Type DWord -Force
```

2. The RDP port is set up correctly using the default port of 3389:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -  
Name PortNumber -Value 3389 -Type DWord -Force
```

When you deploy a VM, the default rules are created for port 3389. To change the port number, do that after the VM is deployed in Azure.

3. The listener is listening on every network interface:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -  
Name LanAdapter -Value 0 -Type DWord -Force
```

4. Configure network-level authentication (NLA) mode for the RDP connections:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp' -Name UserAuthentication -Value 1 -Type DWord -Force
```

5. Set the keep-alive value:

```
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name KeepAliveEnable -Value 1 -Type DWord -Force  
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name KeepAliveInterval -Value 1 -Type DWord -Force  
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name KeepAliveTimeout -Value 1 -Type DWord -Force
```

6. Set the reconnect options:

```
Set-ItemProperty -Path 'HKLM:\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services' -Name fDisableAutoReconnect -Value 0 -Type DWord -Force  
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name fInheritReconnectSame -Value 1 -Type DWord -Force  
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name fReconnectSame -Value 0 -Type DWord -Force
```

7. Limit the number of concurrent connections:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\Winstations\RDP-Tcp' -Name MaxInstanceCount -Value 4294967295 -Type DWord -Force
```

8. Remove any self-signed certificates tied to the RDP listener:

```
if ((Get-Item -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp').Property -contains 'SSLCertificateSHA1Hash')  
{  
    Remove-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Terminal Server\WinStations\RDP-Tcp' -Name SSLCertificateSHA1Hash -Force  
}
```

This code ensures that you can connect when you deploy the VM. You can also review these settings after the VM is deployed in Azure.

9. If the VM is part of a domain, check the following policies to make sure the previous settings aren't reverted.

GOAL	POLICY	VALUE
RDP is enabled	Computer Configuration\Policies\Windows Settings\Administrative Templates\Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Allow users to connect remotely by using Remote Desktop
NLA group policy	Settings\Administrative Templates\Components\Remote Desktop Services\Remote Desktop Session Host\Security	Require user authentication for remote access by using NLA

GOAL	POLICY	VALUE
Keep-alive settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Configure keep-alive connection interval
Reconnect settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Reconnect automatically
Limited number of connection settings	Computer Configuration\Policies\Windows Settings\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections	Limit number of connections

## Configure Windows Firewall rules

- Turn on Windows Firewall on the three profiles (domain, standard, and public):

```
Set-NetFirewallProfile -Profile Domain, Public, Private -Enabled True
```

- Run the following example to allow WinRM through the three firewall profiles (domain, private, and public), and enable the PowerShell remote service:

```
Enable-PSRemoting -Force
Set-NetFirewallRule -Name WINRM-HTTP-In-TCP, WINRM-HTTP-In-TCP-PUBLIC -Enabled True
```

- Enable the following firewall rules to allow the RDP traffic:

```
Set-NetFirewallRule -Group '@FirewallAPI.dll,-28752' -Enabled True
```

- Enable the rule for file and printer sharing so the VM can respond to ping requests inside the virtual network:

```
Set-NetFirewallRule -Name FPS-ICMP4-ERQ-In -Enabled True
```

- Create a rule for the Azure platform network:

```
New-NetFirewallRule -DisplayName AzurePlatform -Direction Inbound -RemoteAddress 168.63.129.16 -Profile Any -Action Allow -EdgeTraversalPolicy Allow
New-NetFirewallRule -DisplayName AzurePlatform -Direction Outbound -RemoteAddress 168.63.129.16 -Profile Any -Action Allow
```

6. If the VM is part of a domain, check the following Azure AD policies to make sure the previous settings aren't reverted.

GOAL	POLICY	VALUE
Enable the Windows Firewall profiles	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Protect all network connections
Enable RDP	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Allow inbound Remote Desktop exceptions
	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Standard Profile\Windows Firewall	Allow inbound Remote Desktop exceptions
Enable ICMP-V4	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Domain Profile\Windows Firewall	Allow ICMP exceptions
	Computer Configuration\Policies\Windows Settings\Administrative Templates\Network\Network Connection\Windows Firewall\Standard Profile\Windows Firewall	Allow ICMP exceptions

## Verify the VM

Make sure the VM is healthy, secure, and RDP accessible:

1. To make sure the disk is healthy and consistent, check the disk at the next VM restart:

```
chkdsk.exe /f
```

Make sure the report shows a clean and healthy disk.

2. Set the Boot Configuration Data (BCD) settings.

```

cmd

bcdedit.exe /set "{bootmgr}" integrityservices enable
bcdedit.exe /set "{default}" device partition=C:
bcdedit.exe /set "{default}" integrityservices enable
bcdedit.exe /set "{default}" recoveryenabled Off
bcdedit.exe /set "{default}" osdevice partition=C:
bcdedit.exe /set "{default}" bootstatuspolicy IgnoreAllFailures

#Enable Serial Console Feature
bcdedit.exe /set "{bootmgr}" displaybootmenu yes
bcdedit.exe /set "{bootmgr}" timeout 5
bcdedit.exe /set "{bootmgr}" bootechos yes
bcdedit.exe /ems "{current}" ON
bcdedit.exe /emssettings EMSPORT:1 EMSBAUDRATE:115200

exit

```

3. The dump log can be helpful in troubleshooting Windows crash issues. Enable the dump log collection:

```

# Set up the guest OS to collect a kernel dump on an OS crash event
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name CrashDumpEnabled -Type DWord -Force -Value 2
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name DumpFile -Type ExpandString -Force -Value "%SystemRoot%\MEMORY.DMP"
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\CrashControl' -Name NMICrashDump -Type DWord -Force -Value 1

# Set up the guest OS to collect user mode dumps on a service crash event
$key = 'HKLM:\SOFTWARE\Microsoft\Windows\Windows Error Reporting\LocalDumps'
if ((Test-Path -Path $key) -eq $false) {(New-Item -Path 'HKLM:\SOFTWARE\Microsoft\Windows\Windows Error Reporting' -Name LocalDumps)}
New-ItemProperty -Path $key -Name DumpFolder -Type ExpandString -Force -Value 'C:\CrashDumps'
New-ItemProperty -Path $key -Name CrashCount -Type DWord -Force -Value 10
New-ItemProperty -Path $key -Name DumpType -Type DWord -Force -Value 2
Set-Service -Name WerSvc -StartupType Manual

```

4. Verify that the Windows Management Instrumentation (WMI) repository is consistent:

```
winmgmt.exe /verifyrepository
```

If the repository is corrupted, see [WMI: Repository corruption or not.](#)

5. Make sure no other applications than TermService are using port 3389. This port is used for the RDP service in Azure. To see which ports are used on the VM, run `netstat.exe -anob`:

```
netstat.exe -anob
```

The following is an example.

```

netstat.exe -anob | findstr 3389
TCP    0.0.0.0:3389          0.0.0.0:0          LISTENING      4056
TCP    [::]:3389             [::]:0            LISTENING      4056
UDP    0.0.0.0:3389          *:*              4056
UDP    [::]:3389             *:*              4056

tasklist /svc | findstr 4056
svchost.exe           4056  TermService

```

6. To upload a Windows VHD that's a domain controller:

- Follow [these extra steps](#) to prepare the disk.
- Make sure you know the Directory Services Restore Mode (DSRM) password in case you ever have to start the VM in DSRM. For more information, see [Set a DSRM password](#).

7. Make sure you know the built-in administrator account and password. You might want to reset the current local administrator password and make sure you can use this account to sign in to Windows through the RDP connection. This access permission is controlled by the "Allow log on through Remote Desktop Services" Group Policy Object. View this object in the Local Group Policy Editor:

- Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment

8. Check the following Azure AD policies to make sure they're not blocking RDP access:

- Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Deny access to this computer from the network

- Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Deny log on through Remote Desktop Services

9. Check the following Azure AD policy to make sure they're not removing any of the required access accounts:

- Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\Access this computer from the network

The policy should list the following groups:

- Administrators
- Backup Operators
- Everyone
- Users

10. Restart the VM to make sure that Windows is still healthy and can be reached through the RDP connection. At this point, consider creating a VM on your local Hyper-V server to make sure the VM starts completely. Then test to make sure you can reach the VM through RDP.

11. Remove any extra Transport Driver Interface (TDI) filters. For example, remove software that analyzes TCP packets or extra firewalls.

12. Uninstall any other third-party software or driver that's related to physical components or any other virtualization technology.

## Install Windows updates

### NOTE

To avoid an accidental reboot during the VM provisioning, we recommend completing all Windows update installations and to make sure there's no pending restart. One way to do this is to install all Windows updates and to reboot the VM before performing the migration to Azure.

If you also need to do a generalization of the OS (sysprep), you must update Windows and restart the VM before running the Sysprep command.

Ideally, you should keep the machine updated to the *patch level*, if this isn't possible, make sure the following updates are installed. To get the latest updates, see the Windows update history pages: [Windows 10](#), and [Windows Server 2019](#), [Windows 8.1](#), and [Windows Server 2012 R2](#) and [Windows 7 SP1](#), and [Windows Server](#)

#### NOTE

To avoid an accidental reboot during VM provisioning, we recommend ensuring that all Windows Update installations are finished and that no updates are pending. One way to do this is to install all possible Windows updates and reboot once before you run the `sysprep.exe` command.

## Determine when to use Sysprep

System Preparation Tool (`sysprep.exe`) is a process you can run to reset a Windows installation. Sysprep provides an "out of the box" experience by removing all personal data and resetting several components.

You typically run `sysprep.exe` to create a template from which you can deploy several other VMs that have a specific configuration. The template is called a *generalized image*.

To create only one VM from one disk, you don't have to use Sysprep. Instead, you can create the VM from a *specialized image*. For information about how to create a VM from a specialized disk, see:

- [Create a VM from a specialized disk](#)
- [Create a VM from a specialized VHD disk](#)

To create a generalized image, you need to run Sysprep. For more information, see [How to use Sysprep: An introduction](#).

Not every role or application that's installed on a Windows-based computer supports generalized images. Before you use this procedure, make sure Sysprep supports the role of the computer. For more information, see

## Sysprep support for server roles.

In particular, Sysprep requires the drives to be fully decrypted before execution. If you have enabled encryption on your VM, disable it before running Sysprep.

### Generalize a VHD

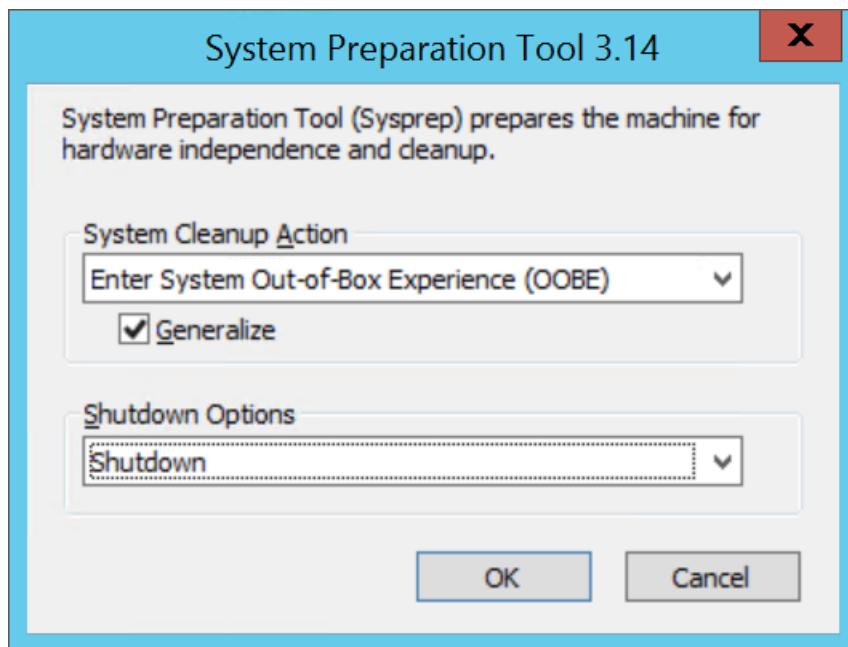

#### NOTE

If you're creating a generalized image from an existing Azure VM, we recommend to remove the VM extensions before running the sysprep.

#### NOTE

After you run `sysprep.exe` in the following steps, turn off the VM. Don't turn it back on until you create an image from it in Azure.

1. Sign in to the Windows VM.
2. Run a PowerShell session as an administrator.
3. Delete the panther directory (`C:\Windows\Panther`).
4. Change the directory to `%windir%\system32\sysprep`. Then run `sysprep.exe`.
5. In the **System Preparation Tool** dialog box, select **Enter System Out-of-Box Experience (OOBE)**, and make sure the **Generalize** checkbox is selected.

6. In **Shutdown Options**, select **Shutdown**.
7. Select **OK**.
8. When Sysprep finishes, shut down the VM. Don't use **Restart** to shut down the VM.

Now the VHD is ready to be uploaded. For more information about how to create a VM from a generalized disk, see [Upload a generalized VHD and use it to create a new VM in Azure](#).

#### **NOTE**

A custom *unattend.xml*/file is not supported. Although we do support the **additionalUnattendContent** property, that provides only limited support for adding [microsoft-windows-shell-setup](#) options into the *unattend.xml*/file that the Azure provisioning agent uses. You can use, for example, **additionalUnattendContent** to add FirstLogonCommands and LogonCommands. For more information, see [additionalUnattendContent FirstLogonCommands example](#).

## Convert the virtual disk to a fixed size VHD

#### **NOTE**

If you're going to use Azure PowerShell to [upload your disk to Azure](#) and you have [Hyper-V](#) enabled, this step is optional. [Add-AzVHD](#) will perform it for you.

Use one of the methods in this section to convert and resize your virtual disk to the required format for Azure:

1. Back up the VM before you run the virtual disk conversion or resize process.
2. Make sure that the Windows VHD works correctly on the local server. Resolve any errors within the VM itself before you try to convert or upload it to Azure.
3. Convert the virtual disk to type fixed.
4. Resize the virtual disk to meet Azure requirements:
  - a. Disks in Azure must have a virtual size aligned to 1 MiB. If your VHD is a fraction of 1 MiB, you'll need to resize the disk to a multiple of 1 MiB. Disks that are fractions of a MiB cause errors when creating images from the uploaded VHD. To verify the size you can use the PowerShell [Get-VHD](#) cmdlet to show "Size", which must be a multiple of 1 MiB in Azure, and "FileSize", which will be equal to "Size" plus 512 bytes for the VHD footer.

```
$vhd = Get-VHD -Path C:\test\MyNewVM.vhd  
$vhd.Size % 1MB  
0  
$vhd.FileSize - $vhd.Size  
512
```

- b. The maximum size allowed for the OS VHD with a generation 1 VM is 2,048 GiB (2 TiB).
- c. The maximum size for a data disk is 32,767 GiB (32 TiB).

#### **NOTE**

- If you are preparing a Windows OS disk after you convert to a fixed disk and resize if needed, create a VM that uses the disk. Start and sign in to the VM and continue with the sections in this article to finish preparing it for uploading.
- If you are preparing a data disk you may stop with this section and proceed to uploading your disk.

### Use Hyper-V Manager to convert the disk

1. Open Hyper-V Manager and select your local computer on the left. In the menu above the computer list, select **Action > Edit Disk**.
2. On the **Locate Virtual Hard Disk** page, select your virtual disk.
3. On the **Choose Action** page, select **Convert > Next**.
4. To convert from VHDX, select **VHD > Next**.

5. To convert from a dynamically expanding disk, select **Fixed size** > **Next**.
6. Locate and select a path to save the new VHD file.
7. Select **Finish**.

## Use PowerShell to convert the disk

You can convert a virtual disk using the [Convert-VHD](#) cmdlet in PowerShell. If you need information about installing this cmdlet see [Install the Hyper-V role](#).

### NOTE

If you're going to use Azure PowerShell to [upload your disk to Azure](#) and you have [Hyper-V](#) enabled, this step is optional. [Add-AzVHD](#) will perform it for you.

The following example converts the disk from VHDX to VHD. It also converts the disk from a dynamically expanding disk to a fixed-size disk.

```
Convert-VHD -Path C:\test\MyVM.vhdx -DestinationPath C:\test\MyNewVM.vhd -VHDTType Fixed
```

In this example, replace the value for **Path** with the path to the virtual hard disk that you want to convert. Replace the value for **DestinationPath** with the new path and name of the converted disk.

## Use Hyper-V Manager to resize the disk

### NOTE

If you're going to use Azure PowerShell to [upload your disk to Azure](#) and you have [Hyper-V](#) enabled, this step is optional. [Add-AzVHD](#) will perform it for you.

1. Open Hyper-V Manager and select your local computer on the left. In the menu above the computer list, select **Action** > **Edit Disk**.
2. On the **Locate Virtual Hard Disk** page, select your virtual disk.
3. On the **Choose Action** page, select **Expand** > **Next**.
4. On the **Locate Virtual Hard Disk** page, enter the new size in GiB > **Next**.
5. Select **Finish**.

## Use PowerShell to resize the disk

### NOTE

If you're going to use Azure PowerShell to [upload your disk to Azure](#) and you have [Hyper-V](#) enabled, this step is optional. [Add-AzVHD](#) will perform it for you.

You can resize a virtual disk using the [Resize-VHD](#) cmdlet in PowerShell. If you need information about installing this cmdlet see [Install the Hyper-V role](#).

The following example resizes the disk from 100.5 MiB to 101 MiB to meet the Azure alignment requirement.

```
Resize-VHD -Path C:\test\MyNewVM.vhd -SizeBytes 105906176
```

In this example, replace the value for **Path** with the path to the virtual hard disk that you want to resize. Replace the value for **SizeBytes** with the new size in bytes for the disk.

## Convert from VMware VMDK disk format

If you have a Windows VM image in the [VMDK file format](#), then you can use [Azure Migrate](#) to convert the VMDK and upload it to Azure.

## Complete the recommended configurations

The following settings don't affect VHD uploading. However, we strongly recommend that you configured them.

- Install the [Azure Virtual Machine Agent](#). Then you can enable VM extensions. The VM extensions implement most of the critical functionality that you might want to use with your VMs. You'll need the extensions, for example, to reset passwords or configure RDP. For more information, see the [Azure Virtual Machine Agent overview](#).
- After you create the VM in Azure, we recommend that you put the page file on the *temporal drive volume* to improve performance. You can set up the file placement as follows:

```
Set-ItemProperty -Path 'HKLM:\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management' -  
Name PagingFiles -Value 'D:\pagefile.sys' -Type MultiString -Force
```

If a data disk is attached to the VM, the temporal drive volume's letter is typically *D*. This designation could be different, depending on your settings and the number of available drives.

- We recommend disabling script blockers that might be provided by antivirus software. They might interfere and block the Windows Provisioning Agent scripts executed when you deploy a new VM from your image.

## Next steps

- [Upload a Windows VM image to Azure for Resource Manager deployments](#)
- [Troubleshoot Azure Windows VM activation problems](#)

# Remove machine specific information by generalizing a VM before creating an image

9/21/2022 • 3 minutes to read • [Edit Online](#)

Generalizing a VM is not necessary for creating an image in an [Azure Compute Gallery](#) unless you specifically want to create a generalized image. Generalizing is required when creating a managed image outside of a gallery.

Generalizing removes machine specific information so the image can be used to create multiple VMs. Once the VM has been generalized, you need to let the platform know so that the boot sequence can be set correctly.

## Linux

Distribution specific instructions for preparing Linux images for Azure are available here:

- [Generic steps](#)
- [CentOS](#)
- [Debian](#)
- [Flatcar](#)
- [FreeBSD](#)
- [Oracle Linux](#)
- [OpenBSD](#)
- [Red Hat](#)
- [SUSE](#)
- [Ubuntu](#)

The following instructions only cover setting the VM to generalized. We recommend you follow the distro specific instructions for production workloads.

First you'll deprovision the VM by using the Azure VM agent to delete machine-specific files and data. Use the `waagent` command with the `-deprovision+user` parameter on your source Linux VM. For more information, see the [Azure Linux Agent user guide](#). This process can't be reversed.

1. Connect to your Linux VM with an SSH client.
2. In the SSH window, enter the following command:

```
sudo waagent -deprovision+user
```

### NOTE

Only run this command on a VM that you'll capture as an image. This command does not guarantee that the image is cleared of all sensitive information or is suitable for redistribution. The `+user` parameter also removes the last provisioned user account. To keep user account credentials in the VM, use only `-deprovision`.

3. Enter `y` to continue. You can add the `-force` parameter to avoid this confirmation step.
4. After the command completes, enter `exit` to close the SSH client. The VM will still be running at this point.

Deallocate the VM that you deprovisioned with `az vm deallocate` so that it can be generalized.

```
az vm deallocate \
--resource-group myResourceGroup \
--name myVM
```

Then the VM needs to be marked as generalized on the platform.

```
az vm generalize \
--resource-group myResourceGroup \
--name myVM
```

## Windows

Sysprep removes all your personal account and security information, and then prepares the machine to be used as an image. For information about Sysprep, see [Sysprep overview](#).

Make sure the server roles running on the machine are supported by Sysprep. For more information, see [Sysprep support for server roles](#) and [Unsupported scenarios](#).

### IMPORTANT

After you have run Sysprep on a VM, that VM is considered *generalized* and cannot be restarted. The process of generalizing a VM is not reversible. If you need to keep the original VM functioning, you should create a [copy of the VM](#) and generalize its copy.

Sysprep requires the drives to be fully decrypted. If you have enabled encryption on your VM, disable encryption before you run Sysprep.

If you plan to run Sysprep before uploading your virtual hard disk (VHD) to Azure for the first time, make sure you have [prepared your VM](#).

We do not support custom answer file in the sysprep step, hence you should not use the "/unattend:*answerfile*" switch with your sysprep command.

To generalize your Windows VM, follow these steps:

1. Sign in to your Windows VM.
2. Open a Command Prompt window as an administrator.
3. Delete the panther directory (C:\Windows\Panther).
4. Then change the directory to %windir%\system32\sysprep, and then run:

```
sysprep.exe /oobe /generalize /mode:vm /shutdown
```

5. The VM will shut down when Sysprep is finished generalizing the VM. Do not restart the VM.

**TIP**

Optional Use **DISM** to optimize your image and reduce your VM's first boot time.

To optimize your image, mount your VHD by double-clicking on it in Windows explorer, and then run DISM with the **/optimize-image** parameter.

```
DISM /image:D:\ /optimize-image /boot
```

Where D: is the mounted VHD's path.

Running **DISM /optimize-image** should be the last modification you make to your VHD. If you make any changes to your VHD prior to deployment, you'll have to run **DISM /optimize-image** again.

Once Sysprep has finished, set the status of the virtual machine to **Generalized**.

```
Set-AzVm -ResourceGroupName $rgName -Name $vmName -Generalized
```

# Upload a generalized Windows VHD and use it to create new VMs in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

This article walks you through using PowerShell to upload a VHD of a generalized VM to Azure, create an image from the VHD, and create a new VM from that image. You can upload a VHD exported from an on-premises virtualization tool or from another cloud. Using [Managed Disks](#) for the new VM simplifies the VM management and provides better availability when the VM is placed in an availability set.

For a sample script, see [Sample script to upload a VHD to Azure and create a new VM](#).

## Before you begin

- Before uploading any VHD to Azure, you should follow [Prepare a Windows VHD or VHDX to upload to Azure](#).
- Review [Plan for the migration to Managed Disks](#) before starting your migration to [Managed Disks](#).

## Generalize the source VM by using Sysprep

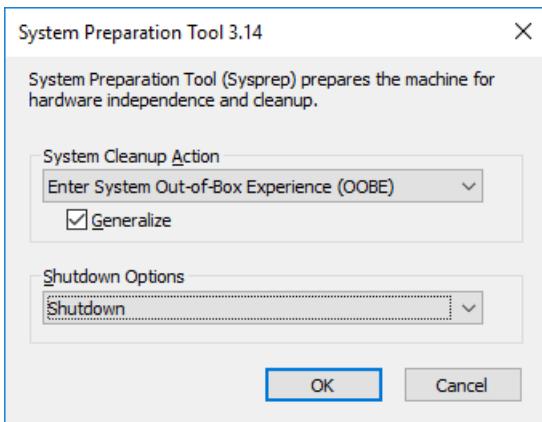

If you haven't already, you need to Sysprep the VM before uploading the VHD to Azure. Sysprep removes all your personal account information, among other things, and prepares the machine to be used as an image. For details about Sysprep, see the [Sysprep Overview](#).

Make sure the server roles running on the machine are supported by Sysprep. For more information, see [Sysprep Support for Server Roles](#).

### IMPORTANT

If you plan to run Sysprep before uploading your VHD to Azure for the first time, make sure you have [prepared your VM](#).

1. Sign in to the Windows virtual machine.
2. Open the Command Prompt window as an administrator.
3. Delete the panther directory (C:\Windows\Panther).
4. Change the directory to %windir%\system32\sysprep, and then run `sysprep.exe`.
5. In the **System Preparation Tool** dialog box, select **Enter System Out-of-Box Experience (OOBE)**, and make sure that the **Generalize** check box is enabled.
6. For **Shutdown Options**, select **Shutdown**.
7. Select **OK**.

- When Sysprep finishes, it shuts down the virtual machine. Do not restart the VM.

## Upload the VHD

You can now upload a VHD straight into a managed disk. For instructions, see [Upload a VHD to Azure using Azure PowerShell](#).

Once the VHD is uploaded to the managed disk, you need to use `Get-AzDisk` to get the managed disk.

```
$disk = Get-AzDisk -ResourceGroupName 'myResourceGroup' -DiskName 'myDiskName'
```

## Create the image

Create a managed image from your generalized OS managed disk. Replace the following values with your own information.

First, set some variables:

```
$location = 'East US'  
$imageName = 'myImage'  
$rgName = 'myResourceGroup'
```

Create the image using your managed disk.

```
$imageConfig = New-AzImageConfig `  
-Location $location  
$imageConfig = Set-AzImageOsDisk `  
-Image $imageConfig `  
-OsState Generalized `  
-OsType Windows `  
-ManagedDiskId $disk.Id
```

Create the image.

```
$image = New-AzImage `  
-ImageName $imageName `  
-ResourceGroupName $rgName `  
-Image $imageConfig
```

## Create the VM

Now that you have an image, you can create one or more new VMs from the image. This example creates a VM

named *myVM* from *myImage*, in *myResourceGroup*.

```
New-AzVm ` 
-ResourceGroupName $rgName ` 
-Name "myVM" ` 
-Image $image.Id ` 
-Location $location ` 
-VirtualNetworkName "myVnet" ` 
-SubnetName "mySubnet" ` 
-SecurityGroupName "myNSG" ` 
-PublicIpAddressName "myPIP"
```

## Next steps

Sign in to your new virtual machine. For more information, see [How to connect and log on to an Azure virtual machine running Windows](#).

# Create a managed image of a generalized VM in Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Managed images are helpful in development and test environments where you need a consistent baseline VM. A managed image resource can be created from a generalized virtual machine (VM) that is stored as either a managed disk or an unmanaged disk in a storage account. The image can then be used to create multiple VMs. For information on how managed images are billed, see [Managed Disks pricing](#).

One managed image supports up to 20 simultaneous deployments. Attempting to create more than 20 VMs concurrently, from the same managed image, may result in provisioning timeouts due to the storage performance limitations of a single VHD. To create more than 20 VMs concurrently, use an [Azure Compute Gallery](#) (formerly known as Shared Image Gallery) image configured with 1 replica for every 20 concurrent VM deployments.

## Prerequisites

You need a [generalized](#) VM in order to create an image.

## Create a managed image from a VM using the portal

1. Go to the [Azure portal](#). Search for and select **Virtual machines**.
2. Select your VM from the list.
3. In the **Virtual machine** page for the VM, on the upper menu, select **Capture**. The **Create an image** page appears.
4. For **Share image to Azure compute gallery**, select **No, capture only a managed image**.
5. For **Resource Group**, you can either create the image in the same resource group as the VM or select another resource group in your subscription.
6. For **Name**, either accept the pre-populated name or type your own name for the image.
7. If you want to delete the source VM after the image has been created, select **Automatically delete this virtual machine after creating the image**.
8. g. If you want the ability to use the image in any [availability zone](#), select **On** for **Zone resiliency**.
9. Select **Create** to create the image.

After the image is created, you can find it as an **Image** resource in the list of resources in the resource group.

## Create a managed image of a VM using PowerShell

Creating an image directly from the VM ensures that the image includes all of the disks associated with the VM, including the OS disk and any data disks. This example shows how to create a managed image from a VM that uses managed disks.

Before you begin, make sure that you have the latest version of the Azure PowerShell module. To find the version, run `Get-Module -ListAvailable Az` in PowerShell. If you need to upgrade, see [Install Azure PowerShell](#)

on Windows with [PowerShellGet](#). If you are running PowerShell locally, run `Connect-AzAccount` to create a connection with Azure.

#### NOTE

If you would like to store your image in zone-redundant storage, you need to create it in a region that supports [availability zones](#) and include the `-ZoneResilient` parameter in the image configuration (`New-AzImageConfig` command).

To create a VM image, follow these steps:

1. Create some variables.

```
$vmName = "myVM"  
$rgName = "myResourceGroup"  
$location = "EastUS"  
$imageName = "myImage"
```

2. Make sure the VM has been deallocated.

```
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force
```

3. Set the status of the virtual machine to **Generalized**.

```
Set-AzVm -ResourceGroupName $rgName -Name $vmName -Generalized
```

4. Get the virtual machine.

```
$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName
```

5. Create the image configuration.

```
$image = New-AzImageConfig -Location $location -SourceVirtualMachineId $vm.Id
```

6. Create the image.

```
New-AzImage -Image $image -ImageName $imageName -ResourceGroupName $rgName
```

## Create an image from a managed disk using PowerShell

If you want to create an image of only the OS disk, specify the managed disk ID as the OS disk:

1. Create some variables.

```
$vmName = "myVM"  
$rgName = "myResourceGroup"  
$location = "EastUS"  
$imageName = "myImage"
```

2. Get the VM.

```
$vm = Get-AzVm -Name $vmName -ResourceGroupName $rgName
```

3. Get the ID of the managed disk.

```
$diskID = $vm.StorageProfile.OsDisk.ManagedDisk.Id
```

4. Create the image configuration.

```
$imageConfig = New-AzImageConfig -Location $location  
$imageConfig = Set-AzImageOsDisk -Image $imageConfig -OsState Generalized -OsType Windows -  
ManagedDiskId $diskID
```

5. Create the image.

```
New-AzImage -ImageName $imageName -ResourceGroupName $rgName -Image $imageConfig
```

## Create a managed image from a snapshot using PowerShell

You can create a managed image from a snapshot of a generalized VM by following these steps:

1. Create some variables.

```
$rgName = "myResourceGroup"  
$location = "EastUS"  
$snapshotName = "mySnapshot"  
$imageName = "myImage"
```

2. Get the snapshot.

```
$snapshot = Get-AzSnapshot -ResourceGroupName $rgName -SnapshotName $snapshotName
```

3. Create the image configuration.

```
$imageConfig = New-AzImageConfig -Location $location  
$imageConfig = Set-AzImageOsDisk -Image $imageConfig -OsState Generalized -OsType Windows -  
SnapshotId $snapshot.Id
```

4. Create the image.

```
New-AzImage -ImageName $imageName -ResourceGroupName $rgName -Image $imageConfig
```

## Create a managed image from a VM that uses a storage account

To create a managed image from a VM that doesn't use managed disks, you need the URI of the OS VHD in the storage account, in the following format:

<https://mystorageaccountblob.core.windows.net/vhdcontainer/vhdfilename.vhd>. In this example, the VHD is in *mystorageaccount*, in a container named *vhdcontainer*, and the VHD filename is *vhdfilename.vhd*.

1. Create some variables.

```
$vmName = "myVM"
$rgName = "myResourceGroup"
$location = "EastUS"
$imageName = "myImage"
$osVhdUri = "https://mystorageaccount.blob.core.windows.net/vhdcontainer/vhdfilename.vhd"
```

2. Stop/deallocate the VM.

```
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force
```

3. Mark the VM as generalized.

```
Set-AzVm -ResourceGroupName $rgName -Name $vmName -Generalized
```

4. Create the image by using your generalized OS VHD.

```
$imageConfig = New-AzImageConfig -Location $location
$imageConfig = Set-AzImageOsDisk -Image $imageConfig -OsType Windows -OsState Generalized -BlobUri
$osVhdUri
$image = New-AzImage -ImageName $imageName -ResourceGroupName $rgName -Image $imageConfig
```

## Next steps

- [Create a VM from a managed image](#).
- Learn more about using an [Azure Compute Gallery](#) (formerly known as Shared Image Gallery)

# Create a VM from a managed image

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

You can create multiple virtual machines (VMs) from an Azure managed VM image using the Azure portal or PowerShell. A managed VM image contains the information necessary to create a VM, including the OS and data disks. The virtual hard disks (VHDs) that make up the image, including both the OS disks and any data disks, are stored as managed disks.

Before creating a new VM, you'll need to [create a managed VM image](#) to use as the source image and grant read access on the image to any user who should have access to the image.

One managed image supports up to 20 simultaneous deployments. Attempting to create more than 20 VMs concurrently, from the same managed image, may result in provisioning timeouts due to the storage performance limitations of a single VHD. To create more than 20 VMs concurrently, use an [Azure Compute Gallery](#) (formerly known as Shared Image Gallery) image configured with 1 replica for every 20 concurrent VM deployments.

## Use the portal

1. Go to the [Azure portal](#) to find a managed image. Search for and select **Images**.
2. Select the image you want to use from the list. The image **Overview** page opens.
3. Select **Create VM** from the menu.
4. Enter the virtual machine information. The user name and password entered here will be used to log in to the virtual machine. When complete, select **OK**. You can create the new VM in an existing resource group, or choose **Create new** to create a new resource group to store the VM.
5. Select a size for the VM. To see more sizes, select **View all** or change the **Supported disk type** filter.
6. Under **Settings**, make changes as necessary and select **OK**.
7. On the summary page, you should see your image name listed as a **Private image**. Select **Ok** to start the virtual machine deployment.

## Use PowerShell

You can use PowerShell to create a VM from an image by using the simplified parameter set for the [New-AzVm](#) cmdlet. The image needs to be in the same resource group where you'll create the VM.

The simplified parameter set for [New-AzVm](#) only requires that you provide a name, resource group, and image name to create a VM from an image. New-AzVm will use the value of the **-Name** parameter as the name of all of the resources that it creates automatically. In this example, we provide more detailed names for each of the resources but let the cmdlet create them automatically. You can also create resources beforehand, such as the virtual network, and pass the resource name into the cmdlet. New-AzVm will use the existing resources if it can find them by their name.

The following example creates a VM named *myVMFromImage*, in the *myResourceGroup* resource group, from the image named *myImage*.

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroup" ` 
    -Name "myVMfromImage" ` 
    -ImageName "myImage" ` 
    -Location "East US" ` 
    -VirtualNetworkName "myImageVnet" ` 
    -SubnetName "myImageSubnet" ` 
    -SecurityGroupName "myImageNSG" ` 
    -PublicIpAddressName "myImagePIP"
```

## Next steps

[Create and manage Windows VMs with the Azure PowerShell module](#)

# Visual Studio images on Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Using Visual Studio in a preconfigured Azure virtual machine (VM) is a quick, easy way to go from nothing to an up-and-running development environment. System images with different Visual Studio configurations are available in the [Azure Marketplace](#).

New to Azure? [Create a free Azure account](#).

## NOTE

Not all subscriptions are eligible to deploy Windows 10 images. For more information see [Use Windows client in Azure for dev/test scenarios](#)

## What configurations and versions are available?

Images for the most recent major versions, Visual Studio 2019, Visual Studio 2017 and Visual Studio 2015, can be found in the Azure Marketplace. For each released major version, you see the originally "released to web" (RTW) version and the latest updated versions. Each of these versions offers the Visual Studio Enterprise and the Visual Studio Community editions. These images are updated at least every month to include the latest Visual Studio and Windows updates. While the names of the images remain the same, each image's description includes the installed product version and the image's "as of" date.

RELEASE VERSION	EDITIONS	PRODUCT VERSION
Visual Studio 2019: Latest (Version 16.8)	Enterprise, Community	Version 16.8.0
Visual Studio 2019: RTW	Enterprise	Version 16.0.20
Visual Studio 2017: Latest (Version 15.9)	Enterprise, Community	Version 15.9.29
Visual Studio 2017: RTW	Enterprise, Community	Version 15.0.28
Visual Studio 2015: Latest (Update 3)	Enterprise, Community	Version 14.0.25431.01

## NOTE

In accordance with Microsoft servicing policy, the originally released (RTW) version of Visual Studio 2015 has expired for servicing. Visual Studio 2015 Update 3 is the only remaining version offered for the Visual Studio 2015 product line.

For more information, see the [Visual Studio Servicing Policy](#).

## What features are installed?

Each image contains the recommended feature set for that Visual Studio edition. Generally, the installation includes:

- All available workloads, including each workload's recommended optional components. More details on the workloads, components, and SDKs included Visual Studio could be found in the [Visual Studio documentation](#)
- .NET 4.6.2 and .NET 4.7 SDKs, Targeting Packs, and Developer Tools
- Visual F#
- GitHub Extension for Visual Studio
- LINQ to SQL Tools

The command line used to install Visual Studio when building the images is as follows:

```
vs_enterprise.exe --allWorkloads --includeRecommended --passive ^
    add Microsoft.Net.Component.4.7.SDK ^
    add Microsoft.Net.Component.4.7.TargetingPack ^
    add Microsoft.Net.Component.4.6.2.SDK ^
    add Microsoft.Net.Component.4.6.2.TargetingPack ^
    add Microsoft.Net.ComponentGroup.4.7.DeveloperTools ^
    add Microsoft.VisualStudio.Component.FSharp ^
    add Component.GitHub.VisualStudio ^
    add Microsoft.VisualStudio.Component.LinqToSql
```

If the images don't include a Visual Studio feature that you require, provide feedback through the feedback tool in the upper-right corner of the page.

## What size VM should I choose?

Azure offers a full range of virtual machine sizes. Because Visual Studio is a powerful, multi-threaded application, you want a VM size that includes at least two processors and 7 GB of memory. We recommend the following VM sizes for the Visual Studio images:

- Standard\_D2\_v3
- Standard\_D2s\_v3
- Standard\_D4\_v3
- Standard\_D4s\_v3
- Standard\_D2\_v2
- Standard\_D2S\_v2
- Standard\_D3\_v2

For more information on the latest machine sizes, see [Sizes for Windows virtual machines in Azure](#).

With Azure, you can rebalance your initial choice by resizing the VM. You can either provision a new VM with a more appropriate size, or resize your existing VM to different underlying hardware. For more information, see [Resize a Windows VM](#).

## After the VM is running, what's next?

Visual Studio follows the "bring your own license" model in Azure. As with an installation on proprietary hardware, one of the first steps is licensing your Visual Studio installation. To unlock Visual Studio, either:

- Sign in with a Microsoft account that's associated with a Visual Studio subscription
- Unlock Visual Studio with the product key that came with your initial purchase

For more information, see [Sign in to Visual Studio](#) and [How to unlock Visual Studio](#).

## How do I save the development VM for future or team use?

The spectrum of development environments is huge, and there's real cost associated with building out the more

complex environments. Regardless of your environment's configuration, you can save, or capture, your configured VM as a "base image" for future use or for other members of your team. Then, when booting a new VM, you provision it from the base image rather than the Azure Marketplace image.

A quick summary: Use the System Preparation tool (Sysprep) and shut down the running VM, and then capture (*Figure 1*) the VM as an image through the UI in the Azure portal. Azure saves the **.vhd** file that contains the image in the storage account of your choosing. The new image then shows up as an Image resource in your subscription's list of resources.

(*Figure 1*) Capture an image through the Azure portal UI.

For more information, see [Create a managed image of a generalized VM in Azure](#).

#### IMPORTANT

Don't forget to use Sysprep to prepare the VM. If you miss that step, Azure can't provision a VM from the image.

#### NOTE

You still incur some cost for storage of the images, but that incremental cost can be insignificant compared to the overhead costs to rebuild the VM from scratch for each team member who needs one. For instance, it costs a few dollars to create and store a 127-GB image for a month that's reusable by your entire team. However, these costs are insignificant compared to hours each employee invests to build out and validate a properly configured dev box for their individual use.

Additionally, your development tasks or technologies might need more scale, like varieties of development configurations and multiple machine configurations. You can use Azure DevTest Labs to create *recipes* that automate construction of your "golden image." You can also use DevTest Labs to manage policies for your team's running VMs. [Using Azure DevTest Labs for developers](#) is the best source for more information on DevTest Labs.

## Next steps

Now that you know about the preconfigured Visual Studio images, the next step is to create a new VM:

- [Create a VM through the Azure portal](#)
- [Windows Virtual Machines overview](#)

# Azure VM Image Builder overview

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

By using standardized virtual machine (VM) images, your organization can more easily migrate to the cloud and help ensure consistency in your deployments. Images ordinarily include predefined security, configuration settings, and any necessary software. Setting up your own imaging pipeline requires time, infrastructure, and many other details. With Azure VM Image Builder, you need only create a configuration that describes your image and submit it to the service, where the image is built and then distributed.

With VM Image Builder, you can migrate your existing image customization pipeline to Azure as you continue to use existing scripts, commands, and processes. You can integrate your core applications into a VM image, so that your VMs can take on workloads after the images are created. You can even add configurations to build images for Azure Virtual Desktop, as virtual hard discs (VHDs) for use in Azure Stack, or for ease of exporting.

VM Image Builder lets you start with Windows or Linux images either from Azure Marketplace or as existing custom images, and then add your own customizations. You can also specify where you want your resulting images to be hosted in [Azure Compute Gallery](#) (formerly Shared Image Gallery), as managed images or as VHDs.

## Features

Although it's possible to create custom VM images by hand or by other tools, the process can be cumbersome and unreliable. VM Image Builder, which is built on [HashiCorp Packer](#), gives you the benefits of a managed service.

### Simplicity

To reduce the complexity of creating VM images, VM Image Builder:

- Removes the need to use complex tooling, processes, and manual steps to create a VM image. VM Image Builder abstracts out all these details and hides Azure-specific requirements, such as the need to generalize the image (Sysprep). And it gives more advanced users the ability to override such requirements.
- Can be integrated with existing image build pipelines for a click-and-go experience. To do so, you can either call VM Image Builder from your pipeline or use an [Azure VM Image Builder service DevOps task \(preview\)](#).
- Can fetch customization data from various sources, which removes the need to collect them all from one place.
- Can be integrated with Compute Gallery, which creates an image management system with which to distribute, replicate, version, and scale images globally. Additionally, you can distribute the same resulting image as a VHD or as one or more managed images, without having to rebuild them from scratch.

### Infrastructure as code

With VM Image Builder, there's no need to manage your long-term infrastructure (for example, storage accounts that hold customization data) or transient infrastructure (for example, temporary VMs for building images).

VM Image Builder stores your VM image build artifacts as Azure resources. This feature removes both the need to maintain offline definitions and the risk of environment drifts that are caused by accidental deletions or updates.

## Security

To help keep your images secure, VM Image Builder:

- Enables you to create baseline images (that is, your minimum security and corporate configurations) and allows other departments to customize them further. You can help keep these images secure and compliant by using VM Image Builder to quickly rebuild a golden image that uses the latest patched version of a source image. VM Image Builder also makes it easier for you to build images that meet the Azure Windows security baseline. For more information, see [VM Image Builder - Windows baseline template](#).
- Enables you to fetch your customization artifacts without having to make them publicly accessible. VM Image Builder can use your [Azure Managed Identity](#) to fetch these resources, and you can restrict the privileges of this identity as tightly as required by using Azure role-based access control (Azure RBAC). You can both keep your artifacts secret and prevent tampering by unauthorized actors.
- Securely stores copies of customization artifacts, transient compute and storage resources, and their resulting images within your subscription, because access is controlled by Azure RBAC. This level of security, which also applies to the build VM that's used to create the customized image, helps prevent your customization scripts and files from being copied to an unknown VM in an unknown subscription. And you can achieve a high degree of separation from other customers' workloads by using [Isolated VM offerings](#) for the build VM.
- Enables you to connect VM Image Builder to your existing virtual networks, so that you can communicate with existing configuration servers, such as DSC (desired state configuration pull server), Chef, and Puppet, file shares, or any other routable servers and services.
- Can be configured to assign your user-assigned identities to the VM Image Builder build VM (that is, the VM that the VM Image Builder service creates in your subscription and uses to build and customize the image). You can then use these identities at customization time to access Azure resources, including secrets, in your subscription. There's no need to assign VM Image Builder direct access to those resources.

## Regions

The VM Image Builder service is available in the following regions:

### NOTE

You can still distribute images outside these regions.

- East US
- East US 2
- West Central US
- West US
- West US 2
- West US 3
- South Central US
- North Europe
- West Europe
- South East Asia
- Australia Southeast
- Australia East
- UK South

- UK West
- Brazil South
- Canada Central
- Central India
- Central US
- France Central
- Germany West Central
- Japan East
- North Central US
- Norway East
- Switzerland North
- Jio India West
- UAE North
- East Asia
- Korea Central
- South Africa North
- USGov Arizona (public preview)
- USGov Virginia (public preview)

To access the Azure VM Image Builder public preview in the Fairfax regions (USGov Arizona and USGov Virginia), you must register the *Microsoft.VirtualMachineImages/FairfaxPublicPreview* feature. To do so, run the following command:

- [Azure PowerShell](#)
- [Azure CLI](#)

```
Register-AzProviderPreviewFeature -ProviderNamespace Microsoft.VirtualMachineImages -Name FairfaxPublicPreview
```

## OS support

VM Image Builder supports the following Azure Marketplace base operating system images:

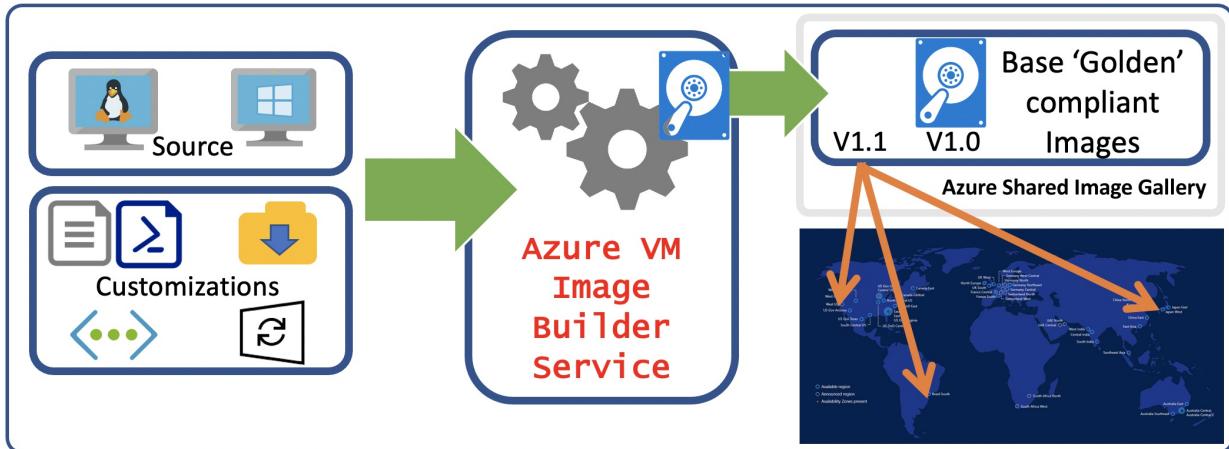

- Ubuntu 18.04
- Ubuntu 16.04
- RHEL 7.6, 7.7
- CentOS 7.6, 7.7
- SLES 12 SP4
- SLES 15, SLES 15 SP1
- Windows 10 RS5 Enterprise/Enterprise multi-session/Professional
- Windows 2016
- Windows 2019
- CBL-Mariner

### IMPORTANT

These operating systems have been tested and now work with VM Image Builder. However, VM Image Builder should work with any Linux or Windows image in the marketplace.

## How it works

VM Image Builder is a fully managed Azure service that's accessible to Azure resource providers. Resource providers configure it by specifying a source image, a customization to perform, and where the new image is to be distributed. A high-level workflow is illustrated in the following diagram:

You can pass template configurations by using Azure PowerShell, the Azure CLI, or Azure Resource Manager templates, or by using a VM Image Builder DevOps task. When you submit the configuration to the service, Azure creates an *image template resource*. When the image template resource is created, a *staging resource group* is created in your subscription, in the following format:

`IT_\<DestinationResourceGroup>_\<TemplateName>_\<(GUID)>`. The staging resource group contains files and scripts, which are referenced in the File, Shell, and PowerShell customization in the ScriptURI property.

To run the build, you invoke `Run` on the VM Image Builder template resource. The service then deploys additional resources for the build, such as a VM, network, disk, and network adapter.

If you build an image without using an existing virtual network, VM Image Builder also deploys a public IP and network security group, and it connects to the build VM by using Secure Shell (SSH) or Windows Remote Management (WinRM) protocol.

If you select an existing virtual network, the service is deployed via Azure Private Link, and a public IP address isn't required. For more information, see [VM Image Builder networking overview](#).

When the build finishes, all resources are deleted, except for the staging resource group and the storage account. You can remove them by deleting the image template resource, or you can leave them in place to run the build again.

For multiple examples, step-by-step guides, configuration templates, and solutions, go to the [VM Image Builder GitHub repository](#).

### Move support

The image template resource is immutable, and it contains links to resources and the staging resource group. Therefore, this resource type doesn't support being moved.

If you want to move the image template resource, either make sure that you have a copy of the configuration template or, if you don't have a copy, extract the existing configuration from the resource. Then, create a new image template resource in the new resource group with a new name, and delete the previous image template resource.

## Permissions

When you register for the VM Image Builder service, you're granting the service permission to create, manage, and delete a staging resource group, which is prefixed with `IT_*`. And you have rights to add to it any resources

that are required for the image build. This happens because a VM Image Builder service principal name is made available in your subscription after you've registered successfully.

To allow VM Image Builder to distribute images to either the managed images or Compute Gallery, you need to create an Azure user-assigned identity that has permissions to read and write images. If you're accessing Azure Storage, you'll need permissions to read private and public containers.

In API version 2021-10-01 and later, VM Image Builder supports adding Azure user-assigned identities to the build VM to enable scenarios where you need to authenticate with services such as Azure Key Vault in your subscription.

For more information about permissions, see

- [Configure VM Image Builder permissions by using PowerShell](#)
- [Configure VM Image Builder permissions by using the Azure CLI](#)
- [Create a VM Image Builder template](#)

## Costs

You'll incur some compute, networking, and storage costs when you create, build, and store images by using VM Image Builder. These costs are similar to those that you incur when you create custom images manually. Your resources are charged at your Azure rates.

During the image-creation process, files are downloaded and stored in the

`IT_<DestinationResourceGroup>_<TemplateName>` resource group, which incurs a small storage cost. If you don't want to keep these files, delete the image template after you've built the image.

VM Image Builder creates a VM by using the default Standard\_D1\_v2 VM size for Gen1 images and Standard\_D2ds\_v4 for Gen2 images, along with the storage and networking that's needed for the VM. These resources last for the duration of the build process and are deleted after VM Image Builder has finished creating the image.

VM Image Builder distributes the image to your chosen regions, which might incur network egress charges.

## Hyper-V generation

VM Image Builder currently supports creating Hyper-V Gen1 and Gen2 images in a Compute Gallery and as managed images or VHDs. Keep in mind that the distributed image is always in the same generation as the provided image.

For Gen2 images, ensure that you're using the correct SKU. For example, the SKU for an Ubuntu Server 18.04 Gen2 image would be 18\_04-Its-gen2. The SKU for an Ubuntu Server 18.04 Gen1 image would be 18.04-Its.

Here's how to find SKUs that are based on the image publisher:

```
# Find all Gen2 SKUs published by Microsoft Windows Desktop
az vm image list --publisher MicrosoftWindowsDesktop --sku g2 --output table --all

# Find all Gen2 SKUs published by Canonical
az vm image list --publisher Canonical --sku gen2 --output table --all
```

For more information about Azure VM images that support Gen2, see [Gen2 VM images in Azure Marketplace](#).

## Next steps

To try out VM Image Builder, see the articles about building [Linux](#) or [Windows](#) images.

# Create a Linux image and distribute it to an Azure Compute Gallery by using the Azure CLI

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In this article, you learn how to use Azure VM Image Builder and the Azure CLI to create an image version in an [Azure Compute Gallery](#) (formerly Shared Image Gallery) and then distribute the image globally. You can also create an image version by using [Azure PowerShell](#).

This article uses a sample JSON template to configure the image. The JSON file is at [helloImageTemplateforSIG.json](#).

To distribute the image to an Azure Compute Gallery, the template uses `sharedImage` as the value for the `distribute` section of the template.

## Register the features

To use VM Image Builder, you need to register the feature. Check your registration by running the following commands:

```
az provider show -n Microsoft.VirtualMachineImages -o json | grep registrationState  
az provider show -n Microsoft.KeyVault -o json | grep registrationState  
az provider show -n Microsoft.Compute -o json | grep registrationState  
az provider show -n Microsoft.Storage -o json | grep registrationState  
az provider show -n Microsoft.Network -o json | grep registrationState
```

If the output doesn't say *registered*, run the following commands:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Set variables and permissions

Because you'll be using some pieces of information repeatedly, create some variables to store that information.

VM Image Builder supports creating custom images only in the same resource group as the source-managed image. In the following example, update the resource group name to be the same resource group as your source-managed image.

```
# Resource group name - ibLinuxGalleryRG in this example
sigResourceGroup=ibLinuxGalleryRG
# Datacenter location - West US 2 in this example
location=westus2
# Additional region to replicate the image to - East US in this example
additionalRegion=eastus
# Name of the Azure Compute Gallery - myGallery in this example
sigName=myIbGallery
# Name of the image definition to be created - myImageDef in this example
imageDefName=myIbImageDef
# Reference name in the image distribution metadata
runOutputName=aibLinuxSIG
```

Create a variable for your subscription ID:

```
subscriptionID=$(az account show --query id --output tsv)
```

Create the resource group:

```
az group create -n $sigResourceGroup -l $location
```

## Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided [user-identity](#) to inject the image into an Azure Compute Gallery. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

```

# Create user-assigned identity for VM Image Builder to access the storage account where the script is stored
identityName=aibBuiUserId$(date +'%s')
az identity create -g $sigResourceGroup -n $identityName

# Get the identity ID
imgBuilderCliId=$(az identity show -g $sigResourceGroup -n $identityName --query clientId -o tsv)

# Get the user identity URI that's needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$sigResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# Download an Azure role-definition template, and update the template with the parameters that were specified earlier
curl
https://raw.githubusercontent.com/Azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# Update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation Role/$imageRoleDefName/g" aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# Grant a role definition to the user-assigned identity
az role assignment create \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

```

## Create an image definition and gallery

To use VM Image Builder with Azure Compute Gallery, you need to have an existing gallery and image definition. VM Image Builder doesn't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them.

First, create a gallery:

```

az sig create \
-g $sigResourceGroup \
--gallery-name $sigName

```

Then, create an image definition:

```

az sig image-definition create \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--publisher myIbPublisher \
--offer myOffer \
--sku 18.04-LTS \
--os-type Linux

```

## Download and configure the JSON file

Download the JSON template and configure it with your variables:

```
curl  
https://raw.githubusercontent.com/Azure/azvmimagebuilder/master/quickstarts/1_Creating_a_Custom_Linux_Shared_Image_Gallery_Image/helloImageTemplateforSIG.json -o helloImageTemplateforSIG.json  
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateforSIG.json  
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIG.json  
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIG.json  
sed -i -e "s/<sharedImageGalName>/$sigName/g" helloImageTemplateforSIG.json  
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIG.json  
sed -i -e "s/<region2>/$additionalRegion/g" helloImageTemplateforSIG.json  
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIG.json  
sed -i -e "s%<imgBuilderId>%$imgBuilderId%" helloImageTemplateforSIG.json
```

## Create the image version

In this section you create the image version in the gallery.

Submit the image configuration to the Azure VM Image Builder service:

```
az resource create \  
    --resource-group $sigResourceGroup \  
    --properties @helloImageTemplateforSIG.json \  
    --is-full-object \  
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \  
    -n helloImageTemplateforSIG01
```

Start the image build:

```
az resource invoke-action \  
    --resource-group $sigResourceGroup \  
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \  
    -n helloImageTemplateforSIG01 \  
    --action Run
```

It can take a few moments to create the image and replicate it to both regions. Wait until this part is finished before you move on to create a VM.

## Create the VM

Create the VM from the image version that was created by VM Image Builder.

```
az vm create \  
    --resource-group $sigResourceGroup \  
    --name myAibGalleryVM \  
    --admin-username aibuser \  
    --location $location \  
    --image  
    "/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \  
    --generate-ssh-keys
```

Connect to the VM via Secure Shell (SSH):

```
ssh aibuser@<publicIpAddress>
```

As soon as your SSH connection is established, you should see that the image was customized with a *Message*

of the Day.

```
*****
** This VM was built from the:      **
** !! AZURE VM IMAGE BUILDER Custom Image !!   **
** You have just been Customized :-)      **
*****
```

## Clean up your resources

### NOTE

If you now want to try to recustomize the image version to create a new version of the same image, *skip the step outlined here* and go to [Use VM Image Builder to create another image version](#).

If you no longer need the resources that were created as you followed the process in this article, you can delete them by doing the following.

This process deletes both the image that you created and all the other resource files. Make sure that you've finished this deployment before you delete the resources.

When you're deleting gallery resources, you need to delete all the image versions before you can delete the image definition that was used to create them. To delete a gallery, you first need to have deleted all the image definitions in the gallery.

1. Delete the VM Image Builder template.

```
az resource delete \
--resource-group $sigResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateforSIG01
```

2. Delete permissions assignments, roles, and identity.

```
az role assignment delete \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

az role definition delete --name "$imageRoleDefName"

az identity delete --ids $imgBuilderId
```

3. Get the image version that was created by VM Image Builder (it always starts with `0.`), and then delete it.

```
sigDefImgVersion=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'name' -o json | grep 0. | tr -d ''')
az sig image-version delete \
-g $sigResourceGroup \
--gallery-image-version $sigDefImgVersion \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

4. Delete the image definition.

```
az sig image-definition delete \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

5. Delete the gallery.

```
az sig delete -r $sigName -g $sigResourceGroup
```

6. Delete the resource group.

```
az group delete -n $sigResourceGroup -y
```

## Next steps

Learn more about [Azure Compute Gallery](#).

# Create a Windows VM by using Azure VM Image Builder

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this article, you learn how to create a customized Windows image by using Azure VM Image Builder. The example in this article uses [customizers](#) for customizing the image:

- PowerShell (ScriptUri): Download and run a [PowerShell script](#).
- Windows Restart: Restarts the VM.
- PowerShell (inline): Runs a specific command. In this example, it creates a directory on the VM by using `mkdir c:\\buildActions`.
- File: Copies a file from GitHub to the VM. This example copies `index.md` to `c:\\buildArtifacts\\index.html` on the VM.
- `buildTimeoutInMinutes` : Specifies a build time, in minutes. The default is 240 minutes, which you can increase to allow for longer-running builds. The minimum allowed value is 6 minutes. Values shorter than 6 minutes will cause errors.
- `vmProfile` : Specifies a `vmSize` and network properties.
- `osDiskSizeGB` : Can be used to increase the size of an image.
- `identity` . Provides an identity for VM Image Builder to use during the build.

Use the following sample JSON template to configure the image: [helloImageTemplateWin.json](#).

## NOTE

Windows users can run the following Azure CLI examples on [Azure Cloud Shell](#) by using Bash.

## Register the features

To use VM Image Builder, you need to register the feature. Check your registration by running the following commands:

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState  
az provider show -n Microsoft.KeyVault | grep registrationState  
az provider show -n Microsoft.Compute | grep registrationState  
az provider show -n Microsoft.Storage | grep registrationState  
az provider show -n Microsoft.Network | grep registrationState
```

If the output doesn't say *registered*, run the following commands:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Set variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information:

```
# Resource group name - we're using myImageBuilderRG in this example
imageResourceGroup='myWinImgBuilderRG'
# Region location
location='WestUS2'
# Run output name
runOutputName='aibWindows'
# The name of the image to be created
imageName='aibWinImage'
```

Create a variable for your subscription ID:

```
subscriptionID=$(az account show --query id --output tsv)
```

## Create the resource group

To store the image configuration template artifact and the image, use the following resource group:

```
az group create -n $imageResourceGroup -l $location
```

## Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided [user-identity](#) to inject the image into the resource group. In this example, you create an Azure role definition with specific permissions for distributing the image. The role definition is then assigned to the user identity.

## Create a user-assigned managed identity and grant permissions

Create a user-assigned identity so that VM Image Builder can access the storage account where the script is stored.

```

identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# Get the identity ID
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName --query clientId -o tsv)

# Get the user identity URI that's needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# Download the preconfigured role definition example
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aib
RoleImageCreation.json -o aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# Update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation Role/$imageRoleDefName/g" aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# Grant a role definition to the user-assigned identity
az role assignment create \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

```

## Download the image configuration template

We've created a parameterized image configuration template for you to try. Download the example JSON file, and then configure it with the variables that you set earlier.

```

curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/0_Creating_a_Custom_Windows
_Managed_Image/helloImageTemplateWin.json -o helloImageTemplateWin.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateWin.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" helloImageTemplateWin.json
sed -i -e "s/<region>/$location/g" helloImageTemplateWin.json
sed -i -e "s/<imageName>/$imageName/g" helloImageTemplateWin.json
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateWin.json
sed -i -e "s/<imgBuilderId>/$imgBuilderId/g" helloImageTemplateWin.json

```

You can modify this example in the terminal by using a text editor such as `vi`.

```
vi helloImageTemplateWin.json
```

### NOTE

For the source image, always [specify a version](#). You can't specify `latest` as the version.

If you add or change the resource group that the image is distributed to, make sure that the [permissions are set](#) on the resource group.

## Create the image

Submit the image configuration to the VM Image Builder service by running the following commands:

```
az resource create \
--resource-group $imageResourceGroup \
--properties @helloImageTemplateWin.json \
--is-full-object \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateWin01
```

When you're done, a success message is returned to the console, and a VM Image Builder configuration template is created in the `$imageResourceGroup`. To view this resource in the resource group, go to the Azure portal, and then enable **Show hidden types**.

In the background, VM Image Builder also creates a staging resource group in your subscription. This resource group is used to build the image in the following format: `IT_<DestinationResourceGroup>_<TemplateName>`.

### NOTE

Don't delete the staging resource group directly. First, delete the image template artifact, which causes the staging resource group to be deleted.

If the service reports a failure when you submit the image configuration template, do the following:

- See [Troubleshoot the Azure VM Image Builder service](#).
- Before you try to resubmit the template, delete it by running the following commands:

```
az resource delete \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateWin01
```

## Start the image build

Start the image-building process by using `az resource invoke-action`.

```
az resource invoke-action \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateWin01 \
--action Run
```

Wait until the build is complete.

If you encounter any errors, see [Troubleshoot the Azure VM Image Builder service](#).

## Create the VM

Create the VM by using the image that you built. In the following code, replace `<password>` with your own password for the `aibuser` on the VM.

```
az vm create \
--resource-group $imageResourceGroup \
--name aibImgWinVm00 \
--admin-username aibususer \
--admin-password <password> \
--image $imageName \
--location $location
```

## Verify the customization

Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM. In the VM, open a Command Prompt window, and then type:

```
dir c:\
```

The following two directories are created during the image customization:

- buildActions
- buildArtifacts

## Clean up your resources

When you're done, delete the resources you've created.

1. Delete the VM Image Builder template.

```
az resource delete \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateWin01
```

2. Delete the role assignment, role definition, and user identity.

```
az role assignment delete \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role definition delete --name "$imageRoleDefName"

az identity delete --ids $imgBuilderId
```

3. Delete the image resource group.

```
az group delete -n $imageResourceGroup
```

## Next steps

To learn more about the components of the JSON file that this article uses, see the [VM Image Builder template reference](#).

# Create a Windows VM with VM Image Builder by using PowerShell

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article demonstrates how to create a customized Windows VM image by using the Azure VM Image Builder PowerShell module.

## Prerequisites

If you don't have an Azure subscription, [create a free account](#) before you begin.

If you choose to use PowerShell locally, this article requires that you install the Azure PowerShell module and connect to your Azure account by using the [Connect-AzAccount](#) cmdlet. For more information, see [Install Azure PowerShell](#).

## Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

OPTION	EXAMPLE/LINK
Select <b>Try It</b> in the upper-right corner of a code or command block. Selecting <b>Try It</b> doesn't automatically copy the code or command to Cloud Shell.	
Go to <a href="https://shell.azure.com">https://shell.azure.com</a> , or select the <b>Launch Cloud Shell</b> button to open Cloud Shell in your browser.	
Select the <b>Cloud Shell</b> button on the menu bar at the upper right in the <a href="#">Azure portal</a> .	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl+Shift+V** on Windows and Linux, or by selecting **Cmd+Shift+V** on macOS.
4. Select **Enter** to run the code or command.

If you have multiple Azure subscriptions, choose the appropriate subscription in which the resources should be billed. Select a specific subscription by using the [Set-AzContext](#) cmdlet.

```
Set-AzContext -SubscriptionId 00000000-0000-0000-0000-000000000000
```

## Register features

If you haven't already done so, register the following resource providers to use with your Azure subscription:

- Microsoft.Compute
- Microsoft.KeyVault
- Microsoft.Storage
- Microsoft.Network
- Microsoft.VirtualMachineImages

```
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute, Microsoft.KeyVault, Microsoft.Storage,  
Microsoft.VirtualMachineImages, Microsoft.Network |  
Where-Object RegistrationState -ne Registered |  
Register-AzResourceProvider
```

## Define variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information:

```
# Destination image resource group name  
$imageResourceGroup = 'myWinImgBuilderRG'  
  
# Azure region  
$location = 'WestUS2'  
  
# Name of the image to be created  
$imageTemplateName = 'myWinImage'  
  
# Distribution properties of the managed image upon completion  
$runOutputName = 'myDistResults'
```

Create a variable for your Azure subscription ID. To confirm that the `subscriptionID` variable contains your subscription ID, you can run the second line in the following example:

```
# Your Azure Subscription ID  
$subscriptionID = (Get-AzContext).Subscription.Id  
Write-Output $subscriptionID
```

## Create a resource group

Create an [Azure resource group](#) by using the `New-AzResourceGroup` cmdlet. A resource group is a logical container in which Azure resources are deployed and managed as a group.

The following example creates a resource group that's based on the name in the `$imageResourceGroup` variable in the region that you've specified in the `$location` variable. This resource group is used to store the image configuration template artifact and the image.

```
New-AzResourceGroup -Name $imageResourceGroup -Location $location
```

## Create a user identity and set role permissions

Grant Azure image builder permissions to create images in the specified resource group by using the following example. Without this permission, the image build process won't finish successfully.

1. Create variables for the role definition and identity names. These values must be unique.

```
[int]$timeInt = $(Get-Date -UFormat '%s')
$imageRoleDefName = "Azure Image Builder Image Def $timeInt"
$identityName = "myIdentity$timeInt"
```

2. Create a user identity.

```
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName
```

3. Store the identity resource and principal IDs in variables.

```
$identityNameResourceId = (Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName).Id
$identityNamePrincipalId = (Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName).PrincipalId
```

## Assign permissions for the identity to distribute the images

1. Download the JSON configuration file, and then modify it based on the settings that are defined in this article.

```
$myRoleImageCreationUrl =
'https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json'
$myRoleImageCreationPath = "$env:TEMP\myRoleImageCreation.json"

Invoke-WebRequest -Uri $myRoleImageCreationUrl -OutFile $myRoleImageCreationPath -UseBasicParsing

$content = Get-Content -Path $myRoleImageCreationPath -Raw
$content = $content -replace '<subscriptionID>', $subscriptionID
$content = $content -replace '<rgName>', $imageResourceGroup
$content = $content -replace 'Azure Image Builder Service Image Creation Role', $imageRoleDefName
$content | Out-File -FilePath $myRoleImageCreationPath -Force
```

2. Create the role definition.

```
New-AzRoleDefinition -InputFile $myRoleImageCreationPath
```

3. Grant the role definition to the VM Image Builder service principal.

```
$RoleAssignParams = @{
    ObjectId = $identityNamePrincipalId
    RoleDefinitionName = $imageRoleDefName
    Scope = "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
}
New-AzRoleAssignment @RoleAssignParams
```

### NOTE

If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see [Troubleshoot Azure RBAC \(role-based access control\)](#).

# Create an Azure Compute Gallery

1. Create the gallery.

```
$myGalleryName = 'myImageGallery'  
$imageDefName = 'winSvrImages'  
  
New-AzGallery -GalleryName $myGalleryName -ResourceGroupName $imageResourceGroup -Location $location
```

2. Create a gallery definition.

```
$GalleryParams = @{  
    GalleryName = $myGalleryName  
    ResourceGroupName = $imageResourceGroup  
    Location = $location  
    Name = $imageDefName  
    OsState = 'generalized'  
    OsType = 'Windows'  
    Publisher = 'myCo'  
    Offer = 'Windows'  
    Sku = 'Win2019'  
}  
New-AzGalleryImageDefinition @GalleryParams
```

# Create an image

1. Create a VM Image Builder source object. For valid parameter values, see [Find Windows VM images in Azure Marketplace with Azure PowerShell](#).

```
$SrcObjParams = @{  
    SourceTypePlatformImage = $true  
    Publisher = 'MicrosoftWindowsServer'  
    Offer = 'WindowsServer'  
    Sku = '2019-Datacenter'  
    Version = 'latest'  
}  
$srcPlatform = New-AzImageBuilderTemplateSourceObject @SrcObjParams
```

2. Create a VM Image Builder distributor object.

```
$disObjParams = @{  
    SharedImageDistributor = $true  
    ArtifactTag = @{$tag='dis-share'}  
    GalleryImageId =  
        "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup/providers/Microsoft.Compute/galleries/$myGalleryName/images/$imageDefName"  
    ReplicationRegion = $location  
    RunOutputName = $runOutputName  
    ExcludeFromLatest = $false  
}  
$disSharedImg = New-AzImageBuilderTemplateDistributorObject @disObjParams
```

3. Create a VM Image Builder customization object.

```
$ImgCustomParams01 = @{
    PowerShellCustomizer = $true
    CustomizerName = 'settingUpMgmtAgtPath'
    RunElevated = $false
    Inline = @("mkdir c:\\buildActions", "mkdir c:\\buildArtifacts", "echo Azure-Image-Builder-Was-Here > c:\\buildActions\\buildActionsOutput.txt")
}
$Customizer01 = New-AzImageBuilderTemplateCustomizerObject @ImgCustomParams01
```

4. Create a second VM Image Builder customization object.

```
$ImgCustomParams02 = @{
    FileCustomizer = $true
    CustomizerName = 'downloadBuildArtifacts'
    Destination = 'c:\\buildArtifacts\\index.html'
    SourceUri =
'https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/exampleArtifacts/buildArtifacts/index.html'
}
$Customizer02 = New-AzImageBuilderTemplateCustomizerObject @ImgCustomParams02
```

5. Create a VM Image Builder template.

```
$ImgTemplateParams = @{
    ImageTemplateName = $imageName
    ResourceGroupName = $imageResourceGroup
    Source = $srcPlatform
    Distribute = $disSharedImg
    Customize = $Customizer01, $Customizer02
    Location = $location
    UserAssignedIdentityId = $identityNameResourceId
}
New-AzImageBuilderTemplate @ImgTemplateParams
```

When the template has been created, a message is returned, and a VM Image Builder configuration template is created in `$imageResourceGroup`.

To determine whether the template creation process was successful, use the following example:

```
Get-AzImageBuilderTemplate -ImageTemplateName $imageName -ResourceGroupName $imageResourceGroup |
Select-Object -Property Name, LastRunStatusRunState, LastRunStatusMessage, ProvisioningState
```

In the background, VM Image Builder also creates a staging resource group in your subscription. This resource group is used for the image build. It's in the format `IT_<DestinationResourceGroup>_<TemplateName>`.

**WARNING**

Don't delete the staging resource group directly. To cause the staging resource group to be deleted, delete the image template artifact.

If the service reports a failure when the image configuration template is submitted, do the following:

- See [Troubleshoot Azure VM Image Builder failures](#).
- Before you retry submitting the template, delete it by following this example:

```
Remove-AzImageBuilderTemplate -ImageTemplateName $imageTemplateName -ResourceGroupName  
$imageResourceGroup
```

## Start the image build

Submit the image configuration to the VM Image Builder service by running the following command:

```
Start-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name $imageTemplateName
```

Wait for the image building process to finish, which could take up to an hour.

If you encounter errors, review [Troubleshoot Azure VM Image Builder failures](#).

## Create a VM

1. Store the VM login credentials in a variable. The password must be complex.

```
$Cred = Get-Credential
```

2. Create the VM by using the image you created.

```
$ArtifactId = (Get-AzImageBuilderTemplateRunOutput -ImageTemplateName $imageTemplateName -  
ResourceGroupName $imageResourceGroup).ArtifactId  
  
New-AzVM -ResourceGroupName $imageResourceGroup -Image $ArtifactId -Name myWinVM01 -Credential $Cred
```

## Verify the customizations

1. Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM.
2. Inside the VM, open PowerShell and run `Get-Content`, as shown in the following example:

```
Get-Content -Path C:\buildActions\buildActionsOutput.txt
```

The output is based on the contents of the file that you created during the image customization process.

```
Azure-Image-Builder-Was-Here
```

3. From the same PowerShell session, verify that the second customization finished successfully by checking for the presence of `c:\buildArtifacts\index.html`, as shown in the following example:

```
Get-ChildItem c:\buildArtifacts\
```

The result should be a directory listing showing that the file was downloaded during the image customization process.

Directory: C:\buildArtifacts			
Mode	LastWriteTime	Length	Name
-a---	29/01/2021 10:04	276	index.html

## Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by doing the following:

1. Delete the VM Image Builder template.

```
Remove-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name $imageTemplateName
```

2. Delete the image resource group.

**Caution**

The following example deletes the specified resource group and all the resources that it contains. If any resources outside the scope of this article exist in the resource group, they'll also be deleted.

```
Remove-AzResourceGroup -Name $imageResourceGroup
```

## Next steps

To learn more about the components of the JSON file that this article uses, see the [VM Image Builder template reference](#).

# Create an Azure Virtual Desktop image by using VM Image Builder and PowerShell

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this article, you learn how to create an Azure Virtual Desktop image with these customizations:

- [FSLogix setup](#)
- [Azure Virtual Desktop optimization](#)
- [Microsoft Teams installation](#)
- [Windows Restart customizer](#)
- [Windows Update customizer](#)

The article discusses how to automate the customizations by using Azure VM Image Builder. You can then distribute the image to an [Azure Compute Gallery](#) (formerly Shared Image Gallery), where you can replicate it to other regions, control the scale, and share the image within and beyond your organization.

To simplify deploying a VM Image Builder configuration, our example uses an Azure Resource Manager template with the VM Image Builder template nested within it. This approach gives you a few more benefits, such as variables and parameter inputs. You can also pass parameters from the command line.

This article is intended as a copy-and-paste exercise.

## NOTE

You'll find the scripts for installing the apps on [GitHub](#). They're for illustration and testing purposes only. Do not use them for production workloads.

## Tips for building Windows images

- VM size: For Windows, use `Standard_D2_v2` or greater. The default size is `Standard_D1_v2`, which isn't suitable for Windows.
- This article uses [PowerShell customizer scripts](#). Use the following settings, or the build will stop responding:

```
"runElevated": true,  
"runAsSystem": true,
```

For example:

```
{  
    "type": "PowerShell",  
    "name": "installFSLogix",  
    "runElevated": true,  
    "runAsSystem": true,  
    "scriptUri":  
        "https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/14_Building_Images_WVD/0_i  
nstallConfFSLogix.ps1"
```

- Comment your code: The VM Image Builder build log, *customization.log*, is verbose. If you comment your scripts by using 'write-host', they'll be sent to the logs, which should make troubleshooting easier.

```
write-host 'AIB Customization: Starting OS Optimizations script'
```

- Exit codes: VM Image Builder expects all scripts to return a `0` exit code. If you use a non-zero exit code, VM Image Builder fails the customization and stops the build. If you have complex scripts, add instrumentation and emit exit codes, which will be shown in the *customization.log* file.

```
Write-Host "Exit code: " $LASTEXITCODE
```

- Test: Test and retest your code on a standalone VM. Ensure that there are no user prompts, that you're using the correct privileges, and so on.
- Networking: `Set-NetAdapterAdvancedProperty` is set in the optimization script but fails the VM Image Builder build. Because it disconnects the network, it's commented out. We're investigating this issue.

## Prerequisites

You must have the latest Azure PowerShell cmdlets installed. For more information, see [Overview of Azure PowerShell](#).

```
# Check to ensure that you're registered for the providers and RegistrationState is set to 'Registered'
Get-AzResourceProvider -ProviderNamespace Microsoft.VirtualMachineImages
Get-AzResourceProvider -ProviderNamespace Microsoft.Storage
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute
Get-AzResourceProvider -ProviderNamespace Microsoft.KeyVault

# If they don't show as 'Registered', run the the following commented-out code

## Register-AzResourceProvider -ProviderNamespace Microsoft.VirtualMachineImages
## Register-AzResourceProvider -ProviderNamespace Microsoft.Storage
## Register-AzResourceProvider -ProviderNamespace Microsoft.Compute
## Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
```

## Set up the environment and variables

```

# Step 1: Import module
Import-Module Az.Accounts

# Step 2: get existing context
$currentAzContext = Get-AzContext

# Destination image resource group
$imageResourceGroup="avdImageDemoRg"

# Location (see possible locations in the main docs)
$location="westus2"

# Your subscription. This command gets your current subscription
$subscriptionID=$currentAzContext.Subscription.Id

# Image template name
$imageTemplateName="avd10ImageTemplate01"

# Distribution properties object name (runOutput). Gives you the properties of the managed image on
completion
$runOutputName="sigOutput"

# Create resource group
New-AzResourceGroup -Name $imageResourceGroup -Location $location

```

## Permissions, user identity, and role

1. Create a user identity.

```

# setup role def names, these need to be unique
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
$identityName="aibIdentity"+$timeInt

## Add Azure PowerShell modules to support AzUserAssignedIdentity and Azure VM Image Builder
'Az.ImageBuilder', 'Az.ManagedServiceIdentity' | ForEach-Object {Install-Module -Name $_ -AllowPrerelease}

# Create the identity
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName

$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).PrincipalId

```

2. Assign permissions to the identity to distribute images. The following commands download and update the template with the previously specified parameters.

```

$aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/1
2_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$aibRoleImageCreationPath = "aibRoleImageCreation.json"

# Download the config
Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile $aibRoleImageCreationPath -UseBasicParsing

((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<subscriptionID>', $subscriptionID) |
Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<rgName>', $imageResourceGroup) | Set-
Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure Image Builder Service Image
Creation Role', $imageRoleDefName) | Set-Content -Path $aibRoleImageCreationPath

# Create a role definition
New-AzRoleDefinition -InputFile ./aibRoleImageCreation.json

# Grant the role definition to the VM Image Builder service principal
New-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"

```

#### NOTE

If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see [Troubleshoot Azure RBAC \(role-based access control\)](#).

## Create an Azure Compute Gallery

If you don't already have an Azure Compute Gallery, you need to create one.

```

$sigGalleryName= "myaibsig01"
$imageDefName ="win10avd"

# Create the gallery
New-AzGallery -GalleryName $sigGalleryName -ResourceGroupName $imageResourceGroup -Location $location

# Create the gallery definition
New-AzGalleryImageDefinition -GalleryName $sigGalleryName -ResourceGroupName $imageResourceGroup -Location
$location -Name $imageDefName -OsState generalized -OsType Windows -Publisher 'myCo' -Offer 'Windows' -Sku
'10avd'

```

## Configure the VM Image Builder template

For this example, we've prepared a template that downloads and updates the VM Image Builder template with the parameters that were specified earlier. The template installs FSLogix, operating system optimizations, and Microsoft Teams, and it runs Windows Update at the end.

If you open the template, you can see in the source property the image that's being used. In this example, it uses a Windows 10 multi-session image.

### Windows 10 images

You should be aware of two key types of images: multi-session and single-session.

Multi-session images are intended for pooled usage. Here's an example of the image details in Azure:

```
"publisher": "MicrosoftWindowsDesktop",
"offer": "Windows-10",
"sku": "20h2-evd",
"version": "latest"
```

Single-session images are intended for individual usage. Here's an example of the image details in Azure:

```
"publisher": "MicrosoftWindowsDesktop",
"offer": "Windows-10",
"sku": "19h2-ent",
"version": "latest"
```

You can also change which Windows 10 images are available:

```
Get-AzVMImageSku -Location westus2 -PublisherName MicrosoftWindowsDesktop -Offer windows-10
```

## Download and configure the template

Now, download the template and configure it for your own use.

```
$templateUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/14_Building_Images_W
VD/armTemplateWVD.json"
$templateFilePath = "armTemplateWVD.json"

Invoke-WebRequest -Uri $templateUrl -OutFile $templateFilePath -UseBasicParsing

((Get-Content -path $templateFilePath -Raw) -replace '<subscriptionID>',$subscriptionID) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<rgName>',$imageResourceGroup) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region>',$location) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<runOutputName>',$runOutputName) | Set-Content -Path
$templateFilePath

((Get-Content -path $templateFilePath -Raw) -replace '<imageDefName>',$imageDefName) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<sharedImageGalName>',$sigGalleryName) | Set-Content -
Path $templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region1>',$location) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<imgBuilderId>',$identityNameResourceId) | Set-Content
-Path $templateFilePath
```

Feel free to view the [template](#). All the code is viewable.

## Submit the template

Your template must be submitted to the service. Doing so downloads any dependent artifacts, such as scripts, and validates, checks permissions, and stores them in the staging resource group, which is prefixed with `/T_`.

```
New-AzResourceGroupDeployment -ResourceGroupName $imageResourceGroup -TemplateFile $templateFilePath -  
TemplateParameterObject @{"api-Version" = "2020-02-14"} -imageName $imageTemplateName -svclocation  
$location  
  
# Optional - if you have any errors running the preceding command, run:  
$getStatus=$(Get-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name $imageTemplateName)  
$getStatus.ProvisioningErrorCode  
$getStatus.ProvisioningErrorMessage
```

## Build the image

```
Start-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name $imageTemplateName -NoWait
```

### NOTE

The command doesn't wait for the VM Image Builder service to complete the image build, so you can query the status as shown here.

```
$getStatus=$(Get-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name $imageTemplateName)  
  
# Shows all the properties  
$getStatus | Format-List -Property *  
  
# Shows the status of the build  
$getStatus.LastRunStatusRunState  
$getStatus.LastRunStatusMessage  
$getStatus.LastRunStatusRunSubState
```

## Create a VM

Now that the image is built, you can build a VM from it. Use the examples from [New-AzVM \(Az PowerShell module.Compute\)](#).

## Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by doing the following:

### IMPORTANT

Delete the resource group template first. If you delete only the resource group, the staging resource group (*/T\_*) that's used by VM Image Builder won't be cleaned up.

1. Remove the VM Image Builder template.

```
Remove-AzImageBuilderTemplate -ResourceGroupName $imageResourceGroup -Name vd10ImageTemplate
```

2. Delete the role assignment.

```
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -  
Scope "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"  
  
## Remove the definitions  
Remove-AzRoleDefinition -Name "$identityNamePrincipalId" -Force -Scope  
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"  
  
## Delete the identity  
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName -Force
```

3. Delete the resource group.

```
Remove-AzResourceGroup $imageResourceGroup -Force
```

## Next steps

# Azure Policy Regulatory Compliance controls for Azure VM Image Builder

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

[Regulatory Compliance in Azure Policy](#) provides initiative definitions, known as *built-ins*, for the compliance domains and security controls related to different compliance standards. Microsoft creates and manages these built-ins.

In this article, you can refer to a list of the compliance domains and security controls for Azure VM Image Builder. You can assign the built-ins for a security control individually, to help make your Azure resources compliant with the specific standard.

The title of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Policy Version** column to view the source on the [Azure Policy GitHub repo](#).

## IMPORTANT

Each control is associated with one or more [Azure Policy](#) definitions. These policies might help you [assess compliance](#) with the control. However, there often isn't a one-to-one or complete match between a control and one or more policies. As such, **Compliant** in Azure Policy refers only to the policies themselves. This doesn't ensure that you're fully compliant with all requirements of a control. In addition, the compliance standard includes controls that aren't addressed by any Azure Policy definitions at this time. Therefore, compliance in Azure Policy is only a partial view of your overall compliance status. The associations between controls and Azure Policy Regulatory Compliance definitions for these compliance standards can change over time.

## Azure Security Benchmark

The [Azure Security Benchmark](#) provides recommendations on how you can secure your cloud solutions on Azure. To see how this service completely maps to the Azure Security Benchmark, see the [Azure Security Benchmark mapping files](#).

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see [Azure Policy Regulatory Compliance - Azure Security Benchmark](#).

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY (AZURE PORTAL)	POLICY VERSION (GITHUB)

# Use Azure VM Image Builder for Linux VMs to access an existing Azure virtual network

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to use Azure VM Image Builder to create a basic, customized Linux image that has access to existing resources on a virtual network. The build virtual machine (VM) you create is deployed to a new or existing virtual network that you specify in your subscription. When you use an existing Azure virtual network, VM Image Builder doesn't require public network connectivity.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Set variables and permissions

For this task, you use some pieces of information repeatedly. Create some variables to store that information.

```
# set your environment variables here!!!!

# destination image resource group
imageResourceGroup=aibImageRG01

# location (see possible locations in main docs)
location=WestUS2

# your subscription
# get the current subID : 'az account show | grep id'
subscriptionID=$(az account show --query id --output tsv)

# name of the image to be created
imageName=aibCustomLinuxImg01

# image distribution metadata reference name
runOutputName=aibCustLinManImg01ro

# VNET properties (update to match your existing VNET, or leave as-is for demo)
# VNET name
vnetName=myexistingvnet01
# subnet name
subnetName=subnet01
# VNET resource group name
# NOTE! The VNET must always be in the same region as the Azure Image Builder service region.
vnetRgName=existingVnetRG
# Existing Subnet NSG Name or the demo will create it
nsgName=aibdemoNsg
```

Create the resource group.

```
az group create -n $imageResourceGroup -l $location
```

## Configure networking

If you don't have an existing virtual network, subnet, or network security group (NSG), use the following script to create one.

```

# Create a resource group

az group create -n $vnetRgName -l $location

# Create VNET

az network vnet create \
    --resource-group $vnetRgName \
    --name $vnetName --address-prefix 10.0.0.0/16 \
    --subnet-name $subnetName --subnet-prefix 10.0.0.0/24

# Create base NSG to simulate an existing NSG

az network nsg create -g $vnetRgName -n $nsgName

az network vnet subnet update \
    --resource-group $vnetRgName \
    --vnet-name $vnetName \
    --name $subnetName \
    --network-security-group $nsgName

# NOTE! The virtual network must always be in the same region as the Azure Image Builder service region.

```

## Add an NSG rule

This rule allows connectivity from the VM Image Builder load balancer to the proxy VM. Port 60001 is for Linux, and port 60000 is for Windows. The proxy VM connects to the build VM by using port 22 for Linux, or port 5986 for Windows.

```

az network nsg rule create \
    --resource-group $vnetRgName \
    --nsg-name $nsgName \
    -n AzureImageBuilderNsgRule \
    --priority 400 \
    --source-address-prefixes AzureLoadBalancer \
    --destination-address-prefixes VirtualNetwork \
    --destination-port-ranges 60000-60001 --direction inbound \
    --access Allow --protocol Tcp \
    --description "Allow Image Builder Private Link Access to Proxy VM"

```

## Disable private service policy on the subnet

Here's how:

```

az network vnet subnet update \
    --name $subnetName \
    --resource-group $vnetRgName \
    --vnet-name $vnetName \
    --disable-private-link-service-network-policies true

```

For more information, see [Azure VM Image Builder networking options](#).

## Modify the example template and create role

After you configure networking, you can modify the example template and create a role. Here's how:

```

# download the example and configure it with your vars

curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/1a_Creating_a_Custom_Linux_
Image_on_Existing_VNET/existingVNETLinux.json -o existingVNETLinux.json
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aib
RoleNetworking.json -o aibRoleNetworking.json
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aib
RoleImageCreation.json -o aibRoleImageCreation.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" existingVNETLinux.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" existingVNETLinux.json
sed -i -e "s/<region>/$location/g" existingVNETLinux.json
sed -i -e "s/<imageName>/$imageName/g" existingVNETLinux.json
sed -i -e "s/<runOutputName>/$runOutputName/g" existingVNETLinux.json

sed -i -e "s/<vnetName>/$vnetName/g" existingVNETLinux.json
sed -i -e "s/<subnetName>/$subnetName/g" existingVNETLinux.json
sed -i -e "s/<vnetRgName>/$vnetRgName/g" existingVNETLinux.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json

sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleNetworking.json
sed -i -e "s/<vnetRgName>/$vnetRgName/g" aibRoleNetworking.json

```

## Set permissions on the resource group

VM Image Builder uses the [user identity](#) provided to inject the image into Azure Compute Gallery. In this example, you create an Azure role definition that can distribute the image to the gallery. The role definition is then assigned to the user identity.

```

# create user assigned identity for image builder
identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# get identity id
imgBuilderCliId=$(az identity show -g $sigResourceGroup -n $identityName --query clientId -o tsv)

# get the user identity URI, needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.ManagedId
entity/userAssignedIdentities/$identityName

# update the template
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" existingVNETLinux.json

# make role name unique, to avoid clashes in the same Azure Active Directory domain
imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')
netRoleDefName="Azure Image Builder Network Def"$(date +'%s')

# update the definitions
sed -i -e "s/Azure Image Builder Service Image Creation Role/$imageRoleDefName/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Networking Role/$netRoleDefName/g" aibRoleNetworking.json

```

Instead of granting VM Image Builder lower granularity and increased privilege, you can create two roles. One role gives the builder permissions to create an image, and the other allows it to connect the build VM and load balancer to your virtual network.

```
# create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json
az role definition create --role-definition ./aibRoleNetworking.json

# grant role definition to the user assigned identity
az role assignment create \
    --assignee $imgBuilderCliId \
    --role $imageRoleDefName \
    --scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role assignment create \
    --assignee $imgBuilderCliId \
    --role $netRoleDefName \
    --scope /subscriptions/$subscriptionID/resourceGroups/$vnetRgName
```

For more information, see [Configure Azure VM Image Builder permissions by using the Azure CLI](#) or [Configure Azure VM Image Builder permissions by using PowerShell](#).

## Create the image

Submit the image configuration to VM Image Builder.

```
az resource create \
    --resource-group $imageResourceGroup \
    --properties @existingVNETLinux.json \
    --is-full-object \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n existingVNETLinuxTemplate01

# Wait approximately 1-3 mins (validation, permissions etc.)
```

Start the image build.

```
az resource invoke-action \
    --resource-group $imageResourceGroup \
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \
    -n existingVNETLinuxTemplate01 \
    --action Run

# Wait approximately 15 mins
```

It can take a while to create the image and replicate it to both regions. Wait until this part is finished before moving on to creating a VM.

## Create a VM

Create a VM from the image version that was created by VM Image Builder.

```
az vm create \
    --resource-group $imageResourceGroup \
    --name aibImgVm0001 \
    --admin-username aibuser \
    --image $imageName \
    --location $location \
    --generate-ssh-keys
```

Use Secure Shell (SSH) to get into the VM.

```
ssh aibuser@<publicIpAddress>
```

You should see the image was customized with a *Message of the Day* as soon as your SSH connection is established!

```
*****
**      This VM was built from the:      **
**      !! AZURE VM IMAGE BUILDER Custom Image !!      **
**      You have just been Customized :-)      **
*****
```

## Clean up resources

If you want to recustomize the image version to create a new version of the same image, skip the next steps and go on to [Use Azure VM Image Builder to create another image version](#).

The following deletes the image that was created, along with all of the other resource files. Make sure you are finished with this deployment before deleting the resources.

When you delete gallery resources, you need to delete all of the image versions before you can delete the image definition used to create them. To delete a gallery, you first need to have deleted all of the image definitions in the gallery.

Delete the VM Image Builder template:

```
az resource delete \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n existingVNETLinuxTemplate01
```

Delete permissions assignments, roles, and identity:

```
az role assignment delete \
--assignee $imgBuilderCliId \
--role $imageRoleDefName \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

az role assignment delete \
--assignee $imgBuilderCliId \
--role $netRoleDefName \
--scope /subscriptions/$subscriptionID/resourceGroups/$vnetRgName

az role definition delete --name "$imageRoleDefName"
az role definition delete --name "$netRoleDefName"

az identity delete --ids $imgBuilderId
```

Delete the resource group:

```
az group delete -n $imageResourceGroup
```

If you created a virtual network for this quickstart, you can delete the virtual network if it's no longer being used.

## Next steps

# Use Azure VM Image Builder to access an existing Azure virtual network

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article shows you how to use Azure VM Image Builder to create a basic, customized Windows image that has access to existing resources on a virtual network. The build virtual machine (VM) you create is deployed to a new or existing virtual network that you specify in your subscription. When you use an existing Azure virtual network, VM Image Builder doesn't require public network connectivity.

## Set variables and permissions

For this task, you use some pieces of information repeatedly. Create some variables to store that information.

```
# Step 1: Import module
Import-Module Az.Accounts

# Step 2: get existing context
$currentAzContext = Get-AzContext

# destination image resource group
$imageResourceGroup="aibImageRG"

# location (see possible locations in main docs)
$location="westus2"

## if you need to change your subscription: Get-AzSubscription / Select-AzSubscription -SubscriptionName

# get subscription, this will get your current subscription
$subscriptionID=$currentAzContext.Subscription.Id

# name of the image to be created
$imageName="win2019image01"

# image distribution metadata reference name
$runOutputName="win2019ManImg02ro"

# image template name
$imageTemplateName="window2019VnetTemplate03"

# distribution properties object name (runOutput), i.e. this gives you the properties of the managed image
# on completion
$runOutputName="winSvrSigR01"

# VNET properties (update to match your existing virtual network, or leave as-is for demo)
# VNET name
$vnetName="myexistingvnet01"
# subnet name
$subnetName="subnet01"
# VNET resource group name
$vnetRgName="existingVnetRG"
# Existing Subnet NSG Name or the demo will create it
$nsgName="aibdemoNsg"
# NOTE! The virtual network must always be in the same region as the VM Image Builder service region.
```

Create the resource group.

```
New-AzResourceGroup -Name $imageResourceGroup -Location $location
```

## Configure networking

If you don't have an existing virtual network, subnet, or network security group (NSG), use the following script to create one.

```
New-AzResourceGroup -Name $vnetRgName -Location $location

## Create base NSG to simulate an existing NSG
New-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName $vnetRgName -location $location

$nsg = Get-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName $vnetRgName

$subnet = New-AzVirtualNetworkSubnetConfig -Name $subnetName -AddressPrefix "10.0.1.0/24" -
PrivateLinkServiceNetworkPoliciesFlag "Disabled" -NetworkSecurityGroup $nsg

New-AzVirtualNetwork -Name $vnetName -ResourceGroupName $vnetRgName -Location $location -AddressPrefix
"10.0.0.0/16" -Subnet $subnet

## NOTE! The virtual network must always be in the same region as the VM Image Builder service region.
```

### Add an NSG rule

This rule allows connectivity from the VM Image Builder load balancer to the proxy VM. Port 60001 is for Linux, and port 60000 is for Windows. The proxy VM connects to the build VM by using port 22 for Linux, or port 5986 for Windows.

```
Get-AzNetworkSecurityGroup -Name $nsgName -ResourceGroupName $vnetRgName | Add-AzNetworkSecurityRuleConfig
-Name AzureImageBuilderAccess -Description "Allow Image Builder Private Link Access to Proxy VM" -Access
Allow -Protocol Tcp -Direction Inbound -Priority 400 -SourceAddressPrefix AzureLoadBalancer -SourcePortRange
* -DestinationAddressPrefix VirtualNetwork -DestinationPortRange 60000-60001 | Set-AzNetworkSecurityGroup
```

### Disable private service policy on the subnet

Here's how:

```
$virtualNetwork= Get-AzVirtualNetwork -Name $vnetName -ResourceGroupName $vnetRgName

($virtualNetwork | Select -ExpandProperty subnets | Where-Object {$_ .Name -eq $subnetName})
.privateLinkServiceNetworkPolicies = "Disabled"

$virtualNetwork | Set-AzVirtualNetwork
```

For more information, see [Azure VM Image Builder networking options](#).

## Modify the example template and create role

After you configure networking, you can modify the example template and create a role. Here's how:

```

$templateUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickquickstarts/1a_Creating_a
_Custom_Win_Image_on_Existing_VNET/existingVNETWindows.json"
$templateFilePath = "existingVNETWindows.json"

$aibRoleNetworkingUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating
_AIB_Security_Roles/aibRoleNetworking.json"
$aibRoleNetworkingPath = "aibRoleNetworking.json"

$aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creat
ing_AIB_Security_Roles/aibRoleImageCreation.json"
$aibRoleImageCreationPath = "aibRoleImageCreation.json"

# download configs
Invoke-WebRequest -Uri $templateUrl -OutFile $templateFilePath -UseBasicParsing

Invoke-WebRequest -Uri $aibRoleNetworkingUrl -OutFile $aibRoleNetworkingPath -UseBasicParsing

Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile $aibRoleImageCreationPath -UseBasicParsing

# update AIB image config template
((Get-Content -path $templateFilePath -Raw) -replace '<subscriptionID>', $subscriptionID) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<rgName>', $imageResourceGroup) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<region>', $location) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<runOutputName>', $runOutputName) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<imageName>', $imageName) | Set-Content -Path
$templateFilePath

((Get-Content -path $templateFilePath -Raw) -replace '<vnetName>', $vnetName) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<subnetName>', $subnetName) | Set-Content -Path
$templateFilePath
((Get-Content -path $templateFilePath -Raw) -replace '<vnetRgName>', $vnetRgName) | Set-Content -Path
$templateFilePath

```

## Create a user-assigned identity and set permissions

Next, you create a user-assigned identity and set permissions. Here's how:

```

# setup role def names, these need to be unique
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
$networkRoleDefName="Azure Image Builder Network Def"+$timeInt
$idenityName="aibIdentity"+$timeInt

# create user identity
## Add AZ PS module to support AzUserAssignedIdentity
Install-Module -Name Az.ManagedServiceIdentity

# create identity
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $idenityName

$idenityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$idenityName).Id
$idenityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$idenityName).PrincipalId

# update template with identity
((Get-Content -path $templateFilePath -Raw) -replace '<imgBuilderId>',$idenityNameResourceId) | Set-Content
-Path $templateFilePath

# update the role definition names
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure Image Builder Service Image Creation
Role',$imageRoleDefName) | Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace 'Azure Image Builder Service Networking
Role',$networkRoleDefName) | Set-Content -Path $aibRoleNetworkingPath

# update role definitions
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace '<subscriptionID>',$subscriptionID) | Set-Content
-Path $aibRoleNetworkingPath
((Get-Content -path $aibRoleNetworkingPath -Raw) -replace '<vnetRgName>',$vnetRgName) | Set-Content -Path
$aibRoleNetworkingPath

((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<subscriptionID>',$subscriptionID) | Set-
Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<rgName>',$imageResourceGroup) | Set-Content
-Path $aibRoleImageCreationPath

# create role definitions from role configurations examples, this avoids granting contributor to the SPN
New-AzRoleDefinition -InputFile ./aibRoleImageCreation.json
New-AzRoleDefinition -InputFile ./aibRoleNetworking.json

# grant role definition to image builder user identity
New-AzRoleAssignment -ObjectId $idenityNamePrincipalId -RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
New-AzRoleAssignment -ObjectId $idenityNamePrincipalId -RoleDefinitionName $networkRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$vnetRgName"

```

For more information, see [Configure Azure VM Image Builder permissions by using the Azure CLI](#) or [Configure Azure VM Image Builder permissions by using PowerShell](#).

## Create the image

Submit the image configuration to Azure VM Image Builder.

```

New-AzResourceGroupDeployment -ResourceGroupName $imageResourceGroup -TemplateFile $templateFilePath -api-
version "2020-02-14" -imageTemplateName $imageTemplateName -svclocation $location

# note this will take minute, as validation is run (security / dependencies etc.)

```

Start the image build.

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -  
 ResourceType Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2020-02-14" -Action Run -Force
```

## Get build status and properties

First, you query the image template for current or last run status, and for image template settings.

```
$managementEp = $currentAzureContext.Environment.ResourceManagerUrl  
  
$urlBuildStatus = [System.String]::Format("{0}subscriptions/{1}/resourceGroups/$imageResourceGroup/providers/Microsoft.VirtualMachineImages/imageTemplates/{2}?api-version=2020-02-14", $managementEp, $currentAzureContext.Subscription.Id,$imageTemplateName)  
  
$buildStatusResult = Invoke-WebRequest -Method GET -Uri $urlBuildStatus -UseBasicParsing -Headers  
@{ "Authorization"= ("Bearer " + $accessToken)} -ContentType application/json  
$buildJsonStatus =$buildStatusResult.Content  
$buildJsonStatus
```

The image build for this example takes approximately 50 minutes (including multiple reboots and Windows updates). When you query the status, look for `lastRunStatus`. The following code shows that the build is still running. If it had completed successfully, it would show `succeeded`.

```
"lastRunStatus": {  
    "startTime": "2019-08-21T00:39:40.61322415Z",  
    "endTime": "0001-01-01T00:00:00Z",  
    "runState": "Running",  
    "runSubState": "Building",  
    "message": ""  
},
```

## Query the distribution properties

If you're distributing to a VHD location, need managed image location properties, or Azure Compute Gallery replications status, you need to query `runOutput`. Every time you have a distribution target, you will have a unique `runOutput`, to describe properties of the distribution type.

```
$managementEp = $currentAzureContext.Environment.ResourceManagerUrl  
$urlRunOutputStatus = [System.String]::Format("{0}subscriptions/{1}/resourceGroups/$imageResourceGroup/providers/Microsoft.VirtualMachineImages/imageTemplates/$imageTemplateName/runOutputs/{2}?api-version=2020-02-14", $managementEp,  
$currentAzureContext.Subscription.Id, $runOutputName)  
  
$runOutStatusResult = Invoke-WebRequest -Method GET -Uri $urlRunOutputStatus -UseBasicParsing -Headers  
@{ "Authorization"= ("Bearer " + $accessToken)} -ContentType application/json  
$runOutJsonStatus =$runOutStatusResult.Content  
$runOutJsonStatus
```

## Create a VM

Now that the build is finished, you can build a VM from the image. Use the examples from the [PowerShell New-AzVM documentation](#).

## Clean up tasks

You can now delete the image template artifact, the role assignment, and the resource groups if you want to.

Here's how to delete the image template artifact:

```
# Get ResourceID of the Image Template
$resTemplateId = Get-AzResource -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -
 ResourceType Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2020-02-14"

### Delete Image Template Artifact
Remove-AzResource -ResourceId $resTemplateId.ResourceId -Force
```

Here's how to delete the role assignment:

```
## remove role assignments
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $networkRoleDefName -Scope
"/subscriptions/$subscriptionID/resourceGroups/$vnetRgName"

## remove definitions
Remove-AzRoleDefinition -Id $imageRoleDefObjId -Force
Remove-AzRoleDefinition -Id $networkRoleObjId -Force

## delete identity
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName -Force
```

Here's how to delete resource groups:

```
Remove-AzResourceGroup $imageResourceGroup -Force

# delete VNET created
# BEWARE! In this example, you have either used an existing virtual network or created one for this example.
# Do not delete your existing virtual network. If you want to delete the virtual network resource group used
# in this example '$vnetRgName', modify the preceding code.
```

[Azure Compute Galleries](#)

# Azure VM Image Builder networking options

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

With Azure VM Image Builder, you choose to deploy the service with or without an existing virtual network. The following sections provide more details about this choice.

## Deploy without specifying an existing virtual network

If you don't specify an existing virtual network, VM Image Builder creates one, along with a subnet, in the staging resource group. The service uses a public IP resource with a network security group to restrict inbound traffic. The public IP facilitates the channel for commands during the image build. After the build completes, the virtual machine (VM), public IP, disks, and virtual network are deleted. To use this option, don't specify any virtual network properties.

## Deploy using an existing VNET

If you specify a virtual network and subnet, VM Image Builder deploys the build VM to your chosen virtual network. You can access resources that are accessible on your virtual network. You can also create a siloed virtual network, unconnected to any other virtual network. If you specify a virtual network, VM Image Builder doesn't use a public IP address. Communication from VM Image Builder to the build virtual machine uses Azure Private Link.

For more information, see one of the following examples:

- [Use Azure VM Image Builder for Windows VMs allowing access to an existing Azure virtual network](#)
- [Use Azure VM Image Builder for Linux VMs allowing access to an existing Azure virtual network](#)

### What is Azure Private Link?

Azure Private Link provides private connectivity from a virtual network to Azure platform as a service (PaaS), or to customer-owned or Microsoft partner services. It simplifies the network architecture, and secures the connection between endpoints in Azure by eliminating data exposure to the public internet. For more information, see the [Private Link documentation](#).

### Required permissions for an existing virtual network

VM Image Builder requires specific permissions to use an existing virtual network. For more information, see [Configure Azure VM Image Builder permissions by using the Azure CLI](#) or [Configure Azure VM Image Builder permissions by using PowerShell](#).

### What is deployed during an image build?

If you use an existing virtual network, VM Image Builder deploys an additional VM (a *proxy* VM), and a load balancer (Azure Load Balancer). These are connected to Private Link. Traffic from the VM Image Builder service goes across the private link to the load balancer. The load balancer communicates to the proxy VM by using port 60001 for Linux, or port 60000 for Windows. The proxy forwards commands to the build VM by using port 22 for Linux, or port 5986 for Windows.

#### NOTE

The virtual network must be in the same region as the VM Image Builder service region.

## Why deploy a proxy VM?

When a VM without a public IP is behind an internal load balancer, it doesn't have internet access. The load balancer used for the virtual network is internal. The proxy VM allows internet access for the build VM during builds. You can use the associated network security groups to restrict the build VM access.

The deployed proxy VM size is *Standard A1\_v2*, in addition to the build VM. The VM Image Builder service uses the proxy VM to send commands between the service and the build VM. You can't change the proxy VM properties (this restriction includes the size and the operating system).

## Image template parameters to support the virtual network

```
"VirtualNetworkConfig": {  
    "name": "",  
    "subnetName": "",  
    "resourceGroupName": ""  
},
```

SETTING	DESCRIPTION
<code>name</code>	(Optional) The name of a pre-existing virtual network.
<code>subnetName</code>	The name of the subnet within the specified virtual network. You must specify this setting if, and only if, the <code>name</code> setting is specified.
<code>resourceGroupName</code>	The name of the resource group containing the specified virtual network. You must specify this setting if, and only if, the <code>name</code> setting is specified.

Private Link requires an IP from the specified virtual network and subnet. Currently, Azure doesn't support network policies on these IPs. Hence, you must disable network policies on the subnet. For more information, see the [Private Link documentation](#).

## Checklist for using your virtual network

- Allow Azure Load Balancer to communicate with the proxy VM in a network security group.
  - [Azure CLI example](#)
  - [PowerShell example](#)
- Disable the private service policy on the subnet.
  - [Azure CLI example](#)
  - [PowerShell example](#)
- Allow VM Image Builder to create a load balancer, and add VMs to the virtual network.
  - [Azure CLI example](#)
  - [PowerShell example](#)
- Allow VM Image Builder to read and write source images, and create images.
  - [Azure CLI example](#)
  - [PowerShell example](#)
- Ensure that you're using a virtual network in the same region as the VM Image Builder service region.

## Next steps

[Azure VM Image Builder overview](#)

# Configure Azure VM Image Builder permissions by using the Azure CLI

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you register for Azure VM Image Builder, this grants the service permission to create, manage, and delete a staging resource group. The service also has rights to add resources to a resource group, required for the image build. During a successful registration, your subscription gets access to a VM Image Builder service principal name (SPN).

If you want VM Image Builder to distribute images, you need to create a user-assigned identity in Azure, with permissions to read and write images. For example, you might want to distribute images to managed images or to Azure Compute Gallery. If you're accessing Azure storage, then the user-assigned identity you create needs permissions to read private or public containers.

You must set up permissions and privileges prior to building an image. The following sections detail how to configure possible scenarios by using the Azure CLI.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Create a user-assigned managed identity

VM Image Builder requires you to create an [Azure user-assigned managed identity](#). VM Image Builder uses this identity to read images, write images, and access Azure storage accounts. You grant the identity permission to do specific actions in your subscription.

### NOTE

User-assigned managed identity is the correct way to grant permissions to the image resource groups. The SPN is deprecated for this purpose.

The following example shows you how to create an Azure user-assigned managed identity. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Resource group>	The resource group where you want to create the user-assigned managed identity.

```
identityName="aibIdentity"
imageResourceGroup=<Resource group>

az identity create \
--resource-group $imageResourceGroup \
--name $identityName
```

For more information, see [Azure user-assigned managed identity](#).

## Allow VM Image Builder to distribute images

For VM Image Builder to distribute images, the service must be allowed to inject the images into resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is built. VM Image Builder doesn't have permission to access resources in other resource groups in the subscription. You need to take explicit actions to allow access, to prevent your builds from failing.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to distribute images. However, the user-assigned managed identity needs the following Azure [Actions](#) permissions in the distribution resource group:

```
Microsoft.Compute/images/write
Microsoft.Compute/images/read
Microsoft.Compute/images/delete
```

If you want to distribute to Azure Compute Gallery, you also need:

```
Microsoft.Compute/galleries/read
Microsoft.Compute/galleries/images/read
Microsoft.Compute/galleries/images/versions/read
Microsoft.Compute/galleries/images/versions/write
```

## Permission to customize existing images

For VM Image Builder to build images from source custom images, the service must be allowed to read the images into these resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is located.

Here's how you build from an existing custom image:

```
Microsoft.Compute/galleries/read
```

Here's how you build from an existing Azure Compute Gallery version:

```
Microsoft.Compute/galleries/read  
Microsoft.Compute/galleries/images/read  
Microsoft.Compute/galleries/images/versions/read
```

## Permission to customize images on your virtual networks

VM Image Builder has the capability to deploy and use an existing virtual network in your subscription, thus allowing customizations access to connected resources.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to deploy a VM to an existing virtual network. However, the user-assigned managed identity needs the following Azure Actions permissions on the virtual network resource group:

```
Microsoft.Network/virtualNetworks/read  
Microsoft.Network/virtualNetworks/subnets/join/action
```

## Create an Azure role definition

The following examples create an Azure role definition from the actions described in the previous sections. The examples are applied at the resource group level. Evaluate and test if the examples are granular enough for your requirements.

The image actions allow read and write. Decide what is appropriate for your environment. For example, create a role to allow VM Image Builder to read images from resource group *example-rg-1*, and write images to resource group *example-rg-2*.

### Custom image Azure role example

The following example creates an Azure role to use and distribute a source custom image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Subscription ID>	Your Azure subscription ID.
<Resource group>	Resource group for the custom image.

```

# Subscription ID - You can get this using `az account show | grep id` or from the Azure portal.
subscriptionID=$(az account show --query id --output tsv)
# Resource group - image builder will only support creating custom images in the same Resource Group as the
# source managed image.
imageResourceGroup=<Resource group>
identityName="aibIdentity"

# Use *cURL* to download the a sample JSON description
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aib
RoleImageCreation.json -o aibRoleImageCreation.json

# Create a unique role name to avoid clashes in the same Azure Active Directory domain
imageRoleDefName="Azure Image Builder Image Def$(date +'%s')

# Update the JSON definition using stream editor
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation Role/$imageRoleDefName/g" aibRoleImageCreation.json

# Create a custom role from the sample aibRoleImageCreation.json description file.
az role definition create --role-definition ./aibRoleImageCreation.json

# Get the user-assigned managed identity id
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName --query clientId -o tsv)

# Grant the custom role to the user-assigned managed identity for Azure Image Builder.
az role assignment create \
--assignee $imgBuilderCliId \
--role $imageRoleDefName \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup

```

### Existing virtual network Azure role example

The following example creates an Azure role to use and distribute an existing virtual network image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Subscription ID>	Your Azure subscription ID.
<Resource group>	The virtual network resource group

```

# Subscription ID - You can get this using `az account show | grep id` or from the Azure portal.
subscriptionID=$(az account show --query id --output tsv)
VnetResourceGroup=<Resource group>
identityName="aibIdentity"

# Use *cURL* to download the a sample JSON description
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aib
RoleNetworking.json -o aibRoleNetworking.json

# Create a unique role name to avoid clashes in the same domain
netRoleDefName="Azure Image Builder Network Def$(date +'%s')

# Update the JSON definition using stream editor
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleNetworking.json
sed -i -e "s/<vnetRgName>/$vnetRgName/g" aibRoleNetworking.json
sed -i -e "s/Azure Image Builder Service Networking Role/$netRoleDefName/g" aibRoleNetworking.json

# Create a custom role from the aibRoleNetworking.json description file.
az role definition create --role-definition ./aibRoleNetworking.json

# Get the user-assigned managed identity id
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName --query clientId -o tsv)

# Grant the custom role to the user-assigned managed identity for Azure Image Builder.
az role assignment create \
--assignee $imgBuilderCliId \
--role $netRoleDefName \
--scope /subscriptions/$subscriptionID/resourceGroups/$VnetResourceGroup

```

## Using managed identity for Azure Storage access

If you want to authenticate with Azure Storage and use private containers, VM Image Builder needs a user-assigned managed identity. VM Image Builder uses the identity to authenticate with Azure Storage.

### NOTE

VM Image Builder only uses the identity at the time that you submit the image template. The build VM doesn't have access to the identity during image build.

Use the Azure CLI to create the user-assigned managed identity:

```

az role assignment create \
--assignee <Image Builder client ID> \
--role "Storage Blob Data Reader" \
--scope /subscriptions/<Subscription ID>/resourceGroups/<Resource
group>/providers/Microsoft.Storage/storageAccounts/$scriptStorageAcc/blobServices/default/containers/<Storag
e account container>

```

In the VM Image Builder template, provide the user-assigned managed identity:

```
"type": "Microsoft.VirtualMachineImages/imageTemplates",
"apiVersion": "2020-02-14",
"location": "<Region>",
..
"identity": {
    "type": "UserAssigned",
    "userAssignedIdentities": {
        "<Image Builder ID>": {}
    }
}
```

Replace the following placeholder settings:

SETTING	DESCRIPTION
<Region>	Template region
<Resource group>	Resource group
<Storage account container>	Storage account container name
<Subscription ID>	Azure subscription

For more information, see [Create an image and use a user-assigned managed identity to access files in Azure Storage](#). You learn how to create and configure the user-assigned managed identity to access a storage account.

## Next steps

[Azure VM Image Builder overview](#)

# Configure Azure VM Image Builder permissions by using PowerShell

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you register for Azure VM Image Builder, this grants the service permission to create, manage, and delete a staging resource group. The service also has rights to add resources to a resource group, required for the image build. During a successful registration, your subscription gets access to a VM Image Builder service principal name (SPN).

If you want VM Image Builder to distribute images, you need to create a user-assigned identity in Azure, with permissions to read and write images. For example, you might want to distribute images to managed images or to Azure Compute Gallery. If you're accessing Azure Storage, then the user-assigned identity you create needs permissions to read private or public containers.

You must set up permissions and privileges prior to building an image. The following sections detail how to configure possible scenarios by using PowerShell.

## Create a user-assigned managed identity

VM Image Builder requires you to create an [Azure user-assigned managed identity](#). VM Image Builder uses this identity to read images, write images, and access Azure Storage accounts. You grant the identity permission to do specific actions in your subscription.

### NOTE

User-assigned managed identity is the correct way to grant permissions to the image resource groups. The SPN is deprecated for this purpose.

The following example shows you how to create an Azure user-assigned managed identity. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Resource group>	The resource group where you want to create the user-assigned managed identity.

```
## Add AZ PS module to support AzUserAssignedIdentity
Install-Module -Name Az.ManagedServiceIdentity

$parameters = @{
    Name = 'aibIdentity'
    ResourceGroupName = '<Resource group>'
}
# create identity
New-AzUserAssignedIdentity @parameters
```

For more information, see [Azure user-assigned managed identity](#).

## Allow VM Image Builder to distribute images

For VM Image Builder to distribute images, the service must be allowed to inject the images into resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is built. VM Image Builder doesn't have permission to access resources in other resource groups in the subscription. You need to take explicit actions to allow access, to prevent your builds from failing.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to distribute images. However, the user-assigned managed identity needs the following Azure **Actions** permissions in the distribution resource group:

```
Microsoft.Compute/images/write  
Microsoft.Compute/images/read  
Microsoft.Compute/images/delete
```

If you want to distribute to Azure Compute Gallery, you also need:

```
Microsoft.Compute/galleries/read  
Microsoft.Compute/galleries/images/read  
Microsoft.Compute/galleries/images/versions/read  
Microsoft.Compute/galleries/images/versions/write
```

## Permission to customize existing images

For VM Image Builder to build images from source custom images, the service must be allowed to read the images into these resource groups. To grant the required permissions, create a user-assigned managed identity, and grant it rights on the resource group where the image is located.

Here's how you build from an existing custom image:

```
Microsoft.Compute/galleries/read
```

Here's how you build from an existing Azure Compute Gallery version:

```
Microsoft.Compute/galleries/read  
Microsoft.Compute/galleries/images/read  
Microsoft.Compute/galleries/images/versions/read
```

## Permission to customize images on your virtual networks

VM Image Builder has the capability to deploy and use an existing virtual network in your subscription, thus allowing customizations access to connected resources.

You don't need to grant the user-assigned managed identity contributor rights on the resource group to deploy a VM to an existing virtual network. However, the user-assigned managed identity needs the following Azure **Actions** permissions on the virtual network resource group:

```
Microsoft.Network/virtualNetworks/read  
Microsoft.Network/virtualNetworks/subnets/join/action
```

## Create an Azure role definition

The following examples create an Azure role definition from the actions described in the previous sections. The examples are applied at the resource group level. Evaluate and test if the examples are granular enough for your requirements.

The image actions allow read and write. Decide what is appropriate for your environment. For example, create a role to allow VM Image Builder to read images from resource group *example-rg-1*, and write images to resource group *example-rg-2*.

### Custom image Azure role example

The following example creates an Azure role to use and distribute a source custom image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Subscription ID>	Your Azure subscription ID.
<Resource group>	Resource group for the custom image.

```

$sub_id = "<Subscription ID>"
# Resource group - image builder will only support creating custom images in the same Resource Group as the
source managed image.
$imageResourceGroup = "<Resource group>"
$identityName = "aibIdentity"

# Use a web request to download the sample JSON description
$sample_uri="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$role_definition="aibRoleImageCreation.json"

Invoke-WebRequest -Uri $sample_uri -Outfile $role_definition -UseBasicParsing

# Create a unique role name to avoid clashes in the same Azure Active Directory domain
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt

# Update the JSON definition placeholders with variable values
((Get-Content -path $role_definition -Raw) -replace '<subscriptionID>', $sub_id) | Set-Content -Path
$role_definition
((Get-Content -path $role_definition -Raw) -replace '<rgName>', $imageResourceGroup) | Set-Content -Path
$role_definition
((Get-Content -path $role_definition -Raw) -replace 'Azure Image Builder Service Image Creation Role',
$imageRoleDefName) | Set-Content -Path $role_definition

# Create a custom role from the aibRoleImageCreation.json description file.
New-AzRoleDefinition -InputFile $role_definition

# Get the user-identity properties
$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).PrincipalId

# Grant the custom role to the user-assigned managed identity for Azure Image Builder.
$parameters = @{
    ObjectId = $identityNamePrincipalId
    RoleDefinitionName = $imageRoleDefName
    Scope = '/subscriptions/' + $sub_id + '/resourceGroups/' + $imageResourceGroup
}
New-AzRoleAssignment @parameters

```

## Existing virtual network Azure role example

The following example creates an Azure role to use and distribute an existing virtual network image. You then grant the custom role to the user-assigned managed identity for VM Image Builder.

To simplify the replacement of values in the example, set the following variables first. Replace the placeholder settings to set your variables.

SETTING	DESCRIPTION
<Subscription ID>	Your Azure subscription ID.
<Resource group>	The virtual network resource group.

```

$sub_id = "<Subscription ID>"
$res_group = "<Resource group>"
$identityName = "aibIdentity"

# Use a web request to download the sample JSON description
$sample_uri="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleNetworking.json"
$role_definition="aibRoleNetworking.json"

Invoke-WebRequest -Uri $sample_uri -Outfile $role_definition -UseBasicParsing

# Create a unique role name to avoid clashes in the same AAD domain
$timeInt=$(get-date -UFormat "%s")
$networkRoleDefName="Azure Image Builder Network Def"+$timeInt

# Update the JSON definition placeholders with variable values
((Get-Content -path $role_definition -Raw) -replace '<subscriptionID>', $sub_id) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace '<vnetRgName>', $res_group) | Set-Content -Path $role_definition
((Get-Content -path $role_definition -Raw) -replace 'Azure Image Builder Service Networking Role', $networkRoleDefName) | Set-Content -Path $role_definition

# Create a custom role from the aibRoleNetworking.json description file
New-AzRoleDefinition -InputFile $role_definition

# Get the user-identity properties
$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName).PrincipalId

# Assign the custom role to the user-assigned managed identity for Azure Image Builder
$parameters = @{
    ObjectId = $identityNamePrincipalId
    RoleDefinitionName = $networkRoleDefName
    Scope = '/subscriptions/' + $sub_id + '/resourceGroups/' + $res_group
}

New-AzRoleAssignment @parameters

```

## Next steps

[Azure VM Image Builder overview](#)

# Azure VM Image Builder service DevOps task (preview)

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In this article, you learn how to use an Azure DevOps task to inject build artifacts into a virtual machine (VM) image, so that you can install and configure your application and operating system.

## DevOps task versions

At this time, there are two Azure VM Image Builder DevOps tasks:

- *Stable* VM Image Builder task: The latest stable build that's been tested, and reports no [General Data Protection Regulation \(GDPR\)](#) issues.
- *Unstable* VM Image Builder task: We offer a so-called *unstable* task so that you can test the latest updates and features before we release the task code as *stable*. After about a week, if there are no customer-reported or telemetry issues, we promote the task code to *stable*.

## Prerequisites

### NOTE

The VM Image Builder task doesn't currently support Windows Restart or running elevated commands as Administrator. That is, the task isn't suitable for Azure Virtual Desktop scenarios or Windows customizations that require those features. To use DevOps with VM Image Builder, nest the template within an Azure Resource Manager task, and use Azure CLI or PowerShell tasks.

Before you begin, you must:

- Install [Stable DevOps task from Visual Studio Marketplace](#).
- Have an Azure DevOps Services (formerly Visual Studio Team Services, or VSTS) account, and a Build Pipeline created.
- Register and enable the VM Image Builder feature requirements in the subscription that's used by the pipelines:
  - [Azure PowerShell](#)
  - [The Azure CLI](#)
- Create a standard Azure storage account in the source image resource group. You can use other resource groups or storage accounts. The storage account is used transfer the build artifacts from the DevOps task to the image.

```
# Azure PowerShell
$timeInt=$(get-date -UFormat "%s")
$storageAccName="aibstorage"+$timeInt
$location=westus
# Create a storage account and blob in the resource group
New-AzStorageAccount -ResourceGroupName $strResourceGroup -Name $storageAccName -Location $location -
SkuName Standard_LRS
```

```
# The Azure CLI
location=westus
scriptStorageAcc=aibstordot$(date +'%s')
# Create a storage account and blob in the resource group
az storage account create -n $scriptStorageAcc -g $strResourceGroup -l $location --sku Standard_LRS
```

## Add a task to the release pipeline

1. Select **Release Pipeline > Edit**.
2. On the User Agent, select the plus sign (+) to add and search for **Image Builder**.
3. Select **Add**.

In the following sections, set the task properties.

### Azure subscription

In the dropdown list, select the subscription that you want VM Image Builder to run. Use the subscription where your source images are stored and the images are to be distributed. You need to grant the VM Image Builder contributor access to the subscription or resource group.

### Resource group

Use the resource group where the temporary image template artifact will be stored. When you create a template artifact, another temporary VM Image Builder resource group,

`IT_<DestinationResourceGroup>_<TemplateName>_guid`, is created. The temporary resource group stores the image metadata, such as scripts. At the end of the task, the image template artifact and temporary VM Image Builder resource group is deleted.

### Location

The location is the region where VM Image Builder will run. Only a set number of [regions](#) are supported. The source images must be present in this location. For example, if you're using Azure Compute Gallery (formerly Shared Image Gallery), a replica must exist in that region.

### Managed identity (required)

VM Image Builder requires a managed identity, which it uses to read source custom images, connect to Azure Storage, and create custom images. For more information, see [Learn about VM Image Builder](#).

### Virtual network support

You can configure the created VM to be in a specific virtual network. When you configure the task, provide the resource ID of a pre-existing subnet in the **VNet Configuration (Optional)** input field. Omit the resource ID if no specific virtual network needs to be used. For more information, see [Azure VM Image Builder service networking options](#).

### Source

The source images must be of the supported VM Image Builder operating systems. You can choose existing custom images in the same region that VM Image Builder is running from:

- Managed Image: Pass in the resource ID. For example:

```
/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/images/<imageName>
```

- Compute Gallery: Pass in the resource ID of the image version. For example:

```
/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/<versionNumber>
```

If you need to get the latest Compute Gallery version, use an Azure PowerShell or Azure CLI task to get it and set a DevOps variable. Use the variable in the VM Image Builder DevOps task. For more information, see the examples in [Get the latest image version resource ID](#).

- (Marketplace) Base image: Use the dropdown list of popular images, which always uses the latest version of the supported operating systems.

If the base image isn't in the list, you can specify the exact image by using `Publisher:Offer:Sku`.

(Optional) Base image version: You can supply the version of the image that you want to use. The default version is `latest`.

## Customize

The following sections discuss various ways to customize tasks.

### Provisioner

Initially, two customizers are supported, Shell and PowerShell. Only inline is supported. If you want to download scripts, you can pass inline commands to do so.

For your operating system, select PowerShell or Shell.

### The Windows Update task

For Windows only, the task runs Windows Update at the end of the customizations. It also handles the required reboots.

The task runs the following Windows Update configuration:

```
"type": "WindowsUpdate",
"searchCriteria": "IsInstalled=0",
"filters": [
    "exclude:$_.Title -like '*Preview*'",
    "include:$true"
```

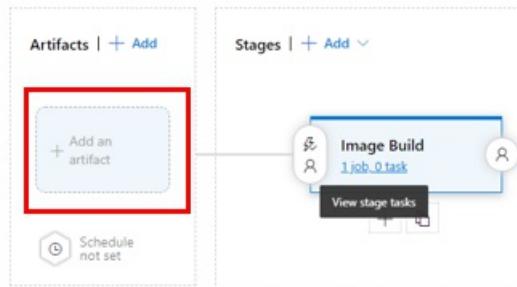

The task installs important and recommended Windows Updates that aren't *preview* versions.

### Handling reboots

The DevOps task doesn't currently support rebooting Windows builds. If you try to reboot with PowerShell code, the build fails. However, you can use code to reboot Linux builds.

### Build path

The task is designed to be able to inject DevOps Build release artifacts into the image. To make this work, you need to set up a build pipeline. In the release pipeline setup, add the repo of the build artifacts.

Select the **Build Path** button to choose the build folder that you want to be placed on the image. The VM Image Builder task copies all the files and directories within it. When the image is being created, VM Image Builder deploys the files and directories into different paths, depending on the operating system.

#### IMPORTANT

When you're adding a repo artifact, you might find that the directory name is prefixed with an underscore character (\_). The underscore can cause issues with the inline commands. Be sure to use the appropriate quotation marks in the commands.

The following example explains how this works:

Select a file or folder X

```

        ▲ └ Linked artifacts
          └ _ImageBuilding (Azure Repos Git)
            └ webapp
              └ webconfig.ps1
              └ azure-pipelines.yml
              └ README.md
    
```

- For Windows: Files exist in the *C*: drive. A directory named *buildArtifacts* is created, which includes the *webapp* directory.
- For Linux: Files exist in the */tmp* directory. The *webapp* directory is created, which includes all the files and directories. Because this is a temporary directory, you must move the files out of it. Otherwise, they'll be deleted.

#### Inline customization script

- For Windows: You can enter PowerShell inline commands, separated by commas. If you want to run a script in your build directory, you can use:

```
& 'c:\buildArtifacts\webapp\webconfig.ps1'
```

You can reference multiple scripts or add more commands. For example:

```
& 'c:\buildArtifacts\webapp\webconfig.ps1'
& 'c:\buildArtifacts\webapp\installAgent.ps1'
```

- For Linux: The build artifacts are put into the */tmp* directory. However, on many Linux operating systems, on a reboot, the */tmp* directory contents are deleted. If you want the artifacts to exist in the image, you must create another directory and copy them over. For example:

```
sudo mkdir /lib/buildArtifacts  
sudo cp -r "/tmp/_ImageBuilding/webapp" /lib/buildArtifacts/.
```

If you're OK with using the `/tmp` directory, you can run the script by using the following code:

```
# Grant execute permissions to run scripts  
sudo chmod +x "/tmp/_ImageBuilding/webapp/coreConfig.sh"  
echo "running script"  
sudo . "/tmp/AppsAndImageBuilderLinux/_WebApp/coreConfig.sh"
```

#### What happens to the build artifacts after the image build?

##### NOTE

VM Image Builder doesn't automatically remove the build artifacts. We strongly suggest that you always use code to remove the build artifacts.

- For Windows: VM Image Builder deploys files to the `C:\buildArtifacts` directory. Because the directory is persisted, you must remove it by running a script. For example:

```
# Clean up buildArtifacts directory  
Remove-Item -Path "C:\buildArtifacts\*" -Force -Recurse  
  
# Delete the buildArtifacts directory  
Remove-Item -Path "C:\buildArtifacts" -Force
```

- For Linux: The build artifacts are put into the `/tmp` directory. However, on many Linux operating systems, the `/tmp` directory contents are deleted on reboot. We suggest that you use code to remove the contents and not rely on the operating system to remove the contents. For example:

```
sudo rm -R "/tmp/AppsAndImageBuilderLinux"
```

#### Total length of image build

Total length can't be changed in the DevOps pipeline task yet. It uses the default of 240 minutes. If you want to increase the `buildTimeoutInMinutes`, you can use an Azure CLI task in the release pipeline. Configure the task to copy a template and submit it. For an example solution, see [Use environment variables and parameters with VM Image Builder](#), or use Azure PowerShell.

#### Storage account

Select the storage account you created in the prerequisites. If you don't see it in the list, VM Image Builder doesn't have permissions to it.

When the build starts, VM Image Builder creates a container called `imagebuilder-vststask`, where the build artifacts from the repo are stored.

##### NOTE

You need to manually delete the storage account or container after each build.

#### Distribute

The following three distribute types are supported.

##### Managed image

- Resource ID:

```
/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/images/<imageName>
```

- Locations

#### Azure Compute Gallery

The Compute Gallery must already exist.

- Resource ID:

```
/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<gallerName>/images/<imageDefName>
```

- Regions: A list of regions, comma separated. For example, `westus`, `eastus`, `centralus`.

#### Virtual hard disk

You can't pass any values to this. VM Image Builder emits the virtual hard disk VHD to the temporary VM Image Builder resource group, `IT_{DestinationResourceGroup}_{TemplateName}`, in the `vhds` container. When you start the release build, VM Image Builder emits logs. When VM Image Builder has finished, it emits the VHD URL.

#### Optional settings

You can override the [VM size](#) setting from its default size of `Standard_D1_v2`. You might want to do so to reduce total customization time. Or you might want to create images that depend on certain VM sizes, such as GPU (graphics processing unit), HPC (high-performance computing), and so on.

## How the task works

When you create the release, the task creates a container in the storage account, named `imagebuilder-vststask`. It zips (compresses) and uploads your build artifacts and creates a shared access signature token for the zip file.

The task uses the properties that are passed to the task to create the VM Image Builder template artifact. The task does the following:

- Downloads the build artifact zip file and any other associated scripts. The files are saved in a storage account in the temporary VM Image Builder resource group `IT_{DestinationResourceGroup}_{TemplateName}`.
- Creates a template that's prefixed with `t_` and a 10-digit monotonic integer. The template is saved to the resource group that you selected, and it exists for the duration of the build in the resource group.

Example output:

```
start reading task parameters...
found build at: /home/vsts/work/r1/a/_ImageBuilding/webapp
end reading parameters
getting storage account details for aibstordot1556933914
created archive /home/vsts/work/_temp/temp_web_package_21475337782320203.zip
Source for image: { type: 'SharedImageVersion',
  imageVersionId:
    '/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageDefName>/versions/<imgVersionNumber>' }
template name: t_1556938436xxx
starting put template...
```

When the image build starts, the run status is reported in the release logs:

```
starting run template...
```

When the image build finishes, the output is similar to following text:

```
2019-05-06T12:49:52.0558229Z starting run template...
2019-05-06T13:36:33.8863094Z run template: Succeeded
2019-05-06T13:36:33.8867768Z getting runOutput for SharedImage_distribute
2019-05-06T13:36:34.6652541Z =====
2019-05-06T13:36:34.6652925Z ## task output variables ##
2019-05-06T13:36:34.6658728Z $(imageUri) =
/subscriptions/<subscriptionID>/resourceGroups/aibwinsig/providers/Microsoft.Compute/galleries/my22stSIG/images/winWAppimages/versions/0.23760.13763
2019-05-06T13:36:34.6659989Z =====
2019-05-06T13:36:34.6663500Z deleting template t_1557146959485...
2019-05-06T13:36:34.6673713Z deleting storage blob imagebuilder-vststask\webapp\18-1\webapp_1557146958741.zip
2019-05-06T13:36:34.9786039Z blob imagebuilder-vststask\webapp\18-1\webapp_1557146958741.zip is deleted
2019-05-06T13:38:37.4884068Z delete template: Succeeded
```

The image template and `IT_{DestinationResourceGroup}_{TemplateName}` are deleted.

You can take the `$(imageUri)` Azure DevOps Services (formerly Visual Studio Team Services, or VSTS) variable and use it in the next task or just use the value and build a VM.

## Output DevOps variables

Here are the publisher, offer, SKU, and version of the source marketplace image:

- `$(pirPublisher)`
- `$(pirOffer)`
- `$(pirSku)`
- `$(pirVersion)`

Here's the image URI, which is the resource ID of the distributed image:

- `$(imageUri)`

## FAQ

**Can I use an existing image template that I've already created, outside of DevOps?**

Not at this time.

**Can I specify the image template name?**

No. A unique template name is used and then deleted.

**The VM Image Builder task failed. How can I troubleshoot the issue?**

If there's a build failure, the DevOps task doesn't delete the staging resource group. You can access the staging resource group that contains the build customization log.

You'll see an error in the DevOps log for the VM Image Builder task, and the message will contain the `customization.log` location. For example:

Agent job		Started: 12/2/2019, 7:09:33 PM
Pool: Azure Pipelines · Agent: Hosted Agent		··· 17m 27s
✓	Initialize job · succeeded	6s
✓	Download Artifacts · succeeded	6s
✗	Azure VM Image Builder Task · 1 error	 17m 14s
✗	Error: post template call failed for template t_1575342592203 with error: Failed in building/customizing image: Failed while waiting for packerizer: Microservice has failed: Failed while processing request: Error when executing packerizer: Packer build command has failed: exit status 1. During the image build, a failure has occurred, please review the build log to identify which build/customization step failed. For more troubleshooting steps go to https://aka.ms/azvmimagebuildert . Image Build log location: https://0huje17fvia32z8xpe7e7h9i.blob.core.windows.net/packerlogs/4288328b-c206-4a7a-8085-e9502a5837a3/customization.log. OperationId: d758bb20-314a-4b81-8747-93437f3fabc8. Use this operationId to search packer logs. (CODE: 200)	

For more information, see [Troubleshoot the VM Image Builder service](#).

After you've investigated the failure, you can delete the staging resource group. First, delete the VM Image Builder template resource artifact. The artifact is prefixed with `t_`, and you can find it in the DevOps task build log:

```
...
Source for image: { type: 'SharedImageVersion',
  imageVersionId:
  '/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<galleryName>
  /images/<imageDefName>/versions/<imgVersionNumber>' }
...
template name: t_1556938436xxx
...
```

The VM Image Builder template resource artifact is in the resource group that was specified initially in the task. When you're done troubleshooting, delete the artifact. If you're deleting it by using the Azure portal, within the resource group, select **Show Hidden Types** to view the artifact.

## Next steps

For more information, see [VM Image Builder overview](#).

# Create an Azure Image Builder Bicep or ARM JSON template

9/21/2022 • 29 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure Image Builder uses a Bicep file or an ARM JSON template file to pass information into the Image Builder service. In this article we'll go over the sections of the files, so you can build your own. For latest API versions, see [template reference](#). To see examples of full json files, see the [Azure Image Builder GitHub](#).

The basic format is:

- [JSON](#)
- [Bicep](#)

```
{  
  "type": "Microsoft.VirtualMachineImages/imageTemplates",  
  "apiVersion": "2022-02-14",  
  "location": "<region>",  
  "tags": {  
    "<name>": "<value>",  
    "<name>": "<value>"  
  },  
  "identity": {},  
  "properties": {  
    "buildTimeoutInMinutes": <minutes>,  
    "customize": [],  
    "distribute": [],  
    "source": {},  
    "stagingResourceGroup": "/subscriptions/<subscriptionID>/resourceGroups/<stagingResourceGroupName>",  
    "validate": {},  
    "vmProfile": {  
      "vmSize": "<vmSize>",  
      "proxyVmSize": "<vmSize>",  
      "osDiskSizeGB": <sizeInGB>,  
      "vnetConfig": {  
        "subnetId": "  
          "/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vn  
          etName>/subnets/<subnetName>"  
        },  
        "userAssignedIdentities": [  
  
          "/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAss  
          ignedIdentities/<identityName1>",  
  
          "/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAss  
          ignedIdentities/<identityName2>",  
  
          "/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAss  
          ignedIdentities/<identityName3>",  
          ...  
        ]  
      }  
    }  
  }  
}
```

## Type and API version

The `type` is the resource type, which must be `Microsoft.VirtualMachineImages/imageTemplates`. The `apiVersion` will change over time as the API changes. See [What's new in Azure VM Image Builder](#) for all major API changes and feature updates for the Azure VM Image Builder service.

- [JSON](#)
- [Bicep](#)

```
"type": "Microsoft.VirtualMachineImages/imageTemplates",  
"apiVersion": "2022-02-14",
```

## Location

The location is the region where the custom image will be created. The following regions are supported:

- East US

- East US 2
- West Central US
- West US
- West US 2
- West US 3
- South Central US
- North Europe
- West Europe
- South East Asia
- Australia Southeast
- Australia East
- UK South
- UK West
- Brazil South
- Canada Central
- Central India
- Central US
- France Central
- Germany West Central
- Japan East
- North Central US
- Norway East
- Switzerland North
- Jio India West
- UAE North
- East Asia
- Korea Central
- South Africa North
- USGov Arizona (Public Preview)
- USGov Virginia (Public Preview)

#### **IMPORTANT**

Register the feature `Microsoft.VirtualMachineImages/FairfaxPublicPreview` to access the Azure Image Builder public preview in Azure Government regions (USGov Arizona and USGov Virginia).

Use the following command to register the feature for Azure Image Builder in Azure Government regions (USGov Arizona and USGov Virginia).

- [Azure PowerShell](#)
- [Azure CLI](#)

```
Register-AzProviderPreviewFeature -ProviderNamespace Microsoft.VirtualMachineImages -Name FairfaxPublicPreview
```

- [JSON](#)
- [Bicep](#)

```
"location": "<region>"
```

#### **Data residency**

The Azure VM Image Builder service doesn't store or process customer data outside regions that have strict single region data residency requirements when a customer requests a build in that region. If a service outage for regions that have data residency requirements, you'll need to create Bicep files/templates in a different region and geography.

#### **Zone redundancy**

Distribution supports zone redundancy, VHDs are distributed to a Zone Redundant Storage (ZRS) account by default and the Azure Compute Gallery (formerly known as Shared Image Gallery) version will support a [ZRS storage type](#) if specified.

## Tags

Tags are key/value pairs you can specify for the image that's generated.

## Identity

There are two ways to add user assigned identities explained below.

### User-assigned identity for Azure Image Builder image template resource

Required - For Image Builder to have permissions to read/write images, and read in scripts from Azure Storage, you must create an Azure user-assigned identity that has permissions to the individual resources. For details on how Image Builder permissions work, and relevant steps, see [Create an image and use a user-assigned managed identity to access files in an Azure storage account](#).

- [JSON](#)
- [Bicep](#)

```
"identity": {  
    "type": "UserAssigned",  
    "userAssignedIdentities": {  
        "<imgBuilderId>": {}  
    }  
}
```

The Image Builder service User Assigned Identity:

- Supports a single identity only.
- Doesn't support custom domain names.

To learn more, see [What is managed identities for Azure resources?](#). For more information on deploying this feature, see [Configure managed identities for Azure resources on an Azure VM using Azure CLI](#).

### User-assigned identity for the Image Builder Build VM

This property is only available in API versions [2021-10-01](#) or newer.

Optional - The Image Builder Build VM, that is created by the Image Builder service in your subscription, is used to build and customize the image. For the Image Builder Build VM to have permissions to authenticate with other services like Azure Key Vault in your subscription, you must create one or more Azure User Assigned Identities that have permissions to the individual resources. Azure Image Builder can then associate these User Assigned Identities with the Build VM. Customizer scripts running inside the Build VM can then fetch tokens for these identities and interact with other Azure resources as needed. Be aware, the user assigned identity for Azure Image Builder must have the "Managed Identity Operator" role assignment on all the user assigned identities for Azure Image Builder to be able to associate them to the build VM.

#### NOTE

Be aware that multiple identities can be specified for the Image Builder Build VM, including the identity you created for the [image template resource](#). By default, the identity you created for the image template resource won't automatically be added to the build VM.

- [JSON](#)
- [Bicep](#)

```
"properties": {  
    "vmProfile": {  
        "userAssignedIdentities": [  
  
            "/subscriptions/<subscriptionID>/resourceGroups/<identityRgName>/providers/Microsoft.ManagedIdentity/userAss  
ignedIdentities/<identityName>"  
        ]  
    }  
}
```

The Image Builder Build VM User Assigned Identity:

- Supports a list of one or more user assigned managed identities to be configured on the VM.
- Supports cross subscription scenarios (identity created in one subscription while the image template is created in another subscription under the same tenant).
- Doesn't support cross tenant scenarios (identity created in one tenant while the image template is created in another tenant).

To learn more, see:

- [How to use managed identities for Azure resources on an Azure VM to acquire an access token](#)
- [How to use managed identities for Azure resources on an Azure VM for sign-in](#)

## Properties: buildTimeoutInMinutes

Maximum duration to wait while building the image template (includes all customizations, validations, and distributions).

If you don't specify the property or set the value to 0, the default value is used, which is 240 minutes or four hours. The minimum value is 6 minutes, and the maximum value is 960 minutes or 16 hours. When the timeout value is hit (whether or not the image build is complete), you'll see an error similar to:

```
[ERROR] Failed while waiting for packerizer: Timeout waiting for microservice to  
[ERROR] complete: 'context deadline exceeded'
```

For Windows, we don't recommend setting `buildTimeoutInMinutes` below 60 minutes. If you find you're hitting the timeout, review the [logs](#) to see if the customization step is waiting on something like user input. If you find you need more time for customizations to complete, increase the `buildTimeoutInMinutes` value. But, don't set it too high because you might have to wait for it to time out before seeing an error.

## Properties: customize

Image Builder supports multiple "customizers", which are functions used to customize your image, such as running scripts, or rebooting servers.

When using `customize`:

- You can use multiple customizers.
- Customizers execute in the order specified in the template.
- If one customizer fails, then the whole customization component will fail and report back an error.
- Test the scripts thoroughly before using them in a template. Debugging the scripts by themselves is easier.
- Don't put sensitive data in the scripts. Inline commands can be viewed in the image template definition. If you have sensitive information (including passwords, SAS token, authentication tokens, etc.), it should be moved into scripts in Azure Storage, where access requires authentication.
- The script locations need to be publicly accessible, unless you're using [MSI](#).

The `customize` section is an array. The supported customizer types are: File, PowerShell, Shell, WindowsRestart, and WindowsUpdate.

- [JSON](#)
- [Bicep](#)

```
"customize": [  
    {  
        "type": "File",  
        "destination": "string",  
        "sha256Checksum": "string",  
        "sourceUri": "string"  
    },  
    {  
        "type": "PowerShell",  
        "inline": [ "string" ],  
        "runAsSystem": "bool",  
        "runElevated": "bool",  
        "scriptUri": "string",  
        "sha256Checksum": "string",  
        "validExitCodes": [ "int" ]  
    },  
    {  
        "type": "Shell",  
        "inline": [ "string" ],  
        "scriptUri": "string",  
        "sha256Checksum": "string"  
    },  
    {  
        "type": "WindowsRestart",  
        "restartCheckCommand": "string",  
        "restartCommand": "string",  
        "restartTimeout": "string"  
    },  
    {  
        "type": "WindowsUpdate",  
        "filters": [ "string" ],  
        "searchCriteria": "string",  
        "updateLimit": "int"  
    }  
]
```

### Shell customizer

The `Shell` customizer supports running shell scripts on Linux. The shell scripts must be publicly accessible or

you must have configured an [MSI](#) for Image Builder to access them.

- [JSON](#)
- [Bicep](#)

```
"customize": [
  {
    "type": "Shell",
    "name": "<name>",
    "scriptUri": "<link to script>",
    "sha256Checksum": "<sha256 checksum>"
  }
],
"customize": [
  {
    "type": "Shell",
    "name": "<name>",
    "inline": "<commands to run>"
  }
]
```

Customize properties:

- **type** – Shell.
- **name** - name for tracking the customization.
- **scriptUri** - URI to the location of the file.
- **inline** - array of shell commands, separated by commas.
- **sha256Checksum** - Value of sha256 checksum of the file, you generate this value locally, and then Image Builder will checksum and validate.

To generate the sha256Checksum, using a terminal on Mac/Linux run: `sha256sum <fileName>`

#### NOTE

Inline commands are stored as part of the image template definition, you can see these when you dump out the image definition. If you have sensitive commands or values (including passwords, SAS token, authentication tokens etc), it's recommended these are moved into scripts, and use a user identity to authenticate to Azure Storage.

#### Super user privileges

Prefix the commands with `sudo` to run them with super user privileges. You can add the commands into scripts or use it inline commands, for example:

- [JSON](#)
- [Bicep](#)

```
"type": "Shell",
"name": "setupBuildPath",
"inline": [
  "sudo mkdir /buildArtifacts",
  "sudo cp /tmp/index.html /buildArtifacts/index.html"
]
```

Example of a script using sudo that you can reference using scriptUri:

```
#!/bin/bash -e

echo "Telemetry: creating files"
mkdir /myfiles

echo "Telemetry: running sudo 'as-is' in a script"
sudo touch /myfiles/somethingElevated.txt
```

#### Windows restart customizer

The `WindowsRestart` customizer allows you to restart a Windows VM and wait for the VM come back online, this customizer allows you to install software that requires a reboot.

- [JSON](#)
- [Bicep](#)

```

"customize": [
  {
    "type": "WindowsRestart",
    "restartCommand": "shutdown /r /f /t 0",
    "restartCheckCommand": "echo Azure-Image-Builder-Restarted-the-VM >
c:\\buildArtifacts\\azureImageBuilderRestart.txt",
    "restartTimeout": "5m"
  }
]

```

Customize properties:

- **Type**: WindowsRestart.
- **restartCommand** - Command to execute the restart (optional). The default is `'shutdown /r /f /t 0 /c \"packer restart\"'`.
- **restartCheckCommand** – Command to check if restart succeeded (optional).
- **restartTimeout** - Restart timeout specified as a string of magnitude and unit. For example, `5m` (5 minutes) or `2h` (2 hours). The default is: `5m`.

#### NOTE

There's no Linux restart customizer. If you're installing drivers, or components that require a restart, you can install them and invoke a restart using the Shell customizer. There's a 20min SSH timeout to the build VM.

### PowerShell customizer

The `PowerShell` customizer supports running PowerShell scripts and inline command on Windows, the scripts must be publicly accessible for the IB to access them.

- [JSON](#)
- [Bicep](#)

```

"customize": [
  {
    "type": "PowerShell",
    "name": "<name>",
    "scriptUri": "<path to script>",
    "runElevated": <true false>,
    "sha256Checksum": "<sha256 checksum>"
  },
  {
    "type": "PowerShell",
    "name": "<name>",
    "inline": "<PowerShell syntax to run>",
    "validExitCodes": [<exit code>],
    "runElevated": <true or false>
  }
]

```

Customize properties:

- **type** – PowerShell.
- **scriptUri** - URI to the location of the PowerShell script file.
- **inline** – Inline commands to be run, separated by commas.
- **validExitCodes** – Optional, valid codes that can be returned from the script/inline command. The `runElevated` property avoids reported failure of the script/inline command.
- **runElevated** – Optional, boolean, support for running commands and scripts with elevated permissions.
- **sha256Checksum** - generate the SHA256 checksum of the file locally, update the checksum value to lowercase, and Image Builder will validate the checksum during the deployment of the image template.

To generate the sha256Checksum, use the [Get-FileHash](#) cmdlet in PowerShell.

### File customizer

The `File` customizer lets Image Builder download a file from a GitHub repo or Azure storage. The customizer supports both Linux and Windows. If you have an image build pipeline that relies on build artifacts, you can set the file customizer to download from the build share, and move the artifacts into the image.

- [JSON](#)
- [Bicep](#)

```

"customize": [
  {
    "type": "File",
    "name": "<name>",
    "sourceUri": "<source location>",
    "destination": "<destination>",
    "sha256Checksum": "<sha256 checksum>"
  }
]

```

File customizer properties:

- **sourceUri** - an accessible storage endpoint, this endpoint can be GitHub or Azure storage. You can only download one file, not an entire directory. If you need to download a directory, use a compressed file, then uncompress it using the Shell or PowerShell customizers.

#### NOTE

If the sourceUri is an Azure Storage Account, irrespective if the blob is marked public, you'll to grant the Managed User Identity permissions to read access on the blob. See this [example](#) to set the storage permissions.

- **destination** – the full destination path and file name. Any referenced path and subdirectories must exist, use the Shell or PowerShell customizers to set up these paths up beforehand. You can use the script customizers to create the path.

This customizer is supported by Windows directories and Linux paths, but there are some differences:

- Linux – the only path Image builder can write to is /tmp.
- Windows – No path restriction, but the path must exist.

If there's an error trying to download the file, or put it in a specified directory, then customize step will fail, and this error will be in the customization.log.

#### NOTE

The file customizer is only suitable for small file downloads, < 20MB. For larger file downloads, use a script or inline command, then use code to download files, such as, Linux `wget` or `curl`, Windows, `Invoke-WebRequest`.

- **sha256Checksum** - generate the SHA256 checksum of the file locally, update the checksum value to lowercase, and Image Builder will validate the checksum during the deployment of the image template.

To generate the sha256Checksum, use the `Get-FileHash` cmdlet in PowerShell.

### Windows update customizer

The `WindowsUpdate` customizer is built on the [community Windows Update Provisioner](#) for Packer, which is an open source project maintained by the Packer community. Microsoft tests and validate the provisioner with the Image Builder service, and will support investigating issues with it, and work to resolve issues, however the open source project isn't officially supported by Microsoft. For detailed documentation on and help with the Windows Update Provisioner, see the project repository.

- **JSON**
- **Bicep**

```

"customize": [
  {
    "type": "WindowsUpdate",
    "searchCriteria": "IsInstalled=0",
    "filters": [
      "exclude:$_.Title -like '*Preview*'",
      "include:$true"
    ],
    "updateLimit": 20
  }
]

```

Customizer properties:

- **type** – WindowsUpdate.
- **searchCriteria** - Optional, defines which type of updates are installed (like Recommended or Important), BrowseOnly=0 and IsInstalled=0 (Recommended) is the default.
- **filters** – Optional, allows you to specify a filter to include or exclude updates.
- **updateLimit** – Optional, defines how many updates can be installed, default 1000.

#### NOTE

The Windows Update customizer can fail if there are any outstanding Windows restarts, or application installations still running, typically you may see this error in the customization.log,

`System.Runtime.InteropServices.COMException (0x80240016): Exception from HRESULT: 0x80240016`. We strongly advise you consider adding in a Windows Restart, and/or allowing applications enough time to complete their installations using `sleep` or `wait` commands in the inline commands or scripts before running Windows Update.

#### Generalize

By default, Azure Image Builder will also run `deprovision` code at the end of each image customization phase, to generalize the image. Generalizing is a process where the image is set up so it can be reused to create multiple VMs. For Windows VMs, Azure Image Builder uses Sysprep. For Linux, Azure Image Builder runs `waagent -deprovision`.

The commands Image Builder users to generalize may not be suitable for every situation, so Azure Image Builder will allow you to customize this command, if needed.

If you're migrating existing customization, and you're using different Sysprep/waagent commands, you can use the Image Builder generic commands, and if the VM creation fails, use your own Sysprep or waagent commands.

If Azure Image Builder creates a Windows custom image successfully, and you create a VM from it, then find that the VM creation fails or doesn't complete successfully, you'll need to review the Windows Server Sysprep documentation or raise a support request with the Windows Server Sysprep Customer Services Support team, who can troubleshoot and advise on the correct Sysprep usage.

#### Default Sysprep command

```
Write-Output '">>>> Waiting for GA Service (RdAgent) to start ...'
while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }
Write-Output '">>>> Waiting for GA Service (WindowsAzureTelemetryService) to start ...'
while ((Get-Service WindowsAzureTelemetryService) -and ((Get-Service WindowsAzureTelemetryService).Status -ne 'Running')) { Start-Sleep -s 5 }
Write-Output '">>>> Waiting for GA Service (WindowsAzureGuestAgent) to start ...'
while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }
Write-Output '">>>> Sysprepping VM ...'
if( Test-Path $Env:SystemRoot\system32\Sysprep\unattend.xml ) {
    Remove-Item $Env:SystemRoot\system32\Sysprep\unattend.xml -Force
}
& $Env:SystemRoot\System32\Sysprep\Sysprep.exe /oobe /generalize /quiet /quit
while($true) {
    $imageState = (Get-ItemProperty HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\Setup\State).ImageState
    Write-Output $imageState
    if ($imageState -eq 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { break }
    Start-Sleep -s 5
}
Write-Output '">>>> Sysprep complete ...'
```

#### Default Linux deprovision command

```
WAAGENT=/usr/sbin/waagent
waagent -version 1> /dev/null 2>&1
if [ $? -eq 0 ]; then
    WAAGENT=waagent
fi
$WAAGENT -force -deprovision+user && export HISTSIZE=0 && sync
```

#### Overriding the Commands

To override the commands, use the PowerShell or Shell script provisioners to create the command files with the exact file name, and put them in the correct directories:

- Windows: c:\DeprovisioningScript.ps1
- Linux: /tmp/DeprovisioningScript.sh

Image Builder will read these commands, these commands are written out to the AIB logs, `customization.log`. See [troubleshooting](#) on how to collect logs.

## Properties: distribute

Azure Image Builder supports three distribution targets:

- **managedImage** - managed image.
- **sharedImage** - Azure Compute Gallery.
- **VHD** - VHD in a storage account.

You can distribute an image to both of the target types in the same configuration.

**NOTE**

The default AIB sysprep command doesn't include "/mode:vm", however this property maybe required when create images that will have the HyperV role installed. If you need to add this command argument, you must override the sysprep command.

Because you can have more than one target to distribute to, Image Builder maintains a state for every distribution target that can be accessed by querying the `runOutputName`. The `runOutputName` is an object you can query post distribution for information about that distribution. For example, you can query the location of the VHD, or regions where the image version was replicated to, or SIG Image version created. This is a property of every distribution target. The `runOutputName` must be unique to each distribution target. Here's an example for querying an Azure Compute Gallery distribution:

```
subscriptionID=<subscriptionID>
imageResourceGroup=<resourceGroup of image template>
runOutputName=<runOutputName>

az resource show \
--ids
"/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.VirtualMachineImages/
imageTemplates/ImageTemplateLinuxRHEL77/runOutputs/$runOutputName" \
--api-version=2021-10-01
```

Output:

```
{
  "id": "/subscriptions/xxxxxx/resourcegroups/rheltest/providers/Microsoft.VirtualMachineImages/imageTemplates/ImageTemplateLinuxRHEL77/runOutputs/rhel77",
  "identity": null,
  "kind": null,
  "location": null,
  "managedBy": null,
  "name": "rhel77",
  "plan": null,
  "properties": {
    "artifactId": "/subscriptions/xxxxxx/resourceGroups/aibDevOpsImg/providers/Microsoft.Compute/galleries/devOpsSIG/images/rhel/versions/0.24105.52755",
    "provisioningState": "Succeeded"
  },
  "resourceGroup": "rheltest",
  "sku": null,
  "tags": null,
  "type": "Microsoft.VirtualMachineImages/imageTemplates/runOutputs"
}
```

**Distribute: managedImage**

The image output will be a managed image resource.

- [JSON](#)
- [Bicep](#)

```
{
  "type": "managedImage",
  "imageId": "<resource ID>",
  "location": "<region>",
  "runOutputName": "<name>",
  "artifactTags": {
    "<name>": "<value>",
    "<name>": "<value>"
  }
}
```

Distribute properties:

- **type** – managedImage
- **imageId** – Resource ID of the destination image, expected format:  
`/subscriptions/<subscriptionId>/resourceGroups/<destinationResourceGroupName>/providers/Microsoft.Compute/images/<imageName>`
- **location** - location of the managed image.
- **runOutputName** – unique name for identifying the distribution.
- **artifactTags** - Optional user specified key\value tags.

#### NOTE

The destination resource group must exist. If you want the image distributed to a different region, it will increase the deployment time.

#### Distribute: sharedImage

The Azure Compute Gallery is a new Image Management service that allows managing of image region replication, versioning and sharing custom images. Azure Image Builder supports distributing with this service, so you can distribute images to regions supported by Azure Compute Galleries.

An Azure Compute Gallery is made up of:

- **Gallery** - Container for multiple images. A gallery is deployed in one region.
- **Image definitions** - a conceptual grouping for images.
- **Image versions** - an image type used for deploying a VM or scale set. Image versions can be replicated to other regions where VMs need to be deployed.

Before you can distribute to the gallery, you must create a gallery and an image definition, see [Create a gallery](#).

- [JSON](#)
- [Bicep](#)

```
{  
    "type": "SharedImage",  
    "galleryImageId": "<resource ID>",  
    "runOutputName": "<name>",  
    "artifactTags": {  
        "<name>": "<value>",  
        "<name>": "<value>"  
    },  
    "replicationRegions": [  
        "<region where the gallery is deployed>",  
        "<region>"  
    ]  
}
```

Distribute properties for galleries:

- **type** - sharedImage
- **galleryImageId** – ID of the Azure Compute Gallery, this property can be specified in two formats:
  - Automatic versioning - Image Builder will generate a monotonic version number for you, this property is useful for when you want to keep rebuilding images from the same template: The format is:  
`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<sharedImageGalleryName>/image`
  - Explicit versioning - You can pass in the version number you want image builder to use. The format is:  
`/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<sharedImageGalName>/images/<imageDefName>` - for example: 1.1.1
- **runOutputName** – unique name for identifying the distribution.
- **artifactTags** - optional user specified key\value tags.
- **replicationRegions** - array of regions for replication. One of the regions must be the region where the Gallery is deployed. Adding regions will mean an increase of build time, as the build doesn't complete until the replication has completed.
- **excludeFromLatest** (optional) - allows you to mark the image version you create not be used as the latest version in the gallery definition, the default is 'false'.
- **storageAccountType** (optional) - AIB supports specifying these types of storage for the image version that is to be created:
  - "Standard\_LRS"
  - "Standard\_ZRS"","

#### NOTE

If the image template and referenced `image definition` aren't in the same location, you'll see additional time to create images. Image Builder currently doesn't have a `location` parameter for the image version resource, we take it from its parent `image definition`. For example, if an image definition is in `westus` and you want the image version replicated to `eastus`, a blob is copied to `westus`, an image version resource in `westus` is created, and then replicate to `eastus`. To avoid the additional replication time, ensure the `image definition` and image template are in the same location.

### Distribute: VHD

You can output to a VHD. You can then copy the VHD, and use it to publish to Azure MarketPlace, or use with Azure Stack.

- [JSON](#)
- [Bicep](#)

```
{  
  "type": "VHD",  
  "runOutputName": "<VHD name>",  
  "artifactTags": {  
    "<name>": "<value>",  
    "<name>": "<value>"  
  }  
}
```

OS Support: Windows and Linux

Distribute VHD parameters:

- **type** - VHD.
- **runOutputName** – unique name for identifying the distribution.
- **tags** - Optional user specified key value pair tags.

Azure Image Builder doesn't allow the user to specify a storage account location, but you can query the status of the `runOutputs` to get the location.

```
az resource show \  
  --ids  
  "/subscriptions/$subscriptionId/resourcegroups/<imageResourceGroup>/providers/Microsoft.VirtualMachineImages  
  /imageTemplates/<imageTemplateName>/runOutputs/<runOutputName>" | grep artifactUri
```

#### NOTE

Once the VHD has been created, copy it to a different location, as soon as possible. The VHD is stored in a storage account in the temporary resource group created when the image template is submitted to the Azure Image Builder service. If you delete the image template, then you'll lose the VHD.

## Properties: source

The `source` section contains information about the source image that will be used by Image Builder.

The API requires a `SourceType` that defines the source for the image build, currently there are three types:

- **PlatformImage** - indicated the source image is a Marketplace image.
- **ManagedImage** - used when starting from a regular managed image.
- **SharedImageVersion** - used when you're using an image version in an Azure Compute Gallery as the source.

#### NOTE

When using existing Windows custom images, you can run the Sysprep command up to three times on a single Windows 7 or Windows Server 2008 R2 image, or 1001 times on a single Windows image for later versions; for more information, see the [sysprep](#) documentation.

### PlatformImage source

Azure Image Builder supports Windows Server and client, and Linux Azure Marketplace images, see [Learn about Azure Image Builder](#) for the full list.

- [JSON](#)
- [Bicep](#)

```
"source": {  
  "type": "PlatformImage",  
  "publisher": "Canonical",  
  "offer": "UbuntuServer",  
  "sku": "18.04-LTS",  
  "version": "latest"  
}
```

The properties here are the same that are used to create VM's, using AZ CLI, run the below to get the properties:

```
az vm image list -l westus -f UbuntuServer -p Canonical --output table --all
```

You can use `latest` in the version, the version is evaluated when the image build takes place, not when the template is submitted. If you use this functionality with the Azure Compute Gallery destination, you can avoid resubmitting the template, and rerun the image build at intervals, so your images are recreated from the most recent images.

#### Support for market place plan information

You can also specify plan information, for example:

- [JSON](#)
- [Bicep](#)

```
"source": {  
    "type": "PlatformImage",  
    "publisher": "RedHat",  
    "offer": "rhel-byos",  
    "sku": "rhel-lvm75",  
    "version": "latest",  
    "planInfo": {  
        "planName": "rhel-lvm75",  
        "planProduct": "rhel-byos",  
        "planPublisher": "redhat"  
    }  
}
```

#### ManagedImage source

Sets the source image as an existing managed image of a generalized VHD or VM.

##### NOTE

The source managed image must be of a supported OS and the image must reside in the same subscription and region as your Azure Image Builder template.

- [JSON](#)
- [Bicep](#)

```
"source": {  
    "type": "ManagedImage",  
    "imageId":  
    "/subscriptions/<subscriptionId>/resourceGroups/{destinationResourceGroupName}/providers/Microsoft.Compute/i  
mages/<imageName>"  
}
```

The `imageId` should be the ResourceId of the managed image. Use `az image list` to list available images.

#### SharedImageVersion source

Sets the source image as an existing image version in an Azure Compute Gallery.

##### NOTE

The source shared image version must be of a supported OS and the image version must reside in the same region as your Azure Image Builder template, if not, replicate the image version to the Image Builder Template region.

- [JSON](#)
- [Bicep](#)

```
"source": {  
    "type": "SharedImageVersion",  
    "imageVersionId":  
    "/subscriptions/<subscriptionId>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<share  
dImageGalleryName>/images/<imageDefinitionName>/versions/<imageVersion>"  
}
```

The `imageVersionId` should be the ResourceId of the image version. Use `az sig image-version list` to list image versions.

## Properties: stagingResourceGroup

The `stagingResourceGroup` property contains information about the staging resource group that the Image

Builder service will create for use during the image build process. The `stagingResourceGroup` is an optional property for anyone who wants more control over the resource group created by Image Builder during the image build process. You can create your own resource group and specify it in the `stagingResourceGroup` section or have Image Builder create one on your behalf.

- [JSON](#)
- [Bicep](#)

```
"properties": {  
    "stagingResourceGroup": "/subscriptions/<subscriptionID>/resourceGroups/<stagingResourceGroupName>"  
}
```

#### Template creation scenarios

- The `stagingResourceGroup` property is left empty

If the `stagingResourceGroup` property isn't specified or specified with an empty string, the Image Builder service will create a staging resource group with the default name convention "IT\_\*\*\*". The staging resource group will have the default tags applied to it: `createdBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. Also, the default RBAC will be applied to the identity assigned to the Azure Image Builder template resource, which is "Contributor".

- The `stagingResourceGroup` property is specified with a resource group that exists

If the `stagingResourceGroup` property is specified with a resource group that does exist, then the Image Builder service will check to make sure the resource group isn't associated with another image template, is empty (no resources inside), in the same region as the image template, and has either "Contributor" or "Owner" RBAC applied to the identity assigned to the Azure Image Builder image template resource. If any of the aforementioned requirements aren't met, an error will be thrown. The staging resource group will have the following tags added to it: `usedBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. Pre-existing tags aren't deleted.

- The `stagingResourceGroup` property is specified with a resource group that doesn't exist

If the `stagingResourceGroup` property is specified with a resource group that doesn't exist, then the Image Builder service will create a staging resource group with the name provided in the `stagingResourceGroup` property. There will be an error if the given name doesn't meet Azure naming requirements for resource groups. The staging resource group will have the default tags applied to it: `createdBy`, `imageTemplateName`, `imageTemplateResourceGroupName`. By default the identity assigned to the Azure Image Builder image template resource will have the "Contributor" RBAC applied to it in the resource group.

#### Template deletion

Any staging resource group created by the Image Builder service will be deleted after the image template is deleted. The deletion includes staging resource groups that were specified in the `stagingResourceGroup` property, but didn't exist prior to the image build.

If Image Builder didn't create the staging resource group, but the resources inside of the resource group, those resources will be deleted after the image template is deleted, given the Image Builder service has the appropriate permissions or role required to delete resources.

## Properties: validate

You can use the `validate` property to validate platform images and any customized images you create regardless of if you used Azure Image Builder to create them.

Azure Image Builder supports a 'Source-Validation-Only' mode that can be set using the `sourceValidationOnly` property. If the `sourceValidationOnly` property is set to true, the image specified in the `source` section will directly be validated. No separate build will be run to generate and then validate a customized image.

The `inVMValidations` property takes a list of validators that will be performed on the image. Azure Image Builder supports both PowerShell and Shell validators.

The `continueDistribute onFailure` property is responsible for whether the output image(s) will be distributed if validation fails. By default, if validation fails and this property is set to false, the output image(s) won't be distributed. If validation fails and this property is set to true, the output image(s) will still be distributed. Use this option with caution as it may result in failed images being distributed for use. In either case (true or false), the end to end image run will be reported as a failed if a validation failure. This property has no effect on whether validation succeeds or not.

When using `validate`:

- You can use multiple validators.
- Validators execute in the order specified in the template.
- If one validator fails, then the whole validation component will fail and report back an error.

- It's advised you test the script thoroughly before using it in a template. Debugging the script on your own VM will be easier.
- Don't put sensitive data in the scripts.
- The script locations need to be publicly accessible, unless you're using [MSI](#).

How to use the `validate` property to validate Windows images:

- [JSON](#)
- [Bicep](#)

```
{
  "properties": {
    "validate": [
      {
        "continueDistributeOnFailure": false,
        "sourceValidationOnly": false,
        "inVMValidations": [
          {
            "type": "PowerShell",
            "name": "test PowerShell validator inline",
            "inline": [
              "<command to run inline>"
            ],
            "validExitCodes": <exit code>,
            "runElevated": <true or false>,
            "runAsSystem": <true or false>
          },
          {
            "type": "PowerShell",
            "name": "<name>",
            "scriptUri": "<path to script>",
            "runElevated": <true false>,
            "sha256Checksum": "<sha256 checksum>"
          }
        ]
      }
    ]
  }
}
```

`inVMValidations` properties:

- **type** – PowerShell.
- **name** - name of the validator
- **scriptUri** - URI of the PowerShell script file.
- **inline** – array of commands to be run, separated by commas.
- **validExitCodes** – Optional, valid codes that can be returned from the script/inline command, this will avoid reported failure of the script/inline command.
- **runElevated** – Optional, boolean, support for running commands and scripts with elevated permissions.
- **sha256Checksum** - Value of sha256 checksum of the file, you generate this locally, and then Image Builder will checksum and validate.

To generate the sha256Checksum, using a PowerShell on Windows [Get-Hash](#)

How to use the `validate` property to validate Linux images:

- [JSON](#)
- [Bicep](#)

```
{
  "properties": {
    "validate": {
      "continueDistributeOnFailure": false,
      "sourceValidationOnly": false,
      "inVMValidations": [
        {
          "type": "Shell",
          "name": "<name>",
          "inline": [
            "<command to run inline>"
          ]
        },
        {
          "type": "Shell",
          "name": "<name>",
          "scriptUri": "<path to script>",
          "sha256Checksum": "<sha256 checksum>"
        }
      ]
    }
  }
}
```

`inVMValidations` properties:

- **type** – Shell
- **name** - name of the validator
- **scriptUri** - URI of the script file
- **inline** - array of commands to be run, separated by commas.
- **sha256Checksum** - Value of sha256 checksum of the file, you generate this locally, and then Image Builder will checksum and validate.

To generate the sha256Checksum, using a terminal on Mac/Linux run: `sha256sum <fileName>`

## Properties: vmProfile

### vmSize (optional)

Image Builder uses a default SKU size of `Standard_D1_v2` for Gen1 images and `Standard_D2ds_v4` for Gen2 images. The generation is defined by the image you specify in the `source`. You can override `vmSize` for these reasons:

- Performing customizations that require increased memory, CPU and handling large files (GBs).
- Running Windows builds, you should use "Standard\_D2\_v2" or equivalent VM size.
- Require [VM isolation](#).
- Customize an image that requires specific hardware. For example, for a GPU VM, you need a GPU VM size.
- Require end to end encryption at rest of the build VM, you need to specify the support build [VM size](#) that don't use local temporary disks.

### osDiskSizeGB

By default, Image Builder doesn't change the size of the image, it uses the size from the source image. You can optionally **only** increase the size of the OS Disk (Win and Linux), and a value of 0 means leaving the same size as the source image. You can't reduce the OS Disk size to smaller than the size from the source image.

- [JSON](#)
- [Bicep](#)

```
{
  "osDiskSizeGB": 100
}
```

### vnetConfig (optional)

If you don't specify any VNet properties, Image Builder will create its own VNet, Public IP, and network security group (NSG). The Public IP is used for the service to communicate with the build VM. If you don't want to have a Public IP or you want Image Builder to have access to your existing VNet resources, such as configuration servers (DSC, Chef, Puppet, Ansible), file shares, then you can specify a VNet. For more information, review the [networking documentation](#).

- [JSON](#)
- [Bicep](#)

```
"vnetConfig": {  
    "subnetId": "  
"/subscriptions/<subscriptionID>/resourceGroups/<vnetRgName>/providers/Microsoft.Network/virtualNetworks/<vn  
etName>/subnets/<subnetName>"  
}
```

## Image Template Operations

### Starting an Image Build

To start a build, you need to invoke 'Run' on the Image Template resource, examples of `run` commands:

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -  
ResourceType Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2021-10-01" -Action Run -Force
```

```
az resource invoke-action \  
--resource-group $imageResourceGroup \  
--resource-type Microsoft.VirtualMachineImages/imageTemplates \  
-n helloImageTemplateLinux01 \  
--action Run
```

### Cancelling an Image Build

If you're running an image build that you believe is incorrect, waiting for user input, or you feel will never complete successfully, then you can cancel the build.

The build can be canceled anytime. If the distribution phase has started you can still cancel, but you'll need to clean up any images that may not be completed. The cancel command doesn't wait for cancel to complete, monitor `lastrunstatus.runstate` for canceling progress, using these status [commands](#).

Examples of `cancel` commands:

```
Invoke-AzResourceAction -ResourceName $imageTemplateName -ResourceGroupName $imageResourceGroup -  
ResourceType Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2021-10-01" -Action Cancel -Force
```

```
az resource invoke-action \  
--resource-group $imageResourceGroup \  
--resource-type Microsoft.VirtualMachineImages/imageTemplates \  
-n helloImageTemplateLinux01 \  
--action Cancel
```

## Next steps

There are sample json files for different scenarios in the [Azure Image Builder GitHub](#).

# Create a Linux image and distribute it to an Azure Compute Gallery

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how you can use the Azure Image Builder, and the Azure CLI, to create an image version in an [Azure Compute Gallery](#) (formerly known as Shared Image Gallery), then distribute the image globally. You can also do this using [Azure PowerShell](#).

We will be using a sample json template to configure the image. The json file we are using is here: [helloImageTemplateforSIG.json](#).

To distribute the image to an Azure Compute Gallery, the template uses `sharedImage` as the value for the `distribute` section of the template.

## Register the features

To use Azure Image Builder, you need to register the feature.

Check your registration.

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState  
az provider show -n Microsoft.KeyVault | grep registrationState  
az provider show -n Microsoft.Compute | grep registrationState  
az provider show -n Microsoft.Storage | grep registrationState  
az provider show -n Microsoft.Network | grep registrationState
```

If they do not say registered, run the following:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Set variables and permissions

We will be using some pieces of information repeatedly, so we will create some variables to store that information.

Image Builder only supports creating custom images in the same Resource Group as the source managed image. Update the resource group name in this example to be the same resource group as your source managed image.

```
# Resource group name - we are using ibLinuxGalleryRG in this example
sigResourceGroup=ibLinuxGalleryRG
# Datacenter location - we are using West US 2 in this example
location=westus2
# Additional region to replicate the image to - we are using East US in this example
additionalRegion=eastus
# name of the Azure Compute Gallery - in this example we are using myGallery
sigName=myIbGallery
# name of the image definition to be created - in this example we are using myImageDef
imageDefName=myIbImageDef
# image distribution metadata reference name
runOutputName=aibLinuxSIG
```

Create a variable for your subscription ID.

```
subscriptionID=$(az account show --query id --output tsv)
```

Create the resource group.

```
az group create -n $sigResourceGroup -l $location
```

## Create a user-assigned identity and set permissions on the resource group

Image Builder will use the [user-identity](#) provided to inject the image into the Azure Compute Gallery. In this example, you will create an Azure role definition that has the granular actions to perform distributing the image to the gallery. The role definition will then be assigned to the user-identity.

```

# create user assigned identity for image builder to access the storage account where the script is located
identityName=aibBuiUserId$(date +'%s')
az identity create -g $sigResourceGroup -n $identityName

# get identity id
imgBuilderCliId=$(az identity show -g $sigResourceGroup -n $identityName --query clientId -o tsv)

# get the user identity URI, needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$sigResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/$identityName

# this command will download an Azure role definition template, and update the template with the parameters specified earlier.
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json -o aibRoleImageCreation.json

imageRoleDefName="Azure Image Builder Image Def"$(date +'%s')

# update the definition
sed -i -e "s/<subscriptionID>/${subscriptionID}/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/${sigResourceGroup}/g" aibRoleImageCreation.json
sed -i -e "s/Azure Image Builder Service Image Creation Role/${imageRoleDefName}/g" aibRoleImageCreation.json

# create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# grant role definition to the user assigned identity
az role assignment create \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

```

## Create an image definition and gallery

To use Image Builder with an Azure Compute Gallery, you need to have an existing gallery and image definition. Image Builder will not create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them. First, create a gallery.

```

az sig create \
-g $sigResourceGroup \
--gallery-name $sigName

```

Then, create an image definition.

```

az sig image-definition create \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--publisher myIbPublisher \
--offer myOffer \
--sku 18.04-LTS \
--os-type Linux

```

## Download and configure the .json

Download the .json template and configure it with your variables.

```
curl  
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/1_Creating_a_Custom_Linux_Shared_Image_Gallery_Image/helloImageTemplateforSIG.json -o helloImageTemplateforSIG.json  
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateforSIG.json  
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIG.json  
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIG.json  
sed -i -e "s/<sharedImageGalName>/$sigName/g" helloImageTemplateforSIG.json  
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIG.json  
sed -i -e "s/<region2>/$additionalRegion/g" helloImageTemplateforSIG.json  
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIG.json  
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateforSIG.json
```

## Create the image version

This next part will create the image version in the gallery.

Submit the image configuration to the Azure Image Builder service.

```
az resource create \  
--resource-group $sigResourceGroup \  
--properties @helloImageTemplateforSIG.json \  
--is-full-object \  
--resource-type Microsoft.VirtualMachineImages/imageTemplates \  
-n helloImageTemplateforSIG01
```

Start the image build.

```
az resource invoke-action \  
--resource-group $sigResourceGroup \  
--resource-type Microsoft.VirtualMachineImages/imageTemplates \  
-n helloImageTemplateforSIG01 \  
--action Run
```

Creating the image and replicating it to both regions can take a while. Wait until this part is finished before moving on to creating a VM.

## Create the VM

Create a VM from the image version that was created by Azure Image Builder.

```
az vm create \  
--resource-group $sigResourceGroup \  
--name myAibGalleryVM \  
--admin-username aibuser \  
--location $location \  
--image  
"/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \  
--generate-ssh-keys
```

SSH into the VM.

```
ssh aibuser@<publicIpAddress>
```

You should see the image was customized with a *Message of the Day* as soon as your SSH connection is established!

```
*****
** This VM was built from the:      **
** !! AZURE VM IMAGE BUILDER Custom Image !!      **
** You have just been Customized :-)      **
*****
```

## Clean up resources

If you want to now try re-customizing the image version to create a new version of the same image, skip the next steps and go on to [Use Azure Image Builder to create another image version](#).

This will delete the image that was created, along with all of the other resource files. Make sure you are finished with this deployment before deleting the resources.

When deleting gallery resources, you need delete all of the image versions before you can delete the image definition used to create them. To delete a gallery, you first need to have deleted all of the image definitions in the gallery.

Delete the image builder template.

```
az resource delete \
--resource-group $sigResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateforSIG01
```

Delete permissions assignments, roles and identity

```
az role assignment delete \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup

az role definition delete --name "$imageRoleDefName"

az identity delete --ids $imgBuilderId
```

Get the image version created by image builder, this always starts with `0.`, and then delete the image version

```
sigDefImgVersion=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'name' -o json | grep 0. | tr -d ''')

az sig image-version delete \
-g $sigResourceGroup \
--gallery-image-version $sigDefImgVersion \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

Delete the image definition.

```
az sig image-definition delete \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID
```

Delete the gallery.

```
az sig delete -r $sigName -g $sigResourceGroup
```

Delete the resource group.

```
az group delete -n $sigResourceGroup -y
```

## Next steps

Learn more about [Azure Compute Galleries](#).

# Create a Windows image and distribute it to an Azure Compute Gallery

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this article, you learn how to use Azure VM Image Builder and Azure PowerShell to create an image version in an [Azure Compute Gallery](#) (formerly Shared Image Gallery) and then distribute the image globally. You can also do this by using the [Azure CLI](#).

To configure the image, this article uses a JSON template, which you can find at [armTemplateWinSIG.json](#). You'll download and edit a local version of the template, so you'll also use a local PowerShell session.

To distribute the image to an Azure Compute Gallery, the template uses `sharedImage` as the value for the `distribute` section of the template.

VM Image Builder automatically runs `Sysprep` to generalize the image. The command is a generic `Sysprep` command, and you can [override](#) it if you need to.

Be aware of the number of times you layer customizations. You can run the `Sysprep` command a limited number of times on a single Windows image. After you've reached the `Sysprep` limit, you must re-create your Windows image. For more information, see [Limits on how many times you can run Sysprep](#).

## Register the features

To use VM Image Builder, you need to register the features.

1. Check your provider registrations. Make sure that each one returns *Registered*.

```
Get-AzResourceProvider -ProviderNamespace Microsoft.VirtualMachineImages | Format-table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Storage | Format-table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Compute | Format-table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.KeyVault | Format-table -Property ResourceTypes,RegistrationState
Get-AzResourceProvider -ProviderNamespace Microsoft.Network | Format-table -Property ResourceTypes,RegistrationState
```

2. If they don't return *Registered*, register the providers by running the following commands:

```
Register-AzResourceProvider -ProviderNamespace Microsoft.VirtualMachineImages
Register-AzResourceProvider -ProviderNamespace Microsoft.Storage
Register-AzResourceProvider -ProviderNamespace Microsoft.Compute
Register-AzResourceProvider -ProviderNamespace Microsoft.KeyVault
Register-AzResourceProvider -ProviderNamespace Microsoft.Network
```

3. Install PowerShell modules:

```
'Az.ImageBuilder', 'Az.ManagedServiceIdentity' | ForEach-Object {Install-Module -Name $_ -AllowPrerelease}
```

## Create variables

Because you'll be using some pieces of information repeatedly, create some variables to store that information.

Replace the values for the variables, such as `username` and `vmpassword`, with your own information.

```
# Get existing context
$currentAzContext = Get-AzContext

# Get your current subscription ID.
$subscriptionID=$currentAzContext.Subscription.Id

# Destination image resource group
$imageResourceGroup="aibwinsig"

# Location
$location="westus"

# Image distribution metadata reference name
$runOutputName="aibCustWinManImg02ro"

# Image template name
$imageTemplateName="helloImageTemplateWin02ps"

# Distribution properties object name (runOutput).
# This gives you the properties of the managed image on completion.
$runOutputName="winclientR01"

# Create a resource group for the VM Image Builder template and Azure Compute Gallery
New-AzResourceGroup ` 
    -Name $imageResourceGroup ` 
    -Location $location
```

## Create a user-assigned identity and set permissions on the resource group

VM Image Builder uses the provided [user-identity](#) to inject the image into Azure Compute Gallery. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

```
# setup role def names, these need to be unique
$timeInt=$(get-date -UFormat "%s")
$imageRoleDefName="Azure Image Builder Image Def"+$timeInt
$identityName="aibIdentity"+$timeInt

## Add an Azure PowerShell module to support AzUserAssignedIdentity
Install-Module -Name Az.ManagedServiceIdentity

# Create an identity
New-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName

$identityNameResourceId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).Id
$identityNamePrincipalId=$(Get-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name
$identityName).PrincipalId
```

## Assign permissions for the identity to distribute the images

Use this command to download an Azure role definition template, and then update it with the previously specified parameters.

```

$aibRoleImageCreationUrl="https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Roles/aibRoleImageCreation.json"
$aibRoleImageCreationPath = "aibRoleImageCreation.json"

# Download the configuration
Invoke-WebRequest -Uri $aibRoleImageCreationUrl -OutFile $aibRoleImageCreationPath -UseBasicParsing

((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<subscriptionID>', $subscriptionID) | Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace '<rgName>', $imageResourceGroup) | Set-Content -Path $aibRoleImageCreationPath
((Get-Content -path $aibRoleImageCreationPath -Raw) -replace 'Azure Image Builder Service Image Creation Role', $imageRoleDefName) | Set-Content -Path $aibRoleImageCreationPath

# Create a role definition
New-AzRoleDefinition -InputFile ./aibRoleImageCreation.json

# Grant the role definition to the VM Image Builder service principal
New-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -Scope "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"

```

#### NOTE

If you receive the error "New-AzRoleDefinition: Role definition limit exceeded. No more role definitions can be created," see [Troubleshoot Azure RBAC \(role-based access control\)](#).

## Create an Azure Compute Gallery

To use VM Image Builder with an Azure Compute Gallery, you need to have an existing gallery and image definition. VM Image Builder doesn't create the gallery and image definition for you.

If you don't already have a gallery and image definition to use, start by creating them.

```

# Gallery name
$sigGalleryName= "myIBSIG"

# Image definition name
$imageDefName ="winSvrimage"

# Additional replication region
$replRegion2="eastus"

# Create the gallery
New-AzGallery `

    -GalleryName $sigGalleryName `

    -ResourceGroupName $imageResourceGroup `

    -Location $location

# Create the image definition
New-AzGalleryImageDefinition `

    -GalleryName $sigGalleryName `

    -ResourceGroupName $imageResourceGroup `

    -Location $location `

    -Name $imageDefName `

    -OsState generalized `

    -OsType Windows `

    -Publisher 'myCompany' `

    -Offer 'WindowsServer' `

    -Sku 'WinSrv2019'

```

# Download and configure the template

Download the JSON template and configure it with your variables.

```
$templateFilePath = "armTemplateWinSIG.json"

Invoke-WebRequest `

    -Uri
    "https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/1_Creating_a_Custom_Win_Shared_Image_Gallery_Image/armTemplateWinSIG.json" `

    -OutFile $templateFilePath `

    -UseBasicParsing

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<subscriptionID>', $subscriptionID | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<rgName>', $imageResourceGroup | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<runOutputName>', $runOutputName | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<imageDefName>', $imageDefName | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<sharedImageGalName>', $sigGalleryName | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<region1>', $location | Set-Content -Path $templateFilePath

(Get-Content -path $templateFilePath -Raw ) `

    -replace '<region2>', $replRegion2 | Set-Content -Path $templateFilePath

((Get-Content -path $templateFilePath -Raw) -replace '<imgBuilderId>', $identityNameResourceId) | Set-Content -Path $templateFilePath
```

# Create the image version

Your template must be submitted to the service. The following commands will download any dependent artifacts, such as scripts, and store them in the staging resource group, which is prefixed with */T\_*.

```
New-AzResourceGroupDeployment `

    -ResourceGroupName $imageResourceGroup `

    -TemplateFile $templateFilePath `

    -ApiVersion "2020-02-14" `

    -imageTemplateName $imageTemplateName `

    -svclocation $location
```

To build the image, invoke 'Run' on the template.

```
Invoke-AzResourceAction `

    -ResourceName $imageTemplateName `

    -ResourceGroupName $imageResourceGroup `

    -ResourceType Microsoft.VirtualMachineImages/imageTemplates `

    -ApiVersion "2020-02-14" `

    -Action Run
```

Creating the image and replicating it to both regions can take a few moments. Before you begin creating a VM, wait until this part is finished.

```
Get-AzImageBuilderTemplate -ImageTemplateName $imageTemplateName -ResourceGroupName $imageResourceGroup | `

    Select-Object -Property Name, LastRunStatusRunState, LastRunStatusMessage, ProvisioningState
```

## Create the VM

Create a VM from the image version that you created with VM Image Builder.

1. Get the image version that you created:

```
$imageVersion = Get-AzGalleryImageVersion `  
-ResourceGroupName $imageResourceGroup `  
-GalleryName $sigGalleryName `  
-GalleryImageDefinitionName $imageDefName
```

2. Create the VM in the second region, where the image was replicated:

```
$vmResourceGroup = "myResourceGroup"  
$vmName = "myVMfromImage"  
  
# Create user object  
$cred = Get-Credential -Message "Enter a username and password for the virtual machine."  
  
# Create a resource group  
New-AzResourceGroup -Name $vmResourceGroup -Location $replRegion2  
  
# Network pieces  
$subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -AddressPrefix 192.168.1.0/24  
$vnet = New-AzVirtualNetwork -ResourceGroupName $vmResourceGroup -Location $replRegion2 `  
-Name MYvNET -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig  
$pip = New-AzPublicIpAddress -ResourceGroupName $vmResourceGroup -Location $replRegion2 `  
-Name "mypublicdns$(Get-Random)" -AllocationMethod Static -IdleTimeoutInMinutes 4  
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name myNetworkSecurityGroupRuleRDP -Protocol Tcp `  
-Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange * -DestinationAddressPrefix  
* `  
-DestinationPortRange 3389 -Access Deny  
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName $vmResourceGroup -Location $replRegion2 `  
-Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP  
$nic = New-AzNetworkInterface -Name myNic -ResourceGroupName $vmResourceGroup -Location $replRegion2  
`  
-SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -NetworkSecurityGroupId $nsg.Id  
  
# Create a virtual machine configuration using $imageVersion.Id to specify the image  
$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1_v2 | `  
Set-AzVMOperatingSystem -Windows -ComputerName $vmName -Credential $cred | `  
Set-AzVMSourceImage -Id $imageVersion.Id | `  
Add-AzVMNetworkInterface -Id $nic.Id  
  
# Create a virtual machine  
New-AzVM -ResourceGroupName $vmResourceGroup -Location $replRegion2 -VM $vmConfig
```

## Verify the customization

Create a Remote Desktop connection to the VM by using the username and password that you set when you created the VM. In the VM, open a Command Prompt window and run the following command:

```
dir c:\
```

You should see a directory named `buildActions` that was created during image customization.

## Clean up your resources

## NOTE

If you now want to try to recustomize the image version to create a new version of the same image, *skip the step outlined here* and go to [Use VM Image Builder to create another image version](#).

If you no longer need the resources that you created as you followed the process in this article, you can delete them.

The following process deletes both the image that you created and all the other resource files. Make sure that you've finished this deployment before you delete the resources.

Delete the resource group template first. Otherwise, the staging resource group (*/T\_*) that VM Image Builder uses won't be cleaned up.

1. Get the ResourceID of the image template.

```
$resTemplateId = Get-AzResource -ResourceName $imageTemplateName -ResourceGroupName  
$imageResourceGroup -ResourceType Microsoft.VirtualMachineImages/imageTemplates -ApiVersion "2020-02-  
14"
```

2. Delete image template.

```
Remove-AzResource -ResourceId $resTemplateId.ResourceId -Force
```

3. Delete the role assignment.

```
Remove-AzRoleAssignment -ObjectId $identityNamePrincipalId -RoleDefinitionName $imageRoleDefName -  
Scope "/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

4. Remove the definitions.

```
Remove-AzRoleDefinition -Name "$identityNamePrincipalId" -Force -Scope  
"/subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup"
```

5. Delete the identity.

```
Remove-AzUserAssignedIdentity -ResourceGroupName $imageResourceGroup -Name $identityName -Force
```

6. Delete the resource group.

```
Remove-AzResourceGroup $imageResourceGroup -Force
```

## Next steps

To update the image version that you created in this article, see [Use VM Image Builder to create another image version](#).

# Create a new VM image from an existing image by using Azure VM Image Builder in Linux

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In this article, you learn how to update an existing image version in an [Azure Compute Gallery](#) (formerly Shared Image Gallery) and publish it to the gallery as a new image version.

To configure the image, you use a sample JSON template, [helloImageTemplateforSIGfromSIG.json](#).

## Register the features

To use VM Image Builder, you need to register the features.

1. Check your provider registrations. Make sure that each one returns *Registered*.

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState  
az provider show -n Microsoft.KeyVault | grep registrationState  
az provider show -n Microsoft.Compute | grep registrationState  
az provider show -n Microsoft.Storage | grep registrationState  
az provider show -n Microsoft.Network | grep registrationState
```

2. If they don't return *Registered*, register the providers by running the following commands:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Set variables and permissions

If you've already created an Azure Compute Gallery by using [Create an image and distribute it to an Azure Compute Gallery](#), you've already created some of the variables you need.

1. If you haven't already created the variables, run the following commands:

```
# Resource group name  
sigResourceGroup=ibLinuxGalleryRG  
# Gallery location  
location=westus2  
# Additional region to replicate the image version to  
additionalRegion=eastus  
# Name of the Azure Compute Gallery  
sigName=myIbGallery  
# Name of the image definition to use  
imageDefName=myIbImageDef  
# image distribution metadata reference name  
runOutputName=aibSIGLinuxUpdate
```

2. Create a variable for your subscription ID:

```
subscriptionID=$(az account show --query id --output tsv)
```

- Get the image version that you want to update:

```
sigDefImgVersionId=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'id' -o tsv)
```

## Create a user-assigned identity and set permissions on the resource group

You've set up the user identity in an earlier example, so now you need to get the resource ID, which will be appended to the template.

```
#get identity used previously
imgBuilderId=$(az identity list -g $sigResourceGroup --query "[?contains(name, 'aibBuiUserId')].id" -o tsv)
```

If you already have an Azure Compute Gallery but didn't set it up by following an earlier example, you need to assign permissions for VM Image Builder to access the resource group so that it can access the gallery. For more information, see [Create an image and distribute it to an Azure Compute Gallery](#).

## Modify the helloImage example

You can review the JSON example you're about to use at [helloImageTemplateforSIGfromSIG.json](#). For information about the JSON file, see [Create an Azure VM Image Builder template](#).

- Download the JSON example, as shown in [Create a Linux image and distribute it to an Azure Compute Gallery by using the Azure CLI](#).
- Configure the JSON with your variables:

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/8_Creating_a_Custom_Linux_Shared_Image_Gallery_Image_from_SIG/helloImageTemplateforSIGfromSIG.json -o
helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<sharedImageGalName>/$sigName/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s%<sigDefImgVersionId>%$sigDefImgVersionId%" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<region2>/$additionalRegion/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIGfromSIG.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%" helloImageTemplateforSIGfromSIG.json
```

## Create the image

- Submit the image configuration to the VM Image Builder service:

```
az resource create \
--resource-group $sigResourceGroup \
--properties @helloImageTemplateforSIGfromSIG.json \
--is-full-object \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateforSIGfromSIG01
```

## 2. Start the image build:

```
az resource invoke-action \
--resource-group $sigResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateforSIGfromSIG01 \
--action Run
```

Wait for the image to be built and replicated before you move along to the next step.

# Create the VM

## 1. Create the VM by doing the following:

```
az vm create \
--resource-group $sigResourceGroup \
--name aibImgVm001 \
--admin-username azureuser \
--location $location \
--image
"/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigName/images/$imageDefName/versions/latest" \
--generate-ssh-keys
```

## 2. Create a Secure Shell (SSH) connection to the VM by using the public IP address of the VM.

```
ssh azureuser@<pubIp>
```

After the SSH connection is established, you should receive a "Message of the Day" saying that the image was customized:

```
*****
**      This VM was built from the:      **
**      !! AZURE VM IMAGE BUILDER Custom Image !!      **
**      You have just been Customized :-)      **
*****
```

## 3. Type `exit` to close the SSH connection.

## 4. To list the image versions that are now available in your gallery, run:

```
az sig image-version list -g $sigResourceGroup -r $sigName -i $imageDefName -o table
```

# Next steps

To learn more about the components of the JSON file that you used in this article, see [Create an Azure VM Image Builder template](#).

# Create a new Windows VM image from an existing image by using Azure VM Image Builder

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this article, you learn how to update an existing Windows image version in an [Azure Compute Gallery](#) (formerly Shared Image Gallery) and publish it to the gallery as a new image version.

To configure the image, you use a sample JSON template, [helloImageTemplateforSIGfromWinSIG.json](#).

## Register the features

To use VM Image Builder, you need to register the features.

1. Check your provider registrations. Make sure that each one returns *Registered*.

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState  
az provider show -n Microsoft.KeyVault | grep registrationState  
az provider show -n Microsoft.Compute | grep registrationState  
az provider show -n Microsoft.Storage | grep registrationState  
az provider show -n Microsoft.Network | grep registrationState
```

2. If they don't return *Registered*, register the providers by running the following commands:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Set variables and permissions

If you've already created an Azure Compute Gallery by using [Create an image and distribute it to an Azure Compute Gallery](#), you've already created some of the variables you need.

### NOTE

VM Image Builder supports creating custom images only in the same resource group that the source-managed image is in. In the following example, update the resource group name, *ibsigRG*, with the name of resource group that your source-managed image is in.

1. If you haven't already created the variables, run the following commands:

```
# Resource group name - we are using ibsigRG in this example
sigResourceGroup=myIBWinRG
# Datacenter location - we are using West US 2 in this example
location=westus
# Additional region to replicate the image to - we are using East US in this example
additionalRegion=eastus
# name of the Azure Compute Gallery - in this example we are using myGallery
sigName=my22stsSIG
# name of the image definition to be created - in this example we are using myImageDef
imageDefName=winSvrImages
# image distribution metadata reference name
runOutputName=w2019SigRo
# User name and password for the VM
username="user name for the VM"
vmpassword="password for the VM"
```

## 2. Create a variable for your subscription ID:

```
subscriptionID=$(az account show --query id --output tsv)
```

## 3. Get the image version that you want to update:

```
sigDefImgVersionId=$(az sig image-version list \
-g $sigResourceGroup \
--gallery-name $sigName \
--gallery-image-definition $imageDefName \
--subscription $subscriptionID --query [].'id' -o tsv)
```

# Create a user-assigned identity and set permissions on the resource group

You've set up the user identity in an earlier example, so now you need to get the resource ID, which will be appended to the template.

```
#get identity used previously
imgBuilderId=$(az identity list -g $sigResourceGroup --query "[?contains(name, 'aibBuiUserId')].id" -o tsv)
```

If you already have an Azure Compute Gallery but didn't set it up by following an earlier example, you need to assign permissions for VM Image Builder to access the resource group so that it can access the gallery. For more information, see [Create an image and distribute it to an Azure Compute Gallery](#).

## Modify the helolimage example

You can review the JSON example you're about to use at [helolimageTemplateforSIGfromSIG.json](#). For information about the JSON file, see [Create an Azure VM Image Builder template](#).

1. Download the JSON example, as shown in [Create a user-assigned identity and set permissions on the resource group](#).
2. Configure the JSON with your variables:

```
curl  
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/8_Creating_a_Custom_  
Win_Shared_Image_Gallery_Image_from_SIG/helloImageTemplateforSIGfromWinSIG.json -o  
helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<rgName>/$sigResourceGroup/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<imageDefName>/$imageDefName/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<sharedImageGalName>/$signInName/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s%<sigDefImgVersionId>%$sigDefImgVersionId%g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<region1>/$location/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<region2>/$additionalRegion/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s/<runOutputName>/$runOutputName/g" helloImageTemplateforSIGfromWinSIG.json  
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateforSIGfromWinSIG.json
```

## Create the image

1. Submit the image configuration to the VM Image Builder service:

```
az resource create \  
    --resource-group $sigResourceGroup \  
    --location $location \  
    --properties @helloImageTemplateforSIGfromWinSIG.json \  
    --is-full-object \  
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \  
    -n imageTemplateforSIGfromWinSIG01
```

2. Start the image build:

```
az resource invoke-action \  
    --resource-group $sigResourceGroup \  
    --resource-type Microsoft.VirtualMachineImages/imageTemplates \  
    -n imageTemplateforSIGfromWinSIG01 \  
    --action Run
```

Wait for the image to be built and replicated before you move along to the next step.

## Create the VM

Create the VM by doing the following:

```
az vm create \  
    --resource-group $sigResourceGroup \  
    --name aibImgWinVm002 \  
    --admin-username $username \  
    --admin-password $vmpassword \  
    --image  
    "/subscriptions/$subscriptionID/resourceGroups/$sigResourceGroup/providers/Microsoft.Compute/galleries/$sigN  
ame/images/$imageDefName/versions/latest" \  
    --location $location
```

## Verify the customization

Create a Remote Desktop connection to the VM by using the username and password you set when you created the VM. Inside the VM, open a Command Prompt window, and then run:

```
dir c:\
```

You should now see two directories:

- *buildActions*: Created in the first image version.
- *buildActions2*: Created when you updated the first image version to create the second image version.

## Next steps

To learn more about the components of the JSON file that you used in this article, see [Create an Azure VM Image Builder template](#).

# Create an image and use a user-assigned managed identity to access files in an Azure storage account

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows how to create a customized image by using Azure VM Image Builder. The service uses a [user-assigned managed identity](#) to access files in an Azure storage account, without your having to make the files publicly accessible.

Azure VM Image Builder supports using scripts and copying files from GitHub, Azure storage accounts, and other locations. If you want to use the locations, they must be externally accessible to VM Image Builder.

In the following example, you'll create two resource groups, one for the custom image and the other to host an Azure storage account that contains a script file. This example simulates a real-life scenario, where you might have build artifacts or image files in various storage accounts. You'll create a user-assigned identity and then grant the identity read permissions on the script file, but you won't allow public access to the file. You'll then use the shell customizer to download and run a script from the storage account.

## Register the features

1. To use VM Image Builder, you need to register the feature:

```
az feature register --namespace Microsoft.VirtualMachineImages --name VirtualMachineTemplatePreview
```

2. Check the status of the feature registration:

```
az feature show --namespace Microsoft.VirtualMachineImages --name VirtualMachineTemplatePreview | grep state
```

3. Check your registration:

```
az provider show -n Microsoft.VirtualMachineImages | grep registrationState  
az provider show -n Microsoft.KeyVault | grep registrationState  
az provider show -n Microsoft.Compute | grep registrationState  
az provider show -n Microsoft.Storage | grep registrationState  
az provider show -n Microsoft.Network | grep registrationState
```

4. If the output doesn't show your features as *Registered*, run the following commands:

```
az provider register -n Microsoft.VirtualMachineImages  
az provider register -n Microsoft.Compute  
az provider register -n Microsoft.KeyVault  
az provider register -n Microsoft.Storage  
az provider register -n Microsoft.Network
```

## Create a resource group

1. Because you'll be using some pieces of information repeatedly, create some variables to store that

information.

```
# Image resource group name
imageResourceGroup=aibmdimsi
# Storage resource group
strResourceGroup=aibmdimsistor
# Location
location=WestUS2
# Name of the image to be created
imageName=aibCustLinuxImgMsi01
# Image distribution metadata reference name
runOutputName=u1804ManImgMsiro
```

2. Create a variable for your subscription ID:

```
subscriptionID=$(az account show --query id --output tsv)
```

3. Create resource groups for both the image and the script storage:

```
# Create a resource group for the image template
az group create -n $imageResourceGroup -l $location
# Create a resource group for the script storage
az group create -n $strResourceGroup -l $location
```

4. Create a user-assigned identity, and set permissions on the resource group:

VM Image Builder uses the provided [user identity](#) to inject the image into the resource group. In this example, you create an Azure role definition with specific actions for distributing the image. The role definition is then assigned to the user identity.

```
# Create a user-assigned identity for VM Image Builder to access the storage account where the script
is located
identityName=aibBuiUserId$(date +'%s')
az identity create -g $imageResourceGroup -n $identityName

# Get an identity ID
imgBuilderCliId=$(az identity show -g $imageResourceGroup -n $identityName --query clientId -o tsv)

# Get the user-identity URI, which is needed for the template
imgBuilderId=/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.Ma
nagedIdentity/userAssignedIdentities/$identityName

# Download the preconfigured role definition example
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/solutions/12_Creating_AIB_Security_Ro
les/aibRoleImageCreation.json -o aibRoleImageCreation.json

# Update the definition
sed -i -e "s/<subscriptionID>/$subscriptionID/g" aibRoleImageCreation.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" aibRoleImageCreation.json

# Create role definitions
az role definition create --role-definition ./aibRoleImageCreation.json

# Grant the role definition to the user-assigned identity
az role assignment create \
--assignee $imgBuilderCliId \
--role "Azure Image Builder Service Image Creation Role" \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
```

5. Create the storage account, and copy the sample script into it from GitHub:

```
# Script storage account
scriptStorageAcc=aibstorscript$(date +'%s')

# Script container
scriptStorageAccContainer=scriptscont$(date +'%s')

# Script URL
scriptUrl=https://$scriptStorageAcc.blob.core.windows.net/$scriptStorageAccContainer/customizeScript.sh

# Create the storage account and blob in the resource group
az storage account create -n $scriptStorageAcc -g $strResourceGroup -l $location --sku Standard_LRS

az storage container create -n $scriptStorageAccContainer --fail-on-exist --account-name $scriptStorageAcc

# Copy in an example script from the GitHub repo
az storage blob copy start \
    --destination-blob customizeScript.sh \
    --destination-container $scriptStorageAccContainer \
    --account-name $scriptStorageAcc \
    --source-uri
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/customizeScript.sh
```

6. Give VM Image Builder permission to create resources in the image resource group. The `--assignee` value is the user-identity ID.

```
az role assignment create \
    --assignee $imgBuilderCliId \
    --role "Storage Blob Data Reader" \
    --scope
/subscriptions/$subscriptionID/resourceGroups/$strResourceGroup/providers/Microsoft.Storage/storageAccounts/$scriptStorageAcc/blobServices/default/containers/$scriptStorageAccContainer
```

## Modify the example

Download the example JSON file and configure it with the variables you created earlier.

```
curl
https://raw.githubusercontent.com/azure/azvmimagebuilder/master/quickstarts/7_Creating_Custom_Image_using_MSIs_to_Access_Storage/helloImageTemplateMsi.json -o helloImageTemplateMsi.json
sed -i -e "s/<subscriptionID>/$subscriptionID/g" helloImageTemplateMsi.json
sed -i -e "s/<rgName>/$imageResourceGroup/g" helloImageTemplateMsi.json
sed -i -e "s/<region>/$location/g" helloImageTemplateMsi.json
sed -i -e "s/<imageName>/$imageName/g" helloImageTemplateMsi.json
sed -i -e "s%<scriptUrl>%$scriptUrl%g" helloImageTemplateMsi.json
sed -i -e "s%<imgBuilderId>%$imgBuilderId%g" helloImageTemplateMsi.json
sed -i -e "s%<runOutputName>%$runOutputName%g" helloImageTemplateMsi.json
```

## Create the image

1. Submit the image configuration to the VM Image Builder service:

```
az resource create \
--resource-group $imageResourceGroup \
--properties @helloImageTemplateMsi.json \
--is-full-object \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateMsi01
```

## 2. Start the image build:

```
az resource invoke-action \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateMsi01 \
--action Run
```

The build can take about 15 minutes to finish.

## Create a VM

### 1. Create a VM from the image:

```
az vm create \
--resource-group $imageResourceGroup \
--name aibImgVm00 \
--admin-username aibuser \
--image $imageName \
--location $location \
--generate-ssh-keys
```

### 2. After the VM has been created, start a Secure Shell (SSH) session with it.

```
ssh aibuser@<publicIp>
```

After the SSH connection is established, you should receive a "Message of the Day" saying that the image was customized:

```
*****
**          This VM was built from the:      **
**      !! AZURE VM IMAGE BUILDER Custom Image !!  **
**          You have just been Customized :-)      **
*****
```

## Clean up your resources

If you no longer need the resources that were created during this process, you can delete them by running the following code:

```
az role definition delete --name "$imageRoleDefName"
```azurecli-interactive
az role assignment delete \
--assignee $imgBuilderCliId \
--role "$imageRoleDefName" \
--scope /subscriptions/$subscriptionID/resourceGroups/$imageResourceGroup
az identity delete --ids $imgBuilderId
az resource delete \
--resource-group $imageResourceGroup \
--resource-type Microsoft.VirtualMachineImages/imageTemplates \
-n helloImageTemplateMsi01
az group delete -n $imageResourceGroup
az group delete -n $strResourceGroup
```

## Next steps

If you have any problems using VM Image Builder, see [Troubleshoot Azure VM Image Builder](#).

# What's new in Azure VM Image Builder

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article contains all major API changes and feature updates for the Azure VM Image Builder service.

## API releases

### Version 2022-02-14

#### Improvements

- [Validation support](#)
  - Shell (Linux): Script or inline
  - PowerShell (Windows): Script or inline, run elevated, run as system
  - Source-Validation-Only mode
- [Customized staging resource group support](#)

### Version 2021-10-01

#### Breaking change

API version 2021-10-01 introduces a change to the error schema that will be part of every future API release. If you have any Azure VM Image Builder automations, be aware of the [new error output](#) when you switch to API version 2021-10-01 or later. We recommend, after you've switched to the latest API version, that you don't revert to an earlier version, because you'll have to change your automation again to produce the earlier error schema. We don't anticipate that we'll change the error schema again in future releases.

Error output for version 2020-02-14 and earlier

```
{  
  "code": "ValidationFailed",  
  "message": "Validation failed: 'ImageTemplate.properties.source': Field 'imageId' has a bad value:  
  '/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft.Compute/images/imageName  
  '. Please review http://aka.ms/azvmimagebuildertmplref for details on fields requirements in the Image  
  Builder Template."  
}
```

Error output for version 2021-10-01 and later

```
{  
  "error": {  
    "code": "ValidationFailed",  
    "message": "Validation failed: 'ImageTemplate.properties.source': Field 'imageId' has a bad value:  
    '/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft.Compute/images/imageName  
    '. Please review http://aka.ms/azvmimagebuildertmplref for details on fields requirements in the Image  
    Builder Template."  
  }  
}
```

#### Improvements

- Added support for [Build VM MSIs](#).
- Added support for Proxy VM size customization.

**Version 2020-02-14**

## Improvements

- Added support for creating images from the following sources:
  - Managed image
  - Azure Compute Gallery
  - Platform Image Repository (including Platform Image Purchase Plan)
- Added support for the following customizations:
  - Shell (Linux): Script or inline
  - PowerShell (Windows): Script or inline, run elevated, run as system
  - File (Linux and Windows)
  - Windows Restart (Windows)
  - Windows Update (Windows): Search criteria, filters, and update limit
- Added support for the following distribution types:
  - VHD (virtual hard disk)
  - Managed image
  - Azure Compute Gallery
- Other features:
  - Added support for customers to use their own virtual network
  - Added support for customers to customize the build VM (VM size, operating system disk size)
  - Added support for user-assigned Microsoft Windows Installer (MSI) (for customize/distribute steps)
  - Added support for [Gen2 images](#)

## Preview APIs

The following APIs are deprecated, but still supported:

- Version 2019-05-01-preview

## Next steps

Learn more about [VM Image Builder](#).

# Troubleshoot Azure VM Image Builder

9/21/2022 • 27 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Use this article to troubleshoot and resolve common issues that you might encounter when you're using Azure VM Image Builder.

## Prerequisites

When you're creating a build, do the following:

- The VM Image Builder service communicates to the build VM by using WinRM or Secure Shell (SSH). Do *not* disable these settings as part of the build.
- VM Image Builder creates resources as part of the build. Be sure to verify that Azure Policy doesn't prevent VM Image Builder from creating or using necessary resources.
  - Create an IT\_ resource group.
  - Create a storage account without a firewall.
- Verify that Azure Policy doesn't install unintended features on the build VM, such as Azure Extensions.
- Ensure that VM Image Builder has the correct permissions to read/write images and to connect to the storage account. For more information, review the permissions documentation for the [Azure CLI](#) or [Azure PowerShell](#).
- VM Image Builder will fail the build if the scripts or inline commands fail with errors (non-zero exit codes). Ensure that you've tested the custom scripts and verified that they run without error (exit code 0) or require user input. For more information, see [Create an Azure Virtual Desktop image by using VM Image Builder and PowerShell](#).

VM Image Builder failures can happen in two areas:

- During image template submission
- During image building

## Troubleshoot image template submission errors

Image template submission errors are returned at submission only. There isn't an error log for image template submission errors. If there's an error during submission, you can return the error by checking the status of the template, specifically by reviewing `ProvisioningState` and `ProvisioningErrorMessage` / `provisioningError`.

```
az image builder show --name $imageTemplateName --resource-group $imageResourceGroup
```

```
Get-AzImageBuilderTemplate -ImageTemplateName <imageTemplateName> -ResourceGroupName <imageTemplateResourceGroup> | Select-Object ProvisioningState, ProvisioningErrorMessage
```

### NOTE

For PowerShell, you'll need to install the [VM Image Builder PowerShell modules](#).

## IMPORTANT

API version 2021-10-01 introduces a change to the error schema that will be part of every future API release. If you have any Azure VM Image Builder automations, be aware of the [new error output](#) when you switch to API version 2021-10-01 or later. We recommend, after you've switched to the latest API version, that you don't revert to an earlier version, because you'll have to change your automation again to produce the earlier error schema. We don't anticipate that we'll change the error schema again in future releases.

Error output for version 2020-02-14 and earlier

```
{  
    "code": "ValidationFailed",  
    "message": "Validation failed: 'ImageTemplate.properties.source': Field 'imageId' has a bad value:  
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft.Compute/images/imageName  
. Please review http://aka.ms/azvmimagebuildertmplref for details on fields requirements in the Image  
Builder Template."  
}
```

Error output for version 2021-10-01 and later

```
{  
    "error": {  
        "code": "ValidationFailed",  
        "message": "Validation failed: 'ImageTemplate.properties.source': Field 'imageId' has a bad value:  
'/subscriptions/subscriptionID/resourceGroups/resourceGroupName/providers/Microsoft.Compute/images/imageName  
. Please review http://aka.ms/azvmimagebuildertmplref for details on fields requirements in the Image  
Builder Template."  
    }  
}
```

The following sections present problem resolution guidance for common image template submission errors.

## Update or upgrade of image templates is currently not supported

### Error

```
'Conflict'. Details: Update/Upgrade of image templates is currently not supported
```

### Cause

The template already exists.

### Solution

If you submit an image configuration template and the submission fails, a failed template artifact still exists. Delete the failed template.

## The resource operation finished with a terminal provisioning state of "Failed"

### Error

```
Microsoft.VirtualMachineImages/imageTemplates 'helloImageTemplateforSIG01' failed with message '{  
    "status": "Failed",  
    "error": {  
        "code": "ResourceDeploymentFailure",  
        "message": "The resource operation completed with terminal provisioning state 'Failed'.",  
        "details": [  
            {  
                "code": "InternalOperationError",  
                "message": "Internal error occurred."  
            }  
        ]  
    }  
}
```

### Cause

In most cases, the resource deployment failure error occurs because of missing permissions. This error may also

be caused by a conflict with the staging resource group.

#### Solution

Depending on your scenario, VM Image Builder might need permissions to:

- The source image or Azure Compute Gallery (formerly Shared Image Gallery) resource group.
- The distribution image or Azure Compute Gallery resource.
- The storage account, container, or blob that the `File` customizer is accessing.

Also, ensure the staging resource group name is uniquely specified for each image template.

For more information about configuring permissions, see [Configure VM Image Builder permissions by using the Azure CLI](#) or [Configure VM Image Builder permissions by using PowerShell](#).

## Error getting a managed image

#### Error

```
Build (Managed Image) step failed: Error getting Managed Image
'/subscriptions/.../providers/Microsoft.Compute/images/mymanagedmg1': Error getting managed image (...):
compute.
ImagesClient#Get: Failure responding to request: StatusCode=403 -- Original Error: autorest/azure: Service
returned an error.
Status=403 Code="AuthorizationFailed" Message="The client '.....' with object id '.....' doesn't have
authorization to perform action 'Microsoft.Compute/images/read' over scope
```

#### Cause

Missing permissions.

#### Solution

Depending on your scenario, VM Image Builder might need permissions to:

- The source image or Azure Compute Gallery resource group.
- The distribution image or Azure Compute Gallery resource.
- The storage account, container, or blob that the `File` customizer is accessing.

For more information about configuring permissions, see [Configure VM Image Builder permissions by using the Azure CLI](#) or [Configure VM Image Builder permissions by using PowerShell](#).

## The build step failed for the image version

#### Error

```
Build (Shared Image Version) step failed for Image Version
'/subscriptions/.../providers/Microsoft.Compute/galleries/.../images/... /versions/0.23768.4001': Error
getting Image Version
'/subscriptions/.../resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/.../images/.../versions/0.
23768.4001': Error getting image version '... :0.23768.4001': compute.GalleryImageVersionsClient#Get:
Failure responding to request: StatusCode=404 -- Original Error: autorest/azure: Service returned an error.
Status=404 Code="ResourceNotFound" Message="The Resource
'Microsoft.Compute/galleries/.../images/.../versions/0.23768.4001' under resource group '<rgName>' was not
found."
```

#### Cause

VM Image Builder can't locate the source image.

#### Solution

Ensure that the source image is correct and exists in the location of VM Image Builder.

## Downloading an external file to a local file

#### Error

```
Downloading external file (<myFile>) to local file (xxxxx.0.customizer.fp) [attempt 1 of 10] failed: Error  
downloading '<myFile>' to 'xxxxx.0.customizer.fp'..
```

## Cause

The file name or location is incorrect, or the location isn't reachable.

## Solution

Ensure that the file is reachable. Verify that the name and location are correct.

## Authorization error creating disk

The Azure Image Builder build fails with an authorization error that looks like the following:

### Error

```
Attempting to deploy created Image template in Azure fails with an 'The client '6df325020-fe22-4e39-bd69-  
10873965ac04' with object id '6df325020-fe22-4e39-bd69-10873965ac04' does not have authorization to perform  
action 'Microsoft.Compute/disks/write' over scope  
'/subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/disks/proxyV  
mDiskWin_<timestampl>' or the scope is invalid. If access was recently granted, please refresh your  
credentials.'
```

## Cause

This error is caused when trying to specify a pre-existing resource group and VNet to the Azure Image Builder service with a Windows source image.

## Solution

You will need to assign the contributor role to the resource group for the service principal corresponding to Azure Image Builder's first party app by using the CLI command or portal instructions below.

First, validate that the service principal is associated with Azure Image Builder's first party app by using the following CLI command:

```
az ad sp show --id {servicePrincipalName, or objectId}
```

Then, to implement this solution using CLI, use the following command:

```
az role assignment create -g {ResourceGroupName} --assignee {AibrpSpOid} --role Contributor
```

To implement this solution in portal, follow the instructions in this documentation: [Assign Azure roles using the Azure portal - Azure RBAC](#).

For [Step 1: Identify the needed scope](#): The needed scope is your resource group.

For [Step 3: Select the appropriate role](#): The role is Contributor.

For [Step 4: Select who needs access](#): Select member "Azure Virtual Machine Image Builder"

Then proceed to [Step 6: Assign role](#) to assign the role.

## Troubleshoot build failures

For image build failures, get the error from the `lastrunstatus`, and then review the details in the `customization.log` file.

```
az image builder show --name $imageTemplateName --resource-group $imageResourceGroup
```

```
Get-AzImageBuilderTemplate -ImageTemplateName <imageTemplateName> -ResourceGroupName  
<imageTemplateResourceGroup> | Select-Object LastRunStatus, LastRunStatusMessage
```

## Customization log

When the image build is running, logs are created and stored in a storage account. VM Image Builder creates the storage account in the temporary resource group when you create an image template artifact.

The storage account name uses the pattern `IT_<ImageResourceGroupName><TemplateName><GUID>` (for example, `IT_aibmdi_helloImageTemplateLinux01`).

To view the `customization.log` file in the resource group, select **Storage Account > Blobs > [packerlogs]**, select **directory**, and then select the `customization.log` file.

## Understand the customization log

The log is verbose. It covers the image build, including any issues with the image distribution, such as Azure Compute Gallery replication. These errors are surfaced in the error message of the image template status.

The `customization.log` file includes the following stages:

1. *Deploy the build VM and dependencies by using ARM templates to the IT\_staging resource group stage.*

This stage includes multiple POSTs to the VM Image Builder resource provider:

```
Azure request method="POST"  
request="https://management.azure.com/subscriptions/<subID>/resourceGroups/IT_aibImageRG200_window201  
9VnetTemplate01_dec33089-1cc3-cccc-cccc-ccccccc/providers/Microsoft.Storage/storageAccounts  
..  
PACKER OUT ==> azure-arm: Deploying deployment template ...  
..
```

2. *Status of the deployments stage.* This stage includes the status of each resource deployment:

```
PACKER ERR 2020/04/30 23:28:50 packer: 2020/04/30 23:28:50 Azure request method="GET"  
request="https://management.azure.com/subscriptions/<subID>/resourcegroups/IT_aibImageRG200_window201  
9VnetTemplate01_dec33089-1cc3-4505-ae28-  
6661e43fac48/providers/Microsoft.Resources/deployments/pkrdp51lc0339jg/operationStatuses/085861331762  
07523519?[REDACTED]" body=""
```

3. *Connect to the build VM stage.*

In Windows, VM Image Builder connects by using WinRM:

```
PACKER ERR 2020/04/30 23:30:50 packer: 2020/04/30 23:30:50 Waiting for WinRM, up to timeout: 10m0s  
..  
PACKER OUT      azure-arm: WinRM connected.
```

In Linux, VM Image Builder connects by using SSH:

```
PACKER OUT ==> azure-arm: Waiting for SSH to become available...  
PACKER ERR 2019/12/10 17:20:51 packer: 2020/04/10 17:20:51 [INFO] Waiting for SSH, up to timeout:  
20m0s  
PACKER OUT ==> azure-arm: Connected to SSH!
```

4. *Run customizations stage.* When customizations run, you can identify them by reviewing the `customization.log` file. Search for (`telemetry`).

```
(telemetry) Starting provisioner windows-update
(telemetry) ending windows-update
(telemetry) Starting provisioner powershell
(telemetry) ending powershell
(telemetry) Starting provisioner file
(telemetry) ending file
(telemetry) Starting provisioner windows-restart
(telemetry) ending windows-restart

(telemetry) Finalizing. - This means the build hasfinished
```

5. *Deprovision* stage. VM Image Builder adds a hidden customizer. This deprovision step is responsible for preparing the VM for deprovisioning. In Windows, it runs `Sysprep` (by using `c:\DeprovisioningScript.ps1`). In Linux, it runs `waagent-deprovision` (by using `/tmp/DeprovisioningScript.sh`).

For example:

```
PACKER ERR 2020/03/04 23:05:04 [INFO] (telemetry) Starting provisioner powershell
PACKER ERR 2020/03/04 23:05:04 packer: 2020/03/04 23:05:04 Found command: if( TEST-PATH
c:\DeprovisioningScript.ps1 ){cat c:\DeprovisioningScript.ps1} else {echo "Deprovisioning script
[c:\DeprovisioningScript.ps1] could not be found. Image build may fail or the VM created from the
Image may not boot. Please make sure the deprovisioning script is not accidentally deleted by a
Customizer in the Template."}
```

6. *Cleanup* stage. After the build has finished, the VM Image Builder resources are deleted.

```
PACKER ERR ==> azure-arm: Deleting individual resources ...
...
PACKER ERR 2020/02/04 02:04:23 packer: 2020/02/04 02:04:23 Azure request method="DELETE"
request="https://management.azure.com/subscriptions/<subId>/resourceGroups/IT_aibDevOpsImg_t_vvvvvv_
yyyyyy-de5f-4f7c-92f2-xxxxxxxx/providers/Microsoft.Network/networkInterfaces/pkrnijamvpo08eo?
[REDACTED]" body=""
...
PACKER ERR ==> azure-arm: The resource group was not created by Packer, not deleting ...
```

## Tips for troubleshooting script or inline customization

- Test the code before you supply it to VM Image Builder.
- Ensure that Azure Policy and Firewall allow connectivity to remote resources.
- Output comments to the console by using `Write-Host` or `echo`. Doing so lets you search the `customization.log` file.

## Troubleshoot common build errors

### Packer build command failure

#### Error

```
"provisioningState": "Succeeded",
"lastRunStatus": {
  "startTime": "2020-04-30T23:24:06.756985789Z",
  "endTime": "2020-04-30T23:39:14.268729811Z",
  "runState": "Failed",
  "message": "Failed while waiting for packerizer: Microservice has failed: Failed while processing request: Error when executing packerizer: Packer build command has failed: exit status 1. During the image build, a failure has occurred, please review the build log to identify which build/customization step failed. For more troubleshooting steps go to https://aka.ms/azvmimagebuilderts. Image Build log location: https://xxxxxxxxx.blob.core.windows.net/packerlogs/xxxxxx-xxxx-xxxx-xxxx-xxxxxxxxx/customization.log. OperationId: xxxxxx-5a8c-4379-xxxx-8d85493bc791. Use this operationId to search packer logs."
```

## Cause

Customization failure.

## Solution

Review the log to locate customizer failures. Search for *(telemetry)*.

For example:

```
(telemetry) Starting provisioner windows-update
(telemetry) ending windows-update
(telemetry) Starting provisioner powershell
(telemetry) ending powershell
(telemetry) Starting provisioner file
(telemetry) ending file
(telemetry) Starting provisioner windows-restart
(telemetry) ending windows-restart

(telemetry) Finalizing. - This means the build has finished
```

## Time-out exceeded

### Error

```
Deployment failed. Correlation ID: xxxxx-xxxx-xxxx-xxxx-xxxxxxxxx. Failed in building/customizing image: Failed while waiting for packerizer: Timeout waiting for microservice to complete: 'context deadline exceeded'
```

## Cause

The build exceeded the build time-out. This error is seen in the 'lastrunstatus'.

## Solution

1. Review the *customization.log* file. Identify the last customizer to run. Search for *(telemetry)*, starting from the bottom of the log.
2. Check script customizations. The customizations might not be suppressing user interaction for commands, such as `quiet` options. For example, `apt-get install -y` results in the script execution waiting for user interaction.
3. If you're using the `File` customizer to download artifacts greater than 20 MB, see workarounds section.
4. Review errors and dependencies in script that might cause the script to wait.
5. If you expect that the customizations need more time, increase the value of `buildTimeoutInMinutes`. The default is 4 hours.
6. If you have resource-intensive actions, such as downloading gigabytes (GB) of files, consider the underlying build VM size. The service uses a Standard\_D1\_v2 VM. The VM has 1 vCPU and 3.5 GB of memory. If you're downloading 50 GB, you'll likely exhaust the VM resources and cause communication

failures between VM Image Builder and the build VM. Retry the build with a larger-memory VM by setting the [VM\\_size](#).

## Long file download time

### Error

```
[086cf9c4-0457-4e8f-bfd4-908cf3fe43c] PACKER OUT  
myBigFile.zip 826 B / 826000 B 1.00%  
[086cf9c4-0457-4e8f-bfd4-908cf3fe43c] PACKER OUT  
myBigFile.zip 1652 B / 826000 B 2.00%  
[086cf9c4-0457-4e8f-bfd4-908cf3fe43c] PACKER OUT  
..  
hours later...  
..  
myBigFile.zip 826000 B / 826000 B 100.00%  
[086cf9c4-0457-4e8f-bfd4-908cf3fe43c] PACKER OUT
```

### Cause

[File](#) customizer is downloading a large file.

### Solution

[File](#) customizer is suitable only for small (less than 20 MB) file downloads. For larger file downloads, use a script or inline command. For example, in Linux you can use [wget](#) or [curl](#). In Windows, you can use [Invoke-WebRequest](#).

## Error waiting on Azure Compute Gallery

### Error

```
Deployment failed. Correlation ID: XXXXXX-XXXX-XXXXXX-XXXX-XXXXXX. Failed in distributing 1 images out of total 1: {[Error 0] [Distribute 0] Error publishing MDI to Azure Compute Gallery:/subscriptions/<subId>/resourceGroups/xxxxxx/providers/Microsoft.Compute/galleries/xxxxx/images/xxxx xx, Location:eastus. Error: Error returned from SIG client while publishing MDI to Azure Compute Gallery for dstImageLocation: eastus, dstSubscription: <subId>, dstResourceGroupName: XXXXXX, dstGalleryName: XXXXXX, dstGalleryImageName: XXXXXX. Error: Error waiting on Azure Compute Gallery future for resource group: XXXXXX, gallery name: XXXXXX, gallery image name: XXXXXX. Error: Future#WaitForCompletion: context has been cancelled: StatusCode=200 -- Original Error: context deadline exceeded}
```

### Cause

VM Image Builder timed out waiting for the image to be added and replicated to Azure Compute Gallery. If the image is being injected into the gallery, you can assume that the image build was successful. However, the overall process failed because VM Image Builder was waiting on Azure Compute Gallery to complete the replication. Even though the build has failed, the replication continues. You can get the properties of the image version by checking the distribution *runOutput*.

```
$runOutputName=<distributionRunOutput>  
az resource show \  
    --ids  
    "/subscriptions/$subscriptionID/resourcegroups/$imageResourceGroup/providers/Microsoft.VirtualMachineImages/  
    imageTemplates/$imageTemplateName/runOutputs/$runOutputName" \  
    --api-version=2020-02-14
```

### Solution

Increase the value of [buildTimeoutInMinutes](#).

## Low Windows resource information events

### Error

[45f485cf-5a8c-4379-9937-8d85493bc791] PACKER OUT Build 'azure-arm' errored: unexpected EOF
```

```
[45f485cf-5a8c-4379-9937-8d85493bc791] PACKER OUT
```

## Cause

Resource exhaustion. This issue is commonly seen with Windows Update running with the default build VM size D1\_V2.

## Solution

Increase the build VM size.

## The build finished but no artifacts were created

### Error

[922bdf36-b53c-4e78-9cd8-6b70b9674685] PACKER ERR ==> azure-arm: The resource group was not created by Packer, deleting individual resources ...
```

## Cause

The cause might be a timing issue because of the D1\_V2 VM size. If customizations are limited and are run in less than three seconds, `Sysprep` commands are run by VM Image Builder to deprovision. When VM Image Builder deprovisions, the `Sysprep` command checks for the *WindowsAzureGuestAgent*, which might not be fully installed and might cause the timing issue.

## Solution

To avoid the timing issue, you can increase the VM size or you can add a 60-second PowerShell sleep customization.

## The build is canceled after the context cancellation context is canceled

### Error

```
PACKER ERR 2020/03/26 22:11:23 Cancelling builder after context cancellation context canceled

PACKER ERR 2020/03/26 22:11:25 [INFO] RPC endpoint: Communicator ended with: 2300218
```

## Cause

VM Image Builder uses port 22 (Linux) or 5986 (Windows) to connect to the build VM. This occurs when the service is disconnected from the build VM during an image build. The reasons for the disconnection can vary, but enabling or configuring a firewall in the script can block the previously mentioned ports.

## Solution

Review your scripts for firewall changes or enablement, or changes to SSH or WinRM, and ensure that any changes allow for constant connectivity between the service and the build VM on the previously mentioned ports. For more information, see [VM Image Builder networking options](#).

## JWT errors in log early in the build

### Error

Early in the build process, the build fails and the log indicates a JSON Web Token (JWT) error:

```
PACKER OUT Error: Failed to prepare build: "azure-arm"
PACKER ERR
PACKER OUT
PACKER ERR * client_jwt will expire within 5 minutes, please use a JWT that is valid for at least 5 minutes
PACKER OUT 1 error(s) occurred:
```

## Cause

The `buildTimeoutInMinutes` value in the template is set to from 1 to 5 minutes.

## Solution

As described in [Create an VM Image Builder template](#), the time-out must be set to 0 to use the default or set to more than 5 minutes to override the default. Change the time-out in your template to 0 to use the default or to a minimum of 6 minutes.

## Resource deletion errors

### Error

Intermediate resources are cleaned up toward the end of the build, and the customization log might show several resource deletion errors:

```
PACKER OUT ==> azure-arm: Error deleting resource. Will retry.
...
PACKER OUT ==> azure-arm: Error: network.PublicIPAddressesClient#Delete: Failure sending request:
StatusCode=0 -- Original Error: Code="PublicIPAddressCannotBeDeleted" Message=...
...
PACKER ERR 2022/03/07 18:43:06 packer-plugin-azure plugin: 2022/03/07 18:43:06 Retryable error:
network.SecurityGroupsClient#Delete: Failure sending request: StatusCode=0 -- Original Error:
Code="InUseNetworkSecurityGroupCannotBeDeleted"...
```

## Cause

These error log messages are mostly harmless, because resource deletions are retried several times and, ordinarily, they eventually succeed. You can verify this by continuing to follow the deletion logs until you observe a success message. Alternatively, you can inspect the staging resource group to confirm whether the resource has been deleted.

Making these observations is especially important in build failures, where these error messages might lead you to conclude that they're the reason for the failures, even when the actual errors might be elsewhere.

## DevOps tasks

### Troubleshoot the task

The task fails only if an error occurs during customization. When this happens, the task reports the failure and leaves the staging resource group, with the logs, so that you can identify the issue.

To locate the log, you need to know the template name. Go to **pipeline > failed build**, and then drill down into the VM Image Builder DevOps task.

You'll see the log and a template name:

```
start reading task parameters...
found build at: /home/vsts/work/r1/a/_ImageBuilding/webapp
end reading parameters
getting storage account details for aibstordot1556933914
created archive /home/vsts/work/_temp/temp_web_package_21475337782320203.zip
Source for image: { type: 'SharedImageVersion',
  imageVersionId:
  '/subscriptions/<subscriptionID>/resourceGroups/<rgName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageDefName>/versions/<imgVersionNumber>' }
template name: t_1556938436xxx
```

1. Go to the Azure portal, search for the template name in the resource group, and then search for the resource group by typing **IT\_\***.
2. Select the storage account name > **blobs** > **containers** > **logs**.

### Troubleshoot successful builds

You might occasionally need to investigate successful builds and review their logs. As mentioned earlier, if the image build is successful, the staging resource group that contains the logs will be deleted as part of the cleanup. To prevent an automatic cleanup, though, you can introduce a `sleep` after the inline command, and then view the logs as the build is paused. To do so, do the following:

1. Update the inline command by adding **Write-Host / Echo "Sleep"**. This gives you time to search in the log.
2. Add a `sleep` value of at least 10 minutes by using a **Start-Sleep** or `sleep` Linux command.
3. Use this method to identify the log location, and then keep downloading or checking the log until it gets to `sleep`.

### Operation was canceled

2020-05-05T19:33:14.3923479Z ##[error]The operation was canceled.
2020-05-05T19:33:14.3939721Z ##[section]Finishing: Azure VM Image Builder Task
```

#### Cause

If the build wasn't canceled by a user, it was canceled by Azure DevOps User Agent. Most likely, the 1-hour time-out has occurred because of Azure DevOps capabilities. If you're using a private project and agent, you get 60 minutes of build time. If the build exceeds the time-out, DevOps cancels the running task.

For more information about Azure DevOps capabilities and limitations, see [Microsoft-hosted agents](#).

### Solution

You can host your own DevOps agents or look to reduce the time of your build. For example, if you're distributing to Azure Compute Gallery, you can replicate them to one region or replicate them asynchronously.

## Slow Windows logon

### Error

This error might occur when you create a Windows 10 image by using VM Image Builder, create a VM from the image, and then use Remote Desktop Protocol (RDP). You wait several minutes at the first logon screen, and then a blue screen displays the following message:

Please wait for the Windows Modules Installer

### Solution

1. In the image build, check to ensure that:
  - There are no outstanding reboots required by adding a Windows Restart customizer as the last customization.
  - All software installation is complete.
2. Add the `/mode:vm` option to the default `Sysprep` that VM Image Builder uses. For more information, go to the "Override the commands" section under "VMs created from VM Image Builder images aren't created successfully."

## VMs created from VM Image Builder images aren't created successfully

By default, VM Image Builder runs *deprovision* code at the end of each image customization phase to *generalize* the image. To generalize an image is to set it up to reuse to create multiple VMs. As part of the process, you can pass in VM settings, such as hostname, username, and so on. In Windows, VM Image Builder runs `Sysprep`, and in Linux, VM Image Builder runs `waagent -deprovision`.

In Windows, VM Image Builder uses a generic `Sysprep` command. However, this command might not be suitable for every successful Windows generalization. With VM Image Builder, you can customize the `Sysprep` command. Note that VM Image Builder is an image automation tool that's responsible for running `Sysprep` command successfully. But you might need different `Sysprep` commands to make your image reusable. In Linux, VM Image Builder uses a generic `waagent -deprovision+user` command. For more information, see [Microsoft Azure Linux Agent documentation](#).

If you're migrating an existing customization and you're using various `Sysprep` or `waagent` commands, you can try the VM Image Builder generic commands. If the VM creation fails, use your previous `Sysprep` or `waagent` commands.

Let's suppose you've used VM Image Builder successfully to create a Windows custom image, but you've failed to create a VM successfully from the image. For example, the VM creation fails to finish or it times out. In this event, do either of the following:

- Review the Windows Server Sysprep documentation.
- Raise a support request with the Windows Server Sysprep Customer Services Support team. They can help troubleshoot your issue and advise you on the correct `Sysprep` command.

### Command locations and file names

In Windows:

```
c:\DeprovisioningScript.ps1
```

In Linux:

```
/tmp/DeprovisioningScript.sh
```

### The `Sysprep` command: Windows

```
Write-Output '">>>> Waiting for GA Service (RdAgent) to start ...'
while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }
Write-Output '">>>> Waiting for GA Service (WindowsAzureTelemetryService) to start ...'
while ((Get-Service WindowsAzureTelemetryService) -and ((Get-Service WindowsAzureTelemetryService).Status -ne 'Running')) { Start-Sleep -s 5 }
Write-Output '">>>> Waiting for GA Service (WindowsAzureGuestAgent) to start ...'
while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }
Write-Output '">>>> Sysprepping VM ...'
if( Test-Path $Env:SystemRoot\system32\Sysprep\unattend.xml ) {
    Remove-Item $Env:SystemRoot\system32\Sysprep\unattend.xml -Force
}
& $Env:SystemRoot\System32\Sysprep\Sysprep.exe /oobe /generalize /quiet /quit
while($true) {
    $imageState = (Get-ItemProperty HKLM:\SOFTWARE\Microsoft\Windows\CurrentVersion\Setup\State).ImageState
    Write-Output $imageState
    if ($imageState -eq 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { break }
    Start-Sleep -s 5
}
Write-Output '">>>> Sysprep complete ...'
```

### The `-deprovision` command: Linux

```
/usr/sbin/waagent -force -deprovision+user && export HISTSIZE=0 && sync
```

## Override the commands

To override the commands, use the PowerShell or shell script provisoners to create the command files with the exact file name and put them in the previously listed directories. VM Image Builder reads these commands and writes output to the *customization.log* file.

## Get support

If you've referred to the guidance and are still having problems, you can open a support case. Be sure to select the correct product and support topic. Doing so will ensure that you're connected with the Azure VM Image Builder support team.

Selecting the case product:

```
Product Family: Azure
Product: Virtual Machine Running (Window\Linux)
Support Topic: Azure Features
Support Subtopic: Azure Image Builder
```

## Next steps

For more information, see [VM Image Builder overview](#).

# How to use Packer to create Linux virtual machine images in Azure

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Each virtual machine (VM) in Azure is created from an image that defines the Linux distribution and OS version. Images can include pre-installed applications and configurations. The Azure Marketplace provides many first and third-party images for most common distributions and application environments, or you can create your own custom images tailored to your needs. This article details how to use the open source tool [Packer](#) to define and build custom images in Azure.

## NOTE

Azure now has a service, Azure Image Builder, for defining and creating your own custom images. Azure Image Builder is built on Packer, so you can even use your existing Packer shell provisioner scripts with it. To get started with Azure Image Builder, see [Create a Linux VM with Azure Image Builder](#).

## Create Azure resource group

During the build process, Packer creates temporary Azure resources as it builds the source VM. To capture that source VM for use as an image, you must define a resource group. The output from the Packer build process is stored in this resource group.

Create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create -n myResourceGroup -l eastus
```

## Create Azure credentials

Packer authenticates with Azure using a service principal. An Azure service principal is a security identity that you can use with apps, services, and automation tools like Packer. You control and define the permissions as to what operations the service principal can perform in Azure.

Create a service principal with [az ad sp create-for-rbac](#) and output the credentials that Packer needs:

```
az ad sp create-for-rbac --role Contributor --scopes /subscriptions/<subscription_id> --query "{ client_id: appId, client_secret: password, tenant_id: tenant }"
```

An example of the output from the preceding commands is as follows:

```
{
  "client_id": "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4",
  "client_secret": "0e760437-bf34-4aad-9f8d-870be799c55d",
  "tenant_id": "72f988bf-86f1-41af-91ab-2d7cd011db47"
}
```

To authenticate to Azure, you also need to obtain your Azure subscription ID with `az account show`:

```
az account show --query "{ subscription_id: id }"
```

You use the output from these two commands in the next step.

## Define Packer template

To build images, you create a template as a JSON file. In the template, you define builders and provisioners that carry out the actual build process. Packer has a [provisioner for Azure](#) that allows you to define Azure resources, such as the service principal credentials created in the preceding step.

Create a file named `ubuntu.json` and paste the following content. Enter your own values for the following parameters:

PARAMETER	WHERE TO OBTAIN
<code>client_id</code>	First line of output from <code>az ad sp create</code> command - <code>appId</code>
<code>client_secret</code>	Second line of output from <code>az ad sp create</code> command - <code>password</code>
<code>tenant_id</code>	Third line of output from <code>az ad sp create</code> command - <code>tenant</code>
<code>subscription_id</code>	Output from <code>az account show</code> command
<code>managed_image_resource_group_name</code>	Name of resource group you created in the first step
<code>managed_image_name</code>	Name for the managed disk image that is created

```
{
  "builders": [
    {
      "type": "azure-arm",
      "client_id": "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4",
      "client_secret": "0e760437-bf34-4aad-9f8d-870be799c55d",
      "tenant_id": "72f988bf-86f1-41af-91ab-2d7cd011db47",
      "subscription_id": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxx",
      "managed_image_resource_group_name": "myResourceGroup",
      "managed_image_name": "myPackerImage",
      "os_type": "Linux",
      "image_publisher": "Canonical",
      "image_offer": "UbuntuServer",
      "image_sku": "16.04-LTS",
      "azure_tags": {
        "dept": "Engineering",
        "task": "Image deployment"
      },
      "location": "East US",
      "vm_size": "Standard_DS2_v2"
    ],
    "provisioners": [
      {
        "execute_command": "chmod +x {{ .Path }}; {{ .Vars }} sudo -E sh '{{ .Path }}'",  

        "inline": [
          "apt-get update",
          "apt-get upgrade -y",
          "apt-get -y install nginx",
          "/usr/sbin/waagent -force -deprovision+user && export HISTSIZE=0 && sync"
        ],
        "inline_shebang": "/bin/sh -x",
        "type": "shell"
      }
    ]
}
```

You can also create a file named *ubuntu.pkr.hcl* and paste the following content with your own values as used for the above parameters table.

```

source "azure-arm" "autogenerated_1" {
  azure_tags = {
    dept = "Engineering"
    task = "Image deployment"
  }
  client_id           = "f5b6a5cf-fbdf-4a9f-b3b8-3c2cd00225a4"
  client_secret        = "0e760437-bf34-4aad-9f8d-870be799c55d"
  image_offer          = "UbuntuServer"
  image_publisher       = "Canonical"
  image_sku             = "16.04-LTS"
  location              = "East US"
  managed_image_name     = "myPackerImage"
  managed_image_resource_group_name = "myResourceGroup"
  os_type                = "Linux"
  subscription_id        = "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
  tenant_id              = "72f988bf-86f1-41af-91ab-2d7cd011db47"
  vm_size                = "Standard_DS2_v2"
}

build {
  sources = ["source.azure-arm.autogenerated_1"]

  provisioner "shell" {
    execute_command = "chmod +x {{ .Path }}; {{ .Vars }} sudo -E sh '{{ .Path }}'"
    inline         = ["apt-get update", "apt-get upgrade -y", "apt-get -y install nginx",
      "/usr/sbin/waagent -force -deprovision+user && export HISTSIZE=0 && sync"]
    inline_shbang   = "/bin/sh -x"
  }
}

```

This template builds an Ubuntu 16.04 LTS image, installs NGINX, then deprovisions the VM.

#### NOTE

If you expand on this template to provision user credentials, adjust the provisioner command that deprovisions the Azure agent to read `-deprovision` rather than `deprovision+user`. The `+user` flag removes all user accounts from the source VM.

## Build Packer image

If you don't already have Packer installed on your local machine, [follow the Packer installation instructions](#).

Build the image by specifying your Packer template file as follows:

```
./packer build ubuntu.json
```

You can also build the image by specifying the `ubuntu.pkr.hcl` file as follows:

```
packer build ubuntu.pkr.hcl
```

An example of the output from the preceding commands is as follows:

```

azure-arm output will be in this color.

==> azure-arm: Running builder ...
    azure-arm: Creating Azure Resource Manager (ARM) client ...
==> azure-arm: Creating resource group ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> Location        : 'East US'
==> azure-arm: -> Tags          :
==> azure-arm: ->> dept : Engineering
==> azure-arm: ->> task : Image deployment
==> azure-arm: Validating deployment template ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> DeploymentName   : 'pkrdpswtxmqm7ly'
==> azure-arm: Deploying deployment template ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> DeploymentName   : 'pkrdpswtxmqm7ly'
==> azure-arm: Getting the VM's IP address ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'

==> azure-arm: -> NicName         : 'packerNic'
==> azure-arm: -> Network Connection : 'PublicEndpoint'
==> azure-arm: -> IP Address       : '40.76.218.147'
==> azure-arm: Waiting for SSH to become available...
==> azure-arm: Connected to SSH!
==> azure-arm: Provisioning with shell script: /var/folders/h1/ymh5bdx15wgdn5hvgj1wc0zh0000gn/T/packer-
shell1868574263
    azure-arm: WARNING! The waagent service will be stopped.
    azure-arm: WARNING! Cached DHCP leases will be deleted.
    azure-arm: WARNING! root password will be disabled. You will not be able to login as root.
    azure-arm: WARNING! /etc/resolvconf/resolv.conf.d/tail and /etc/resolvconf/resolv.conf.d/original will
be deleted.
    azure-arm: WARNING! packer account and entire home directory will be deleted.
==> azure-arm: Querying the machine's properties ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> ComputeName      : 'pkrvmswtxmqm7ly'
==> azure-arm: -> Managed OS Disk  : '/subscriptions/guid/resourceGroups/packer-Resource-Group-
swtxmqm7ly/providers/Microsoft.Compute/disks/osdisk'
==> azure-arm: Powering off machine ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> ComputeName      : 'pkrvmswtxmqm7ly'
==> azure-arm: Capturing image ...
==> azure-arm: -> Compute ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: -> Compute Name       : 'pkrvmswtxmqm7ly'
==> azure-arm: -> Compute Location     : 'East US'
==> azure-arm: -> Image ResourceGroupName : 'myResourceGroup'
==> azure-arm: -> Image Name         : 'myPackerImage'
==> azure-arm: -> Image Location       : 'eastus'
==> azure-arm: Deleting resource group ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-swtxmqm7ly'
==> azure-arm: Deleting the temporary OS disk ...
==> azure-arm: -> OS Disk : skipping, managed disk was used...
Build 'azure-arm' finished.

==> Builds finished. The artifacts of successful builds are:
--> azure-arm: Azure.ResourceManagement.VMImage:

ManagedImageResourceGroupName: myResourceGroup
ManagedImageName: myPackerImage
ManagedImageLocation: eastus

```

It takes a few minutes for Packer to build the VM, run the provisioners, and clean up the deployment.

## Create VM from Azure Image

You can now create a VM from your Image with [az vm create](#). Specify the Image you created with the `--image`

parameter. The following example creates a VM named *myVM* from *myPackerImage* and generates SSH keys if they don't already exist:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image myPackerImage \
--admin-username azureuser \
--generate-ssh-keys
```

If you wish to create VMs in a different resource group or region than your Packer image, specify the image ID rather than image name. You can obtain the image ID with [az image show](#).

It takes a few minutes to create the VM. Once the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access the NGINX site via a web browser.

To allow web traffic to reach your VM, open port 80 from the Internet with [az vm open-port](#):

```
az vm open-port \
--resource-group myResourceGroup \
--name myVM \
--port 80
```

## Test VM and NGINX

Now you can open a web browser and enter `http://publicIpAddress` in the address bar. Provide your own public IP address from the VM create process. The default NGINX page is displayed as in the following example:

## Next steps

You can also use existing Packer provisioner scripts with [Azure Image Builder](#).

# PowerShell: How to use Packer to create virtual machine images in Azure

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Each virtual machine (VM) in Azure is created from an image that defines the Windows distribution and OS version. Images can include pre-installed applications and configurations. The Azure Marketplace provides many first and third-party images for most common OS' and application environments, or you can create your own custom images tailored to your needs. This article details how to use the open-source tool [Packer](#) to define and build custom images in Azure.

This article was last tested on 8/5/2020 using [Packer](#) version 1.6.1.

## NOTE

Azure now has a service, Azure Image Builder, for defining and creating your own custom images. Azure Image Builder is built on Packer, so you can even use your existing Packer shell provisioner scripts with it. To get started with Azure Image Builder, see [Create a Windows VM with Azure Image Builder](#).

## Create Azure resource group

During the build process, Packer creates temporary Azure resources as it builds the source VM. To capture that source VM for use as an image, you must define a resource group. The output from the Packer build process is stored in this resource group.

Create a resource group with [New-AzResourceGroup](#). The following example creates a resource group named *myPackerGroup* in the *eastus* location:

```
$rgName = "myPackerGroup"  
$location = "East US"  
New-AzResourceGroup -Name $rgName -Location $location
```

## Create Azure credentials

Packer authenticates with Azure using a service principal. An Azure service principal is a security identity that you can use with apps, services, and automation tools like Packer. You control and define the permissions as to what operations the service principal can perform in Azure.

Create a service principal with [New-AzADServicePrincipal](#). The value for `-DisplayName` needs to be unique; replace with your own value as needed.

```
$sp = New-AzADServicePrincipal -DisplayName "PackerPrincipal" -role Contributor -scope  
/subscriptions/yyyyyyyy-yyyy-yyyy-yyyy-yyyyyyyy  
$plainPassword = (New-AzADSPrinciple -ObjectId $sp.Id).SecretText
```

Then output the password and application ID.

```
$plainPassword  
$sp.AppId
```

To authenticate to Azure, you also need to obtain your Azure tenant and subscription IDs with [Get-AzSubscription](#):

```
$subName = "mySubscriptionName"  
$sub = Get-AzSubscription -SubscriptionName $subName
```

## Define Packer template

To build images, you create a template as a JSON file. In the template, you define builders and provisioners that carry out the actual build process. Packer has a [builder for Azure](#) that allows you to define Azure resources, such as the service principal credentials created in the preceding step.

Create a file named *windows.json* and paste the following content. Enter your own values for the following:

PARAMETER	WHERE TO OBTAIN
<i>client_id</i>	View service principal ID with <code>\$sp.AppId</code>
<i>client_secret</i>	View the auto-generated password with <code>\$plainPassword</code>
<i>tenant_id</i>	Output from <code>\$sub.TenantId</code> command
<i>subscription_id</i>	Output from <code>\$sub.SubscriptionId</code> command
<i>managed_image_resource_group_name</i>	Name of resource group you created in the first step
<i>managed_image_name</i>	Name for the managed disk image that is created

```
{
  "builders": [
    {
      "type": "azure-arm",
      "client_id": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxx",
      "client_secret": "ppppppp-pppp-pppp-pppppppppp",
      "tenant_id": "zzzzzz-zzzz-zzzz-zzzzzzzzzz",
      "subscription_id": "yyyyyy-yyyy-yyyy-yyyyyyyyyy",
      "managed_image_resource_group_name": "myPackerGroup",
      "managed_image_name": "myPackerImage",
      "os_type": "Windows",
      "image_publisher": "MicrosoftWindowsServer",
      "image_offer": "WindowsServer",
      "image_sku": "2016-Datacenter",
      "communicator": "winrm",
      "winrm_use_ssl": true,
      "winrm_insecure": true,
      "winrm_timeout": "5m",
      "winrm_username": "packer",
      "azure_tags": {
        "dept": "Engineering",
        "task": "Image deployment"
      },
      "build_resource_group_name": "myPackerGroup",
      "vm_size": "Standard_D2_v2"
    ],
    "provisioners": [
      {
        "type": "powershell",
        "inline": [
          "Add-WindowsFeature Web-Server",
          "while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }",
          "while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }",
          "& $env:SystemRoot\\System32\\Sysprep\\Sysprep.exe /oobe /generalize /quiet /quit",
          "while($true) { $imageState = Get-ItemProperty HKLM:\\SOFTWARE\\Microsoft\\Windows\\CurrentVersion\\Setup\\State | Select ImageState;
          if($imageState.ImageState -ne 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { Write-Output $imageState.ImageState; Start-Sleep -s 10 } else { break } }"
        ]
      }
    ]
  }
}
```

You can also create a file named *windows.pkr.hcl* and paste the following content with your own values as used for the above parameters table.

```

source "azure-arm" "autogenerated_1" {
  azure_tags = {
    dept = "Engineering"
    task = "Image deployment"
  }
  build_resource_group_name      = "myPackerGroup"
  client_id                     = "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
  client_secret                 = "ppppppp-pppp-pppp-pppp-ppppppppppp"
  communicator                  = "winrm"
  image_offer                   = "WindowsServer"
  image_publisher               = "MicrosoftWindowsServer"
  image_sku                      = "2016-Datacenter"
  managed_image_name             = "myPackerImage"
  managed_image_resource_group_name = "myPackerGroup"
  os_type                        = "Windows"
  subscription_id                = "yyyyyyy-yyyy-yyyy-yyyy-yyyyyyyyyy"
  tenant_id                      = "zzzzzz-zzzz-zzzz-zzzz-zzzzzzzzzz"
  vm_size                        = "Standard_D2_v2"
  winrm_insecure                 = true
  winrm_timeout                  = "5m"
  winrm_use_ssl                  = true
  winrm_username                 = "packer"
}

build {
  sources = ["source.azure-arm.autogenerated_1"]

  provisioner "powershell" {
    inline = ["Add-WindowsFeature Web-Server", "while ((Get-Service RdAgent).Status -ne 'Running') { Start-Sleep -s 5 }", "while ((Get-Service WindowsAzureGuestAgent).Status -ne 'Running') { Start-Sleep -s 5 }", "& $env:SystemRoot\\System32\\Sysprep\\Sysprep.exe /oobe /generalize /quiet /quit", "while($true) { $imageState = Get-ItemProperty HKLM:\\SOFTWARE\\Microsoft\\Windows\\CurrentVersion\\Setup\\State | Select ImageState; if($imageState.ImageState -ne 'IMAGE_STATE_GENERALIZE_RESEAL_TO_OOBE') { Write-Output $imageState.ImageState; Start-Sleep -s 10 } else { break } }"]
  }
}

```

This template builds a Windows Server 2016 VM, installs IIS, then generalizes the VM with Sysprep. The IIS install shows how you can use the PowerShell provisioner to run additional commands. The final Packer image then includes the required software install and configuration.

The Windows Guest Agent participates in the Sysprep process. The agent must be fully installed before the VM can be sysprep'ed. To ensure that this is true, all agent services must be running before you execute sysprep.exe. The preceding JSON snippet shows one way to do this in the PowerShell provisioner. This snippet is required only if the VM is configured to install the agent, which is the default.

## Build Packer image

If you don't already have Packer installed on your local machine, [follow the Packer installation instructions](#).

Build the image by opening a cmd prompt and specifying your Packer template file as follows:

```
./packer build windows.json
```

You can also build the image by specifying the *windows.pkr.hcl* file as follows:

```
packer build windows.pkr.hcl
```

An example of the output from the preceding commands is as follows:

```

azure-arm output will be in this color.

==> azure-arm: Running builder ...
    azure-arm: Creating Azure Resource Manager (ARM) client ...
==> azure-arm: Creating resource group ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-pq0mthbt'

==> azure-arm: -> Image ResourceGroupName : 'myResourceGroup'
==> azure-arm: -> Image Name         : 'myPackerImage'
==> azure-arm: -> Image Location      : 'eastus'
==> azure-arm: Deleting resource group ...
==> azure-arm: -> ResourceGroupName : 'packer-Resource-Group-pq0mthbt'
==> azure-arm: Deleting the temporary OS disk ...
==> azure-arm: -> OS Disk : skipping, managed disk was used...
Build 'azure-arm' finished.

```

```
==> Builds finished. The artifacts of successful builds are:  
--> azure-arm: Azure.ResourceManagement.VMImage:  
  
ManagedImageResourceGroupName: myResourceGroup  
ManagedImageName: myPackerImage  
ManagedImageLocation: eastus
```

It takes a few minutes for Packer to build the VM, run the provisioners, and clean up the deployment.

## Create a VM from the Packer image

You can now create a VM from your Image with [New-AzVM](#). The supporting network resources are created if they do not already exist. When prompted, enter an administrative username and password to be created on the VM. The following example creates a VM named *myVM* from *myPackerImage*.

```
New-AzVm `  
-ResourceGroupName $rgName `  
-Name "myVM" `  
-Location $location `  
-VirtualNetworkName "myVnet" `  
-SubnetName "mySubnet" `  
-SecurityGroupName "myNetworkSecurityGroup" `  
-PublicIpAddressName "myPublicIpAddress" `  
-OpenPorts 80 `  
-Image "myPackerImage"
```

If you wish to create VMs in a different resource group or region than your Packer image, specify the image ID rather than image name. You can obtain the image ID with [Get-AzImage](#).

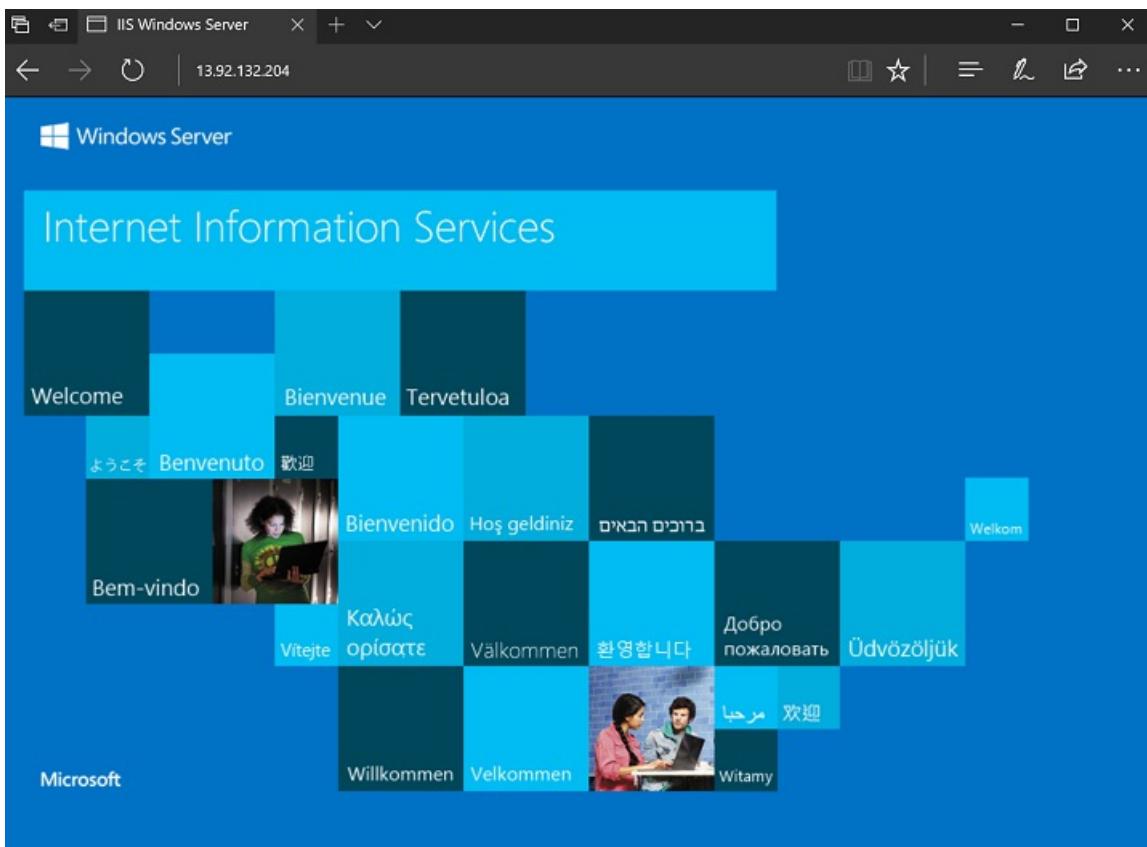

It takes a few minutes to create the VM from your Packer image.

## Test VM and webserver

Obtain the public IP address of your VM with [Get-AzPublicIPAddress](#). The following example obtains the IP address for *myPublicIP* created earlier:

```
Get-AzPublicIPAddress `  
-ResourceGroupName $rgName `  
-Name "myPublicIPAddress" | select "IpAddress"
```

To see your VM, that includes the IIS install from the Packer provisioner, in action, enter the public IP address in to a web browser.

## Next steps

You can also use existing Packer provisioner scripts with [Azure Image Builder](#).

# Azure Dedicated Hosts

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale sets

Azure Dedicated Host is a service that provides physical servers - able to host one or more virtual machines - dedicated to one Azure subscription. Dedicated hosts are the same physical servers used in our data centers, provided as a resource. You can provision dedicated hosts within a region, availability zone, and fault domain. Then, you can place VMs directly into your provisioned hosts, in whatever configuration best meets your needs.

## Benefits

Reserving the entire host provides the following benefits:

- Hardware isolation at the physical server level. No other VMs will be placed on your hosts. Dedicated hosts are deployed in the same data centers and share the same network and underlying storage infrastructure as other, non-isolated hosts.
- Control over maintenance events initiated by the Azure platform. While the majority of maintenance events have little to no impact on your virtual machines, there are some sensitive workloads where each second of pause can have an impact. With dedicated hosts, you can opt in to a maintenance window to reduce the impact to your service.
- With the Azure hybrid benefit, you can bring your own licenses for Windows and SQL to Azure. Using the hybrid benefits provides you with additional benefits. For more information, see [Azure Hybrid Benefit](#).

## Groups, hosts, and VMs

A **host group** is a resource that represents a collection of dedicated hosts. You create a host group in a region and an availability zone, and add hosts to it.

A **host** is a resource, mapped to a physical server in an Azure data center. The physical server is allocated when the host is created. A host is created within a host group. A host has a SKU describing which VM sizes can be created. Each host can host multiple VMs, of different sizes, as long as they are from the same size series.

## High Availability considerations

For high availability, you should deploy multiple VMs, spread across multiple hosts (minimum of 2). With Azure Dedicated Hosts, you have several options to provision your infrastructure to shape your fault isolation boundaries.

### Use Availability Zones for fault isolation

Availability zones are unique physical locations within an Azure region. Each zone is made up of one or more datacenters equipped with independent power, cooling, and networking. A host group is created in a single availability zone. Once created, all hosts will be placed within that zone. To achieve high availability across zones,

you need to create multiple host groups (one per zone) and spread your hosts accordingly.

If you assign a host group to an availability zone, all VMs created on that host must be created in the same zone.

### Use Fault Domains for fault isolation

A host can be created in a specific fault domain. Just like VM in a scale set or availability set, hosts in different fault domains will be placed on different physical racks in the data center. When you create a host group, you are required to specify the fault domain count. When creating hosts within the host group, you assign fault domain for each host. The VMs do not require any fault domain assignment.

Fault domains are not the same as colocation. Having the same fault domain for two hosts does not mean they are in proximity with each other.

Fault domains are scoped to the host group. You should not make any assumption on anti-affinity between two host groups (unless they are in different availability zones).

VMs deployed to hosts with different fault domains, will have their underlying managed disks services on multiple storage stamps, to increase the fault isolation protection.

### Using Availability Zones and Fault Domains

You can use both capabilities together to achieve even more fault isolation. In this case, you will specify the availability zone and fault domain count in for each host group, assign a fault domain to each of your hosts in the group, and assign an availability zone to each of your VMs

The [Resource Manager sample template](#) uses zones and fault domains to spread hosts for maximum resiliency in a region.

## Manual vs. automatic placement

When creating a VM in Azure, you can select which dedicated host to use. You can also use the option to automatically place your VMs on existing hosts, within a host group.

When creating a new host group, make sure the setting for automatic VM placement is selected. When creating your VM, select the host group and let Azure pick the best host for your VM.

Host groups that are enabled for automatic placement do not require all the VMs to be automatically placed. You will still be able to explicitly pick a host, even when automatic placement is selected for the host group.

### Limitations

Known issues and limitations when using automatic VM placement:

- You will not be able to redeploy your VM.
- You will not be able to use DCv2, Lsv2, NVasv4, NVsv3, Msv2, or M-series VMs with dedicated hosts

## Virtual machine scale set support

Virtual machine scale sets let you treat a group of virtual machines as a single resource, and apply availability, management, scaling and orchestration policies as a group. Your existing dedicated hosts can also be used for virtual machine scale sets.

When creating a virtual machine scale set you can specify an existing host group to have all of the VM instances created on dedicated hosts.

The following requirements apply when creating a virtual machine scale set in a dedicated host group:

- Automatic VM placement needs to be enabled.
- The availability setting of your host group should match your scale set.
  - A regional host group (created without specifying an availability zone) should be used for regional

scale sets.

- The host group and the scale set must be using the same availability zone.
- The fault domain count for the host group level should match the fault domain count for your scale set. The Azure portal lets you specify *max spreading* for your scale set, which sets the fault domain count of 1.
- Dedicated hosts should be created first, with sufficient capacity, and the same settings for scale set zones and fault domains.
- The supported VM sizes for your dedicated hosts should match the one used for your scale set.

Not all scale-set orchestration and optimizations settings are supported by dedicated hosts. Apply the following settings to your scale set:

- Overprovisioning is not recommended, and it is disabled by default. You can enable overprovisioning, but the scale set allocation will fail if the host group does not have capacity for all of the VMs, including the overprovisioned instances.
- Use the ScaleSetVM orchestration mode
- Do not use proximity placement groups for co-location

## Maintenance control

The infrastructure supporting your virtual machines may occasionally be updated to improve reliability, performance, security, and to launch new features. The Azure platform tries to minimize the impact of platform maintenance whenever possible, but customers with *maintenance sensitive* workloads can't tolerate even few seconds that the VM needs to be frozen or disconnected for maintenance.

**Maintenance Control** provides customers with an option to skip regular platform updates scheduled on their dedicated hosts, then apply it at the time of their choice within a 35-day rolling window. Within the maintenance window, you can apply maintenance directly at the host level, in any order. Once the maintenance window is over, Microsoft will move forward and apply the pending maintenance to the hosts in an order which may not follow the user defined fault domains.

For more information, see [Managing platform updates with Maintenance Control](#).

## Capacity considerations

Once a dedicated host is provisioned, Azure assigns it to physical server. This guarantees the availability of the capacity when you need to provision your VM. Azure uses the entire capacity in the region (or zone) to pick a physical server for your host. It also means that customers can expect to be able to grow their dedicated host footprint without the concern of running out of space in the cluster.

## Quotas

There are two types of quota that are consumed when you deploy a dedicated host.

1. Dedicated host vCPU quota. The default quota limit is 3000 vCPUs, per region.
2. VM size family quota. For example, a **Pay-as-you-go** subscription may only have a quota of 10 vCPUs available for the Dsv3 size series, in the East US region. To deploy a Dsv3 dedicated host, you would need to request a quota increase to at least 64 vCPUs before you can deploy the dedicated host.

To request a quota increase, create a support request in the [Azure portal](#).

Provisioning a dedicated host will consume both dedicated host vCPU and the VM family vCPU quota, but it will not consume the regional vCPU. VMs placed on a dedicated host will not count against VM family vCPU quota. Should a VM be moved off a dedicated host into a multi-tenant environment, the VM will consume VM family vCPU quota.

The screenshot shows the Azure portal's 'Pay-As-You-Go - Usage + quotas' section. On the left, there's a sidebar with options like 'Billing', 'Invoices', 'External services', 'Payment methods', 'Partner information', 'Programmatic deployment', 'Resource groups', 'Resources', and 'Usage + quotas'. The 'Usage + quotas' option is highlighted. The main area has a search bar and a 'Refresh' button. It displays a message about quotas and usage per subscription. Below that, there are dropdown menus for 'All service quotas', 'Microsoft.Compute', and 'East US', and a 'Show all' button. A search bar contains 'dsv3'. A table header includes 'QUOTA', 'PROVIDER', 'LOCATION', and 'USAGE'. A single row is shown: 'Standard Dsv3 Family vCPUs' under 'Microsoft.Compute' in 'East US', with a usage bar at 0% and '0 of 10'.

For more information, see [Virtual machine vCPU quotas](#).

Free trial and MSDN subscriptions do not have quota for Azure Dedicated Hosts.

## Pricing

Users are charged per dedicated host, regardless how many VMs are deployed. In your monthly statement you will see a new billable resource type of hosts. The VMs on a dedicated host will still be shown in your statement, but will carry a price of 0.

The host price is set based on VM family, type (hardware size), and region. A host price is relative to the largest VM size supported on the host.

Software licensing, storage and network usage are billed separately from the host and VMs. There is no change to those billable items.

For more information, see [Azure Dedicated Host pricing](#).

You can also save on costs with a [Reserved Instance of Azure Dedicated Hosts](#).

## Sizes and hardware generations

A SKU is defined for a host and it represents the VM size series and type. You can mix multiple VMs of different sizes within a single host as long as they are of the same size series.

The *type* is the hardware generation. Different hardware types for the same VM series will be from different CPU vendors and have different CPU generations and number of cores.

The sizes and hardware types vary by region. Refer to the host [pricing page](#) to learn more.

### NOTE

Once a Dedicated host is provisioned, you can't change the size or type. If you need a different size or type, you will need to create a new host.

## Host life cycle

Azure monitors and manages the health status of your hosts. The following states will be returned when you query your host:

HEALTH STATE	DESCRIPTION
Host Available	There are no known issues with your host.

Health State	Description
Host Under Investigation	We're having some issues with the host which we're looking into. This is a transitional state required for Azure to try and identify the scope and root cause for the issue identified. Virtual machines running on the host may be impacted.
Host Pending Deallocate	Azure can't restore the host back to a healthy state and ask you to redeploy your virtual machines out of this host. If <code>autoReplaceOnFailure</code> is enabled, your virtual machines are <i>service healed</i> to healthy hardware. Otherwise, your virtual machine may be running on a host that is about to fail.
Host deallocated	All virtual machines have been removed from the host. You are no longer being charged for this host since the hardware was taken out of rotation.

## Next steps

- To deploy a dedicated host, see [Deploy VMs and scale sets to dedicated hosts](#).
- There is a [sample template](#) that uses both zones and fault domains for maximum resiliency in a region.
- You can also save on costs with a [Reserved Instance of Azure Dedicated Hosts](#).

# Deploy VMs and scale sets to dedicated hosts

9/21/2022 • 16 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale sets

This article guides you through how to create an Azure [dedicated host](#) to host your virtual machines (VMs) and scale set instances.

## Limitations

- The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.
- Not all Azure VM SKUs, regions and availability zones support ultra disks, for more information about this topic, see [Azure ultra disks](#).
- The fault domain count of the virtual machine scale set can't exceed the fault domain count of the host group.

## Create a host group

A **host group** is a resource that represents a collection of dedicated hosts. You create a host group in a region and an availability zone, and add hosts to it. You can use one or both of the following options with your dedicated hosts to ensure high availability:

- Span across multiple availability zones. In this case, you're required to have a host group in each of the zones you wish to use.
- Span across multiple fault domains, which are mapped to physical racks.

In either case, you need to provide the fault domain count for your host group. If you don't want to span fault domains in your group, use a fault domain count of 1.

You can also decide to use both availability zones and fault domains.

Enabling ultra disks is a host group level setting and can't be changed after a host group is created.

If you intend to use LSv2 or M series VMs, with ultra disks on dedicated hosts, set host group's **Fault domain count** to 1.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

In this example, we'll create a host group using one availability zone and two fault domains.

1. Open the Azure [portal](#).
2. Select **Create a resource** in the upper left corner.
3. Search for **Host group** and then select **Host Groups** from the results.
4. In the **Host Groups** page, select **Create**.
5. Select the subscription you would like to use, and then select **Create new** to create a new resource group.
6. Type *myDedicatedHostsRG* as the **Name** and then select **OK**.
7. For **Host group name**, type *myHostGroup*.

8. For **Location**, select **East US**.
9. For **Availability Zone**, select **1**.
10. Select **Enable Ultra SSD** to use ultra disks with supported Virtual Machines.
11. For **Fault domain count**, select **2**.
12. Select **Automatic placement** to automatically assign VMs and scale set instances to an available host in this group.
13. Select **Review + create** and then wait for validation.
14. Once you see the **Validation passed** message, select **Create** to create the host group.

It should only take a few moments to create the host group.

## Create a dedicated host

Now create a dedicated host in the host group. In addition to a name for the host, you're required to provide the SKU for the host. Host SKU captures the supported VM series and the hardware generation for your dedicated host.

For more information about the host SKUs and pricing, see [Azure Dedicated Host pricing](#).

If you set a fault domain count for your host group, you'll need to specify the fault domain for your host.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Select **Create a resource** in the upper left corner.
2. Search for **Dedicated host** and then select **Dedicated hosts** from the results.
3. In the **Dedicated Hosts** page, select **Create**.
4. Select the subscription you would like to use.
5. Select *myDedicatedHostsRG* as the **Resource group**.
6. In **Instance details**, type *myHost* for the **Name** and select *East US* for the location.
7. In **Hardware profile**, select *Standard Es3 family - Type 1* for the **Size family**, select *myHostGroup* for the **Host group** and then select *1* for the **Fault domain**. Leave the defaults for the rest of the fields.
8. When you're done, select **Review + create** and wait for validation.
9. Once you see the **Validation passed** message, select **Create** to create the host.

## Create a VM

Now create a VM on the host.

If you would like to create a VM with ultra disks support, make sure the host group in which the VM will be placed is ultra SSD enabled. Once you've confirmed, create the VM in the same host group. See [Deploy an ultra disk](#) for the steps to attach an ultra disk to a VM.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the search box above the list of Azure Marketplace resources, search for and select the image you want to use, then choose **Create**.
3. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and then select *myDedicatedHostsRG* as the **Resource group**.

4. Under **Instance details**, type *myVM* for the **Virtual machine name** and choose *East US* for your **Location**.
5. In **Availability options** select **Availability zone**, select *1* from the drop-down.
6. For the size, select **Change size**. In the list of available sizes, choose one from the Esv3 series, like **Standard E2s v3**. You may need to clear the filter in order to see all of the available sizes.
7. Complete the rest of the fields on the **Basics** tab as needed.
8. If you want to specify which host to use for your VM, then at the top of the page, select the **Advanced** tab and in the **Host** section, select *myHostGroup* for **Host group** and *myHost* for the **Host**. Otherwise, your VM will automatically be placed on a host with capacity.

**Host**

Optionally placing your virtual machine in a host [Learn more](#)

Host group	myHostGroup   Zone 1   eastus	
Host	myHost	

9. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.
10. When you see the message that validation has passed, select **Create**.

It will take a few minutes for your VM to be deployed.

## Create a scale set

You can also create a scale set on your host.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

When you deploy a scale set, you specify the host group.

1. Search for **Scale set** and select **Virtual machine scale sets** from the list.
2. Select **Add** to create a new scale set.
3. Complete the fields on the **Basics** tab as you usually would, but make sure you select a VM size that is from the series you chose for your dedicated host, like **Standard E2s v3**.
4. On the **Advanced** tab, for **Spreading algorithm** select **Max spreading**.
5. In **Host group**, select the host group from the drop-down. If you recently created the group, it might take a minute to get added to the list.

## Add an existing VM

You can add an existing VM to a dedicated host, but the VM must first be Stop\Deallocated. Before you move a VM to a dedicated host, make sure that the VM configuration is supported:

- The VM size must be in the same size family as the dedicated host. For example, if your dedicated host is DSv3, then the VM size could be Standard\_D4s\_v3, but it couldn't be a Standard\_A4\_v2.
- The VM needs to be located in same region as the dedicated host.
- The VM can't be part of a proximity placement group. Remove the VM from the proximity placement group before moving it to a dedicated host. For more information about this topic, see [Move a VM out of a proximity placement group](#)
- The VM can't be in an availability set.
- If the VM is in an availability zone, it must be the same availability zone as the host group. The availability zone settings for the VM and the host group must match.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

Move the VM to a dedicated host using the [portal](#).

1. Open the page for the VM.
2. Select **Stop** to stop\deallocate the VM.
3. Select **Configuration** from the left menu.
4. Select a host group and a host from the drop-down menus.
5. When you're done, select **Save** at the top of the page.
6. After the VM has been added to the host, select **Overview** from the left menu.
7. At the top of the page, select **Start** to restart the VM.

## Check the status of the host

If you need to know how much capacity is still available on a host, you can check the status.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Search for and select the host.
2. In the **Overview** page for the host, scroll down to see the list of sizes still available for the host. It should look similar to:

---

### Available VM capacity

VM Size	Number remaining
Standard_D2ds_v4	32
Standard_D4ds_v4	17
Standard_D8ds_v4	8
Standard_D16ds_v4	4
Standard_D32ds_v4	2
Standard_D48ds_v4	1
Standard_D64ds_v4	1

## Restart a host (Preview)

You can restart the entire host, meaning that the host's not completely powered off. Because the host will be restarted, the underlying VMs will also be restarted. The host will remain on the same underlying physical hardware as it restarts and both the host ID and asset ID will remain the same after the restart. The host SKU will also remain the same after the restart.

Note: Host restart is in preview.

- [Portal](#)

- [CLI](#)
- [PowerShell](#)

1. Search for and select the host.
2. In the top menu bar, select the **Restart** button. Note, this feature is in Preview.
3. In the **Essentials** section of the Host Resource Pane, Host Status will switch to **Host undergoing restart** during the restart.
4. Once the restart has completed, the Host Status will return to **Host available**.

## Deleting a host

You're being charged for your dedicated host even when no virtual machines are deployed on the host. You should delete any hosts you're currently not using to save costs.

You can only delete a host when there are no any longer virtual machines using it.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Search for and select the host.
2. In the left menu, select **Instances**.
3. Select and delete each virtual machine.
4. When all of the VMs have been deleted, go back to the **Overview** page for the host and select **Delete** from the top menu.
5. Once the host has been deleted, open the page for the host group and select **Delete host group**.

## Next steps

- For more information about this topic, see the [Dedicated hosts](#) overview.
- There's sample template, available at [Azure Quickstart Templates](#), which uses both zones and fault domains for maximum resiliency in a region.

# General Purpose Azure Dedicated Host SKUs

9/21/2022 • 10 minutes to read • [Edit Online](#)

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision [Dsv3-series](#) VMs.

This document goes through the hardware specifications and VM packings for all general purpose Dedicated Host SKUs.

## Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.

## Dadsv5

### Dadsv5-Type1

The Dadsv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Dadsv5-Type1 runs [Dadsv5-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dadsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	D2ads v5	32
			D4ads v5	27
			D8ads v5	14
			D16ads v5	7
			D32ads v5	3
			D48ads v5	2
			D64ads v5	1
			D96ads v5	1

## Dasv5

### Dasv5-Type1

The Dasv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Dasv5-Type1 runs [Dasv5-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	D2as v5	32
			D4as v5	28
			D8as v5	14
			D16as v5	7
			D32as v5	3
			D48as v5	2
			D64as v5	1
			D96as v5	1

## Dasv4

### **Dasv4-Type1**

The Dasv4-Type1 is a Dedicated Host SKU utilizing AMD's 2.35 GHz EPYC™ 7452 processor. It offers 64 physical cores, 96 vCPUs, and 672 GiB of RAM. The Dasv4-Type1 runs [Dasv4-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv4-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	96	672 GiB	D2as v4	32
			D4as v4	24
			D8as v4	12
			D16as v4	6
			D32as v4	3
			D48as v4	2
			D64as v4	1
			D96as v4	1

You can also mix multiple VM sizes on the Dasv4-Type1. The following are sample combinations of VM packings on the Dasv4-Type1:

- 1 D48asv4 + 3 D16asv4

- 1 D32asv4 + 2 D16asv4 + 8 D4asv4
- 20 D4asv4 + 8 D2asv4

### **Dasv4-Type2**

The Dasv4-Type2 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Dasv4-Type2 runs [Dasv4-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dasv4-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	D2as v4	32
			D4as v4	25
			D8as v4	12
			D16as v4	6
			D32as v4	3
			D48as v4	2
			D64as v4	1
			D96as v4	1

## **DCadsv5**

### **DCadsv5-Type1**

The DCadsv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The DCadsv5-Type1 runs [DCadsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an DCadsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	DC2ads v5	32
			DC4ads v5	27
			DC8ads v5	14
			DC16ads v5	7
			DC32ads v5	3
			DC48ads v5	2
			DC64ads v5	1

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			DC96ads v5	1

## DCasv5

### DCasv5-Type1

The DCasv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The DCasv5-Type1 runs [DCasv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an DCasv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	DC2as v5	32
			DC4as v5	28
			DC8as v5	14
			DC16as v5	7
			DC32as v5	3
			DC48as v5	2
			DC64as v5	1
			DC96as v5	1

## DCsv3

### DCsv3-Type1

The DCsv3-Type1 is a Dedicated Host SKU utilizing the 3rd Generation Intel® Xeon Scalable Processor 8370C. It offers 48 physical cores, 48 vCPUs, and 384 GiB of RAM. The DCsv3-Type1 runs [DCsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a DCsv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
48	48	384 GiB	DC1s v3	32
			DC2s v3	24
			DC4s v3	12
			DC8s v3	6
			DC16s v3	3

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			DC24s v3	2

## DCcsv3

### DCcsv3-Type1

The DCcsv3-Type1 is a Dedicated Host SKU utilizing the 3rd Generation Intel® Xeon Scalable Processor 8370C. It offers 48 physical cores, 48 vCPUs, and 384 GiB of RAM. The DCcsv3-Type1 runs [DCcsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a DCcsv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
48	48	384 GiB	DC16ds v3	2
			DC24ds v3	1
			DC32ds v3	1
			DC48ds v3	1

## DCsv2

### DCsv2-Type1

The DCsv2-Type1 is a Dedicated Host SKU utilizing the Intel® Coffee Lake (Xeon® E-2288G with SGX technology) processor. It offers 8 physical cores, 8 vCPUs, and 64 GiB of RAM. The DCsv2-Type1 runs [DCsv2-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a DCsv2-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
8	8	64 GiB	DC8 v2	1

## Ddsv5

### Ddsv5-Type1

The Ddsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ddsv5-Type1 runs [Ddsv5-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Ddsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	D2ds v5	32
			D4ds v5	22

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
			D8ds v5	11
			D16ds v5	5
			D32ds v5	2
			D48ds v5	1
			D64ds v5	1
			D96ds v5	1

## Ddsv4

### Ddsv4-Type1

The Ddsv4-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Ddsv4-Type1 runs [Ddsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Ddsv4-Type1 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
52	80	504 GiB	D2ds v4	32
			D4ds v4	17
			D8ds v4	8
			D16ds v4	4
			D32ds v4	2
			D48ds v4	1
			D64ds v4	1

You can also mix multiple VM sizes on the Ddsv4-Type1. The following are sample combinations of VM packings on the Ddsv4-Type1:

- 1 D48dsv4 + 4 D4dsv4 + 2 D2dsv4
- 1 D32dsv4 + 2 D16dsv4 + 1 D4dsv4
- 10 D4dsv4 + 14 D2dsv4

### Ddsv4-Type2

The Ddsv4-Type2 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ddsv4-Type2 runs [Ddsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Ddsv4-Type2

host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	D2ds v4	32
			D4ds v4	19
			D8ds v4	9
			D16ds v4	4
			D32ds v4	2
			D48ds v4	1
			D64ds v4	1

## Dsv5

### Dsv5-Type1

The Dsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Dsv5-Type1 runs [Dsv5-series](#) VMs. Refer to the VM size documentation to better understand specific VM performance information.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	D2s v5	32
			D4s v5	25
			D8s v5	12
			D16s v5	6
			D32s v5	3
			D48s v5	2
			D64s v5	1
			D96s v5	1

## Dsv4

### Dsv4-Type1

The Dsv4-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Dsv4-Type1 runs [Dsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv4-Type1

host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	D2s v4	32
			D4s v4	20
			D8s v4	10
			D16s v4	5
			D32s v4	2
			D48s v4	1
			D64s v4	1

You can also mix multiple VM sizes on the Dsv4-Type1. The following are sample combinations of VM packings on the Dsv4-Type1:

- 1 D64sv4 + 1 D16sv4
- 1 D32sv4 + 2 D16sv4 + 2 D8sv4
- 10 D4sv4 + 20 D2sv4

## Dsv4-Type2

The Dsv4-Type2 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Dsv4-Type2 runs [Dsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv4-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	D2s v4	32
			D4s v4	25
			D8s v4	12
			D16s v4	6
			D32s v4	3
			D48s v4	2
			D64s v4	1

## Dsv3

### Dsv3-Type1

**NOTE**

The Dsv3-Type1 will be retired on March 31, 2023. Refer to the [dedicated host retirement guide](#) to learn more.

The Dsv3-Type1 is a Dedicated Host SKU utilizing the Intel® Broadwell (2.3 GHz Xeon® E5-2673 v4) processor. It offers 40 physical cores, 64 vCPUs, and 256 GiB of RAM. The Dsv3-Type1 runs [Dsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
40	64	256 GiB	D2s v3	32
			D4s v3	17
			D8s v3	8
			D16s v3	4
			D32s v3	2
			D48s v3	1
			D64s v3	1

You can also mix multiple VM sizes on the Dsv3-Type1. The following are sample combinations of VM packings on the Dsv3-Type1:

- 1 D32sv3 + 1 D16sv3 + 1 D8sv3
- 1 D48sv3 + 3 D4sv3 + 2 D2sv3
- 10 D4sv3 + 12 D2sv3

## Dsv3-Type2

**NOTE**

The Dsv3-Type2 will be retired on March 31, 2023. Refer to the [dedicated host retirement guide](#) to learn more.

The Dsv3-Type2 is a Dedicated Host SKU utilizing the Intel® Skylake (2.1 GHz Xeon® Platinum 8171M) processor. It offers 48 physical cores, 76 vCPUs, and 504 GiB of RAM. The Dsv3-Type2 runs [Dsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv3-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
48	76	504 GiB	D2s v3	32
			D4s v3	20
			D8s v3	10

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			D16s v3	5
			D32s v3	2
			D48s v3	1
			D64s v3	1

You can also mix multiple VM sizes on the Dsv3-Type2. The following are sample combinations of VM packings on the Dsv3-Type2:

- 1 D64sv3 + 2 D4sv3 + 2 D2sv3
- 1 D48sv3 + 4 D4sv3 + 6 D2sv3
- 12 D4sv3 + 14 D2sv3

### Dsv3-Type3

The Dsv3-Type3 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Dsv3-Type3 runs [Dsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv3-Type3 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	D2s v3	32
			D4s v3	21
			D8s v3	10
			D16s v3	5
			D32s v3	2
			D48s v3	1
			D64s v3	1

You can also mix multiple VM sizes on the Dsv3-Type3. The following are sample combinations of VM packings on the Dsv3-Type3:

- 1 D64sv3 + 1 D8sv3 + 2 D4sv3
- 1 D48sv3 + 1 D16sv3 + 4 D4sv3
- 15 D4sv3 + 10 D2sv3

### Dsv3-Type4

The Dsv3-Type4 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Dsv3-Type4 runs [Dsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Dsv3-Type4 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
64	119	768 GiB	D2s v3	32
			D4s v3	24
			D8s v3	12
			D16s v3	6
			D32s v3	3
			D48s v3	2
			D64s v3	1

- There is sample template, available at [Azure Quickstart Templates](#) that uses both zones and fault domains for maximum resiliency in a region.

# Compute Optimized Azure Dedicated Host SKUs

9/21/2022 • 2 minutes to read • [Edit Online](#)

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision [Dsv3-series](#) VMs.

This document goes through the hardware specifications and VM packings for all compute optimized Dedicated Host SKUs.

## Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.

## Fsv2

### Fsv2-Type2

The Fsv2-Type2 is a Dedicated Host SKU utilizing the Intel® Skylake (Xeon® Platinum 8168) processor. It offers 48 physical cores, 72 vCPUs, and 144 GiB of RAM. The Fsv2-Type2 runs [Fsv2-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMs
48	72	144 GiB	F2s v2	32
			F4s v2	18
			F8s v2	9
			F16s v2	4
			F32s v2	2
			F48s v2	1
			F64s v2	1
			F72s v2	1

### Fsv2-Type3

The Fsv2-Type3 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Fsv2-Type3 runs [Fsv2-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type3 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	F2s v2	32
			F4s v2	21
			F8s v2	10
			F16s v2	5
			F32s v2	2
			F48s v2	1
			F64s v2	1
			F72s v2	1

### Fsv2-Type4

The Fsv2-Type4 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Fsv2-Type4 runs [Fsv2-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Fsv2-Type4 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	F2s v2	32
			F4s v2	24
			F8s v2	12
			F16s v2	6
			F32s v2	3
			F48s v2	2
			F64s v2	1
			F72s v2	1

## FXmds

### FXmds-Type1

The FXmds-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Gold 6246R) processor. It offers 32 physical cores, 48 vCPUs, and 1,152 GiB of RAM. The FXmds-Type1 runs [FX-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a FXmds-Type1 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
32	48	1,152 GiB	FX4mds	12
			FX12mds	4
			FX24mds	2
			FX36mds	1
			FX48mds	1

## Next steps

# Memory Optimized Azure Dedicated Host SKUs

9/21/2022 • 12 minutes to read • [Edit Online](#)

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision [Dsv3-series](#) VMs.

This document goes through the hardware specifications and VM packings for all memory optimized Dedicated Host SKUs.

## Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.

## Eadsv5

### **Eadsv5-Type1**

The Eadsv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Eadsv5-Type1 runs [Eadsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Eadsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMs
64	112	768 GiB	E2ads v5	32
			E4ads v5	21
			E8ads v5	10
			E16ads v5	5
			E20ads v5	4
			E32ads v5	2
			E48ads v5	1
			E64ads v5	1
			E96ads v5	1

## Easv5

### **Easv5-Type1**

The Easv5-Type1 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Easv5-Type1 runs [Easv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	E2as v5	32
			E4as v5	21
			E8as v5	10
			E16as v5	5
			E20as v5	4
			E32as v5	2
			E48as v5	1
			E64as v5	1
			E96as v5	1

## Easv4

### Easv4-Type1

The Easv4-Type1 is a Dedicated Host SKU utilizing AMD's 2.35 GHz EPYC™ 7452 processor. It offers 64 physical cores, 96 vCPUs, and 672 GiB of RAM. The Easv4-Type1 runs [Easv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv4-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	96	672 GiB	E2as v4	32
			E4as v4	21
			E8as v4	10
			E16as v4	5
			E20as v4	4
			E32as v4	2
			E48as v4	1
			E64as v4	1
			E96as v4	1

### Easv4-Type2

The Easv4-Type2 is a Dedicated Host SKU utilizing AMD's EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The Easv4-Type2 runs [Easv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Easv4-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	E2as v4	32
			E4as v4	21
			E8as v4	10
			E16as v4	5
			E20as v4	4
			E32as v4	2
			E48as v4	1
			E64as v4	1
			E96as v4	1

## Ebdsv5

### Ebdsv5-Type1

The Ebdsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ebdsv5-Type1 runs [Ebdsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Ebdsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2bds v5	8
			E4bds v5	8
			E8bds v5	6
			E16bds v5	3
			E32bds v5	1
			E48bds v5	1
			E64bds v5	1

## Ebsv5

## Ebsv5-Type1

The Ebsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Ebsv5-Type1 runs [Ebsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Ebsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2bs v5	8
			E4bs v5	8
			E8bs v5	6
			E16bs v5	3
			E32bs v5	1
			E48bs v5	1
			E64bs v5	1

## ECadsv5

### ECadsv5-Type1

The ECadsv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The ECadsv5-Type1 runs [ECadsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an ECadsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	EC2ads v5	32
			EC4ads v5	21
			EC8ads v5	10
			EC16ads v5	5
			EC20ads v5	4
			EC32ads v5	3
			EC48ads v5	1
			EC64ads v5	1
			EC96ads v5	1

# ECasv5

## ECasv5-Type1

The ECasv5-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 768 GiB of RAM. The ECasv5-Type1 runs [ECasv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an ECasv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	112	768 GiB	EC2as v5	32
			EC4as v5	21
			EC8as v5	10
			EC16as v5	5
			EC20as v5	4
			EC32as v5	3
			EC48as v5	1
			EC64as v5	1
			EC96as v5	1

# Edsv5

## Edsv5-Type1

The Edsv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Edsv5-Type1 runs [Edsv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Edsv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2ds v5	32
			E4ds v5	21
			E8ds v5	10
			E16ds v5	5
			E20ds v5	4
			E32ds v5	2
			E48ds v5	1

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			E64ds v5	1

## Edsv4

### Edsv4-Type1

The Edsv4-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Edsv4-Type1 runs [Edsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Edsv4-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	E2ds v4	31
			E4ds v4	15
			E8ds v4	7
			E16ds v4	3
			E20ds v4	3
			E32ds v4	1
			E48ds v4	1
			E64ds v4	1

### Edsv4-Type2

The Edsv4-Type2 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Edsv4-Type2 runs [Edsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Edsv4-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2ds v4	32
			E4ds v4	19
			E8ds v4	9
			E16ds v4	4
			E20ds v4	3

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			E32ds v4	2
			E48ds v4	1
			E64ds v4	1

## Esv5

### Esv5-Type1

The Esv5-Type1 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Esv5-Type1 runs [Esv5-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv5-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2s v5	32
			E4s v5	21
			E8s v5	10
			E16s v5	5
			E20s v5	4
			E32s v5	2
			E48s v5	1
			E64s v5	1

## Esv4

### Esv4-Type1

The Esv4-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Esv4-Type1 runs [Esv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv4-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	E2s v4	31
			E4s v4	15
			E8s v4	7

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			E16s v4	3
			E20s v4	3
			E32s v4	1
			E48s v4	1
			E64s v4	1

### Esv4-Type2

The Esv4-Type2 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Esv4-Type2 runs [Esv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv4-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2s v4	32
			E4s v4	21
			E8s v4	10
			E16s v4	5
			E20s v4	4
			E32s v4	2
			E48s v4	1
			E64s v4	1

## Esv3

### Esv3-Type1

#### NOTE

The Esv3-Type1 will be retired on March 31, 2023. Refer to the [dedicated host retirement guide](#) to learn more.

The Esv3-Type1 is a Dedicated Host SKU utilizing the Intel® Broadwell (2.3 GHz Xeon® E5-2673 v4) processor. It offers 40 physical cores, 64 vCPUs, and 448 GiB of RAM. The Esv3-Type1 runs [Esv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMs
40	64	448 GiB	E2s v3	28
			E4s v3	14
			E8s v3	7
			E16s v3	3
			E20s v3	2
			E32s v3	1
			E48s v3	1
			E64s v3	1

## Esv3-Type2

### NOTE

The Esv3-Type2 will be retired on March 31, 2023. Refer to the [dedicated host retirement guide](#) to learn more.

The Esv3-Type2 is a Dedicated Host SKU utilizing the Intel® Skylake (Xeon® 8171M) processor. It offers 48 physical cores, 76 vCPUs, and 504 GiB of RAM. The Esv3-Type2 runs [Esv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv3-Type2 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMs
48	76	504 GiB	E2s v3	31
			E4s v3	15
			E8s v3	7
			E16s v3	3
			E20s v3	3
			E32s v3	1
			E48s v3	1
			E64s v3	1

## Esv3-Type3

The Esv3-Type3 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8272CL) processor. It offers 52 physical cores, 80 vCPUs, and 504 GiB of RAM. The Esv3-Type3 runs [Esv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv3-Type3

host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
52	80	504 GiB	E2s v3	31
			E4s v3	15
			E8s v3	7
			E16s v3	3
			E20s v3	3
			E32s v3	1
			E48s v3	1
			E64s v3	1

#### Esv3-Type4

The Esv3-Type4 is a Dedicated Host SKU utilizing the Intel® Ice Lake (Xeon® Platinum 8370C) processor. It offers 64 physical cores, 119 vCPUs, and 768 GiB of RAM. The Esv3-Type4 runs [Esv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto an Esv3-Type4 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	768 GiB	E2s v3	32
			E4s v3	21
			E8s v3	10
			E16s v3	5
			E20s v3	4
			E32s v3	2
			E48s v3	1
			E64s v3	1

## M

#### Ms-Type1

The Ms-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 128 vCPUs, and 2,048 GiB of RAM. The Ms-Type1 runs [M-series](#) VMs, including M, MIs, Ms, and Mts VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Ms-Type1

host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	128	2,048 GiB	M32ls	4
			M32ts	4
			M64	2
			M64s	2
			M64ls	2
			M128	1
			M128s	1

### Msm-Type1

The Msm-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 128 vCPUs, and 3,892 GiB of RAM. The Msm-Type1 runs [M-series](#) VMs, including Ms, Mms, Mts, and Mls VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Msm-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	128	3,892 GiB	M8ms	16
			M8-2ms	16
			M8-4ms	16
			M16ms	8
			M16-4ms	8
			M16-8ms	8
			M32ts	4
			M32ls	4
			M32ms	4
			M32-8ms	4
			M32-16ms	4
			M64ms	2
			M64	2

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			M64s	2
			M64m	2
			M64ls	2
			M64-16ms	2
			M64-32ms	2
			M128ms	1
			M128s	1
			M128m	1
			M128	1
			M128-32ms	1
			M128-64ms	1

## Mdsv2

### Mdmsv2MedMem-Type1

The Mdmsv2MedMem-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 192 vCPUs, and 4,096 GiB of RAM. The Mdmsv2MedMem-Type1 runs [Msv2-series](#) VMs, including Mdsv2 and Mdmsv2 VMs.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	192	4,096 GiB	M32dms v2	4
			M64ds v2	2
			M64dms v2	2
			M128ds v2	1
			M128dms v2	1

### Mdsv2MedMem-Type1

The Mdsv2MedMem-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 192 vCPUs, and 2,048 GiB of RAM. The Mdsv2MedMem-Type1 runs [Msv2-series](#) VMs, including Mdsv2 and Mdmsv2 VMs.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	192	2,048 GiB	M32dms v2	2

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
			M64ds v2	2
			M64dms v2	1
			M128ds v2	1

## Msv2

### Mmsv2MedMem-Type1

The Mmsv2MedMem-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 192 vCPUs, and 4,096 GiB of RAM. The Mmsv2MedMem-Type1 runs [Msv2-series](#) VMs, including Msv2 and Mmsv2 VMs.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	192	4,096 GiB	M32ms v2	4
			M64s v2	3
			M64ms v2	2
			M128ms v2	1
			M128s v2	1

### Msv2MedMem-Type1

The Msv2MedMem-Type1 is a Dedicated Host SKU utilizing the Intel® Cascade Lake (Xeon® Platinum 8280) processor. It offers 112 physical cores, 192 vCPUs, and 2,048 GiB of RAM. The Msv2MedMem-Type1 runs [Msv2-series](#) VMs, including Msv2 and Mmsv2 VMs.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
112	192	2,048 GiB	M32ms v2	2
			M64s v2	2
			M64ms v2	1
			M128s v2	1

## Mv2

### Msmv2-Type1

The Msm-Type1 is a Dedicated Host SKU utilizing the Intel® Skylake (Xeon® Platinum 8180M) processor. It offers 224 physical cores, 416 vCPUs, and 11,400 GiB of RAM. The Msmv2-Type1 runs [Mv2-series](#) VMs, including Msv2 and Mmsv2 VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Msm-Type1 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
224	416	11,400 GiB	M208ms v2	2
			M208s v2	2
			M416-208ms v2	1
			M416-208s v2	1
			M416ms v2	1
			M416s v2	1

### Msv2-Type1

The Msv2-Type1 is a Dedicated Host SKU utilizing the Intel® Skylake (Xeon® Platinum 8180M) processor. It offers 224 physical cores, 416 vCPUs, and 5,700 GiB of RAM. The Msv2-Type1 runs [Mv2-series](#) VMs, including Msv2 and Mmsv2 VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Msv2-Type1 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
224	416	5,700 GiB	M208ms v2	2
			M208s v2	1
			M416-208s v2	1
			M416s v2	1

## Next steps

- For more information, see the [Dedicated hosts](#) overview.
- There's sample template, available at [Azure Quickstart Templates](#), which uses both zones and fault domains for maximum resiliency in a region.

# Storage Optimized Azure Dedicated Host SKUs

9/21/2022 • 2 minutes to read • [Edit Online](#)

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision [Dsv3-series](#) VMs.

This document goes through the hardware specifications and VM packings for all storage optimized Dedicated Host SKUs.

## Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.

## Lasv3

### Lasv3-Type1

The Lasv3-Type1 is a Dedicated Host SKU utilizing the AMD 3rd Generation EPYC™ 7763v processor. It offers 64 physical cores, 112 vCPUs, and 1024 GiB of RAM. The Lasv3-Type1 runs [Lasv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Lasv3-Type1 host.

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
64	112	1024 GiB	L8as v3	10
			L16as v3	5
			L32as v3	2
			L48as v3	1
			L64as v3	1
			L80as v3	1

## Lsv3

### Lsv3-Type1

The Lsv3-Type1 is a Dedicated Host SKU utilizing the Intel® 3rd Generation Xeon® Platinum 8370C (Ice Lake) processor. It offers 64 physical cores, 119 vCPUs, and 1024 GiB of RAM. The Lsv3-Type1 runs [Lsv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a Lsv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	119	1024 GiB	L8s v3	10
			L16s v3	5
			L32s v3	2
			L48s v3	1
			L64s v3	1
			L80s v3	1

## Lsv2

### Lsv2-Type1

The Lsv2-Type1 is a Dedicated Host SKU utilizing the AMD 2.55 GHz EPYC™ 7551 processor. It offers 64 physical cores, 80 vCPUs, and 640 GiB of RAM. The Lsv2-Type1 runs [Lsv2-series VMs](#).

The following packing configuration outlines the max packing of uniform VMs you can put onto a Lsv2-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
64	80	640 GiB	L8s v2	10
			L16s v2	5
			L32s v2	2
			L48s v2	1
			L64s v2	1
			L80s v2	1

## Next steps

- For more information, see the [Dedicated hosts](#) overview.
- There's a sample template, available at [Azure Quickstart Templates](#) that uses both zones and fault domains for maximum resiliency in a region.

# GPU Optimized Azure Dedicated Host SKUs

9/21/2022 • 2 minutes to read • [Edit Online](#)

Azure Dedicated Host SKUs are the combination of a VM family and a certain hardware specification. You can only deploy VMs of the VM series that the Dedicated Host SKU specifies. For example, on the Dsv3-Type3, you can only provision [Dsv3-series](#) VMs.

This document goes through the hardware specifications and VM packings for all GPU optimized Dedicated Host SKUs.

## Limitations

The sizes and hardware types available for dedicated hosts vary by region. Refer to the host [pricing page](#) to learn more.

## NVasv4

### NVasv4-Type1

The NVasv4-Type1 is a Dedicated Host SKU utilizing the AMD® Rome (EPYC™ 7V12) processor with AMD Radeon Instinct MI25 GPUs. It offers 128 physical cores, 128 vCPUs, and 448 GiB of RAM. The NVasv4-Type1 runs [NVsv4-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a NVasv4-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
128	128	448 GiB	NV4as v4	30
			NV8as v4	15
			NV16as v4	7
			NV32as v4	3

## NVsv3

### NVsv3-Type1

The NVsv3-Type1 is a Dedicated Host SKU utilizing the Intel® Broadwell (E5-2690 v4) processor with NVIDIA Tesla M60 GPUs and NVIDIA GRID technology. It offers 28 physical cores, 48 vCPUs, and 448 GiB of RAM. The NVsv3-Type1 runs [NVv3-series](#) VMs.

The following packing configuration outlines the max packing of uniform VMs you can put onto a NVsv3-Type1 host.

PHYSICAL CORES	AVAILABLE VCPUS	AVAILABLE RAM	VM SIZE	# VMS
28	48	448 GiB	NV12s v3	4

Physical Cores	Available vCPUs	Available RAM	VM Size	# VMs
			NV24s v3	2
			NV48s v3	1

## Next steps

- For more information, see the [Dedicated hosts](#) overview.
- There is sample template, available at [Azure quickstart templates](#), that uses both zones and fault domains for maximum resiliency in a region.

# Azure Dedicated Host SKU Retirement

9/21/2022 • 2 minutes to read • [Edit Online](#)

We continue to modernize and optimize Azure Dedicated Host by using the latest innovations in processor and datacenter technologies. Azure Dedicated Host is a combination of a virtual machine (VM) series and a specific Intel or AMD-based physical server. As we innovate and work with our technology partners, we also need to plan how we retire aging technology.

## Migrations required by 31 March 2023

All hardware has a finite lifespan, including the underlying hardware for Azure Dedicated Host. As we continue to modernize Azure datacenters, hardware is decommissioned and eventually retired. The hardware that runs the following Dedicated Host SKUs will be reaching end of life:

- Dsv3-Type1
- Dsv3-Type2
- Esv3-Type1
- Esv3-Type2

As a result we'll retire these Dedicated Host SKUs on 31 March 2023.

## How does the retirement of Azure Dedicated Host SKUs affect you?

The current retirement impacts the following Azure Dedicated Host SKUs:

- Dsv3-Type1
- Esv3-Type1
- Dsv3-Type2
- Esv3-Type2

Note: If you're running a Dsv3-Type3, Dsv3-Type4, an Esv3-Type3, or an Esv3-Type4 Dedicated Host, you won't be impacted.

## What actions should you take?

For manually placed VMs, you'll need to create a Dedicated Host of a newer SKU, stop the VMs on your existing Dedicated Host, reassign them to the new host, start the VMs, and delete the old host. For automatically placed VMs or for virtual machine scale sets, you'll need to create a Dedicated Host of a newer SKU, stop the VMs or virtual machine scale set, delete the old host, and then start the VMs or virtual machine scale set.

Refer to the [Azure Dedicated Host Migration Guide](#) for more detailed instructions. We recommend moving to the latest generation of Dedicated Host for your VM family.

If you have any questions, contact us through customer support.

## FAQs

### Q: Will migration result in downtime?

A: Yes, you'll need to stop/deallocate your VMs or virtual machine scale sets before moving them to the target host.

**Q: When will the other Dedicated Host SKUs retire?**

A: We'll announce Dedicated Host SKU retirements 12 months in advance of the official retirement date of a given Dedicated Host SKU.

**Q: What are the milestones for the Dsv3-Type1, Dsv3-Type2, Esv3-Type1, and Esv3-Type2 retirement?**

A:

DATE	ACTION
15 March 2022	Dsv3-Type1, Dsv3-Type2, Esv3-Type1, Esv3-Type2 retirement announcement
31 March 2023	Dsv3-Type1, Dsv3-Type2, Esv3-Type1, Esv3-Type2 retirement

**Q: What will happen to my Azure Reservation?**

A: You'll need to [exchange your reservation](#) through the Azure portal to match the new Dedicated Host SKU.

# Azure Dedicated Host SKU Retirement Migration Guide

9/21/2022 • 4 minutes to read • [Edit Online](#)

As hardware ages, it must be retired and workloads must be migrated to newer, faster, and more efficient Azure Dedicated Host SKUs. The legacy Dedicated Host SKUs should be migrated to newer Dedicated Host SKUs. The main differences between the retiring Dedicated Host SKUs and the newly recommended Dedicated Host SKUs are:

- Newer, more efficient processors
- Increased RAM
- Increased available vCPUs
- Greater regional capacity compared to the retiring Dedicated Host SKUs

Review the [FAQs](#) before you get started on migration. The next section will go over which Dedicated Host SKUs to migrate to help aid in migration planning and execution.

## Azure Dedicated Host Retirement

Some Azure Dedicated Host SKUs will be retired soon. Refer to the [Azure Dedicated Host SKU Retirement](#) documentation to learn more.

## Dsv3-Type1 and Dsv3-Type2

The Dsv3-Type1 and Dsv3-Type2 run Dsv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most general-purpose workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Dsv3-Type3
- Dsv3-Type4

Note that both the Dsv3-Type3 and Dsv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Dsv3-Type3 or Dsv3-Type4 based on regional availability, pricing, and your organization's needs.

## Esv3-Type1 and Esv3-Type2

The Esv3-Type1 and Esv3-Type2 run Esv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most memory-intensive workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Esv3-Type3
- Esv3-Type4

Note that both the Esv3-Type3 and Esv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Esv3-Type3 or Esv3-Type4 based on regional availability, pricing, and your organization's needs.

## Migration steps

To migrate your workloads to avoid Dedicated Host SKU retirement, please go through the respective steps for your manually placed VMs, automatically VMs, and virtual machine scale set on your Dedicated Host:

- [Manually Placed VMs](#)
- [Automatically Placed VMs](#)
- [VMSS](#)

1. Choose a target Dedicated Host SKU to migrate to.
2. Ensure you have quota for the VM family associated with the target Dedicated Host SKU in your given region.
3. Provision a new Dedicated Host of the target Dedicated Host SKU in the same Host Group.
4. Stop and deallocate the VM(s) on your old Dedicated Host.
5. Reassign the VM(s) to the target Dedicated Host.
6. Start the VM(s).
7. Delete the old host.

More detailed instructions can be found in the following sections.

**NOTE**

Certain sections are different for automatically placed VMs or virtual machine scale set. These differences will explicitly be called out in the respective steps.

### Ensure quota for the target VM family

Be sure that you have enough vCPU quota for the VM family of the Dedicated Host SKU that you'll be using. If you need quota, follow this guide to [request an increase in vCPU quota](#) for your target VM family in your target region. Select the Dsv3-series or Esv3-series as the VM family, depending on the target Dedicated Host SKU.

### Create a new Dedicated Host

Within the same Host Group as the existing Dedicated Host, [create a Dedicated Host](#) of the target Dedicated Host SKU.

### Stop the VM(s) or virtual machine scale set

- [PowerShell](#)
- [CLI](#)
- [Portal](#)

Refer to the PowerShell documentation to [stop a VM through PowerShell](#) or [stop a virtual machine scale set through PowerShell](#).

### Reassign the VM(s) to the target Dedicated Host

**NOTE**

Skip this step for automatically placed VMs and virtual machine scale set.

Once the target Dedicated Host has been created and the VM has been stopped, [reassign the VM to the target Dedicated Host](#).

### Start the VM(s) or virtual machine scale set

**NOTE**

Automatically placed VM(s) and virtual machine scale set require that you delete the old host *before* starting the autoplaced VM(s) or virtual machine scale set.

- [PowerShell](#)
- [CLI](#)
- [Portal](#)

Refer to the PowerShell documentation to [start a VM through PowerShell](#) or [start a virtual machine scale set through PowerShell](#).

**Delete the old Dedicated Host**

Once all VMs have been migrated from your old Dedicated Host to the target Dedicated Host, [delete the old Dedicated Host](#).

## Help and support

If you have questions, ask community experts in [Microsoft Q&A](#).

# Use Azure Spot Virtual Machines

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Using Azure Spot Virtual Machines allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

The amount of available capacity can vary based on size, region, time of day, and more. When deploying Azure Spot Virtual Machines, Azure will allocate the VMs if there's capacity available, but there's no SLA for these VMs. An Azure Spot Virtual Machine offers no high availability guarantees. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines with 30-seconds notice.

## Eviction policy

VMs can be evicted based on capacity or the max price you set. When creating an Azure Spot Virtual Machine, you can set the eviction policy to *Deallocate* (default) or *Delete*.

The *Deallocate* policy moves your VM to the stopped-deallocated state, allowing you to redeploy it later. However, there's no guarantee that the allocation will succeed. The deallocated VMs will count against your quota and you'll be charged storage costs for the underlying disks.

If you would like your VM to be deleted when it's evicted, you can set the eviction policy to *delete*. The evicted VMs are deleted together with their underlying disks, so you'll not continue to be charged for the storage.

You can opt in to receive in-VM notifications through [Azure Scheduled Events](#). This will notify you if your VMs are being evicted and you will have 30 seconds to finish any jobs and perform shutdown tasks prior to the eviction.

OPTION	OUTCOME
Max price is set to $\geq$ the current price.	VM is deployed if capacity and quota are available.
Max price is set to $<$ the current price.	The VM isn't deployed. You'll get an error message that the max price needs to be $\geq$ current price.
Restarting a stopped/deallocated VM if the max price is $\geq$ the current price	If there's capacity and quota, then the VM is deployed.
Restarting a stopped/deallocated VM if the max price is $<$ the current price	You'll get an error message that the max price needs to be $\geq$ current price.
Price for the VM has gone up and is now $>$ the max price.	The VM gets evicted. You get a 30s notification before actual eviction.
After eviction, the price for the VM goes back to being $<$ the max price.	The VM won't be automatically restarted. You can restart the VM yourself, and it will be charged at the current price.

OPTION	OUTCOME
If the max price is set to <code>-1</code>	The VM won't be evicted for pricing reasons. The max price will be the current price, up to the price for standard VMs. You'll never be charged above the standard price.
Changing the max price	You need to deallocate the VM to change the max price. Deallocate the VM, set a new max price, then update the VM.

#### TIP

Check out our [Azure Virtual Machine Spot Eviction](#) guide to learn how to create a reliable interruptible workload in Azure.

## Limitations

The following VM sizes aren't supported for Azure Spot Virtual Machines:

- B-series
- Promo versions of any size (like Dv2, NV, NC, H promo sizes)

Azure Spot Virtual Machines can be deployed to any region, except Microsoft Azure China 21Vianet.

The following [offer types](#) are currently supported:

- Enterprise Agreement
- Pay-as-you-go offer code (003P)
- Sponsored (0036P and 0136P)
- For Cloud Service Provider (CSP), see the [Partner Center](#) or contact your partner directly.

## Pricing

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for [Linux](#) and [Windows](#).

You can also query pricing information using the [Azure retail prices API](#) to query for information about Spot pricing. The `meterName` and `skuName` will both contain `spot`.

With variable pricing, you have option to set a max price, in US dollars (USD), using up to five decimal places. For example, the value `0.98765` would be a max price of \$0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, whichever is less, as long as there's capacity and quota available.

## Pricing and eviction history

### Portal

You can see historical pricing and eviction rates per size in a region in the portal. Select **View pricing history and compare prices in nearby regions** to see a table or graph of pricing for a specific size. The pricing and eviction rates in the following images are only examples.

Azure Resource Graph

You can programmatically access relevant Spot VM SKU data through [Azure Resource Graph](#). Get pricing history in the last 90 days and eviction rates for the last 28 trailing days to identify SKUs that better meet your specific

needs.

Key benefits:

- Query Spot eviction rates and the last few months of Spot prices programmatically through ARM or the [ARG Explorer in Azure portal](#)
- Create a custom query to extract the specific data relevant to your scenario with the ability to filter across a variety of parameters, such as SKU and region
- Easily compare data across multiple regions and SKUs
- Find a different Spot SKU or region with a lower price and/or eviction rate

Try out the following sample queries for Spot pricing history and eviction rates using the [ARG Explorer in Azure portal](#). Spot pricing history and eviction rates data are available in the `SpotResources` table.

**Spot pricing history sample query:**

```
SpotResources
|wheretype=~'microsoft.compute/skupsotpricehistory/ostype/location'
|wheresku.namein~('standard_d2s_v4','standard_d4s_v4')
|whereproperties.osType=~'linux'
|wherelocationin~('eastus','southcentralus')
|projectskuName=tostring(sku.name),osType=tostring(properties.osType),location,latestSpotPriceUSD=todouble(properties.spotPrices[0].priceUSD)
|orderbylatestSpotPriceUSDAsc
```

**Spot eviction rates sample query:**

```

|wheretype=~'microsoft.compute/skuspotevictionrate/location'
|wheresku.namein~('standard_d2s_v4','standard_d4s_v4')
|wherelocationin~('eastus','southcentralus')
|projectskuName=tostring(sku.name),location,spotEvictionRate=tostring(properties.evictionRate)
|orderbyskuNameasc,locationasc
```

Alternatively, try out the [ARG REST API](#) to get the pricing history and eviction rate history data.

## Frequently asked questions

**Q:** Once created, is an Azure Spot Virtual Machine the same as regular standard VM?

**A:** Yes, except there's no SLA for Azure Spot Virtual Machines and they can be evicted at any time.

**Q:** What to do when you get evicted, but still need capacity?

**A:** We recommend you use standard VMs instead of Azure Spot Virtual Machines if you need capacity right away.

**Q:** How is quota managed for Azure Spot Virtual Machines?

**A:** Azure Spot Virtual Machines will have a separate quota pool. Spot quota will be shared between VMs and scale-set instances. For more information, see [Azure subscription and service limits, quotas, and constraints](#).

**Q:** Can I request for additional quota for Azure Spot Virtual Machines?

**A:** Yes, you'll be able to submit the request to increase your quota for Azure Spot Virtual Machines through the [standard quota request process](#).

**Q:** Where can I post questions?

A: You can post and tag your question with `azure-spot` at [Q&A](#).

Q: How can I change the max price for a spot VM?

A: Before you can change the max price, you need to deallocate the VM. Then you can change the max price in the portal, from the **Configuration** section for the VM.

## Next steps

Use the [CLI](#), [portal](#), [ARM template](#), or [PowerShell](#) to deploy Azure Spot Virtual Machines.

You can also deploy a [scale set with Azure Spot Virtual Machine instances](#).

If you encounter an error, see [Error codes](#).

# Deploy Azure Spot Virtual Machines using the Azure CLI

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Using [Azure Spot Virtual Machines](#) allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for [Linux](#) and [Windows](#).

You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.98765` would be a max price of \$0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for Azure Spot Virtual Machine or the price for a standard VM, whichever is less, as long as there is capacity and quota available. For more information about setting the max price, see [Azure Spot Virtual Machines - Pricing](#).

The process to create an Azure Spot Virtual Machine using the Azure CLI is the same as detailed in the [quickstart article](#). Just add the '--priority Spot' parameter, set the `--eviction-policy` to either Deallocate (this is the default) or `Delete`, and provide a max price or `-1`.

## Install Azure CLI

To create Azure Spot Virtual Machines, you need to be running the Azure CLI version 2.0.74 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install the Azure CLI](#).

Sign in to Azure using [az login](#).

```
az login
```

## Create an Azure Spot Virtual Machine

This example shows how to deploy a Linux Azure Spot Virtual Machine that will not be evicted based on price. The eviction policy is set to deallocate the VM, so that it can be restarted at a later time. If you want to delete the VM and the underlying disk when the VM is evicted, set `--eviction-policy` to `Delete`.

```
az group create -n mySpotGroup -l eastus
az vm create \
    --resource-group mySpotGroup \
    --name myVM \
    --image UbuntuLTS \
    --admin-username azureuser \
    --generate-ssh-keys \
    --priority Spot \
    --max-price -1 \
    --eviction-policy Deallocate
```

After the VM is created, you can query to see the max billing price for all of the VMs in the resource group.

```
az vm list \
-g mySpotGroup \
--query '[].{Name:name, MaxPrice:billingProfile.maxPrice}' \
--output table
```

## Simulate an eviction

You can simulate an eviction of an Azure Spot Virtual Machine using REST, PowerShell, or the CLI, to test how well your application will respond to a sudden eviction.

In most cases, you will want to use the REST API [Virtual Machines - Simulate Eviction](#) to help with automated testing of applications. For REST, a `Response Code: 204` means the simulated eviction was successful. You can combine simulated evictions with the [Scheduled Event service](#), to automate how your app will respond when the VM is evicted.

To see scheduled events in action, watch [Azure Friday - Using Azure Scheduled Events to prepare for VM maintenance](#).

### Quick test

For a quick test to show how a simulated eviction will work, let's walk through querying the scheduled event service to see what it looks like when you simulate an eviction using the Azure CLI.

The Scheduled Event service is enabled for your service the first time you make a request for events.

Remote into your VM, and then open a command prompt.

From the command prompt on your VM, type:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

This first response could take up to 2 minutes. From now on, they should display output almost immediately.

From a computer that has the Azure CLI installed (like your local machine), simulate an eviction using `az vm simulate-eviction`. Replace the resource group name and VM name with your own.

```
az vm simulate-eviction --resource-group mySpotRG --name mySpot
```

The response output will have `Status: Succeeded` if the request was successfully made.

Quickly go back to your remote connection to your Spot Virtual Machine and query the Scheduled Events endpoint again. Repeat the following command until you get an output that contains more information:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

When the Scheduled Event Service gets the eviction notification, you will get a response that looks similar to this:

```
{"DocumentIncarnation":1,"Events":[{"EventId":"A123BC45-1234-5678-AB90-ABCDEF123456","EventStatus":"Scheduled","EventType":"Preempt","ResourceType":"VirtualMachine","Resources":["myspotvm"],"NotBefore":"Tue, 16 Mar 2021 00:58:46 GMT","Description":"","EventSource":"Platform"}]}
```

You can see that `"EventType": "Preempt"`, and the resource is the VM resource `"Resources": ["myspotvm"]`.

You can also see when the VM will be evicted by checking the `"NotBefore"` - the VM will not be evicted before the time given, so that is your window for your application to gracefully close out.

## Next steps

You can also create an Azure Spot Virtual Machine using [Azure PowerShell](#), [portal](#), or a [template](#).

Query current pricing information using the [Azure retail prices API](#) for information about Azure Spot Virtual Machine. The `meterName` and `skuName` will both contain `Spot`.

If you encounter an error, see [Error codes](#).

# Deploy Azure Spot Virtual Machines using the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale sets

Using [Azure Spot Virtual Machines](#) allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for [Linux](#) and [Windows](#). For more information about setting the max price, see [Azure Spot Virtual Machines - Pricing](#).

You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.05701` would be a max price of \$0.05701 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, whichever is less, as long as there is capacity and quota available.

When the VM is evicted, you have the option to either delete the VM and the underlying disk or deallocate the VM so that it can be restarted later.

## Create the VM

When you are deploying a VM, you can choose to use an Azure spot instance.

On the **Basics** tab, in the **Instance details** section, **No** is the default for using an Azure spot instance.

The screenshot shows the 'Instance details' section of the Azure portal's VM creation form. It includes fields for Virtual machine name, Region, Availability options, Image, and Azure Spot instance selection. The 'Azure Spot instance' field is highlighted with a red border, and the 'No' radio button is selected.

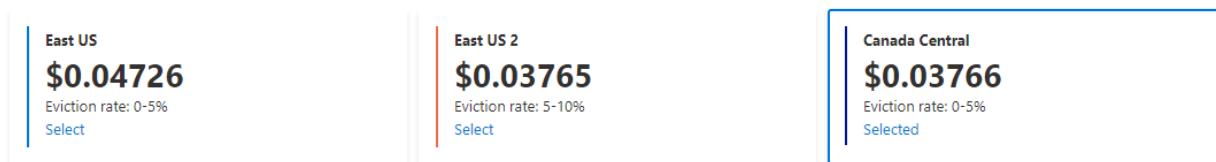

Instance details	
Virtual machine name *	<input type="text"/>
Region *	(US) West US
Availability options	No infrastructure redundancy required
Image *	Ubuntu Server 18.04 LTS <a href="#">Browse all public and private images</a>
Azure Spot instance	<input type="radio"/> Yes <input checked="" type="radio"/> No
Size *	<a href="#">Select size</a>

If you select **Yes**, the section expands and you can choose your [eviction type and eviction policy](#).

Azure Spot instance <a href="#">(i)</a>	<input checked="" type="radio"/> Yes <input type="radio"/> No
Eviction type <a href="#">(i)</a>	<input checked="" type="radio"/> Capacity only: evict virtual machine when Azure needs the capacity for pay as you go workloads. Your max price is set to the pay as you go rate. <input type="radio"/> Price or capacity: choose a max price and Azure will evict your virtual machine when the cost of the instance is greater than your max price or when Azure needs the capacity for pay as you go workloads.
Eviction policy <a href="#">(i)</a>	<input checked="" type="radio"/> Stop / Deallocate <input type="radio"/> Delete

You can also compare the pricing and eviction rates with other similar regions by selecting [View pricing history and compare prices in nearby regions](#).

In this example, the Canada Central region is less expensive and has a lower eviction rate than the East US region.

You can change the region by selecting the choice that works best for you and then selecting OK.

## Simulate an eviction

You can [simulate an eviction](#) of an Azure Spot Virtual Machine, to test how well your application will respond to a sudden eviction.

Replace the following with your information:

- `subscriptionId`
- `resourceGroupName`
- `vmName`

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}/simulateEviction?api-version=2020-06-01
```

Response Code: 204 means the simulated eviction was successful.

## Next steps

You can also create Azure Spot Virtual Machines using [PowerShell](#), [CLI](#), or a [template](#).

# Deploy Azure Spot Virtual Machines using Azure PowerShell

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

Using [Azure Spot Virtual Machines](#) allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for [Linux](#) and [Windows](#). For more information about setting the max price, see [Azure Spot Virtual Machines - Pricing](#).

You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.98765` would be a max price of \$0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for spot or the price for a standard VM, whichever is less, as long as there is capacity and quota available.

## Create the VM

Create a spotVM using [New-AzVmConfig](#) to create the configuration. Include `-Priority Spot` and set `-MaxPrice` to either:

- `-1` so the VM is not evicted based on price.
- a dollar amount, up to 5 digits. For example, `-MaxPrice .98765` means that the VM will be deallocated once the price for a spotVM goes about \$.98765 per hour.

This example creates a spotVM that will not be deallocated based on pricing (only when Azure needs the capacity back). The eviction policy is set to deallocate the VM, so that it can be restarted at a later time. If you want to delete the VM and the underlying disk when the VM is evicted, set `-EvictionPolicy` to `Delete` in [New-AzVMConfig](#).

```

$resourceGroup = "mySpotRG"
$location = "eastus"
$vmName = "mySpotVM"
$cred = Get-Credential -Message "Enter a username and password for the virtual machine."
New-AzResourceGroup -Name $resourceGroup -Location $location
$subnetConfig = New-AzVirtualNetworkSubnetConfig ` 
    -Name mySubnet -AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork -ResourceGroupName $resourceGroup ` 
    -Location $location -Name MYvNET -AddressPrefix 192.168.0.0/16 ` 
    -Subnet $subnetConfig
$pip = New-AzPublicIpAddress -ResourceGroupName $resourceGroup -Location $location ` 
    -Name "mypublicdns$(Get-Random)" -AllocationMethod Static -IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name myNetworkSecurityGroupRuleRDP -Protocol Tcp ` 
    -Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange * -DestinationAddressPrefix * ` 
    -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName $resourceGroup -Location $location ` 
    -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface -Name myNic -ResourceGroupName $resourceGroup -Location $location ` 
    -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration and set this to be an Azure Spot Virtual Machine

$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1 -Priority "Spot" -MaxPrice -1 -EvictionPolicy
Deallocate | ` 
Set-AzVMOperatingSystem -Windows -ComputerName $vmName -Credential $cred | ` 
Set-AzVMSourceImage -PublisherName MicrosoftWindowsServer -Offer WindowsServer -Skus 2016-Datacenter - 
Version latest | ` 
Add-AzVMNetworkInterface -Id $nic.Id

New-AzVM -ResourceGroupName $resourceGroup -Location $location -VM $vmConfig

```

After the VM is created, you can query to see the max price for all of the VMs in the resource group.

```

Get-AzVM -ResourceGroupName $resourceGroup | ` 
Select-Object Name,@{Name="maxPrice"; Expression={$_['BillingProfile.MaxPrice}}}

```

## Simulate an eviction

You can simulate an eviction of an Azure Spot Virtual Machine using REST, PowerShell, or the CLI, to test how well your application will respond to a sudden eviction.

In most cases, you will want to use the REST API [Virtual Machines - Simulate Eviction](#) to help with automated testing of applications. For REST, a `Response Code: 204` means the simulated eviction was successful. You can combine simulated evictions with the [Scheduled Event service](#), to automate how your app will respond when the VM is evicted.

To see scheduled events in action, watch Azure Friday - Using Azure Scheduled Events to prepare for VM maintenance.

### Quick test

For a quick test to show how a simulated eviction will work, let's walk through querying the scheduled event service to see what it looks like when you simulate an eviction using PowerShell.

The Scheduled Event service is enabled for your service the first time you make a request for events.

Remote into your VM, and then open a command prompt.

From the command prompt on your VM, type:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

This first response could take up to 2 minutes. From now on, they should display output almost immediately.

From a computer that has the Az PowerShell module installed (like your local machine), simulate an eviction using [Set-AzVM](#). Replace the resource group name and VM name with your own.

```
Set-AzVM -ResourceGroupName "mySpotRG" -Name "mySpotVM" -SimulateEviction
```

The response output will have `Status: Succeeded` if the request was successfully made.

Quickly go back to your remote connection to your Spot Virtual Machine and query the Scheduled Events endpoint again. Repeat the following command until you get an output that contains more information:

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2019-08-01
```

When the Scheduled Event Service gets the eviction notification, you will get a response that looks similar to this:

```
{"DocumentIncarnation":1,"Events":[{"EventId":"A123BC45-1234-5678-AB90-ABCDEF123456","EventStatus":"Scheduled","EventType":"Preempt","ResourceType":"VirtualMachine","Resources":["myspotvm"],"NotBefore":"Tue, 16 Mar 2021 00:58:46 GMT","Description":"","EventSource":"Platform"}]}
```

You can see that `"EventType": "Preempt"`, and the resource is the VM resource `"Resources": ["myspotvm"]`.

You can also see when the VM will be evicted by checking the `"NotBefore"` value. The VM will not be evicted before the time given in `NotBefore`, so that is your window for your application to gracefully close out.

## Next steps

You can also create an Azure Spot Virtual Machine using the [Azure CLI](#), [portal](#) or a [template](#).

Query current pricing information using the [Azure retail prices API](#) for information about Azure Spot Virtual Machine pricing. The `meterName` and `skuName` will both contain `Spot`.

If you encounter an error, see [Error codes](#).

# Deploy Azure Spot Virtual Machines using a Resource Manager template

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Using [Azure Spot Virtual Machines](#) allows you to take advantage of our unused capacity at a significant cost savings. At any point in time when Azure needs the capacity back, the Azure infrastructure will evict Azure Spot Virtual Machines. Therefore, Azure Spot Virtual Machines are great for workloads that can handle interruptions like batch processing jobs, dev/test environments, large compute workloads, and more.

Pricing for Azure Spot Virtual Machines is variable, based on region and SKU. For more information, see VM pricing for [Linux](#) and [Windows](#).

You have option to set a max price you are willing to pay, per hour, for the VM. The max price for an Azure Spot Virtual Machine can be set in US dollars (USD), using up to 5 decimal places. For example, the value `0.98765` would be a max price of \$0.98765 USD per hour. If you set the max price to be `-1`, the VM won't be evicted based on price. The price for the VM will be the current price for Azure Spot Virtual Machines or the price for a standard VM, whichever is less, as long as there is capacity and quota available. For more information about setting the max price, see [Azure Spot Virtual Machines - Pricing](#).

## Use a template

For Azure Spot Virtual Machine template deployments, use `"apiVersion": "2019-03-01"` or later. Add the `priority`, `evictionPolicy` and `billingProfile` properties to in your template:

```
"priority": "Spot",
"evictionPolicy": "Deallocate",
"billingProfile": {
    "maxPrice": -1
}
```

Here is a sample template with the added properties for an Azure Spot Virtual Machine. Replace the resource names with your own and `<password>` with a password for the local administrator account on the VM.

```
{
    "$schema": "http://schema.management.azure.com/schemas/2019-03-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {},
    "variables": {
        "vnetId": "/subscriptions/ec9fcd04-e188-48b9-abfc-
abcd515f1836/resourceGroups/spotVM/providers/Microsoft.Network/virtualNetworks/spotVM",
        "subnetName": "default",
        "networkInterfaceName": "spotVMNIC",
        "publicIpAddressName": "spotVM-ip",
        "publicIpAddressType": "Dynamic",
        "publicIpAddressSku": "Basic",
        "virtualMachineName": "spotVM",
        "osDiskType": "Premium_LRS",
        "virtualMachineSize": "Standard_D2s_v3",
        "adminUsername": "azureuser",
        "adminPassword": "<password>",
        "diagnosticsStorageAccountName": "diagstoragespot2019",
```

```

    "diagnosticsStorageAccountId": "Microsoft.Storage/storageAccounts/diagstoragespot2019",
    "diagnosticsStorageAccountType": "Standard_LRS",
    "diagnosticsStorageAccountKind": "Storage",
    "subnetRef": "[concat(variables('vnetId'), '/subnets/', variables('subnetName'))]"
},
"resources": [
{
    "name": "spotVM",
    "type": "Microsoft.Network/networkInterfaces",
    "apiVersion": "2019-03-01",
    "location": "eastus",
    "dependsOn": [
        "[concat('Microsoft.Network/publicIpAddresses/', variables('publicIpAddressName'))]"
    ],
    "properties": {
        "ipConfigurations": [
            {
                "name": "ipconfig1",
                "properties": {
                    "subnet": {
                        "id": "[variables('subnetRef')]"
                    },
                    "privateIPAllocationMethod": "Dynamic",
                    "publicIpAddress": {
                        "id": "[resourceId(resourceGroup().name,
'Microsoft.Network/publicIpAddresses', variables('publicIpAddressName'))]"
                    }
                }
            }
        ]
    }
},

}

```

## Simulate an eviction

You can [simulate an eviction](#) of an Azure Spot Virtual Machine, to testing how well your application will respond to a sudden eviction.

Replace the following with your information:

- 
- 
- 

```

POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}/simulateEviction?api-version=2020-06-01

```

## Next steps

You can also create an Azure Spot Virtual Machine using [Azure PowerShell](#) or the [Azure CLI](#).

Query current pricing information using the [Azure retail prices API](#) for information about Azure Spot Virtual Machine pricing. The `meterName` and `skuName` will both contain `Spot`.

If you encounter an error, see [Error codes](#).

# Spot Virtual Machine size recommendation

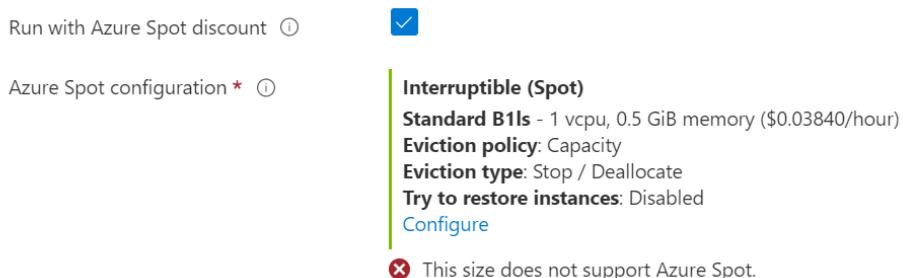

9/21/2022 • 2 minutes to read • [Edit Online](#)

The Spot VM size recommendations tool is an easy way to view and select alternative VM sizes that are better suited for your stateless, flexible, and fault tolerant workload needs during the Virtual Machine Scale Set deployment process in the Azure portal. This tool allows Azure to recommend appropriate VM sizes to you after you filter by region, price, and eviction rate. You can further filter the recommended VMs list by size, type, generation, and disk (premium or ephemeral OS disk).

## Azure portal

You can access Azure's size recommendations through the virtual machine scale sets creation process in the Azure portal. The following steps will instruct you on how to access this tool during that process.

1. Log in to the [Azure portal](#).
2. In the search bar, search for and select **Virtual machine scale sets**.
3. Select **Create** on the **Virtual machine scale sets** page.
4. In the **Basics** tab, fill out the required fields.
5. Under **Instance details**, select **Run with Azure Spot discount**.

6. In the same section, under **Azure Spot configuration**, select **Configure**.
7. On the **Azure Spot configuration** page, in the **Spot details** tab, go to the **Size** selector.
8. Expand the **Size** drop-down and select **See all sizes** option at the bottom of the list.

## Azure Spot configuration

(USD) \*Size (i)

This size does not support Azure Spot.

9. On the **Select a VM size** page, click **Add filter**.

10. You can choose which filters to apply. For this example, we will only apply **Size** and set it to *Medium (7-16)* for the number of vCPU.

11. Click **OK**.

12. From the resulting list of VMs, select a preferred VM size.

13. Click **Select** at the bottom to continue.

14. Back on the **Spot details** tab, click **Next** to go to the next tab.

15. The **Size recommendations** tab allows you to view and select alternative VM sizes that are better suited for your stateless, flexible, and fault tolerant workload needs with regard to region, pricing, and eviction rates.

## Azure Spot configuration

# Error messages for Azure Spot Virtual Machines and scale sets

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Here are some possible error codes you could receive when using Azure Spot Virtual Machines and scale sets.

KEY	MESSAGE	DESCRIPTION
SkuNotAvailable	The requested tier for resource '<resource>' is currently not available in location '<location>' for subscription '<subscriptionID>'. Try another tier or deploy to a different location.	There is not enough Azure Spot Virtual Machine capacity in this location to create your VM or scale set instance.
EvictionPolicyCanBeSetOnlyOnAzureSpotVirtualMachines	Eviction policy can be set only on Azure Spot Virtual Machines.	This VM is not an Azure Spot Virtual Machine, so you can't set the eviction policy.
AzureSpotVMNotSupportedInAvailabilitySet	Azure Spot Virtual Machine is not supported in Availability Set.	You need to choose to either use an Azure Spot Virtual Machine or use a VM in an availability set, you can't choose both.
AzureSpotFeatureNotEnabledForSubscription	Subscription not enabled with Azure Spot Virtual Machine feature.	Use a subscription that supports Azure Spot Virtual Machines.
VMPriorityCannotBeApplied	The specified priority value '{0}' cannot be applied to the Virtual Machine '{1}' since no priority was specified when the Virtual Machine was created.	Specify the priority when the VM is created.
SpotPriceGreater ThanProvidedMaxPrice	Unable to perform operation '{0}' since the provided max price '{1} USD' is lower than the current spot price '{2} USD' for Azure Spot Virtual Machine size '{3}'.	Select a higher max price. For more information, see pricing information for <a href="#">Linux</a> or <a href="#">Windows</a> .
MaxPriceValueInvalid	Invalid max price value. The only supported values for max price are -1 or a decimal greater than zero. Max price value of -1 indicates the Azure Spot Virtual Machine will not be evicted for price reasons.	Enter a valid max price. For more information, see pricing for <a href="#">Linux</a> or <a href="#">Windows</a> .
MaxPriceChangeNotAllowedForAllocatedVMs	Max price change is not allowed when the VM '{0}' is currently allocated. Deallocate and try again.	Stop\Deallocate the VM so that you can change the max price.
MaxPriceChangeNotAllowed	Max price change is not allowed.	You cannot change the max price for this VM.

KEY	MESSAGE	DESCRIPTION
AzureSpotIsNotSupportedForThisAPIVersion	Azure Spot Virtual Machine is not supported for this API version.	The API version needs to be 2019-03-01.
AzureSpotIsNotSupportedForThisVMSize	Azure Spot Virtual Machine is not supported for this VM size {0}.	Select another VM size. For more information, see <a href="#">Azure Spot Virtual Machines</a> .
MaxPriceIsSupportedOnlyForAzureSpotVirtualMachines	Max price is supported only for Azure Spot Virtual Machines.	For more information, see <a href="#">Azure Spot Virtual Machines</a> .
MoveResourcesWithAzureSpotVMNotSupported	The Move resources request contains an Azure Spot Virtual Machine. Not supported. Check the error details for virtual machine Ids.	You cannot move Azure Spot Virtual Machines.
MoveResourcesWithAzureSpotVmssNotSupported	The Move resources request contains an Azure Spot virtual machine scale set. Not supported. Check the error details for virtual machine scale set Ids.	You cannot move Azure Spot virtual machine scale set instances.
AzureSpotVMNotSupportedInVmssWithVMOrchestrationMode	Azure Spot Virtual Machine is not supported in Virtual machine scale set with VM Orchestration mode.	Set the orchestration mode to virtual machine scale set in order to use Azure Spot Virtual Machine instances.
SpotRestorationIsNotSupportedForThisAPIVersion	Spot restoration feature is not supported for this API version.	<p>For an existing scaleset, perform a PATCH using API version 2021-07-01 or later.</p> <p>For new scale set deployments, add the following property to the Azure Resource Manager template using API version 2021-07-01 or later:</p> <pre>{   "properties":{     "spotRestorePolicy":{       "enabled":false,       "restoreTimeout":"PT48H"     }   } }</pre>
SpotRestorationIsSupportedOnlyForAzureSpotScaleSets	Spot restoration feature is supported only for Azure Spot virtual machine scale sets.	Spot restoration feature is only supported for Azure Spot virtual machine scale sets. To use this feature, deploy Azure Spot using virtual machine scale sets.

**Next steps** For more information, see [spot Virtual Machines](#).

# Explore Azure Hybrid Benefit for pay-as-you-go Linux virtual machines

9/21/2022 • 11 minutes to read • [Edit Online](#)

Azure Hybrid Benefit for pay-as-you-go virtual machines or virtual machine scale sets (Flexible orchestration mode only) is an optional licensing benefit. It significantly reduces the cost of running Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server (SLES) virtual machines in the cloud.

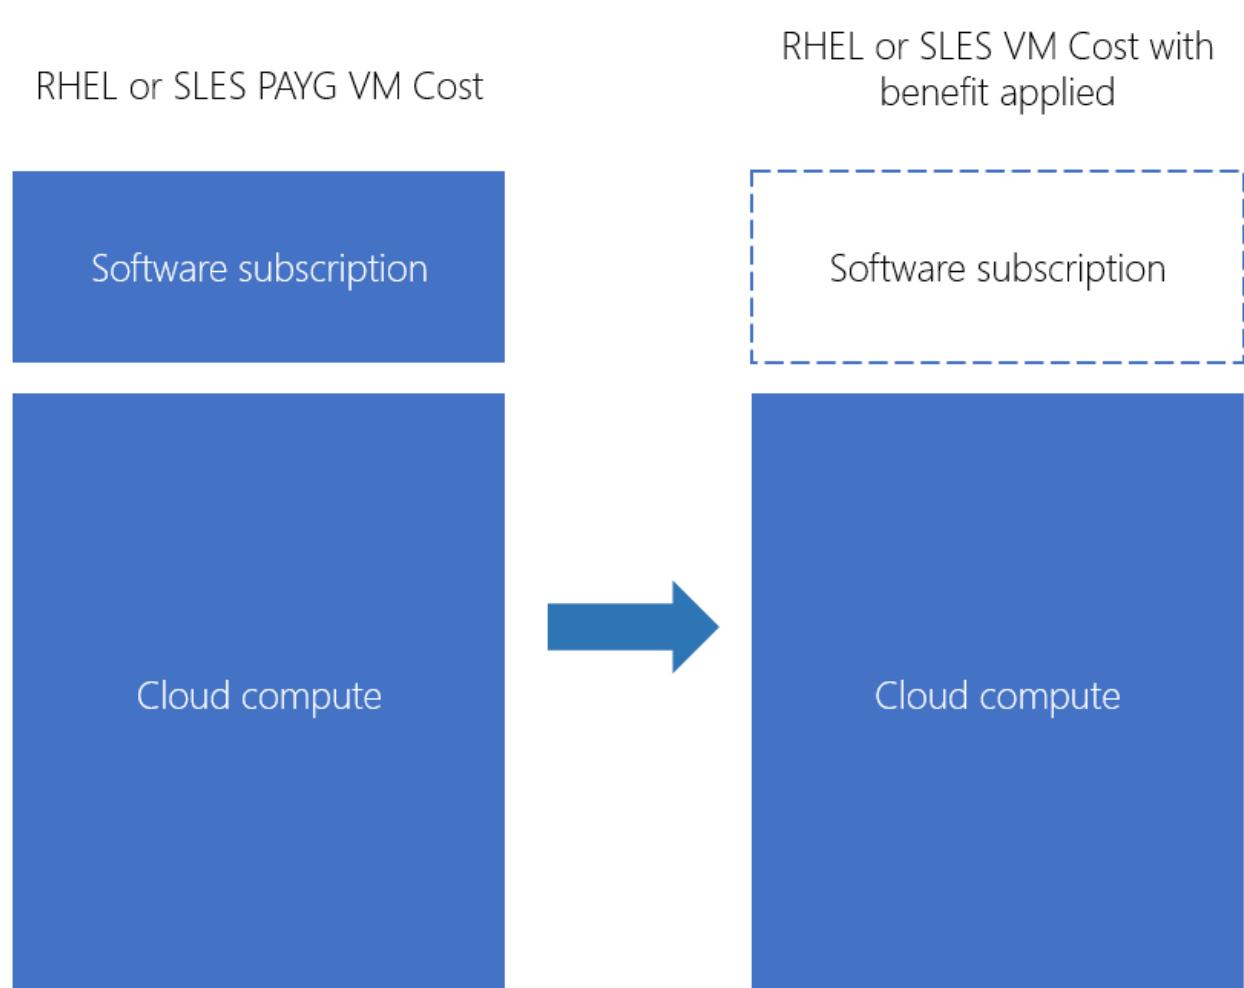

This article explores how to use Azure Hybrid Benefit to switch your virtual machines or virtual machine scale sets (Flexible orchestration mode only) to RHEL bring-your-own-subscription (BYOS) and SLES BYOS billing. With this benefit, your RHEL or SLES subscription covers your software fee. So you pay only infrastructure costs for your virtual machine.

## IMPORTANT

To do the reverse and switch from BYOS to pay-as-you-go billing, see [Explore Azure Hybrid Benefit for bring-your-own-subscription Linux virtual machines](#).

## How does Azure Hybrid Benefit work?

Virtual machines deployed from pay-as-you-go images on Azure incur both an infrastructure fee and a software fee. You can convert existing RHEL and SLES pay-as-you-go virtual machines to BYOS billing by using Azure Hybrid Benefit without having to redeploy.

After you apply Azure Hybrid Benefit to your RHEL or SLES virtual machine, you're no longer charged a software fee. Your virtual machine is charged a BYOS fee instead. You can use Azure Hybrid Benefit to switch back to pay-as-you-go billing at any time.

## Which Linux virtual machines qualify for Azure Hybrid Benefit?

Azure Hybrid Benefit for pay-as-you-go virtual machines is available for all RHEL and SLES pay-as-you-go images in Azure Marketplace.

Azure dedicated host instances and SQL hybrid benefits are not eligible for Azure Hybrid Benefit if you already use Azure Hybrid Benefit with Linux virtual machines.

## Get started

### Apply Azure Hybrid Benefit to Red Hat

Azure Hybrid Benefit for pay-as-you-go virtual machines for RHEL is available to Red Hat customers who meet the following criteria:

- Have active or unused RHEL subscriptions that are eligible for use in Azure
- Have correctly enabled one or more of their subscriptions for use in Azure with the [Red Hat Cloud Access](#) program

To start using Azure Hybrid Benefit for Red Hat:

1. Enable one or more of your eligible RHEL subscriptions for use in Azure by using the [Red Hat Cloud Access customer interface](#).

The Azure subscriptions that you provide during the Red Hat Cloud Access enablement process will then be permitted to use Azure Hybrid Benefit.

2. Apply Azure Hybrid Benefit to any RHEL pay-as-you-go virtual machines that you deploy in Azure Marketplace pay-as-you-go images. You can use the Azure portal or the Azure CLI to enable Azure Hybrid Benefit.
3. Follow the recommended [next steps](#) to configure update sources for your RHEL virtual machines and for RHEL subscription compliance guidelines.

### Apply Azure Hybrid Benefit to SUSE

Azure Hybrid Benefit for pay-as-you-go virtual machines for SUSE is available to customers who have:

- Unused SUSE subscriptions that are eligible to use in Azure.
- One or more active SUSE subscriptions to use on-premises that should be moved to Azure.
- Purchased subscriptions that they activated in the SUSE Customer Center to use in Azure.

#### IMPORTANT

Ensure that you select the correct subscription to use in Azure.

To start using Azure Hybrid Benefit for SUSE:

1. Register the subscription that you purchased from SUSE or a SUSE distributor with the [SUSE Customer Center](#).
2. Activate the subscription in the SUSE Customer Center.
3. Register your virtual machines that are receiving Azure Hybrid Benefit with the SUSE Customer Center to get the updates from the SUSE Customer Center.

# Enable Azure Hybrid Benefit in the Azure portal

In the Azure portal, you can enable Azure Hybrid Benefit on existing virtual machines or on new virtual machines at the time that you create them.

## Enable Azure Hybrid Benefit on an existing virtual machine in the Azure portal

To enable Azure Hybrid Benefit on an existing virtual machine:

1. Go to the [Azure portal](#).
2. Open the virtual machine page on which you want to apply the conversion.
3. Go to **Configuration > Licensing**. To enable the Azure Hybrid Benefit conversion, select **Yes**, and then select the confirmation checkbox.

The screenshot shows the Azure portal interface for managing a virtual machine. The left sidebar lists various settings like Overview, Activity log, and Configuration. The Configuration section is currently selected. In the main content area, under the 'Licensing' heading, there is a note about Red Hat Enterprise Linux subscriptions. Below this, there are two radio buttons for 'Would you like to use an existing Red Hat Enterprise Linux subscription?': 'Yes' (selected) and 'No'. A checkbox below the radio buttons is checked, stating 'I confirm I have an eligible Red Hat Enterprise Linux subscription to attach to this VM.' A red box highlights this checkbox. At the bottom of the configuration section, there is a note about proximity placement groups.

## Enable Azure Hybrid Benefit when you create a virtual machine in the Azure portal

To enable Azure Hybrid Benefit when you create a virtual machine, use the following procedure. (The SUSE workflow is the same as the RHEL example shown here.)

1. Go to the [Azure portal](#).
2. Go to [Create a virtual machine](#).

Home &gt; New &gt;

## Create a virtual machine

Username \* ⓘ  ✓

SSH public key source  ▾

Key pair name \*

**Inbound port rules**

Select which virtual machine network ports are accessible from the public internet. You can specify more limited or granular network access on the Networking tab.

Public inbound ports \* ⓘ  None  Allow selected ports

Select inbound ports \*  ▾

**⚠ This will allow all IP addresses to access your virtual machine.** This is only recommended for testing. Use the Advanced controls in the Networking tab to create rules to limit inbound traffic to known IP addresses.

### Licensing

If you have eligible Red Hat Enterprise Linux subscriptions that are enabled for Red Hat Cloud Access, you can use Azure Hybrid Benefit to attach your Red Hat subscriptions to this VM and save money on compute costs [Learn more ↗](#)

Would you like to use an existing Red Hat  Enterprise Linux subscription? \*

3. In the **Licensing** section, select the checkbox that asks if you want to use an existing RHEL subscription and the checkbox to confirm that your subscription is eligible.

### Licensing

If you have eligible Red Hat Enterprise Linux subscriptions that are enabled for Red Hat Cloud Access, you can use Azure Hybrid Benefit to attach your Red Hat subscriptions to this VM and save money on compute costs [Learn more ↗](#)

Would you like to use an existing Red Hat  Enterprise Linux subscription? \*

I confirm I have an eligible Red Hat Enterprise Linux subscription to attach to this VM. \*

4. Create a virtual machine by following the next set of instructions.

5. On the Configuration pane, confirm that the option is enabled.

Just-in-time VM access  
To improve security, enable just-in-time VM access.  
[Upgrade your Security Center subscription to enable a just-in-time access](#)

**Licensing**

If you have eligible Red Hat Enterprise Linux subscriptions that are enabled for Red Hat Cloud Access, you can use Azure Hybrid Benefit to attach your Red Hat subscriptions to this VM and save money on compute costs. [Learn more about Azure Hybrid Benefit](#)

Would you like to use an existing Red Hat Enterprise Linux subscription? \*

Yes  No

I confirm I have an eligible Red Hat Enterprise Linux subscription to attach to this VM. \*

Proximity placement group  
Proximity placement group ⓘ  
No proximity placement groups found

Proximity placement group can only be updated when the virtual machine is deallocated.

## Enable and disable Azure Hybrid Benefit by using the Azure CLI

You can use the `az vm update` command to update existing virtual machines. For RHEL virtual machines, run the command with a `--license-type` parameter of `RHEL_BYOS`. For SLES virtual machines, run the command with a `--license-type` parameter of `SLES_BYOS`.

### Enable Azure Hybrid Benefit by using the Azure CLI

```
# This will enable Azure Hybrid Benefit on a RHEL virtual machine
az vm update -g myResourceGroup -n myVmName --license-type RHEL_BYOS

# This will enable Azure Hybrid Benefit on a SLES virtual machine
az vm update -g myResourceGroup -n myVmName --license-type SLES_BYOS
```

### Disable Azure Hybrid Benefit by using the Azure CLI

To disable Azure Hybrid Benefit, use a `--license-type` value of `None`:

```
# This will disable Azure Hybrid Benefit on a virtual machine
az vm update -g myResourceGroup -n myVmName --license-type None
```

### Enable Azure Hybrid Benefit on a large number of virtual machines by using the Azure CLI

To enable Azure Hybrid Benefit on a large number of virtual machines, you can use the `--ids` parameter in the Azure CLI:

```
# This will enable Azure Hybrid Benefit on a RHEL virtual machine. In this example, ids.txt is an
# existing text file that contains a delimited list of resource IDs corresponding
# to the virtual machines using Azure Hybrid Benefit
az vm update -g myResourceGroup -n myVmName --license-type RHEL_BYOS --ids $(cat ids.txt)
```

The following examples show two methods of getting a list of resource IDs: one at the resource group level, and one at the subscription level.

```
# To get a list of all the resource IDs in a resource group:  
$(az vm list -g MyResourceGroup --query "[].id" -o tsv)  
  
# To get a list of all the resource IDs of virtual machines in a subscription:  
az vm list -o json | jq '.[] | {Virtual MachineName: .name, ResourceID: .id}'
```

## Apply Azure Hybrid Benefit to pay-as-you-go virtual machines at creation time

In addition to applying Azure Hybrid Benefit to existing pay-as-you-go virtual machines, you can invoke it at the time of virtual machine creation. Benefits of doing so are threefold:

- You can provision both pay-as-you-go and BYOS virtual machines by using the same image and process.
- It enables future licensing mode changes. These changes aren't available with a BYOS-only image or if you bring your own virtual machine.
- The virtual machine will be connected to Red Hat Update Infrastructure (RHUI) by default, to help keep it up to date and secure. You can change the updated mechanism after deployment at any time.

## Check the Azure Hybrid Benefit status of a virtual machine

You can view the Azure Hybrid Benefit status of a virtual machine by using the Azure CLI or by using Azure Instance Metadata Service.

### Check status by using the Azure CLI

You can use the `az vm get-instance-view` command to check the status. Look for a `licenseType` field in the response. If the `licenseType` field exists and the value is `RHEL_BYOS` or `SLES_BYOS`, your virtual machine has Azure Hybrid Benefit enabled.

```
az vm get-instance-view -g MyResourceGroup -n MyVm
```

### Check status by using Azure Instance Metadata Service

From within the virtual machine itself, you can query the attested metadata in Azure Instance Metadata Service to determine the virtual machine's `licenseType` value. A `licenseType` value of `RHEL_BYOS` or `SLES_BYOS` indicates that your virtual machine has Azure Hybrid Benefit enabled. [Learn more about attested metadata](#).

## Compliance

### Red Hat compliance

Customers who use Azure Hybrid Benefit for pay-as-you-go RHEL virtual machines agree to the standard [legal terms](#) and [privacy statement](#) associated with the Azure Marketplace RHEL offers.

Customers who use Azure Hybrid Benefit for pay-as-you-go RHEL virtual machines have three options for providing software updates and patches to those virtual machines:

- [Red Hat Update Infrastructure](#) (default option)
- Red Hat Satellite Server
- Red Hat Subscription Manager

Customers who choose the RHUI option can continue to use RHUI as the main update source for Azure Hybrid Benefit for pay-as-you-go RHEL virtual machines without attaching RHEL subscriptions to those virtual machines. Customers who choose the RHUI option are responsible for ensuring RHEL subscription compliance.

Customers who choose either Red Hat Satellite Server or Red Hat Subscription Manager should remove the

RHUI configuration and then attach a cloud-access-enabled RHEL subscription to Azure Hybrid Benefit for pay-as-you-go RHEL virtual machines.

For more information about Red Hat subscription compliance, software updates, and sources for Azure Hybrid Benefit for pay-as-you-go RHEL virtual machines, see the [Red Hat article about using RHEL subscriptions with Azure Hybrid Benefit](#).

## SUSE compliance

To use Azure Hybrid Benefit for pay-as-you-go SLES virtual machines, and to get information about moving from SLES pay-as-you-go to BYOS or moving from SLES BYOS to pay-as-you-go, see [SUSE Linux Enterprise and Azure Hybrid Benefit](#).

Customers who use Azure Hybrid Benefit for pay-as-you-go SLES virtual machines need to move the cloud update infrastructure to one of three options that provide software updates and patches to those virtual machines:

- [SUSE Customer Center](#)
- SUSE Manager
- SUSE Repository Mirroring Tool

## Apply Azure Hybrid Benefit for pay-as-you-go virtual machines on reserved instances

[Azure reservations](#) (Azure Reserved Virtual Machine Instances) help you save money by committing to one-year or three-year plans for multiple products. Azure Hybrid Benefit for pay-as-you-go virtual machines is available for reserved instances.

This means that if you've purchased compute costs at a discounted rate by using reserved instances, you can apply Azure Hybrid Benefit on the licensing costs for RHEL and SUSE on top of it. The steps to apply Azure Hybrid Benefit for a reserved instance remain exactly same as they are for a regular virtual machine.

The screenshot shows the Microsoft Azure portal interface. At the top, there's a blue header bar with the Microsoft Azure logo and a navigation menu. Below the header, the URL 'Home > Reservations >' is visible. The main title is 'Purchase reservations'. Underneath, there are two tabs: 'Products' (which is underlined in blue) and 'Review + buy'. A sub-section title 'Receive discounts on your Azure services by purchasing reservations. See FAQs' is followed by a 'Filter by name...' search bar. A list of service icons and names follows, with 'Virtual machine' highlighted with a red border. Other listed services include SQL Database, Azure Dedicated Host, Azure Managed Disks, SUSE Linux, App Services, Data Factory, Azure Red Hat OpenShift, Azure Data Explorer, Azure Database for PostgreSQL, Azure Blob Storage, and another 'Virtual machine' entry.

Service	Description
Virtual machine	Selected
Azure Blob Storage	
Azure Database for PostgreSQL	
Azure Data Explorer	
Azure Red Hat OpenShift	
Data Factory	
SQL Database	
Azure Dedicated Host	
Azure Managed Disks	
SUSE Linux	
App Services	

## NOTE

If you've already purchased reservations for RHEL or SUSE pay-as-you-go software on Azure Marketplace, please wait for the reservation tenure to finish before using Azure Hybrid Benefit for pay-as-you-go virtual machines.

## Frequently asked questions

*Q: Can I use a license type of `RHEL_BYOS` with a SLES image, or vice versa?*

A: No, you can't. Trying to enter a license type that incorrectly matches the distribution running on your virtual machine will not update any billing metadata. But if you accidentally enter the wrong license type, updating your virtual machine again to the correct license type will still enable Azure Hybrid Benefit.

*Q: I've registered with Red Hat Cloud Access but still can't enable Azure Hybrid Benefit on my RHEL virtual machines. What should I do?*

A: It might take some time for your Red Hat Cloud Access subscription registration to propagate from Red Hat to Azure. If you still see the error after one business day, contact Microsoft support.

*Q: I've deployed a virtual machine by using a RHEL BYOS "golden image." Can I convert the billing on this image from BYOS to pay-as-you-go?*

A: Yes, you can use Azure Hybrid Benefit for BYOS virtual machines to do this. [Learn more about this capability](#).

*Q: I've uploaded my own RHEL or SLES image from on-premises (via Azure Migrate, Azure Site Recovery, or otherwise) to Azure. Can I convert the billing on these images from BYOS to pay-as-you-go?*

A: Yes, you can use Azure Hybrid Benefit for BYOS virtual machines to do this. [Learn more about this capability](#).

*Q: I've uploaded my own RHEL or SLES image from on-premises (via Azure Migrate, Azure Site Recovery, or otherwise) to Azure. Do I need to do anything to benefit from Azure Hybrid Benefit?*

A: No, you don't. RHEL or SLES images that you upload are already considered BYOS, and you're charged only for Azure infrastructure costs. You're responsible for RHEL subscription costs, just as you are for your on-premises environments.

*Q: Can I use Azure Hybrid Benefit for pay-as-you-go virtual machines for Azure Marketplace RHEL and SLES SAP images?*

A: Yes. You can use the license type of `RHEL_BYOS` for RHEL virtual machines and `SLES_BYOS` for conversions of virtual machines deployed from Azure Marketplace RHEL and SLES SAP images.

*Q: Can I use Azure Hybrid Benefit for pay-as-you-go virtual machines on virtual machine scale sets for RHEL and SLES?*

A: Yes. Azure Hybrid Benefit on virtual machine scale sets for RHEL and SLES is available to all users. [Learn more about this benefit and how to use it](#).

*Q: Can I use Azure Hybrid Benefit for pay-as-you-go virtual machines on reserved instances for RHEL and SLES?*

A: Yes. Azure Hybrid Benefit for pay-as-you-go virtual machines on reserved instances for RHEL and SLES is available to all users.

*Q: Can I use Azure Hybrid Benefit for pay-as-you-go virtual machines on a virtual machine deployed for SQL Server on RHEL images?*

A: No, you can't. There's no plan for supporting these virtual machines.

*Q: Can I use Azure Hybrid Benefit on my RHEL for Virtual Datacenters subscription?*

A: No. RHEL for Virtual Datacenters isn't supported on Azure at all, including Azure Hybrid Benefit.

## Common problems

This section lists common problems that you might encounter and steps for mitigation.

ERROR	MITIGATION
"The action could not be completed because our records show that you have not successfully enabled Red Hat Cloud Access on your Azure subscription."	To use Azure Hybrid Benefit with RHEL virtual machines, you must first <a href="#">register your Azure subscriptions with Red Hat Cloud Access</a> .

## Next steps

- [Learn how to create and update virtual machines and add license types \(RHEL\\_BYOS, SLES\\_BYOS\) for Azure Hybrid Benefit by using the Azure CLI](#)
- [Learn about Azure Hybrid Benefit on virtual machine scale sets for RHEL and SLES and how to use it](#)

# Explore Azure Hybrid Benefit for bring-your-own-subscription Linux virtual machines

9/21/2022 • 10 minutes to read • [Edit Online](#)

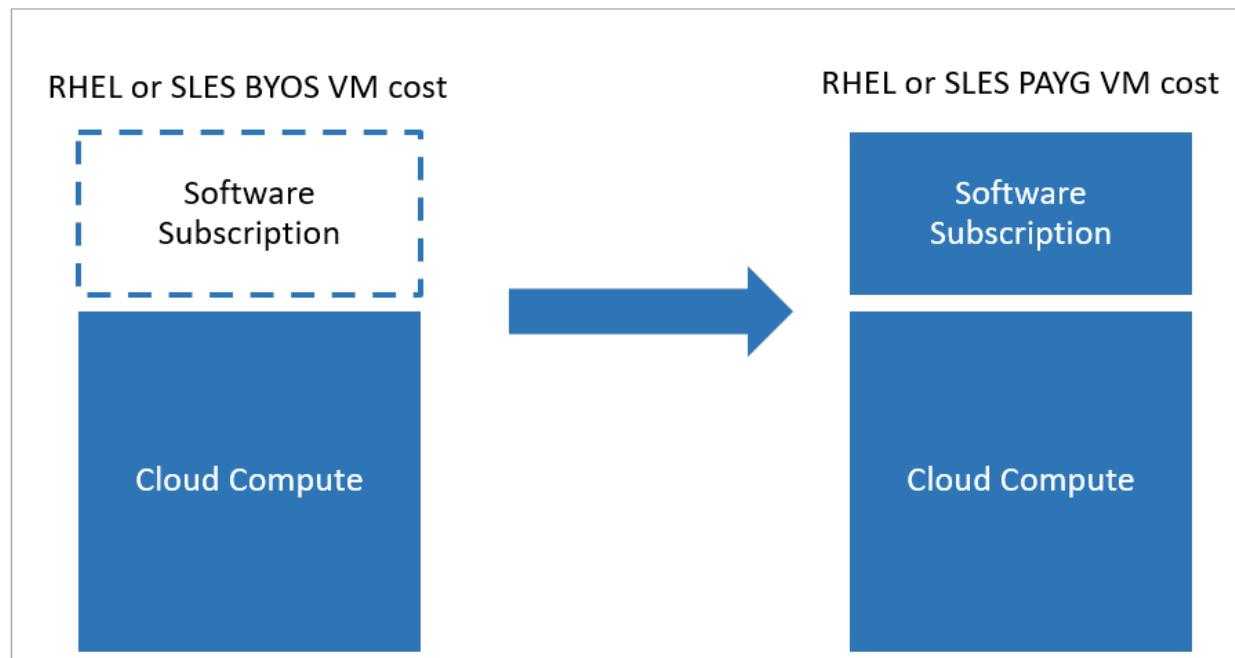

Azure Hybrid Benefit provides software updates and integrated support directly from Azure for Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server (SLES) virtual machines. Azure Hybrid Benefit for bring-your-own-subscription (BYOS) virtual machines is a licensing benefit that lets you switch RHEL and SLES BYOS virtual machines generated from custom on-premises images or from Azure Marketplace to pay-as-you-go billing.

## IMPORTANT

To do the reverse and switch from a RHEL pay-as-you-go virtual machine or SLES pay-as-you-go virtual machine to a BYOS virtual machine, see [Explore Azure Hybrid Benefit for pay-as-you-go Linux virtual machines](#).

## How does Azure Hybrid Benefit work?

Azure Hybrid Benefit converts BYOS billing to pay-as-you-go, so that you pay only pay-as-you-go software fees. You don't have to restart a machine for Azure Hybrid Benefit to be applied.

## Which Linux virtual machines qualify for Azure Hybrid Benefit?

Azure Hybrid Benefit for BYOS virtual machines is available to all RHEL and SLES virtual machines that come from a custom image. It's also available to all RHEL and SLES BYOS virtual machines that come from an Azure Marketplace image.

Azure Dedicated Host instances and SQL hybrid benefits aren't eligible for Azure Hybrid Benefit if you're already using Azure Hybrid Benefit with Linux virtual machines. Virtual machine scale sets are reserved instances, so they also can't use Azure Hybrid Benefit for BYOS virtual machines.

# Get started

## Azure Hybrid Benefit for Red Hat customers

To start using Azure Hybrid Benefit for Red Hat:

1. Install the **AHBForRHEL** extension on the virtual machine on which you want to apply the Azure Hybrid Benefit BYOS benefit. You can do this installation via the Azure CLI or PowerShell.
2. Depending on the software updates that you want, change the license type to a relevant value. Here are the available license type values and the software updates associated with them:

LICENSE TYPE	SOFTWARE UPDATES	ALLOWED VIRTUAL MACHINES
RHEL_BASE	Installs Red Hat regular/base repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines
RHEL_EUS	Installs Red Hat Extended Update Support (EUS) repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines
RHEL_SAPAPPS	Installs RHEL for SAP Business Apps repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines
RHEL_SAPHA	Installs RHEL for SAP with High Availability (HA) repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines
RHEL_BASESAPAPPS	Installs RHEL regular/base SAP Business Apps repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines
RHEL_BASESAPHA	Installs regular/base RHEL for SAP with HA repositories on your virtual machine.	RHEL BYOS virtual machines, RHEL custom image virtual machines

3. Wait one hour for the extension to read the license type value and install the repositories.

### NOTE

If the extension isn't running by itself, you can run it on demand.

4. You should now be connected to Azure Red Hat Update. The relevant repositories will be installed on your machine.
5. If you want to switch back to the bring-your-own-subscription model, just change the license type to **None** and run the extension. This action will remove all Red Hat Update Infrastructure (RHUI) repositories from your virtual machine and stop the billing.

### NOTE

In the unlikely event that the extension can't install repositories or there are any other issues, switch the license type back to empty and reach out to Microsoft support. This ensures that you don't get billed for software updates.

## Azure Hybrid Benefit for SUSE customers

To start using Azure Hybrid Benefit for SLES virtual machines:

1. Install the `AHBForSLES` extension on the virtual machine that will use it.
2. Change the license type to the value that reflects the software updates you want. Here are the available license type values and the software updates associated with them:

LICENSE TYPE	SOFTWARE UPDATES	ALLOWED VIRTUAL MACHINES
SLES	Installs SLES Standard repositories on your virtual machine.	SLES BYOS virtual machines, SLES custom image virtual machines
SLES_SAP	Installs SLES SAP repositories on your virtual machine.	SLES SAP BYOS virtual machines, SLES custom image virtual machines
SLES_HPC	Installs SLES High Performance Computing repositories on your virtual machine.	SLES HPC BYOS virtual machines, SLES custom image virtual machines

3. Wait five minutes for the extension to read the license type value and install the repositories.

**NOTE**

If the extension isn't running by itself, you can run it on demand.

4. You should now be connected to the SUSE public cloud update infrastructure on Azure. The relevant repositories will be installed on your machine.
5. If you want to switch back to the bring-your-own-subscription model, just change the license type to `None` and run the extension. This action will remove all repositories from your virtual machine and stop the billing.

## Enable Azure Hybrid Benefit for RHEL

After you successfully install the `AHBForRHEL` extension, you can use the `az vm update` command to update the existing license type on your running virtual machines. For SLES virtual machines, run the command and set the `--license-type` parameter to one of the following license types: `RHEL_BASE`, `RHEL_EUS`, `RHEL_SAPHA`, `RHEL_SAPAPP`, `RHEL_BASESAPAPP`, or `RHEL_BASESAPHA`.

### Enable Azure Hybrid Benefit for RHEL by using the Azure CLI

1. Install the Azure Hybrid Benefit extension on a running virtual machine. You can use the Azure portal or use the following command via the Azure CLI:

```
az vm extension set -n AHBForRHEL --publisher Microsoft.Azure.AzureHybridBenefit --vm-name myVMName --resource-group myResourceGroup
```

2. After the extension is installed successfully, change the license type based on what you need:

```
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL base/regular repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_BASE  
  
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL EUS repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_EUS  
  
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL SAP APPS repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_SAPAPPS  
  
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL SAP HA repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_SAPHA  
  
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL BASE SAP APPS repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_BASESAPAPPS  
  
# This will enable Azure Hybrid Benefit to fetch software updates for RHEL BASE SAP HA repositories  
az vm update -g myResourceGroup -n myVmName --license-type RHEL_BASESAPHA
```

3. Wait five minutes for the extension to read the license type value and install the repositories.
4. You should now be connected to Red Hat Update Infrastructure. The relevant repositories will be installed on your machine. You can validate the installation by running the following command on your virtual machine:

```
yum repolist
```

5. If the extension isn't running by itself, you can try the following command on the virtual machine:

```
systemctl start azure-hybrid-benefit.service
```

6. You can use the following command in your RHEL virtual machine to get the current status of the service:

```
ahb-service -status
```

## Enable and disable Azure Hybrid Benefit for SLES

After you successfully install the `AHBForSLES` extension, you can use the `az vm update` command to update the existing license type on your running virtual machines. For SLES virtual machines, run the command and set the `--license-type` parameter to one of the following license types: `SLES_STANDARD`, `SLES_SAP`, or `SLES_HPC`.

### Enable Azure Hybrid Benefit for SLES by using the Azure CLI

1. Install the Azure Hybrid Benefit extension on a running virtual machine. You can use the Azure portal or use the following command via the Azure CLI:

```
az vm extension set -n AHBForSLES --publisher SUSE.AzureHybridBenefit --vm-name myVMName --resource-group myResourceGroup
```

2. After the extension is installed successfully, change the license type based on what you need:

```
# This will enable Azure Hybrid Benefit to fetch software updates for SLES Standard repositories  
az vm update -g myResourceGroup -n myVmName --license-type SLES  
  
# This will enable Azure Hybrid Benefit to fetch software updates for SLES SAP repositories  
az vm update -g myResourceGroup -n myVmName --license-type SLES_SAP  
  
# This will enable Azure Hybrid Benefit to fetch software updates for SLES HPC repositories  
az vm update -g myResourceGroup -n myVmName --license-type SLES_HPC
```

3. Wait five minutes for the extension to read the license type value and install the repositories.
4. You should now be connected to the SUSE public cloud update infrastructure on Azure. The relevant repositories will be installed on your machine. You can verify this change by running the following command to list SUSE repositories on your machine:

```
zypper repos
```

### Disable Azure Hybrid Benefit by using the Azure CLI

1. Ensure that the Azure Hybrid Benefit extension is installed on your virtual machine.
2. To disable Azure Hybrid Benefit, use the following command:

```
# This will disable Azure Hybrid Benefit on a virtual machine  
az vm update -g myResourceGroup -n myVmName --license-type None
```

## Check the Azure Hybrid Benefit status of a virtual machine

1. Ensure that the Azure Hybrid Benefit extension is installed.
2. In the Azure CLI or Azure Instance Metadata Service, run the following command:

```
az vm get-instance-view -g MyResourceGroup -n MyVm
```

3. Look for a `licenseType` field in the response. If the `licenseType` field exists and the value is one of the following, your virtual machine has Azure Hybrid Benefit enabled:

`RHEL_BASE` , `RHEL_EUS` , `RHEL_BASESAPAPPS` , `RHEL_SAPHA` , `RHEL_BASESAPAPPS` , `RHEL_BASESAPHA` , `SLES` ,  
`SLES_SAP` , `SLES_HPC`

## Compliance

### Red Hat compliance

Customers who use Azure Hybrid Benefit for BYOS virtual machines for RHEL agree to the standard [legal terms](#) and [privacy statement](#) associated with the Azure Marketplace RHEL offerings.

### SUSE compliance

If you use Azure Hybrid Benefit for BYOS virtual machines for SLES and want more information about moving from SLES pay-as-you-go to BYOS, or moving from SLES BYOS to pay-as-you-go, see [Azure Hybrid Benefit Support](#) on the SUSE website.

## Frequently asked questions

*Q: What is the licensing cost I pay with Azure Hybrid Benefit for BYOS virtual machines?*

A: When you start using Azure Hybrid Benefit for BYOS virtual machines, you'll essentially convert the bring-your-own-subscription billing model to a pay-as-you-go billing model. What you pay will be similar to a software subscription cost for pay-as-you-go virtual machines.

The following table maps the pay-as-you-go options on Azure and links to pricing information to help you understand the cost associated with Azure Hybrid Benefit for BYOS virtual machines. When you go to the pricing pages, keep the Azure Hybrid Benefit for pay-as-you-go filter off.

LICENSE TYPE	RELEVANT PAY-AS-YOU-GO VIRTUAL MACHINE IMAGE AND PRICING LINK
RHEL_BASE	<a href="#">Red Hat Enterprise Linux</a>
RHEL_SAPAPPS	<a href="#">RHEL for SAP Business Applications</a>
RHEL_SAPHA	<a href="#">RHEL for SAP with HA</a>
RHEL_BASESAPAPPS	<a href="#">RHEL for SAP Business Applications</a>
RHEL_BASESAPHA	<a href="#">RHEL for SAP with HA</a>
RHEL_EUS	<a href="#">Red Hat Enterprise Linux</a>
SLES	<a href="#">SLES</a>
SLES_SAP	<a href="#">SLES for SAP</a>
SLES_HPC	<a href="#">SLE HPC</a>

*Q: Can I use a license type designated for RHEL (such as `RHEL_BASE`) with a SLES image, or vice versa?*

A: No, you can't. Trying to enter a license type that incorrectly matches the distribution running on your virtual machine will fail, and you might end up getting billed incorrectly.

If you accidentally enter the wrong license type, remove the billing by changing the license type to empty. Then update your virtual machine to the correct license type to enable Azure Hybrid Benefit.

*Q: What are the supported versions for RHEL with Azure Hybrid Benefit for BYOS virtual machines?*

A: Azure Hybrid Benefit for BYOS virtual machines supports RHEL versions later than 7.4.

*Q: I've uploaded my own RHEL or SLES image from on-premises (via Azure Migrate, Azure Site Recovery, or otherwise) to Azure. Can I convert the billing on these images from BYOS to pay-as-you-go?*

A: Yes, this capability supports images uploaded from on-premises to Azure. Follow the steps in the [Get started](#) section earlier in this article.

*Q: Can I use Azure Hybrid Benefit for BYOS virtual machines on RHEL and SLES pay-as-you-go Azure Marketplace virtual machines?*

A: No, because these virtual machines are already pay-as-you-go. However, with Azure Hybrid Benefit, you can use the license type of `RHEL_BYOS` for RHEL virtual machines and `SLES_BYOS` for conversions of RHEL and SLES pay-as-you-go Azure Marketplace virtual machines. For more information, see [Explore Azure Hybrid Benefit for pay-as-you-go Linux virtual machines](#).

*Q: Can I use Azure Hybrid Benefit for BYOS virtual machines on virtual machine scale sets for RHEL and SLES?*

A: No. Hybrid Benefit for BYOS virtual machines isn't currently available for virtual machine scale sets.

*Q: Can I use Azure Hybrid Benefit for BYOS virtual machines on a virtual machine deployed for SQL Server on RHEL images?*

A: No, you can't. There's no plan for supporting these virtual machines.

*Q: Can I use Azure Hybrid Benefit for BYOS virtual machines on my RHEL for Virtual Datacenters subscription?*

A: No. RHEL for Virtual Datacenters isn't supported on Azure at all, including Azure Hybrid Benefit.
