There are four disk types of Azure managed disks: Azure ultra disks, premium SSD, standard SSD, and standard HDD. You can switch between premium SSD, standard SSD, and standard HDD based on your performance needs. You are not yet able to switch from or to an ultra disk, you must deploy a new one.

This functionality is not supported for unmanaged disks. But you can easily [convert an unmanaged disk to a managed disk](#) to be able to switch between disk types.

## Before you begin

- Because conversion requires a restart of the virtual machine (VM), you should schedule the migration of your disk storage during a pre-existing maintenance window.
- If your disk is unmanaged, first [convert it to a managed disk](#) so you can switch between storage options.

## Switch all managed disks of a VM between from one account to another

This example shows how to convert all of a VM's disks to premium storage. However, by changing the \$storageType variable in this example, you can convert the VM's disks type to standard SSD or standard HDD. To use Premium managed disks, your VM must use a [VM size](#) that supports Premium storage. This example also switches to a size that supports premium storage:

```

# Name of the resource group that contains the VM
$rgName = 'yourResourceGroup'

# Name of your virtual machine
$vmName = 'yourVM'

# Choose between Standard_LRS, StandardSSD_LRS and Premium_LRS based on your scenario
$storageType = 'Premium_LRS'

# Premium capable size
# Required only if converting storage from Standard to Premium
$size = 'Standard_DS2_v2'

# Stop and deallocate the VM before changing the size
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force

$vm = Get-AzVM -Name $vmName -resourceGroupName $rgName

# Change the VM size to a size that supports Premium storage
# Skip this step if converting storage from Premium to Standard
$vm.HardwareProfile.VmSize = $size
Update-AzVM -VM $vm -ResourceGroupName $rgName

# Get all disks in the resource group of the VM
$vmDisks = Get-AzDisk -ResourceGroupName $rgName

# For disks that belong to the selected VM, convert to Premium storage
foreach ($disk in $vmDisks)
{
    if ($disk.ManagedBy -eq $vm.Id)
    {
        $disk.Sku = [Microsoft.Azure.Management.Compute.Models.DiskSku]::new($storageType)
        $disk | Update-AzDisk
    }
}

Start-AzVM -ResourceGroupName $rgName -Name $vmName

```

## Switch individual managed disks between Standard and Premium

For your dev/test workload, you might want a mix of Standard and Premium disks to reduce your costs. You can choose to upgrade only those disks that need better performance. This example shows how to convert a single VM disk from Standard to Premium storage. However, by changing the \$storageType variable in this example, you can convert the VM's disks type to standard SSD or standard HDD. To use Premium managed disks, your VM must use a [VM size](#) that supports Premium storage. This example also shows how to switch to a size that supports Premium storage:

```

$diskName = 'yourDiskName'
# resource group that contains the managed disk
$rgName = 'yourResourceGroupName'
# Choose between Standard_LRS, StandardSSD_LRS and Premium_LRS based on your scenario
$storageType = 'Premium_LRS'
# Premium capable size
$size = 'Standard_DS2_v2'

$disk = Get-AzDisk -DiskName $diskName -ResourceGroupName $rgName

# Get parent VM resource
$vmResource = Get-AzResource -ResourceId $disk.ManagedBy

# Stop and deallocate the VM before changing the storage type
Stop-AzVM -ResourceGroupName $vmResource.ResourceGroupName -Name $vmResource.Name -Force

$vm = Get-AzVM -ResourceGroupName $vmResource.ResourceGroupName -Name $vmResource.Name

# Change the VM size to a size that supports Premium storage
# Skip this step if converting storage from Premium to Standard
$vm.HardwareProfile.VmSize = $size
Update-AzVM -VM $vm -ResourceGroupName $rgName

# Update the storage type
$disk.Sku = [Microsoft.Azure.Management.Compute.Models.DiskSku]::new($storageType)
$disk | Update-AzDisk

Start-AzVM -ResourceGroupName $vm.ResourceGroupName -Name $vm.Name

```

## Switch managed disks from one disk type to another

Follow these steps:

1. Sign in to the [Azure portal](#).
2. Select the VM from the list of **Virtual machines**.
3. If the VM isn't stopped, select **Stop** at the top of the **VM Overview** pane, and wait for the VM to stop.
4. In the pane for the VM, select **Disks** from the menu.
5. Select the disk that you want to convert.
6. Select **Size + performance** from the menu.
7. Change the **Account type** from the original disk type to the desired disk type.
8. Select **Save**, and close the disk pane.

The disk type conversion is instantaneous. You can start your VM after the conversion.

## Next steps

Make a read-only copy of a VM by using a [snapshot](#).

# Use Site Recovery to migrate to Premium Storage

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

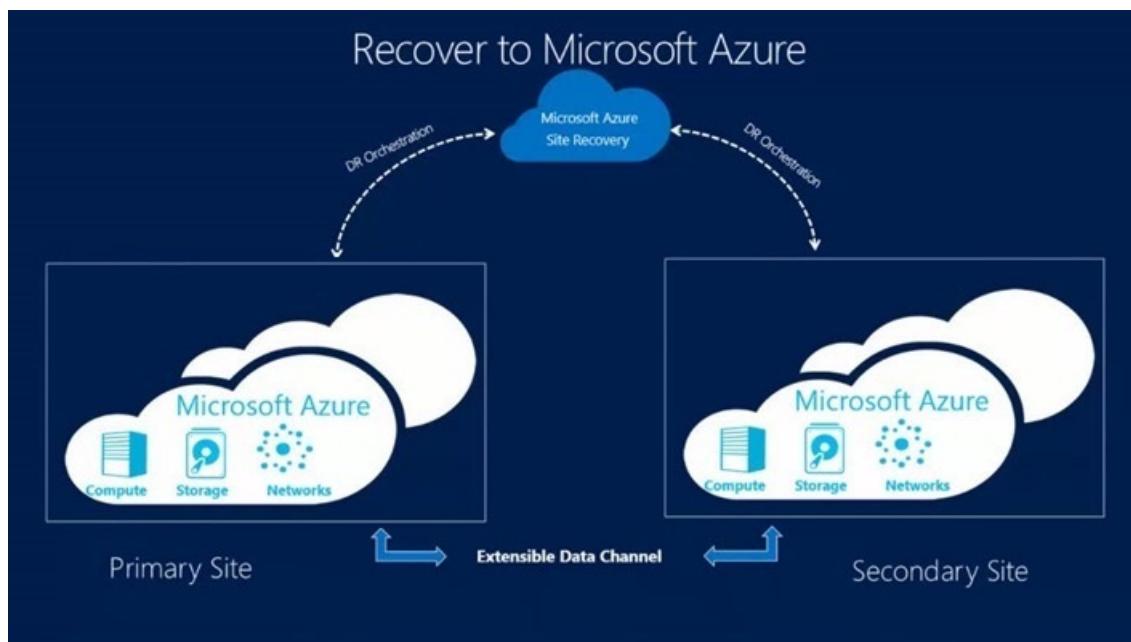

Azure premium SSDs delivers high-performance, low-latency disk support for virtual machines (VMs) that are running I/O-intensive workloads. This guide helps you migrate your VM disks from a standard storage account to a premium storage account by using [Azure Site Recovery](#).

Site Recovery is an Azure service that contributes to your strategy for business continuity and disaster recovery by orchestrating the replication of on-premises physical servers and VMs to the cloud (Azure) or to a secondary datacenter. When outages occur in your primary location, you fail over to the secondary location to keep applications and workloads available. You fail back to your primary location when it returns to normal operation.

Site Recovery provides test failovers to support disaster recovery drills without affecting production environments. You can run failovers with minimal data loss (depending on replication frequency) for unexpected disasters. In the scenario of migrating to Premium Storage, you can use the [failover in Site Recovery](#) to migrate target disks to a premium storage account.

We recommend migrating to Premium Storage by using Site Recovery because this option provides minimal downtime. This option also avoids the manual execution of copying disks and creating new VMs. Site Recovery will systematically copy your disks and create new VMs during failover.

Site Recovery supports a number of types of failover with minimal or no downtime. To plan your downtime and estimate data loss, see the [types of failover in Site Recovery](#). If you [prepare to connect to Azure VMs after failover](#), you should be able to connect to the Azure VM by using RDP after failover.

## Azure Site Recovery components

These Site Recovery components are relevant to this migration scenario:

- **Configuration server** is an Azure VM that coordinates communication and manages data replication and recovery processes. On this VM, you run a single setup file to install the configuration server and an additional component, called a process server, as a replication gateway. Read about [configuration server](#)

prerequisites. You set up the configuration server only once, and you can use it for all migrations to the same region.

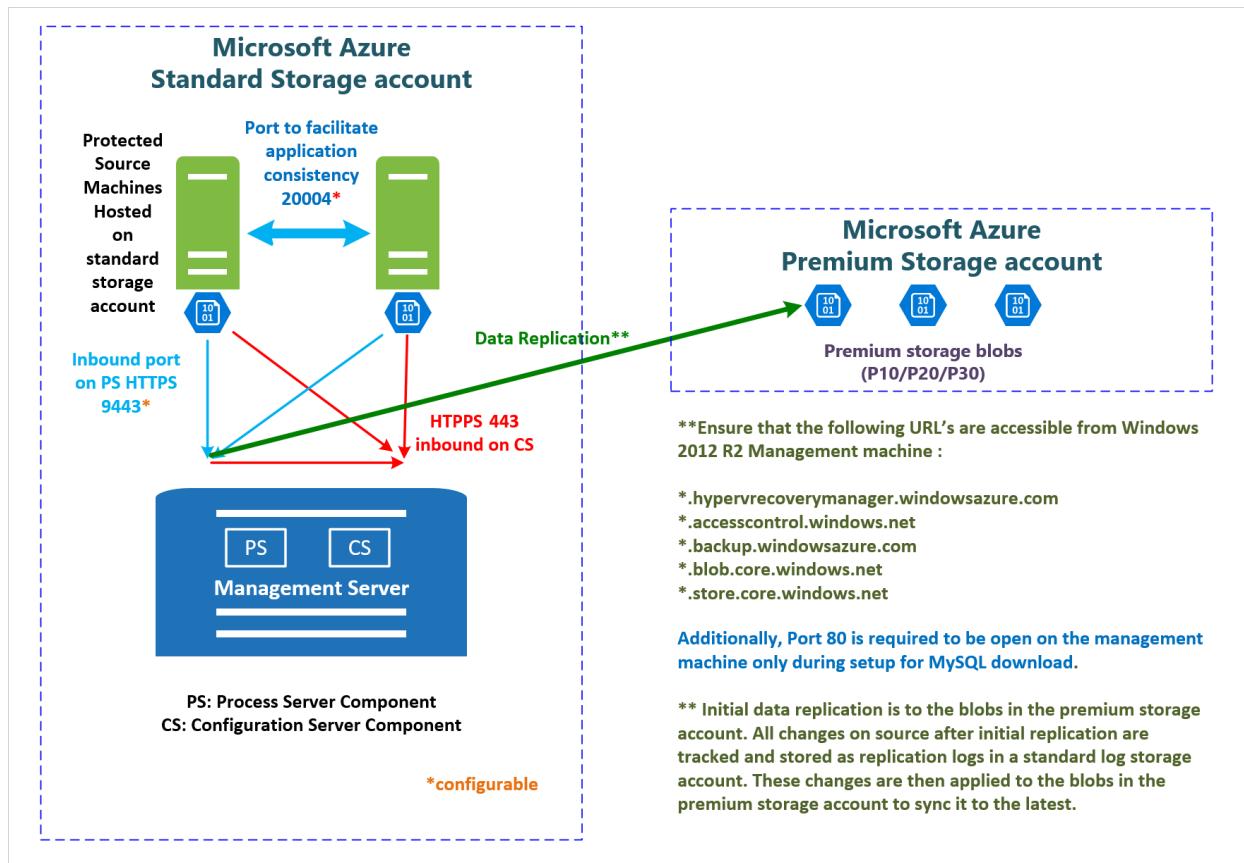

- **Process server** is a replication gateway that:

1. Receives replication data from source VMs.
2. Optimizes the data with caching, compression, and encryption.
3. Sends the data to a storage account.

It also handles push installation of the mobility service to source VMs and performs automatic discovery of source VMs. The default process server is installed on the configuration server. You can deploy additional standalone process servers to scale your deployment. Read about [best practices for process server deployment](#) and [deploying additional process servers](#). You set up the process server only once, and you can use it for all migrations to the same region.

- **Mobility service** is a component that is deployed on every standard VM that you want to replicate. It captures data writes on the standard VM and forwards them to the process server. Read about [replicated machine prerequisites](#).

This graphic shows how these components interact:

#### NOTE

Site Recovery does not support the migration of Storage Spaces disks.

For additional components for other scenarios, see [Scenario architecture](#).

## Azure essentials

These are the Azure requirements for this migration scenario:

- An Azure subscription.

- An Azure premium storage account to store replicated data.
- An Azure virtual network to which VMs will connect when they're created at failover. The Azure virtual network must be in the same region as the one in which Site Recovery runs.
- An Azure standard storage account to store replication logs. This can be the same storage account for the VM disks that are being migrated.

## Prerequisites

- Understand the relevant migration scenario components in the preceding section.
- Plan your downtime by learning about [failover in Site Recovery](#).

## Setup and migration steps

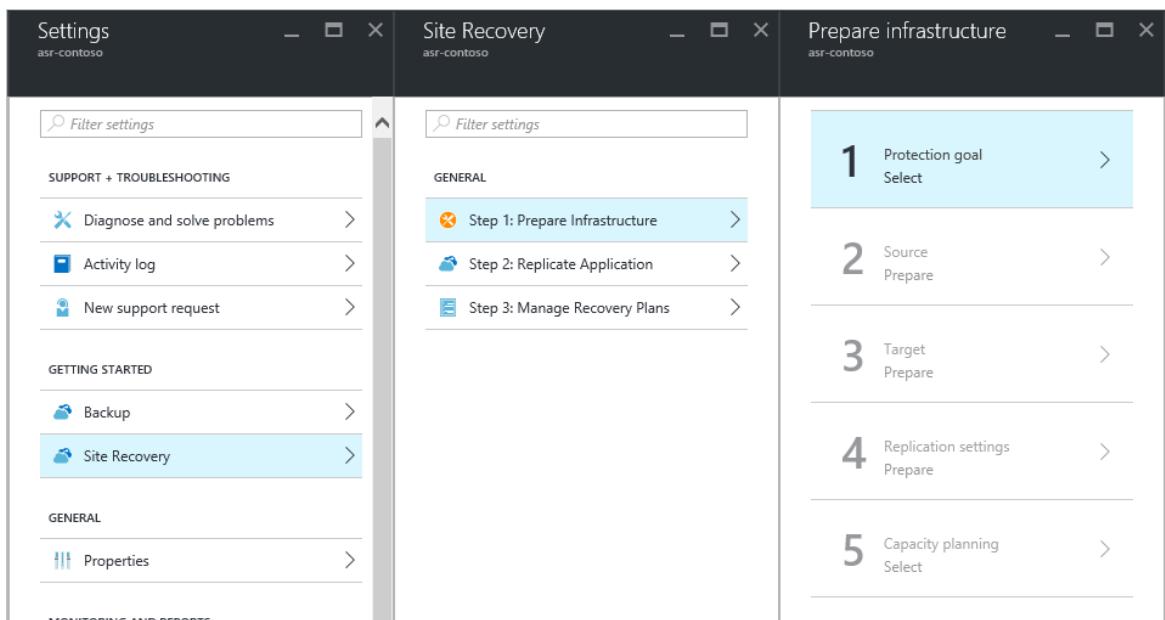

You can use Site Recovery to migrate Azure IaaS VMs between regions or within same region. The following instructions are tailored for this migration scenario from the article [Replicate VMware VMs or physical servers to Azure](#). Please follow the links for detailed steps in addition to the instructions in this article.

### Step 1: Create a Recovery Services vault

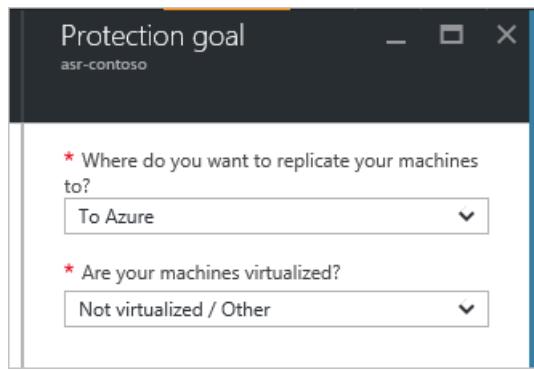

1. Open the [Azure portal](#).
2. Select **Create a resource > Management > Backup and Site Recovery (OMS)**. Alternatively, you can select **Browse > Recovery Services Vault > Add**.
3. Specify a region that VMs will be replicated to. For the purpose of migration in the same region, select the region where your source VMs and source storage accounts are.

### Step 2: Choose your protection goals

1. On the VM where you want to install the configuration server, open the [Azure portal](#).
2. Go to **Recovery Services vaults > Settings > Site Recovery > Step 1: Prepare Infrastructure > Protection goal**.

3. Under **Protection goal**, in the first drop-down list, select **To Azure**. In the second drop-down list, select **Not virtualized / Other**, and then select **OK**.

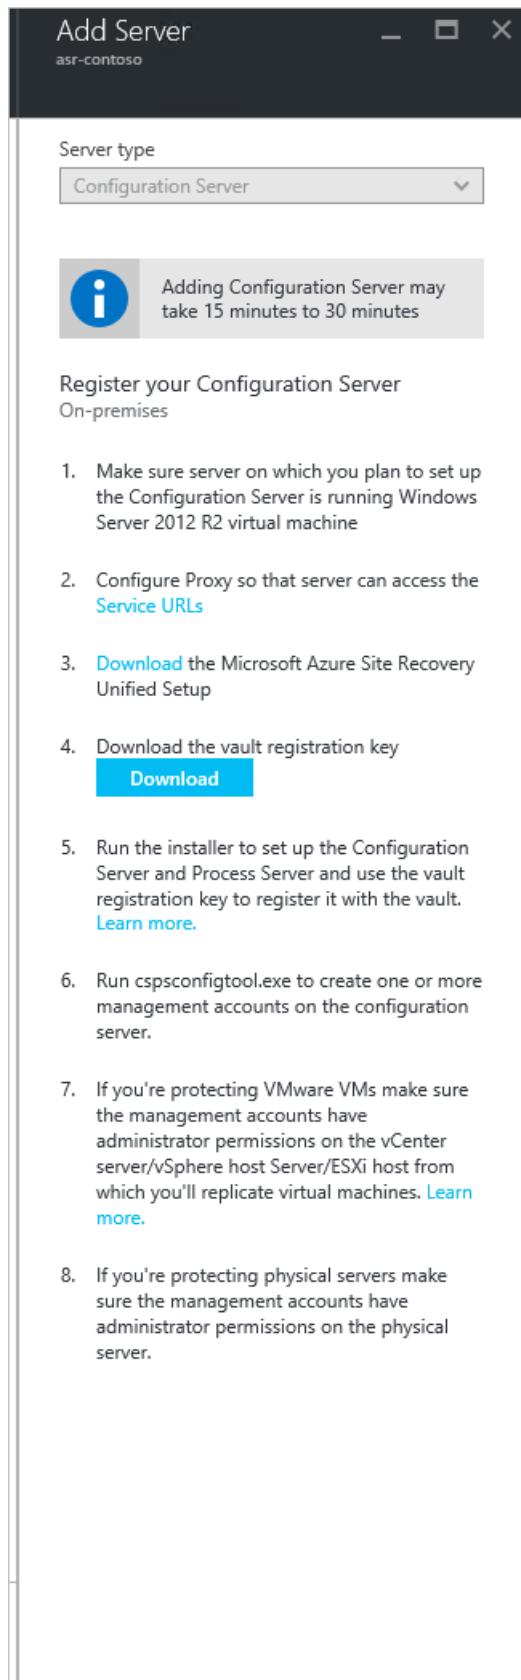

### Step 3: Set up the source environment (configuration server)

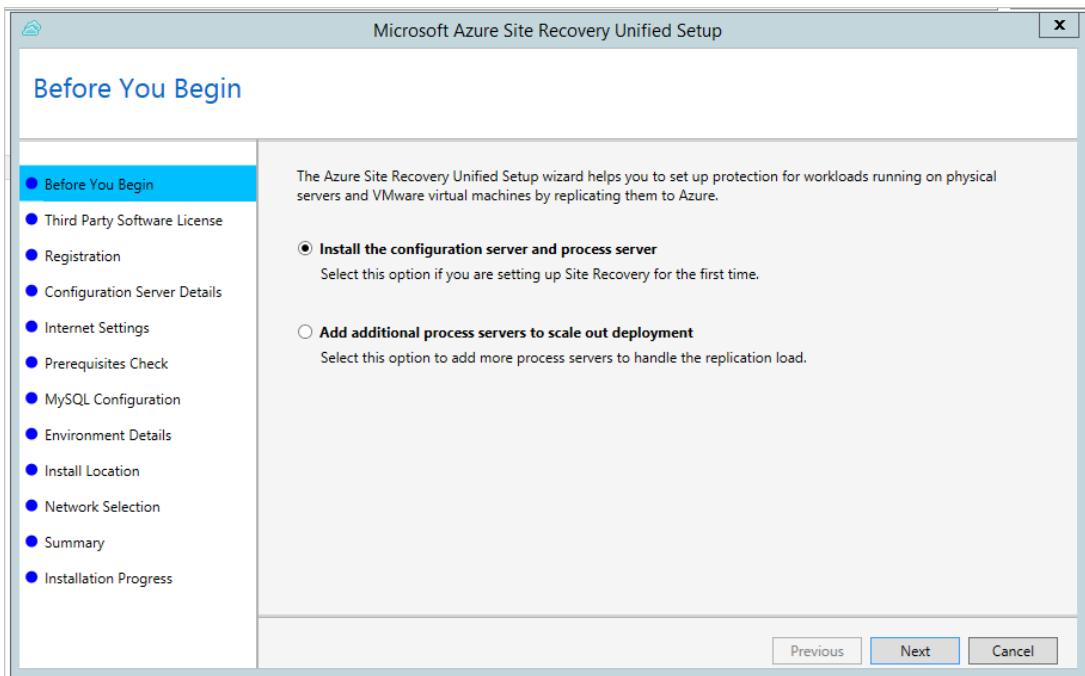

1. Download Azure Site Recovery Unified Setup and the vault registration key by going to the **Prepare infrastructure** > **Prepare source** > **Add Server** panes.

You will need the vault registration key to run the unified setup. The key is valid for five days after you generate it.

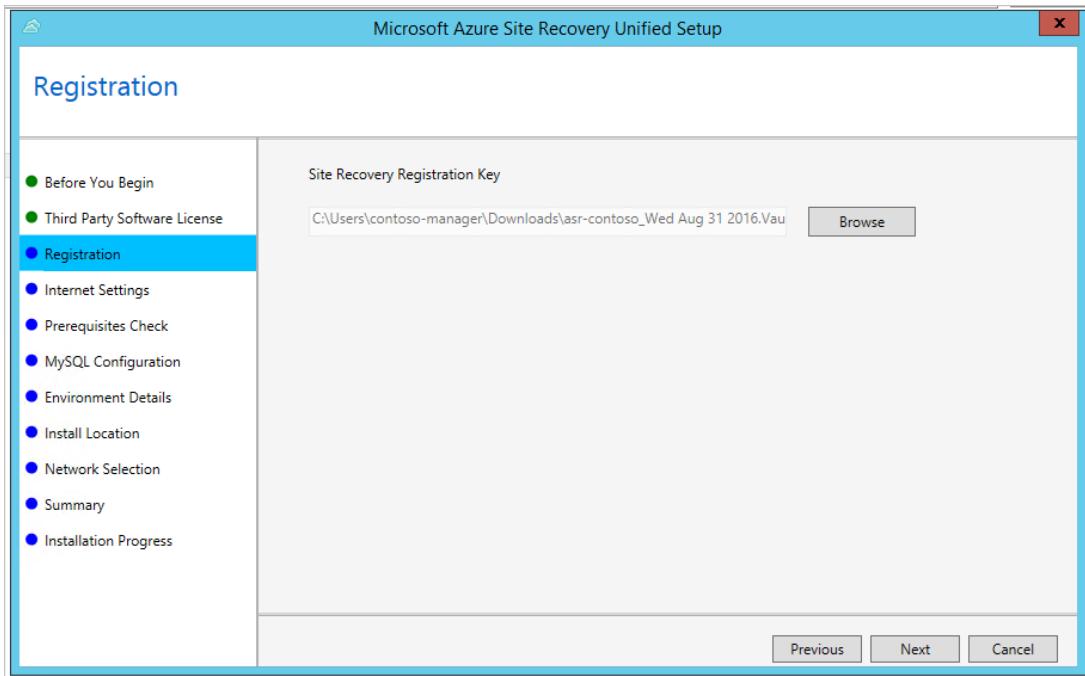

2. In the Add Server pane, add a configuration server.

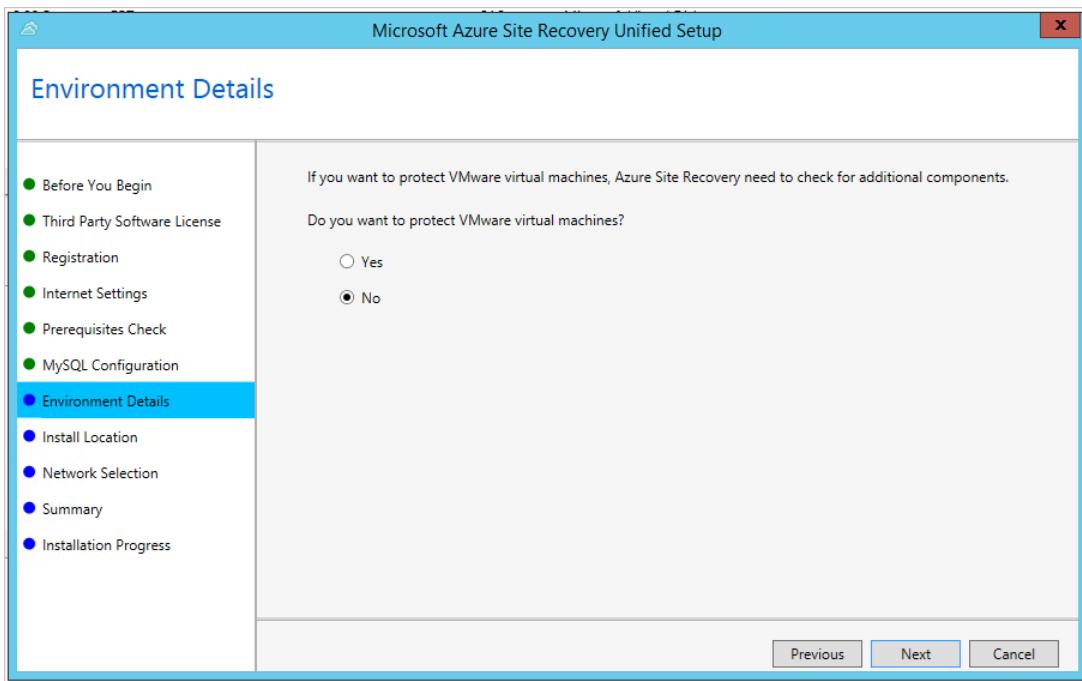

3. On the VM that you're using as the configuration server, run Unified Setup to install the configuration server and the process server. You can [walk through the screenshots](#) to complete the installation. You can refer to the following screenshots for steps specified for this migration scenario.
  - a. In **Before You Begin**, select **Install the configuration server and process server**.

- b. In **Registration**, browse and select the registration key that you downloaded from the vault.

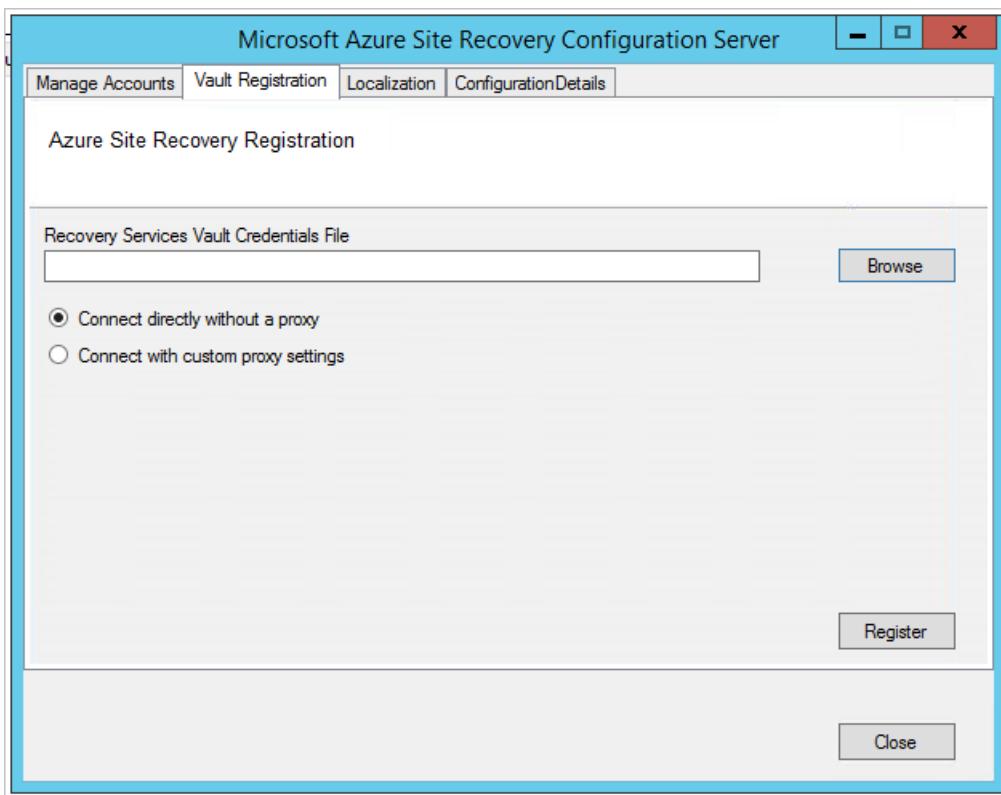

- c. In **Environment Details**, select whether you're going to replicate VMware VMs. For this migration scenario, choose **No**.

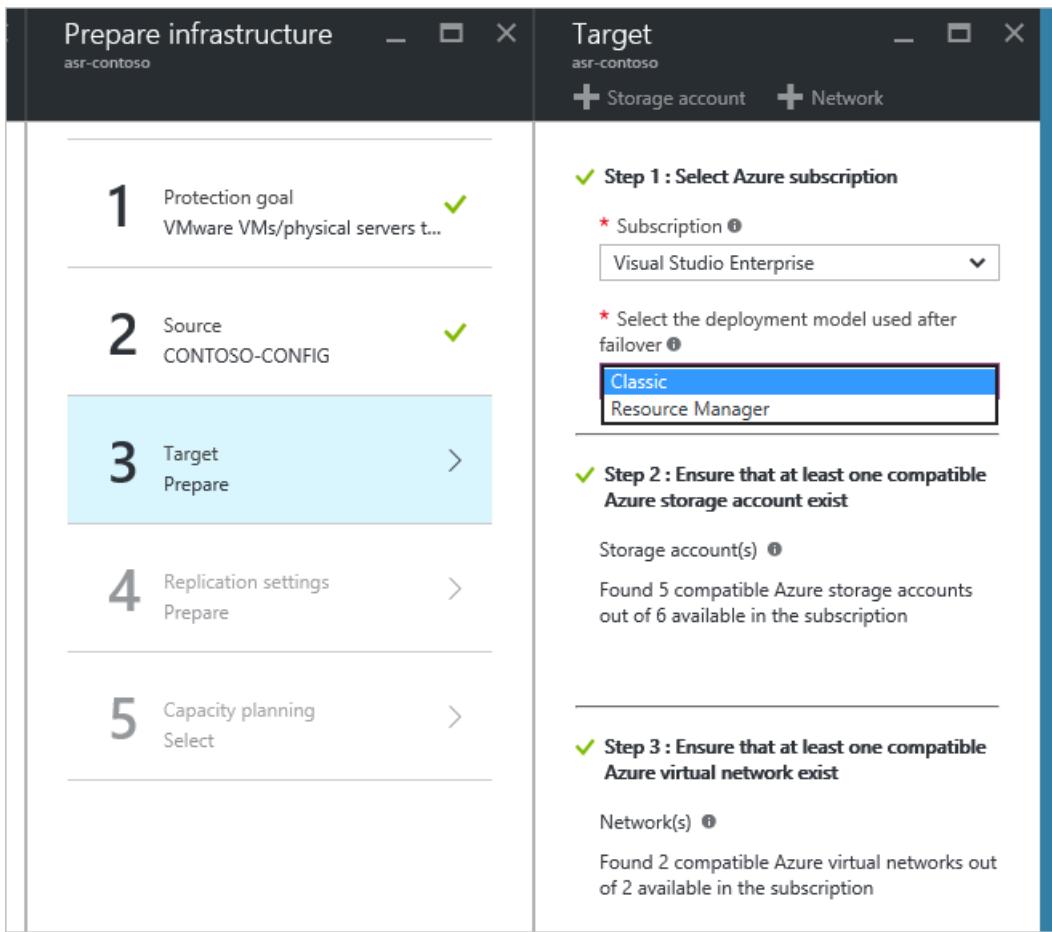

4. After the installation is complete, do the following in the **Microsoft Azure Site Recovery Configuration Server** window:

- Use the **Manage Accounts** tab to create the account that Site Recovery can use for automatic discovery. (In the scenario about protecting physical machines, setting up the account isn't relevant, but you need at least one account to enable one of the following steps. In this case, you can name the account and password as any.)
- Use the **Vault Registration** tab to upload the vault credential file.

#### Step 4: Set up the target environment

Select **Prepare infrastructure > Target**, and specify the deployment model that you want to use for VMs after failover. You can choose **Classic** or **Resource Manager**, depending on your scenario.

Site Recovery checks that you have one or more compatible Azure storage accounts and networks.

#### NOTE

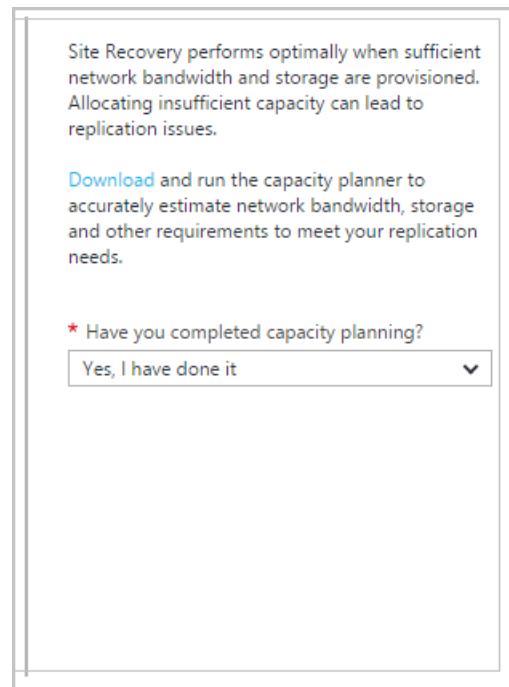

If you're using a premium storage account for replicated data, you need to set up an additional standard storage account to store replication logs.

#### Step 5: Set up replication settings

To verify that your configuration server is successfully associated with the replication policy that you create, follow [Set up replication settings](#).

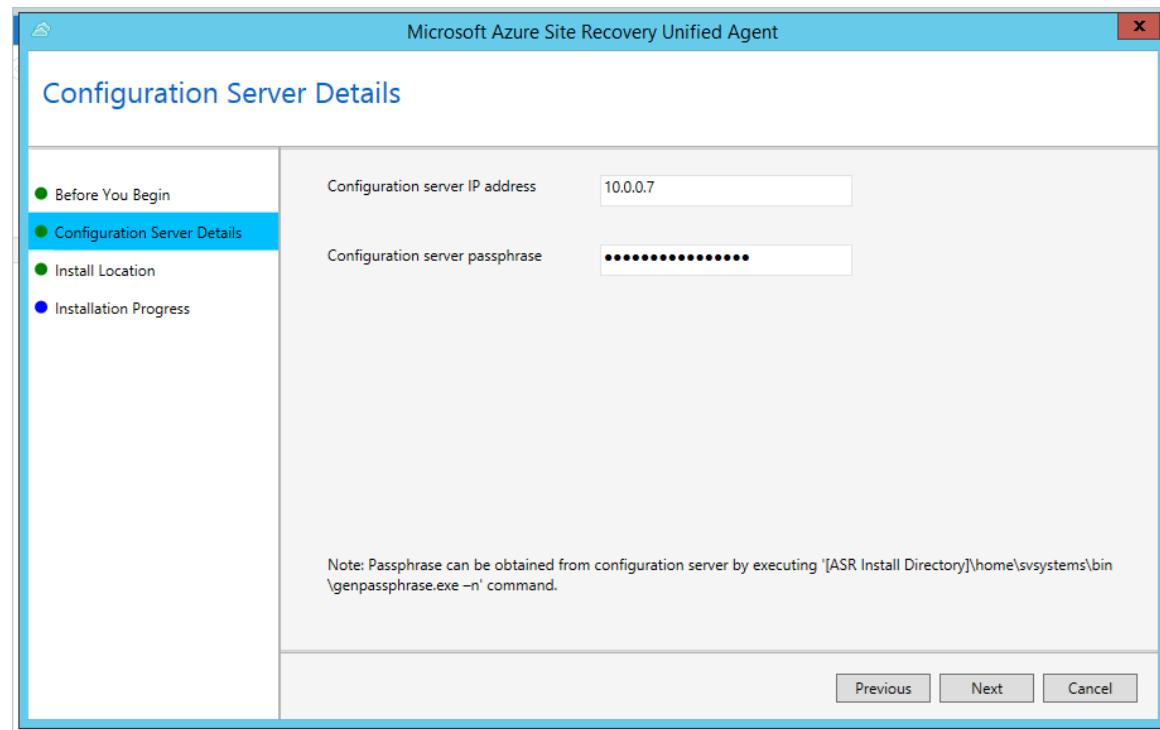

#### Step 6: Plan capacity

1. Use the [capacity planner](#) to accurately estimate network bandwidth, storage, and other requirements to meet your replication needs.
2. When you're done, select **Yes, I have done it** in **Have you completed capacity planning?**.

### Step 7: Install the mobility service and enable replication

1. You can choose to [push installation](#) to your source VMs or to [manually install the mobility service](#) on your source VMs. You can find the requirement of pushing installation and the path of the manual installer in the provided link. If you're doing a manual installation, you might need to use an internal IP address to find the configuration server.

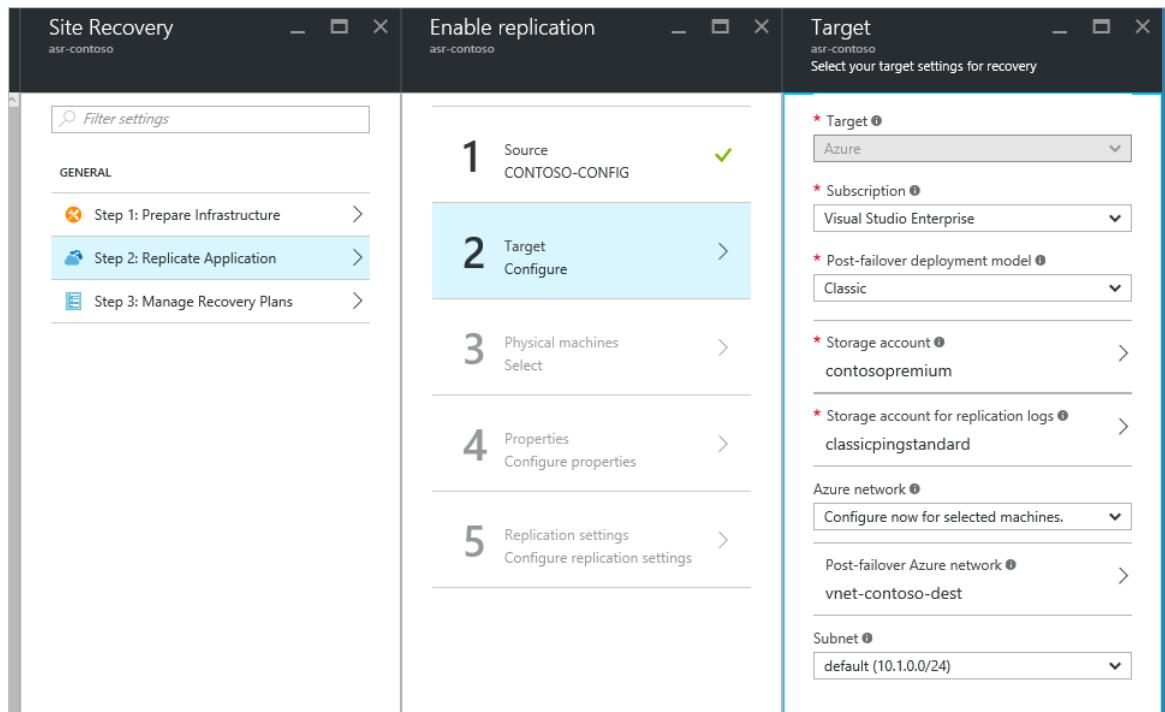

The failed-over VM will have two temporary disks: one from the primary VM and the other created during the provisioning of the VM in the recovery region. To exclude the temporary disk before replication, install the mobility service before you enable replication. To learn more about how to exclude the temporary disk, see [Exclude disks from replication](#).

2. Enable replication as follows:
  - a. Select **Replicate Application > Source**. After you've enabled replication for the first time, select **+ Replicate** in the vault to enable replication for additional machines.
  - b. In step 1, set up **Source** as your process server.

- c. In step 2, specify the post-failover deployment model, a premium storage account to migrate to, a standard storage account to save logs, and a virtual network to fail to.
- d. In step 3, add protected VMs by IP address. (You might need an internal IP address to find them.)
- e. In step 4, configure the properties by selecting the accounts that you set up previously on the process server.
- f. In step 5, choose the replication policy that you created previously in "Step 5: Set up replication settings."
- g. Select OK.

#### **NOTE**

When an Azure VM is deallocated and started again, there is no guarantee that it will get the same IP address. If the IP address of the configuration server/process server or the protected Azure VMs changes, the replication in this scenario might not work correctly.

When you design your Azure Storage environment, we recommend that you use separate storage accounts for each VM in an availability set. We recommend that you follow the best practice in the storage layer to [use multiple storage accounts for each availability set](#). Distributing VM disks to multiple storage accounts helps to improve storage availability and distributes the I/O across the Azure storage infrastructure.

If your VMs are in an availability set, instead of replicating disks of all VMs into one storage account, we highly recommend migrating multiple VMs multiple times. That way, the VMs in the same availability set do not share a single storage account. Use the **Enable Replication** pane to set up a destination storage account for each VM, one at a time.

You can choose a post-failover deployment model according to your need. If you choose Azure Resource Manager as your post-failover deployment model, you can fail over a VM (Resource Manager) to a VM (Resource Manager), or you can fail over a VM (classic) to a VM (Resource Manager).

#### **Step 8: Run a test failover**

To check whether your replication is complete, select your Site Recovery instance and then select **Settings > Replicated Items**. You will see the status and percentage of your replication process.

After initial replication is complete, run a test failover to validate your replication strategy. For detailed steps of a test failover, see [Run a test failover in Site Recovery](#).

#### **NOTE**

Before you run any failover, make sure that your VMs and replication strategy meet the requirements. For more information about running a test failover, see [Test failover to Azure in Site Recovery](#).

You can see the status of your test failover in **Settings > Jobs > YOUR\_FAILOVER\_PLAN\_NAME**. In the pane, you can see a breakdown of the steps and success/failure results. If the test failover fails at any step, select the step to check the error message.

#### **Step 9: Run a failover**

After the test failover is completed, run a failover to migrate your disks to Premium Storage and replicate the VM instances. Follow the detailed steps in [Run a failover](#).

Be sure to select **Shut down VMs and synchronize the latest data**. This option specifies that Site Recovery should try to shut down the protected VMs and synchronize the data so that the latest version of the data will be failed over. If you don't select this option or the attempt doesn't succeed, the failover will be from the latest available recovery point for the VM.

Site Recovery will create a VM instance whose type is the same as or similar to a Premium Storage-capable VM. You can check the performance and price of various VM instances by going to [Windows Virtual Machines Pricing](#) or [Linux Virtual Machines Pricing](#).

## Post-migration steps

1. **Configure replicated VMs to the availability set if applicable.** Site Recovery does not support migrating VMs along with the availability set. Depending on the deployment of your replicated VM, do one of the following:
  - For a VM created through the classic deployment model: Add the VM to the availability set in the Azure portal. For detailed steps, go to [Add an existing virtual machine to an availability set](#).
  - For a VM created through the Resource Manager deployment model: Save your configuration of the VM and then delete and re-create the VMs in the availability set. To do so, use the script at [Set Azure Resource Manager VM Availability Set](#). Before you run this script, check its limitations and plan your downtime.
2. **Delete old VMs and disks.** Make sure that the Premium disks are consistent with source disks and that the new VMs perform the same function as the source VMs. Delete the VM and delete the disks from your source storage accounts in the Azure portal. If there's a problem in which the disk is not deleted even though you deleted the VM, see [Troubleshoot storage resource deletion errors](#).
3. **Clean the Azure Site Recovery infrastructure.** If Site Recovery is no longer needed, you can clean its infrastructure. Delete replicated items, the configuration server, and the recovery policy, and then delete the Azure Site Recovery vault.

## Troubleshooting

# Migrate to Premium Storage by using Azure Site Recovery

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

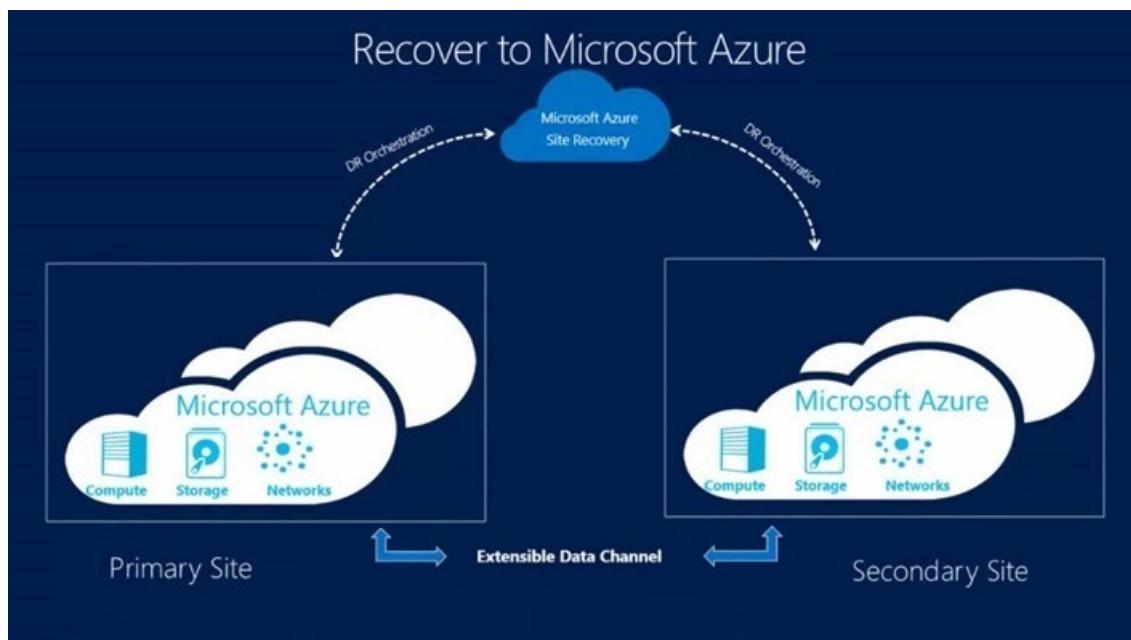

Azure premium SSDs deliver high-performance, low-latency disk support for virtual machines (VMs) that are running I/O-intensive workloads. This guide helps you migrate your VM disks from a standard storage account to a premium storage account by using [Azure Site Recovery](#).

Site Recovery is an Azure service that contributes to your strategy for business continuity and disaster recovery by orchestrating the replication of on-premises physical servers and VMs to the cloud (Azure) or to a secondary datacenter. When outages occur in your primary location, you fail over to the secondary location to keep applications and workloads available. You fail back to your primary location when it returns to normal operation.

Site Recovery provides test failovers to support disaster recovery drills without affecting production environments. You can run failovers with minimal data loss (depending on replication frequency) for unexpected disasters. In the scenario of migrating to Premium Storage, you can use the [failover in Site Recovery](#) to migrate target disks to a premium storage account.

We recommend migrating to Premium Storage by using Site Recovery because this option provides minimal downtime. This option also avoids the manual execution of copying disks and creating new VMs. Site Recovery will systematically copy your disks and create new VMs during failover.

Site Recovery supports a number of types of failover with minimal or no downtime. To plan your downtime and estimate data loss, see the [types of failover in Site Recovery](#). If you [prepare to connect to Azure VMs after failover](#), you should be able to connect to the Azure VM by using RDP after failover.

## Azure Site Recovery components

These Site Recovery components are relevant to this migration scenario:

- **Configuration server** is an Azure VM that coordinates communication and manages data replication and recovery processes. On this VM, you run a single setup file to install the configuration server and an

additional component, called a process server, as a replication gateway. Read about [configuration server prerequisites](#). You set up the configuration server only once, and you can use it for all migrations to the same region.

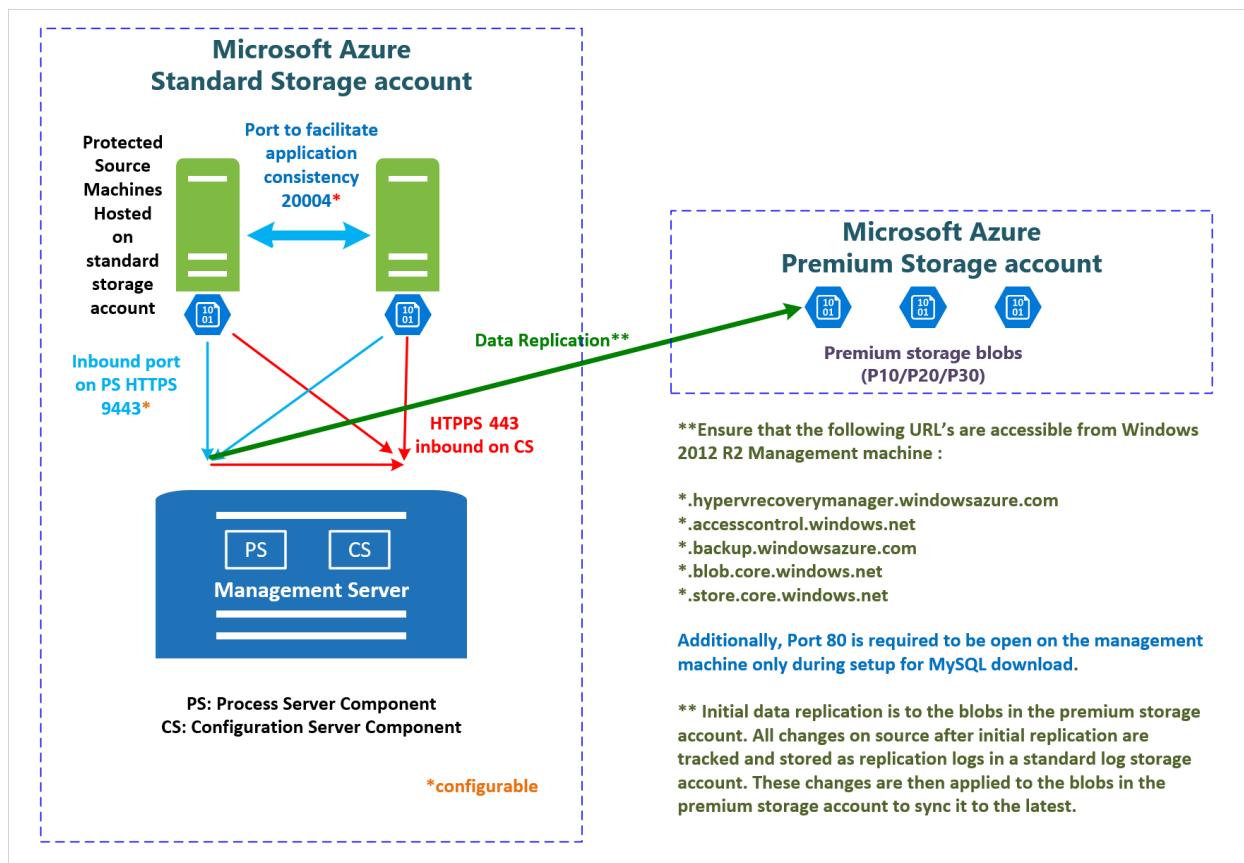

- **Process server** is a replication gateway that:

1. Receives replication data from source VMs.
2. Optimizes the data with caching, compression, and encryption.
3. Sends the data to a storage account.

It also handles push installation of the mobility service to source VMs and performs automatic discovery of source VMs. The default process server is installed on the configuration server. You can deploy additional standalone process servers to scale your deployment. Read about [best practices for process server deployment](#) and [deploying additional process servers](#). You set up the process server only once, and you can use it for all migrations to the same region.

- **Mobility service** is a component that is deployed on every standard VM that you want to replicate. It captures data writes on the standard VM and forwards them to the process server. Read about [replicated machine prerequisites](#).

This graphic shows how these components interact:

#### NOTE

Site Recovery does not support the migration of Storage Spaces disks.

For additional components for other scenarios, see [Scenario architecture](#).

## Azure essentials

These are the Azure requirements for this migration scenario:

- An Azure subscription.
- An Azure premium storage account to store replicated data.
- An Azure virtual network to which VMs will connect when they're created at failover. The Azure virtual network must be in the same region as the one in which Site Recovery runs.
- An Azure standard storage account to store replication logs. This can be the same storage account for the VM disks that are being migrated.

## Prerequisites

- Understand the relevant migration scenario components in the preceding section.
- Plan your downtime by learning about [failover in Site Recovery](#).

## Setup and migration steps

You can use Site Recovery to migrate Azure IaaS VMs between regions or within same region. The following instructions are tailored for this migration scenario from the article [Replicate VMware VMs or physical servers to Azure](#). Please follow the links for detailed steps in addition to the instructions in this article.

### Step 1: Create a Recovery Services vault

1. Open the [Azure portal](#).
2. Select **Create a resource > Management > Backup and Site Recovery (OMS)**. Alternatively, you can select **Browse > Recovery Services Vault > Add**.

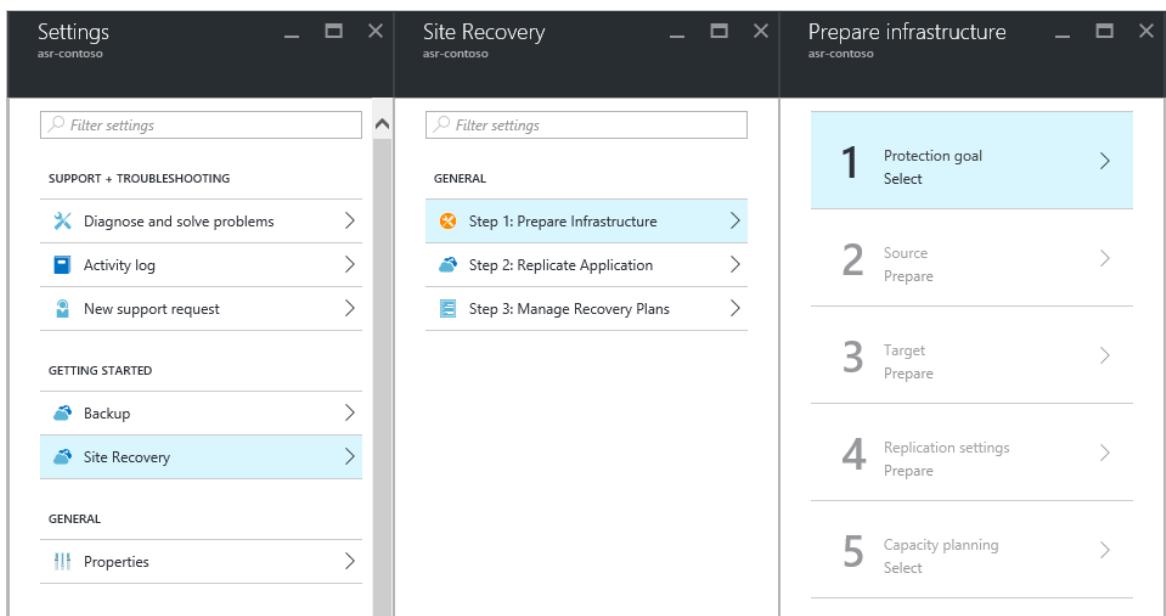

#### NOTE

Backup and Site Recovery was formerly part of the [OMS suite](#).

3. Specify a region that VMs will be replicated to. For the purpose of migration in the same region, select the region where your source VMs and source storage accounts are.

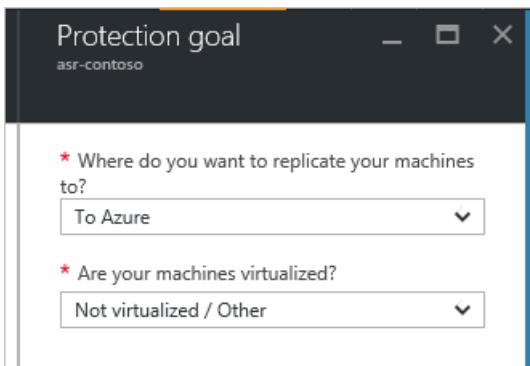

### Step 2: Choose your protection goals

1. On the VM where you want to install the configuration server, open the [Azure portal](#).
2. Go to **Recovery Services vaults > Settings > Site Recovery > Step 1: Prepare Infrastructure > Protection goal**.

3. Under **Protection goal**, in the first drop-down list, select **To Azure**. In the second drop-down list, select

Not virtualized / Other, and then select OK.

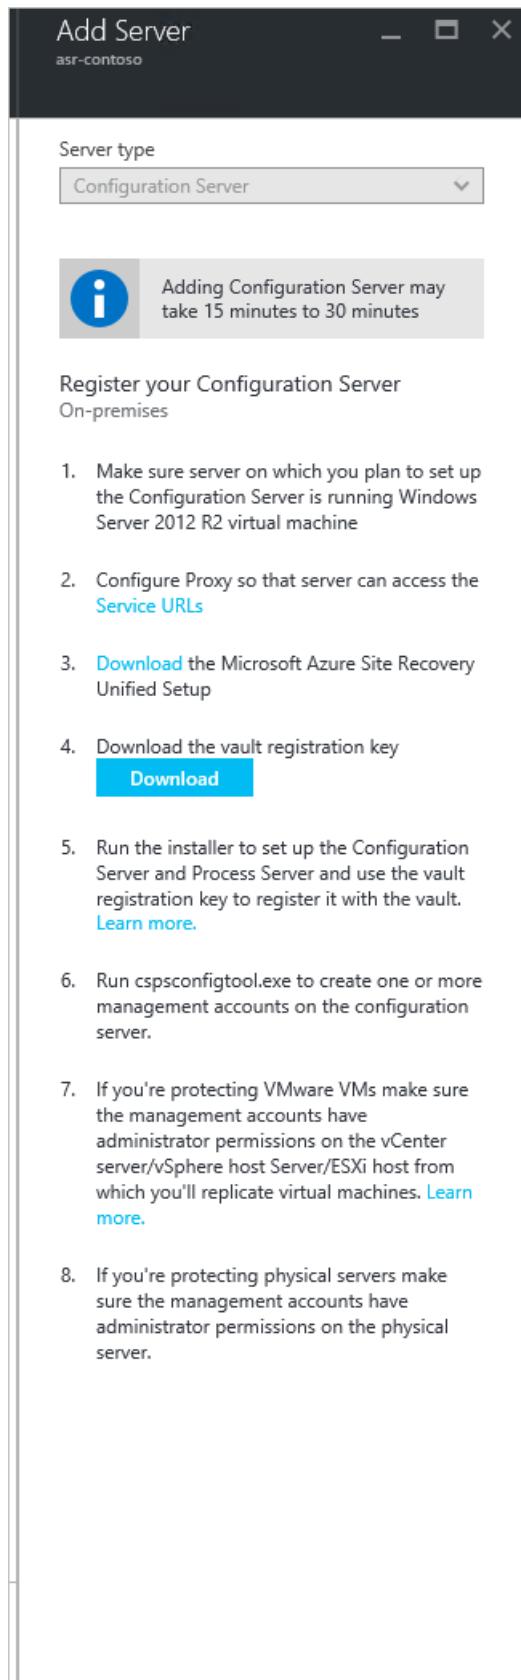

### Step 3: Set up the source environment (configuration server)

1. Download Azure Site Recovery Unified Setup and the vault registration key by going to the **Prepare infrastructure** > **Prepare source** > **Add Server** panes.

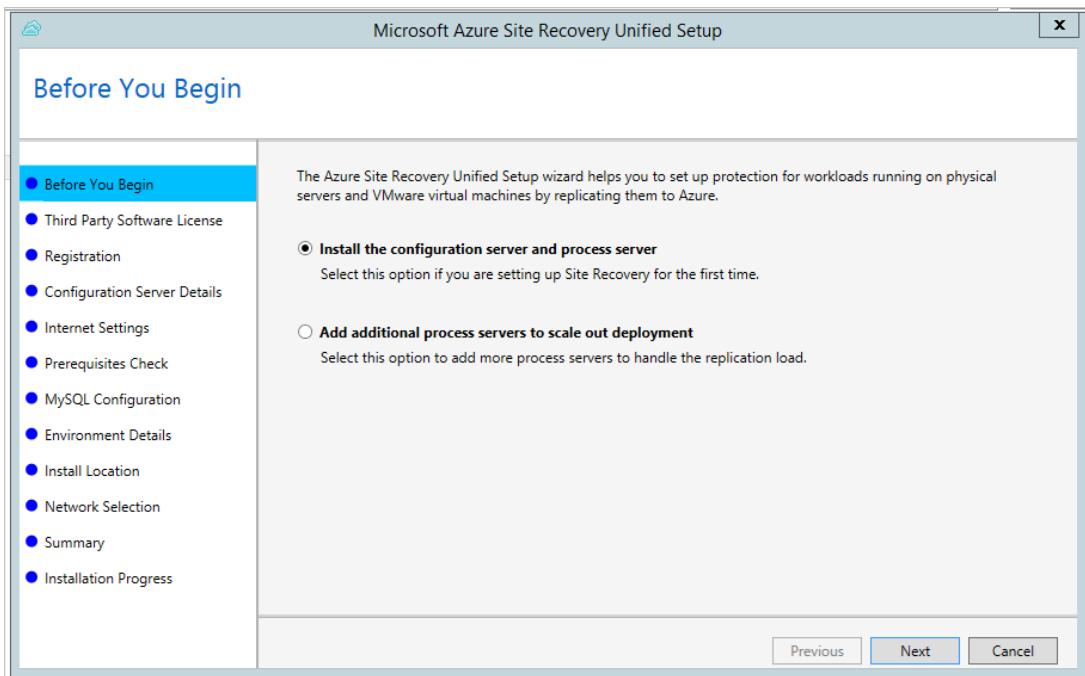

You will need the vault registration key to run the unified setup. The key is valid for five days after you generate it.

The screenshot displays two side-by-side windows. The left window is 'Prepare infrastructure' for 'asr-contoso', showing a numbered list from 1 to 5: 1. Protection goal (checkmark), 2. Source Prepare, 3. Target Prepare, 4. Replication settings, and 5. Capacity planning. The 'Source Prepare' step is highlighted with a blue background. The right window is 'Prepare source' for 'asr-contoso', titled '+ Configuration...'. It contains a section titled '→ Step 1 : Select Configuration Server' with a note: '(0 servers found) Click on +Configuration Server in the command bar above to setup one on your source environment and register it with this vault.' There is also an orange wrench icon.

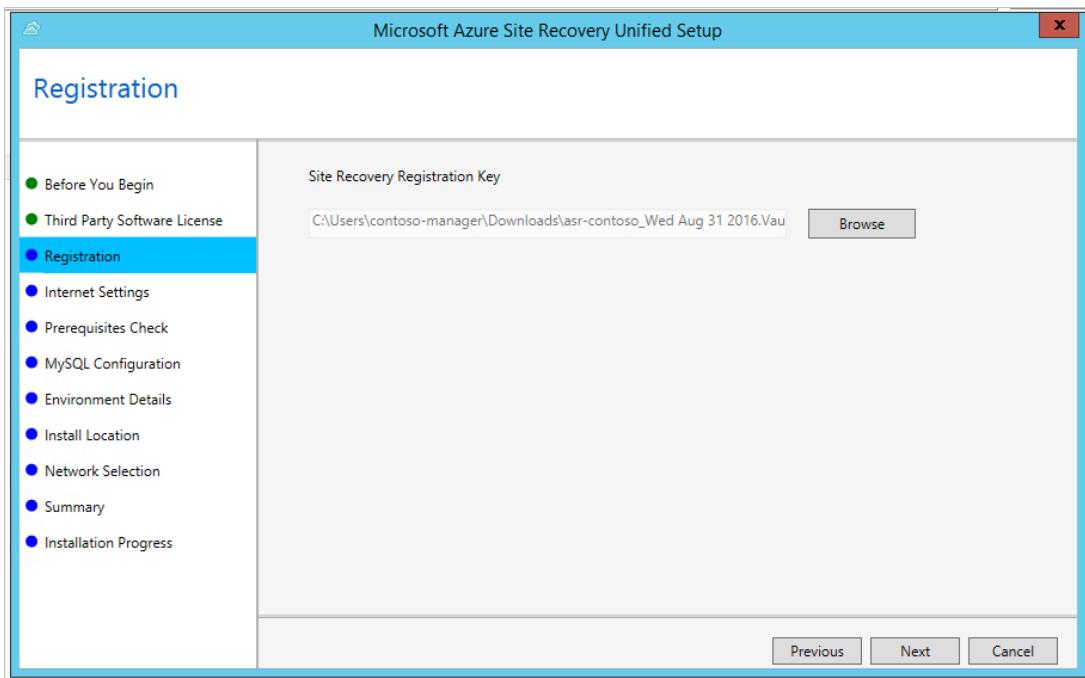

2. In the **Add Server** pane, add a configuration server.

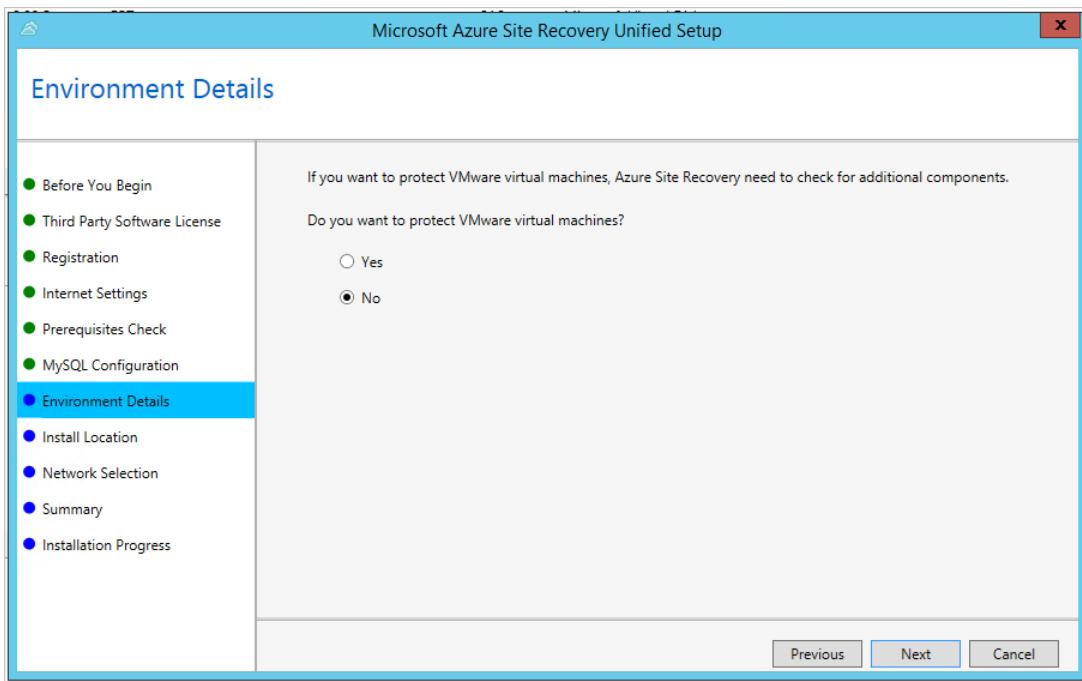

3. On the VM that you're using as the configuration server, run Unified Setup to install the configuration server and the process server. You can [walk through the screenshots](#) to complete the installation. You can refer to the following screenshots for steps specified for this migration scenario.
  - a. In **Before You Begin**, select **Install the configuration server and process server**.

- b. In **Registration**, browse and select the registration key that you downloaded from the vault.

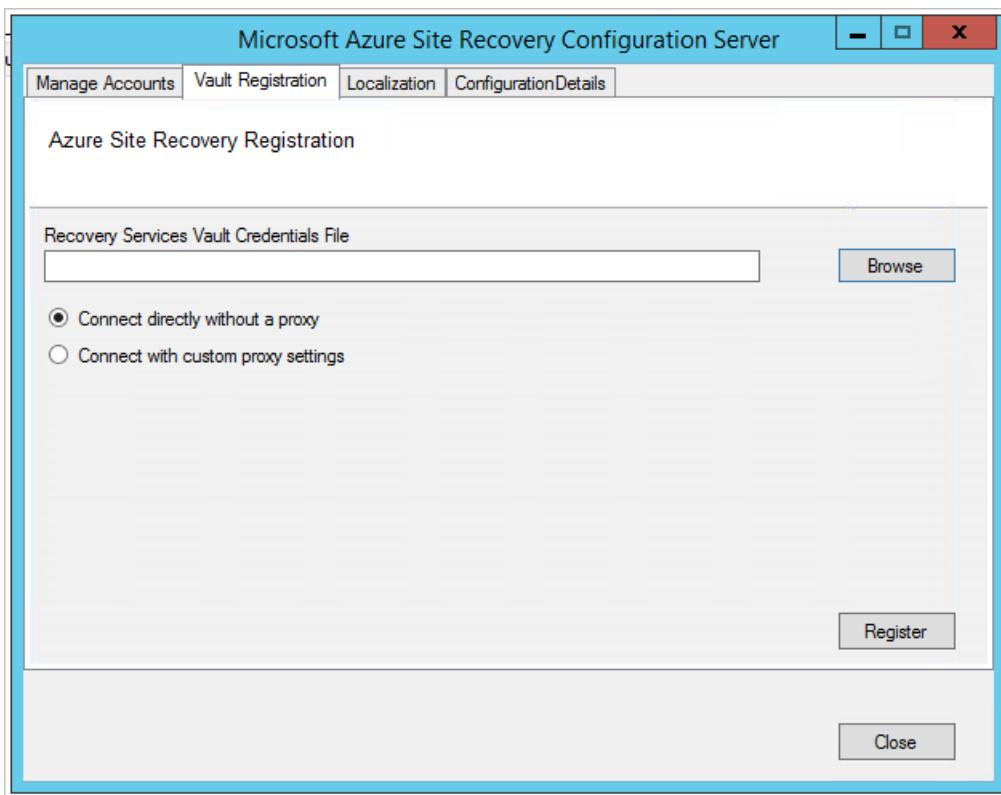

- c. In **Environment Details**, select whether you're going to replicate VMware VMs. For this migration scenario, choose **No**.

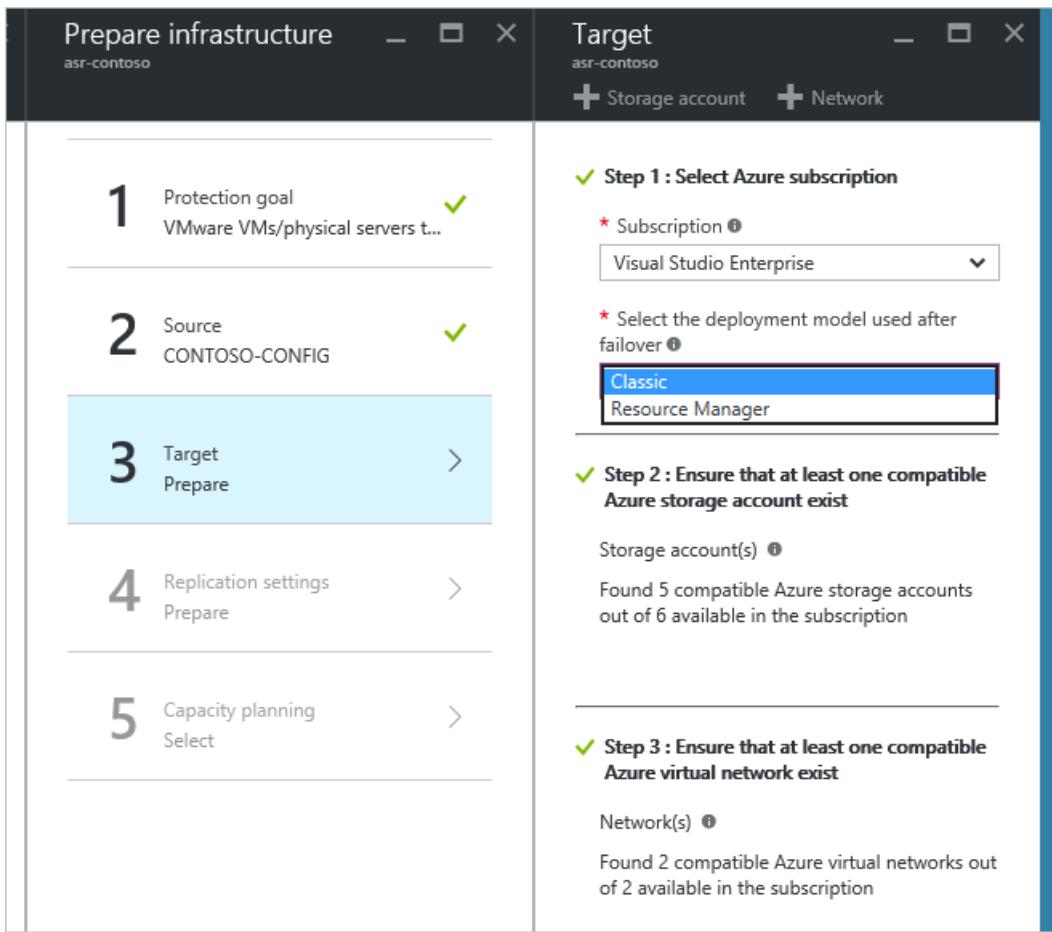

4. After the installation is complete, do the following in the **Microsoft Azure Site Recovery Configuration Server** window:

- Use the **Manage Accounts** tab to create the account that Site Recovery can use for automatic discovery. (In the scenario about protecting physical machines, setting up the account isn't relevant, but you need at least one account to enable one of the following steps. In this case, you can name the account and password as any.)
- Use the **Vault Registration** tab to upload the vault credential file.

#### Step 4: Set up the target environment

Select **Prepare infrastructure > Target**, and specify the deployment model that you want to use for VMs after failover. You can choose **Classic** or **Resource Manager**, depending on your scenario.

Site Recovery checks that you have one or more compatible Azure storage accounts and networks.

#### NOTE

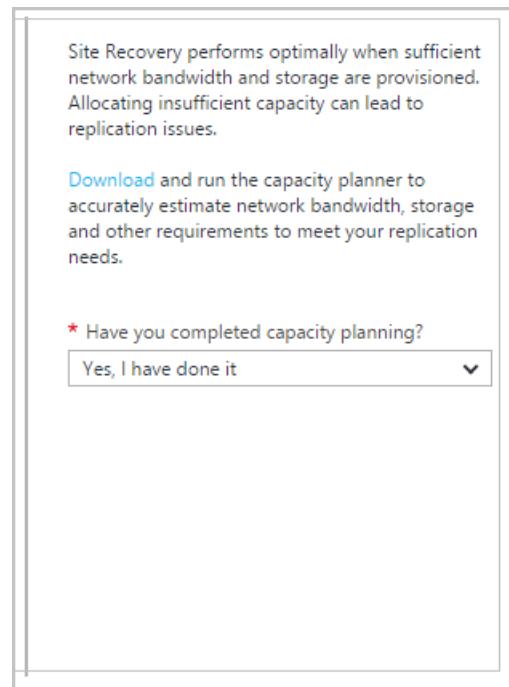

If you're using a premium storage account for replicated data, you need to set up an additional standard storage account to store replication logs.

#### Step 5: Set up replication settings

To verify that your configuration server is successfully associated with the replication policy that you create, follow [Set up replication settings](#).

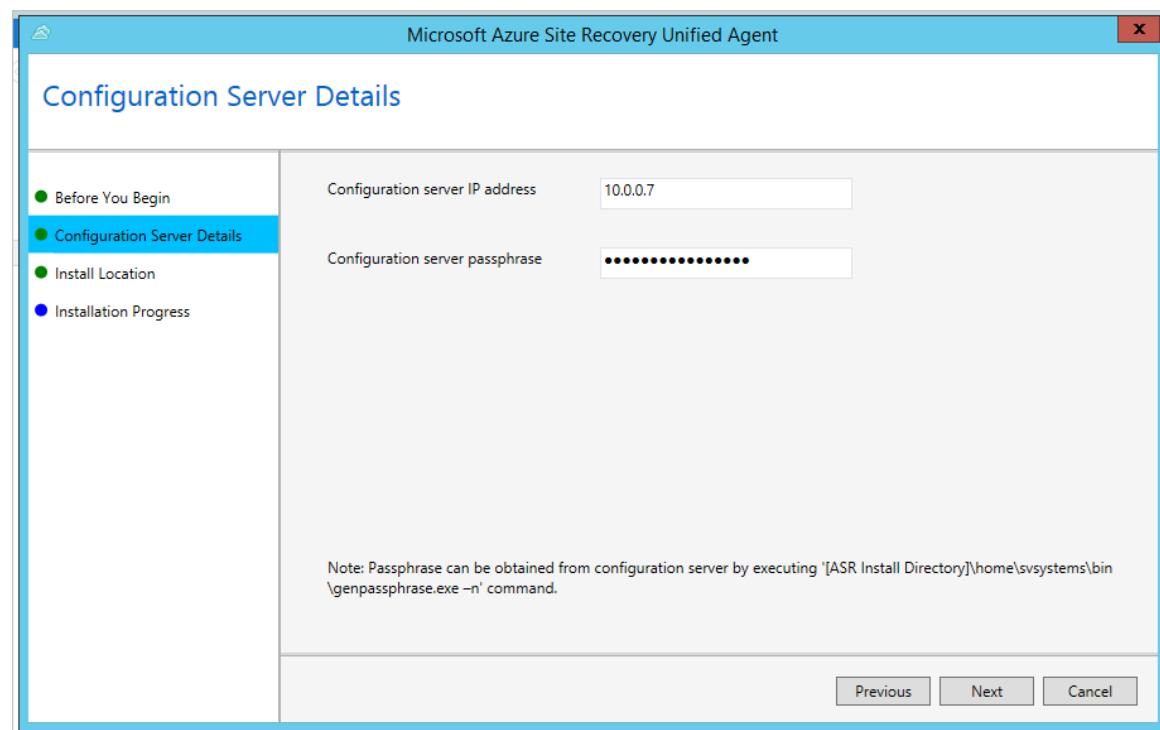

#### Step 6: Plan capacity

1. Use the [capacity planner](#) to accurately estimate network bandwidth, storage, and other requirements to meet your replication needs.
2. When you're done, select **Yes, I have done it** in **Have you completed capacity planning?**.

### Step 7: Install the mobility service and enable replication

1. You can choose to [push installation](#) to your source VMs or to [manually install the mobility service](#) on your source VMs. You can find the requirement of pushing installation and the path of the manual installer in the provided link. If you're doing a manual installation, you might need to use an internal IP address to find the configuration server.

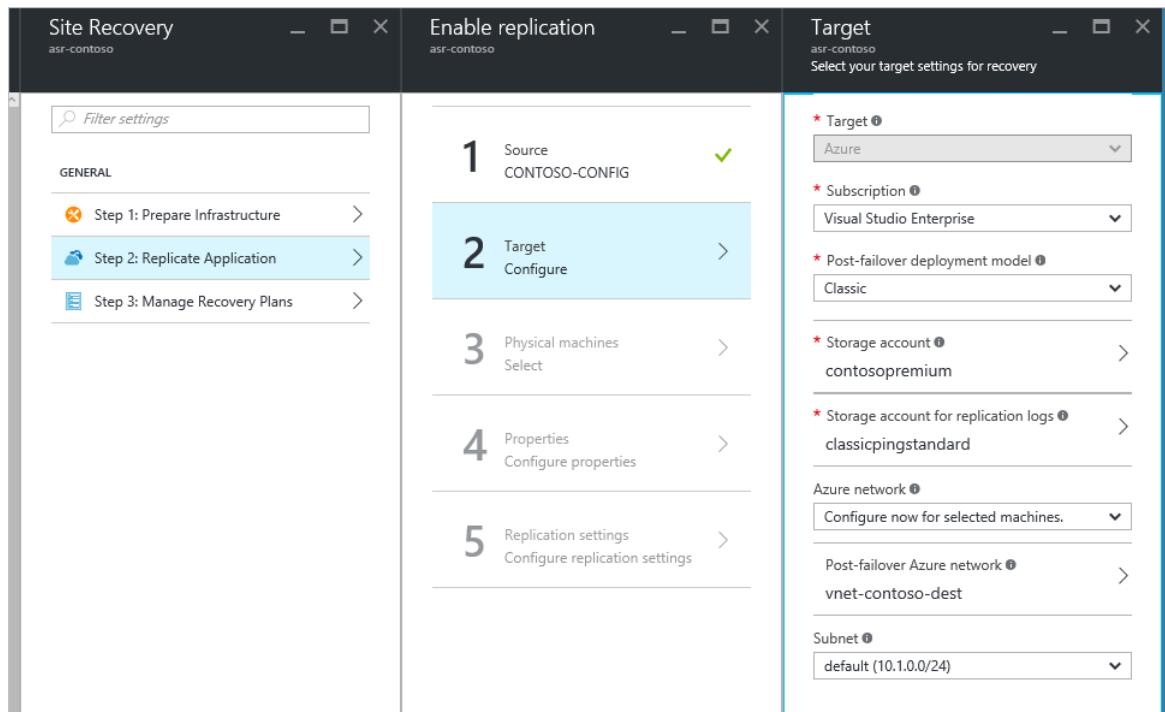

The failed-over VM will have two temporary disks: one from the primary VM and the other created during the provisioning of the VM in the recovery region. To exclude the temporary disk before replication, install the mobility service before you enable replication. To learn more about how to exclude the temporary disk, see [Exclude disks from replication](#).

2. Enable replication as follows:
  - a. Select **Replicate Application > Source**. After you've enabled replication for the first time, select **+ Replicate** in the vault to enable replication for additional machines.
  - b. In step 1, set up **Source** as your process server.

- c. In step 2, specify the post-failover deployment model, a premium storage account to migrate to, a standard storage account to save logs, and a virtual network to fail to.
- d. In step 3, add protected VMs by IP address. (You might need an internal IP address to find them.)
- e. In step 4, configure the properties by selecting the accounts that you set up previously on the process server.
- f. In step 5, choose the replication policy that you created previously in "Step 5: Set up replication settings."
- g. Select OK.

#### **NOTE**

When an Azure VM is deallocated and started again, there is no guarantee that it will get the same IP address. If the IP address of the configuration server/process server or the protected Azure VMs changes, the replication in this scenario might not work correctly.

When you design your Azure Storage environment, we recommend that you use separate storage accounts for each VM in an availability set. We recommend that you follow the best practice in the storage layer to [use multiple storage accounts for each availability set](#). Distributing VM disks to multiple storage accounts helps to improve storage availability and distributes the I/O across the Azure storage infrastructure.

If your VMs are in an availability set, instead of replicating disks of all VMs into one storage account, we highly recommend migrating multiple VMs multiple times. That way, the VMs in the same availability set do not share a single storage account. Use the **Enable Replication** pane to set up a destination storage account for each VM, one at a time.

You can choose a post-failover deployment model according to your need. If you choose Azure Resource Manager as your post-failover deployment model, you can fail over a VM (Resource Manager) to a VM (Resource Manager), or you can fail over a VM (classic) to a VM (Resource Manager).

#### **Step 8: Run a test failover**

To check whether your replication is complete, select your Site Recovery instance and then select **Settings > Replicated Items**. You will see the status and percentage of your replication process.

After initial replication is complete, run a test failover to validate your replication strategy. For detailed steps of a test failover, see [Run a test failover in Site Recovery](#).

#### **NOTE**

Before you run any failover, make sure that your VMs and replication strategy meet the requirements. For more information about running a test failover, see [Test failover to Azure in Site Recovery](#).

You can see the status of your test failover in **Settings > Jobs > YOUR\_FAILOVER\_PLAN\_NAME**. In the pane, you can see a breakdown of the steps and success/failure results. If the test failover fails at any step, select the step to check the error message.

#### **Step 9: Run a failover**

After the test failover is completed, run a failover to migrate your disks to Premium Storage and replicate the VM instances. Follow the detailed steps in [Run a failover](#).

Be sure to select **Shut down VMs and synchronize the latest data**. This option specifies that Site Recovery should try to shut down the protected VMs and synchronize the data so that the latest version of the data will be failed over. If you don't select this option or the attempt doesn't succeed, the failover will be from the latest available recovery point for the VM.

Site Recovery will create a VM instance whose type is the same as or similar to a Premium Storage-capable VM. You can check the performance and price of various VM instances by going to [Windows Virtual Machines Pricing](#) or [Linux Virtual Machines Pricing](#).

## Post-migration steps

1. **Configure replicated VMs to the availability set if applicable.** Site Recovery does not support migrating VMs along with the availability set. Depending on the deployment of your replicated VM, do one of the following:
  - For a VM created through the classic deployment model: Add the VM to the availability set in the Azure portal. For detailed steps, go to [Add an existing virtual machine to an availability set](#).
  - For a VM created through the Resource Manager deployment model: Save your configuration of the VM and then delete and re-create the VMs in the availability set. To do so, use the script at [Set Azure Resource Manager VM Availability Set](#). Before you run this script, check its limitations and plan your downtime.
2. **Delete old VMs and disks.** Make sure that the Premium disks are consistent with source disks and that the new VMs perform the same function as the source VMs. Delete the VM and delete the disks from your source storage accounts in the Azure portal. If there's a problem in which the disk is not deleted even though you deleted the VM, see [Troubleshoot storage resource deletion errors](#).
3. **Clean the Azure Site Recovery infrastructure.** If Site Recovery is no longer needed, you can clean its infrastructure. Delete replicated items, the configuration server, and the recovery policy, and then delete the Azure Site Recovery vault.

## Troubleshooting

# Migrate Azure VMs to Managed Disks in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

Azure Managed Disks simplifies your storage management by removing the need to separately manage storage accounts. You can also migrate your existing Azure VMs to Managed Disks to benefit from better reliability of VMs in an Availability Set. It ensures that the disks of different VMs in an Availability Set are sufficiently isolated from each other to avoid single point of failures. It automatically places disks of different VMs in an Availability Set in different Storage scale units (stamps) which limits the impact of single Storage scale unit failures caused due to hardware and software failures. Based on your needs, you can choose from four types of storage options. To learn about the available disk types, see our article [Select a disk type](#)

## Migration scenarios

You can migrate to Managed Disks in following scenarios:

SCENARIO	ARTICLE
Convert stand alone VMs and VMs in an availability set to managed disks	<a href="#">Convert VMs to use managed disks</a>
Convert a single VM from classic to Resource Manager on managed disks	<a href="#">Create a VM from a classic VHD</a>
Convert all the VMs in a vNet from classic to Resource Manager on managed disks	<a href="#">Migrate IaaS resources from classic to Resource Manager</a> and then <a href="#">Convert a VM from unmanaged disks to managed disks</a>
Upgrade VMs with standard unmanaged disks to VMs with managed premium disks	First, <a href="#">Convert a Windows virtual machine from unmanaged disks to managed disks</a> . Then <a href="#">Update the storage type of a managed disk</a> .

### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

# Migrate a Linux virtual machine from unmanaged disks to managed disks

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

If you have existing Linux virtual machines (VMs) that use unmanaged disks, you can migrate the VMs to use [Azure Managed Disks](#). This process converts both the OS disk and any attached data disks.

This article shows you how to migrate VMs by using the Azure CLI. If you need to install or upgrade it, see [Install Azure CLI](#).

## Before you begin

- Review [the FAQ about migration to Managed Disks](#).
- The migration will restart the VM, so schedule the migration of your VMs during a pre-existing maintenance window.
- The migration isn't reversible.
- Any users with the [Virtual Machine Contributor](#) role won't be able to change the VM size (as they could pre-migration). This is because VMs with managed disks require the user to have the Microsoft.Compute/disks/write permission on the OS disks.
- Be sure to test the migration. Migrate a test virtual machine before you perform the migration in production.
- During the migration, you deallocate the VM. The VM receives a new IP address when it's started after the migration. If needed, you can [assign a static IP address](#) to the VM.
- Review the minimum version of the Azure VM agent required to support the migration process. For information on how to check and update your agent version, see [Minimum version support for VM agents in Azure](#)
- The original VHDs and the storage account used by the VM before migration are not deleted. They continue to incur charges. To avoid being billed for these artifacts, delete the original VHD blobs after you verify that the migration is complete. If you need to find these unattached disks in order to delete them, see our article [Find and delete unattached Azure managed and unmanaged disks](#).

## Migrate single-instance VMs

This section covers how to migrate single-instance Azure VMs from unmanaged disks to managed disks. (If your VMs are in an availability set, see the next section.) You can use this process to migrate the VMs from premium (SSD) unmanaged disks to premium managed disks, or from standard (HDD) unmanaged disks to standard managed disks.

1. Deallocate the VM by using `az vm deallocate`. The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

2. Migrate the VM to managed disks by using [az vm convert](#). The following process converts the VM named `myVM`, including the OS disk and any data disks:

```
az vm convert --resource-group myResourceGroup --name myVM
```

3. Start the VM after the migration to managed disks by using [az vm start](#). The following example starts the VM named `myVM` in the resource group named `myResourceGroup`.

```
az vm start --resource-group myResourceGroup --name myVM
```

## Migrate VMs in an availability set

If the VMs that you want to migrate to managed disks are in an availability set, you first need to migrate the availability set to a managed availability set.

All VMs in the availability set must be deallocated before you migrate the availability set. Plan to migrate all VMs to managed disks after the availability set itself has been converted to a managed availability set. Then, start all the VMs and continue operating as normal.

1. List all VMs in an availability set by using [az vm availability-set list](#). The following example lists all VMs in the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

```
az vm availability-set show \
--resource-group myResourceGroup \
--name myAvailabilitySet \
--query [virtualMachines[*].id] \
--output table
```

2. Deallocate all the VMs by using [az vm deallocate](#). The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

3. Migrate the availability set by using [az vm availability-set convert](#). The following example converts the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

```
az vm availability-set convert \
--resource-group myResourceGroup \
--name myAvailabilitySet
```

4. Migrate all the VMs to managed disks by using [az vm convert](#). The following process converts the VM named `myVM`, including the OS disk and any data disks:

```
az vm convert --resource-group myResourceGroup --name myVM
```

5. Start all the VMs after the migration to managed disks by using [az vm start](#). The following example starts the VM named `myVM` in the resource group named `myResourceGroup`:

```
az vm start --resource-group myResourceGroup --name myVM
```

## Migrate using the Azure portal

You can also migrate unmanaged disks to managed disks using the Azure portal.

1. Sign in to the [Azure portal](#).
2. Select the VM from the list of VMs in the portal.
3. In the blade for the VM, select **Disks** from the menu.
4. At the top of the **Disks** blade, select **Migrate to managed disks**.
5. If your VM is in an availability set, there will be a warning on the **Migrate to managed disks** blade that you need to migrate the availability set first. The warning should have a link you can click to migrate the availability set. Once the availability set is converted or if your VM is not in an availability set, click **Migrate** to start the process of migrating your disks to managed disks.

The VM will be stopped and restarted after migration is complete.

## Next steps

For more information about storage options, see [Azure Managed Disks overview](#).

# Migrate a Windows virtual machine from unmanaged disks to managed disks

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

If you have existing Windows virtual machines (VMs) that use unmanaged disks, you can migrate the VMs to use managed disks through the [Azure Managed Disks](#) service. This process converts both the operating system (OS) disk and any attached data disks.

## Before you begin

- Review [Plan for the migration to Managed Disks](#).
- Review [the FAQ about migration to Managed Disks](#).
- The migration will restart the VM, so schedule the migration of your VMs during a pre-existing maintenance window.
- The migration isn't reversible.
- Any users with the [Virtual Machine Contributor](#) role won't be able to change the VM size (as they could pre-migration). This is because VMs with managed disks require the user to have the Microsoft.Compute/disks/write permission on the OS disks.
- Be sure to test the migration. Migrate a test virtual machine before you perform the migration in production.
- During the migration, you deallocate the VM. The VM receives a new IP address when it's started after the migration. If needed, you can [assign a static IP address](#) to the VM.
- Review the minimum version of the Azure VM agent required to support the migration process. For information on how to check and update your agent version, see [Minimum version support for VM agents in Azure](#)
- The original VHDs and the storage account used by the VM before migration are not deleted. They continue to incur charges. To avoid being billed for these artifacts, delete the original VHD blobs after you verify that the migration is complete. If you need to find these unattached disks in order to delete them, see our article [Find and delete unattached Azure managed and unmanaged disks](#).

## Migrate single-instance VMs

This section covers how to migrate single-instance Azure VMs from unmanaged disks to managed disks. (If your VMs are in an availability set, see the next section.)

1. Deallocate the VM by using the [Stop-AzVM](#) cmdlet. The following example deallocates the VM named `myVM` in the resource group named `myResourceGroup`:

```
$rgName = "myResourceGroup"  
$vmName = "myVM"  
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force
```

- Migrate the VM to managed disks by using the [ConvertTo-AzVMManagedDisk](#) cmdlet. The following process converts the previous VM, including the OS disk and any data disks, and starts the Virtual Machine:

```
ConvertTo-AzVMManagedDisk -ResourceGroupName $rgName -VMName $vmName
```

## Migrate VMs in an availability set

If the VMs that you want to migrate to managed disks are in an availability set, you first need to migrate the availability set to a managed availability set.

- Migrate the availability set by using the [Update-AzAvailabilitySet](#) cmdlet. The following example updates the availability set named `myAvailabilitySet` in the resource group named `myResourceGroup`:

```
$rgName = 'myResourceGroup'
$avSetName = 'myAvailabilitySet'

$avSet = Get-AzAvailabilitySet -ResourceGroupName $rgName -Name $avSetName
Update-AzAvailabilitySet -AvailabilitySet $avSet -Sku Aligned
```

If the region where your availability set is located has only 2 managed fault domains but the number of unmanaged fault domains is 3, this command shows an error similar to "The specified fault domain count 3 must fall in the range 1 to 2." To resolve the error, update the fault domain to 2 and update `Sku` to `Aligned` as follows:

```
$avSet.PlatformFaultDomainCount = 2
Update-AzAvailabilitySet -AvailabilitySet $avSet -Sku Aligned
```

- Deallocate and migrate the VMs in the availability set. The following script deallocates each VM by using the [Stop-AzVM](#) cmdlet, converts it by using [ConvertTo-AzVMManagedDisk](#), and restarts it automatically as part of the migration process:

```
$avSet = Get-AzAvailabilitySet -ResourceGroupName $rgName -Name $avSetName

foreach($vmInfo in $avSet.VirtualMachinesReferences)
{
    $vm = Get-AzVM -ResourceGroupName $rgName | Where-Object {$_.Id -eq $vmInfo.id}
    Stop-AzVM -ResourceGroupName $rgName -Name $vm.Name -Force
    ConvertTo-AzVMManagedDisk -ResourceGroupName $rgName -VMName $vm.Name
}
```

## Troubleshooting

- Before converting, make sure all the VM extensions are in the 'Provisioning succeeded' state or the migration will fail with the error code 409.
- If there is an error during migration, or if a VM is in a failed state because of issues in a previous migration, run the `ConvertTo-AzVMManagedDisk` cmdlet again. A simple retry usually unblocks the situation.
- If you are converting a Linux VM to managed disks, use the latest version of the Azure Linux Agent. Operations using Azure Linux Agent versions '2.2.0' and earlier will likely fail. Running the migration on a generalized VM or a VM that belongs to a classic availability set is also not supported.
- If the migration fails with the "SnapshotCountExceeded" error, delete some snapshots and attempt the operation again.

## Migrate using the Azure portal

You can also migrate unmanaged disks to managed disks using the Azure portal.

1. Sign in to the [Azure portal](#).
2. Select the VM from the list of VMs in the portal.
3. In the blade for the VM, select **Disks** from the menu.
4. At the top of the **Disks** blade, select **Migrate to managed disks**.
5. If your VM is in an availability set, there will be a warning on the **Migrate to managed disks** blade that you need to migrate the availability set first. The warning should have a link you can click to migrate the availability set. Once the availability set is converted or if your VM is not in an availability set, click **Migrate** to start the process of migrating your disks to managed disks.

The VM will be stopped and restarted after migration is complete.

# Add a disk to a Linux VM

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to attach a persistent disk to your VM so that you can preserve your data - even if your VM is reprovisioned due to maintenance or resizing.

## Attach a new disk to a VM

If you want to add a new, empty data disk on your VM, use the `az vm disk attach` command with the `--new` parameter. If your VM is in an Availability Zone, the disk is automatically created in the same zone as the VM. For more information, see [Overview of Availability Zones](#). The following example creates a disk named *myDataDisk* that is 50 Gb in size:

```
az vm disk attach \
  -g myResourceGroup \
  --vm-name myVM \
  --name myDataDisk \
  --new \
  --size-gb 50
```

### Lower latency

In select regions, the disk attach latency has been reduced, so you'll see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk attach command, `az vm disk attach`. You won't see the performance improvement if you call a command that may implicitly perform an attach, like `az vm update`. You don't need to take any action other than calling the explicit attach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US
- West US 2
- Germany North
- Jio India West
- North Europe
- West Europe

## Attach an existing disk

To attach an existing disk, find the disk ID and pass the ID to the `az vm disk attach` command. The following example queries for a disk named *myDataDisk* in *myResourceGroup*, then attaches it to the VM named *myVM*.

```
diskId=$(az disk show -g myResourceGroup -n myDataDisk --query 'id' -o tsv)
```

```
az vm disk attach -g myResourceGroup --vm-name myVM --name $diskId
```

## Format and mount the disk

To partition, format, and mount your new disk so your Linux VM can use it, SSH into your VM. For more information, see [How to use SSH with Linux on Azure](#). The following example connects to a VM with the public IP address of 10.123.123.25 with the username *azureuser*:

```
ssh azureuser@10.123.123.25
```

### Find the disk

Once connected to your VM, you need to find the disk. In this example, we are using `lsblk` to list the disks.

```
lsblk -o NAME,HCTL,SIZE,MOUNTPOINT | grep -i "sd"
```

The output is similar to the following example:

```
sda      0:0:0:0      30G
└─sda1        29.9G  /
└─sda14        4M
└─sda15       106M /boot/efi
sdb      1:0:1:0      14G
└─sdb1        14G /mnt
sdc      3:0:0:0      50G
```

Here, `sdc` is the disk that we want, because it is 50G. If you add multiple disks, and aren't sure which disk it is based on size alone, you can go to the VM page in the portal, select **Disks**, and check the LUN number for the disk under **Data disks**. Compare the LUN number from the portal to the last number of the HCTL portion of the output, which is the LUN.

### Format the disk

Format the disk with `parted`, if the disk size is 2 tebibytes (TiB) or larger then you must use GPT partitioning, if it is under 2TiB, then you can use either MBR or GPT partitioning.

#### NOTE

It is recommended that you use the latest version `parted` that is available for your distro. If the disk size is 2 tebibytes (TiB) or larger, you must use GPT partitioning. If disk size is under 2 TiB, then you can use either MBR or GPT partitioning.

The following example uses `parted` on `/dev/sdc`, which is where the first data disk will typically be on most VMs. Replace `sdc` with the correct option for your disk. We are also formatting it using the [XFS](#) filesystem.

```
sudo parted /dev/sdc --script mklabel gpt mkpart xfspart xfs 0% 100%
sudo mkfs.xfs /dev/sdc1
sudo partprobe /dev/sdc1
```

Use the `partprobe` utility to make sure the kernel is aware of the new partition and filesystem. Failure to use `partprobe` can cause the `blkid` or `lsblk` commands to not return the UUID for the new filesystem immediately.

### Mount the disk

Now, create a directory to mount the file system using `mkdir`. The following example creates a directory at `/datadrive`:

```
sudo mkdir /datadrive
```

Use `mount` to then mount the filesystem. The following example mounts the `/dev/sdc1` partition to the `/datadrive` mount point:

```
sudo mount /dev/sdc1 /datadrive
```

## Persist the mount

To ensure that the drive is remounted automatically after a reboot, it must be added to the `/etc/fstab` file. It is also highly recommended that the UUID (Universally Unique Identifier) is used in `/etc/fstab` to refer to the drive rather than just the device name (such as, `/dev/sdc1`). If the OS detects a disk error during boot, using the UUID avoids the incorrect disk being mounted to a given location. Remaining data disks would then be assigned those same device IDs. To find the UUID of the new drive, use the `blkid` utility:

```
sudo blkid
```

The output looks similar to the following example:

```
/dev/sda1: LABEL="cloudimg-rootfs" UUID="11111111-1b1b-1c1c-1d1d-1e1e1e1e1e1e" TYPE="ext4"
PARTUUID="1a1b1c1d-11aa-1234-1a1a1a1a1a1a"
/dev/sda15: LABEL="UEFI" UUID="BCD7-96A6" TYPE="vfat" PARTUUID="1e1g1cg1h-11aa-1234-1u1u1a1a1u1u"
/dev/sdb1: UUID="2222222-2b2b-2c2c-2d2d-2e2e2e2e2e" TYPE="ext4" TYPE="ext4" PARTUUID="1a2b3c4d-01"
/dev/sda14: PARTUUID="2e2g2cg2h-11aa-1234-1u1u1a1a1u1u"
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e" TYPE="xfs" PARTLABEL="xfspart" PARTUUID="c1c2c3c4-
1234-cdef-asdf3456ghjk"
```

### NOTE

Improperly editing the `/etc/fstab` file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the `/etc/fstab` file is created before editing.

Next, open the `/etc/fstab` file in a text editor as follows:

```
sudo nano /etc/fstab
```

In this example, use the UUID value for the `/dev/sdc1` device that was created in the previous steps, and the mountpoint of `/datadrive`. Add the following line to the end of the `/etc/fstab` file:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e   /datadrive   xfs   defaults,nofail   1   2
```

In this example, we are using the nano editor, so when you are done editing the file, use `Ctrl+O` to write the file and `Ctrl+X` to exit the editor.

## NOTE

Later removing a data disk without editing fstab could cause the VM to fail to boot. Most distributions provide either the *nofail* and/or *nobootwait* fstab options. These options allow a system to boot even if the disk fails to mount at boot time. Consult your distribution's documentation for more information on these parameters.

The *nofail* option ensures that the VM starts even if the filesystem is corrupt or the disk does not exist at boot time. Without this option, you may encounter behavior as described in [Cannot SSH to Linux VM due to FSTAB errors](#).

The Azure VM Serial Console can be used for console access to your VM if modifying fstab has resulted in a boot failure. More details are available in the [Serial Console documentation](#).

## TRIM/UNMAP support for Linux in Azure

Some Linux kernels support TRIM/UNMAP operations to discard unused blocks on the disk. This feature is primarily useful in standard storage to inform Azure that deleted pages are no longer valid and can be discarded, and can save money if you create large files and then delete them.

There are two ways to enable TRIM support in your Linux VM. As usual, consult your distribution for the recommended approach:

- Use the `discard` mount option in `/etc/fstab`, for example:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e /datadrive xfs defaults,discard 1 2
```

- In some cases, the `discard` option may have performance implications. Alternatively, you can run the `fstrim` command manually from the command line, or add it to your crontab to run regularly:

### Ubuntu

```
sudo apt-get install util-linux
sudo fstrim /datadrive
```

### RHEL/CentOS

```
sudo yum install util-linux
sudo fstrim /datadrive
```

## Troubleshooting

When adding data disks to a Linux VM, you may encounter errors if a disk does not exist at LUN 0. If you are adding a disk manually using the `az vm disk attach -new` command and you specify a LUN (`--lun`) rather than allowing the Azure platform to determine the appropriate LUN, take care that a disk already exists / will exist at LUN 0.

Consider the following example showing a snippet of the output from `lsscsi`:

```
[5:0:0:0]    disk    Msft    Virtual Disk    1.0    /dev/sdc
[5:0:0:1]    disk    Msft    Virtual Disk    1.0    /dev/sdd
```

The two data disks exist at LUN 0 and LUN 1 (the first column in the `lsscsi` output details `[host:channel:target:lun]`). Both disks should be accessible from within the VM. If you had manually specified the first disk to be added at LUN 1 and the second disk at LUN 2, you may not see the disks correctly from within your VM.

**NOTE**

The Azure `host` value is 5 in these examples, but this may vary depending on the type of storage you select.

This disk behavior is not an Azure problem, but the way in which the Linux kernel follows the SCSI specifications. When the Linux kernel scans the SCSI bus for attached devices, a device must be found at LUN 0 in order for the system to continue scanning for additional devices. As such:

- Review the output of `lsscsi` after adding a data disk to verify that you have a disk at LUN 0.
- If your disk does not show up correctly within your VM, verify a disk exists at LUN 0.

## Next steps

- To ensure your Linux VM is configured correctly, review the [Optimize your Linux machine performance](#) recommendations.
- Expand your storage capacity by adding additional disks and [configure RAID](#) for additional performance.

# Use the portal to attach a data disk to a Linux VM

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to attach both new and existing disks to a Linux virtual machine through the Azure portal. You can also [attach a data disk to a Windows VM in the Azure portal](#).

Before you attach disks to your VM, review these tips:

- The size of the virtual machine controls how many data disks you can attach. For details, see [Sizes for virtual machines](#).
- Disks attached to virtual machines are actually .vhdx files stored in Azure. For details, see our [Introduction to managed disks](#).
- After attaching the disk, you need to [connect to the Linux VM to mount the new disk](#).

## Find the virtual machine

1. Go to the [Azure portal](#) to find the VM. Search for and select **Virtual machines**.
2. Choose the VM from the list.
3. In the **Virtual machines** page, under **Settings**, choose **Disks**.

## Attach a new disk

1. On the **Disks** pane, under **Data disks**, select **Create and attach a new disk**.
2. Enter a name for your managed disk. Review the default settings, and update the **Storage type**, **Size (GiB)**, **Encryption** and **Host caching** as necessary.

LUN	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (GiB/s)	Encryption	Host caching
0	Data disk name	Premium SSD	4	120	25	Platform-managed	None

3. When you are done, select **Save** at the top of the page to create the managed disk and update the VM configuration.

## Attach an existing disk

1. On the **Disks** pane, under **Data disks**, select **Attach existing disks**.
2. Click the drop-down menu for **Disk name** and select a disk from the list of available managed disks.
3. Click **Save** to attach the existing managed disk and update the VM configuration:

## Connect to the Linux VM to mount the new disk

To partition, format, and mount your new disk so your Linux VM can use it, SSH into your VM. For more information, see [How to use SSH with Linux on Azure](#). The following example connects to a VM with the public IP address of `10.123.123.25` with the username `azureuser`.

```
ssh azureuser@10.123.123.25
```

## Find the disk

Once connected to your VM, you need to find the disk. In this example, we are using `lsblk` to list the disks.

```
lsblk -o NAME,HCTL,SIZE,MOUNTPOINT | grep -i "sd"
```

The output is similar to the following example:

```
sda      0:0:0:0      30G
└─sda1        29.9G /
└─sda14       4M
└─sda15      106M /boot/efi
sdb      1:0:1:0      14G
└─sdb1        14G /mnt
sdc      3:0:0:0      4G
```

In this example, the disk that I added is `sdc`. It is a LUN 0 and is 4GB.

For a more complex example, here is what multiple data disks look like in the portal:

LUN	Disk name	Storage type	Size (GiB)
0	datadisk1	Premium SSD	4
1	datadisk2	Premium SSD	16
2	datadisk3	Standard HDD	32

In the image, you can see that there are 3 data disks: 4 GB on LUN 0, 16GB at LUN 1, and 32G at LUN 2.

Here is what that might look like using `lsblk`:

```
sda      0:0:0:0      30G
└─sda1        29.9G /
└─sda14       4M
└─sda15      106M /boot/efi
sdb      1:0:1:0      14G
└─sdb1        14G /mnt
sdc      3:0:0:0      4G
sdd      3:0:0:1      16G
sde      3:0:0:2      32G
```

From the output of `lsblk` you can see that the 4GB disk at LUN 0 is `sdc`, the 16GB disk at LUN 1 is `sdd`, and the 32G disk at LUN 2 is `sde`.

## Prepare a new empty disk

### IMPORTANT

If you are using an existing disk that contains data, skip to [mounting the disk](#). The following instructions will delete data on the disk.

If you are attaching a new disk, you need to partition the disk.

The `parted` utility can be used to partition and to format a data disk.

- It is recommended that you use the latest version `parted` that is available for your distro.
- If the disk size is 2 tebibytes (TiB) or larger, you must use GPT partitioning. If disk size is under 2 TiB, then you can use either MBR or GPT partitioning.

The following example uses `parted` on `/dev/sdc`, which is where the first data disk will typically be on most VMs. Replace `sdc` with the correct option for your disk. We are also formatting it using the [XFS](#) filesystem.

```
sudo parted /dev/sdc --script mklabel gpt mkpart xfspart xfs 0% 100%
sudo mkfs.xfs /dev/sdc1
sudo partprobe /dev/sdc1
```

Use the `partprobe` utility to make sure the kernel is aware of the new partition and filesystem. Failure to use `partprobe` can cause the `blkid` or `lsblk` commands to not return the UUID for the new filesystem immediately.

## Mount the disk

Create a directory to mount the file system using `mkdir`. The following example creates a directory at `/datadrive`:

```
sudo mkdir /datadrive
```

Use `mount` to then mount the filesystem. The following example mounts the `/dev/sdc1` partition to the `/datadrive` mount point:

```
sudo mount /dev/sdc1 /datadrive
```

To ensure that the drive is remounted automatically after a reboot, it must be added to the `/etc/fstab` file. It is also highly recommended that the UUID (Universally Unique Identifier) is used in `/etc/fstab` to refer to the drive rather than just the device name (such as, `/dev/sdc1`). If the OS detects a disk error during boot, using the UUID avoids the incorrect disk being mounted to a given location. Remaining data disks would then be assigned those same device IDs. To find the UUID of the new drive, use the `blkid` utility:

```
sudo blkid
```

The output looks similar to the following example:

```
/dev/sda1: LABEL="cloudimg-rootfs" UUID="11111111-1b1b-1c1c-1d1d-1e1e1e1e1e" TYPE="ext4"
PARTUUID="1a1b1c1d-11aa-1234-1a1a1a1a1a1a"
/dev/sda15: LABEL="UEFI" UUID="BCD7-96A6" TYPE="vfat" PARTUUID="1e1g1cg1h-11aa-1234-1u1u1a1a1u1u"
/dev/sdb1: UUID="2222222-2b2b-2c2c-2d2d-2e2e2e2e2e" TYPE="ext4" PARTUUID="1a2b3c4d-01"
/dev/sda14: PARTUUID="2e2g2cg2h-11aa-1234-1u1u1a1a1u1u"
/dev/sdc1: UUID="3333333-3b3b-3c3c-3d3d-3e3e3e3e3e" TYPE="xfs" PARTLABEL="xfspart" PARTUUID="c1c2c3c4-
1234-cdef-asdf3456ghjk"
```

### NOTE

Improperly editing the `/etc/fstab` file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the `/etc/fstab` file is created before editing.

Next, open the `/etc/fstab` file in a text editor as follows:

```
sudo nano /etc/fstab
```

In this example, use the UUID value for the `/dev/sdc1` device that was created in the previous steps, and the mountpoint of `/datadrive`. Add the following line to the end of the `/etc/fstab` file:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e /datadrive xfs defaults,nofail 1 2
```

We used the nano editor, so when you are done editing the file, use `Ctrl+O` to write the file and `Ctrl+X` to exit the editor.

#### NOTE

Later removing a data disk without editing fstab could cause the VM to fail to boot. Most distributions provide either the `nofail` and/or `nobootwait` fstab options. These options allow a system to boot even if the disk fails to mount at boot time. Consult your distribution's documentation for more information on these parameters.

The `nofail` option ensures that the VM starts even if the filesystem is corrupt or the disk does not exist at boot time. Without this option, you may encounter behavior as described in [Cannot SSH to Linux VM due to FSTAB errors](#)

## Verify the disk

You can now use `lsblk` again to see the disk and the mountpoint.

```
lsblk -o NAME,HCTL,SIZE,MOUNTPOINT | grep -i "sd"
```

The output will look something like this:

```
sda      0:0:0:0      30G
└─sda1        29.9G /
└─sda14       4M
└─sda15     106M /boot/efi
sdb      1:0:1:0      14G
└─sdb1        14G /mnt
sdc      3:0:0:0      4G
└─sdc1        4G /datadrive
```

You can see that `sdc` is now mounted at `/datadrive`.

### TRIM/UNMAP support for Linux in Azure

Some Linux kernels support TRIM/UNMAP operations to discard unused blocks on the disk. This feature is primarily useful in standard storage to inform Azure that deleted pages are no longer valid and can be discarded, and can save money if you create large files and then delete them.

There are two ways to enable TRIM support in your Linux VM. As usual, consult your distribution for the recommended approach:

- Use the `discard` mount option in `/etc/fstab`, for example:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e /datadrive xfs defaults,discard 1 2
```

- In some cases, the `discard` option may have performance implications. Alternatively, you can run the

`fstrim` command manually from the command line, or add it to your crontab to run regularly:

## Ubuntu

```
sudo apt-get install util-linux  
sudo fstrim /datadrive
```

## RHEL/CentOS

```
sudo yum install util-linux  
sudo fstrim /datadrive
```

## Next steps

For more information, and to help troubleshoot disk issues, see [Troubleshoot Linux VM device name changes](#).

You can also [attach a data disk](#) using the Azure CLI.

# Attach a data disk to a Windows VM with PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

This article shows you how to attach both new and existing disks to a Windows virtual machine by using PowerShell.

First, review these tips:

- The size of the virtual machine controls how many data disks you can attach. For more information, see [Sizes for virtual machines](#).
- To use premium SSDs, you'll need a [premium storage-enabled VM type](#), like the DS-series or GS-series virtual machine.

This article uses PowerShell within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

## Lower latency

In select regions, the disk attach latency has been reduced, so you'll see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk attach command, `Add-AzVMDataDisk`. You won't see the performance improvement if you call a command that may implicitly perform an attach, like `Update-AzVM`. You don't need to take any action other than calling the explicit attach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US
- West US 2
- Germany North
- Jio India West
- North Europe
- West Europe

## Add an empty data disk to a virtual machine

This example shows how to add an empty data disk to an existing virtual machine.

### Using managed disks

```

$rgName = 'myResourceGroup'
$vmName = 'myVM'
$location = 'East US'
$storageType = 'Premium_LRS'
$dataDiskName = $vmName + '_datadisk1'

$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -CreateOption Empty -DiskSizeGB 128
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -ResourceGroupName $rgName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -ManagedDiskId $dataDisk1.Id -Lun 1

Update-AzVM -VM $vm -ResourceGroupName $rgName

```

## Using managed disks in an Availability Zone

To create a disk in an Availability Zone, use [New-AzDiskConfig](#) with the `-Zone` parameter. The following example creates a disk in zone 1.

```

$rgName = 'myResourceGroup'
$vmName = 'myVM'
$location = 'East US 2'
$storageType = 'Premium_LRS'
$dataDiskName = $vmName + '_datadisk1'

$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $location -CreateOption Empty -DiskSizeGB 128
-Zone 1
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -ResourceGroupName $rgName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -ManagedDiskId $dataDisk1.Id -Lun 1

Update-AzVM -VM $vm -ResourceGroupName $rgName

```

## Initialize the disk

After you add an empty disk, you'll need to initialize it. To initialize the disk, you can sign in to a VM and use disk management. If you enabled [WinRM](#) and a certificate on the VM when you created it, you can use remote PowerShell to initialize the disk. You can also use a custom script extension:

```

$location = "location-name"
$scriptName = "script-name"
$fileName = "script-file-name"
Set-AzVMCustomScriptExtension -ResourceGroupName $rgName -Location $locName -VMName $vmName -Name
$scriptName -TypeHandlerVersion "1.4" -StorageAccountName "mystore1" -StorageAccountKey "primary-key" -
FileName $fileName -ContainerName "scripts"

```

The script file can contain code to initialize the disks, for example:

```
$disks = Get-Disk | Where partitionstyle -eq 'raw' | sort number

$letters = 70..89 | ForEach-Object { [char]$_ }

$count = 0
$labels = "data1","data2"

foreach ($disk in $disks) {
    $driveLetter = $letters[$count].ToString()
    $disk |
        Initialize-Disk -PartitionStyle MBR -PassThru |
        New-Partition -UseMaximumSize -DriveLetter $driveLetter |
        Format-Volume -FileSystem NTFS -NewFileSystemLabel $labels[$count] -Confirm:$false -Force
$count++
}
```

## Attach an existing data disk to a VM

You can attach an existing managed disk to a VM as a data disk.

```
$rgName = "myResourceGroup"
$vmName = "myVM"
$dataDiskName = "myDisk"
$disk = Get-AzDisk -ResourceGroupName $rgName -DiskName $dataDiskName

$vm = Get-AzVM -Name $vmName -ResourceGroupName $rgName

$vm = Add-AzVMDataDisk -CreateOption Attach -Lun 0 -VM $vm -ManagedDiskId $disk.Id

Update-AzVM -VM $vm -ResourceGroupName $rgName
```

## Next steps

You can also deploy managed disks using templates. For more information, see [Using Managed Disks in Azure Resource Manager Templates](#) or the [quickstart template](#) for deploying multiple data disks.

# Attach a managed data disk to a Windows VM by using the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

This article shows you how to attach a new managed data disk to a Windows virtual machine (VM) by using the Azure portal. The size of the VM determines how many data disks you can attach. For more information, see [Sizes for virtual machines](#).

## Add a data disk

1. Sign in to the [Azure portal](#).
2. Search for and select **Virtual machines**.
3. Select a virtual machine from the list.
4. On the **Virtual machine** pane, select **Disks**.
5. On the **Disks** pane, select **Create and attach a new disk**.
6. In the drop-downs for the new disk, make the selections you want, and name the disk.
7. Select **Save** to create and attach the new data disk to the VM.

## Initialize a new data disk

1. Connect to the VM.
2. Select the Windows **Start** menu inside the running VM and enter **diskmgmt.msc** in the search box. The **Disk Management** console opens.
3. Disk Management recognizes that you have a new, uninitialized disk and the **Initialize Disk** window appears.
4. Verify the new disk is selected and then select **OK** to initialize it.
5. The new disk appears as **unallocated**. Right-click anywhere on the disk and select **New simple volume**. The **New Simple Volume Wizard** window opens.
6. Proceed through the wizard, keeping all of the defaults, and when you're done select **Finish**.
7. Close **Disk Management**.
8. A pop-up window appears notifying you that you need to format the new disk before you can use it. Select **Format disk**.
9. In the **Format new disk** window, check the settings, and then select **Start**.
10. A warning appears notifying you that formatting the disks erases all of the data. Select **OK**.
11. When the formatting is complete, select **OK**.

## Next steps

- You can also [attach a data disk by using PowerShell](#).
- If your application needs to use the *D:* drive to store data, you can [change the drive letter of the Windows temporary disk](#).

# Use the D: drive as a data drive on a Windows VM

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

If your application needs to use the D drive to store data, follow these instructions to use a different drive letter for the temporary disk. Never use the temporary disk to store data that you need to keep.

If you resize or **Stop (Deallocate)** a virtual machine, this may trigger placement of the virtual machine to a new hypervisor. A planned or unplanned maintenance event may also trigger this placement. In this scenario, the temporary disk will be reassigned to the first available drive letter. If you have an application that specifically requires the D: drive, you need to follow these steps to temporarily move the pagefile.sys, attach a new data disk and assign it the letter D and then move the pagefile.sys back to the temporary drive. Once complete, Azure will not take back the D: if the VM moves to a different hypervisor.

For more information about how Azure uses the temporary disk, see [Understanding the temporary drive on Microsoft Azure Virtual Machines](#)

## Attach the data disk

First, you'll need to attach the data disk to the virtual machine. To do this using the portal, see [How to attach a managed data disk in the Azure portal](#).

## Temporarily move pagefile.sys to C drive

1. Connect to the virtual machine.
2. Right-click the **Start** menu and select **System**.
3. In the left-hand menu, search for and select **View advanced system settings**.
4. In the **Performance** section, select **Settings**.
5. Select the **Advanced** tab.
6. In the **Virtual memory** section, select **Change**.
7. Select the C drive and then click **System managed size** and then click **Set**.
8. Select the D drive and then click **No paging file** and then click **Set**.
9. Click **Apply**. You will get a warning that the computer needs to be restarted for the changes to take affect.
10. Restart the virtual machine.

## Change the drive letters

1. Once the VM restarts, log back on to the VM.
2. Click the **Start** menu and type **diskmgmt.msc** and hit Enter. Disk Management will start.
3. Right-click on D, the Temporary Storage drive, and select **Change Drive Letter and Paths**.
4. Under Drive letter, select a new drive such as T and then click **OK**.
5. Right-click on the data disk, and select **Change Drive Letter and Paths**.
6. Under Drive letter, select drive D and then click **OK**.

## Move pagefile.sys back to the temporary storage drive

1. Right-click the **Start** menu and select **System**
2. In the left-hand menu, search for and select **View advanced system settings**.

3. In the **Performance** section, select **Settings**.
4. Select the **Advanced** tab.
5. In the **Virtual memory** section, select **Change**.
6. Select the OS drive C and click **No paging file** and then click **Set**.
7. Select the temporary storage drive T and then click **System managed size** and then click **Set**.
8. Click **Apply**. You will get a warning that the computer needs to be restarted for the changes to take affect.
9. Restart the virtual machine.

## Next steps

- You can increase the storage available to your virtual machine by [attaching an additional data disk](#).

# How to detach a data disk from a Linux virtual machine

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you no longer need a data disk that's attached to a virtual machine, you can easily detach it. This removes the disk from the virtual machine, but doesn't remove it from storage. In this article, we are working with an Ubuntu LTS 16.04 distribution. If you are using a different distribution, the instructions for unmounting the disk might be different.

## WARNING

If you detach a disk it is not automatically deleted. If you have subscribed to Premium storage, you will continue to incur storage charges for the disk. For more information, see [Pricing and Billing when using Premium Storage](#).

If you want to use the existing data on the disk again, you can reattach it to the same virtual machine, or another one.

## Connect to the VM to unmount the disk

Before you can detach the disk using either CLI or the portal, you need to unmount the disk and removed references to it from your fstab file.

Connect to the VM. In this example, the public IP address of the VM is *10.0.1.4* with the username *azureuser*:

```
ssh azureuser@10.0.1.4
```

First, find the data disk that you want to detach. The following example uses dmesg to filter on SCSI disks:

```
dmesg | grep SCSI
```

The output is similar to the following example:

```
[    0.294784] SCSI subsystem initialized
[    0.573458] Block layer SCSI generic (bsg) driver version 0.4 loaded (major 252)
[    7.110271] sd 2:0:0:0: [sda] Attached SCSI disk
[   8.079653] sd 3:0:1:0: [sdb] Attached SCSI disk
[ 1828.162306] sd 5:0:0:0: [sdc] Attached SCSI disk
```

Here, *sdc* is the disk that we want to detach. You also should grab the UUID of the disk.

```
sudo -i blkid
```

The output looks similar to the following example:

```
/dev/sda1: UUID="11111111-1b1b-1c1c-1d1d-1e1e1e1e1e" TYPE="ext4"
/dev/sdb1: UUID="22222222-2b2b-2c2c-2d2d-2e2e2e2e2e" TYPE="ext4"
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e" TYPE="ext4"
```

Edit the `/etc/fstab` file to remove references to the disk.

#### NOTE

Improperly editing the `/etc/fstab` file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the `/etc/fstab` file is created before editing.

Open the `/etc/fstab` file in a text editor as follows:

```
sudo vi /etc/fstab
```

In this example, the following line needs to be deleted from the `/etc/fstab` file:

```
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e    /datadrive    ext4    defaults,nofail    1    2
```

Use `umount` to unmount the disk. The following example unmounts the `/dev/sdc1` partition from the `/datadrive` mount point:

```
sudo umount /dev/sdc1 /datadrive
```

## Detach a data disk using Azure CLI

This example detaches the `myDataDisk` disk from VM named `myVM` in `myResourceGroup`.

```
az vm disk detach \
  -g myResourceGroup \
  --vm-name myVm \
  -n myDataDisk
```

The disk stays in storage but is no longer attached to a virtual machine.

#### Lower latency

In select regions, the disk detach latency has been reduced, so you'll see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk detach command, `az vm disk detach`. You won't see the performance improvement if you call a command that may implicitly perform a detach, like `az vm update`. You don't need to take any action other than calling the explicit detach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US
- East US 2
- South Central US

- West US 2
- Germany North
- Jio India West
- North Europe
- West Europe

## Detach a data disk using the portal

1. In the left menu, select **Virtual Machines**.
2. In the virtual machine blade, select **Disks**.
3. In the **Disks** blade, to the far right of the data disk that you would like to detach, select the **X** button, to detach the disk.
4. After the disk has been removed, select **Save** on the top of the blade.

The disk stays in storage but is no longer attached to a virtual machine. The disk is not deleted.

## Next steps

If you want to reuse the data disk, you can just [attach it to another VM](#).

If you want to delete the disk, so that you no longer incur storage costs, see [Find and delete unattached Azure managed and unmanaged disks - Azure portal](#).

# How to detach a data disk from a Windows virtual machine

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

When you no longer need a data disk that's attached to a virtual machine, you can easily detach it. This removes the disk from the virtual machine, but doesn't remove it from storage.

## WARNING

If you detach a disk it is not automatically deleted. If you have subscribed to Premium storage, you will continue to incur storage charges for the disk. For more information, see [Pricing and Billing when using Premium Storage](#).

If you want to use the existing data on the disk again, you can reattach it to the same virtual machine, or another one.

## Detach a data disk using PowerShell

You can *hot* remove a data disk using PowerShell, but make sure nothing is actively using the disk before detaching it from the VM.

In this example, we remove the disk named `myDisk` from the VM `myVM` in the `myResourceGroup` resource group. First you remove the disk using the `Remove-AzVMDataDisk` cmdlet. Then, you update the state of the virtual machine, using the `Update-AzVM` cmdlet, to complete the process of removing the data disk.

```
$VirtualMachine = Get-AzVM ` 
    -ResourceGroupName "myResourceGroup" ` 
    -Name "myVM"
Remove-AzVMDataDisk ` 
    -VM $VirtualMachine ` 
    -Name "myDisk"
Update-AzVM ` 
    -ResourceGroupName "myResourceGroup" ` 
    -VM $VirtualMachine
```

The disk stays in storage but is no longer attached to a virtual machine.

## Lower latency

In select regions, the disk detach latency has been reduced, so you'll see an improvement of up to 15%. This is useful if you have planned/unplanned failovers between VMs, you're scaling your workload, or are running a high scale stateful workload such as Azure Kubernetes Service. However, this improvement is limited to the explicit disk detach command, `Remove-AzVMDataDisk`. You won't see the performance improvement if you call a command that may implicitly perform a detach, like `Update-AzVM`. You don't need to take any action other than calling the explicit detach command to see this improvement.

Lower latency is currently available in every public region except for:

- Canada Central
- Central US
- East US

- East US 2
- South Central US
- West US 2
- Germany North
- Jio India West
- North Europe
- West Europe

## Detach a data disk using the portal

You can *hot* remove a data disk, but make sure nothing is actively using the disk before detaching it from the VM.

1. In the left menu, select **Virtual Machines**.
2. Select the virtual machine that has the data disk you want to detach.
3. Under **Settings**, select **Disks**.
4. In the **Disks** pane, to the far right of the data disk that you would like to detach, select the X button to detach.
5. Select **Save** on the top of the page to save your changes.

The disk stays in storage but is no longer attached to a virtual machine. The disk isn't deleted.

## Next steps

If you want to reuse the data disk, you can just [attach it to another VM](#).

If you want to delete the disk, so that you no longer incur storage costs, see [Find and delete unattached Azure managed and unmanaged disks - Azure portal](#).

# Expand virtual hard disks on a Linux VM with the Azure CLI

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article describes how to expand managed disks for a Linux virtual machine (VM) with the Azure CLI. You can [add data disks](#) to provide for additional storage space, and you can also expand an existing data disk. The default virtual hard disk size for the operating system (OS) is typically 30 GB on a Linux VM in Azure. This article covers expanding either OS disks or data disks.

## WARNING

Always make sure that your filesystem is in a healthy state, your disk partition table type will support the new size, and ensure your data is backed up before you perform disk expansion operations. For more information, see the [Azure Backup quickstart](#).

## Expand an Azure Managed Disk

### Expand without downtime

You can now expand your managed disks without deallocating your VM.

This feature has the following limitations:

- Only supported for data disks.
- If a disk is 4 TiB or less, you can't expand it beyond 4 TiB without deallocating the VM. If a disk is already greater than 4 TiB, you can expand it without deallocating the VM.
- Not supported for Ultra disks, Premium SSD v2 (preview) disks, or standard HDDs.
- Not supported for shared disks.
- Install and use either:
  - The [latest Azure CLI](#)
  - The [latest Azure PowerShell module](#)
  - The [Azure portal](#)
  - Or an Azure Resource Manager template with an API version that's 2021-04-01 or newer.

### Get started

Make sure that you have the latest [Azure CLI](#) installed and are signed in to an Azure account by using [az login](#).

This article requires an existing VM in Azure with at least one data disk attached and prepared. If you do not already have a VM that you can use, see [Create and prepare a VM with data disks](#).

In the following samples, replace example parameter names such as `myResourceGroup` and `myVM` with your own values.

## IMPORTANT

If your disk meets the requirements in [Expand without downtime](#), you can skip step 1 and 3.

- Operations on virtual hard disks can't be performed with the VM running. Deallocate your VM with `az vm deallocate`. The following example deallocates the VM named *myVM* in the resource group named *myResourceGroup*.

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

**NOTE**

The VM must be deallocated to expand the virtual hard disk. Stopping the VM with `az vm stop` does not release the compute resources. To release compute resources, use `az vm deallocate`.

- View a list of managed disks in a resource group with `az disk list`. The following example displays a list of managed disks in the resource group named *myResourceGroup*.

```
az disk list \  
  --resource-group myResourceGroup \  
  --query '[*].{Name:name,Gb:diskSizeGb,Tier:accountType}' \  
  --output table
```

Expand the required disk with `az disk update`. The following example expands the managed disk named *myDataDisk* to 200 GB:

```
az disk update \  
  --resource-group myResourceGroup \  
  --name myDataDisk \  
  --size-gb 200
```

**NOTE**

When you expand a managed disk, the updated size is rounded up to the nearest managed disk size. For a table of the available managed disk sizes and tiers, see [Azure Managed Disks Overview - Pricing and Billing](#).

- Start your VM with `az vm start`. The following example starts the VM named *myVM* in the resource group named *myResourceGroup*.

```
az vm start --resource-group myResourceGroup --name myVM
```

## Expand a disk partition and filesystem

To use an expanded disk, expand the underlying partition and filesystem.

- SSH to your VM with the appropriate credentials. You can see the public IP address of your VM with `az vm show`:

```
az vm show --resource-group myResourceGroup --name myVM -d --query [publicIps] --output tsv
```

- Expand the underlying partition and filesystem.

- If the disk is already mounted, unmount it:

```
sudo umount /dev/sdc1
```

b. Use `parted` to view disk information and resize the partition:

```
sudo parted /dev/sdc
```

View information about the existing partition layout with `print`. The output is similar to the following example, which shows the underlying disk is 215 GB:

```
GNU Parted 3.2
Using /dev/sdc1
Welcome to GNU Parted! Type 'help' to view a list of commands.
(parted) print
Model: Unknown Msft Virtual Disk (scsi)
Disk /dev/sdc1: 215GB
Sector size (logical/physical): 512B/4096B
Partition Table: loop
Disk Flags:

Number  Start   End     Size   File system  Flags
      0.00B  107GB  107GB   ext4
```

c. Expand the partition with `resizepart`. Enter the partition number, *1*, and a size for the new partition:

```
(parted) resizepart
Partition number? 1
End? [107GB]? 215GB
```

d. To exit, enter `quit`.

3. With the partition resized, verify the partition consistency with `e2fsck`:

```
sudo e2fsck -f /dev/sdc1
```

4. Resize the filesystem with `resize2fs`:

```
sudo resize2fs /dev/sdc1
```

5. Mount the partition to the desired location, such as `/datadrive`:

```
sudo mount /dev/sdc1 /datadrive
```

6. To verify the data disk has been resized, use `df -h`. The following example output shows the data drive `/dev/sdc1` is now 200 GB:

```
Filesystem      Size  Used  Avail Use% Mounted on
/dev/sdc1       197G  60M  187G   1% /datadrive
```

## Next steps

- If you need additional storage, you can also [add data disks to a Linux VM](#).

- For more information about disk encryption, see [Azure Disk Encryption for Linux VMs](#).

# How to expand virtual hard disks attached to a Windows virtual machine

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

When you create a new virtual machine (VM) in a resource group by deploying an image from [Azure Marketplace](#), the default operating system (OS) disk is usually 127 GiB (some images have smaller OS disk sizes by default). You can add data disks to your VM (the amount depends on the VM SKU you selected) and we recommend installing applications and CPU-intensive workloads on data disks. You may need to expand the OS disk if you're supporting a legacy application that installs components on the OS disk or if you're migrating a physical PC or VM from on-premises that has a larger OS disk. This article covers expanding either OS disks or data disks.

## IMPORTANT

Unless you use [Expand without downtime](#), expanding a data disk requires the VM to be deallocated.

Shrinking an existing disk isn't supported and may result in data loss.

After expanding the disks, you need to [Expand the volume in the operating system](#) to take advantage of the larger disk.

## Expand without downtime

You can now expand your data disks without deallocating your VM.

This feature has the following limitations:

- Only supported for data disks.
- If a disk is 4 TiB or less, you can't expand it beyond 4 TiB without deallocating the VM. If a disk is already greater than 4 TiB, you can expand it without deallocating the VM.
- Not supported for Ultra disks, Premium SSD v2 (preview) disks, or standard HDDs.
- Not supported for shared disks.
- Install and use either:
  - The [latest Azure CLI](#)
  - The [latest Azure PowerShell module](#)
  - The [Azure portal](#)
  - Or an Azure Resource Manager template with an API version that's 2021-04-01 or newer.

## Resize a managed disk in the Azure portal

## IMPORTANT

If your disk meets the requirements in [Expand without downtime](#), you can skip step 1.

1. In the [Azure portal](#), go to the virtual machine in which you want to expand the disk. Select **Stop** to deallocate the VM.
2. In the left menu under **Settings**, select **Disks**.

**Essentials**

Resource group (change) [reproRG](#)

Status Stopped (deallocated)

Location West US 2

Subscription (change) [Microsoft Azure Internal Consumption](#)

Subscription ID example-subscription-id-sequence

Tags (change) [Click here to add tags](#)

Operating system Windows

Size Standard D2s v3 (2 vcpus, 8 GiB memory)

Public IP address [windowsRepro-ip](#)

Virtual network/subnet [reproRG-vnet/default](#)

DNS name [Configure](#)

**Properties** Monitoring Capabilities Recommendations Tutorials

**Virtual machine** **Networking**

3. Under Disk name, select the disk you want to expand.

Disk name	Storage type	Size (GiB)
windowsRepro_disk1_1c8	Premium SSD	127

4. In the left menu under Settings, select Size + performance.

Show data for last: 1 hour 6 hours 12 hours 1 day 7 days

Series	Value
OS Disk Read Bytes/S... win10vm	401.9 kB/s
OS Disk Write Bytes/... win10vm	285.7 kB/s
OS Disk Read Operat... win10vm	8.97 /s
OS Disk Write Operat... win10vm	10.76 /s

5. In Size + performance, select the disk size you want.

**WARNING**

The new size should be greater than the existing disk size. The maximum allowed is 4,095 GB for OS disks. (It's possible to expand the VHD blob beyond that size, but the OS works only with the first 4,095 GB of space.)

Size	Disk tier	Provisioned IOPS	Provisioned through...	Max Shares	Max burst IOPS	Max burst throughput
4 GiB	P1	120	25	-	3500	170
8 GiB	P2	120	25	-	3500	170
16 GiB	P3	120	25	-	3500	170
32 GiB	P4	120	25	-	3500	170
64 GiB	P6	240	50	-	3500	170
128 GiB	P10	500	100	-	3500	170
256 GiB	P15	1100	125	2	3500	170
512 GiB	P20	2300	150	2	3500	170
1024 GiB	P30	5000	200	5	-	-
2048 GiB	P40	7500	250	5	-	-
4096 GiB	P50	7500	250	5	-	-
8192 GiB	P60	16000	500	10	-	-
16384 GiB	P70	18000	750	10	-	-
32767 GiB	P80	20000	900	10	-	-

Custom disk size (GiB) \*

**Resize** **Discard**

## 6. Select **Resize** at the bottom of the page.

Size	Disk tier	Provisioned IOPS	Provisioned through...	Max Shares	Max burst IOPS	Max burst throughput
4 GiB	P1	120	25	-	3500	170
8 GiB	P2	120	25	-	3500	170
16 GiB	P3	120	25	-	3500	170
32 GiB	P4	120	25	-	3500	170
64 GiB	P6	240	50	-	3500	170
128 GiB	P10	500	100	-	3500	170
256 GiB	P15	1100	125	2	3500	170
512 GiB	P20	2300	150	2	3500	170
1024 GiB	P30	5000	200	5	-	-
2048 GiB	P40	7500	250	5	-	-
4096 GiB	P50	7500	250	5	-	-
8192 GiB	P60	16000	500	10	-	-
16384 GiB	P70	18000	750	10	-	-
32767 GiB	P80	20000	900	10	-	-

Custom disk size (GiB) \*

**Resize** **Discard**

## Resize a managed disk by using PowerShell

Open your PowerShell ISE or PowerShell window in administrative mode and follow the steps below:

Sign in to your Microsoft Azure account in resource management mode and select your subscription:

```
Connect-AzAccount
Select-AzSubscription -SubscriptionName 'my-subscription-name'
```

Set your resource group name and VM name:

```
$rgName = 'my-resource-group-name'
$vmName = 'my-vm-name'
$diskName = 'my-disk-name'
```

Obtain a reference to your VM:

```
$vm = Get-AzVM -ResourceGroupName $rgName -Name $vmName
```

### IMPORTANT

If your disk meets the requirements in [expand without downtime](#), you can skip step 4 and 6.

Stop the VM before resizing the disk:

```
Stop-AzVM -ResourceGroupName $rgName -Name $vmName
```

Obtain a reference to the managed OS disk. Set the size of the managed OS disk to the desired value and update the Disk:

```
$disk= Get-AzDisk -ResourceGroupName $rgName -DiskName $diskName  
$disk.DiskSizeGB = 1023  
Update-AzDisk -ResourceGroupName $rgName -Disk $disk -DiskName $disk.Name
```

### WARNING

The new size should be greater than the existing disk size. The maximum allowed is 4,095 GB for OS disks. (It is possible to expand the VHD blob beyond that size, but the OS works only with the first 4,095 GB of space.)

Updating the VM might take a few seconds. When the command finishes executing, restart the VM:

```
Start-AzVM -ResourceGroupName $rgName -Name $vmName
```

Remote into the VM, open **Computer Management** (or **Disk Management**) and expand the drive using the newly allocated space.

## Expand the volume in the operating system

When you've expanded the disk for the VM, you need to go into the OS and expand the volume to encompass the new space. There are several methods for expanding a partition. This section covers connecting the VM using an RDP connection to expand the partition using [Using Diskpart](#) or [Using Disk Manager](#).

### Using DiskPart

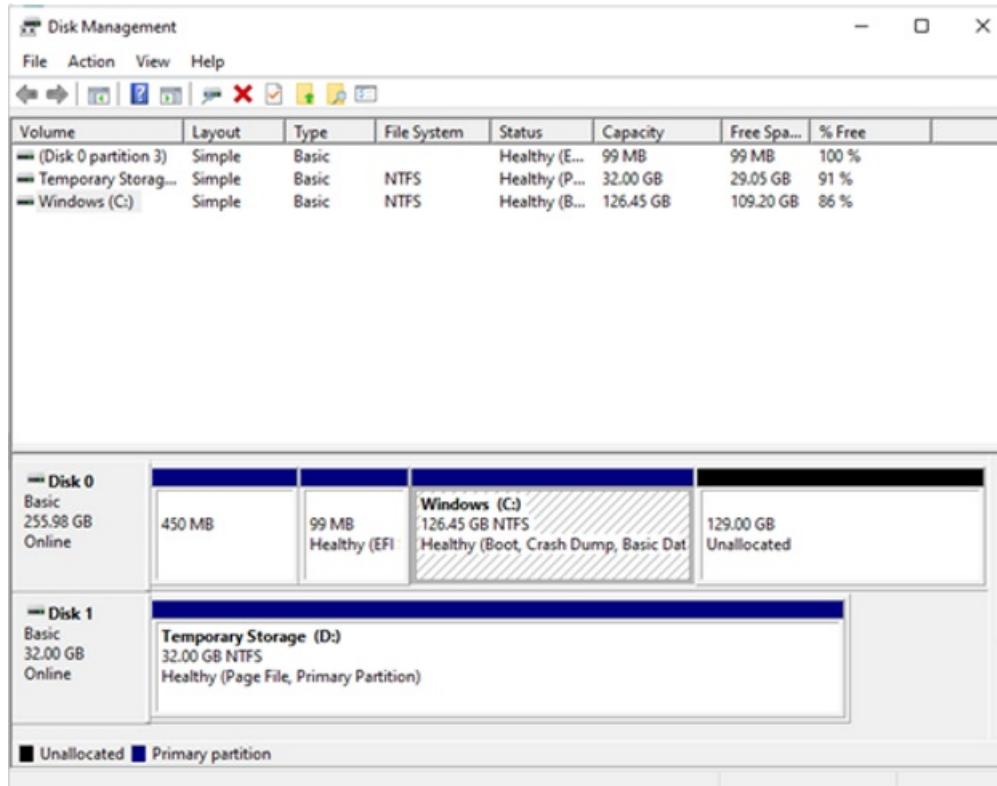

When you've expanded the disk for the VM, you need to go into the OS and expand the volume to encompass the new space. There are several methods for expanding a partition. This section covers connecting the VM using an RDP connection to expand the partition using **DiskPart**.

1. Open an RDP connection to your VM.
2. Open a command prompt and type **diskpart**.
3. At the **DISKPART** prompt, type `list volume`. Make note of the volume you want to extend.
4. At the **DISKPART** prompt, type `select volume <volumenumber>`. This selects the volume *volumenumber* that you want to extend into contiguous, empty space on the same disk.
5. At the **DISKPART** prompt, type `extend [size=<size>]`. This extends the selected volume by *size* in megabytes (MB).

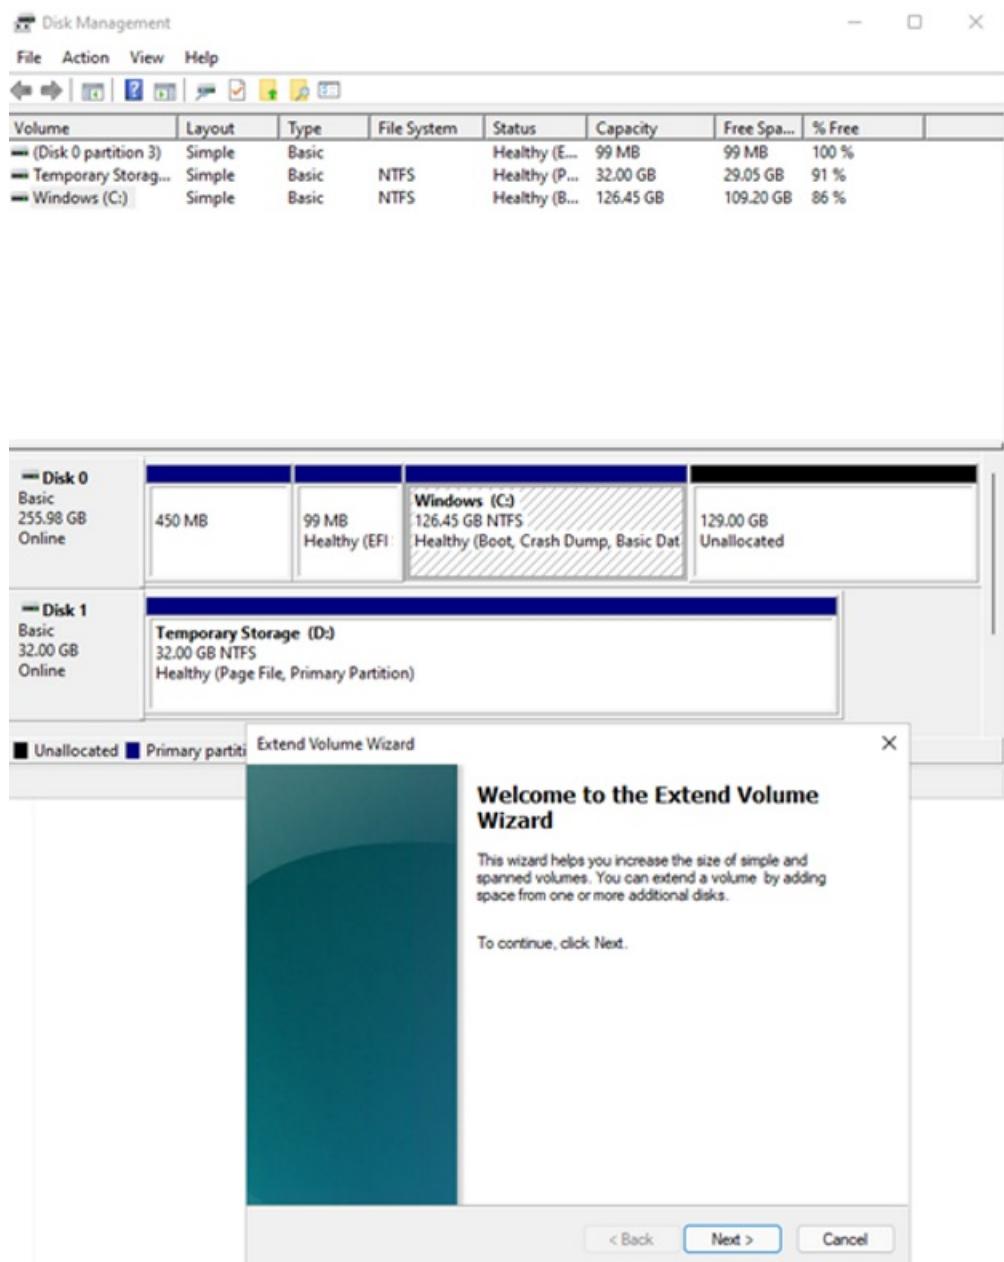

## Using Disk Manager

1. Start a remote desktop session with the VM.

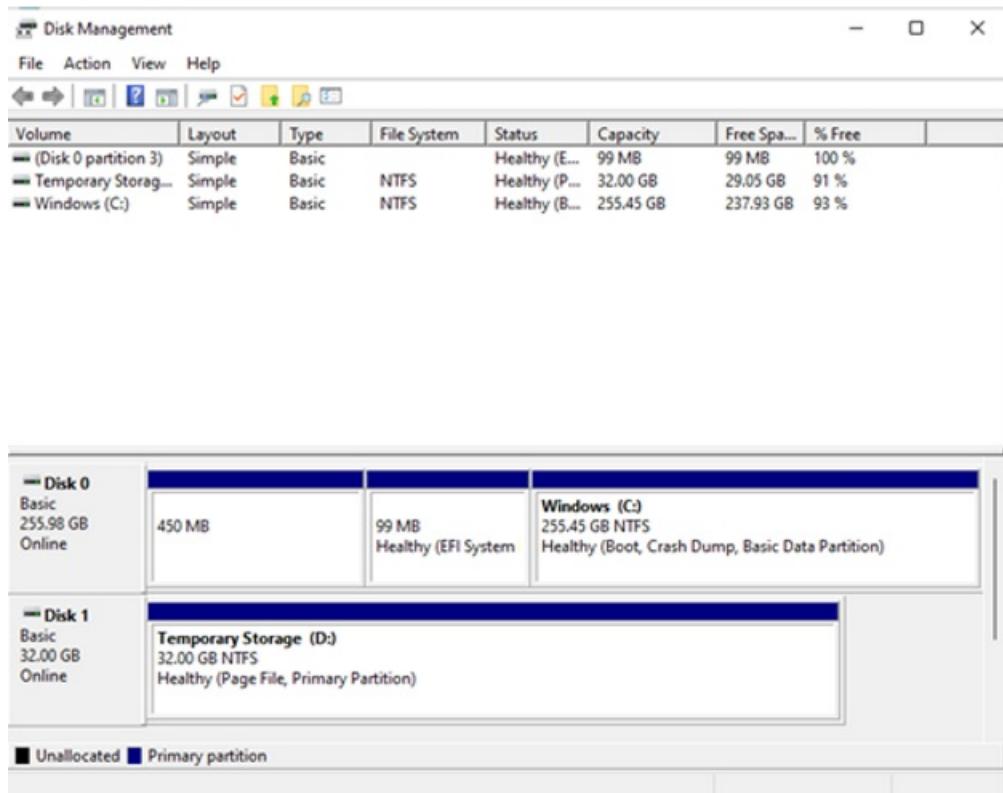

2. Open Disk Management.

3. Right-click on existing C: drive partition -> Extend Volume.

4. Follow the steps you should be able to see the disk with updated capacity:

## Next steps

You can also attach disks using the [Azure portal](#).

# Expand unmanaged virtual hard disks attached to a virtual machine

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article covers how to expand unmanaged disks. To learn how to expand a managed disk, use either the [Windows](#) or [Linux](#) articles.

**Applies to:** ✓ Windows VMs ✓ Linux VMs ✓ Flexible scale sets

When you create a new virtual machine (VM) in a resource group by deploying an image from [Azure Marketplace](#), the default operating system (OS) drive is often 127 GB (some images have smaller OS disk sizes by default). Even though it's possible to add data disks to the VM (the number depends on the SKU you chose) and we recommend installing applications and CPU-intensive workloads on these addendum disks, often, customers need to expand the OS drive to support specific scenarios:

- To support legacy applications that install components on the OS drive.
- To migrate a physical PC or VM from on-premises with a larger OS drive.

## IMPORTANT

Resizing an OS or data disk of an Azure VM requires the VM to be deallocated.

Shrinking an existing disk isn't supported, and can potentially result in data loss.

After expanding the disks, you need to expand the volume within the OS in either [Windows](#) or [Linux](#) to take advantage of the larger disk.

## Resize an unmanaged disk by using PowerShell

Open your PowerShell ISE or PowerShell window in administrative mode and follow the steps below:

- Sign in to your Microsoft Azure account in resource management mode and select your subscription:

```
Connect-AzAccount  
Select-AzSubscription -SubscriptionName 'my-subscription-name'
```

- Set your resource group name and VM names:

```
$rgName = 'my-resource-group-name'  
$vmName = 'my-vm-name'
```

- Obtain a reference to your VM:

```
$vm = Get-AzVM -ResourceGroupName $rgName -Name $vmName
```

- Stop the VM before resizing the disk:

```
Stop-AzVM -ResourceGroupName $rgName -Name $vmName
```

- Set the size of the unmanaged OS disk to the desired value and update the VM:

```
$vm.StorageProfile.OSDisk.DiskSizeGB = 1023  
Update-AzVM -ResourceGroupName $rgName -VM $vm
```

#### WARNING

The new size should be greater than the existing disk size. The maximum allowed is 2,048 GB for OS disks. (It's possible to expand the VHD blob beyond that size, but the OS will only be able to work with the first 2,048 GB of space.)

- Update the size of any data disks you want to resize. To expand the first data disk attached to the VM, use a numeric index to obtain a reference to first attached data disk:

```
$vm.StorageProfile.DataDisks[0].DiskSizeGB = 1023
```

Similarly, you can reference other data disks attached to the VM, either by using an index or the **Name** property of the disk:

```
($vm.StorageProfile.DataDisks | Where ($_.Name -eq 'my-second-data-disk')).DiskSizeGB = 1023
```

- Updating the VM might take a few seconds. When the command finishes executing, restart the VM:

```
Start-AzVM -ResourceGroupName $rgName -Name $vmName
```

## Next steps

You can also attach disks using the [Azure portal](#).

# Using disks in Azure Resource Manager Templates

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This document walks through the differences between managed and unmanaged disks when using Azure Resource Manager templates to provision virtual machines. The examples help you to update existing templates that are using unmanaged Disks to managed disks. For reference, we are using the [vm-simple-windows](#) template as a guide. You can see the template using both [managed Disks](#) and a prior version using [unmanaged disks](#) if you'd like to directly compare them.

## Unmanaged Disks template formatting

To begin, let's take a look at how unmanaged disks are deployed. When creating unmanaged disks, you need a storage account to hold the VHD files. You can create a new storage account or use one that already exists. This article shows you how to create a new storage account. Create a storage account resource in the resources block as shown below.

```
{
  "type": "Microsoft.Storage/storageAccounts",
  "apiVersion": "2018-07-01",
  "name": "[variables('storageAccountName')]",
  "location": "[resourceGroup().location]",
  "sku": {
    "name": "Standard_LRS"
  },
  "kind": "Storage",
  "properties": {}
}
```

Within the virtual machine object, add a dependency on the storage account to ensure that it's created before the virtual machine. Within the `storageProfile` section, specify the full URI of the VHD location, which references the storage account and is needed for the OS disk and any data disks.

```
{
  "type": "Microsoft.Compute/virtualMachines",
  "apiVersion": "2018-10-01",
  "name": "[variables('vmName')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[resourceId('Microsoft.Storage/storageAccounts/', variables('storageAccountName'))]",
    "[resourceId('Microsoft.Network/networkInterfaces/', variables('nicName'))]"
  ],
  "properties": {
    "hardwareProfile": {...},
    "osProfile": {...},
    "storageProfile": {
      "imageReference": {
        "publisher": "MicrosoftWindowsServer",
        "offer": "WindowsServer",
        "sku": "[parameters('windowsOSVersion')]",
        "version": "latest"
      },
      "osDisk": {
        "name": "osdisk",
        "vhd": {
          "uri": "[concat(reference(resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))).primaryEndpoints.blob, 'vhds/osdisk.vhd')]"
        },
        "caching": "ReadWrite",
        "createOption": "FromImage"
      },
      "dataDisks": [
        {
          "name": "datadisk1",
          "diskSizeGB": 1023,
          "lun": 0,
          "vhd": {
            "uri": "[concat(reference(resourceId('Microsoft.Storage/storageAccounts/',
variables('storageAccountName'))).primaryEndpoints.blob, 'vhds/datadisk1.vhd')]"
          },
          "createOption": "Empty"
        }
      ]
    },
    "networkProfile": {...},
    "diagnosticsProfile": {...}
  }
}
```

## Managed disks template formatting

With Azure Managed Disks, the disk becomes a top-level resource and no longer requires a storage account to be created by the user. Managed disks were first exposed in the `2016-04-30-preview` API version, they are available in all subsequent API versions and are now the default disk type. The following sections walk through the default settings and detail how to further customize your disks.

### NOTE

It is recommended to use an API version later than `2016-04-30-preview` as there were breaking changes between `2016-04-30-preview` and `2017-03-30`.

### Default managed disk settings

To create a VM with managed disks, you no longer need to create the storage account resource. Referencing the template example below, there are some differences from the previous unmanaged disk examples to note:

- The `apiVersion` is a version that supports managed disks.
- `osDisk` and `dataDisks` no longer refer to a specific URI for the VHD.
- When deploying without specifying additional properties, the disk will use a storage type based on the size of the VM. For example, if you are using a VM size that supports premium storage (sizes with "s" in their name such as Standard\_D2s\_v3) then premium disks will be configured by default. You can change this by using the sku setting of the disk to specify a storage type.
- If no name for the disk is specified, it takes the format of `<VMName>_OsDisk_1_<randomstring>` for the OS disk and `<VMName>_disk<#>_<randomstring>` for each data disk.
  - If a VM is being created from a custom image then the default settings for storage account type and disk name are retrieved from the disk properties defined in the custom image resource. These can be overridden by specifying values for these in the template.
- By default, Azure disk encryption is disabled.
- By default, disk caching is Read/Write for the OS disk and None for data disks.
- In the example below there is still a storage account dependency, though this is only for storage of diagnostics and is not needed for disk storage.

```
{
  "type": "Microsoft.Compute/virtualMachines",
  "apiVersion": "2018-10-01",
  "name": "[variables('vmName')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[resourceId('Microsoft.Storage/storageAccounts/', variables('storageAccountName'))]",
    "[resourceId('Microsoft.Network/networkInterfaces/', variables('nicName'))]"
  ],
  "properties": {
    "hardwareProfile": {...},
    "osProfile": {...},
    "storageProfile": {
      "imageReference": {
        "publisher": "MicrosoftWindowsServer",
        "offer": "WindowsServer",
        "sku": "[parameters('windowsOSVersion')]",
        "version": "latest"
      },
      "osDisk": {
        "createOption": "FromImage"
      },
      "dataDisks": [
        {
          "diskSizeGB": 1023,
          "lun": 0,
          "createOption": "Empty"
        }
      ]
    },
    "networkProfile": {...},
    "diagnosticsProfile": {...}
  }
}
```

## Using a top-level managed disk resource

As an alternative to specifying the disk configuration in the virtual machine object, you can create a top-level disk resource and attach it as part of the virtual machine creation. For example, you can create a disk resource as follows to use as a data disk.

```
{
    "type": "Microsoft.Compute/disks",
    "apiVersion": "2018-06-01",
    "name": "[concat(variables('vmName'), '-datadisk1')]",
    "location": "[resourceGroup().location]",
    "sku": {
        "name": "Standard_LRS"
    },
    "properties": {
        "creationData": {
            "createOption": "Empty"
        },
        "diskSizeGB": 1023
    }
}
```

Within the VM object, reference the disk object to be attached. Specifying the resource ID of the managed disk created in the `managedDisk` property allows the attachment of the disk as the VM is created. The `apiVersion` for the VM resource is set to `2017-03-30`. A dependency on the disk resource is added to ensure it's successfully created before VM creation.

```
{
    "type": "Microsoft.Compute/virtualMachines",
    "apiVersion": "2018-10-01",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[resourceId('Microsoft.Storage/storageAccounts/', variables('storageAccountName'))]",
        "[resourceId('Microsoft.Network/networkInterfaces/', variables('nicName'))]",
        "[resourceId('Microsoft.Compute/disks/', concat(variables('vmName'), '-datadisk1'))]"
    ],
    "properties": {
        "hardwareProfile": {...},
        "osProfile": {...},
        "storageProfile": {
            "imageReference": {
                "publisher": "MicrosoftWindowsServer",
                "offer": "WindowsServer",
                "sku": "[parameters('windowsOSVersion')]",
                "version": "latest"
            },
            "osDisk": {
                "createOption": "FromImage"
            },
            "dataDisks": [
                {
                    "lun": 0,
                    "name": "[concat(variables('vmName'), '-datadisk1')]",
                    "createOption": "attach",
                    "managedDisk": {
                        "id": "[resourceId('Microsoft.Compute/disks/', concat(variables('vmName'), '-datadisk1'))]"
                    }
                }
            ]
        },
        "networkProfile": {...},
        "diagnosticsProfile": {...}
    }
}
```

## Create managed availability sets with VMs using managed disks

To create managed availability sets with VMs using managed disks, add the `sku` object to the availability set

resource and set the `name` property to `Aligned`. This property ensures that the disks for each VM are sufficiently isolated from each other to avoid single points of failure. Also note that the `apiVersion` for the availability set resource is set to `2018-10-01`.

```
{  
    "type": "Microsoft.Compute/availabilitySets",  
    "apiVersion": "2018-10-01",  
    "location": "[resourceGroup().location]",  
    "name": "[variables('avSetName')]",  
    "properties": {  
        "PlatformUpdateDomainCount": 3,  
        "PlatformFaultDomainCount": 2  
    },  
    "sku": {  
        "name": "Aligned"  
    }  
}
```

## Standard SSD disks

Below are the parameters needed in the Resource Manager template to create Standard SSD Disks:

- `apiVersion` for Microsoft.Compute must be set as `2018-04-01` (or later)
- Specify `managedDisk.storageAccountType` as `StandardSSD_LRS`

The following example shows the `properties.storageProfile.osDisk` section for a VM that uses Standard SSD Disks:

```
"osDisk": {  
    "osType": "Windows",  
    "name": "myOsDisk",  
    "caching": "ReadWrite",  
    "createOption": "FromImage",  
    "managedDisk": {  
        "storageAccountType": "StandardSSD_LRS"  
    }  
}
```

For a complete template example of how to create a Standard SSD disk with a template, see [Create a VM from a Windows Image with Standard SSD Data Disks](#).

## Additional scenarios and customizations

To find full information on the REST API specifications, please review the [create a managed disk REST API documentation](#). You will find additional scenarios, as well as default and acceptable values that can be submitted to the API through template deployments.

## Next steps

- For full templates that use managed disks visit the following Azure Quickstart Repo links.
  - [Windows VM with managed disk](#)
  - [Linux VM with managed disk](#)
- Visit the [Azure Managed Disks Overview](#) document to learn more about managed disks.
- Review the template reference documentation for virtual machine resources by visiting the [Microsoft.Compute/virtualMachines template reference](#) document.
- Review the template reference documentation for disk resources by visiting the [Microsoft.Compute/disks template reference](#) document.
- For information on how to use managed disks in Azure virtual machine scale sets, visit the [Use data disks](#)

[with scale sets](#) document.

# Use Azure Storage Explorer to manage Azure managed disks

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure Storage Explorer contains a rich set of features that allows you to:

- Upload, download, and copy managed disks.
- Create snapshots from operating system or data disk virtual hard disk.
- Migrate data from on-premises to Azure.
- Migrate data across Azure regions.

## Prerequisites

To complete this article, you'll need:

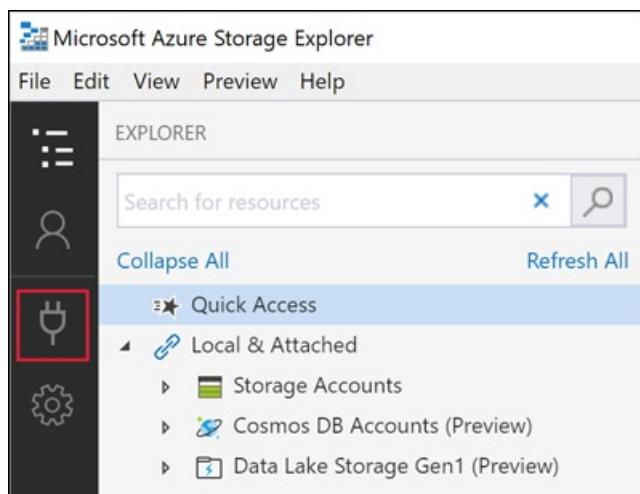

- An Azure subscription.
- At least one Azure managed disk.
- The latest version of [Azure Storage Explorer](#).

If you don't have an Azure subscription, create a [free account](#) before you begin.

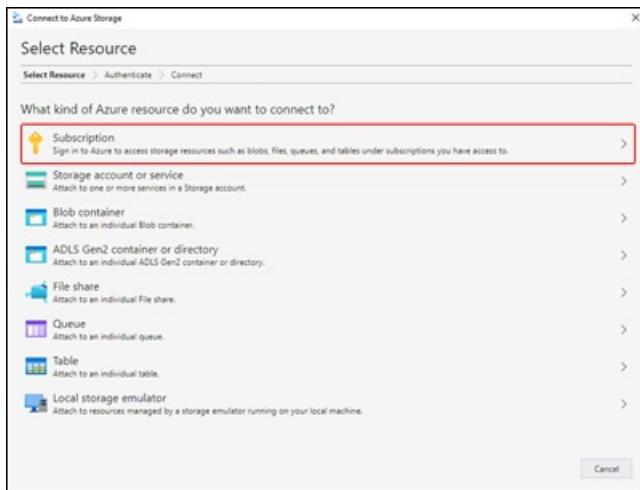

## Connect to an Azure subscription

If your Storage Explorer isn't connected to Azure, you can't use it to manage resources. Follow the steps in this section to connect Storage Explorer to your Azure account. Afterward, you can use it to manage your disks.

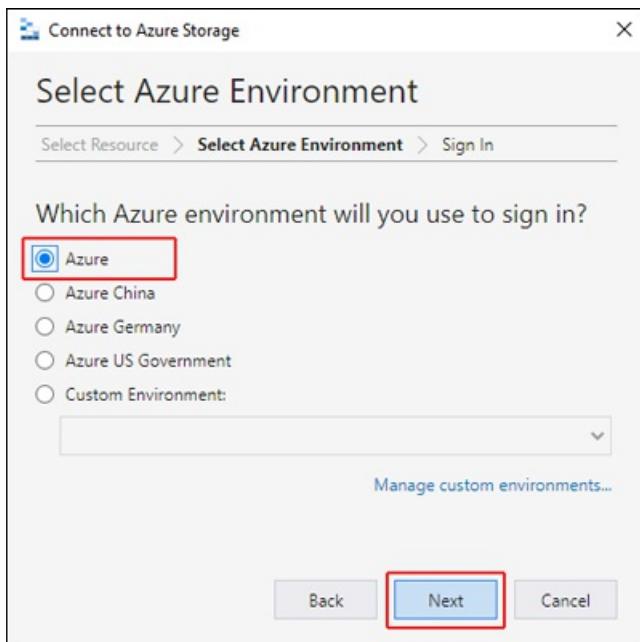

1. Open Azure Storage Explorer and select the **Connect** icon in the toolbar.

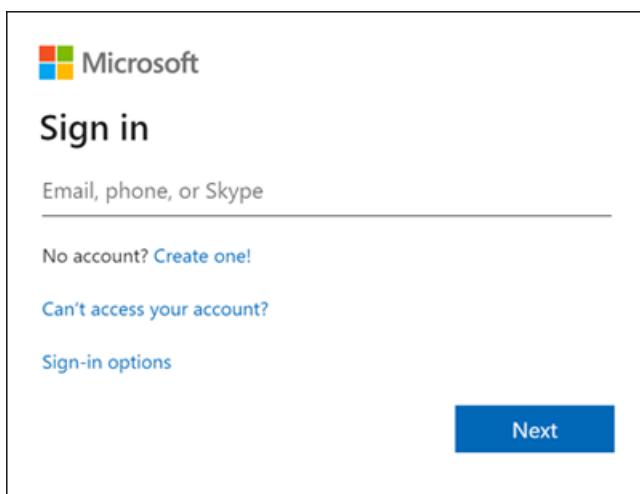

2. In the **Connect to Azure Storage** dialog box, select **Subscription**.

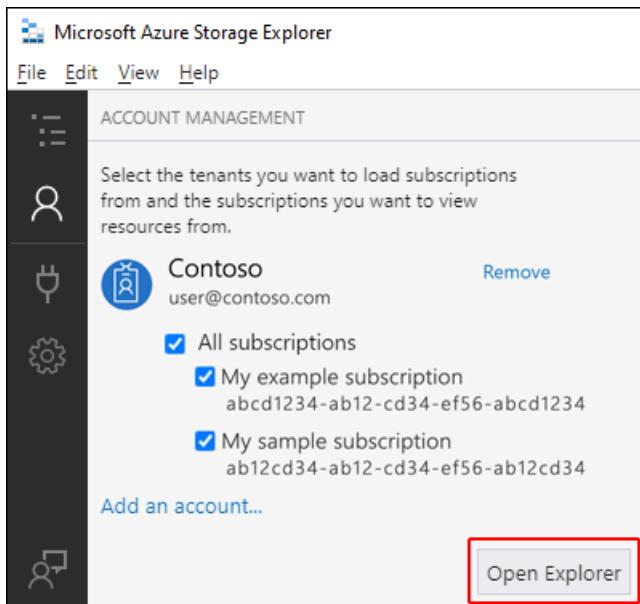

3. Select the appropriate environment and select **Next**. You can also select **Manage custom environments** to configure and add a custom environment.

4. In the **Sign in** dialog box, enter your Azure credentials.

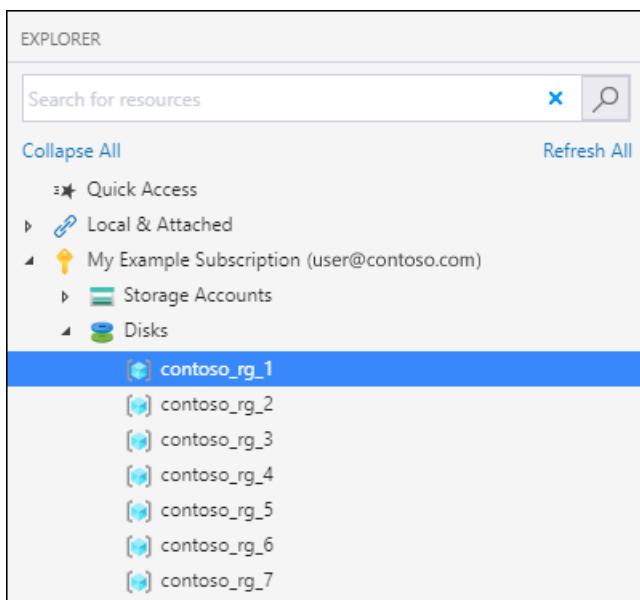

5. Select your subscription from the list and then select **Open Explorer**.

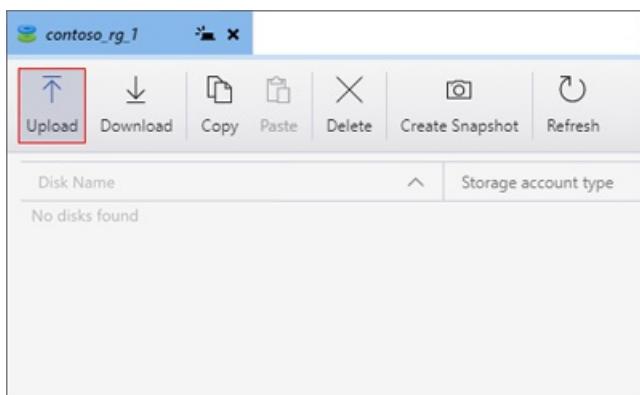

## Upload an on-premises VHD

You can upload an on-premises virtual hard disk (VHD) file to Azure and use it to create an image. Follow the steps in this section to upload your source file.

1. In the **Explorer** pane, expand **Disks** and select the resource group to which you'll upload your disk.

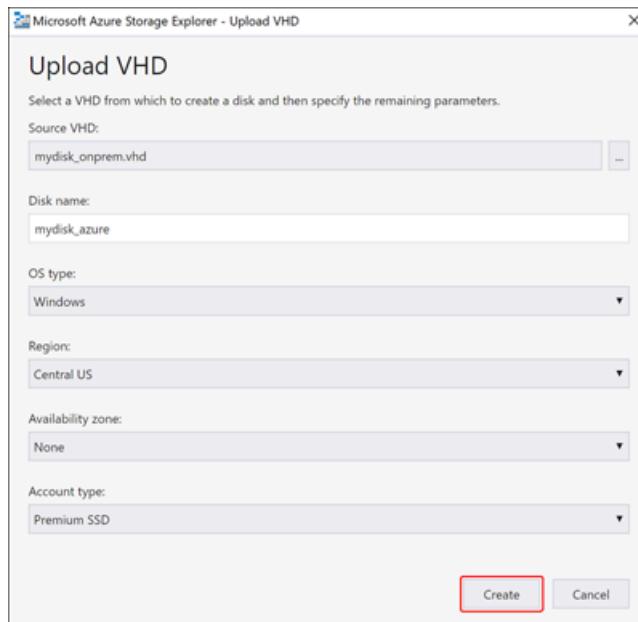

2. In the resource group details pane, select **Upload**.

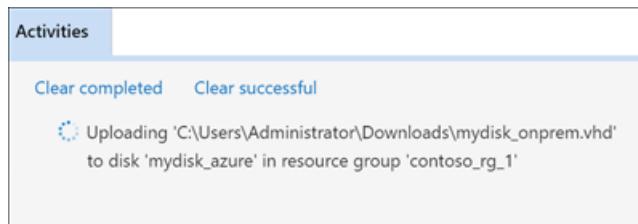

3. In the **Upload VHD** dialog box, specify your VHD source file, the name of the disk, the operating system type, the region to which you want to upload the disk, and the account type. If the region supports

availability zones, you can select a zone of your choice. Select **Create** to begin uploading your disk.

4. The status of the upload will now display in Activities.

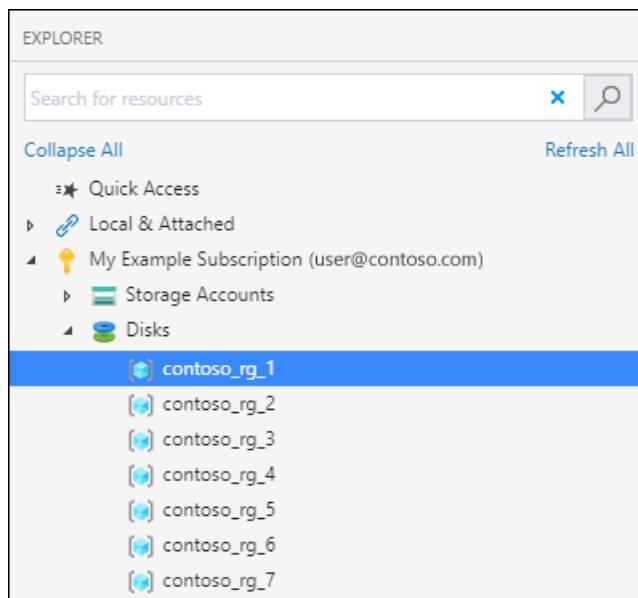

If the upload has finished and you don't see the disk in the Activities pane, select **Refresh**.

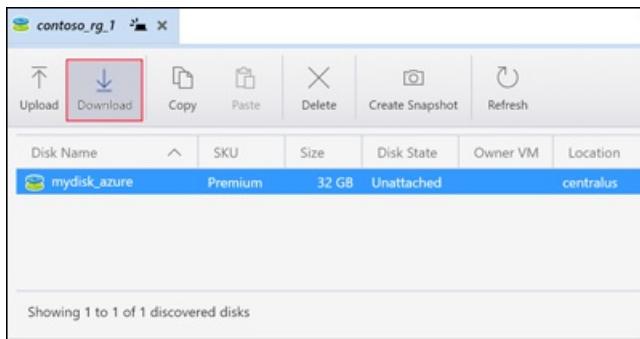

## Download a managed disk

Follow the steps in this section to download a managed disk to an on-premises VHD. A disk's state must be **Unattached** before it can be downloaded.

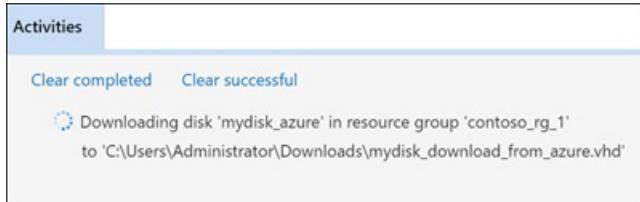

1. In the **Explorer** pane, expand **Disks** and select the resource group from which you'll download your disk.

2. In the resource group details pane, select the disk you want to download.
3. Select **Download** and then choose where you would like to save the disk.

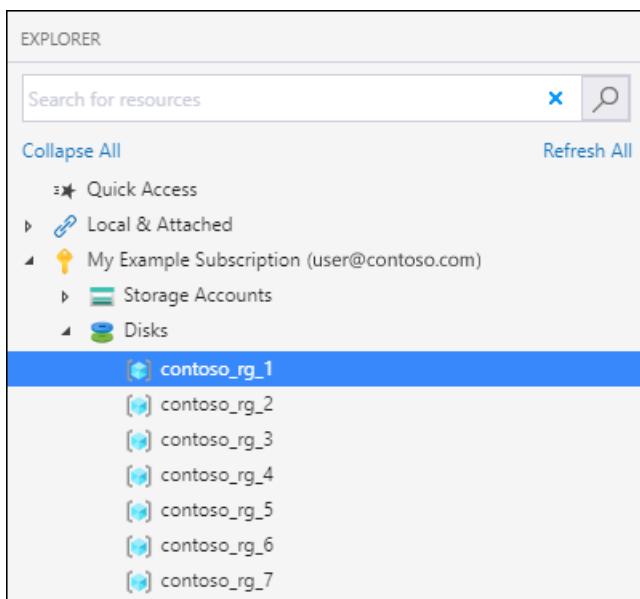

4. Select **Save** to begin the download. The download status will display in **Activities**.

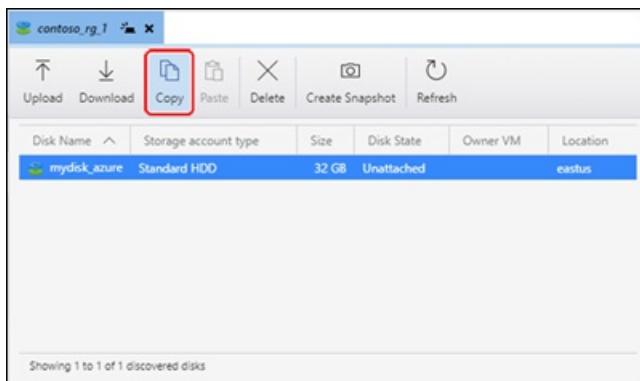

## Copy a managed disk

With Storage Explorer, you can copy a managed disk within or across regions. To copy a disk:

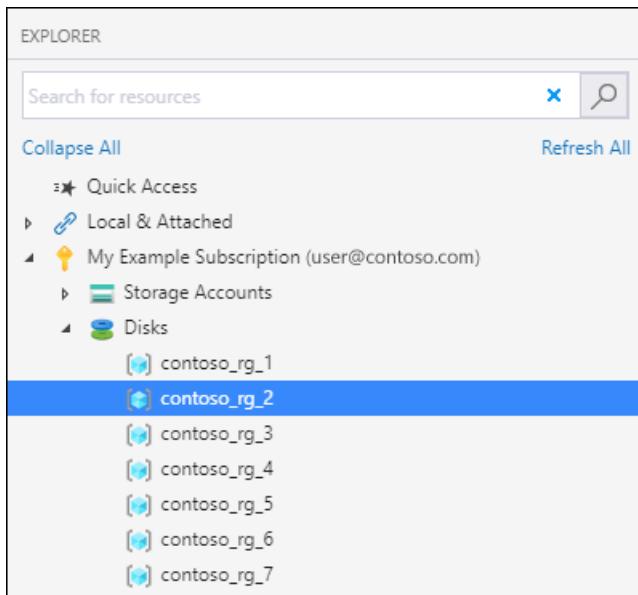

1. In the **Explorer** pane, expand the **Disks** dropdown and select the resource group that contains the disk you want to copy.

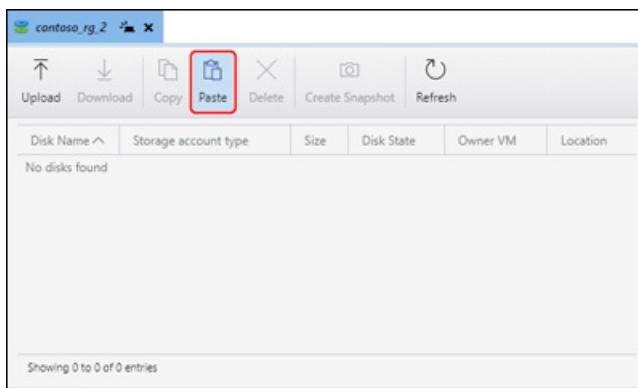

2. In the resource group details pane, select the disk you'd like to copy and select **Copy**.

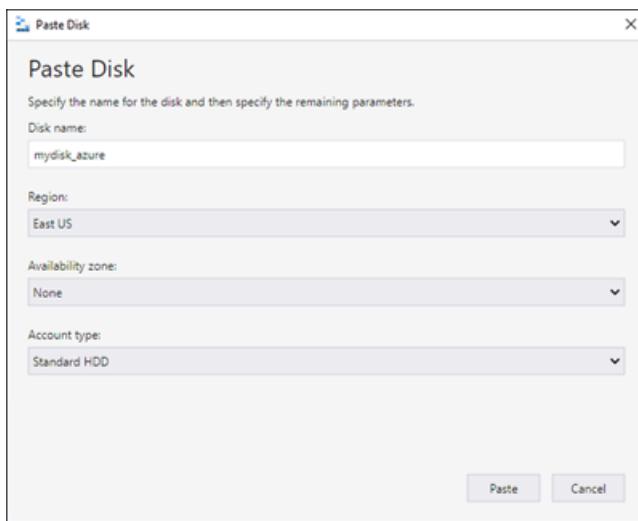

3. In the **Explorer** pane, expand **Disks** and select the resource group in which you'd like to paste the disk.

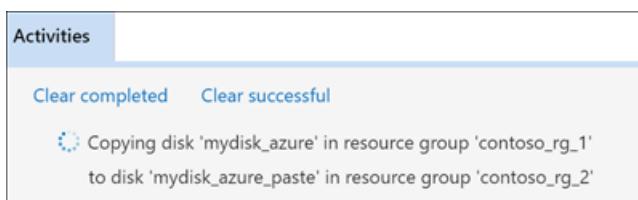

4. Select **Paste** in the resource group details pane.

5. In the **Paste Disk** dialog box, fill in the values. You can also specify an availability zone in supported regions.

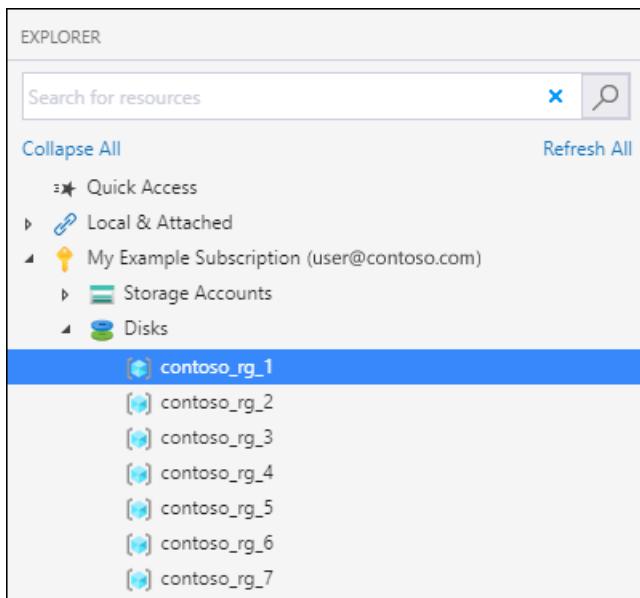

6. Select **Paste** to begin the disk copy. The status is displayed in **Activities**.

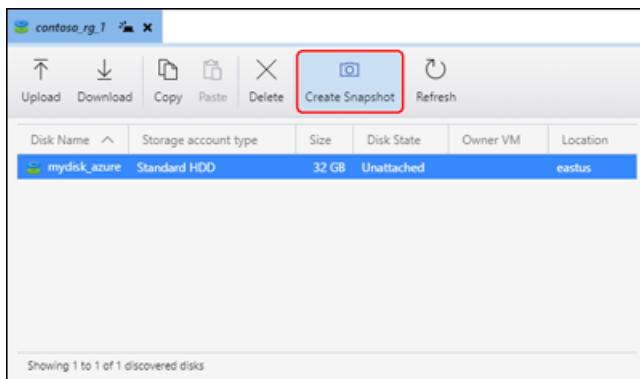

## Create a snapshot

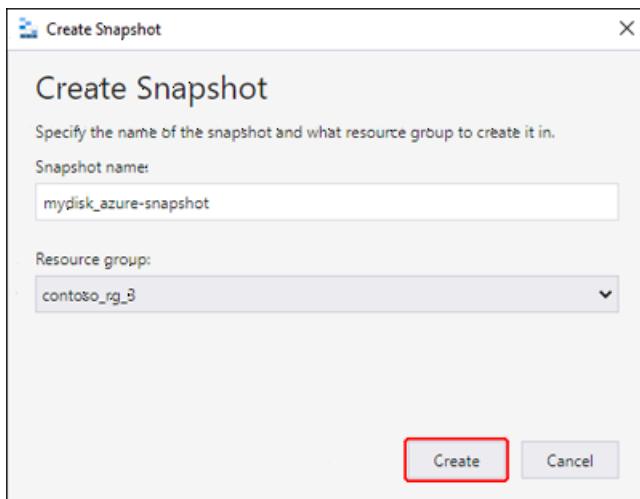

1. In the **Explorer** pane, expand **Disks** and select the resource group that contains the disk you want to snapshot.

2. In the resource group details pane, select the disk you'd like to snapshot and select **Create Snapshot**.

3. In **Create Snapshot**, specify the name of the snapshot and the resource group in which you'll create it. Select **Create**.

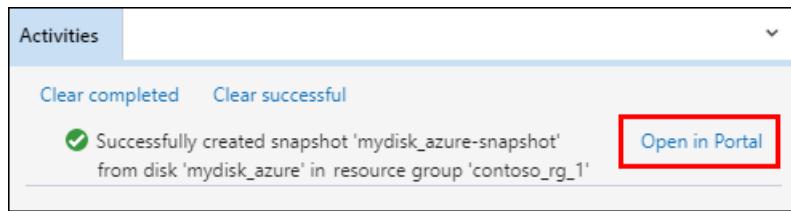

4. After the snapshot has been created, you can select **Open in Portal** in **Activities** to view the snapshot in the Azure portal.

Activities

Clear completed   Clear successful

Successfully created snapshot 'mydisk\_azure-snapshot'  
from disk 'mydisk\_azure' in resource group 'contoso\_rg\_1'

[Open in Portal](#)

The screenshot shows the 'Activities' blade in the Azure portal. It displays a single activity: 'Successfully created snapshot 'mydisk\_azure-snapshot' from disk 'mydisk\_azure' in resource group 'contoso\_rg\_1''. Below the message is a blue link labeled 'Open in Portal'. A red box highlights this link.

# Change the OS disk used by an Azure VM using the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

If you have an existing VM, but you want to swap the disk for a backup disk or another OS disk, you can use the Azure CLI to swap the OS disks. You don't have to delete and recreate the VM. You can even use a managed disk in another resource group, as long as it isn't already in use.

The VM does not need to be stopped\deallocated. The resource ID of the managed disk can be replaced with the resource ID of a different managed disk.

Make sure that the VM size and storage type are compatible with the disk you want to attach. For example, if the disk you want to use is in Premium Storage, then the VM needs to be capable of Premium Storage (like a DS-series size).

This article requires Azure CLI version 2.0.25 or greater. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

Use [az disk list](#) to get a list of the disks in your resource group.

```
az disk list \
-g myResourceGroupDisk \
--query '[*].{diskId:id}' \
--output table
```

(Optional) Use [az vm stop](#) to stop\deallocate the VM before swapping the disks.

```
az vm stop \
-n myVM \
-g myResourceGroup
```

Use [az vm update](#) with the full resource ID of the new disk for the `--osdisk` parameter

```
az vm update \
-g myResourceGroup \
-n myVM \
--os-disk /subscriptions/<subscription ID>/resourceGroups/<resource group>/providers/Microsoft.Compute/disks/myDisk
```

Restart the VM using [az vm start](#).

```
az vm start \
-n myVM \
-g myResourceGroup
```

## Next steps

To create a copy of a disk, see [Snapshot a disk](#).

# Change the OS disk used by an Azure VM using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

If you have an existing VM, but you want to swap the disk for a backup disk or another OS disk, you can use Azure PowerShell to swap the OS disks. You don't have to delete and recreate the VM. You can even use a managed disk in another resource group, as long as it isn't already in use.

The VM does not need to be stopped\deallocated. The resource ID of the managed disk can be replaced with the resource ID of a different managed disk.

Make sure that the VM size and storage type are compatible with the disk you want to attach. For example, if the disk you want to use is in Premium Storage, then the VM needs to be capable of Premium Storage (like a DS-series size). Both disks must also be the same size. And ensure that you're not mixing an un-encrypted VM with an encrypted OS disk, this is not supported. If the VM doesn't use Azure Disk Encryption, then the OS disk being swapped in shouldn't be using Azure Disk Encryption. If disks are using Disk Encryption Sets, both disks should belong to same Disk Encryption set.

Get a list of disks in a resource group using [Get-AzDisk](#)

```
Get-AzDisk -ResourceGroupName myResourceGroup | Format-Table -Property Name
```

When you have the name of the disk that you would like to use, set that as the OS disk for the VM. This example stop\deallocates the VM named *myVM* and assigns the disk named *newDisk* as the new OS disk.

```
# Get the VM
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM

# (Optional) Stop/ deallocate the VM
Stop-AzVM -ResourceGroupName myResourceGroup -Name $vm.Name -Force

# Get the new disk that you want to swap in
$disk = Get-AzDisk -ResourceGroupName myResourceGroup -Name newDisk

# Set the VM configuration to point to the new disk
Set-AzVMOSDisk -VM $vm -ManagedDiskId $disk.Id -Name $disk.Name

# Update the VM with the new OS disk
Update-AzVM -ResourceGroupName myResourceGroup -VM $vm

# Start the VM
Start-AzVM -Name $vm.Name -ResourceGroupName myResourceGroup
```

## Next steps

To create a copy of a disk, see [Snapshot a disk](#).

# How to map Azure Disks to Linux VM guest disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You may need to determine the Azure Disks that back a VM's guest disks. In some scenarios, you can compare the disk or volume size to the size of the attached Azure Disks. In scenarios where there are multiple Azure Disks of the same size attached to the VM you need to use the Logical Unit Number (LUN) of the data disks.

## What is a LUN?

A Logical Unit Number (LUN) is a number that is used to identify a specific storage device. Each storage device is assigned a unique numeric identifier, starting at zero. The full path to a device is represented by the bus number, target ID number, and Logical Unit Number (LUN).

For example: ***Bus Number 0, Target ID 0, LUN 3***

For our exercise, you only need to use the LUN.

## Finding the LUN

Below we have listed two methods for finding the LUN of a disk in Linux.

### **lsscsi**

1. Connect to the VM
2. `sudo lsscsi`

The first column listed will contain the LUN, the format is [Host:Channel:Target:LUN].

### **Listing block devices**

1. Connect to the VM
2. `sudo ls -l /sys/block/*/device`

The last column listed will contain the LUN, the format is [Host:Channel:Target:LUN]

## Finding the LUN for the Azure Disks

You can locate the LUN for an Azure Disk using the Azure portal, Azure CLI.

### **Finding an Azure Disk's LUN in the Azure portal**

1. In the Azure portal, select "Virtual Machines" to display a list of your Virtual Machines
2. Select the Virtual Machine
3. Select "Disks"
4. Select a data disk from the list of attached disks.
5. The LUN of the disk will be displayed in the disk detail pane. The LUN displayed here correlate to the LUNs that you looked up in the Guest using lsscsi, or listing the block devices.

### **Finding an Azure Disk's LUN using Azure CLI**

```
az vm show -g myResourceGroup -n myVM --query "storageProfile.dataDisks"
```

# How to map Azure Disks to Windows VM guest disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

You may need to determine the Azure Disks that back a VM's guest disks. In some scenarios, you can compare the disk or volume size to the size of the attached Azure Disks. In scenarios where there are multiple Azure Disks of the same size attached to the VM you need to use the Logical Unit Number (LUN) of the data disks.

## What is a LUN?

A Logical Unit Number (LUN) is a number that is used to identify a specific storage device. Each storage device is assigned a unique numeric identifier, starting at zero. The full path to a device is represented by the bus number, target ID number, and Logical Unit Number (LUN).

For example: ***Bus Number 0, Target ID 0, LUN 3***

For our exercise, you only need to use the LUN.

## Finding the LUN

There are two methods to finding the LUN, which one you choose will depend on if you are using [Storage Spaces](#) or not.

### Disk Management

If you are not using Storage Pools, you can use [Disk Management](#) to find the LUN.

1. Connect to the VM and open Disk Management a. Right-click on the Start button and choose "Disk Management" a. You can also type `diskmgmt.msc` into the Start Search box
2. In the lower pane, right-click any of the Disks and choose "Properties"
3. The LUN will be listed in the "Location" property on the "General" tab

### Storage Pools

1. Connect to the VM and open Server Manager
2. Select "File and Storage Services", "Volumes", "Storage Pools"
3. In the bottom-right corner of Server Manager, there will be a "Physical Disks" section. The disks that make up the Storage Pool are listed here as well as the LUN for each disk.

## Finding the LUN for the Azure Disks

You can locate the LUN for an Azure Disk using the Azure portal, Azure CLI, or Azure PowerShell

### Finding an Azure Disk's LUN in the Azure portal

1. In the Azure portal, select "Virtual Machines" to display a list of your Virtual Machines
2. Select the Virtual Machine
3. Select "Disks"
4. Select a data disk from the list of attached disks.
5. The LUN of the disk will be displayed in the disk detail pane. The LUN displayed here correlates to the LUNs that were looked up in the Guest using Device Manager or Server Manager.

## Finding an Azure Disk's LUN using Azure CLI or Azure PowerShell

- [Azure CLI](#)
- [Azure PowerShell](#)

```
az vm show -g myResourceGroup -n myVM --query "storageProfile.dataDisks"
```

# Use SCP to move files to and from a VM

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article shows how to move files from your workstation up to an Azure VM, or from an Azure VM down to your workstation, using Secure Copy (SCP). Moving files between your workstation and a VM, quickly and securely, is critical for managing your Azure infrastructure.

For this article, you need a VM deployed in Azure with SSH enabled. You also need an SCP client for your local computer. It is built on top of SSH and included in the default shell of most computers.

## Quick commands

Copy a file up to the VM

```
scp file azureuser@azurehost:directory/targetfile
```

Copy a file down from the VM

```
scp azureuser@azurehost:directory/file targetfile
```

## Detailed walkthrough

As examples, we move an Azure configuration file up to a VM and pull down a log file directory, both using SCP.

## SSH key pair authentication

SCP uses SSH for the transport layer. SSH handles the authentication on the destination host, and it moves the file in an encrypted tunnel provided by default with SSH. For SSH authentication, usernames and passwords can be used. However, SSH public and private key authentication are recommended as a security best practice. Once SSH has authenticated the connection, SCP then begins copying the file. Using a properly configured `~/.ssh/config` and SSH public and private keys, the SCP connection can be established by just using a server name (or IP address). If you only have one SSH key, SCP looks for it in the `~/.ssh/` directory, and uses it by default to log in to the VM.

For more information on configuring your `~/.ssh/config` and SSH public and private keys, see [Create SSH keys](#).

## SCP a file to a VM

For the first example, we copy an Azure configuration file up to a VM that is used to deploy automation. Because this file contains Azure API credentials, which include secrets, security is important. The encrypted tunnel provided by SSH protects the contents of the file.

The following command copies the local `.azure/config` file to an Azure VM with FQDN `myserver.eastus.cloudapp.azure.com`. If you don't have an [FQDN set](#), you can also use the IP address of the VM. The admin user name on the Azure VM is `azureuser`. The file is targeted to the `/home/azureuser/` directory. Substitute your own values in this command.

```
scp ~/azure/config azureuser@myserver.eastus.cloudapp.com:/home/azureuser/config
```

## SCP a directory from a VM

For this example, we copy a directory of log files from the VM down to your workstation. A log file may or may not contain sensitive or secret data. However, using SCP ensures the contents of the log files are encrypted. Using SCP to transfer the files is the easiest way to get the log directory and files down to your workstation while also being secure.

The following command copies files in the `/home/azureuser/logs/` directory on the Azure VM to the local `/tmp` directory:

```
scp -r azureuser@myserver.eastus.cloudapp.com:/home/azureuser/logs/. /tmp/
```

The `-r` flag instructs SCP to recursively copy the files and directories from the point of the directory listed in the command. Also notice that the command-line syntax is similar to a `cp` copy command.

# Find and delete unattached Azure managed and unmanaged disks using the Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you delete a virtual machine (VM) in Azure, by default, any disks that are attached to the VM aren't deleted. This feature helps to prevent data loss due to the unintentional deletion of VMs. After a VM is deleted, you will continue to pay for unattached disks. This article shows you how to find and delete any unattached disks and reduce unnecessary costs.

## Managed disks: Find and delete unattached disks

The following script looks for unattached [managed disks](#) by examining the value of the **ManagedBy** property. When a managed disk is attached to a VM, the **ManagedBy** property contains the resource ID of the VM. When a managed disk is unattached, the **ManagedBy** property is null. The script examines all the managed disks in an Azure subscription. When the script locates a managed disk with the **ManagedBy** property set to null, the script determines that the disk is unattached.

### IMPORTANT

First, run the script by setting the **deleteUnattachedDisks** variable to 0. This action lets you find and view all the unattached managed disks.

After you review all the unattached disks, run the script again and set the **deleteUnattachedDisks** variable to 1. This action lets you delete all the unattached managed disks.

```
# Set deleteUnattachedDisks=1 if you want to delete unattached Managed Disks
# Set deleteUnattachedDisks=0 if you want to see the Id of the unattached Managed Disks
deleteUnattachedDisks=0
unattachedDiskIds=$(az disk list --query '[?managedBy==`null`].[id]' -o tsv)
for id in ${unattachedDiskIds[@]}
do
    if (( $deleteUnattachedDisks == 1 ))
    then
        echo "Deleting unattached Managed Disk with Id: "$id
        az disk delete --ids $id --yes
        echo "Deleted unattached Managed Disk with Id: "$id
    else
        echo $id
    fi
done
```

## Unmanaged disks: Find and delete unattached disks

Unmanaged disks are VHD files that are stored as [page blobs](#) in [Azure storage accounts](#). The following script looks for unattached unmanaged disks (page blobs) by examining the value of the **LeaseStatus** property. When an unmanaged disk is attached to a VM, the **LeaseStatus** property is set to **Locked**. When an unmanaged disk is unattached, the **LeaseStatus** property is set to **Unlocked**. The script examines all the unmanaged disks in all the Azure storage accounts in an Azure subscription. When the script locates an unmanaged disk with a

**LeaseStatus** property set to **Unlocked**, the script determines that the disk is unattached.

#### IMPORTANT

First, run the script by setting the **deleteUnattachedVHDs** variable to 0. This action lets you find and view all the unattached unmanaged VHDs.

After you review all the unattached disks, run the script again and set the **deleteUnattachedVHDs** variable to 1. This action lets you delete all the unattached unmanaged VHDs.

```
# Set deleteUnattachedVHDs=1 if you want to delete unattached VHDs
# Set deleteUnattachedVHDs=0 if you want to see the details of the unattached VHDs
deleteUnattachedVHDs=0
storageAccountIds=$(az storage account list --query [].[id] -o tsv)
for id in ${storageAccountIds[@]}
do
    connectionString=$(az storage account show-connection-string --ids $id --query connectionString -o tsv)
    containers=$(az storage container list --connection-string $connectionString --query [].[name] -o tsv)

    for container in ${containers[@]}
    do

        blobs=$(az storage blob list --show-next-marker -c $container --connection-string $connectionString
--query "[?properties.blobType=='PageBlob' && ends_with(name, '.vhd')].[name]" -o tsv)

        for blob in ${blobs[@]}
        do
            leaseStatus=$(az storage blob show -n $blob -c $container --connection-string $connectionString
--query "properties.lease.status" -o tsv)

            if [ "$leaseStatus" == "unlocked" ]
            then

                if (( $deleteUnattachedVHDs == 1 ))
                then

                    echo "Deleting VHD: \"$blob\" in container: \"$container\" in storage account: \"$id"

                    az storage blob delete --delete-snapshots include -n $blob -c $container --connection-
string $connectionString

                    echo "Deleted VHD: \"$blob\" in container: \"$container\" in storage account: \"$id"
                else
                    echo "StorageAccountId: \"$id\" container: \"$container\" VHD: \"$blob"
                fi

            fi
        done
    done
done
```

## Next steps

# Find and delete unattached Azure managed and unmanaged disks

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

When you delete a virtual machine (VM) in Azure, by default, any disks that are attached to the VM aren't deleted. This feature helps to prevent data loss due to the unintentional deletion of VMs. After a VM is deleted, you will continue to pay for unattached disks. This article shows you how to find and delete any unattached disks and reduce unnecessary costs.

## Managed disks: Find and delete unattached disks

The following script looks for unattached [managed disks](#) by examining the value of the **ManagedBy** property. When a managed disk is attached to a VM, the **ManagedBy** property contains the resource ID of the VM. When a managed disk is unattached, the **ManagedBy** property is null. The script examines all the managed disks in an Azure subscription. When the script locates a managed disk with the **ManagedBy** property set to null, the script determines that the disk is unattached.

### IMPORTANT

First, run the script by setting the **deleteUnattachedDisks** variable to 0. This action lets you find and view all the unattached managed disks.

After you review all the unattached disks, run the script again and set the **deleteUnattachedDisks** variable to 1. This action lets you delete all the unattached managed disks.

```
# Set deleteUnattachedDisks=1 if you want to delete unattached Managed Disks
# Set deleteUnattachedDisks=0 if you want to see the Id of the unattached Managed Disks
$deleteUnattachedDisks=0
$managedDisks = Get-AzDisk
foreach ($md in $managedDisks) {
    # ManagedBy property stores the Id of the VM to which Managed Disk is attached to
    # If ManagedBy property is $null then it means that the Managed Disk is not attached to a VM
    if($md.ManagedBy -eq $null){
        if($deleteUnattachedDisks -eq 1){
            Write-Host "Deleting unattached Managed Disk with Id: $($md.Id)"
            $md | Remove-AzDisk -Force
            Write-Host "Deleted unattached Managed Disk with Id: $($md.Id) "
        }else{
            $md.Id
        }
    }
}
```

## Unmanaged disks: Find and delete unattached disks

Unmanaged disks are VHD files that are stored as [page blobs](#) in [Azure storage accounts](#). The following script looks for unattached unmanaged disks (page blobs) by examining the value of the **LeaseStatus** property. When an unmanaged disk is attached to a VM, the **LeaseStatus** property is set to **Locked**. When an unmanaged disk is unattached, the **LeaseStatus** property is set to **Unlocked**. The script examines all the unmanaged disks in all the Azure storage accounts in an Azure subscription. When the script locates an unmanaged disk with a

**LeaseStatus** property set to **Unlocked**, the script determines that the disk is unattached.

#### IMPORTANT

First, run the script by setting the **deleteUnattachedVHDs** variable to `$false`. This action lets you find and view all the unattached unmanaged VHDs.

After you review all the unattached disks, run the script again and set the **deleteUnattachedVHDs** variable to `$true`. This action lets you delete all the unattached unmanaged VHDs.

```
# Set deleteUnattachedVHDs=$true if you want to delete unattached VHDs
# Set deleteUnattachedVHDs=$false if you want to see the Uri of the unattached VHDs
$deleteUnattachedVHDs=$false
$storageAccounts = Get-AzStorageAccount
foreach($storageAccount in $storageAccounts){
    $storageKey = (Get-AzStorageAccountKey -ResourceGroupName $storageAccount.ResourceGroupName -Name
    $storageAccount.StorageAccountName)[0].Value
    $context = New-AzStorageContext -StorageAccountName $storageAccount.StorageAccountName -
    StorageAccountKey $storageKey
    $containers = Get-AzStorageContainer -Context $context
    foreach($container in $containers){
        $blobs = Get-AzStorageBlob -Container $container.Name -Context $context
        #Fetch all the Page blobs with extension .vhd as only Page blobs can be attached as disk to Azure
        VMs
        $blobs | Where-Object {$_._BlobType -eq 'PageBlob' -and $_.Name.EndsWith('.vhd')} | ForEach-Object {
            #If a Page blob is not attached as disk then LeaseStatus will be unlocked
            if($_.ICloudBlob.Properties.LeaseStatus -eq 'Unlocked'){
                if($deleteUnattachedVHDs){
                    Write-Host "Deleting unattached VHD with Uri: $($_.ICloudBlob.Uri.AbsoluteUri)"
                    $_ | Remove-AzStorageBlob -Force
                    Write-Host "Deleted unattached VHD with Uri: $($_.ICloudBlob.Uri.AbsoluteUri)"
                }
                else{
                    $_.ICloudBlob.Uri.AbsoluteUri
                }
            }
        }
    }
}
```

# Find and delete unattached Azure managed and unmanaged disks - Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

When you delete a virtual machine (VM) in Azure, by default, any disks that are attached to the VM aren't deleted. This helps to prevent data loss due to the unintentional deletion of VMs. After a VM is deleted, you will continue to pay for unattached disks. This article shows you how to find and delete any unattached disks using the Azure portal, and reduce unnecessary costs. Deletions are permanent, you will not be able to recover data once you delete a disk.

## Managed disks: Find and delete unattached disks

If you have unattached managed disks and no longer need the data on them, the following process explains how to find them from the Azure portal:

1. Sign in to the [Azure portal](#).
  2. Search for and select **Disk**.
- On the **Disk** blade, you are presented with a list of all your disks.
3. Select the disk you'd like to delete, this brings you to the individual disk's blade.
  4. On the individual disk's blade, confirm the disk state is unattached, then select **Delete**.

The screenshot shows the 'data-detach' blade for a disk named 'linvm'. At the top, there's a search bar labeled 'Search (Ctrl+ /)' and several action buttons: '+ Create VM', '+ Create snapshot', 'Delete' (which is highlighted with a red box), and 'Refresh'. Below the search bar, there's a navigation menu with 'Overview' selected (also highlighted with a red box). To the right of the menu, it says 'Resource group (change)' followed by 'linvm'. Further down, under 'Disk state', it shows 'Unattached' (also highlighted with a red box).

## Unmanaged disks: Find and delete unattached disks

Unmanaged disks are VHD files that are stored as [page blobs](#) in [Azure storage accounts](#).

If you have unmanaged disks that aren't attached to a VM, no longer need the data on them, and would like to delete them, the following process explains how to do so from the Azure portal:

1. Sign in to the [Azure portal](#).
2. Search for and select **Disk (Classic)**.

You are presented with a list of all your unmanaged disks. Any disk that has "-" in the **Attached to** column is an unattached disk.

## Disks (classic) ☁

Microsoft

[+ Add](#) [Edit columns](#) [⟳ Refresh](#) | [Assign tags](#)

**Subscriptions:** All 24 selected – Don't see a subscription? [Open Directory + Subscription settings](#)

All subscriptions

5 items

<input type="checkbox"/>	Name ↑↓	IO type	Size	Attached to
<input type="checkbox"/>	 asrde...	Standard	32 GiB	-

3. Select the unattached disk you'd like to delete, this brings up the individual disk's blade.

4. On that individual disk's blade, you can confirm it is unattached, since **Attached to** will still be -.

5. Select **Delete**.

[+ Create VM](#) [Delete](#)

## Next steps

If you'd like an automated way of finding and deleting unattached storage accounts, see our [CLI](#) or [PowerShell](#) articles.

For more information, see [Delete a storage account](#) and [Identify Orphaned Disks Using PowerShell](#)

# Create a managed disk from a VHD file in a storage account in the same subscription with CLI (Linux)

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script creates a managed disk from a VHD file in a storage account in the same subscription. Use this script to import a specialized (not generalized/sysprepped) VHD to managed OS disk to create a virtual machine. Or, use it to import a data VHD to managed data disk.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id  
subscriptionId=<subscriptionId>  
  
#Provide the name of your resource group.  
#Ensure that resource group is already created  
resourceGroupName=myResourceGroupName  
  
#Provide the name of the Managed Disk  
diskName=myDiskName  
  
#Provide the size of the disks in GB. It should be greater than the VHD file size.  
diskSize=128  
  
#Provide the URI of the VHD file that will be used to create Managed Disk.  
# VHD file can be deleted as soon as Managed Disk is created.  
# e.g. https://contosostorageaccount1.blob.core.windows.net/vhds/contosovhd123.vhd  
vhdUri=https://contosostorageaccount1.blob.core.windows.net/vhds/contosoumd78620170425131836.vhd  
  
#Provide the storage type for the Managed Disk. Premium_LRS or Standard_LRS.  
storageType=Premium_LRS  
  
#Provide the Azure location (e.g. westus) where Managed Disk will be located.  
#The location should be same as the location of the storage account where VHD file is stored.  
#Get all the Azure location supported for your subscription using command below:  
#az account list-locations  
location=westus  
  
#Set the context to the subscription Id where Managed Disk will be created  
az account set --subscription $subscriptionId  
  
#Create the Managed disk from the VHD file  
az disk create --resource-group $resourceGroupName --name $diskName --sku $storageType --location $location  
--size-gb $diskSize --source $vhdUri
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroupName
```

## Sample reference

This script uses following commands to create a managed disk from a VHD. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az disk create</a>	Creates a managed disk using URI of a VHD in a storage account in the same subscription

## Next steps

[Create a virtual machine by attaching a managed disk as OS disk](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Create a managed disk from a snapshot with CLI (Linux)

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script creates a managed disk from a snapshot. Use it to restore a virtual machine from snapshots of OS and data disks. Create OS and data managed disks from respective snapshots and then create a new virtual machine by attaching managed disks. You can also restore data disks of an existing VM by attaching data disks created from snapshots.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id of the subscription where you want to create Managed Disks  
subscriptionId=<subscriptionId>"  
  
#Provide the name of your resource group  
resourceGroupName=myResourceGroupName  
  
#Provide the name of the snapshot that will be used to create Managed Disks  
snapshotName=mySnapshotName  
  
#Provide the name of the new Managed Disks that will be created  
diskName=myDiskName  
  
#Provide the size of the disks in GB. It should be greater than the VHD file size.  
diskSize=128  
  
#Provide the storage type for Managed Disk. Premium_LRS or Standard_LRS.  
storageType=Premium_LRS  
  
#Set the context to the subscription Id where Managed Disk will be created  
az account set --subscription $subscriptionId  
  
#Get the snapshot Id  
snapshotId=$(az snapshot show --name $snapshotName --resource-group $resourceGroupName --query [id] -o tsv)  
  
#Create a new Managed Disks using the snapshot Id  
#Note that managed disk will be created in the same location as the snapshot  
az disk create --resource-group $resourceGroupName --name $diskName --sku $storageType --size-gb $diskSize -  
-source $snapshotId
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroupName
```

## Sample reference

This script uses following commands to create a managed disk from a snapshot. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az snapshot show</a>	Gets all the properties of a snapshot using the name and resource group properties of the snapshot. Id property is used to create managed disk.
<a href="#">az disk create</a>	Creates a managed disk using snapshot Id of a managed snapshot

## Next steps

[Create a virtual machine by attaching a managed disk as OS disk](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Copy managed disks to same or different subscription with CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script copies a managed disk to same or different subscription but in the same region. The copy works only when the subscriptions are part of the same Azure AD tenant.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

[Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id of the subscription where managed disk exists  
sourceSubscriptionId=<subscriptionId>  
  
#Provide the name of your resource group where managed disk exists  
sourceResourceGroupName=mySourceResourceGroupName  
  
#Provide the name of the managed disk  
managedDiskName=myDiskName  
  
#Set the context to the subscription Id where managed disk exists  
az account set --subscription $sourceSubscriptionId  
  
#Get the managed disk Id  
managedDiskId=$(az disk show --name $managedDiskName --resource-group $sourceResourceGroupName --query [id] -o tsv)  
  
#If managedDiskId is blank then it means that managed disk does not exist.  
echo 'source managed disk Id is: ' $managedDiskId  
  
#Provide the subscription Id of the subscription where managed disk will be copied to  
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0  
  
#Name of the resource group where managed disk will be copied to  
targetResourceGroupName=mytargetResourceGroupName  
  
#Set the context to the subscription Id where managed disk will be copied to  
az account set --subscription $targetSubscriptionId  
  
#Copy managed disk to different subscription using managed disk Id  
az disk create --resource-group $targetResourceGroupName --name $managedDiskName --source $managedDiskId
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name mySourceResourceGroupName
```

## Sample reference

This script uses following commands to create a new managed disk in the target subscription using the **Id** of the source managed disk. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az disk show</a>	Gets all the properties of a managed disk using the name and resource group properties of the managed disk. The <b>Id</b> property is used to copy the managed disk to different subscription.

COMMAND	NOTES
<code>az disk create</code>	Copies a managed disk by creating a new managed disk in different subscription using the <code>Id</code> and name the parent managed disk.

## Next steps

[Create a virtual machine from a managed disk](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Export/Copy a snapshot to a storage account in different region with CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script exports a managed snapshot to a storage account in different region. It first generates the SAS URI of the snapshot and then uses it to copy it to a storage account in different region. Use this script to maintain backup of your managed disks in different region for disaster recovery.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id where snapshot is created  
subscriptionId=<subscriptionId>"  
  
#Provide the name of your resource group where snapshot is created  
resourceGroupName=myResourceGroupName  
  
#Provide the snapshot name  
snapshotName=mySnapshotName  
  
#Provide Shared Access Signature (SAS) expiry duration in seconds e.g. 3600.  
#Know more about SAS here: https://docs.microsoft.com/en-us/azure/storage/storage-dotnet-shared-access-signature-part-1  
sasExpiryDuration=3600  
  
#Provide storage account name where you want to copy the snapshot.  
storageAccountName=mystorageaccountname  
  
#Name of the storage container where the downloaded snapshot will be stored  
storageContainerName=mystoragecontainername  
  
#Provide the key of the storage account where you want to copy snapshot.  
storageAccountKey=mystorageaccountkey  
  
#Provide the name of the VHD file to which snapshot will be copied.  
destinationVHDFilename=myvhdfilename  
  
az account set --subscription $subscriptionId  
  
sas=$(az snapshot grant-access --resource-group $resourceGroupName --name $snapshotName --duration-in-seconds $sasExpiryDuration --query [accessSas] -o tsv)  
  
az storage blob copy start --destination-blob $destinationVHDFilename --destination-container $storageContainerName --account-name $storageAccountName --account-key $storageAccountKey --source-uri $sas
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroupName
```

## Sample reference

This script uses following commands to generate SAS URI for a managed snapshot and copies the snapshot to a storage account using SAS URI. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az snapshot grant-access</a>	Generates read-only SAS that is used to copy underlying VHD file to a storage account or download it to on-premises

COMMAND	NOTES
<code>az storage blob copy start</code>	Copies a blob asynchronously from one storage account to another

## Next steps

[Create a managed disk from a VHD](#)

[Create a virtual machine from a managed disk](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Export/Copy a managed disk to a storage account using the Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script exports the underlying VHD of a managed disk to a storage account in same or different region. It first generates the SAS URI of the managed disk and then uses it to copy the VHD to a storage account. Use this script to copy managed disks to another region for regional expansion. If you want to publish the VHD file of a managed disk in Azure Marketplace, you can use this script to copy the VHD file to a storage account and then generate a SAS URI of the copied VHD to publish it in the Marketplace.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).

[Create a virtual machine from a managed disk](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Copy snapshot of a managed disk to same or different subscription with CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script copies a snapshot of a managed disk to same or different subscription. Use this script for the following scenarios:

- Migrate a snapshot in Premium storage (Premium\_LRS) to Standard storage (Standard\_LRS or Standard\_ZRS) to reduce your cost.
- Migrate a snapshot from locally redundant storage (Premium\_LRS, Standard\_LRS) to zone redundant storage (Standard\_ZRS) to benefit from the higher reliability of ZRS storage.
- Move a snapshot to different subscription in the same region for longer retention.

## NOTE

Both subscriptions must be located under the same tenant

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

[Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).

  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure

CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

## Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing <Subscription ID> with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id of the subscription where snapshot exists  
sourceSubscriptionId=<subscriptionId>  
  
#Provide the name of your resource group where snapshot exists  
sourceResourceGroupName=mySourceResourceGroupName  
  
#Provide the name of the snapshot  
snapshotName=mySnapshotName  
  
#Set the context to the subscription Id where snapshot exists  
az account set --subscription $sourceSubscriptionId  
  
#Get the snapshot Id  
snapshotId=$(az snapshot show --name $snapshotName --resource-group $sourceResourceGroupName --query [id] -o tsv)  
  
#If snapshotId is blank then it means that snapshot does not exist.  
echo 'source snapshot Id is: '$snapshotId  
  
#Provide the subscription Id of the subscription where snapshot will be copied to  
#If snapshot is copied to the same subscription then you can skip this step  
targetSubscriptionId=6492b1f7-f219-446b-b509-314e17e1efb0  
  
#Name of the resource group where snapshot will be copied to  
targetResourceGroupName=mytargetResourceGroupName  
  
#Set the context to the subscription Id where snapshot will be copied to  
#If snapshot is copied to the same subscription then you can skip this step  
az account set --subscription $targetSubscriptionId  
  
#Copy snapshot to different subscription using the snapshot Id  
#We recommend you to store your snapshots in Standard storage to reduce cost. Please use Standard_ZRS in  
regions where zone redundant storage (ZRS) is available, otherwise use Standard_LRS  
#Please check out the availability of ZRS here: https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-zrs#support-coverage-and-regional-availability  
az snapshot create --resource-group $targetResourceGroupName --name $snapshotName --source $snapshotId --sku Standard_LRS
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name mySourceResourceGroupName
```

## Sample reference

This script uses following commands to create a snapshot in the target subscription using the `Id` of the source snapshot. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az snapshot show</a>	Gets all the properties of a snapshot using the name and resource group properties of the snapshot. The <code>Id</code> property is used to copy the snapshot to different subscription.
<a href="#">az snapshot create</a>	Copies a snapshot by creating a snapshot in different subscription using the <code>Id</code> and name of the parent snapshot.

## Next steps

[Create a virtual machine from a snapshot](#)

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine and managed disks CLI script samples can be found in the [Azure Linux VM documentation](#).

# Create a virtual machine from a snapshot with CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script creates a virtual machine from a snapshot of an OS disk.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription="<subscriptionId>" # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id of the subscription where you want to create Managed Disks
subscriptionId=<subscriptionId>"c

#Provide the name of your resource group
resourceGroupName=myResourceGroupName

#Provide the name of the snapshot that will be used to create Managed Disks
snapshotName=mySnapshotName

#Provide the name of the Managed Disk
osDiskName=myOSDiskName

#Provide the size of the disks in GB. It should be greater than the VHD file size.
diskSize=128

#Provide the storage type for Managed Disk. Premium_LRS or Standard_LRS.
storageType=Premium_LRS

#Provide the OS type
osType=linux

#Provide the name of the virtual machine
virtualMachineName=myVirtualMachineName

#Set the context to the subscription Id where Managed Disk will be created
az account set --subscription $subscriptionId

#Get the snapshot Id
snapshotId=$(az snapshot show --name $snapshotName --resource-group $resourceGroupName --query [id] -o tsv)

#Create a new Managed Disks using the snapshot Id
az disk create --resource-group $resourceGroupName --name $osDiskName --sku $storageType --size-gb $diskSize --source $snapshotId

#Create VM by attaching created managed disks as OS
az vm create --name $virtualMachineName --resource-group $resourceGroupName --attach-os-disk $osDiskName --os-type $osType
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroupName
```

## Sample reference

This script uses the following commands to create a managed disk, virtual machine, and all related resources. Each command in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az snapshot show</a>	Gets snapshot using snapshot name and resource group name. Id property of the returned object is used to create a managed disk.
<a href="#">az disk create</a>	Creates managed disks from a snapshot using snapshot Id, disk name, storage type, and size

COMMAND	NOTES
<code>az vm create</code>	Creates a VM using a managed OS disk

## Next steps

For more information on the Azure CLI, see [Azure CLI documentation](#).

Additional virtual machine CLI script samples can be found in the [Azure Linux VM documentation](#).

# Create a virtual machine using an existing managed OS disk with CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

This script creates a virtual machine by attaching an existing managed disk as OS disk. Use this script in preceding scenarios:

- Create a VM from an existing managed OS disk that was copied from a managed disk in different subscription
- Create a VM from an existing managed disk that was created from a specialized VHD file
- Create a VM from an existing managed OS disk that was created from a snapshot

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

[Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

### Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com>.

When Cloud Shell opens, verify that **Bash** is selected for your environment. Subsequent sessions will use Azure CLI in a Bash environment. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

### Sign in to Azure

Cloud Shell is automatically authenticated under the initial account signed-in with. Use the following script to sign in using a different subscription, replacing `<Subscription ID>` with your Azure Subscription ID. If you don't

have an [Azure subscription](#), create an [Azure free account](#) before you begin.

```
subscription=<subscriptionId> # add subscription here  
az account set -s $subscription # ...or use 'az login'
```

For more information, see [set active subscription](#) or [log in interactively](#)

## Run the script

```
#Provide the subscription Id  
subscriptionId=<subscriptionId>  
  
#Provide the name of your resource group  
resourceGroupName=myResourceGroupName  
  
#Provide the name of the Managed Disk  
managedDiskName=myDiskName  
  
#Provide the OS type  
osType=linux  
  
#Provide the name of the virtual machine  
virtualMachineName=myVirtualMachineName123  
  
#Set the context to the subscription Id where Managed Disk exists and where VM will be created  
az account set --subscription $subscriptionId  
  
#Get the resource Id of the managed disk  
managedDiskId=$(az disk show --name $managedDiskName --resource-group $resourceGroupName --query [id] -o tsv)  
  
#Create VM by attaching existing managed disks as OS  
az vm create --name $virtualMachineName --resource-group $resourceGroupName --attach-os-disk $managedDiskId --os-type $osType
```

## Clean up resources

Run the following command to remove the resource group, VM, and all related resources.

```
az group delete --name myResourceGroupName
```

## Sample reference

This script uses the following commands to get managed disk properties, attach a managed disk to a new VM and create a VM. Each item in the table links to command specific documentation.

COMMAND	NOTES
<a href="#">az disk show</a>	Gets managed disk properties using disk name and resource group name. Id property is used to attach a managed disk to a new VM
<a href="#">az vm create</a>	Creates a VM using a managed OS disk

## Next steps

For more information on the Azure CLI, see [Azure CLI documentation](#).

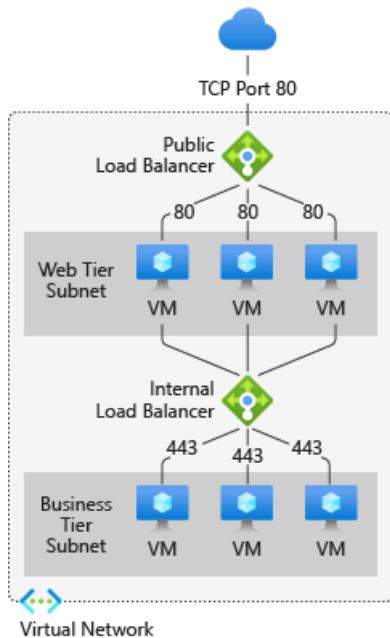

Additional virtual machine CLI script samples can be found in the [Azure Linux VM documentation](#).

# Virtual networks and virtual machines in Azure

9/21/2022 • 17 minutes to read • [Edit Online](#)

When you create a virtual machine (VM), you create a [virtual network](#) or use an existing one. Decide how your virtual machines are intended to be accessed on the virtual network. It's important to [plan before creating resources](#) and make sure you understand the [limits of networking resources](#).

In the following figure, virtual machines are represented as web servers and application servers. Each set of virtual machines is assigned to separate subnets in the virtual network.

You can create a virtual network before you create a virtual machine or you can create the virtual network as you create a virtual machine.

You create these resources to support communication with a virtual machine:

- Network interfaces
- IP addresses
- Virtual network and subnets

Additionally, consider these optional resources:

- Network security groups
- Load balancers

## Network interfaces

A [network interface \(NIC\)](#) is the interconnection between a virtual machine and a virtual network. A virtual machine must have at least one NIC. A virtual machine can have more than one NIC, depending on the size of the VM you create. To learn about the number of NICs each virtual machine size supports, see [VM sizes](#).

You can create a VM with multiple NICs, and add or remove NICs through the lifecycle of a VM. Multiple NICs allow a VM to connect to different subnets.

Each NIC attached to a VM must exist in the same location and subscription as the VM. Each NIC must be connected to a VNet that exists in the same Azure location and subscription as the NIC. You can change the

subnet a VM is connected to after it's created. You can't change the virtual network. Each NIC attached to a VM is assigned a MAC address that doesn't change until the VM is deleted.

This table lists the methods that you can use to create a network interface.

METHOD	DESCRIPTION
Azure portal	When you create a VM in the Azure portal, a network interface is automatically created for you. The portal creates a VM with only one NIC. If you want to create a VM with more than one NIC, you must create it with a different method.
Azure PowerShell	Use <a href="#">New-AzNetworkInterface</a> with the <code>-PublicIpAddressId</code> parameter to provide the identifier of the public IP address that you previously created.
Azure CLI	To provide the identifier of the public IP address that you previously created, use <a href="#">az network nic create</a> with the <code>--public-ip-address</code> parameter.
Template	For information on deploying a networking interface using a template, see <a href="#">Network Interface in a Virtual Network with Public IP Address</a> .

## IP addresses

You can assign these types of [IP addresses](#) to a network interface in Azure:

- **Public IP addresses** - Used to communicate inbound and outbound (without network address translation (NAT)) with the Internet and other Azure resources not connected to a virtual network. Assigning a public IP address to a NIC is optional. Public IP addresses have a nominal charge, and there's a maximum number that can be used per subscription.
- **Private IP addresses** - Used for communication within a virtual network, your on-premises network, and the Internet (with NAT). At least one private IP address must be assigned to a VM. To learn more about NAT in Azure, read [Understanding outbound connections in Azure](#).

You can assign public IP addresses to:

- Virtual machines
- Public load balancers

You can assign private IP address to:

- Virtual machines
- Internal load balancers

You assign IP addresses to a VM using a network interface.

There are two methods in which an IP address is given to a resource, dynamic or static. The default method that Azure gives IP addresses is dynamic. An IP address isn't given when it's created. Instead, the IP address is given when you create a VM or start a stopped VM. The IP address is released when you stop or delete the VM.

To ensure the IP address for the VM remains the same, you can set the allocation method explicitly to static. In this case, an IP address is assigned immediately. It's released only when you delete the VM or change its allocation method to dynamic.

This table lists the methods that you can use to create an IP address.

METHOD	DESCRIPTION
Azure portal	By default, public IP addresses are dynamic. The IP address may change when the VM is stopped or deleted. To guarantee that the VM always uses the same public IP address, create a static public IP address. By default, the portal assigns a dynamic private IP address to a NIC when creating a VM. You can change this IP address to static after the VM is created.
Azure PowerShell	You use <a href="#">New-AzPublicIpAddress</a> with the <code>-AllocationMethod</code> parameter as Dynamic or Static.
Azure CLI	You use <a href="#">az network public-ip create</a> with the <code>--allocation-method</code> parameter as Dynamic or Static.
Template	For more information on deploying a public IP address using a template, see <a href="#">Network Interface in a Virtual Network with Public IP Address</a> .

After you create a public IP address, you can associate it with a VM by assigning it to a NIC.

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Virtual network and subnets

A subnet is a range of IP addresses in the virtual network. You can divide a virtual network into multiple subnets for organization and security. Each NIC in a VM is connected to one subnet in one virtual network. NICs connected to subnets (same or different) within a virtual network can communicate with each other without any extra configuration.

When you set up a virtual network, you specify the topology, including the available address spaces and subnets. Select address ranges that don't overlap if the virtual network is connected to other virtual networks or on-premises networks. The IP addresses are private and can't be accessed from the Internet. Azure treats any address range as part of the private virtual network IP address space. The address range is only reachable within the virtual network, within interconnected virtual networks, and from your on-premises location.

If you work within an organization in which someone else is responsible for the internal networks, talk to that person before selecting your address space. Ensure there's no overlap in the address space. Communicate to them the space you want to use so they don't try to use the same range of IP addresses.

There aren't security boundaries by default between subnets. Virtual machines in each of these subnets can

communicate. If your deployment requires security boundaries, use **Network Security Groups (NSGs)**, which control the traffic flow to and from subnets and to and from VMs.

This table lists the methods that you can use to create a virtual network and subnets.

METHOD	DESCRIPTION
Azure portal	If you let Azure create a virtual network when you create a VM, the name is a combination of the resource group name that contains the virtual network and <code>-vnet</code> . The address space is 10.0.0.0/24, the required subnet name is <b>default</b> , and the subnet address range is 10.0.0.0/24.
Azure PowerShell	You use <a href="#">New-AzVirtualNetworkSubnetConfig</a> and <a href="#">New-AzVirtualNetwork</a> to create a subnet and a virtual network. You can also use <a href="#">Add-AzVirtualNetworkSubnetConfig</a> to add a subnet to an existing virtual network.
Azure CLI	The subnet and the virtual network are created at the same time. Provide a <code>--subnet-name</code> parameter to <a href="#">az network vnet create</a> with the subnet name.
Template	For more information on using a template to create a virtual network and subnets, see <a href="#">Virtual Network with two subnets</a> .

## Network security groups

A **network security group (NSG)** contains a list of Access Control List (ACL) rules that allow or deny network traffic to subnets, NICs, or both. NSGs can be associated with either subnets or individual NICs connected to a subnet. When an NSG is associated with a subnet, the ACL rules apply to all the VMs in that subnet. Traffic to an individual NIC can be restricted by associating an NSG directly to a NIC.

NSGs contain two sets of rules, inbound and outbound. The priority for a rule must be unique within each set.

Each rule has properties of:

- Protocol
- Source and destination port ranges
- Address prefixes
- Direction of traffic
- Priority
- Access type

All NSGs contain a set of default rules. The default rules cannot be deleted. They're assigned the lowest priority and can't be overridden by the rules that you create.

When you associate an NSG to a NIC, the network access rules in the NSG are applied only to that NIC. If an NSG is applied to a single NIC on a multi-NIC VM, it doesn't affect traffic to the other NICs. You can associate different NSGs to a NIC (or VM, depending on the deployment model) and the subnet that a NIC or VM is bound to. Priority is given based on the direction of traffic.

Be sure to [plan](#) your NSGs when you plan your virtual machines and virtual network.

This table lists the methods that you can use to create a network security group.

METHOD	DESCRIPTION
Azure portal	<p>When you create a VM in the Azure portal, an NSG is automatically created and associated to the NIC the portal creates. The name of the NSG is a combination of the name of the VM and <code>-nsg</code>.</p> <p>This NSG contains one inbound rule:  With a priority of 1000.  The service set to RDP.  The protocol set to TCP.  The port set to 3389.  The action set to <b>Allow</b>.  If you want to allow any other inbound traffic to the VM, create another rule or rules.</p>
Azure PowerShell	<p>Use <a href="#">New-AzNetworkSecurityRuleConfig</a> and provide the required rule information. Use <a href="#">New-AzNetworkSecurityGroup</a> to create the NSG. Use <a href="#">Set-AzVirtualNetworkSubnetConfig</a> to configure the NSG for the subnet. Use <a href="#">Set-AzVirtualNetwork</a> to add the NSG to the virtual network.</p>
Azure CLI	<p>Use <a href="#">az network nsg create</a> to initially create the NSG. Use <a href="#">az network nsg rule create</a> to add rules to the NSG. Use <a href="#">az network vnet subnet update</a> to add the NSG to the subnet.</p>
Template	<p>Use <a href="#">Create a Network Security Group</a> as a guide for deploying a network security group using a template.</p>

## Load balancers

[Azure Load Balancer](#) delivers high availability and network performance to your applications. A load balancer can be configured to [balance incoming Internet traffic](#) to VMs or [balance traffic between VMs in a VNet](#). A load balancer can also balance traffic between on-premises computers and VMs in a cross-premises network, or forward external traffic to a specific VM.

The load balancer maps incoming and outgoing traffic between:

- The public IP address and port on the load balancer.
- The private IP address and port of the VM.

When you create a load balancer, you must also consider these configuration elements:

- **Front-end IP configuration** – A load balancer can include one or more front-end IP addresses. These IP addresses serve as ingress for the traffic.
- **Back-end address pool** – IP addresses that are associated with the NIC to which load is distributed.
- **Port Forwarding** - Defines how inbound traffic flows through the front-end IP and distributed to the back-end IP using inbound NAT rules.
- **Load balancer rules** - Maps a given front-end IP and port combination to a set of back-end IP addresses and port combination. A single load balancer can have multiple load-balancing rules. Each rule is a combination of a front-end IP and port and back-end IP and port associated with VMs.
- **Probes** - Monitors the health of VMs. When a probe fails to respond, the load balancer stops sending new connections to the unhealthy VM. The existing connections aren't affected, and new connections are sent to healthy VMs.
- **Outbound rules** - An outbound rule configures outbound Network Address Translation (NAT) for all virtual machines or instances identified by the backend pool of your Standard Load Balancer to be translated to the

frontend.

This table lists the methods that you can use to create an internet-facing load balancer.

METHOD	DESCRIPTION
Azure portal	You can <a href="#">load balance internet traffic to VMs using the Azure portal</a> .
Azure PowerShell	To provide the identifier of the public IP address that you previously created, use <code>New-AzLoadBalancerFrontendIpConfig</code> with the <code>-PublicIpAddress</code> parameter. Use <code>New-AzLoadBalancerBackendAddressPoolConfig</code> to create the configuration of the back-end address pool. Use <code>New-AzLoadBalancerInboundNatRuleConfig</code> to create inbound NAT rules associated with the front-end IP configuration that you created. Use <code>New-AzLoadBalancerProbeConfig</code> to create the probes that you need. Use <code>New-AzLoadBalancerRuleConfig</code> to create the load balancer configuration. Use <code>New-AzLoadBalancer</code> to create the load balancer.
Azure CLI	Use <code>az network lb create</code> to create the initial load balancer configuration. Use <code>az network lb frontend-ip create</code> to add the public IP address that you previously created. Use <code>az network lb address-pool create</code> to add the configuration of the back-end address pool. Use <code>az network lb inbound-nat-rule create</code> to add NAT rules. Use <code>az network lb rule create</code> to add the load balancer rules. Use <code>az network lb probe create</code> to add the probes.
Template	Use <a href="#">3 VMs in a Load Balancer</a> as a guide for deploying a load balancer using a template.

This table lists the methods that you can use to create an internal load balancer.

METHOD	DESCRIPTION
Azure portal	You can <a href="#">balance internal traffic load with a load balancer in the Azure portal</a> .
Azure PowerShell	To provide a private IP address in the network subnet, use <code>New-AzLoadBalancerFrontendIpConfig</code> with the <code>-PrivateIpAddress</code> parameter. Use <code>New-AzLoadBalancerBackendAddressPoolConfig</code> to create the configuration of the back-end address pool. Use <code>New-AzLoadBalancerInboundNatRuleConfig</code> to create inbound NAT rules associated with the front-end IP configuration that you created. Use <code>New-AzLoadBalancerProbeConfig</code> to create the probes that you need. Use <code>New-AzLoadBalancerRuleConfig</code> to create the load balancer configuration. Use <code>New-AzLoadBalancer</code> to create the load balancer.

METHOD	DESCRIPTION
Azure CLI	Use the <a href="#">az network lb create</a> command to create the initial load balancer configuration. To define the private IP address, use <a href="#">az network lb frontend-ip create</a> with the <code>--private-ip-address</code> parameter. Use <a href="#">az network lb address-pool create</a> to add the configuration of the backend address pool. Use <a href="#">az network lb inbound-nat-rule create</a> to add NAT rules. Use <a href="#">az network lb rule create</a> to add the load balancer rules. Use <a href="#">az network lb probe create</a> to add the probes.
Template	Use <a href="#">2 VMs in a Load Balancer</a> as a guide for deploying a load balancer using a template.

## Virtual machines

Virtual machines can be created in the same virtual network and they can connect to each other using private IP addresses. Virtual machines can connect if they're in different subnets. They connect without the need to configure a gateway or use public IP addresses. To put VMs into a virtual network, you create the virtual network. As you create each VM, you assign it to the virtual network and subnet. Virtual machines acquire their network settings during deployment or startup.

Virtual machines are assigned an IP address when they're deployed. When you deploy multiple VMs into a virtual network or subnet, they're assigned IP addresses as they boot up. You can also assign a static IP to a VM. If you assign a static IP, you should consider using a specific subnet to avoid accidentally reusing a static IP for another VM.

If you create a VM and later want to migrate it into a virtual network, it isn't a simple configuration change. Redeploy the VM into the virtual network. The easiest way to redeploy is to delete the VM, but not any disks attached to it, and then re-create the VM using the original disks in the virtual network.

This table lists the methods that you can use to create a VM in a VNet.

METHOD	DESCRIPTION
Azure portal	Uses the default network settings that were previously mentioned to create a VM with a single NIC. To create a VM with multiple NICs, you must use a different method.
Azure PowerShell	Includes the use of <a href="#">Add-AzVMNetworkInterface</a> to add the NIC that you previously created to the VM configuration.
Azure CLI	Create and connect a VM to a virtual network, subnet, and NIC that builds as individual steps.
Template	Use <a href="#">Very simple deployment of a Windows VM</a> as a guide for deploying a VM using a template.

## Virtual network NAT

Virtual Network NAT (network address translation) simplifies outbound-only Internet connectivity for virtual networks. When configured on a subnet, all outbound connectivity uses your specified static public IP addresses. Outbound connectivity is possible without load balancer or public IP addresses directly attached to virtual machines. NAT is fully managed and highly resilient.

Outbound connectivity can be defined for each subnet with NAT. Multiple subnets within the same virtual network can have different NATs. A subnet is configured by specifying which NAT gateway resource to use. All UDP and TCP outbound flows from any virtual machine instance will use NAT. NAT is compatible with standard SKU public IP address resources or public IP prefix resources or a combination of both. You can use a public IP prefix directly or distribute the public IP addresses of the prefix across multiple NAT gateway resources. NAT will groom all traffic to the range of IP addresses of the prefix. Any IP filtering of your deployments is easier.

All outbound traffic for the subnet is processed by NAT automatically without any customer configuration. User-defined routes aren't necessary. NAT takes precedence over other outbound scenarios and replaces the default Internet destination of a subnet.

Virtual machines created by Virtual machine scale sets Flexible Orchestration mode don't have default outbound access. Virtual network NAT is the recommended outbound access method for Virtual machine scale sets Flexible Orchestration Mode.

For more information about the NAT gateway resource and virtual network NAT, see [What is Azure Virtual Network NAT?](#).

This table lists the methods that you can use to create a NAT gateway resource.

METHOD	DESCRIPTION
<a href="#">Azure portal</a>	Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.
<a href="#">Azure PowerShell</a>	Includes the use of <a href="#">New-AzNatGateway</a> to create a NAT gateway resource. Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.
<a href="#">Azure CLI</a>	Includes the use of <a href="#">az network nat gateway create</a> to create a NAT gateway resource. Creates a virtual network, subnet, public IP, NAT gateway, and a virtual machine to test the NAT gateway resource.
<a href="#">Template</a>	Creates a virtual network, subnet, public IP, and NAT gateway resource.

## Azure Bastion

Azure Bastion is deployed to provide secure management connectivity to virtual machines in a virtual network. Azure Bastion Service enables you to securely and seamlessly RDP & SSH to the VMs in your virtual network. Azure bastion enables connections without exposing a public IP on the VM. Connections are made directly from the Azure portal, without the need of an extra client/agent or piece of software. Azure Bastion supports standard SKU public IP addresses.

For more information about Azure Bastion, see [What is Azure Bastion?](#).

This table lists the methods you can use to create an Azure Bastion deployment.

METHOD	DESCRIPTION
<a href="#">Azure portal</a>	Creates a virtual network, subnets, public IP, bastion host, and virtual machines.

METHOD	DESCRIPTION
Azure PowerShell	Creates a virtual network, subnets, public IP, and bastion host. Includes the use of <a href="#">New-AzBastion</a> to create the bastion host.
Azure CLI	Creates a virtual network, subnets, public IP, and bastion host. Includes the use of <a href="#">az network bastion create</a> to create the bastion host.
Template	For an example of a template deployment that integrates an Azure Bastion host with a sample deployment, see <a href="#">Quickstart: Create a public load balancer to load balance VMs by using an ARM template</a> .

# Optimize network throughput for Azure virtual machines

9/21/2022 • 3 minutes to read • [Edit Online](#)

Azure virtual machines (VM) have default network settings that can be further optimized for network throughput. This article describes how to optimize network throughput for Microsoft Azure Windows and Linux VMs, including major distributions such as Ubuntu, CentOS, and Red Hat.

## Windows VM

If your Windows VM supports [Accelerated Networking](#), enabling that feature would be the optimal configuration for throughput. For all other Windows VMs, using Receive Side Scaling (RSS) can reach higher maximal throughput than a VM without RSS. RSS may be disabled by default in a Windows VM. To determine whether RSS is enabled, and enable it if it's currently disabled, complete the following steps:

1. See if RSS is enabled for a network adapter with the `Get-NetAdapterRss` PowerShell command. In the following example output returned from the `Get-NetAdapterRss`, RSS is not enabled.

```
Name          : Ethernet
InterfaceDescription : Microsoft Hyper-V Network Adapter
Enabled       : False
```

2. To enable RSS, enter the following command:

```
Get-NetAdapter | % {Enable-NetAdapterRss -Name $_.Name}
```

The previous command does not have an output. The command changed NIC settings, causing temporary connectivity loss for about one minute. A Reconnecting dialog box appears during the connectivity loss. Connectivity is typically restored after the third attempt.

3. Confirm that RSS is enabled in the VM by entering the `Get-NetAdapterRss` command again. If successful, the following example output is returned:

```
Name      : Ethernet
InterfaceDescription : Microsoft Hyper-V Network Adapter
Enabled    : True
```

## Linux VM

RSS is always enabled by default in an Azure Linux VM. Linux kernels released since October 2017 include new network optimizations options that enable a Linux VM to achieve higher network throughput.

### Ubuntu for new deployments

The Ubuntu Azure kernel is the most optimized for network performance on Azure. To get the latest optimizations, first install the latest supported version of 18.04-LTS, as follows:

```
"Publisher": "Canonical",
"Offer": "UbuntuServer",
"Sku": "18.04-LTS",
"Version": "latest"
```

After the creation is complete, enter the following commands to get the latest updates. These steps also work for VMs currently running the Ubuntu Azure kernel.

```
#run as root or preface with sudo
apt-get -y update
apt-get -y upgrade
apt-get -y dist-upgrade
```

The following optional command set may be helpful for existing Ubuntu deployments that already have the Azure kernel but that have failed to further updates with errors.

```
#optional steps may be helpful in existing deployments with the Azure kernel
#run as root or preface with sudo
apt-get -f install
apt-get --fix-missing install
apt-get clean
apt-get -y update
apt-get -y upgrade
apt-get -y dist-upgrade
```

#### **Ubuntu Azure kernel upgrade for existing VMs**

Significant throughput performance can be achieved by upgrading to the Azure Linux kernel. To verify whether you have this kernel, check your kernel version. It should be the same or later than the example.

```
#Azure kernel name ends with "-azure"
uname -r

#sample output on Azure kernel:
#4.13.0-1007-azure
```

If your VM does not have the Azure kernel, the version number usually begins with "4.4." If the VM does not have the Azure kernel, run the following commands as root:

```
#run as root or preface with sudo
apt-get update
apt-get upgrade -y
apt-get dist-upgrade -y
apt-get install "linux-azure"
reboot
```

#### **CentOS**

In order to get the latest optimizations, it is best to create a VM with the latest supported version by specifying the following parameters:

```
"Publisher": "OpenLogic",
"Offer": "Centos",
"Sku": "7.7",
"Version": "latest"
```

New and existing VMs can benefit from installing the latest Linux Integration Services (LIS). The throughput

optimization is in LIS, starting from 4.2.2-2, although later versions contain further improvements. Enter the following commands to install the latest LIS:

```
sudo yum update  
sudo reboot  
sudo yum install microsoft-hyper-v
```

## Red Hat

In order to get the optimizations, it is best to create a VM with the latest supported version by specifying the following parameters:

```
"Publisher": "RedHat"  
"Offer": "RHEL"  
"Sku": "7-RAW"  
"Version": "latest"
```

New and existing VMs can benefit from installing the latest Linux Integration Services (LIS). The throughput optimization is in LIS, starting from 4.2. Enter the following commands to download and install LIS:

```
wget https://aka.ms/lis  
tar xvf lis  
cd LISISO  
sudo ./install.sh #or upgrade.sh if prior LIS was previously installed
```

Learn more about Linux Integration Services Version 4.2 for Hyper-V by viewing the [download page](#).

## Next steps

- Deploy VMs close to each other for low latency with [Proximity Placement Group](#)
- See the optimized result with [Bandwidth/Throughput testing Azure VM](#) for your scenario.

# Azure Virtual Network concepts and best practices

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article describes key concepts and best practices for Azure Virtual Network (VNet).

## VNet concepts

- **Address space:** When creating a VNet, you must specify a custom private IP address space using public and private (RFC 1918) addresses. Azure assigns resources in a virtual network a private IP address from the address space that you assign. For example, if you deploy a VM in a VNet with address space, 10.0.0.0/16, the VM will be assigned a private IP like 10.0.0.4.
- **Subnets:** Subnets enable you to segment the virtual network into one or more sub-networks and allocate a portion of the virtual network's address space to each subnet. You can then deploy Azure resources in a specific subnet. Just like in a traditional network, subnets allow you to segment your VNet address space into segments that are appropriate for the organization's internal network. This also improves address allocation efficiency. You can secure resources within subnets using Network Security Groups. For more information, see [Network security groups](#).
- **Regions:** VNet is scoped to a single region/location; however, multiple virtual networks from different regions can be connected together using Virtual Network Peering.
- **Subscription:** VNet is scoped to a subscription. You can implement multiple virtual networks within each Azure [subscription](#) and Azure [region](#).

## Best practices

As you build your network in Azure, it is important to keep in mind the following universal design principles:

- Ensure non-overlapping address spaces. Make sure your VNet address space (CIDR block) does not overlap with your organization's other network ranges.
- Your subnets should not cover the entire address space of the VNet. Plan ahead and reserve some address space for the future.
- It is recommended you have fewer large VNets rather than multiple small VNets. This will prevent management overhead.
- Secure your VNets by assigning Network Security Groups (NSGs) to the subnets beneath them. For more information about network security concepts, see [Azure network security overview](#).

## Next steps

To get started using a virtual network, create one, deploy a few VMs to it, and communicate between the VMs. To learn how, see the [Create a virtual network](#) quickstart.

# Quickstart: Create a virtual network using the Azure CLI

9/21/2022 • 4 minutes to read • [Edit Online](#)

A virtual network enables Azure resources, like virtual machines (VMs), to communicate privately with each other, and with the internet.

In this quickstart, you learn how to create a virtual network. After creating a virtual network, you deploy two VMs into the virtual network. You then connect to the VMs from the internet, and communicate privately over the new virtual network.

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This quickstart requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group and a virtual network

Before you can create a virtual network, you have to create a resource group to host the virtual network. Create a resource group with [az group create](#). This example creates a resource group named `CreateVNetQS-rg` in the `Eastus` location:

```
az group create \
  --name CreateVNetQS-rg \
  --location eastus
```

Create a virtual network with [az network vnet create](#). This example creates a default virtual network named `myVNet` with one subnet named `default`:

```
az network vnet create \
--name myVNet \
--resource-group CreateVNetQS-rg \
--subnet-name default
```

## Create virtual machines

Create two VMs in the virtual network.

### Create the first VM

Create a VM with [az vm create](#).

If SSH keys don't already exist in a default key location, the command creates them. To use a specific set of keys, use the `--ssh-key-value` option.

The `--no-wait` option creates the VM in the background. You can continue to the next step.

This example creates a VM named **myVM1**:

```
az vm create \
--resource-group CreateVNetQS-rg \
--name myVM1 \
--image UbuntuLTS \
--generate-ssh-keys \
--public-ip-address myPublicIP-myVM1 \
--no-wait
```

### Create the second VM

You used the `--no-wait` option in the previous step. You can go ahead and create the second VM named **myVM2**.

```
az vm create \
--resource-group CreateVNetQS-rg \
--name myVM2 \
--image UbuntuLTS \
--public-ip-address myPublicIP-myVM2 \
--generate-ssh-keys
```

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

#### Azure CLI output message

The VMs take a few minutes to create. After Azure creates the VMs, the Azure CLI returns output like this:

```
{  
  "fqdns": "",  
  "id": "/subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/CreateVNetQS-  
rg/providers/Microsoft.Compute/virtualMachines/myVM2",  
  "location": "eastus",  
  "macAddress": "00-0D-3A-23-9A-49",  
  "powerState": "VM running",  
  "privateIpAddress": "10.0.0.5",  
  "publicIpAddress": "40.68.254.142",  
  "resourceGroup": "CreateVNetQS-rg"  
  "zones": ""  
}
```

## VM public IP

To get the public IP address myVM2, use [az network public-ip show](#):

```
az network public-ip show \  
  --resource-group CreateVNetQS-rg \  
  --name myPublicIP-myVM2 \  
  --query ipAddress \  
  --output tsv
```

## Connect to a VM from the internet

In this command, replace <publicIpAddress> with the public IP address of your myVM2 VM:

```
ssh <publicIpAddress>
```

## Communicate between VMs

To confirm private communication between the myVM2 and myVM1 VMs, enter [ping myVM1 -c 4](#).

You'll receive a reply message like this:

```
azureuser@myVM2:~$ ping myVM1 -c 4  
PING myVM1.h0o2foz2r0tefnccdcnfqm2lid.bx.internal.cloudapp.net (10.0.0.4) 56(84) bytes of data.  
64 bytes from myvm1.internal.cloudapp.net (10.0.0.4): icmp_seq=1 ttl=64 time=2.77 ms  
64 bytes from myvm1.internal.cloudapp.net (10.0.0.4): icmp_seq=2 ttl=64 time=1.95 ms  
64 bytes from myvm1.internal.cloudapp.net (10.0.0.4): icmp_seq=3 ttl=64 time=2.19 ms  
64 bytes from myvm1.internal.cloudapp.net (10.0.0.4): icmp_seq=4 ttl=64 time=1.85 ms  
  
--- myVM1.h0o2foz2r0tefnccdcnfqm2lid.bx.internal.cloudapp.net ping statistics ---  
4 packets transmitted, 4 received, 0% packet loss, time 3003ms  
rtt min/avg/max/mdev = 1.859/2.195/2.770/0.357 ms
```

Exit the SSH session with the myVM2 VM.

## Clean up resources

When no longer needed, you can use [az group delete](#) to remove the resource group and all the resources it has:

```
az group delete \
--name CreateVNetQS-rg \
--yes
```

## Next steps

In this quickstart:

- You created a default virtual network and two VMs.
- You connected to one VM from the internet and communicated privately between the two VMs.

Private communication between VMs is unrestricted in a virtual network.

Advance to the next article to learn more about configuring different types of VM network communications:

[Filter network traffic](#)

# Tutorial: Filter network traffic with a network security group using the Azure portal

9/21/2022 • 8 minutes to read • [Edit Online](#)

You can use a network security group to filter inbound and outbound network traffic to and from Azure resources in an Azure virtual network.

Network security groups contain security rules that filter network traffic by IP address, port, and protocol. When a network security group is associated with a subnet, security rules are applied to resources deployed in that subnet.

In this tutorial, you learn how to:

- Create a network security group and security rules
- Create application security groups
- Create a virtual network and associate a network security group to a subnet
- Deploy virtual machines and associate their network interfaces to the application security groups
- Test traffic filters

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Prerequisites

- An Azure subscription

## Sign in to Azure

Sign in to the [Azure portal](#).

## Create a virtual network

1. From the Azure portal menu, select + **Create a resource** > **Networking** > **Virtual network**, or search for *Virtual Network* in the portal search box.
2. Select **Create**.
3. On the **Basics** tab of **Create virtual network**, enter or select this information:

SETTING	VALUE
Project details	
Subscription	Select your subscription.
Resource group	Select <b>Create new</b> . Enter <i>myResourceGroup</i> . Select <b>OK</b> .
Instance details	

SETTING	VALUE
Name	Enter <i>myVNet</i> .
Region	Select <b>East US</b> .

4. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.
5. Select **Create**.

## Create application security groups

An [application security group \(ASGs\)](#) enables you to group together servers with similar functions, such as web servers.

1. From the Azure portal menu, select **+ Create a resource > Networking > Application security group**, or search for *Application security group* in the portal search box.
2. Select **Create**.
3. On the **Basics** tab of **Create an application security group**, enter or select this information:

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>myResourceGroup</b> .
<b>Instance details</b>	
Name	Enter <i>myAsgWebServers</i> .
Region	Select <b>(US) East US</b> .

4. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.
5. Select **Create**.
6. Repeat the previous steps, specifying the following values:

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>myResourceGroup</b> .
<b>Instance details</b>	
Name	Enter <i>myAsgMgmtServers</i> .
Region	Select <b>(US) East US</b> .

7. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.

8. Select **Create**.

## Create a network security group

A [network security group \(NSG\)](#) secures network traffic in your virtual network.

1. From the Azure portal menu, select **+ Create a resource > Networking > Network security group**, or search for *Network security group* in the portal search box.

2. Select **Create**.

3. On the **Basics** tab of **Create network security group**, enter or select this information:

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>myResourceGroup</b> .
<b>Instance details</b>	
Name	Enter <i>myNSG</i> .
Location	Select <b>(US) East US</b> .

4. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.

5. Select **Create**.

## Associate network security group to subnet

In this section, you'll associate the network security group with the subnet of the virtual network you created earlier.

1. Search for *myNsg* in the portal search box.

2. Select **Subnets** from the **Settings** section of **myNSG**.

3. In the **Subnets** page, select **+ Associate**:

**myNSG | Subnets**

Network security group

+ Associate

Name	Address range	Virtual network
No results.		

Search (Cmd+/)

Overview

Activity log

Access control (IAM)

Tags

Diagnose and solve problems

Settings

- Inbound security rules
- Outbound security rules
- Network interfaces
- Subnets** (highlighted with a red box)
- Properties
- Locks

4. Under **Associate subnet**, select myVNet for **Virtual network**.

5. Select **default** for **Subnet**, and then select **OK**.

## Create security rules

1. Select **Inbound security rules** from the **Settings** section of myNSG.

2. In **Inbound security rules** page, select **+ Add**:

**myNSG | Inbound security rules**

Network security group

+ Add

Priority ↑	Name ↑	Port ↑↓	Protocol ↑↓	Source ↑↓	Destination ↑↓	Action ↑↓
65000	AllowVnetInBound	Any	Any	VirtualNetwork	VirtualNetwork	Allow
65001	AllowAzureLoadBalancerInBound	Any	Any	AzureLoadBalancer	Any	Allow
65500	DenyAllInBound	Any	Any	Any	Any	Deny

Search (Cmd+/)

Diagnose and solve problems

Settings

- Inbound security rules** (highlighted with a red box)
- Outbound security rules
- Network interfaces

3. Create a security rule that allows ports 80 and 443 to the **myAsgWebServers** application security group. In **Add inbound security rule** page, enter or select this information:

SETTING	VALUE
Source	Leave the default of <b>Any</b> .
Source port ranges	Leave the default of <b>(*)</b> .
Destination	Select <b>Application security group</b> .
Destination application security groups	Select <b>myAsgWebServers</b> .

SETTING	VALUE
Service	Leave the default of <b>Custom</b> .
Destination port ranges	Enter <b>80,443</b> .
Protocol	Select <b>TCP</b> .
Action	Leave the default of <b>Allow</b> .
Priority	Leave the default of <b>100</b> .
Name	Enter <b>Allow-Web-All</b> .

 Add inbound security rule ×

myNSG

---

Source ⓘ

 UDP  
 ICMP

Action  
 Allow  
 Deny

Priority \* ⓘ

Name \*

Description

---

Add Cancel

4. Select **Add**.

5. Complete steps 3-4 again using this information:

SETTING	VALUE
Source	Leave the default of Any.
Source port ranges	Leave the default of (*).
Destination	Select <b>Application security group</b> .
Destination application security group	Select <b>myAsgMgmtServers</b> .
Service	Leave the default of <b>Custom</b> .
Destination port ranges	Enter <b>3389</b> .
Protocol	Select <b>Any</b> .
Action	Leave the default of <b>Allow</b> .
Priority	Leave the default of <b>110</b> .
Name	Enter <b>Allow-RDP-All</b> .

6. Select **Add**.

**Caution**

In this article, RDP (port 3389) is exposed to the internet for the VM that is assigned to the **myAsgMgmtServers** application security group.

For production environments, instead of exposing port 3389 to the internet, it's recommended that you connect to Azure resources that you want to manage using a VPN, private network connection, or Azure Bastion.

For more information on Azure Bastion, see [What is Azure Bastion?](#).

Once you've completed steps 1-3, review the rules you created. Your list should look like the list in the following example:

Priority	Name	Port	Protocol	Source	Destination	Action
100	Allow-Web-All	80,443	TCP	Any	myAsgWebServers	Allow
110	Allow-RDP-All	3389	Any	Any	myAsgMgmtServers	Allow
65000	AllowVnetInBound	Any	Any	VirtualNetwork	VirtualNetwork	Allow
65001	AllowAzureLoadBalancerInBound	Any	Any	AzureLoadBalancer	Any	Allow
65500	DenyAllInBound	Any	Any	Any	Any	Deny

# Create virtual machines

Create two virtual machines (VMs) in the virtual network.

## Create the first virtual machine

1. From the Azure portal menu, select + **Create a resource** > **Compute** > **Virtual machine**, or search for *Virtual machine* in the portal search box.
2. In **Create a virtual machine**, enter or select this information in the **Basics** tab:

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>myResourceGroup</b> .
<b>Instance details</b>	
Virtual machine name	Enter <i>myVMWeb</i> .
Region	Select <b>(US) East US</b> .
Availability options	Leave the default of <b>No infrastructure redundancy required</b> .
Security type	Leave the default of <b>Standard</b> .
Image	Select <b>Windows Server 2019 Datacenter - Gen2</b> .
Azure Spot instance	Leave the default of unchecked.
Size	Select <b>Standard_D2s_V3</b> .
<b>Administrator account</b>	
Username	Enter a username.
Password	Enter a password.
Confirm password	Reenter password.
<b>Inbound port rules</b>	
Select inbound ports	Select <b>None</b> .

3. Select the **Networking** tab.
4. In the **Networking** tab, enter or select the following information:

SETTING	VALUE
<b>Network interface</b>	

SETTING	VALUE
Virtual network	Select myVNet.
Subnet	Select default (10.0.0.0/24).
Public IP	Leave the default of a new public IP.
NIC network security group	Select None.

5. Select the **Review + create** tab, or select the blue **Review + create** button at the bottom of the page.

6. Select **Create**. The VM may take a few minutes to deploy.

### Create the second virtual machine

Complete steps 1-6 again, but in step 2, enter *myVMMgmt* for Virtual machine name.

Wait for the VMs to complete deployment before advancing to the next section.

## Associate network interfaces to an ASG

When you created the VMs, Azure created a network interface for each VM, and attached it to the VM.

Add the network interface of each VM to one of the application security groups you created previously:

1. Search for *myVMWeb* in the portal search box.
2. Select **Networking** from the **Settings** section of **myVMWeb** VM.
3. Select the **Application security groups** tab, then select **Configure the application security groups**.

The screenshot shows the Azure portal interface for managing a virtual machine named 'myVMWeb'. The left sidebar has a 'Settings' section with a 'Networking' item highlighted by a red box. The main content area is titled 'myVMWeb | Networking' and shows a list of network interfaces. One interface, 'myvmweb829', is selected and its details are shown: IP configuration is 'ipconfig1 (Primary)'. Below the interface list, there are tabs for 'Inbound port rules', 'Outbound port rules', 'Application security groups' (which is highlighted with a red box), and 'Load balancing'. A button labeled 'Configure the application security groups' is also highlighted with a red box at the bottom of the interface details.

4. In **Configure the application security groups**, select **myAsgWebServers**. Select **Save**.

Configure the application security groups

myvmweb829

 Save  Discard

 Showing only application security groups in the same region as the network interface. If you choose more than one application security group, they must all exist in the same virtual network.

Application security groups

myAsgWebServers

Filter the application security groups

myresourcegroup

myAsgMgmtServers

myAsgWebServers

5. Complete steps 1 and 2 again, searching for the *myVMMgmt* virtual machine and selecting the **myAsgMgmtServers** ASG.

## Test traffic filters

1. Search for *myVMMgmt* in the portal search box.
2. On the **Overview** page, select the **Connect** button and then select **RDP**.
3. Select **Download RDP file**.
4. Open the downloaded rdp file and select **Connect**. Enter the username and password you specified when creating the VM.
5. Select **OK**.
6. You may receive a certificate warning during the connection process. If you receive the warning, select **Yes or Continue**, to continue with the connection.

The connection succeeds, because inbound traffic from the internet to the **myAsgMgmtServers** application security group is allowed through port 3389.

The network interface for **myVMMgmt** is associated with the **myAsgMgmtServers** application security group and allows the connection.

7. Open a PowerShell session on **myVMMgmt**. Connect to **myVMWeb** using the following:

```
mstsc /v:myVmWeb
```

The RDP connection from **myVMMgmt** to **myVMWeb** succeeds because virtual machines in the same network can communicate with each other over any port by default.

You can't create an RDP connection to the **myVMWeb** virtual machine from the internet. The security rule for the **myAsgWebServers** prevents connections to port 3389 inbound from the internet. Inbound traffic from the Internet is denied to all resources by default.

8. To install Microsoft IIS on the **myVMWeb** virtual machine, enter the following command from a

PowerShell session on the **myVMWeb** virtual machine:

```
Install-WindowsFeature -name Web-Server -IncludeManagementTools
```

9. After the IIS installation is complete, disconnect from the **myVMWeb** virtual machine, which leaves you in the **myVMMgmt** virtual machine remote desktop connection.
10. Disconnect from the **myVMMgmt** VM.
11. Search for *myVMWeb* in the portal search box.
12. On the **Overview** page of **myVMWeb**, note the **Public IP address** for your VM. The address shown in the following example is 23.96.39.113, but your address is different:

The screenshot shows the Azure portal interface. In the top left, there's a breadcrumb navigation: Home >. Below it, a search bar contains 'Search (Cmd+/' followed by a dropdown arrow. To the right of the search bar are several action buttons: Connect, Start, Restart, Stop, Capture, Delete, Refresh, and Open in mobile. The main content area is titled 'myVMWeb' and 'Virtual machine'. On the left, a sidebar menu includes: Overview (selected), Activity log, Access control (IAM), Tags, Diagnose and solve problems, Settings, Networking, Connect, Windows Admin Center (previous), Disks, and Size. The main panel displays the VM details under the 'Essentials' section. Key information includes:

- Resource group: myResourceGroup
- Status: Running
- Location: East US
- Subscription: (change)
- Tags: (change) Click here to add tags
- Operating system: Windows (Windows Server 2019 Datacenter)
- Size: Standard D2s v3 (2 vcpus, 8 GiB memory)
- Public IP address: **23.96.39.113** (highlighted with a red box)
- Virtual network/subnet: myVNet/default
- DNS name: Configure

13. To confirm that you can access the **myVMWeb** web server from the internet, open an internet browser on your computer and browse to `http://<public-ip-address-from-previous-step>`.

You see the IIS default page, because inbound traffic from the internet to the **myAsgWebServers** application security group is allowed through port 80.

The network interface attached for **myVMWeb** is associated with the **myAsgWebServers** application security group and allows the connection.

## Clean up resources

When no longer needed, delete the resource group and all of the resources it contains:

1. Enter *myResourceGroup* in the **Search** box at the top of the portal. When you see **myResourceGroup** in the search results, select it.
2. Select **Delete resource group**.
3. Enter **myResourceGroup** for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

## Next steps

In this tutorial, you:

- Created a network security group and associated it to a virtual network subnet.
- Created application security groups for web and management.
- Created two virtual machines and associated their network interfaces with the application security groups.
- Tested the application security group network filtering.

To learn more about network security groups, see [Network security group overview](#) and [Manage a network security group](#).

Azure routes traffic between subnets by default. You may instead, choose to route traffic between subnets through a VM, serving as a firewall, for example.

To learn how to create a route table, advance to the next tutorial.

[Create a route table](#)

# Filter network traffic with a network security group using PowerShell

9/21/2022 • 8 minutes to read • [Edit Online](#)

You can filter network traffic inbound to and outbound from a virtual network subnet with a network security group. Network security groups contain security rules that filter network traffic by IP address, port, and protocol. Security rules are applied to resources deployed in a subnet. In this article, you learn how to:

- Create a network security group and security rules
- Create a virtual network and associate a network security group to a subnet
- Deploy virtual machines (VM) into a subnet
- Test traffic filters

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

OPTION	EXAMPLE/LINK
Select <b>Try It</b> in the upper-right corner of a code or command block. Selecting <b>Try It</b> doesn't automatically copy the code or command to Cloud Shell.	
Go to <a href="https://shell.azure.com">https://shell.azure.com</a> , or select the <b>Launch Cloud Shell</b> button to open Cloud Shell in your browser.	
Select the <b>Cloud Shell</b> button on the menu bar at the upper right in the <a href="#">Azure portal</a> .	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl+Shift+V** on Windows and Linux, or by selecting **Cmd+Shift+V** on macOS.
4. Select **Enter** to run the code or command.

If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 1.0.0 or later. Run `Get-Module -ListAvailable Az` to find the installed version. If you need to upgrade, see [Install Azure PowerShell module](#). If you are running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

# Create a network security group

A network security group contains security rules. Security rules specify a source and destination. Sources and destinations can be application security groups.

## Create application security groups

First create a resource group for all the resources created in this article with [New-AzResourceGroup](#). The following example creates a resource group in the *eastus* location:

```
New-AzResourceGroup -ResourceGroupName myResourceGroup -Location EastUS
```

Create an application security group with [New-AzApplicationSecurityGroup](#). An application security group enables you to group servers with similar port filtering requirements. The following example creates two application security groups.

```
$webAsg = New-AzApplicationSecurityGroup ` -ResourceGroupName myResourceGroup ` -Name myAsgWebServers ` -Location eastus

$mgmtAsg = New-AzApplicationSecurityGroup ` -ResourceGroupName myResourceGroup ` -Name myAsgMgmtServers ` -Location eastus
```

## Create security rules

Create a security rule with [New-AzNetworkSecurityRuleConfig](#). The following example creates a rule that allows traffic inbound from the internet to the *myWebServers* application security group over ports 80 and 443:

```
$webRule = New-AzNetworkSecurityRuleConfig ` -Name "Allow-Web-All" ` -Access Allow ` -Protocol Tcp ` -Direction Inbound ` -Priority 100 ` -SourceAddressPrefix Internet ` -SourcePortRange * ` -DestinationApplicationSecurityGroupId $webAsg.id ` -DestinationPortRange 80,443
```

The following example creates a rule that allows traffic inbound from the internet to the *\*myMgmtServers\** application security group over port 3389:

```
$mgmtRule = New-AzNetworkSecurityRuleConfig ` -Name "Allow-RDP-All" ` -Access Allow ` -Protocol Tcp ` -Direction Inbound ` -Priority 110 ` -SourceAddressPrefix Internet ` -SourcePortRange * ` -DestinationApplicationSecurityGroupId $mgmtAsg.id ` -DestinationPortRange 3389
```

In this article, RDP (port 3389) is exposed to the internet for the *myAsgMgmtServers* VM. For production environments, instead of exposing port 3389 to the internet, it's recommended that you connect to Azure resources that you want to manage using a [VPN](#) or [private](#) network connection.

## Create a network security group

Create a network security group with [New-AzNetworkSecurityGroup](#). The following example creates a network security group named *myNsg*:

```
$nsg = New-AzNetworkSecurityGroup `  
    -ResourceGroupName myResourceGroup `  
    -Location eastus `  
    -Name myNsg `  
    -SecurityRules $webRule,$mgmtRule
```

## Create a virtual network

Create a virtual network with [New-AzVirtualNetwork](#). The following example creates a virtual named *myVirtualNetwork*:

```
$virtualNetwork = New-AzVirtualNetwork `  
    -ResourceGroupName myResourceGroup `  
    -Location EastUS `  
    -Name myVirtualNetwork `  
    -AddressPrefix 10.0.0.0/16
```

Create a subnet configuration with [New-AzVirtualNetworkSubnetConfig](#), and then write the subnet configuration to the virtual network with [Set-AzVirtualNetwork](#). The following example adds a subnet named *mySubnet* to the virtual network and associates the *myNsg* network security group to it:

```
Add-AzVirtualNetworkSubnetConfig `  
    -Name mySubnet `  
    -VirtualNetwork $virtualNetwork `  
    -AddressPrefix "10.0.2.0/24" `  
    -NetworkSecurityGroup $nsg  
$virtualNetwork | Set-AzVirtualNetwork
```

## Create virtual machines

Before creating the VMs, retrieve the virtual network object with the subnet with [Get-AzVirtualNetwork](#):

```
$virtualNetwork = Get-AzVirtualNetwork `  
    -Name myVirtualNetwork `  
    -Resourcegroupname myResourceGroup
```

Create a public IP address for each VM with [New-AzPublicIpAddress](#):

```
$publicIpWeb = New-AzPublicIpAddress `  
    -AllocationMethod Dynamic `  
    -ResourceGroupName myResourceGroup `  
    -Location eastus `  
    -Name myVmWeb  
  
$publicIpMgmt = New-AzPublicIpAddress `  
    -AllocationMethod Dynamic `  
    -ResourceGroupName myResourceGroup `  
    -Location eastus `  
    -Name myVmMgmt
```

Create two network interfaces with [New-AzNetworkInterface](#), and assign a public IP address to the network interface. The following example creates a network interface, associates the *myVmWeb* public IP address to it,

and makes it a member of the *myAsgWebServers* application security group:

```
$webNic = New-AzNetworkInterface `  
    -Location eastus `  
    -Name myVmWeb `  
    -ResourceGroupName myResourceGroup `  
    -SubnetId $virtualNetwork.Subnets[0].Id `  
    -ApplicationSecurityGroupId $webAsg.Id `  
    -PublicIpAddressId $publicIpWeb.Id
```

The following example creates a network interface, associates the *myVmMgmt* public IP address to it, and makes it a member of the *myAsgMgmtServers* application security group:

```
$mgmtNic = New-AzNetworkInterface `  
    -Location eastus `  
    -Name myVmMgmt `  
    -ResourceGroupName myResourceGroup `  
    -SubnetId $virtualNetwork.Subnets[0].Id `  
    -ApplicationSecurityGroupId $mgmtAsg.Id `  
    -PublicIpAddressId $publicIpMgmt.Id
```

Create two VMs in the virtual network so you can validate traffic filtering in a later step.

Create a VM configuration with [New-AzVMConfig](#), then create the VM with [New-AzVM](#). The following example creates a VM that will serve as a web server. The `-AsJob` option creates the VM in the background, so you can continue to the next step:

```
# Create user object  
$cred = Get-Credential -Message "Enter a username and password for the virtual machine."  
  
$webVmConfig = New-AzVMConfig `  
    -VMName myVmWeb `  
    -VMSize Standard_DS1_V2 | `  
Set-AzVMOperatingSystem -Windows `  
    -ComputerName myVmWeb `  
    -Credential $cred | `  
Set-AzVMSourceImage `  
    -PublisherName MicrosoftWindowsServer `  
    -Offer WindowsServer `  
    -Skus 2016-Datacenter `  
    -Version latest | `  
Add-AzVMNetworkInterface `  
    -Id $webNic.Id  
New-AzVM `  
    -ResourceGroupName myResourceGroup `  
    -Location eastus `  
    -VM $webVmConfig `  
    -AsJob
```

Create a VM to serve as a management server:

```

# Create user object
$cred = Get-Credential -Message "Enter a username and password for the virtual machine."

# Create the web server virtual machine configuration and virtual machine.
$mgmtVmConfig = New-AzVMConfig `

    -VMName myVmMgmt `

    -VMSize Standard_DS1_V2 | `

Set-AzVMOperatingSystem -Windows `

    -ComputerName myVmMgmt `

    -Credential $cred | `

Set-AzVMSourceImage `

    -PublisherName MicrosoftWindowsServer `

    -Offer WindowsServer `

    -Skus 2016-Datacenter `

    -Version latest | `

Add-AzVMNetworkInterface `

    -Id $mgmtNic.Id

New-AzVM `

    -ResourceGroupName myResourceGroup `

    -Location eastus `

    -VM $mgmtVmConfig

```

The virtual machine takes a few minutes to create. Don't continue with the next step until Azure finishes creating the VM.

## Test traffic filters

Use [Get-AzPublicIpAddress](#) to return the public IP address of a VM. The following example returns the public IP address of the *myVmMgmt* VM:

```

Get-AzPublicIpAddress `

    -Name myVmMgmt `

    -ResourceGroupName myResourceGroup `

    | Select IpAddress

```

Use the following command to create a remote desktop session with the *myVmMgmt* VM from your local computer. Replace `<publicIpAddress>` with the IP address returned from the previous command.

```
mstsc /v:<publicIpAddress>
```

Open the downloaded RDP file. If prompted, select **Connect**.

Enter the user name and password you specified when creating the VM (you may need to select **More choices**, then **Use a different account**, to specify the credentials you entered when you created the VM), then select **OK**. You may receive a certificate warning during the sign-in process. Select **Yes** to proceed with the connection.

The connection succeeds, because port 3389 is allowed inbound from the internet to the *myAsgMgmtServers* application security group that the network interface attached to the *myVmMgmt* VM is in.

Use the following command to create a remote desktop connection to the *myVmWeb* VM, from the *myVmMgmt* VM, with the following command, from PowerShell:

```
mstsc /v:myvmWeb
```

The connection succeeds because a default security rule within each network security group allows traffic over all ports between all IP addresses within a virtual network. You can't create a remote desktop connection to the *myVmWeb* VM from the internet because the security rule for the *myAsgWebServers* doesn't allow port 3389

inbound from the internet.

Use the following command to install Microsoft IIS on the *myVmWeb* VM from PowerShell:

```
Install-WindowsFeature -name Web-Server -IncludeManagementTools
```

After the IIS installation is complete, disconnect from the *myVmWeb* VM, which leaves you in the *myVmMgmt* VM remote desktop connection. To view the IIS welcome screen, open an internet browser and browse to <http://myVmWeb>.

Disconnect from the *myVmMgmt* VM.

On your computer, enter the following command from PowerShell to retrieve the public IP address of the *myVmWeb* server:

```
Get-AzPublicIpAddress  
-Name myVmWeb  
-ResourceGroupName myResourceGroup  
| Select IpAddress
```

To confirm that you can access the *myVmWeb* web server from outside of Azure, open an internet browser on your computer and browse to <http://<public-ip-address-from-previous-step>>. The connection succeeds, because port 80 is allowed inbound from the internet to the *myAsgWebServers* application security group that the network interface attached to the *myVmWeb* VM is in.

## Clean up resources

When no longer needed, you can use [Remove-AzResourceGroup](#) to remove the resource group and all of the resources it contains:

```
Remove-AzResourceGroup -Name myResourceGroup -Force
```

## Next steps

In this article, you created a network security group and associated it to a virtual network subnet. To learn more about network security groups, see [Network security group overview](#) and [Manage a network security group](#).

Azure routes traffic between subnets by default. You may instead, choose to route traffic between subnets through a VM, serving as a firewall, for example. To learn how, see [Create a route table](#).

# Filter network traffic with a network security group using the Azure CLI

9/21/2022 • 7 minutes to read • [Edit Online](#)

You can filter network traffic inbound to and outbound from a virtual network subnet with a network security group. Network security groups contain security rules that filter network traffic by IP address, port, and protocol. Security rules are applied to resources deployed in a subnet. In this article, you learn how to:

- Create a network security group and security rules
- Create a virtual network and associate a network security group to a subnet
- Deploy virtual machines (VM) into a subnet
- Test traffic filters

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This article requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a network security group

A network security group contains security rules. Security rules specify a source and destination. Sources and destinations can be application security groups.

### Create application security groups

First create a resource group for all the resources created in this article with `az group create`. The following example creates a resource group in the `eastus` location:

```
az group create \
--name myResourceGroup \
--location eastus
```

Create an application security group with [az network asg create](#). An application security group enables you to group servers with similar port filtering requirements. The following example creates two application security groups.

```
az network asg create \
--resource-group myResourceGroup \
--name myAsgWebServers \
--location eastus

az network asg create \
--resource-group myResourceGroup \
--name myAsgMgmtServers \
--location eastus
```

## Create a network security group

Create a network security group with [az network nsg create](#). The following example creates a network security group named *myNsg*.

```
# Create a network security group
az network nsg create \
--resource-group myResourceGroup \
--name myNsg
```

## Create security rules

Create a security rule with [az network nsg rule create](#). The following example creates a rule that allows traffic inbound from the internet to the *myWebServers* application security group over ports 80 and 443:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNsg \
--name Allow-Web-All \
--access Allow \
--protocol Tcp \
--direction Inbound \
--priority 100 \
--source-address-prefix Internet \
--source-port-range "*" \
--destination-asgs "myAsgWebServers" \
--destination-port-range 80 443
```

The following example creates a rule that allows traffic inbound from the Internet to the *myMgmtServers* application security group over port 22:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNsg \
--name Allow-SSH-All \
--access Allow \
--protocol Tcp \
--direction Inbound \
--priority 110 \
--source-address-prefix Internet \
--source-port-range "*" \
--destination-asgs "myAsgMgmtServers" \
--destination-port-range 22
```

In this article, SSH (port 22) is exposed to the internet for the *myAsgMgmtServers* VM. For production environments, instead of exposing port 22 to the internet, it's recommended that you connect to Azure resources that you want to manage using a [VPN](#) or [private](#) network connection.

## Create a virtual network

Create a virtual network with [az network vnet create](#). The following example creates a virtual named *myVirtualNetwork*:

```
az network vnet create \
--name myVirtualNetwork \
--resource-group myResourceGroup \
--address-prefixes 10.0.0.0/16
```

Add a subnet to a virtual network with [az network vnet subnet create](#). The following example adds a subnet named *mySubnet* to the virtual network and associates the *myNsg* network security group to it:

```
az network vnet subnet create \
--vnet-name myVirtualNetwork \
--resource-group myResourceGroup \
--name mySubnet \
--address-prefix 10.0.0.0/24 \
--network-security-group myNsg
```

## Create virtual machines

Create two VMs in the virtual network so you can validate traffic filtering in a later step.

Create a VM with [az vm create](#). The following example creates a VM that will serve as a web server. The `--asgs myAsgWebServers` option causes Azure to make the network interface it creates for the VM a member of the *myAsgWebServers* application security group.

The `--nsg ""` option is specified to prevent Azure from creating a default network security group for the network interface Azure creates when it creates the VM. To streamline this article, a password is used. Keys are typically used in production deployments. If you use keys, you must also configure SSH agent forwarding for the remaining steps. For more information, see the documentation for your SSH client. Replace `<replace-with-your-password>` in the following command with a password of your choosing.

```
adminPassword=<replace-with-your-password>

az vm create \
--resource-group myResourceGroup \
--name myVmWeb \
--image UbuntuLTS \
--vnet-name myVirtualNetwork \
--subnet mySubnet \
--nsg "" \
--asgs myAsgWebServers \
--admin-username azureuser \
--admin-password $adminPassword
```

The VM takes a few minutes to create. After the VM is created, output similar to the following example is returned:

```
{
  "fqdns": "",
  "id": "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVmWeb",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "13.90.242.231",
  "resourceGroup": "myResourceGroup"
}
```

Take note of the **publicIpAddress**. This address is used to access the VM from the internet in a later step. Create a VM to serve as a management server:

```
az vm create \
--resource-group myResourceGroup \
--name myVmMgmt \
--image UbuntuLTS \
--vnet-name myVirtualNetwork \
--subnet mySubnet \
--nsg "" \
--asgs myAsgMgmtServers \
--admin-username azureuser \
--admin-password $adminPassword
```

The VM takes a few minutes to create. After the VM is created, note the **publicIpAddress** in the returned output. This address is used to access the VM in the next step. Don't continue with the next step until Azure finishes creating the VM.

## Test traffic filters

Use the command that follows to create an SSH session with the *myVmMgmt* VM. Replace **<publicIpAddress>** with the public IP address of your VM. In the example above, the IP address is *13.90.242.231*.

```
ssh azureuser@<publicIpAddress>
```

When prompted for a password, enter the password you entered in [Create VMs](#).

The connection succeeds, because port 22 is allowed inbound from the Internet to the *myAsgMgmtServers* application security group that the network interface attached to the *myVmMgmt* VM is in.

Use the following command to SSH to the *myVmWeb* VM from the *myVmMgmt* VM:

```
ssh azureuser@myVmWeb
```

The connection succeeds because a default security rule within each network security group allows traffic over all ports between all IP addresses within a virtual network. You can't SSH to the *myVmWeb* VM from the Internet because the security rule for the *myAsgWebServers* doesn't allow port 22 inbound from the Internet.

Use the following commands to install the nginx web server on the *myVmWeb* VM:

```
# Update package source  
sudo apt-get -y update  
  
# Install NGINX  
sudo apt-get -y install nginx
```

The *myVmWeb* VM is allowed outbound to the Internet to retrieve nginx because a default security rule allows all outbound traffic to the Internet. Exit the *myVmWeb* SSH session, which leaves you at the `username@myVmMgmt:~$` prompt of the *myVmMgmt* VM. To retrieve the nginx welcome screen from the *myVmWeb* VM, enter the following command:

```
curl myVmWeb
```

Logout of the *myVmMgmt* VM. To confirm that you can access the *myVmWeb* web server from outside of Azure, enter `curl <publicIpAddress>` from your own computer. The connection succeeds, because port 80 is allowed inbound from the Internet to the *myAsgWebServers* application security group that the network interface attached to the *myVmWeb* VM is in.

## Clean up resources

When no longer needed, use [az group delete](#) to remove the resource group and all of the resources it contains.

```
az group delete --name myResourceGroup --yes
```

## Next steps

In this article, you created a network security group and associated it to a virtual network subnet. To learn more about network security groups, see [Network security group overview](#) and [Manage a network security group](#).

Azure routes traffic between subnets by default. You may instead, choose to route traffic between subnets through a VM, serving as a firewall, for example. To learn how, see [Create a route table](#).

# Create a virtual machine with a static public IP address using the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

A public IP address enables you to communicate to a virtual machine from the internet.

Assign a static public IP address, rather than a dynamic address, to ensure that the address never changes.

## Sign in to Azure

Sign in to the [Azure portal](#).

## Create a virtual machine

1. On the upper-left side of the portal, select **Create a resource > Compute > Virtual machine** or search for **Virtual machine** in the search box.
2. In **Create a virtual machine**, type or select the values in the **Basics** tab:

SETTING	VALUE
Project Details	
Subscription	Select your Azure subscription
Resource Group	Select <b>Create new</b> . In <b>Name</b> , enter <b>myResourceGroup</b> . Select <b>OK</b> .
Instance details	
Virtual machine name	Enter <b>myVM</b>
Region	Select <b>East US</b>
Availability Options	Select <b>No infrastructure redundancy required</b>
Image	Select <b>Windows Server 2019 Datacenter - Gen1</b>
Azure Spot instance	Select <b>No</b>
Size	Choose VM size or take default setting
Administrator account	
Username	Enter a username
Password	Enter a password

SETTING	VALUE
Confirm password	Reenter password
Public inbound ports	Select <b>Allow selected ports</b> .
Select inbound ports	Select RDP (3389)

**WARNING**

Portal 3389 is selected, to enable remote access to the Windows Server virtual machine from the internet.

Opening port 3389 to the internet is not recommended to manage production workloads.

For secure access to Azure virtual machines, see [What is Azure Bastion?](#)

3. Select the **Networking** tab, or select **Next: Disks**, then **Next: Networking**.

4. In the Networking tab, select or enter:

SETTING	VALUE
<b>Network interface</b>	
Virtual network	Accept the default network name.
Subnet	Accept the default subnet configuration.
Public IP	Select <b>Create new</b> . In <b>Create public IP address</b> , in name enter <b>myPublicIP</b> . For <b>SKU</b> , select <b>Standard</b> . <b>Assignment</b> , select <b>Static</b> . Select <b>OK</b> .
NIC network security group	Select <b>Basic</b>
Public inbound ports	Select <b>Allow selected ports</b> .
Select inbound ports	Select RDP (3389)

5. Select **Review + create**.

6. Review the settings, and then select **Create**.

#### **NOTE**

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Clean up resources

When no longer needed, delete the resource group and all of the resources it contains:

1. Enter **myResourceGroup** in the **Search** box at the top of the portal. When you see **myResourceGroup** in the search results, select it.
2. Select **Delete resource group**.
3. Enter **myResourceGroup** for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

## Next steps

See [Add, change, or remove IP addresses](#):

- To change a public IP address from dynamic to static.
- Work with private IP addresses.

Public IP addresses have a [nominal charge](#). There's a [limit](#) to the number of public IP addresses that you can use per subscription.

The SKU of the virtual machine's public IP address must match the public IP SKU of Azure Load Balancer when added to a backend pool. For details, see [Azure Load Balancer](#).

You can download the list of ranges (prefixes) for the Azure [Public](#), [US government](#), [China](#), and [Germany](#) clouds.

- Learn more about [static public IP addresses](#).
- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.

# Create a virtual machine with a static public IP address using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

In this article, you'll create a VM with a static public IP address. A public IP address enables communication to a virtual machine from the internet. Assign a static public IP address, instead of a dynamic address, to ensure the address never changes.

Public IP addresses have a [nominal charge](#). There's a [limit](#) to the number of public IP addresses that you can use per subscription.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- Azure PowerShell installed locally or Azure Cloud Shell

If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 5.4.1 or later. Run `Get-Module -ListAvailable Az` to find the installed version. If you need to upgrade, see [Install Azure PowerShell module](#). If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with [New-AzResourceGroup](#) named **myResourceGroup** in the **eastus2** location.

```
$rg =@{  
    Name = 'myResourceGroup'  
    Location = 'eastus2'  
}  
New-AzResourceGroup @rg
```

## Create a public IP address

Use [New-AzPublicIpAddress](#) to create a standard public IPv4 address.

The following command creates a zone-redundant public IP address named **myPublicIP** in **myResourceGroup**.

```

## Create IP. ##
$ip = @{
    Name = 'myPublicIP'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
   IpAddressVersion = 'IPv4'
    Zone = 1,2,3
}
New-AzPublicIpAddress @ip

```

## Create a virtual machine

Create a virtual machine with [New-AzVM](#).

The following command creates a Windows Server virtual machine. You'll enter the name of the public IP address created previously in the `-PublicIpAddressName` parameter. When prompted, provide a username and password to be used as the credentials for the virtual machine:

```

## Create virtual machine. ##
$vm = @{
    ResourceGroupName = 'myResourceGroup'
    Location = 'East US 2'
    Name = 'myVM'
    PublicIpAddressName = 'myPublicIP'
}
New-AzVM @vm

```

For more information on public IP SKUs, see [Public IP address SKUs](#). A virtual machine can be added to the backend pool of an Azure Load Balancer. The SKU of the public IP address must match the SKU of a load balancer's public IP. For more information, see [Azure Load Balancer](#).

View the public IP address assigned and confirm that it was created as a static address, with [Get-AzPublicIpAddress](#):

```

## Retrieve public IP address settings. ##
$ip = @{
    Name = 'myPublicIP'
    ResourceGroupName = 'myResourceGroup'
}
Get-AzPublicIpAddress @ip | Select "IpAddress","PublicIpAllocationMethod" | Format-Table

```

### WARNING

Do not modify the IP address settings within the virtual machine's operating system. The operating system is unaware of Azure public IP addresses. Though you can add private IP address settings to the operating system, we recommend not doing so unless necessary, and not until after reading [Add a private IP address to an operating system](#).

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Clean up resources

When no longer needed, you can use [Remove-AzResourceGroup](#) to remove the resource group and all of the resources it contains:

```
Remove-AzResourceGroup -Name myResourceGroup -Force
```

## Next steps

- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.
- Learn more about creating [Linux](#) and [Windows](#) virtual machines.

# Create a virtual machine with a static public IP address using the Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

In this article, you'll create a VM with a static public IP address. A public IP address enables communication to a virtual machine from the internet. Assign a static public IP address, instead of a dynamic address, to ensure the address never changes.

Public IP addresses have a [nominal charge](#). There's a [limit](#) to the number of public IP addresses that you can use per subscription.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the [az login](#) command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run [az version](#) to find the version and dependent libraries that are installed. To upgrade to the latest version, run [az upgrade](#).
- An Azure account with an active subscription. [Create an account for free](#).
- This tutorial requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with [az group create](#) named **myResourceGroup** in the **eastus2** location.

```
az group create \
--name myResourceGroup \
--location eastus2
```

## Create a public IP address

Use [az network public-ip create](#) to create a standard public IPv4 address.

The following command creates a zone-redundant public IP address named **myPublicIP** in

myResourceGroup.

```
az network public-ip create \
--resource-group myResourceGroup \
--name myPublicIP \
--version IPv4 \
--sku Standard \
--zone 1 2 3
```

## Create a virtual machine

Create a virtual machine with [az vm create](#).

The following command creates a Windows Server virtual machine. You'll enter the name of the public IP address created previously in the `-PublicIPAddressName` parameter. When prompted, provide a username and password to be used as the credentials for the virtual machine:

```
az vm create \
--name myVM \
--resource-group TutorVMRoutePref-rg \
--public-ip-address myPublicIP \
--size Standard_A2 \
--image MicrosoftWindowsServer:WindowsServer:2019-Datacenter:latest \
--admin-username azureuser
```

For more information on public IP SKUs, see [Public IP address SKUs](#). A virtual machine can be added to the backend pool of an Azure Load Balancer. The SKU of the public IP address must match the SKU of a load balancer's public IP. For more information, see [Azure Load Balancer](#).

View the public IP address assigned and confirm that it was created as a static address, with [az network public-ip show](#):

```
az network public-ip show \
--resource-group myResourceGroup \
--name myPublicIP \
--query [ipAddress,publicIpAllocationMethod,sku] \
--output table
```

### WARNING

Do not modify the IP address settings within the virtual machine's operating system. The operating system is unaware of Azure public IP addresses. Though you can add private IP address settings to the operating system, we recommend not doing so unless necessary, and not until after reading [Add a private IP address to an operating system](#).

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Clean up resources

When no longer needed, you can use `az group delete` to remove the resource group and all of the resources it contains:

```
az group delete --name myResourceGroup --yes
```

## Next steps

- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.
- Learn more about creating [Linux](#) and [Windows](#) virtual machines.

# Associate a public IP address to a virtual machine

9/21/2022 • 11 minutes to read • [Edit Online](#)

In this article, you learn how to associate a public IP address to an existing virtual machine (VM). If you want to connect to a VM from the internet, the VM must have a public IP address associated to it. If you want to create a new VM with a public IP address, you can do so using the [Azure portal](#), the [Azure CLI](#), or [Azure PowerShell](#). Public IP addresses have a nominal fee. For details, see [pricing](#). There is a limit to the number of public IP addresses that you can use per subscription. For details, see [limits](#).

You can use the [Azure portal](#), the [Azure CLI](#), or [Azure PowerShell](#) to associate a public IP address to a VM.

## NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

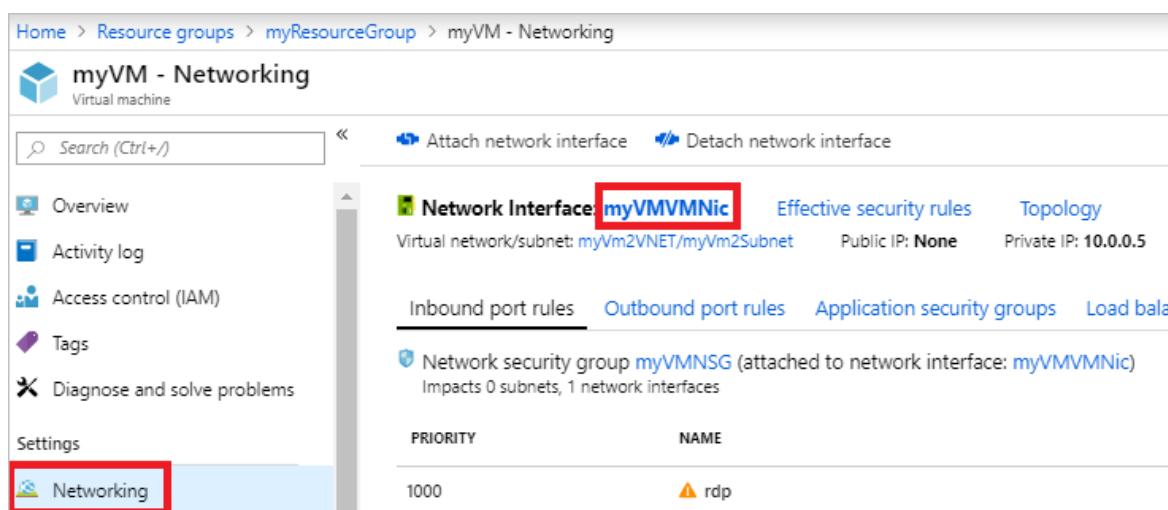

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Azure portal

1. Sign in to the [Azure portal](#).
2. Browse to, or search for the virtual machine that you want to add the public IP address to and then select it.
3. Under **Settings**, select **Networking**, and then select the network interface you want to add the public IP address to, as shown in the following picture:

The screenshot shows the Azure portal interface for managing a virtual machine named 'myVM'. The 'Networking' section is open, displaying the 'myVMVMNic' network interface. Key details shown include:

- Virtual network/subnet:** myVm2VNET/myVm2Subnet
- Public IP:** None
- Private IP:** 10.0.0.5

The 'Inbound port rules' tab is selected, showing one rule:

PRIORITY	NAME
1000	rdp

Other tabs visible include 'Effective security rules' and 'Topology'. The left sidebar shows other settings like 'Overview', 'Activity log', 'Access control (IAM)', 'Tags', 'Diagnose and solve problems', and 'Networking' (which is highlighted with a red box).

#### NOTE

Public IP addresses are associated to network interfaces attached to a VM. In the previous picture, the VM only has one network interface. If the VM had multiple network interfaces, they would all appear, and you'd select the network interface you want to associate the public IP address to.

4. Select **IP configurations** and then select an IP configuration, as shown in the following picture:

Home > myVMVMNic - IP configurations

## myVMVMNic - IP configurations

Network interface

Search (Ctrl+ /) Add Save Discard

Overview Activity log Access control (IAM) Tags

Settings

IP configurations

Subnet: myVm2Subnet (10.0.0.0/24)

NAME	IP VERSIO...	TYPE	PRIVATE IP ADDRESS	PUBLIC IP ADDRESS
ipconfigmyVM	IPv4	Primary	10.0.0.5 (Dynamic)	-

#### NOTE

Public IP addresses are associated to IP configurations for a network interface. In the previous picture, the network interface has one IP configuration. If the network interface had multiple IP configurations, they would all appear in the list, and you'd select the IP configuration that you want to associate the public IP address to.

5. Select **Enabled**, then select **IP address (Configure required settings)**. Choose an existing public IP address, which automatically closes the **Choose public IP address** box. If you don't have any available public IP addresses listed, you need to create one. To learn how, see [Create a public IP address](#). Select **Save**, as shown in the picture that follows, and then close the box for the IP configuration.

Home > myVMVMNic - IP configurations > ipconfigmyVM > Choose public IP address

### ipconfigmyVM

Save Discard

Public IP address settings

Enabled

IP address Configure required settings

Choose public IP address

These are the public IP addresses in the selected subscription and location 'East US'.

Create new

myVMPublicIP myResourceGroup

#### NOTE

The public IP addresses that appear are those that exist in the same region as the VM. If you have multiple public IP addresses created in the region, all will appear here. If any are grayed out, it's because the address is already associated to a different resource.

6. View the public IP address assigned to the IP configuration, as shown in the picture that follows. It may take a few seconds for an IP address to appear.

The screenshot shows the Azure portal's 'IP configurations' page for a network interface named 'myVMVMNic'. On the left, there's a sidebar with options like Overview, Activity log, Access control (IAM), Tags, Settings, IP configurations (which is selected), DNS servers, Network security group, and Properties. The main area shows 'IP forwarding settings' with 'IP forwarding' set to 'Enabled'. Below that is a section for 'Virtual network' and 'myVm2VNET'. Under 'IP configurations', there's a dropdown for 'Subnet' set to 'myVm2Subnet (10.0.0.0/24)'. A table lists one IP configuration: 'ipconfig...' (IPv4), Type 'Primary', Private IP Address '10.0.0.5 (Dynamic)', and Public IP Address '52.179.3.114 (myVMPublicIP)'. The public IP address is highlighted with a red box.

#### NOTE

The address is assigned from a pool of addresses used in each Azure region. To see a list of address pools used in each region, see [Microsoft Azure Datacenter IP Ranges](#). The address assigned can be any address in the pools used for the region. If you need the address to be assigned from a specific pool in the region, use a [Public IP address prefix](#).

7. [Allow network traffic to the VM](#) with security rules in a network security group.

## Azure CLI

Install the [Azure CLI](#), or use the Azure Cloud Shell. The Azure Cloud Shell is a free Bash shell that you can run directly within the Azure portal. It has the Azure CLI preinstalled and configured to use with your account. Select the Try it button in the CLI commands that follow. Selecting Try it invokes a Cloud Shell that you can sign in to your Azure account with.

1. If using the CLI locally in Bash, sign in to Azure with `az login`.
2. A public IP address is associated to an IP configuration of a network interface attached to a VM. Use the `az network nic-ip-config update` command to associate a public IP address to an IP configuration. The following example associates an existing public IP address named *myVMPublicIP* to the IP configuration named *ipconfigmyVM* of an existing network interface named *myVMVMNic* that exists in a resource group named *myResourceGroup*.

```
az network nic ip-config update \
--name ipconfigmyVM \
--nic-name myVMVMNic \
--resource-group myResourceGroup \
--public-ip-address myVMPublicIP
```

- If you don't have an existing public IP address, use the `az network public-ip create` command to create one. For example, the following command creates a public IP address named *myVMPublicIP* in a resource group named *myResourceGroup*.

```
az network public-ip create --name myVMPublicIP --resource-group myResourceGroup
```

#### NOTE

The previous command creates a public IP address with default values for several settings that you may want to customize. To learn more about all public IP address settings, see [Create a public IP address](#). The address is assigned from a pool of public IP addresses used for each Azure region. To see a list of address pools used in each region, see [Microsoft Azure Datacenter IP Ranges](#).

- If you don't know the name of a network interface attached to your VM, use the [az vm nic list](#) command to view them. For example, the following command lists the names of the network interfaces attached to a VM named *myVM* in a resource group named *myResourceGroup*:

```
az vm nic list --vm-name myVM --resource-group myResourceGroup
```

The output includes one or more lines that are similar to the following example:

```
"id": "/subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVMVMNic",
```

In the previous example, *myVMVMNic* is the name of the network interface.

- If you don't know the name of an IP configuration for a network interface, use the [az network nic ip-config list](#) command to retrieve them. For example, the following command lists the names of the IP configurations for a network interface named *myVMVMNic* in a resource group named *myResourceGroup*:

```
az network nic ip-config list --nic-name myVMVMNic --resource-group myResourceGroup --out table
```

3. View the public IP address assigned to the IP configuration with the [az vm list-ip-addresses](#) command. The following example shows the IP addresses assigned to an existing VM named *myVM* in a resource group named *myResourceGroup*.

```
az vm list-ip-addresses --name myVM --resource-group myResourceGroup --out table
```

#### NOTE

The address is assigned from a pool of addresses used in each Azure region. To see a list of address pools used in each region, see [Microsoft Azure Datacenter IP Ranges](#). The address assigned can be any address in the pools used for the region. If you need the address to be assigned from a specific pool in the region, use a [Public IP address prefix](#).

4. [Allow network traffic to the VM](#) with security rules in a network security group.

## PowerShell

Install [PowerShell](#), or use the Azure Cloud Shell. The Azure Cloud Shell is a free shell that you can run directly within the Azure portal. It has PowerShell preinstalled and configured to use with your account. Select the **Try it** button in the PowerShell commands that follow. Selecting **Try it** invokes a Cloud Shell that you can sign in to your Azure account with.

1. If using PowerShell locally, sign in to Azure with `Connect-AzAccount`.
2. A public IP address is associated to an IP configuration of a network interface attached to a VM. Use the [Get-AzVirtualNetwork](#) and [Get-AzVirtualNetworkSubnetConfig](#) commands to get the virtual network and subnet that the network interface is in. Next, use the [Get-AzNetworkInterface](#) command to get a network interface and the [Get-AzPublicIpAddress](#) command to get an existing public IP address. Then use the [Set-AzNetworkInterfaceIpConfig](#) command to associate the public IP address to the IP configuration and the [Set-AzNetworkInterface](#) command to write the new IP configuration to the network interface.

The following example associates an existing public IP address named *myVMPublicIP* to the IP configuration named *ipconfigmyVM* of an existing network interface named *myVMVNic* that exists in a subnet named *myVMSubnet* in a virtual network named *myVMVNet*. All resources are in a resource group named *myResourceGroup*.

```
$vnet = Get-AzVirtualNetwork -Name myVMVNet -ResourceGroupName myResourceGroup
$subnet = Get-AzVirtualNetworkSubnetConfig -Name myVMSubnet -VirtualNetwork $vnet
$nic = Get-AzNetworkInterface -Name myVMVNic -ResourceGroupName myResourceGroup
$pip = Get-AzPublicIpAddress -Name myVMPublicIP -ResourceGroupName myResourceGroup
$nic | Set-AzNetworkInterfaceIpConfig -Name ipconfigmyVM -PublicIPAddress $pip -Subnet $subnet
$nic | Set-AzNetworkInterface
```

- If you don't have an existing public IP address, use the [New-AzPublicIpAddress](#) command to create one. For example, the following command creates a *dynamic* public IP address named *myVMPublicIP* in a resource group named *myResourceGroup* in the *eastus* region.

```
New-AzPublicIpAddress -Name myVMPublicIP -ResourceGroupName myResourceGroup -AllocationMethod Dynamic -Location eastus
```

#### NOTE

The previous command creates a public IP address with default values for several settings that you may want to customize. To learn more about all public IP address settings, see [Create a public IP address](#). The address is assigned from a pool of public IP addresses used for each Azure region. To see a list of address pools used in each region, see [Microsoft Azure Datacenter IP Ranges](#).

- If you don't know the name of a network interface attached to your VM, use the [Get-AzVM](#) command to view them. For example, the following command lists the names of the network interfaces attached to a VM named *myVM* in a resource group named *myResourceGroup*.

```
$vm = Get-AzVM -name myVM -ResourceGroupName myResourceGroup
$vm.NetworkProfile
```

The output includes one or more lines that are similar to the example that follows. In the example output, *myVMVNic* is the name of the network interface.

```
"id": "/subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVMVNic",
```

- If you don't know the name of the virtual network or subnet that the network interface is in, use the [Get-AzNetworkInterface](#) command to view the information. For example, the following command gets the virtual network and subnet information for a network interface named *myVMVNic* in a resource group named *myResourceGroup*.

```
$nic = Get-AzNetworkInterface -Name myVMVMNic -ResourceGroupName myResourceGroup  
$ipConfigs = $nic.IpConfigurations  
$ipConfigs.Subnet | Select Id
```

The output includes one or more lines that are similar to the example that follows. In the example output, *myVMVNET* is the name of the virtual network and *myVMSubnet* is the name of the subnet.

```
"/subscriptions/00000000-0000-0000-0000-  
0000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/virtualNetworks/myVMV-  
NET/subnets/myVMSubnet",
```

- If you don't know the name of an IP configuration for a network interface, use the [Get-AzNetworkInterface](#) command to retrieve them. For example, the following command lists the names of the IP configurations for a network interface named *myVMVMNic* in a resource group named *myResourceGroup*.

```
$nic = Get-AzNetworkInterface -Name myVMVMNic -ResourceGroupName myResourceGroup  
$nic.IPCConfigurations
```

The output includes one or more lines that are similar to the example that follows. In the example output, *ipconfigmyVM* is the name of an IP configuration.

```
Id      : /subscriptions/00000000-0000-0000-0000-  
0000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVM-  
VMNic/ipConfigurations/ipconfigmyVM
```

3. View the public IP address assigned to the IP configuration with the [Get-AzPublicIpAddress](#) command. The following example shows the address assigned to a public IP address named *myVMPublicIP* in a resource group named *myResourceGroup*.

```
Get-AzPublicIpAddress -Name myVMPublicIP -ResourceGroupName myResourceGroup | Select IpAddress
```

If you don't know the name of the public IP address assigned to an IP configuration, run the following commands to get it:

```
$nic = Get-AzNetworkInterface -Name myVMVMNic -ResourceGroupName myResourceGroup  
$nic.IPCConfigurations  
$address = $nic.IPCConfigurations.PublicIpAddress  
$address | Select Id
```

The output includes one or more lines that are similar to the example that follows. In the example output, *myVMPublicIP* is the name of the public IP address assigned to the IP configuration.

```
"/subscriptions/00000000-0000-0000-0000-  
0000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/publicIPAddresses/myVMPublicI-  
P"
```

**NOTE**

The address is assigned from a pool of addresses used in each Azure region. To see a list of address pools used in each region, see [Microsoft Azure Datacenter IP Ranges](#). The address assigned can be any address in the pools used for the region. If you need the address to be assigned from a specific pool in the region, use a [Public IP address prefix](#).

4. [Allow network traffic to the VM](#) with security rules in a network security group.

## Allow network traffic to the VM

Before you can connect to the public IP address from the internet, ensure that you have the necessary ports open in any network security group that you might have associated to the network interface, the subnet the network interface is in, or both. Though security groups filter traffic to the private IP address of the network interface, once inbound internet traffic arrives at the public IP address, Azure translates the public address to the private IP address, so if a network security group prevents the traffic flow, the communication with the public IP address fails. You can view the effective security rules for a network interface and its subnet using the [Portal](#), [CLI](#), or [PowerShell](#).

## Next steps

Allow inbound internet traffic to your VM with a network security group. To learn how to create a network security group, see [Work with network security groups](#). To learn more about network security groups, see [Security groups](#).

# Dissociate a public IP address from an Azure VM

9/21/2022 • 4 minutes to read • [Edit Online](#)

In this article, you learn how to dissociate a public IP address from an Azure virtual machine (VM).

You can use the [Azure portal](#), the [Azure CLI](#), or [Azure PowerShell](#) to dissociate a public IP address from a VM.

## Azure portal

1. Sign in to the [Azure portal](#).
2. Browse to, or search for the virtual machine that you want to disassociate the public IP address from and then select it.
3. In the VM page, select **Overview**, select the public IP address as shown in the following picture:

The screenshot shows the Microsoft Azure portal interface. The top navigation bar includes 'Microsoft Azure', a search bar, and various icons. Below the navigation is a breadcrumb trail: 'Dashboard > Resource groups > myResourceGroup > myVM'. The main content area has a left sidebar with options like 'Search (Ctrl+J)', 'Connect', 'Start', 'Restart', 'Stop', 'Capture', 'Delete', 'Refresh', and a link to 'Advisor (1 of 3): Enable virtual machine replication to protect your applications from regional outage'. The main panel is titled 'myVM Virtual machine' and shows the 'Overview' tab selected. It displays details such as Resource group (changed), Status, Location, Subscription, Computer name, Operating system, Size, Tags, and several IP addresses (Public and Private). The 'Public IP address' field is explicitly highlighted with a red box, containing the value '52.170.252.185'.

4. In the public IP address page, select **Overview**, and then select **Dissociate**, as shown in the following picture:

The screenshot shows the Microsoft Azure portal interface. The top navigation bar includes 'Microsoft Azure', a search bar, and various icons. Below the navigation is a breadcrumb trail: 'Dashboard > Resource groups > myResourceGroup > myVM > myPublicIpAddress'. The main content area has a left sidebar with options like 'Search (Ctrl+J)', 'Associate', 'Dissociate' (which is highlighted with a red box), 'Move', 'Delete', and 'Refresh'. The main panel is titled 'myPublicIpAddress Public IP address' and shows the 'Overview' tab selected. It displays details such as Resource group, Location, Subscription, SKU, IP address, DNS name, Associated to, and Virtual machine.

5. In **Dissociate public IP address**, select **Yes**.

## Azure CLI

Install the [Azure CLI](#), or use the Azure Cloud Shell. The Azure Cloud Shell is a free Bash shell that you can run directly within the Azure portal. It has the Azure CLI preinstalled and configured to use with your account. Select the **Try it** button in the CLI commands that follow. Selecting **Try it** invokes a Cloud Shell that you can sign in to your Azure account with.

1. If using the CLI locally in Bash, sign in to Azure with `az login`.
2. A public IP address is associated to an IP configuration of a network interface attached to a VM. Use the `az network nic-ip-config update` command to dissociate a public IP address from an IP configuration. The

following example dissociates a public IP address named *myVMPublicIP* from the IP configuration named *ipconfigmyVM* of an existing network interface named *myVMVMNic* that is attached to a VM named *myVM* in a resource group named *myResourceGroup*.

```
az network nic ip-config update \
--name ipconfigmyVM \
--resource-group myResourceGroup \
--nic-name myVMVMNic \
--remove PublicIpAddress
```

If you don't know the name of a network interface attached to your VM, use the [az vm nic list](#) command to view them. For example, the following command lists the names of the network interfaces attached to a VM named *myVM* in a resource group named *myResourceGroup*.

```
az vm nic list --vm-name myVM --resource-group myResourceGroup
```

The output includes one or more lines that are similar to the following example:

```
"id": "/subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVMVMNic",
```

In the previous example, *myVMVMNic* is the name of the network interface.

- If you don't know the name of an IP configuration for a network interface, use the [az network nic ip-config list](#) command to retrieve them. For example, the following command lists the names of the public IP configurations for a network interface named *myVMVMNic* in a resource group named *myResourceGroup*.

```
az network nic ip-config list --nic-name myVMVMNic --resource-group myResourceGroup --out table
```

- If you don't know the name of a public IP configuration for a network interface, use the [az network nic ip-config show](#) command to retrieve them. For example, the following command lists the names of the public IP configurations for a network interface named *myVMVMNic* in a resource group named *myResourceGroup*.

```
az network nic ip-config show --name ipconfigmyVM --nic-name myVMVMNic --resource-group myResourceGroup --query publicIPAddress.id
```

## PowerShell

Install [PowerShell](#), or use the Azure Cloud Shell. The Azure Cloud Shell is a free shell that you can run directly within the Azure portal. It has PowerShell preinstalled and configured to use with your account. Select the **Try it** button in the PowerShell commands that follow. Selecting **Try it** invokes a Cloud Shell that you can sign in to your Azure account with.

1. If using PowerShell locally, sign in to Azure with `Connect-AzAccount`.
2. A public IP address is associated to an IP configuration of a network interface attached to a VM. Use the [Get-AzNetworkInterface](#) command to get a network interface. Set the Public IP address value to null and then use the [Set-AzNetworkInterface](#) command to write the new IP configuration to the network interface.

The following example dissociates a public IP address named *myVMPublicIP* from a network interface named *myVMVMNic* that is attached to a VM named *myVM*. All resources are in a resource group named *myResourceGroup*.

```
$nic = Get-AzNetworkInterface -Name myVMVMNic -ResourceGroupName myResourceGroup  
$nic.IpConfigurations.publicipaddress.id = $null  
Set-AzNetworkInterface -NetworkInterface $nic
```

- If you don't know the name of a network interface attached to your VM, use the [Get-AzVM](#) command to view them. For example, the following command lists the names of the network interfaces attached to a VM named *myVM* in a resource group named *myResourceGroup*.

```
$vm = Get-AzVM -name myVM -ResourceGroupName myResourceGroup  
$vm.NetworkProfile
```

The output includes one or more lines that are similar to the example that follows. In the example output, *myVMVMNic* is the name of the network interface.

```
"id": "/subscriptions/00000000-0000-0000-0000-  
000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVMVMNic",
```

- If you don't know the name of an IP configuration for a network interface, use the [Get-AzNetworkInterface](#) command to retrieve them. For example, the following command lists the names of the IP configurations for a network interface named *myVMVMNic* in a resource group named *myResourceGroup*.

```
$nic = Get-AzNetworkInterface -Name myVMVMNic -ResourceGroupName myResourceGroup  
$nic.IPCConfigurations.id
```

The output includes one or more lines that are similar to the example that follows. In the example output, *ipconfigmyVM* is the name of an IP configuration.

```
"id": "/subscriptions/00000000-0000-0000-0000-  
000000000000/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myVMVMNic/i  
pConfigurations/ipconfigmyVM"
```

## Next steps

- Learn how to [associate a public IP address to a VM](#).

# Create a virtual machine with a static private IP address using the Azure portal

9/21/2022 • 4 minutes to read • [Edit Online](#)

A virtual machine (VM) is automatically assigned a private IP address from a range that you specify. This range is based on the subnet in which the VM is deployed. The VM keeps the address until the VM is deleted. Azure dynamically assigns the next available private IP address from the subnet you create a VM in. Assign a static IP address to the VM if you want a specific IP address in the subnet.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).

## Create virtual machine

Use the following steps to create a virtual machine, virtual network, and subnet.

1. Sign in to the [Azure portal](#).
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
3. Select + **Create**, then + **Virtual machine** in **Virtual machines**.
4. In **Create a virtual machine**, enter or select the following information:

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>Create new</b> . Enter <b>myResourceGroup</b> in <b>Name</b> . Select <b>OK</b> .
<b>Instance details</b>	
Virtual machine name	Enter <b>myVM</b> .
Region	Select <b>(US) East US 2</b> .
Availability options	Select <b>No infrastructure redundancy required</b> .
Image	Select <b>Windows Server 2019 Datacenter - Gen2</b> .
Azure Spot instance	Leave unchecked.
Size	Select a size.

SETTING	VALUE
Administrator account	
Username	Enter a username.
Password	Enter a password.
Confirm password	Reenter password.
Public inbound ports	Select <b>Allow selected ports</b> .
Select inbound ports	Select RDP (3389)

The screenshot shows the Microsoft Azure portal interface for creating a new virtual machine. The left sidebar contains a navigation menu with various service icons. The main content area is titled 'Create a virtual machine' and is currently on the 'Basics' tab. The page includes sections for 'Project details', 'Instance details', 'Administrator account', and 'Inbound port rules'. A warning message at the bottom of the 'Inbound port rules' section states: '⚠️ This will allow all IP addresses to access your virtual machine. This is only recommended for testing. Use the Advanced controls in the Networking tab to create rules to limit inbound traffic to known IP addresses.' Navigation buttons at the bottom include 'Review + create', '< Previous', and 'Next : Disks >'.

### WARNING

Portal 3389 is selected, to enable remote access to the Windows Server virtual machine from the internet.  
Opening port 3389 to the internet is not recommended to manage production workloads.  
For secure access to Azure virtual machines, see [What is Azure Bastion?](#)

5. Select the **Networking** tab, or select **Next: Disks**, then **Next: Networking**.

6. In the **Networking** tab, select or enter:

SETTING	VALUE
<b>Network interface</b>	
Virtual network	Accept the default network name.
Subnet	Accept the default subnet configuration.
Public IP	Accept the default public IP configuration.
NIC network security group	Select <b>Basic</b>
Public inbound ports	Select <b>Allow selected ports</b> .
Select inbound ports	Select <b>RDP (3389)</b>

7. Select **Review + create**.

8. Review the settings, and then select **Create**.

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Change private IP address to static

In this section, you'll change the private IP address from **dynamic** to **static** for the virtual machine you created previously.

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. In **Virtual machines**, select **myVM**.
3. Select **Networking** in **Settings** in **myVM**.
4. In **Networking**, select the name of the network interface next to **Network interface**. In this example, the name of the NIC is **myvm472**.

Assignment

Dynamic Static

IP address \*

10.1.0.4

**NOTE**

If you notice after selecting **Save** that the assignment is still set to **Dynamic**, the IP address you typed is already in use. Try another IP address.

To change the IP address back to dynamic set the assignment for your private IP address to **Dynamic**, and then select **Save**.

**WARNING**

From within the operating system of a VM, you shouldn't statically assign the *private IP* that's assigned to the Azure VM. Only do static assignment of a private IP when it's necessary, such as when [assigning many IP addresses to VMs](#).

If you manually set the private IP address within the operating system, make sure it matches the private IP address assigned to the Azure [network interface](#). Otherwise, you can lose connectivity to the VM. Learn more about [private IP address settings](#).

## Clean up resources

When no longer needed, delete the resource group and all of the resources it contains:

1. Enter **myResourceGroup** in the **Search** box at the top of the portal. When you see **myResourceGroup** in the search results, select it.
2. Select **Delete resource group**.
3. Enter **myResourceGroup** for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

## Next steps

- Learn more about [static public IP addresses](#).
- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.

# Create a virtual machine with a static private IP address using Azure PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

A virtual machine (VM) is automatically assigned a private IP address from a range that you specify. This range is based on the subnet in which the VM is deployed. The VM keeps the address until the VM is deleted. Azure dynamically assigns the next available private IP address from the subnet you create a VM in. Assign a static IP address to the VM if you want a specific IP address in the subnet.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- Azure PowerShell installed locally or Azure Cloud Shell

If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 5.4.1 or later. Run `Get-Module -ListAvailable Az` to find the installed version. If you need to upgrade, see [Install Azure PowerShell module](#). If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with [New-AzResourceGroup](#) named **myResourceGroup** in the **eastus2** location.

```
$rg =@{  
    Name = 'myResourceGroup'  
    Location = 'eastus2'  
}  
New-AzResourceGroup @rg
```

## Create a virtual machine

Create a virtual machine with [New-AzVM](#).

The following command creates a Windows Server virtual machine. When prompted, provide a username and password to be used as the credentials for the virtual machine:

```
## Create virtual machine. ##  
$vm = @{  
    ResourceGroupName = 'myResourceGroup'  
    Location = 'East US 2'  
    Name = 'myVM'  
    PublicIpAddressName = 'myPublicIP'  
}  
New-AzVM @vm
```

## Change private IP address to static

In this section, you'll change the private IP address from **dynamic** to **static** for the virtual machine you created previously.

Use [Get-AzVirtualNetwork](#) to place the virtual network configuration into a variable. Use [Get-AzVirtualNetworkSubnetConfig](#) to place the subnet configuration into a variable. Use [Get-AzNetworkInterface](#) to obtain the network interface configuration and place into a variable. Use [Set-AzNetworkInterfaceIpConfig](#) to set the configuration of the network interface. Finally, use [Set-AzNetworkInterface](#) to set the configuration for the virtual machine.

The following command changes the private IP address of the virtual machine to static:

```
## Place virtual network configuration into a variable. ##
$net = @{
    Name = 'myVM'
    ResourceGroupName = 'myResourceGroup'
}
$vnet = Get-AzVirtualNetwork @net

## Place subnet configuration into a variable. ##
$sub = @{
    Name = 'myVM'
    VirtualNetwork = $vnet
}
$subnet = Get-AzVirtualNetworkSubnetConfig @sub

## Get name of network interface and place into a variable ##
$int1 = @{
    Name = 'myVM'
    ResourceGroupName = 'myResourceGroup'
}
$vm = Get-AzVM @int1

## Place network interface configuration into a variable. ##
$nic = Get-AzNetworkInterface -ResourceId $vm.NetworkProfile.NetworkInterfaces.Id

## Set interface configuration. ##
$config = @{
    Name = 'myVM'
    PrivateIpAddress = '192.168.1.4'
    Subnet = $subnet
}
$nic | Set-AzNetworkInterfaceIpConfig @config -Primary

## Save interface configuration. ##
$nic | Set-AzNetworkInterface
```

#### WARNING

Though you can add private IP address settings to the operating system, we recommend not doing so until after reading [Add a private IP address to an operating system](#).

## Clean up resources

When no longer needed, you can use [Remove-AzResourceGroup](#) to remove the resource group and all of the resources it contains:

```
Remove-AzResourceGroup -Name myResourceGroup -Force
```

## Next steps

- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.
- Learn more about creating [Linux](#) and [Windows](#) virtual machines.

# Create a virtual machine with a static private IP address using the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

A virtual machine (VM) is automatically assigned a private IP address from a range that you specify. This range is based on the subnet in which the VM is deployed. The VM keeps the address until the VM is deleted. Azure dynamically assigns the next available private IP address from the subnet you create a VM in. Assign a static IP address to the VM if you want a specific IP address in the subnet.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- An Azure account with an active subscription. [Create an account for free](#).
- This tutorial requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with `az group create` named `myResourceGroup` in the `eastus2` location.

```
az group create \
--name myResourceGroup \
--location eastus2
```

## Create a virtual machine

Create a virtual machine with `az vm create`.

The following command creates a Windows Server virtual machine. When prompted, provide a username and password to be used as the credentials for the virtual machine:

```
az vm create \
--name myVM \
--resource-group myResourceGroup \
--public-ip-address myPublicIP \
--public-ip-sku Standard \
--size Standard_A2 \
--image MicrosoftWindowsServer:WindowsServer:2019-Datacenter:latest \
--admin-username azureuser
```

## Change private IP address to static

In this section, you'll change the private IP address from **dynamic** to **static** for the virtual machine you created previously.

Use [az network nic ip-config update](#) to update the network interface configuration.

The following command changes the private IP address of the virtual machine to static:

```
az network nic ip-config update \
--name ipconfigmyVM \
--resource-group myResourceGroup \
--nic-name myVMVNNic \
--private-ip-address 10.0.0.4
```

### WARNING

Though you can add private IP address settings to the operating system, we recommend not doing so until after reading [Add a private IP address to an operating system](#).

## Clean up resources

When no longer needed, you can use [az group delete](#) to remove the resource group and all of the resources it contains:

```
az group delete --name myResourceGroup --yes
```

## Next steps

- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.
- Learn more about creating [Linux](#) and [Windows](#) virtual machines.

# Assign multiple IP addresses to virtual machines using the Azure portal

9/21/2022 • 16 minutes to read • [Edit Online](#)

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any of the private IP addresses for any of the NICs to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary NIC could be added to a back-end pool. For more information about load balancing multiple IP configurations, see [Load balancing multiple IP configurations](#).

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, read the [IP addresses in Azure](#) article.

## NOTE

All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, read the [Create VM with Multiple NICs](#) article.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See the [Azure limits](#) article for details.

This article explains how to add multiple IP addresses to a virtual machine using the Azure portal.

## NOTE

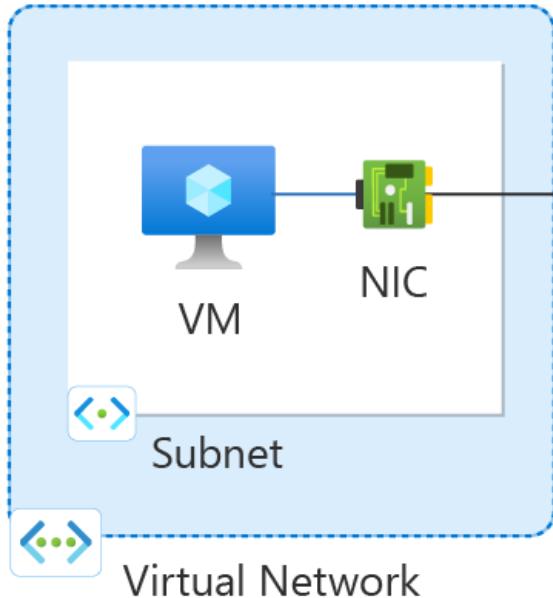

If you want to create a virtual machine with multiple IP addresses, or a static private IP address, you must create it using [PowerShell](#) or the [Azure CLI](#).

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- An existing Azure virtual machine. For more information about creating a virtual machine, see [Create a Windows VM](#) or [Create a Linux VM](#).
  - The example used in this article is named **myVM**. Replace this value with your virtual machine name.

**NOTE**

Though the steps in this article assigns all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see [Create a VM with multiple NICs](#).

**ipconfig1**

- Private IP address: Dynamic
- Public IP address: Static

**ipconfig2**

- Private IP address: Static
- Public IP address: Static

**ipconfig3**

- Private IP address: Static

Figure: Diagram of network configuration resources cerated in How-to article.

## Add public and private IP address to a VM

You can add a private and public IP address to an Azure network interface by completing the following steps.

1. Sign in to the [Azure portal](#).
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
3. In **Virtual machines**, select **myVM** or the name of your virtual machine.
4. Select **Networking** in **Settings**.
5. Select the name of the network interface of the virtual machine. In this example, it's named **myvm889\_z1**.

myVM | Networking

Virtual machine

Search (Ctrl+ /) < Attach network interface Detach network interface Feedback

Overview Activity log Access control (IAM) Tags Diagnose and solve problems Settings Networking

**myvm889\_z1**

IP configuration ipconfig1 (Primary)

**Network Interface myvm889\_z1** Effective security rules Troubleshoot VM connection issues

Topology Virtual network/subnet: myVNet/myBackendSubnet NIC Public IP: 20.246.73.15 NIC Private IP: 10.1.0.4 Accelerated networking: Disabled

Inbound port rules Outbound port rules Application security groups Load balancing

6. In the network interface, select **IP configurations** in **Settings**.
7. The existing IP configuration is displayed. This configuration is created when the virtual machine is created. To add a private and public IP address to the virtual machine, select **+ Add**.
8. In **Add IP configuration**, enter or select the following information.

SETTING	VALUE
Name	Enter ipconfig2.
Private IP address settings	
Allocation	Select <b>Static</b> .
IP address	Enter an unused address in the network for your virtual machine. For the 10.1.0.0/24 subnet in the example, an IP would be <b>10.1.0.5</b> .
Public IP address	Select <b>Associate</b>
Public IP address	Select <b>Create new</b> . Enter <b>myPublicIP-2</b> in Name. Select <b>Standard</b> in SKU. Select <b>OK</b> .

9. Select **OK**.

# Add IP configuration

## NOTE

When adding a static IP address, you must specify an unused, valid address on the subnet the NIC is connected to. If the address you select is not available, the portal displays an X for the IP address and you must select a different one.

## IMPORTANT

After you change the IP address configuration, you must restart the VM for the changes to take effect in the VM.

## Add private IP address to a virtual machine

You can add a private IP address to a virtual machine by completing the following steps.

1. Sign in to the [Azure portal](#).

2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
3. In **Virtual machines**, select **myVM** or the name of your virtual machine.
4. Select **Networking** in **Settings**.
5. Select the name of the network interface of the virtual machine. In this example, it's named **myvm889\_z1**.

**myVM | Networking**

# Assign multiple IP addresses to virtual machines using Azure PowerShell

9/21/2022 • 18 minutes to read • [Edit Online](#)

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any of the private IP addresses for any of the NICs to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary NIC could be added to a back-end pool. For more information about load balancing multiple IP configurations, see [Load balancing multiple IP configurations](#).

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, read the [IP addresses in Azure](#) article.

## NOTE

All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, read the [Create VM with Multiple NICs](#) article.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See the [Azure limits](#) article for details.

This article explains how to add multiple IP addresses to a virtual machine using the Azure portal.

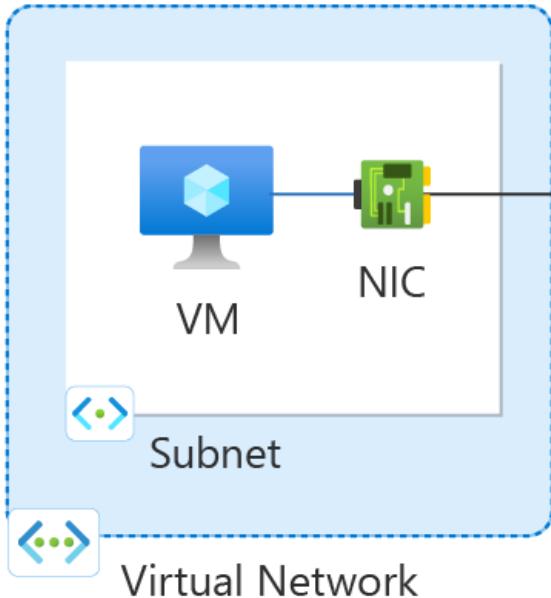

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- Azure PowerShell installed locally or Azure Cloud Shell.
- Sign in to Azure PowerShell and ensure you've selected the subscription with which you want to use this feature. For more information, see [Sign in with Azure PowerShell](#).
- Ensure your Az. Network module is 4.3.0 or later. To verify the installed module, use the command `Get-InstalledModule -Name "Az.Network"`. If the module requires an update, use the command `Update-Module -Name "Az. Network"` if necessary.

If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 5.4.1 or later. Run `Get-Module -ListAvailable Az` to find the installed version. If you need to upgrade, see [Install Azure PowerShell module](#). If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

#### NOTE

Though the steps in this article assigns all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see [Create a VM with multiple NICs](#).

#### ipconfig1

- Private IP address: Dynamic
- Public IP address: Static

#### ipconfig2

- Private IP address: Static
- Public IP address: Static

#### ipconfig3

- Private IP address: Static

Figure: Diagram of network configuration resources created in How-to article.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with [New-AzResourceGroup](#) named **myResourceGroup** in the **eastus2** location.

```
$rg =@{  
    Name = 'myResourceGroup'  
    Location = 'eastus2'  
}  
New-AzResourceGroup @rg
```

## Create a virtual network

In this section, you'll create a virtual network for the virtual machine.

Use [New-AzVirtualNetwork](#) and [New-AzVirtualNetworkSubnetConfig](#) to create a virtual network.

```
## Create backend subnet config ##
$subnet = @{
    Name = 'myBackendSubnet'
    AddressPrefix = '10.1.0.0/24'
}
$subnetConfig = New-AzVirtualNetworkSubnetConfig @subnet

## Create the virtual network ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    AddressPrefix = '10.1.0.0/16'
    Subnet = $subnetConfig
}
New-AzVirtualNetwork @net
```

## Create primary public IP address

Use [New-AzPublicIpAddress](#) to create a primary public IP address.

```
$ip1 = @{
    Name = 'myPublicIP-1'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
    ipAddressVersion = 'IPv4'
    Zone = 1,2,3
}
New-AzPublicIpAddress @ip1
```

## Create a network security group

In this section, you'll create a network security group for the virtual machine and virtual network. You'll create a rule to allow connections to the virtual machine on port 22 for SSH.

Use [New-AzNetworkSecurityGroup](#) and [New-AzNetworkSecurityRuleConfig](#) to create the network security group and rules.

```

## Create rule for network security group and place in variable. ##
$nsgrule1 = @{
    Name = 'myNSGRuleSSH'
    Description = 'Allow SSH'
    Protocol = '*'
    SourcePortRange = '*'
    DestinationPortRange = '22'
    SourceAddressPrefix = 'Internet'
    DestinationAddressPrefix = '*'
    Access = 'Allow'
    Priority = '200'
    Direction = 'Inbound'
}
$rule1 = New-AzNetworkSecurityRuleConfig @nsgrule1

## Create network security group ##
$nsg = @{
    Name = 'myNSG'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    SecurityRules = $rule1
}
New-AzNetworkSecurityGroup @nsg

```

## Create network interface

You'll use [New-AzNetworkInterface](#) and [New-AzNetworkInterfaceIpConfig](#) to create the network interface for the virtual machine. The public IP addresses and the NSG created previously are associated with the NIC. The network interface is attached to the virtual network you created previously.

```

## Place the virtual network into a variable. ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
}
$vnet = Get-AzVirtualNetwork @net

## Place the network security group into a variable. ##
$ns = @{
    Name = 'myNSG'
    ResourceGroupName = 'myResourceGroup'
}
$nsg = Get-AzNetworkSecurityGroup @ns

## Place the primary public IP address into a variable. ##
$pub1 = @{
    Name = 'myPublicIP-1'
    ResourceGroupName = 'myResourceGroup'
}
$pubIP1 = Get-AzPublicIPAddress @pub1

## Create primary configuration for NIC. ##
$IP1 = @{
    Name = 'ipconfig1'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PublicIPAddress = $pubIP1
}
$IP1Config = New-AzNetworkInterfaceIpConfig @IP1 -Primary

## Create tertiary configuration for NIC. ##
$IP3 = @{
    Name = 'ipconfig3'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PrivateIpAddress = '10.1.0.6'
}
$IP3Config = New-AzNetworkInterfaceIpConfig @IP3

## Command to create network interface for VM ##
$nic = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    NetworkSecurityGroup = $nsg
    IpConfiguration = $IP1Config,$IP3Config
}
New-AzNetworkInterface @nic

```

#### **NOTE**

When adding a static IP address, you must specify an unused, valid address on the subnet the NIC is connected to.

## **Create virtual machine**

Use the following commands to create the virtual machine:

- [New-AzVM](#)
- [New-AzVMConfig](#)
- [Set-AzVMOperatingSystem](#)
- [Set-AzVMSourceImage](#)

- [Add-AzVMNetworkInterface](#)

```
$cred = Get-Credential

## Place network interface into a variable. ##
$nic = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
}
$nicVM = Get-AzNetworkInterface @nic

## Create a virtual machine configuration for VMs ##
$vmsz = @{
    VMName = 'myVM'
    VMSize = 'Standard_DS1_v2'
}
$vmos = @{
    ComputerName = 'myVM'
    Credential = $cred
}
$vmimage = @{
    PublisherName = 'Debian'
    Offer = 'debian-11'
    Skus = '11'
    Version = 'latest'
}
$vmConfig = New-AzVMConfig @vmsz `

| Set-AzVMOperatingSystem @vmos -Linux `

| Set-AzVMSourceImage @vmimage `

| Add-AzVMNetworkInterface -Id $nicVM.Id

## Create the virtual machine for VMs ##
$vm = @{
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    VM = $vmConfig
    SshKeyName = 'mySSHKey'
}
New-AzVM @vm -GenerateSshKey
```

## Add secondary private and public IP address

Use [New-AzPublicIpAddress](#) to create a secondary public IP address.

```
$ip2 = @{
    Name = 'myPublicIP-2'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
    IpAddressVersion = 'IPv4'
    Zone = 1,2,3
}
New-AzPublicIpAddress @ip2
```

Use [New-AzNetworkInterfaceIpConfig](#) to create the secondary IP configuration for the virtual machine.

```

## Place the virtual network into a variable. ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
}
$vnet = Get-AzVirtualNetwork @net

## Place your virtual network subnet into a variable. ##
$sub = @{
    Name = 'myBackendSubnet'
    VirtualNetwork = $vnet
}
$subnet = Get-AzVirtualNetworkSubnetConfig @sub

## Place the secondary public IP address you created previously into a variable. ##
$pip = @{
    Name = 'myPublicIP-2'
    ResourceGroupName = 'myResourceGroup'
}
$pubIP2 = Get-AzPublicIPAddress @pip

## Place the network interface into a variable. ##
$net = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
}
$nic = Get-AzNetworkInterface @net

## Create secondary configuration for NIC. ##
$IPc2 = @{
    Name = 'ipconfig2'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PrivateIpAddress = '10.1.0.5'
    PublicIPAddress = $pubIP2
}
$IP2Config = New-AzNetworkInterfaceIpConfig @IPc2

## Add the IP configuration to the network interface. ##
$nic.IpConfigurations.Add($IP2Config)

## Save the configuration to the network interface. ##
$nic | Set-AzNetworkInterface

```

## Add IP addresses to a VM operating system

Connect and sign in to a VM you created with multiple private IP addresses. You must manually add all the private IP addresses, including the primary, that you added to the VM. Complete the following steps for your VM operating system.

# Assign multiple IP addresses to virtual machines using the Azure CLI

9/21/2022 • 17 minutes to read • [Edit Online](#)

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any of the private IP addresses for any of the NICs to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary NIC could be added to a back-end pool. For more information about load balancing multiple IP configurations, see [Load balancing multiple IP configurations](#).

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, read the [IP addresses in Azure](#) article.

## NOTE

All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, read the [Create VM with Multiple NICs](#) article.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See the [Azure limits](#) article for details.

This article explains how to add multiple IP addresses to a virtual machine using the Azure portal.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

[Launch Cloud Shell](#)

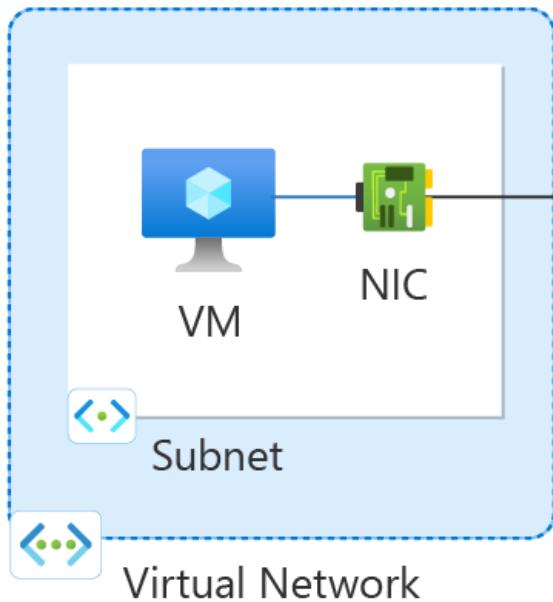

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about

extensions, see [Use extensions with the Azure CLI](#).

- Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This tutorial requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

#### NOTE

Though the steps in this article assigns all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see [Create a VM with multiple NICs](#).

#### ipconfig1

- Private IP address: Dynamic
- Public IP address: Static

#### ipconfig2

- Private IP address: Static
- Public IP address: Static

#### ipconfig3

- Private IP address: Static

Figure: Diagram of network configuration resources created in How-to article.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with `az group create` named `myResourceGroup` in the `eastus2` location.

```
az group create \
--name myResourceGroup \
--location eastus2
```

## Create a virtual network

In this section, you'll create a virtual network for the virtual machine.

Use `az network vnet create` to create a virtual network.

```
az network vnet create \
--resource-group myResourceGroup \
--location eastus2 \
--name myVNet \
--address-prefixes 10.1.0.0/16 \
--subnet-name myBackendSubnet \
--subnet-prefixes 10.1.0.0/24
```

## Create public IP addresses

Use [az network public-ip create](#) to create two public IP addresses.

```
az network public-ip create \
--resource-group myResourceGroup \
--name myPublicIP-1 \
--sku Standard \
--version IPv4 \
--zone 1 2 3

az network public-ip create \
--resource-group myResourceGroup \
--name myPublicIP-2 \
--sku Standard \
--version IPv4 \
--zone 1 2 3
```

## Create a network security group

In this section, you'll create a network security group for the virtual machine and virtual network.

Use [az network nsg create](#) to create the network security group.

```
az network nsg create \
--resource-group myResourceGroup \
--name myNSG
```

### Create network security group rules

You'll create a rule to allow connections to the virtual machine on port 22 for SSH.

Use [az network nsg rule create](#) to create the network security group rules.

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNSG \
--name myNSGRuleSSH \
--protocol '*' \
--direction inbound \
--source-address-prefix '*' \
--source-port-range '*' \
--destination-address-prefix '*' \
--destination-port-range 22 \
--access allow \
--priority 200
```

## Create network interface

You'll use [az network nic create](#) to create the network interface for the virtual machine. The public IP addresses and the NSG created previously are associated with the NIC. The network interface is attached to the virtual network you created previously.

```
az network nic create \
--resource-group myResourceGroup \
--name myNIC1 \
--private-ip-address-version IPv4 \
--vnet-name myVNet \
--subnet myBackendSubnet \
--network-security-group myNSG \
--public-ip-address myPublicIP-1
```

### Create secondary private and public IP configuration

Use [az network nic ip-config create](#) to create the secondary private and public IP configuration for the NIC.

Replace 10.1.0.5 with your secondary private IP address.

```
az network nic ip-config create \
--resource-group myResourceGroup \
--name ipconfig2 \
--nic-name myNIC1 \
--private-ip-address 10.1.0.5 \
--private-ip-address-version IPv4 \
--vnet-name myVNet \
--subnet myBackendSubnet \
--public-ip-address myPublicIP-2
```

### Create tertiary private IP configuration

Use [az network nic ip-config create](#) to create the tertiary private IP configuration for the NIC. Replace 10.1.0.6 with your secondary private IP address.

```
az network nic ip-config create \
--resource-group myResourceGroup \
--name ipconfig3 \
--nic-name myNIC1 \
--private-ip-address 10.1.0.6 \
--private-ip-address-version IPv4 \
--vnet-name myVNet \
--subnet myBackendSubnet
```

#### NOTE

When adding a static IP address, you must specify an unused, valid address on the subnet the NIC is connected to.

### Create virtual machine

Use [az vm create](#) to create the virtual machine.

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--nics myNIC1 \
--image UbuntuLTS \
--admin-username azureuser \
--authentication-type ssh \
--generate-ssh-keys
```

## Add IP addresses to a VM operating system

Connect and sign in to a VM you created with multiple private IP addresses. You must manually add all the private IP addresses, including the primary, that you added to the VM. Complete the following steps for your VM operating system.

# Add network interfaces to or remove network interfaces from virtual machines

9/21/2022 • 8 minutes to read • [Edit Online](#)

Learn how to add an existing network interface when you create an Azure virtual machine (VM). Also learn to add or remove network interfaces from an existing VM in the stopped (deallocated) state. A network interface enables an Azure VM to communicate with internet, Azure, and on-premises resources. A VM has one or more network interfaces.

If you need to add, change, or remove IP addresses for a network interface, see [Manage network interface IP addresses](#). To create, change, or delete network interfaces, see [Manage network interfaces](#).

## Before you begin

### NOTE

To interact with Azure, the Azure Az PowerShell module is recommended. See [Install Azure PowerShell](#) to get started. To learn how to migrate to the Az PowerShell module, see [Migrate Azure PowerShell from AzureRM to Az](#).

If you don't have one, set up an Azure account with an active subscription. [Create an account for free](#). Complete one of these tasks before starting the remainder of this article:

- **Portal users:** Sign in to the [Azure portal](#) with your Azure account.
- **PowerShell users:** Either run the commands in the [Azure Cloud Shell](#), or run PowerShell from your computer. The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account. In the Azure Cloud Shell browser tab, find the **Select environment** dropdown list, then pick **PowerShell** if it isn't already selected.

If you're running PowerShell locally, use Azure PowerShell module version 1.0.0 or later. Run `Get-Module -ListAvailable Az.Network` to find the installed version. If you need to upgrade, see [Install Azure PowerShell module](#). Run `Connect-AzAccount` to create a connection with Azure.

- **Azure CLI users:** Run the commands via either the [Azure Cloud Shell](#) or the Azure CLI running locally. Use Azure CLI version 2.0.26 or later if you're running the Azure CLI locally. Run `az --version` to find the installed version. If you need to install or upgrade, see [Install Azure CLI](#). Run `az login` to create a connection with Azure.

## Add existing network interfaces to a new VM

When you create a virtual machine through the portal, the portal creates a network interface with default settings and attaches the network interface to the VM for you. You can't use the portal to add existing network interfaces to a new VM, or to create a VM with multiple network interfaces. You can do both by using the CLI or PowerShell. Be sure to familiarize yourself with the [constraints](#). If you create a VM with multiple network interfaces, you must also configure the operating system to use them properly after you create the VM. Learn how to configure [Linux](#) or [Windows](#) for multiple network interfaces.

### Commands

Before you create the VM, [Create a network interface](#).

TOOL	COMMAND
CLI	<a href="#">az network nic create</a>
PowerShell	<a href="#">New-AzNetworkInterface</a>

## Add a network interface to an existing VM

To add a network interface to your virtual machine:

1. Go to the [Azure portal](#) to find an existing virtual machine. Search for and select **Virtual machines**.
2. Select the name of your VM. The VM must support the number of network interfaces you want to add. To find out how many network interfaces each VM size supports, see the sizes in Azure for [Linux VMs](#) or [Windows VMs](#).
3. In the VM command bar, select **Stop**, and then **OK** in the confirmation dialog box. Then wait until the **Status** of the VM changes to **Stopped (deallocated)**.
4. From the VM menu bar, choose **Networking > Attach network interface**. Then in **Attach existing network interface**, choose the network interface you'd like to attach, and select **OK**.

### NOTE

The network interface you select can't have accelerated networking enabled, can't have an IPv6 address assigned to it, and must exist in the same virtual network with the network interface currently attached to the VM.

If you don't have an existing network interface, you must first create one. To do so, select **Create network interface**. To learn more about how to create a network interface, see [Create a network interface](#). To learn more about additional constraints when adding network interfaces to virtual machines, see [Constraints](#).

5. From the VM menu bar, choose **Overview > Start** to restart the virtual machine.

Now you can configure the VM operating system to use multiple network interfaces properly. Learn how to configure [Linux](#) or [Windows](#) for multiple network interfaces.

## Commands

TOOL	COMMAND
CLI	<a href="#">az vm nic add</a> (reference); <a href="#">detailed steps</a>
PowerShell	<a href="#">Add-AzVMNetworkInterface</a> (reference); <a href="#">detailed steps</a>

## View network interfaces for a VM

You can view the network interfaces currently attached to a VM to learn about each network interface's configuration, and the IP addresses assigned to each network interface.

1. Go to the [Azure portal](#) to find an existing virtual machine. Search for and select **Virtual machines**.

**NOTE**

Sign in using an account that is assigned the Owner, Contributor, or Network Contributor role for your subscription. To learn more about how to assign roles to accounts, see [Built-in roles for Azure role-based access control](#).

2. Select the name of the VM for which you want to view attached network interfaces.

3. In the VM menu bar, select **Networking**.

To learn about network interface settings and how to change them, see [Manage network interfaces](#). To learn about how to add, change, or remove IP addresses assigned to a network interface, see [Manage network interface IP addresses](#).

**Commands**

TOOL	COMMAND
CLI	<code>az vm nic list</code>
PowerShell	<code>Get-AzVM</code>

## Remove a network interface from a VM

1. Go to the [Azure portal](#) to find an existing virtual machine. Search for and select **Virtual machines**.
2. Select the name of the VM for which you want to view attached network interfaces.
3. In the VM toolbar, pick **Stop**.
4. Wait until the **Status** of the VM changes to **Stopped (deallocated)**.
5. From the VM menu bar, choose **Networking > Detach network interface**.
6. In the **Detach network interface** dialog box, select the network interface you'd like to detach. Then select **OK**.

**NOTE**

If only one network interface is listed, you can't detach it, because a virtual machine must always have at least one network interface attached to it.

**Commands**

TOOL	COMMAND
CLI	<code>az vm nic remove</code> (reference); <a href="#">detailed steps</a>
PowerShell	<code>Remove-AzVMNetworkInterface</code> (reference); <a href="#">detailed steps</a>

## Constraints

- A VM must have at least one network interface attached to it.
- A VM can only have as many network interfaces attached to it as the VM size supports. To learn more about how many network interfaces each VM size supports, see the sizes in Azure for [Linux VMs](#) or

[Windows VMs](#). All sizes support at least two network interfaces.

- The network interfaces you add to a VM can't currently be attached to another VM. To learn more about how to create network interfaces, see [Create a network interface](#).
- In the past, you could add network interfaces only to VMs that supported multiple network interfaces and were created with at least two network interfaces. You couldn't add a network interface to a VM that was created with one network interface, even if the VM size supported more than one network interface. Conversely, you could only remove network interfaces from a VM with at least three network interfaces, because VMs created with at least two network interfaces always had to have at least two network interfaces. These constraints no longer apply. You can now create a VM with any number of network interfaces (up to the number supported by the VM size).
- By default, the first network interface attached to a VM is the *primary* network interface. All other network interfaces in the VM are *secondary* network interfaces.
- You can control which network interface you send outbound traffic to. However, a VM by default sends all outbound traffic to the IP address that's assigned to the primary IP configuration of the primary network interface.
- In the past, all VMs within the same availability set were required to have a single, or multiple, network interfaces. VMs with any number of network interfaces can now exist in the same availability set, up to the number supported by the VM size. You can only add a VM to an availability set when it's created. To learn more about availability sets, see [Manage the availability of VMs in Azure](#).
- You can connect network interfaces in the same VM to different subnets within a virtual network. However, the network interfaces must all be connected to the same virtual network.
- You can add any IP address for any IP configuration of any primary or secondary network interface to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary network interface could be added to a back-end pool. To learn more about IP addresses and configurations, see [Add, change, or remove IP addresses](#).
- Deleting a VM doesn't delete the network interfaces that are attached to it. When you delete a VM, the network interfaces are detached from the VM. You can add those network interfaces to different VMs or delete them.
- Achieving the optimal performance documented requires Accelerated Networking. In some cases, you must explicitly enable Accelerated Networking for [Windows](#) or [Linux](#) virtual machines.

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Next steps

To create a VM with multiple network interfaces or IP addresses, see:

TASK	TOOL
Create a VM with multiple NICs	<a href="#">CLI</a> , <a href="#">PowerShell</a>
Create a single NIC VM with multiple IPv4 addresses	<a href="#">CLI</a> , <a href="#">PowerShell</a>
Create a single NIC VM with a private IPv6 address (behind an Azure Load Balancer)	<a href="#">CLI</a> , <a href="#">PowerShell</a> , <a href="#">Azure Resource Manager template</a>

# Create and manage a Windows virtual machine that has multiple NICs

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Virtual machines (VMs) in Azure can have multiple virtual network interface cards (NICs) attached to them. A common scenario is to have different subnets for front-end and back-end connectivity. You can associate multiple NICs on a VM to multiple subnets, but those subnets must all reside in the same virtual network (vNet). This article details how to create a VM that has multiple NICs attached to it. You also learn how to add or remove NICs from an existing VM. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly.

## NOTE

If multiple subnets are not required for a scenario, it may be more straightforward to utilize multiple IP configurations on a single NIC. Instructions for this setup can be found [here](#).

## Prerequisites

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

## Create a VM with multiple NICs

First, create a resource group. The following example creates a resource group named *myResourceGroup* in the *EastUs* location:

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

### Create virtual network and subnets

A common scenario is for a virtual network to have two or more subnets. One subnet may be for front-end traffic, the other for back-end traffic. To connect to both subnets, you then use multiple NICs on your VM.

1. Define two virtual network subnets with [New-AzVirtualNetworkSubnetConfig](#). The following example defines the subnets for *mySubnetFrontEnd* and *mySubnetBackEnd*.

```
$mySubnetFrontEnd = New-AzVirtualNetworkSubnetConfig -Name "mySubnetFrontEnd" `  
    -AddressPrefix "192.168.1.0/24"  
$mySubnetBackEnd = New-AzVirtualNetworkSubnetConfig -Name "mySubnetBackEnd" `  
    -AddressPrefix "192.168.2.0/24"
```

2. Create your virtual network and subnets with [New-AzVirtualNetwork](#). The following example creates a virtual network named *myVnet*.

```
$myVnet = New-AzVirtualNetwork -ResourceGroupName "myResourceGroup" ` 
    -Location "EastUs" ` 
    -Name "myVnet" ` 
    -AddressPrefix "192.168.0.0/16" ` 
    -Subnet $mySubnetFrontEnd,$mySubnetBackEnd
```

## Create multiple NICs

Create two NICs with [New-AzNetworkInterface](#). Attach one NIC to the front-end subnet and one NIC to the back-end subnet. The following example creates NICs named *myNic1* and *myNic2*:

```
$frontEnd = $myVnet.Subnets|?{$_._Name -eq 'mySubnetFrontEnd'} 
$myNic1 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" ` 
    -Name "myNic1" ` 
    -Location "EastUs" ` 
    -SubnetId $frontEnd.Id

$backEnd = $myVnet.Subnets|?{$_._Name -eq 'mySubnetBackEnd'} 
$myNic2 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" ` 
    -Name "myNic2" ` 
    -Location "EastUs" ` 
    -SubnetId $backEnd.Id
```

Typically you also create a [network security group](#) to filter network traffic to the VM and a [load balancer](#) to distribute traffic across multiple VMs.

## Create the virtual machine

Now start to build your VM configuration. Each VM size has a limit for the total number of NICs that you can add to a VM. For more information, see [Windows VM sizes](#).

- Set your VM credentials to the `$cred` variable as follows:

```
$cred = Get-Credential
```

- Define your VM with [New-AzVMConfig](#). The following example defines a VM named *myVM* and uses a VM size that supports more than two NICs (*Standard\_DS3\_v2*):

```
$vmConfig = New-AzVMConfig -VMName "myVM" -VMSize "Standard_DS3_v2"
```

- Create the rest of your VM configuration with [Set-AzVMOperatingSystem](#) and [Set-AzVMSourceImage](#). The following example creates a Windows Server 2016 VM:

```
$vmConfig = Set-AzVMOperatingSystem -VM $vmConfig ` 
    -Windows ` 
    -ComputerName "myVM" ` 
    -Credential $cred ` 
    -ProvisionVMAgent ` 
    -EnableAutoUpdate
$vmConfig = Set-AzVMSourceImage -VM $vmConfig ` 
    -PublisherName "MicrosoftWindowsServer" ` 
    -Offer "WindowsServer" ` 
    -Skus "2016-Datacenter" ` 
    -Version "latest"
```

- Attach the two NICs that you previously created with [Add-AzVMNetworkInterface](#):

```
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic1.Id -Primary  
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic2.Id
```

5. Create your VM with [New-AzVM](#):

```
New-AzVM -VM $vmConfig -ResourceGroupName "myResourceGroup" -Location "EastUs"
```

6. Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Add a NIC to an existing VM

To add a virtual NIC to an existing VM, you deallocate the VM, add the virtual NIC, then start the VM. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly. If needed, you can [resize a VM](#).

1. Deallocate the VM with [Stop-AzVM](#). The following example deallocates the VM named *myVM* in *myResourceGroup*:

```
Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

2. Get the existing configuration of the VM with [Get-AzVm](#). The following example gets information for the VM named *myVM* in *myResourceGroup*:

```
$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

3. The following example creates a virtual NIC with [New-AzNetworkInterface](#) named *myNic3* that is attached to *mySubnetBackEnd*. The virtual NIC is then attached to the VM named *myVM* in *myResourceGroup* with [Add-AzVMNetworkInterface](#):

```
# Get info for the back end subnet  
$myVnet = Get-AzVirtualNetwork -Name "myVnet" -ResourceGroupName "myResourceGroup"  
$backEnd = $myVnet.Subnets | ?{$_ . Name -eq 'mySubnetBackEnd' }  
  
# Create a virtual NIC  
$myNic3 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `  
    -Name "myNic3" `  
    -Location "EastUs" `  
    -SubnetId $backEnd.Id  
  
# Get the ID of the new virtual NIC and add to VM  
$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -Name "MyNic3").Id  
Add-AzVMNetworkInterface -VM $vm -Id $nicId | Update-AzVm -ResourceGroupName "myResourceGroup"
```

### Primary virtual NICs

One of the NICs on a multi-NIC VM needs to be primary. If one of the existing virtual NICs on the VM is already set as primary, you can skip this step. The following example assumes that two virtual NICs are now present on a VM and you wish to add the first NIC ([0]) as the primary:

```

# List existing NICs on the VM and find which one is primary
$vm.NetworkProfile.NetworkInterfaces

# Set NIC 0 to be primary
$vm.NetworkProfile.NetworkInterfaces[0].Primary = $true
$vm.NetworkProfile.NetworkInterfaces[1].Primary = $false

# Update the VM state in Azure
Update-AzVM -VM $vm -ResourceGroupName "myResourceGroup"

```

4. Start the VM with [Start-AzVm](#):

```
Start-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM"
```

5. Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Remove a NIC from an existing VM

To remove a virtual NIC from an existing VM, you deallocate the VM, remove the virtual NIC, then start the VM.

1. Deallocation the VM with [Stop-AzVM](#). The following example deallocated the VM named *myVM* in *myResourceGroup*:

```
Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

2. Get the existing configuration of the VM with [Get-AzVm](#). The following example gets information for the VM named *myVM* in *myResourceGroup*:

```
$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

3. Get information about the NIC remove with [Get-AzNetworkInterface](#). The following example gets information about *myNic3*:

```

# List existing NICs on the VM if you need to determine NIC name
$vm.NetworkProfile.NetworkInterfaces

$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -Name "myNic3").Id

```

4. Remove the NIC with [Remove-AzVMNetworkInterface](#) and then update the VM with [Update-AzVm](#). The following example removes *myNic3* as obtained by `$nicId` in the preceding step:

```
Remove-AzVMNetworkInterface -VM $vm -NetworkInterfaceIDs $nicId | ` 
Update-AzVm -ResourceGroupName "myResourceGroup"
```

5. Start the VM with [Start-AzVm](#):

```
Start-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

## Create multiple NICs with templates

Azure Resource Manager templates provide a way to create multiple instances of a resource during deployment,

such as creating multiple NICs. Resource Manager templates use declarative JSON files to define your environment. For more information, see [overview of Azure Resource Manager](#). You can use `copy` to specify the number of instances to create:

```
"copy": {  
    "name": "multiplenics",  
    "count": "[parameters('count')]"  
}
```

For more information, see [creating multiple instances by using `copy`](#).

You can also use `copyIndex()` to append a number to a resource name. You can then create `myNic1`, `MyNic2` and so on. The following code shows an example of appending the index value:

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of [creating multiple NICs by using Resource Manager templates](#).

Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Configure guest OS for multiple NICs

Azure assigns a default gateway to the first (primary) network interface attached to the virtual machine. Azure does not assign a default gateway to additional (secondary) network interfaces attached to a virtual machine. Therefore, you are unable to communicate with resources outside the subnet that a secondary network interface is in, by default. Secondary network interfaces can, however, communicate with resources outside their subnet, though the steps to enable communication are different for different operating systems.

- From a Windows command prompt, run the `route print` command, which returns output similar to the following output for a virtual machine with two attached network interfaces:

```
=====  
Interface List  
3...00 0d 3a 10 92 ce .....Microsoft Hyper-V Network Adapter #3  
7...00 0d 3a 10 9b 2a .....Microsoft Hyper-V Network Adapter #4  
=====
```

In this example, **Microsoft Hyper-V Network Adapter #4** (interface 7) is the secondary network interface that doesn't have a default gateway assigned to it.

- From a command prompt, run the `ipconfig` command to see which IP address is assigned to the secondary network interface. In this example, 192.168.2.4 is assigned to interface 7. No default gateway address is returned for the secondary network interface.
- To route all traffic destined for addresses outside the subnet of the secondary network interface to the gateway for the subnet, run the following command:

```
route add -p 0.0.0.0 MASK 0.0.0.0 192.168.2.1 METRIC 5015 IF 7
```

The gateway address for the subnet is the first IP address (ending in .1) in the address range defined for the subnet. If you don't want to route all traffic outside the subnet, you could add individual routes to specific destinations, instead. For example, if you only wanted to route traffic from the secondary network interface to the 192.168.3.0 network, you enter the command:

```
route add -p 192.168.3.0 MASK 255.255.255.0 192.168.2.1 METRIC 5015 IF 7
```

4. To confirm successful communication with a resource on the 192.168.3.0 network, for example, enter the following command to ping 192.168.3.4 using interface 7 (192.168.2.4):

```
ping 192.168.3.4 -S 192.168.2.4
```

You may need to open ICMP through the Windows firewall of the device you're pinging with the following command:

```
netsh advfirewall firewall add rule name=Allow-ping protocol=icmpv4 dir=in action=allow
```

5. To confirm the added route is in the route table, enter the `route print` command, which returns output similar to the following text:

```
=====
Active Routes:
Network Destination      Netmask          Gateway        Interface Metric
      0.0.0.0          0.0.0.0    192.168.1.1    192.168.1.4      15
      0.0.0.0          0.0.0.0    192.168.2.1    192.168.2.4    5015
```

The route listed with **192.168.1.1** under **Gateway**, is the route that is there by default for the primary network interface. The route with **192.168.2.1** under **Gateway**, is the route you added.

## Next steps

Review [Windows VM sizes](#) when you're trying to create a VM that has multiple NICs. Pay attention to the maximum number of NICs that each VM size supports.

# How to create a Linux virtual machine in Azure with multiple network interface cards

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article details how to create a VM with multiple NICs with the Azure CLI.

## Create supporting resources

Install the latest [Azure CLI](#) and log in to an Azure account using [az login](#).

In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *mystorageaccount*, and *myVM*.

First, create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name myResourceGroup --location eastus
```

Create the virtual network with [az network vnet create](#). The following example creates a virtual network named *myVnet* and subnet named *mySubnetFrontEnd*.

```
az network vnet create \
--resource-group myResourceGroup \
--name myVnet \
--address-prefix 10.0.0.0/16 \
--subnet-name mySubnetFrontEnd \
--subnet-prefix 10.0.1.0/24
```

Create a subnet for the back-end traffic with [az network vnet subnet create](#). The following example creates a subnet named *mySubnetBackEnd*.

```
az network vnet subnet create \
--resource-group myResourceGroup \
--vnet-name myVnet \
--name mySubnetBackEnd \
--address-prefix 10.0.2.0/24
```

Create a network security group with [az network nsg create](#). The following example creates a network security group named *myNetworkSecurityGroup*.

```
az network nsg create \
--resource-group myResourceGroup \
--name myNetworkSecurityGroup
```

## Create and configure multiple NICs

Create two NICs with [az network nic create](#). The following example creates two NICs, named *myNic1* and *myNic2*, connected the network security group, with one NIC connecting to each subnet:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic1 \
--vnet-name myVnet \
--subnet mySubnetFrontEnd \
--network-security-group myNetworkSecurityGroup
az network nic create \
--resource-group myResourceGroup \
--name myNic2 \
--vnet-name myVnet \
--subnet mySubnetBackEnd \
--network-security-group myNetworkSecurityGroup
```

## Create a VM and attach the NICs

When you create the VM, specify the NICs you created with `--nics`. You also need to take care when you select the VM size. There are limits for the total number of NICs that you can add to a VM. Read more about [Linux VM sizes](#).

Create a VM with [az vm create](#). The following example creates a VM named *myVM*:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image UbuntuLTS \
--size Standard_DS3_v2 \
--admin-username azureuser \
--generate-ssh-keys \
--nics myNic1 myNic2
```

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Add a NIC to a VM

The previous steps created a VM with multiple NICs. You can also add NICs to an existing VM with the Azure CLI. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly. If needed, you can [resize a VM](#).

Create another NIC with [az network nic create](#). The following example creates a NIC named *myNic3* connected to the back-end subnet and network security group created in the previous steps:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic3 \
--vnet-name myVnet \
--subnet mySubnetBackEnd \
--network-security-group myNetworkSecurityGroup
```

To add a NIC to an existing VM, first deallocate the VM with [az vm deallocate](#). The following example deallocates the VM named *myVM*:

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Add the NIC with [az vm nic add](#). The following example adds *myNic3* to *myVM*:

```
az vm nic add \
--resource-group myResourceGroup \
--vm-name myVM \
--nics myNic3
```

Start the VM with [az vm start](#):

```
az vm start --resource-group myResourceGroup --name myVM
```

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Remove a NIC from a VM

To remove a NIC from an existing VM, first deallocate the VM with [az vm deallocate](#). The following example deallocates the VM named *myVM*.

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Remove the NIC with [az vm nic remove](#). The following example removes *myNic3* from *myVM*.

```
az vm nic remove \
--resource-group myResourceGroup \
--vm-name myVM \
--nics myNic3
```

Start the VM with [az vm start](#):

```
az vm start --resource-group myResourceGroup --name myVM
```

## Create multiple NICs using Resource Manager templates

Azure Resource Manager templates use declarative JSON files to define your environment. You can read an [overview of Azure Resource Manager](#). Resource Manager templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. You use *copy* to specify the number of instances to create:

```
"copy": {
  "name": "multiplenics"
  "count": "[parameters('count')]"
}
```

Read more about [creating multiple instances using copy](#).

You can also use a `copyIndex()` to then append a number to a resource name, which allows you to create `myNic1`, `myNic2`, etc. The following shows an example of appending the index value:

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of [creating multiple NICs using Resource Manager templates](#).

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Configure guest OS for multiple NICs

The previous steps created a virtual network and subnet, attached NICs, then created a VM. A public IP address and network security group rules that allow SSH traffic were not created. To configure the guest OS for multiple NICs, you need to allow remote connections and run commands locally on the VM.

To allow SSH traffic, create a network security group rule with [az network nsg rule create](#) as follows:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name allow_ssh \
--priority 101 \
--destination-port-ranges 22
```

Create a public IP address with [az network public-ip create](#) and assign it to the first NIC with [az network nic ip-config update](#):

```
az network public-ip create --resource-group myResourceGroup --name myPublicIP

az network nic ip-config update \
--resource-group myResourceGroup \
--nic-name myNic1 \
--name ipconfig1 \
--public-ip myPublicIP
```

To view the public IP address of the VM, use [az vm show](#) as follows::

```
az vm show --resource-group myResourceGroup --name myVM -d --query publicIps -o tsv
```

Now SSH to the public IP address of your VM. The default username provided in a previous step was *azureuser*. Provide your own username and public IP address:

```
ssh azureuser@137.117.58.232
```

To send to or from a secondary network interface, you have to manually add persistent routes to the operating system for each secondary network interface. In this article, *eth1* is the secondary interface. Instructions for adding persistent routes to the operating system vary by distro. See documentation for your distro for instructions.

When adding the route to the operating system, the gateway address is the first address of the subnet the network interface is in. For example, if the subnet has been assigned the range *10.0.2.0/24*, the gateway you specify for the route is *10.0.2.1* or if the subnet has been assigned the range *10.0.2.128/25*, the gateway you specify for the route is *10.0.2.129*. You can define a specific network for the route's destination, or specify a destination of *0.0.0.0*, if you want all traffic for the interface to go through the specified gateway. The gateway for each subnet is managed by the virtual network.

Once you've added the route for a secondary interface, verify that the route is in your route table with `route -n`. The following example output is for the route table that has the two network interfaces added to the VM in this article:

Kernel IP routing table							
Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
0.0.0.0	10.0.1.1	0.0.0.0	UG	0	0	0	eth0
0.0.0.0	10.0.2.1	0.0.0.0	UG	0	0	0	eth1
10.0.1.0	0.0.0.0	255.255.255.0	U	0	0	0	eth0
10.0.2.0	0.0.0.0	255.255.255.0	U	0	0	0	eth1
168.63.129.16	10.0.1.1	255.255.255.255	UGH	0	0	0	eth0
169.254.169.254	10.0.1.1	255.255.255.255	UGH	0	0	0	eth0

Confirm that the route you added persists across reboots by checking your route table again after a reboot. To test connectivity, you can enter the following command, for example, where *eth1* is the name of a secondary network interface:

```
ping bing.com -c 4 -I eth1
```

## Next steps

Review [Linux VM sizes](#) when trying to creating a VM with multiple NICs. Pay attention to the maximum number of NICs each VM size supports.

To further secure your VMs, use just in time VM access. This feature opens network security group rules for SSH traffic when needed, and for a defined period of time. For more information, see [Manage virtual machine access using just in time](#).

# Create a Windows VM with accelerated networking using Azure PowerShell

9/21/2022 • 8 minutes to read • [Edit Online](#)

## VM creation using the portal

Though this article provides steps to create a VM with accelerated networking using Azure PowerShell, you can also use the Azure portal to create a virtual machine that enables accelerated networking. When [creating a VM in the Azure Portal](#), in the **Create a virtual machine** page, choose the **Networking** tab. This tab has an option for **Accelerated networking**. If you have chosen a [supported operating system](#) and [VM size](#), this option is automatically set to **On**. Otherwise, the option is set to **Off**, and Azure displays the reason why it can't be enabled. You can also enable or disable accelerated networking through the portal after VM creation by navigating to the network interface and clicking the button at the top of the **Overview** blade.

### NOTE

Only supported operating systems can be enabled through the portal. If you are using a custom image, and your image supports accelerated networking, please create your VM using CLI or PowerShell.

After you create the VM, you can confirm whether accelerated networking is enabled. Follow these instructions:

1. Go to the [Azure portal](#) to manage your VMs. Search for and select **Virtual machines**.
2. In the virtual machine list, choose your new VM.
3. In the VM menu bar, choose **Networking**.

In the network interface information, next to the **Accelerated networking** label, the portal displays either **Disabled** or **Enabled** for the accelerated networking status.

## VM creation using PowerShell

Before you proceed, install [Azure PowerShell](#) version 1.0.0 or later. To find your currently installed version, run `Get-Module -ListAvailable Az`. If you need to install or upgrade, install the latest version of the Az module from the [PowerShell Gallery](#). In a PowerShell session, sign in to an Azure account using [Connect-AzAccount](#).

In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *myNic*, and *myVM*.

### Create a virtual network

1. Create a resource group with [New-AzResourceGroup](#). The following command creates a resource group named *myResourceGroup* in the *centralus* location:

```
New-AzResourceGroup -Name "myResourceGroup" -Location "centralus"
```

2. Create a subnet configuration with [New-AzVirtualNetworkSubnetConfig](#). The following command creates a subnet named *mySubnet*.

```
$subnet = New-AzVirtualNetworkSubnetConfig `  
    -Name "mySubnet" `  
    -AddressPrefix "192.168.1.0/24"
```

3. Create a virtual network with [New-AzVirtualNetwork](#), with the *mySubnet* subnet.

```
$vnet = New-AzVirtualNetwork -ResourceGroupName "myResourceGroup" `  
    -Location "centralus" `  
    -Name "myVnet" `  
    -AddressPrefix "192.168.0.0/16" `  
    -Subnet $subnet
```

## Create a network security group

1. Create a network security group rule with [New-AzNetworkSecurityRuleConfig](#).

```
$rdp = New-AzNetworkSecurityRuleConfig `  
    -Name 'Allow-RDP-All' `  
    -Description 'Allow RDP' `  
    -Access Allow `  
    -Protocol Tcp `  
    -Direction Inbound `  
    -Priority 100 `  
    -SourceAddressPrefix * `  
    -SourcePortRange * `  
    -DestinationAddressPrefix * `  
    -DestinationPortRange 3389
```

2. Create a network security group with [New-AzNetworkSecurityGroup](#) and assign the *Allow-RDP-All* security rule to it. Aside from the *Allow-RDP-All* rule, the network security group contains several default rules. One default rule disables all inbound access from the internet. Once it's created, the *Allow-RDP-All* rule is assigned to the network security group so that you can remotely connect to the VM.

```
$nsg = New-AzNetworkSecurityGroup `  
    -ResourceGroupName myResourceGroup `  
    -Location centralus `  
    -Name "myNsg" `  
    -SecurityRules $rdp
```

3. Associate the network security group to the *mySubnet* subnet with [Set-AzVirtualNetworkSubnetConfig](#).

The rule in the network security group is effective for all resources deployed in the subnet.

```
Set-AzVirtualNetworkSubnetConfig `  
    -VirtualNetwork $vnet `  
    -Name 'mySubnet' `  
    -AddressPrefix "192.168.1.0/24" `  
    -NetworkSecurityGroup $nsg
```

## Create a network interface with accelerated networking

1. Create a public IP address with [New-AzPublicIpAddress](#). A public IP address is unnecessary if you don't plan to access the VM from the internet. However, it's required to complete the steps in this article.

```
$publicIp = New-AzPublicIpAddress  
    -ResourceGroupName myResourceGroup  
    -Name 'myPublicIp'  
    -location centralus  
    -AllocationMethod Dynamic
```

2. Create a network interface with [New-AzNetworkInterface](#) with accelerated networking enabled, and assign the public IP address to the network interface. The following example creates a network interface named *myNic* in the *mySubnet* subnet of the *myVnet* virtual network, assigning the *myPublicIp* public IP address to it:

```
$nic = New-AzNetworkInterface  
    -ResourceGroupName "myResourceGroup"  
    -Name "myNic"  
    -Location "centralus"  
    -SubnetId $vnet.Subnets[0].Id  
    -PublicIpAddressId $publicIp.Id  
    -EnableAcceleratedNetworking
```

### Create a VM and attach the network interface

1. Set your VM credentials to the `$cred` variable using [Get-Credential](#), which prompts you to sign in:

```
$cred = Get-Credential
```

2. Define your VM with [New-AzVMConfig](#). The following command defines a VM named *myVM* with a VM size that supports accelerated networking (*Standard\_DS4\_v2*):

```
$vmConfig = New-AzVMConfig -VMName "myVm" -VMSize "Standard_DS4_v2"
```

For a list of all VM sizes and characteristics, see [Windows VM sizes](#).

3. Create the rest of your VM configuration with [Set-AzVMOperatingSystem](#) and [Set-AzVMSourceImage](#). The following command creates a Windows Server 2016 VM:

```
$vmConfig = Set-AzVMOperatingSystem -VM $vmConfig  
    -Windows  
    -ComputerName "myVM"  
    -Credential $cred  
    -ProvisionVMAgent  
    -EnableAutoUpdate  
$vmConfig = Set-AzVMSourceImage -VM $vmConfig  
    -PublisherName "MicrosoftWindowsServer"  
    -Offer "WindowsServer"  
    -Skus "2016-Datacenter"  
    -Version "latest"
```

4. Attach the network interface that you previously created with [Add-AzVMNetworkInterface](#):

```
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $nic.Id
```

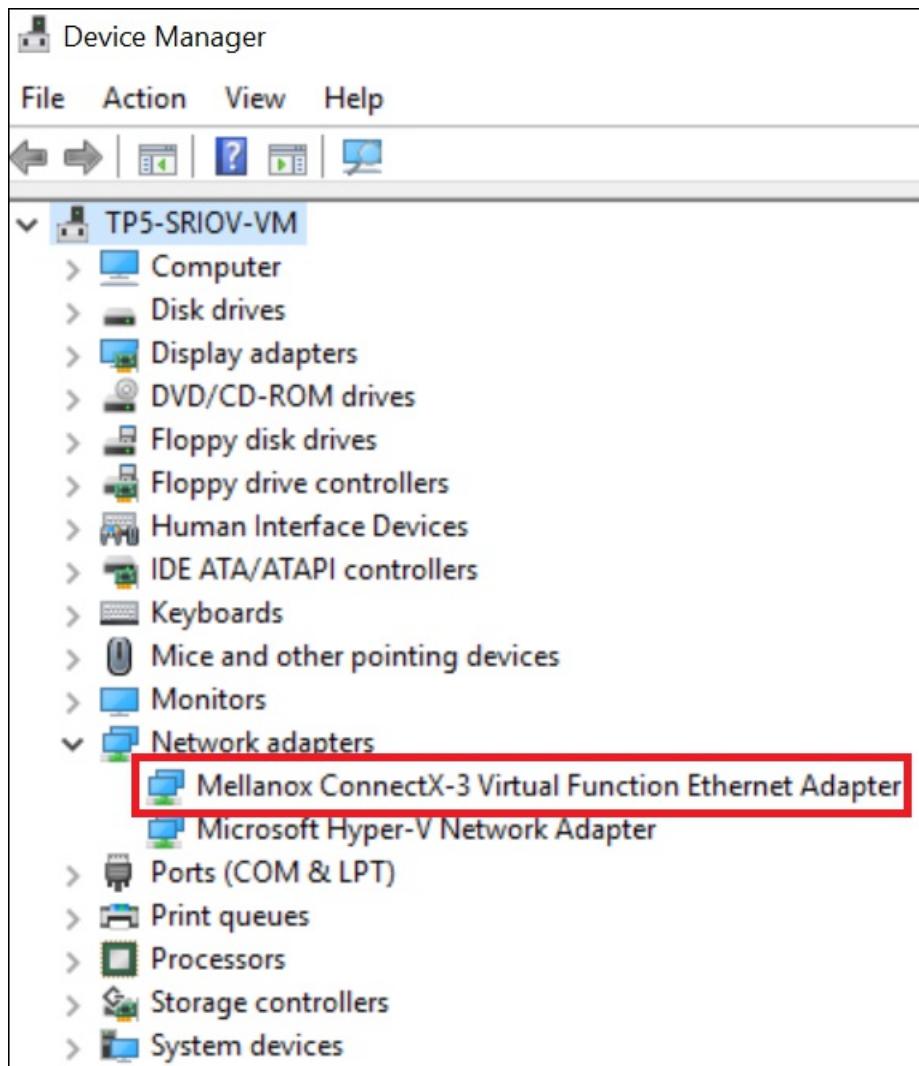

5. Create your VM with [New-AzVM](#).

```
New-AzVM -VM $vmConfig -ResourceGroupName "myResourceGroup" -Location "centralus"
```

## Confirm the Ethernet controller is installed in the Windows VM

Once you create the VM in Azure, connect to the VM and confirm that the Ethernet controller is installed in Windows.

1. Go to the [Azure portal](#) to manage your VMs. Search for and select **Virtual machines**.
2. In the virtual machine list, choose your new VM.
3. In the VM overview page, if the **Status** of the VM is listed as **Creating**, wait until Azure finishes creating the VM. The **Status** will be changed to **Running** after VM creation is complete.
4. From the VM overview toolbar, select **Connect > RDP > Download RDP File**.
5. Open the .rdp file, and then sign in to the VM with the credentials you entered in the [Create a VM and attach the network interface](#) section. If you've never connected to a Windows VM in Azure, see [Connect to virtual machine](#).
6. After the remote desktop session for your VM appears, right-click the Windows Start button and choose **Device Manager**.
7. In the **Device Manager** window, expand the **Network adapters** node.
8. Confirm that the **Mellanox ConnectX-3 Virtual Function Ethernet Adapter** appears, as shown in the following image:

Accelerated networking is now enabled for your VM.

#### NOTE

If the Mellanox adapter fails to start, open an administrator prompt in the remote desktop session and enter the following command:

```
netsh int tcp set global rss = enabled
```

## Enable accelerated networking on existing VMs

If you've created a VM without accelerated networking, you may enable this feature on an existing VM. The VM must support accelerated networking by meeting the following prerequisites, which are also outlined above:

- The VM must be a supported size for accelerated networking.
- The VM must be a supported Azure Gallery image (and kernel version for Linux).
- All VMs in an availability set or a virtual machine scale set must be stopped or deallocated before you enable accelerated networking on any NIC.

### Individual VMs and VMs in an availability set

1. Stop or deallocate the VM or, if an availability set, all the VMs in the set:

```
Stop-AzVM -ResourceGroup "myResourceGroup" -Name "myVM"
```

#### NOTE

When you create a VM individually, without an availability set, you only need to stop or deallocate the individual VM to enable accelerated networking. If your VM was created with an availability set, you must stop or deallocate all VMs contained in the availability set before enabling accelerated networking on any of the NICs, so that the VMs end up on a cluster that supports accelerated networking. The stop or deallocate requirement is unnecessary if you disable accelerated networking, because clusters that support accelerated networking also work fine with NICs that don't use accelerated networking.

2. Enable accelerated networking on the NIC of your VM:

```
$nic = Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" `  
-Name "myNic"  
  
$nic.EnableAcceleratedNetworking = $true  
  
$nic | Set-AzNetworkInterface
```

3. Restart your VM or, if in an availability set, all the VMs in the set, and confirm that accelerated networking is enabled:

```
Start-AzVM -ResourceGroup "myResourceGroup" `  
-Name "myVM"
```

### Virtual machine scale set

A virtual machine scale set is slightly different, but it follows the same workflow.

1. Stop the VMs:

```
Stop-AzVmss -ResourceGroupName "myResourceGroup" `  
-VMScaleSetName "myScaleSet"
```

2. Update the accelerated networking property under the network interface:

```
$vmss = Get-AzVmss -ResourceGroupName "myResourceGroup" `  
-VMScaleSetName "myScaleSet"  
  
$vmss.VirtualMachineProfile.NetworkProfile.NetworkInterfaceConfigurations[0].EnableAcceleratedNetwork  
ing = $true  
  
Update-AzVmss -ResourceGroupName "myResourceGroup" `  
-VMScaleSetName "myScaleSet" `  
-VirtualMachineScaleSet $vmss
```

3. Set the applied updates to automatic so that the changes are immediately picked up:

```
$vmss.UpgradePolicy.Mode = "Automatic"  
  
Update-AzVmss -ResourceGroupName "myResourceGroup" `  
-VMScaleSetName "myScaleSet" `  
-VirtualMachineScaleSet $vmss
```

#### NOTE

A scale set has VM upgrades that apply updates using three different settings: automatic, rolling, and manual. In these instructions, the policy is set to automatic, so the scale set picks up the changes immediately after it restarts.

4. Restart the scale set:

```
Start-AzVmss -ResourceGroupName "myResourceGroup" `  
-VMScaleSetName "myScaleSet"
```

Once you restart, wait for the upgrades to finish. After the upgrades are done, the virtual function (VF) appears inside the VM. Make sure you're using a supported OS and VM size.

### Resizing existing VMs with accelerated networking

If a VM has accelerated networking enabled, you're only able to resize it to a VM that supports accelerated networking.

A VM with accelerated networking enabled can't be resized to a VM instance that doesn't support accelerated networking using the resize operation. Instead, to resize one of these VMs:

1. Stop or deallocate the VM. For an availability set or scale set, stop or deallocate all the VMs in the availability set or scale set.
2. Disable accelerated networking on the NIC of the VM. For an availability set or scale set, disable accelerated networking on the NICs of all VMs in the availability set or scale set.
3. After you disable accelerated networking, move the VM, availability set, or scale set to a new size that doesn't support accelerated networking, and then restart them.

- Learn how to [create a VM with Accerelated Networking using Azure CLI](#)
- Improve latency with an [Azure proximity placement group](#)

# Create a Linux virtual machine with Accelerated Networking using Azure CLI

9/21/2022 • 8 minutes to read • [Edit Online](#)

## Portal creation

Though this article provides steps to create a virtual machine with accelerated networking using the Azure CLI, you can also [create a virtual machine with accelerated networking using the Azure portal](#). When creating a virtual machine in the portal, in the **Create a virtual machine** blade, choose the **Networking** tab. In this tab, there is an option for **Accelerated networking**. If you have chosen a [supported operating system](#) and [VM size](#), this option will automatically populate to "On." If not, it will populate the "Off" option for Accelerated Networking and give the user a reason why it isn't enabled.

You can also enable or disable accelerated networking through the portal after VM creation by navigating to the network interface and clicking the button at the top of the **Overview** blade.

### NOTE

The Accelerated Networking setting in the portal reflects the user-selected state. AccelNet allows choosing "Disabled" even if the VM size requires AccelNet. For those AccelNet-required VM sizes, AccelNet will be enabled at runtime regardless of the user setting seen in the portal.

Only supported operating systems can be enabled through the portal. If you're using a custom image, and your image supports Accelerated Networking, create your VM using CLI or PowerShell.

After the VM is created, you can confirm that Accelerated Networking is enabled by following the [confirmation instructions](#).

## CLI creation

### Create a virtual network

Install the latest [Azure CLI](#) and log in to an Azure account using [az login](#). In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *myNic*, and *myVm*.

Create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroup* in the *centralus* location:

```
az group create --name myResourceGroup --location centralus
```

Select a supported Linux region listed in [Linux Accelerated Networking](#).

Create a virtual network with [az network vnet create](#). The following example creates a virtual network named *myVnet* with one subnet:

```
az network vnet create \
--resource-group myResourceGroup \
--name myVnet \
--address-prefix 192.168.0.0/16 \
--subnet-name mySubnet \
--subnet-prefix 192.168.1.0/24
```

## Create a network security group

Create a network security group with [az network nsg create](#). The following example creates a network security group named *myNetworkSecurityGroup*:

```
az network nsg create \
--resource-group myResourceGroup \
--name myNetworkSecurityGroup
```

The network security group contains several default rules, one of which disables all inbound access from the Internet. Open a port to allow SSH access to the virtual machine with [az network nsg rule create](#):

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name Allow-SSH-Internet \
--access Allow \
--protocol Tcp \
--direction Inbound \
--priority 100 \
--source-address-prefix Internet \
--source-port-range "*" \
--destination-address-prefix "*" \
--destination-port-range 22
```

## Create a network interface with Accelerated Networking

Create a public IP address with [az network public-ip create](#). A public IP address isn't required if you don't plan to access the VM from the Internet. However, it's required to complete the steps in this article.

```
az network public-ip create \
--name myPublicIp \
--resource-group myResourceGroup
```

Create a network interface with [az network nic create](#) with Accelerated Networking enabled. The following example creates a network interface named *myNic* in the *mySubnet* subnet of the *myVnet* virtual network and associates the *myNetworkSecurityGroup* network security group to the network interface:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic \
--vnet-name myVnet \
--subnet mySubnet \
--accelerated-networking true \
--public-ip-address myPublicIp \
--network-security-group myNetworkSecurityGroup
```

## Create a VM and attach the NIC

When you create the VM, specify the NIC you created with `--nics`. Select a size and distribution listed in [Linux accelerated networking](#).

Create a VM with [az vm create](#). The following example creates a VM named *myVM* with the UbuntuLTS image and a size that supports Accelerated Networking (*Standard\_DS4\_v2*):

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image UbuntuLTS \
    --size Standard_DS4_v2 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --nics myNic
```

For a list of all VM sizes and characteristics, see [Linux VM sizes](#).

Once the VM is created, output similar to the following example output is returned. Take note of the **publicIpAddress**. This address is used to access the VM in subsequent steps.

```
{
  "fqdns": "",
  "id": "/subscriptions/<ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "centralus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "192.168.0.4",
  "publicIpAddress": "40.68.254.142",
  "resourceGroup": "myResourceGroup"
}
```

### Confirm that accelerated networking is enabled

Use the following command to create an SSH session with the VM. Replace `<your-public-ip-address>` with the public IP address assigned to the virtual machine that you created, and replace *azureuser* if you used a different value for `--admin-username` when you created the VM.

```
ssh azureuser@<your-public-ip-address>
```

From the Bash shell, enter `uname -r` and confirm that the kernel version is one of the following versions, or greater:

- **Ubuntu 16.04:** 4.11.0-1013
- **SLES SP3:** 4.4.92-6.18
- **RHEL:** 3.10.0-693, 2.6.32-573\*
- **CentOS:** 3.10.0-693

#### NOTE

Other kernel versions may be supported. For the most up to date list, reference the compatibility tables for each distribution at [Supported Linux and FreeBSD virtual machines for Hyper-V](#) and confirm that SR-IOV is supported.

Additional details can be found in the release notes for the [Linux Integration Services for Hyper-V and Azure](#). \* RHEL 6.7-6.10 are supported if the Mellanox VF version 4.5+ is installed before Linux Integration Services 4.3+.

Confirm that the Mellanox VF device is exposed to the VM with the `lspci` command. The returned output is similar to the following output:

```
0000:00:00.0 Host bridge: Intel Corporation 440BX/ZX/DX - 82443BX/ZX/DX Host bridge (AGP disabled) (rev 03)
0000:00:07.0 ISA bridge: Intel Corporation 82371AB/EB/MB PIIX4 ISA (rev 01)
0000:00:07.1 IDE interface: Intel Corporation 82371AB/EB/MB PIIX4 IDE (rev 01)
0000:00:07.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 02)
0000:00:08.0 VGA compatible controller: Microsoft Corporation Hyper-V virtual VGA
0001:00:02.0 Ethernet controller: Mellanox Technologies MT27500/MT27520 Family [ConnectX-3/ConnectX-3 Pro
Virtual Function]
```

Check for activity on the VF (virtual function) with the `ethtool -S eth0 | grep vf_` command. If you receive output similar to the following sample output, accelerated networking is enabled and active.

```
vf_rx_packets: 992956
vf_rx_bytes: 2749784180
vf_tx_packets: 2656684
vf_tx_bytes: 1099443970
vf_tx_dropped: 0
```

Accelerated Networking is now enabled for your VM.

## Handle dynamic binding and revocation of virtual function

Applications must run over the synthetic NIC that is exposed in VM. If the application runs directly over the VF NIC, it doesn't receive **all** packets that are destined to the VM, since some packets show up over the synthetic interface. If you run an application over the synthetic NIC, it guarantees that the application receives **all** packets that are destined to it. It also makes sure that the application keeps running, even if the VF is revoked during host servicing. Applications binding to the synthetic NIC is a **mandatory** requirement for all applications taking advantage of **Accelerated Networking**.

For more details on application binding requirements, see [How Accelerated Networking works in Linux and FreeBSD VMs](#).

## Enable Accelerated Networking on existing VMs

If you've created a VM without Accelerated Networking, it's possible to enable this feature on an existing VM. The VM must support Accelerated Networking by meeting the following prerequisites that are also outlined:

- The VM must be a supported size for Accelerated Networking
- The VM must be a supported Azure Gallery image (and kernel version for Linux)
- All VMs in an availability set or VMSS must be stopped/deallocated before enabling Accelerated Networking on any NIC

### Individual VMs & VMs in an availability set

First stop/deallocate the VM or, if an Availability Set, all the VMs in the Set:

```
az vm deallocate \
--resource-group myResourceGroup \
--name myVM
```

If your VM was created individually without an availability set, you only must stop or deallocate the individual VM to enable Accelerated Networking. If your VM was created with an availability set, all VMs contained in the set must be stopped or deallocated before enabling Accelerated Networking on any of the NICs.

Once stopped, enable Accelerated Networking on the NIC of your VM:

```
az network nic update \
--name myNic \
--resource-group myResourceGroup \
--accelerated-networking true
```

Restart your VM or, if in an Availability Set, all the VMs in the Set and confirm that Accelerated Networking is enabled:

```
az vm start --resource-group myResourceGroup \
--name myVM
```

## VMSS

VMSS is slightly different but follows the same workflow. First, stop the VMs:

```
az vmss deallocate \
--name myvmss \
--resource-group myrg
```

Once the VMs are stopped, update the Accelerated Networking property under the network interface:

```
az vmss update --name myvmss \
--resource-group myrg \
--set
virtualMachineProfile.networkProfile.networkInterfaceConfigurations[0].enableAcceleratedNetworking=true
```

### NOTE

A VMSS has VM upgrades that apply updates using three different settings, automatic, rolling, and manual. In these instructions, the policy is set to automatic so that the VMSS will pick up the changes immediately after reboot. To set it to automatic so that the changes are immediately picked up:

```
az vmss update \
--name myvmss \
--resource-group myrg \
--set upgradePolicy.mode="automatic"
```

Finally, restart the VMSS:

```
az vmss start \
--name myvmss \
--resource-group myrg
```

Once you restart, wait for the upgrades to finish but once completed, the VF appears inside the VM. (Make sure you're using a supported OS and VM size.)

## Resizing existing VMs with Accelerated Networking

VMs with Accelerated Networking enabled can only be resized to VMs that support Accelerated Networking.

A VM with Accelerated Networking enabled can't be resized to a VM instance that doesn't support Accelerated Networking using the resize operation. Instead, to resize one of these VMs:

- Stop/Deallocate the VM or if in an availability set/VMSS, stop/deallocate all the VMs in the set/VMSS.

- Accelerated Networking must be disabled on the NIC of the VM or if in an availability set/VMSS, all VMs in the set/VMSS.
- Once Accelerated Networking is disabled, the VM/availability set/VMSS can be moved to a new size that doesn't support Accelerated Networking and restarted.

# Set up DPDK in a Linux virtual machine

9/21/2022 • 7 minutes to read • [Edit Online](#)

Data Plane Development Kit (DPDK) on Azure offers a faster user-space packet processing framework for performance-intensive applications. This framework bypasses the virtual machine's kernel network stack.

In typical packet processing that uses the kernel network stack, the process is interrupt-driven. When the network interface receives incoming packets, there is a kernel interrupt to process the packet and a context switch from the kernel space to the user space. DPDK eliminates context switching and the interrupt-driven method in favor of a user-space implementation that uses poll mode drivers for fast packet processing.

DPDK consists of sets of user-space libraries that provide access to lower-level resources. These resources can include hardware, logical cores, memory management, and poll mode drivers for network interface cards.

DPDK can run on Azure virtual machines that are supporting multiple operating system distributions. DPDK provides key performance differentiation in driving network function virtualization implementations. These implementations can take the form of network virtual appliances (NVAs), such as virtual routers, firewalls, VPNs, load balancers, evolved packet cores, and denial-of-service (DDoS) applications.

## Benefit

**Higher packets per second (PPS):** Bypassing the kernel and taking control of packets in the user space reduces the cycle count by eliminating context switches. It also improves the rate of packets that are processed per second in Azure Linux virtual machines.

## Supported operating systems minimum versions

The following distributions from the Azure Marketplace are supported:

LINUX OS	KERNEL VERSION
Ubuntu 18.04	4.15.0-1014-azure+
SLES 15 SP1	4.12.14-8.19-azure+
RHEL 7.5	3.10.0-862.11.6.el7.x86_64+
CentOS 7.5	3.10.0-862.11.6.el7.x86_64+
Debian 10	4.19.0-1-cloud+

The noted versions are the minimum requirements. Newer versions are supported too.

## Custom kernel support

For any Linux kernel version that's not listed, see [Patches for building an Azure-tuned Linux kernel](#). For more information, you can also contact [aznetdpdk@microsoft.com](mailto:aznetdpdk@microsoft.com).

## Region support

All Azure regions support DPDK.

## Prerequisites

Accelerated networking must be enabled on a Linux virtual machine. The virtual machine should have at least two network interfaces, with one interface for management. Enabling Accelerated networking on management interface is not recommended. Learn how to [create a Linux virtual machine with accelerated networking enabled](#).

On virtual machines that are using InfiniBand, ensure the appropriate `mlx4_ib` or `mlx5_ib` drivers are loaded, see [Enable InfiniBand](#).

## Install DPDK via system package (recommended)

### Ubuntu 18.04

```
sudo add-apt-repository ppa:canonical-server/server-backports -y  
sudo apt-get update  
sudo apt-get install -y dpdk
```

### Ubuntu 20.04 and newer

```
sudo apt-get install -y dpdk
```

### Debian 10 and newer

```
sudo apt-get install -y dpdk
```

## Install DPDK manually (not recommended)

### Install build dependencies

#### Ubuntu 18.04

```
sudo add-apt-repository ppa:canonical-server/server-backports -y  
sudo apt-get update  
sudo apt-get install -y build-essential librdmacm-dev libnuma-dev libmnl-dev meson
```

#### Ubuntu 20.04 and newer

```
sudo apt-get install -y build-essential librdmacm-dev libnuma-dev libmnl-dev meson
```

#### Debian 10 and newer

```
sudo apt-get install -y build-essential librdmacm-dev libnuma-dev libmnl-dev meson
```

#### RHEL7.5/CentOS 7.5

```
yum -y groupinstall "Infiniband Support"  
sudo dracut --add-drivers "mlx4_en mlx4_ib mlx5_ib" -f  
yum install -y gcc kernel-devel-`uname -r` numactl-devel.x86_64 librdmacm-devel libmnl-devel meson
```

#### SLES 15 SP1

#### Azure kernel

```
zypper \
--no-gpg-checks \
--non-interactive \
--gpg-auto-import-keys install kernel-azure kernel-devel-azure gcc make libnuma-devel numactl librdmacm1
rdma-core-devel meson
```

## Default kernel

```
zypper \
--no-gpg-checks \
--non-interactive \
--gpg-auto-import-keys install kernel-default-devel gcc make libnuma-devel numactl librdmacm1 rdma-core-
devel meson
```

## Compile and install DPDK manually

1. [Download the latest DPDK](#). Version 19.11 LTS or newer is required for Azure.
2. Build the default config with `meson builddir`.
3. Compile with `ninja -C builddir`.
4. Install with `DESTDIR=<output folder> ninja -C builddir install`.

## Configure the runtime environment

After restarting, run the following commands once:

1. Hugepages
  - Configure hugepage by running the following command, once for each numa node:

```
echo 1024 | sudo tee /sys/devices/system/node/node*/hugepages/hugepages-2048kB/nr_hugepages
```
  - Create a directory for mounting with `mkdir /mnt/huge`.
  - Mount hugepages with `mount -t hugetlbfs nodev /mnt/huge`.
  - Check that hugepages are reserved with `grep Huge /proc/meminfo`.

[NOTE] There is a way to modify the grub file so that hugepages are reserved on boot by following the [instructions](#) for the DPDK. The instructions are at the bottom of the page. When you're using an Azure Linux virtual machine, modify files under `/etc/config/grub.d` instead, to reserve hugepages across reboots.
2. MAC & IP addresses: Use `ifconfig -a` to view the MAC and IP address of the network interfaces. The *VF* network interface and *NETVSC* network interface have the same MAC address, but only the *NETVSC* network interface has an IP address. *VF* interfaces are running as subordinate interfaces of *NETVSC* interfaces.
3. PCI addresses
  - Use `ethtool -i <vf interface name>` to find out which PCI address to use for *VF*.
  - If *eth0* has accelerated networking enabled, make sure that testpmd doesn't accidentally take over the *VF* pci device for *eth0*. If the DPDK application accidentally takes over the management network interface and causes you to lose your SSH connection, use the serial console to stop the DPDK application. You can also use the serial console to stop or start the virtual machine.
4. Load *ibuverbs* on each reboot with `modprobe -a ib_uverbs`. For SLES 15 only, also load *mlx4\_ib* with

```
modprobe -a mlx4_ib .
```

## Failsafe PMD

DPDK applications must run over the failsafe PMD that is exposed in Azure. If the application runs directly over the VFPM, it doesn't receive all packets that are destined to the VM, since some packets show up over the synthetic interface.

If you run a DPDK application over the failsafe PMD, it guarantees that the application receives all packets that are destined to it. It also makes sure that the application keeps running in DPDK mode, even if the VF is revoked when the host is being serviced. For more information about failsafe PMD, see [Fail-safe poll mode driver library](#).

## Run testpmd

To run testpmd in root mode, use `sudo` before the `testpmd` command.

### Basic: Sanity check, failsafe adapter initialization

1. Run the following commands to start a single port testpmd application:

```
testpmd -w <pci address from previous step> \
--vdev="net_vdev_netvsc0,iface=eth1" \
-- -i \
--port-topology=chained
```

2. Run the following commands to start a dual port testpmd application:

```
testpmd -w <pci address nic1> \
-w <pci address nic2> \
--vdev="net_vdev_netvsc0,iface=eth1" \
--vdev="net_vdev_netvsc1,iface=eth2" \
-- -i
```

If you're running testpmd with more than two NICs, the `--vdev` argument follows this pattern:

```
net_vdev_netvsc<id>,iface=<vf's pairing eth> .
```

3. After it's started, run `show port info all` to check port information. You should see one or two DPDK ports that are `net_failsafe` (not `net_mlx4`).
4. Use `start <port> /stop <port>` to start traffic.

The previous commands start `testpmd` in interactive mode, which is recommended for trying out testpmd commands.

### Basic: Single sender/single receiver

The following commands periodically print the packets per second statistics:

1. On the TX side, run the following command:

```
testpmd \
-l <core-list> \
-n <num of mem channels> \
-w <pci address of the device you plan to use> \
--vdev="net_vdev_netvsc<id>,iface=<the iface to attach to>" \
--port-topology=chained \
--nb-cores <number of cores to use for test pmd> \
--forward-mode=txonly \
--eth-peer=<port id>,<receiver peer MAC address> \
--stats-period <display interval in seconds>
```

2. On the RX side, run the following command:

```
testpmd \
-l <core-list> \
-n <num of mem channels> \
-w <pci address of the device you plan to use> \
--vdev="net_vdev_netvsc<id>,iface=<the iface to attach to>" \
--port-topology=chained \
--nb-cores <number of cores to use for test pmd> \
--forward-mode=rxonly \
--eth-peer=<port id>,<sender peer MAC address> \
--stats-period <display interval in seconds>
```

When you're running the previous commands on a virtual machine, change *IP\_SRC\_ADDR* and *IP\_DST\_ADDR* in `app/test-pmd/txonly.c` to match the actual IP address of the virtual machines before you compile. Otherwise, the packets are dropped before reaching the receiver.

### **Advanced: Single sender/single forwarder**

The following commands periodically print the packets per second statistics:

1. On the TX side, run the following command:

```
testpmd \
-l <core-list> \
-n <num of mem channels> \
-w <pci address of the device you plan to use> \
--vdev="net_vdev_netvsc<id>,iface=<the iface to attach to>" \
--port-topology=chained \
--nb-cores <number of cores to use for test pmd> \
--forward-mode=txonly \
--eth-peer=<port id>,<receiver peer MAC address> \
--stats-period <display interval in seconds>
```

2. On the FWD side, run the following command:

```
testpmd \
-l <core-list> \
-n <num of mem channels> \
-w <pci address NIC1> \
-w <pci address NIC2> \
--vdev="net_vdev_netvsc<id>,iface=<the iface to attach to>" \
--vdev="net_vdev_netvsc<2nd id>,iface=<2nd iface to attach to>" (you need as many --vdev arguments as the number of devices used by testpmd, in this case) \
--nb-cores <number of cores to use for test pmd> \
--forward-mode=io \
--eth-peer=<recv port id>,<sender peer MAC address> \
--stats-period <display interval in seconds>
```

When you're running the previous commands on a virtual machine, change *IP\_SRC\_ADDR* and *IP\_DST\_ADDR* in `app/test-pmd/txonly.c` to match the actual IP address of the virtual machines before you compile. Otherwise, the packets are dropped before reaching the forwarder. You won't be able to have a third machine receive forwarded traffic, because the *testpmd* forwarder doesn't modify the layer-3 addresses, unless you make some code changes.

# TCP/IP performance tuning for Azure VMs

9/21/2022 • 23 minutes to read • [Edit Online](#)

This article discusses common TCP/IP performance tuning techniques and some things to consider when you use them for virtual machines running on Azure. It will provide a basic overview of the techniques and explore how they can be tuned.

## Common TCP/IP tuning techniques

### MTU, fragmentation, and large send offload

#### MTU

The maximum transmission unit (MTU) is the largest size frame (packet), specified in bytes, that can be sent over a network interface. The MTU is a configurable setting. The default MTU used on Azure VMs, and the default setting on most network devices globally, is 1,500 bytes.

#### Fragmentation

Fragmentation occurs when a packet is sent that exceeds the MTU of a network interface. The TCP/IP stack will break the packet into smaller pieces (fragments) that conform to the interface's MTU. Fragmentation occurs at the IP layer and is independent of the underlying protocol (such as TCP). When a 2,000-byte packet is sent over a network interface with an MTU of 1,500, the packet will be broken down into one 1,500-byte packet and one 500-byte packet.

Network devices in the path between a source and destination can either drop packets that exceed the MTU or fragment the packet into smaller pieces.

#### The Don't Fragment bit in an IP packet

The Don't Fragment (DF) bit is a flag in the IP protocol header. The DF bit indicates that network devices on the path between the sender and receiver must not fragment the packet. This bit could be set for many reasons. (See the "Path MTU Discovery" section of this article for one example.) When a network device receives a packet with the Don't Fragment bit set, and that packet exceeds the device's interface MTU, the standard behavior is for the device to drop the packet. The device sends an ICMP Fragmentation Needed message back to the original source of the packet.

#### Performance implications of fragmentation

Fragmentation can have negative performance implications. One of the main reasons for the effect on performance is the CPU/memory impact of the fragmentation and reassembly of packets. When a network device needs to fragment a packet, it will have to allocate CPU/memory resources to perform fragmentation.

The same thing happens when the packet is reassembled. The network device has to store all the fragments until they're received so it can reassemble them into the original packet. This process of fragmentation and reassembly can also cause latency.

The other possible negative performance implication of fragmentation is that fragmented packets might arrive out of order. When packets are received out of order, some types of network devices can drop them. When that happens, the whole packet has to be retransmitted.

Fragments are typically dropped by security devices like network firewalls or when a network device's receive buffers are exhausted. When a network device's receive buffers are exhausted, a network device is attempting to reassemble a fragmented packet but doesn't have the resources to store and reassemble the packet.

Fragmentation can be seen as a negative operation, but support for fragmentation is necessary when you're connecting diverse networks over the internet.

## **Benefits and consequences of modifying the MTU**

Generally speaking, you can create a more efficient network by increasing the MTU. Every packet that's transmitted has header information that's added to the original packet. When fragmentation creates more packets, there's more header overhead, and that makes the network less efficient.

Here's an example. The Ethernet header size is 14 bytes plus a 4-byte frame check sequence to ensure frame consistency. If one 2,000-byte packet is sent, 18 bytes of Ethernet overhead is added on the network. If the packet is fragmented into a 1,500-byte packet and a 500-byte packet, each packet will have 18 bytes of Ethernet header, a total of 36 bytes.

Keep in mind that increasing the MTU won't necessarily create a more efficient network. If an application sends only 500-byte packets, the same header overhead will exist whether the MTU is 1,500 bytes or 9,000 bytes. The network will become more efficient only if it uses larger packet sizes that are affected by the MTU.

### **Azure and VM MTU**

The default MTU for Azure VMs is 1,500 bytes. The Azure Virtual Network stack will attempt to fragment a packet at 1,400 bytes.

Note that the Virtual Network stack isn't inherently inefficient because it fragments packets at 1,400 bytes even though VMs have an MTU of 1,500. A large percentage of network packets are much smaller than 1,400 or 1,500 bytes.

### **Azure and fragmentation**

Virtual Network stack is set up to drop "out of order fragments," that is, fragmented packets that don't arrive in their original fragmented order. These packets are dropped mainly because of a network security vulnerability announced in November 2018 called FragmentSmack.

FragmentSmack is a defect in the way the Linux kernel handled reassembly of fragmented IPv4 and IPv6 packets. A remote attacker could use this flaw to trigger expensive fragment reassembly operations, which could lead to increased CPU and a denial of service on the target system.

### **Tune the MTU**

You can configure an Azure VM MTU, as you can in any other operating system. But you should consider the fragmentation that occurs in Azure, described above, when you're configuring an MTU.

We don't encourage customers to increase VM MTUs. This discussion is meant to explain the details of how Azure implements MTU and performs fragmentation.

#### **IMPORTANT**

Increasing MTU isn't known to improve performance and could have a negative effect on application performance.

### **Large send offload**

Large send offload (LSO) can improve network performance by offloading the segmentation of packets to the Ethernet adapter. When LSO is enabled, the TCP/IP stack creates a large TCP packet and sends it to the Ethernet adapter for segmentation before forwarding it. The benefit of LSO is that it can free the CPU from segmenting packets into sizes that conform to the MTU and offload that processing to the Ethernet interface where it's performed in hardware. To learn more about the benefits of LSO, see [Supporting large send offload](#).

When LSO is enabled, Azure customers might see large frame sizes when they perform packet captures. These large frame sizes might lead some customers to think fragmentation is occurring or that a large MTU is being used when it's not. With LSO, the Ethernet adapter can advertise a larger maximum segment size (MSS) to the TCP/IP stack to create a larger TCP packet. This entire non-segmented frame is then forwarded to the Ethernet adapter and would be visible in a packet capture performed on the VM. But the packet will be broken down into many smaller frames by the Ethernet adapter, according to the Ethernet adapter's MTU.

### **TCP MSS window scaling and PMTUD**

## TCP maximum segment size

TCP maximum segment size (MSS) is a setting that limits the size of TCP segments, which avoids fragmentation of TCP packets. Operating systems will typically use this formula to set MSS:

$$\text{MSS} = \text{MTU} - (\text{IP header size} + \text{TCP header size})$$

The IP header and the TCP header are 20 bytes each, or 40 bytes total. So an interface with an MTU of 1,500 will have an MSS of 1,460. But the MSS is configurable.

This setting is agreed to in the TCP three-way handshake when a TCP session is set up between a source and a destination. Both sides send an MSS value, and the lower of the two is used for the TCP connection.

Keep in mind that the MTUs of the source and destination aren't the only factors that determine the MSS value. Intermediary network devices, like VPN gateways, including Azure VPN Gateway, can adjust the MTU independently of the source and destination to ensure optimal network performance.

### Path MTU Discovery

MSS is negotiated, but it might not indicate the actual MSS that can be used. This is because other network devices in the path between the source and the destination might have a lower MTU value than the source and destination. In this case, the device whose MTU is smaller than the packet will drop the packet. The device will send back an ICMP Fragmentation Needed (Type 3, Code 4) message that contains its MTU. This ICMP message allows the source host to reduce its Path MTU appropriately. The process is called Path MTU Discovery (PMTUD).

The PMTUD process is inefficient and affects network performance. When packets are sent that exceed a network path's MTU, the packets need to be retransmitted with a lower MSS. If the sender doesn't receive the ICMP Fragmentation Needed message, maybe because of a network firewall in the path (commonly referred to as a *PMTUD blackhole*), the sender doesn't know it needs to lower the MSS and will continuously retransmit the packet. This is why we don't recommend increasing the Azure VM MTU.

### VPN and MTU

If you use VMs that perform encapsulation (like IPsec VPNs), there are some additional considerations regarding packet size and MTU. VPNs add more headers to packets, which increases the packet size and requires a smaller MSS.

For Azure, we recommend that you set TCP MSS clamping to 1,350 bytes and tunnel interface MTU to 1,400. For more information, see the [VPN devices and IPsec/IKE parameters page](#).

## Latency, round-trip time, and TCP window scaling

### Latency and round-trip time

Network latency is governed by the speed of light over a fiber optic network. Network throughput of TCP is also effectively governed by the round-trip time (RTT) between two network devices.

ROUTE	DISTANCE	ONE-WAY TIME	RTT
New York to San Francisco	4,148 km	21 ms	42 ms
New York to London	5,585 km	28 ms	56 ms
New York to Sydney	15,993 km	80 ms	160 ms

This table shows the straight-line distance between two locations. In networks, the distance is typically longer than the straight-line distance. Here's a simple formula to calculate minimum RTT as governed by the speed of light:

$$\text{minimum RTT} = 2 * (\text{Distance in kilometers} / \text{Speed of propagation})$$

You can use 200 for the speed of propagation. This is the distance, in kilometers, that light travels in 1

millisecond.

Let's take New York to San Francisco as an example. The straight-line distance is 4,148 km. Plugging that value into the equation, we get the following:

$$\text{Minimum RTT} = 2 * (4,148 / 200)$$

The output of the equation is in milliseconds.

If you want to get the best network performance, the logical option is to select destinations with the shortest distance between them. You should also design your virtual network to optimize the path of traffic and reduce latency. For more information, see the "Network design considerations" section of this article.

#### Latency and round-trip time effects on TCP

Round-trip time has a direct effect on maximum TCP throughput. In TCP protocol, *window size* is the maximum amount of traffic that can be sent over a TCP connection before the sender needs to receive acknowledgement from the receiver. If the TCP MSS is set to 1,460 and the TCP window size is set to 65,535, the sender can send 45 packets before it has to receive acknowledgement from the receiver. If the sender doesn't get acknowledgement, it will retransmit the data. Here's the formula:

$$\text{TCP window size} / \text{TCP MSS} = \text{packets sent}$$

In this example, 65,535 / 1,460 is rounded up to 45.

This "waiting for acknowledgement" state, a mechanism to ensure reliable delivery of data, is what causes RTT to affect TCP throughput. The longer the sender waits for acknowledgement, the longer it needs to wait before sending more data.

Here's the formula for calculating the maximum throughput of a single TCP connection:

$$\text{Window size} / (\text{RTT latency in milliseconds} / 1,000) = \text{maximum bytes/second}$$

This table shows the maximum megabytes/second throughput of a single TCP connection. (For readability, megabytes is used for the unit of measure.)

TCP WINDOW SIZE (BYTES)	RTT LATENCY (MS)	MAXIMUM MEGABYTE/SECOND THROUGHPUT	MAXIMUM MEGABIT/SECOND THROUGHPUT
65,535	1	65.54	524.29
65,535	30	2.18	17.48
65,535	60	1.09	8.74
65,535	90	.73	5.83
65,535	120	.55	4.37

If packets are lost, the maximum throughput of a TCP connection will be reduced while the sender retransmits data it has already sent.

#### TCP window scaling

TCP window scaling is a technique that dynamically increases the TCP window size to allow more data to be sent before an acknowledgement is required. In the previous example, 45 packets would be sent before an acknowledgement was required. If you increase the number of packets that can be sent before an acknowledgement is needed, you're reducing the number of times a sender is waiting for acknowledgement, which increases the TCP maximum throughput.

This table illustrates those relationships:

TCP WINDOW SIZE (BYTES)	RTT LATENCY (MS)	MAXIMUM MEGABYTE/SECOND THROUGHPUT	MAXIMUM MEGABIT/SECOND THROUGHPUT
65,535	30	2.18	17.48
131,070	30	4.37	34.95
262,140	30	8.74	69.91
524,280	30	17.48	139.81

But the TCP header value for TCP window size is only 2 bytes long, which means the maximum value for a receive window is 65,535. To increase the maximum window size, a TCP window scale factor was introduced.

The scale factor is also a setting that you can configure in an operating system. Here's the formula for calculating the TCP window size by using scale factors:

```
TCP window size = TCP window size in bytes \* (2^scale factor)
```

Here's the calculation for a window scale factor of 3 and a window size of 65,535:

```
65,535 \* (2^3) = 262,140 bytes
```

A scale factor of 14 results in a TCP window size of 14 (the maximum offset allowed). The TCP window size will be 1,073,725,440 bytes (8.5 gigabits).

#### Support for TCP window scaling

Windows can set different scaling factors for different connection types. (Classes of connections include datacenter, internet, and so on.) You use the `Get-NetTCPConnection` PowerShell command to view the window scaling connection type:

```
Get-NetTCPConnection
```

You can use the `Get-NetTCPSetting` PowerShell command to view the values of each class:

```
Get-NetTCPSetting
```

You can set the initial TCP window size and TCP scaling factor in Windows by using the `Set-NetTCPSetting` PowerShell command. For more information, see [Set-NetTCPSetting](#).

```
Set-NetTCPSetting
```

These are the effective TCP settings for `AutoTuningLevel`:

AUTOTUNINGLEVEL	SCALING FACTOR	SCALING MULTIPLIER	FORMULA TO CALCULATE MAXIMUM WINDOW SIZE
Disabled	None	None	Window size
Restricted	4	$2^4$	Window size * $(2^4)$

AUTOTUNINGLEVEL	SCALING FACTOR	SCALING MULTIPLIER	FORMULA TO CALCULATE MAXIMUM WINDOW SIZE
Highly restricted	2	$2^2$	Window size * $(2^2)$
Normal	8	$2^8$	Window size * $(2^8)$
Experimental	14	$2^{14}$	Window size * $(2^{14})$

These settings are the most likely to affect TCP performance, but keep in mind that many other factors across the internet, outside the control of Azure, can also affect TCP performance.

#### Increase MTU size

Because a larger MTU means a larger MSS, you might wonder whether increasing the MTU can increase TCP performance. Probably not. There are pros and cons to packet size beyond just TCP traffic. As discussed earlier, the most important factors affecting TCP throughput performance are TCP window size, packet loss, and RTT.

#### IMPORTANT

We don't recommend that Azure customers change the default MTU value on virtual machines.

## Accelerated networking and receive side scaling

### Accelerated networking

Virtual machine network functions have historically been CPU intensive on both the guest VM and the hypervisor/host. Every packet that transits through the host is processed in software by the host CPU, including all virtual network encapsulation and decapsulation. So the more traffic that goes through the host, the higher the CPU load. And if the host CPU is busy with other operations, that will also affect network throughput and latency. Azure addresses this issue with accelerated networking.

Accelerated networking provides consistent ultralow network latency via the in-house programmable hardware of Azure and technologies like SR-IOV. Accelerated networking moves much of the Azure software-defined networking stack off the CPUs and into FPGA-based SmartNICs. This change enables end-user applications to reclaim compute cycles, which puts less load on the VM, decreasing jitter and inconsistency in latency. In other words, performance can be more deterministic.

Accelerated networking improves performance by allowing the guest VM to bypass the host and establish a datapath directly with a host's SmartNIC. Here are some benefits of accelerated networking:

- **Lower latency / higher packets per second (pps):** Removing the virtual switch from the datapath eliminates the time packets spend in the host for policy processing and increases the number of packets that can be processed in the VM.
- **Reduced jitter:** Virtual switch processing depends on the amount of policy that needs to be applied and the workload of the CPU that's doing the processing. Offloading the policy enforcement to the hardware removes that variability by delivering packets directly to the VM, eliminating the host-to-VM communication and all software interrupts and context switches.
- **Decreased CPU utilization:** Bypassing the virtual switch in the host leads to less CPU utilization for processing network traffic.

To use accelerated networking, you need to explicitly enable it on each applicable VM. See [Create a Linux virtual machine with Accelerated Networking](#) for instructions.

### Receive side scaling

Receive side scaling (RSS) is a network driver technology that distributes the receiving of network traffic more

efficiently by distributing receive processing across multiple CPUs in a multiprocessor system. In simple terms, RSS allows a system to process more received traffic because it uses all available CPUs instead of just one. For a more technical discussion of RSS, see [Introduction to receive side scaling](#).

To get the best performance when accelerated networking is enabled on a VM, you need to enable RSS. RSS can also provide benefits on VMs that don't use accelerated networking. For an overview of how to determine if RSS is enabled and how to enable it, see [Optimize network throughput for Azure virtual machines](#).

### TCP TIME\_WAIT and TIME\_WAIT assassination

TCP TIME\_WAIT is another common setting that affects network and application performance. On busy VMs that are opening and closing many sockets, either as clients or as servers (Source IP:Source Port + Destination IP:Destination Port), during the normal operation of TCP, a given socket can end up in a TIME\_WAIT state for a long time. The TIME\_WAIT state is meant to allow any additional data to be delivered on a socket before closing it. So TCP/IP stacks generally prevent the reuse of a socket by silently dropping the client's TCP SYN packet.

The amount of time a socket is in TIME\_WAIT is configurable. It could range from 30 seconds to 240 seconds. Sockets are a finite resource, and the number of sockets that can be used at any given time is configurable. (The number of available sockets is typically about 30,000.) If the available sockets are consumed, or if clients and servers have mismatched TIME\_WAIT settings, and a VM tries to reuse a socket in a TIME\_WAIT state, new connections will fail as TCP SYN packets are silently dropped.

The value for port range for outbound sockets is usually configurable within the TCP/IP stack of an operating system. The same thing is true for TCP TIME\_WAIT settings and socket reuse. Changing these numbers can potentially improve scalability. But, depending on the situation, these changes could cause interoperability issues. You should be careful if you change these values.

You can use TIME\_WAIT assassination to address this scaling limitation. TIME\_WAIT assassination allows a socket to be reused in certain situations, like when the sequence number in the IP packet of the new connection exceeds the sequence number of the last packet from the previous connection. In this case, the operating system will allow the new connection to be established (it will accept the new SYN/ACK) and force close the previous connection that was in a TIME\_WAIT state. This capability is supported on Windows VMs in Azure. To learn about support in other VMs, check with the OS vendor.

To learn about configuring TCP TIME\_WAIT settings and source port range, see [Settings that can be modified to improve network performance](#).

## Virtual network factors that can affect performance

### VM maximum outbound throughput

Azure provides a variety of VM sizes and types, each with a different mix of performance capabilities. One of these capabilities is network throughput (or bandwidth), which is measured in megabits per second (Mbps). Because virtual machines are hosted on shared hardware, the network capacity needs to be shared fairly among the virtual machines using the same hardware. Larger virtual machines are allocated more bandwidth than smaller virtual machines.

The network bandwidth allocated to each virtual machine is metered on egress (outbound) traffic from the virtual machine. All network traffic leaving the virtual machine is counted toward the allocated limit, regardless of destination. For example, if a virtual machine has a 1,000-Mbps limit, that limit applies whether the outbound traffic is destined for another virtual machine in the same virtual network or one outside of Azure.

Ingress is not metered or limited directly. But there are other factors, like CPU and storage limits, that can affect a virtual machine's ability to process incoming data.

Accelerated networking is designed to improve network performance, including latency, throughput, and CPU utilization. Accelerated networking can improve a virtual machine's throughput, but it can do that only up to the virtual machine's allocated bandwidth.

Azure virtual machines have at least one network interface attached to them. They might have several. The bandwidth allocated to a virtual machine is the sum of all outbound traffic across all network interfaces attached to the machine. In other words, the bandwidth is allocated on a per-virtual machine basis, regardless of how many network interfaces are attached to the machine.

Expected outbound throughput and the number of network interfaces supported by each VM size are detailed in [Sizes for Windows virtual machines in Azure](#). To see maximum throughput, select a type, like **General purpose**, and then find the section about the size series on the resulting page (for example, "Dv2-series"). For each series, there's a table that provides networking specifications in the last column, which is titled "Max NICs / Expected network bandwidth (Mbps)."

The throughput limit applies to the virtual machine. Throughput is not affected by these factors:

- **Number of network interfaces:** The bandwidth limit applies to the sum of all outbound traffic from the virtual machine.
- **Accelerated networking:** Though this feature can be helpful in achieving the published limit, it doesn't change the limit.
- **Traffic destination:** All destinations count toward the outbound limit.
- **Protocol:** All outbound traffic over all protocols counts towards the limit.

For more information, see [Virtual machine network bandwidth](#).

## Internet performance considerations

As discussed throughout this article, factors on the internet and outside the control of Azure can affect network performance. Here are some of those factors:

- **Latency:** The round-trip time between two destinations can be affected by issues on intermediate networks, by traffic that doesn't take the "shortest" distance path, and by suboptimal peering paths.
- **Packet loss:** Packet loss can be caused by network congestion, physical path issues, and underperforming network devices.
- **MTU size/Fragmentation:** Fragmentation along the path can lead to delays in data arrival or in packets arriving out of order, which can affect the delivery of packets.

Traceroute is a good tool for measuring network performance characteristics (like packet loss and latency) along every network path between a source device and a destination device.

## Network design considerations

Along with the considerations discussed earlier in this article, the topology of a virtual network can affect the network's performance. For example, a hub-and-spoke design that backhauls traffic globally to a single-hub virtual network will introduce network latency, which will affect overall network performance.

The number of network devices that network traffic passes through can also affect overall latency. For example, in a hub-and-spoke design, if traffic passes through a spoke network virtual appliance and a hub virtual appliance before transiting to the internet, the network virtual appliances can introduce latency.

## Azure regions, virtual networks, and latency

Azure regions are made up of multiple datacenters that exist within a general geographic area. These datacenters might not be physically next to each other. In some cases they're separated by as much as 10 kilometers. The virtual network is a logical overlay on top of the Azure physical datacenter network. A virtual network doesn't imply any specific network topology within the datacenter.

For example, two VMs that are in the same virtual network and subnet might be in different racks, rows, or even datacenters. They could be separated by feet of fiber optic cable or by kilometers of fiber optic cable. This

variation could introduce variable latency (a few milliseconds difference) between different VMs.

The geographic placement of VMs, and the potential resulting latency between two VMs, can be influenced by the configuration of availability sets and Availability Zones. But the distance between datacenters in a region is region-specific and primarily influenced by datacenter topology in the region.

### Source NAT port exhaustion

A deployment in Azure can communicate with endpoints outside of Azure on the public internet and/or in the public IP space. When an instance initiates an outbound connection, Azure dynamically maps the private IP address to a public IP address. After Azure creates this mapping, return traffic for the outbound originated flow can also reach the private IP address where the flow originated.

For every outbound connection, the Azure Load Balancer needs to maintain this mapping for some period of time. With the multitenant nature of Azure, maintaining this mapping for every outbound flow for every VM can be resource intensive. So there are limits that are set and based on the configuration of the Azure Virtual Network. Or, to say that more precisely, an Azure VM can only make a certain number of outbound connections at a given time. When these limits are reached, the VM won't be able to make more outbound connections.

But this behavior is configurable. For more information about SNAT and SNAT port exhaustion, see [this article](#).

## Measure network performance on Azure

A number of the performance maximums in this article are related to the network latency / round-trip time (RTT) between two VMs. This section provides some suggestions for how to test latency/RTT and how to test TCP performance and VM network performance. You can tune and performance test the TCP/IP and network values discussed earlier by using the techniques described in this section. You can plug latency, MTU, MSS, and window size values into the calculations provided earlier and compare theoretical maximums to actual values that you observe during testing.

### Measure round-trip time and packet loss

TCP performance relies heavily on RTT and packet Loss. The PING utility available in Windows and Linux provides the easiest way to measure RTT and packet loss. The output of PING will show the minimum/maximum/average latency between a source and destination. It will also show packet loss. PING uses the ICMP protocol by default. You can use PsPing to test TCP RTT. For more information, see [PsPing](#).

### Measure actual throughput of a TCP connection

NTttcp is a tool for testing the TCP performance of a Linux or Windows VM. You can change various TCP settings and then test the benefits by using NTttcp. For more information, see these resources:

- [Bandwidth/Throughput testing \(NTttcp\)](#)
- [NTttcp Utility](#)

### Measure actual bandwidth of a virtual machine

You can test the performance of different VM types, accelerated networking, and so on, by using a tool called iPerf. iPerf is also available on Linux and Windows. iPerf can use TCP or UDP to test overall network throughput. iPerf TCP throughput tests are influenced by the factors discussed in this article (like latency and RTT). So UDP might yield better results if you just want to test maximum throughput.

For more information, see these articles:

- [Troubleshooting Expressroute network performance](#)
- [How to validate VPN throughput to a virtual network](#)

### Detect inefficient TCP behaviors

In packet captures, Azure customers might see TCP packets with TCP flags (SACK, DUP ACK, RETRANSMIT, and

FAST RETRANSMIT) that could indicate network performance problems. These packets specifically indicate network inefficiencies that result from packet loss. But packet loss isn't necessarily caused by Azure performance problems. Performance problems could be the result of application problems, operating system problems, or other problems that might not be directly related to the Azure platform.

Also, keep in mind that some retransmission and duplicate ACKs are normal on a network. TCP protocols were built to be reliable. Evidence of these TCP packets in a packet capture doesn't necessarily indicate a systemic network problem, unless they're excessive.

Still, these packet types are indications that TCP throughput isn't achieving its maximum performance, for reasons discussed in other sections of this article.

## Next steps

Now that you've learned about TCP/IP performance tuning for Azure VMs, you might want to read about other considerations for [planning virtual networks](#) or [learn more about connecting and configuring virtual networks](#).

# Virtual machine network bandwidth

9/21/2022 • 3 minutes to read • [Edit Online](#)

Azure offers a variety of VM sizes and types, each with a different mix of performance capabilities. One capability is network throughput (or bandwidth), measured in megabits per second (Mbps). Because virtual machines are hosted on shared hardware, the network capacity must be shared fairly among the virtual machines sharing the same hardware. Larger virtual machines are allocated relatively more bandwidth than smaller virtual machines.

The network bandwidth allocated to each virtual machine is metered on egress (outbound) traffic from the virtual machine. All network traffic leaving the virtual machine is counted toward the allocated limit, regardless of destination. For example, if a virtual machine has a 1,000 Mbps limit, that limit applies whether the outbound traffic is destined for another virtual machine in the same virtual network, or outside of Azure.

Ingress is not metered or limited directly. However, there are other factors, such as CPU and storage limits, which can impact a virtual machine's ability to process incoming data.

Accelerated networking is a feature designed to improve network performance, including latency, throughput, and CPU utilization. While accelerated networking can improve a virtual machine's throughput, it can do so only up to the virtual machine's allocated bandwidth. To learn more about Accelerated networking, see Accelerated networking for [Windows](#) or [Linux](#) virtual machines.

Azure virtual machines must have one, but may have several, network interfaces attached to them. Bandwidth allocated to a virtual machine is the sum of all outbound traffic across all network interfaces attached to a virtual machine. In other words, the allocated bandwidth is per virtual machine, regardless of how many network interfaces are attached to the virtual machine. To learn how many network interfaces different Azure VM sizes support, see Azure [Windows](#) and [Linux](#) VM sizes.

## Expected network throughput

Expected outbound throughput and the number of network interfaces supported by each VM size is detailed in Azure [Windows](#) and [Linux](#) VM sizes. Select a type, such as General purpose, then select a size-series on the resulting page, such as the Dv2-series. Each series has a table with networking specifications in the last column titled, **Max NICs / Expected network performance (Mbps)**.

The throughput limit applies to the virtual machine. Throughput is unaffected by the following factors:

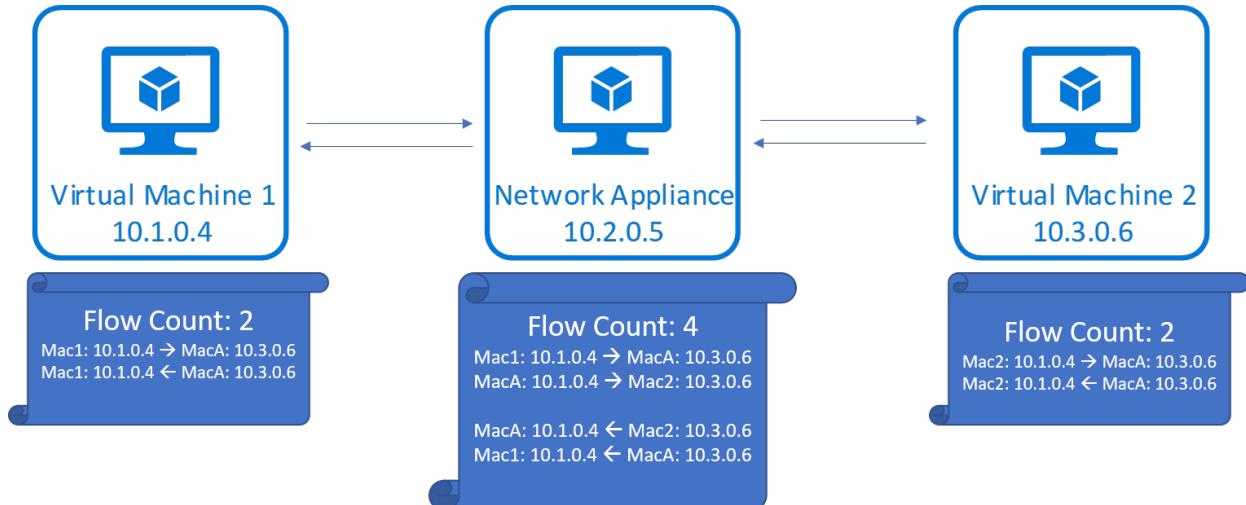

- **Number of network interfaces:** The bandwidth limit is cumulative of all outbound traffic from the virtual machine.
- **Accelerated networking:** Though the feature can be helpful in achieving the published limit, it does not change the limit.
- **Traffic destination:** All destinations count toward the outbound limit.
- **Protocol:** All outbound traffic over all protocols counts towards the limit.

## Network Flow Limits

In addition to bandwidth, the number of network connections present on a VM at any given time can affect its network performance. The Azure networking stack maintains state for each direction of a TCP/UDP connection in data structures called 'flows'. A typical TCP/UDP connection will have 2 flows created, one for the inbound and another for the outbound direction.

Data transfer between endpoints requires creation of several flows in addition to those that perform the data

transfer. Some examples are flows created for DNS resolution and flows created for load balancer health probes. Also note that network virtual appliances (NVAs) such as gateways, proxies, firewalls, will see flows being created for connections terminated at the appliance and originated by the appliance.

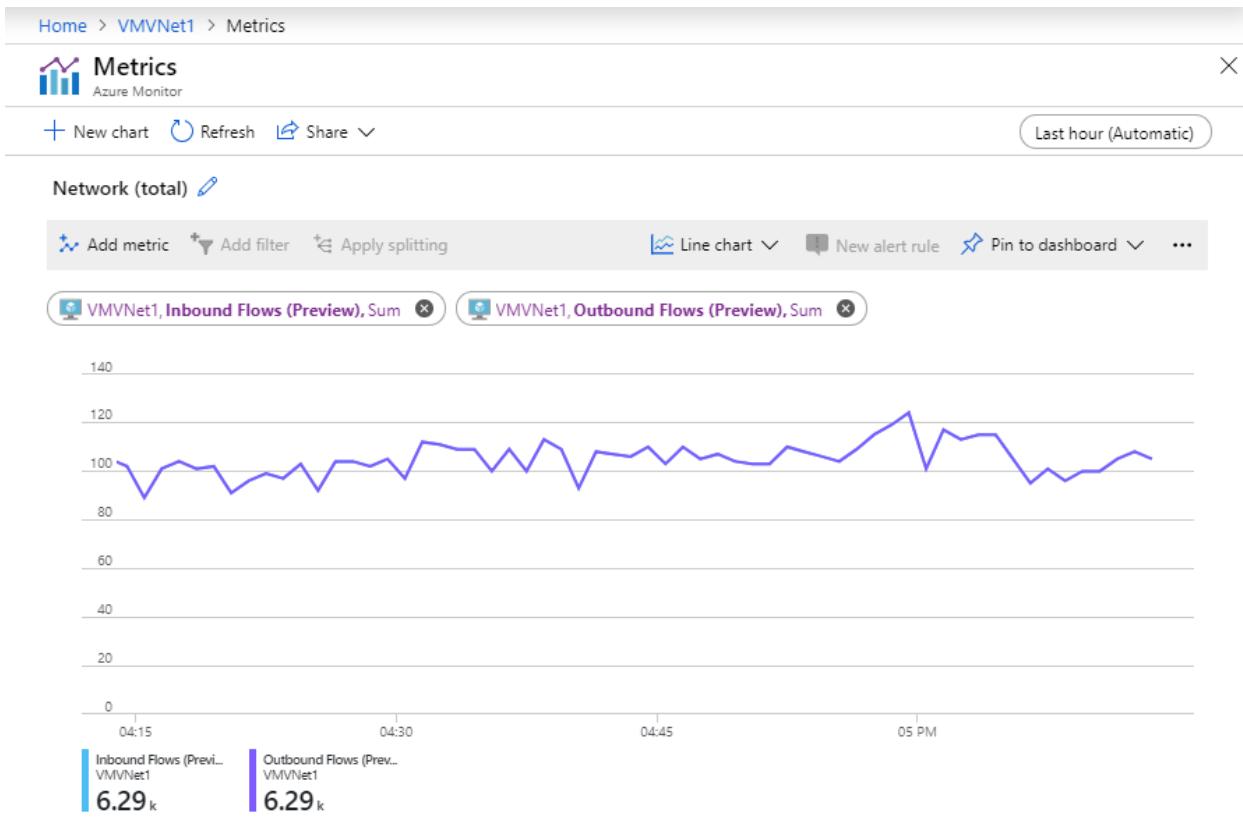

## Flow Limits and Active Connections Recommendations

Today, the Azure networking stack supports 1M total flows (500k inbound and 500k outbound) for a VM. Total active connections that can be handled by a VM in different scenarios are as follows.

- VMs that belong to VNET can handle 500k **active connections** for all VM sizes with 500k **active flows in each direction**.
- VMs with network virtual appliances (NVAs) such as gateway, proxy, firewall can handle 250k **active connections** with 500k **active flows in each direction** due to the forwarding and additional new flow creation on new connection setup to the next hop as shown in the above diagram.

Once this limit is hit, additional connections are dropped. Connection establishment and termination rates can also affect network performance as connection establishment and termination shares CPU with packet processing routines. We recommend that you benchmark workloads against expected traffic patterns and scale out workloads appropriately to match your performance needs.

Metrics are available in [Azure Monitor](#) to track the number of network flows and the flow creation rate on your VM or VMSS instances.

## Next steps

- Optimize network throughput for a virtual machine operating system
- Test network throughput for a virtual machine.

# Quickstart: Create and configure Azure DDoS Protection Standard

9/21/2022 • 5 minutes to read • [Edit Online](#)

Get started with Azure DDoS Protection Standard by using the Azure portal.

A DDoS protection plan defines a set of virtual networks that have DDoS Protection Standard enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions under a single AAD tenant to the same plan.

In this quickstart, you'll create a DDoS protection plan and link it to a virtual network.

## Prerequisites

- If you don't have an Azure subscription, create a [free account](#) before you begin.
- Sign in to the Azure portal at <https://portal.azure.com>. Ensure that your account is assigned to the [network contributor](#) role or to a [custom role](#) that is assigned the appropriate actions listed in the how-to guide on [Permissions](#).

## Create a DDoS protection plan

1. Select **Create a resource** in the upper left corner of the Azure portal.
2. Search the term *DDoS*. When **DDoS protection plan** appears in the search results, select it.
3. Select **Create**.
4. Enter or select the following values.

SETTING	VALUE
Subscription	Select your subscription.
Resource group	Select <b>Create new</b> and enter <b>MyResourceGroup</b> .
Name	Enter <b>MyDdosProtectionPlan</b> .
Region	Enter <b>East US</b> .

5. Select **Review + create** then **Create**

### NOTE

Although DDoS Protection Plan resources need to be associated with a region, users can enable DDoS protection on Virtual Networks in different regions and across multiple subscriptions under a single Azure Active Directory Tenant.

## Enable DDoS protection for a virtual network

### Enable DDoS protection for a new virtual network

1. Select **Create a resource** in the upper left corner of the Azure portal.

2. Select **Networking**, and then select **Virtual network**.

3. Enter or select the following values.

SETTING	VALUE
Subscription	Select your subscription.
Resource group	Select <b>Use existing</b> , and then select <b>MyResourceGroup</b>
Name	Enter <b>MyVnet</b> .
Region	Enter <b>East US</b> .

4. Select **Next: IP Addresses** and enter the following values.

SETTING	VALUE
IPv4 address space	Enter <b>10.1.0.0/16</b> .
Subnet name	Under <b>Subnet name</b> , select the <b>Add subnet</b> link and enter <b>mySubnet</b> .
Subnet address range	Enter <b>10.1.0.0/24</b> .

5. Select **Add**.

6. Select **Next: Security**.

7. Select **Enable** on the **DDoS Protection Standard** radio.

8. Select **MyDdosProtectionPlan** from the **DDoS protection plan** pane. The plan you select can be in the same, or different subscription than the virtual network, but both subscriptions must be associated to the same Azure Active Directory tenant.

9. Select **Review + create** then **Create**.

#### NOTE

You cannot move a virtual network to another resource group or subscription when DDoS Standard is enabled for the virtual network. If you need to move a virtual network with DDoS Standard enabled, disable DDoS Standard first, move the virtual network, and then enable DDoS standard. After the move, the auto-tuned policy thresholds for all the protected public IP addresses in the virtual network are reset.

#### Enable DDoS protection for an existing virtual network

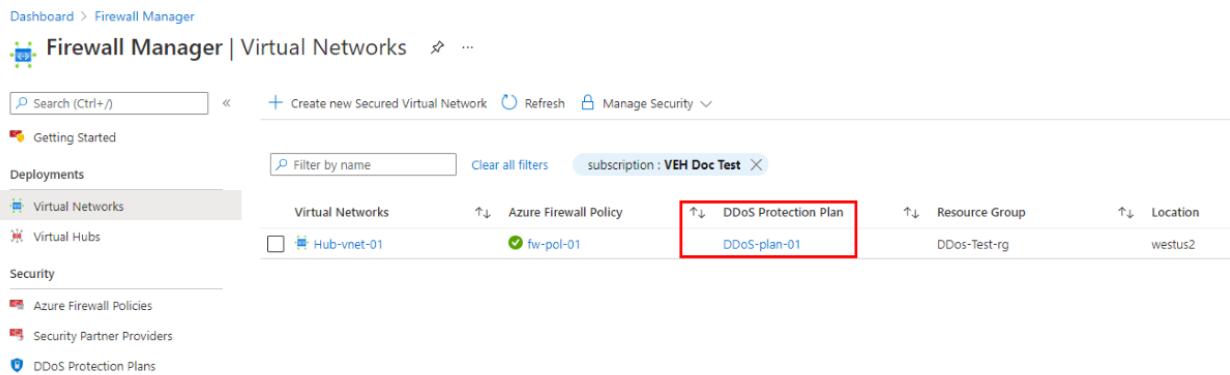

1. Create a DDoS protection plan by completing the steps in [Create a DDoS protection plan](#), if you don't have an existing DDoS protection plan.
2. Enter the name of the virtual network that you want to enable DDoS Protection Standard for in the **Search resources, services, and docs** box at the top of the Azure portal. When the name of the virtual network appears in the search results, select it.
3. Select **DDoS protection**, under **Settings**.
4. Select **Enable**. Under **DDoS protection plan**, select an existing DDoS protection plan, or the plan you created in step 1, and then click **Save**. The plan you select can be in the same, or different subscription than the virtual network, but both subscriptions must be associated to the same Azure Active Directory tenant.

You can also enable the DDoS protection plan for an existing virtual network from the DDoS Protection plan, not from the virtual network.

1. Search for "DDoS protection plans" in the **Search resources, services, and docs** box at the top of the Azure portal. When **DDoS protection plans** appears in the search results, select it.
2. Select the desired DDoS protection plan you want to enable for your virtual network.
3. Select **Protected resources** under **Settings**.
4. Click **+Add** and select the right subscription, resource group and the virtual network name. Click **Add** again.

## Configure an Azure DDoS Protection Plan using Azure Firewall Manager (preview)

Azure Firewall Manager is a platform to manage and protect your network resources at scale. You can associate your virtual networks with a DDoS protection plan within Azure Firewall Manager. This functionality is currently available in Public Preview. See [Configure an Azure DDoS Protection Plan using Azure Firewall Manager](#).

The screenshot shows the Azure Firewall Manager interface. On the left, there's a sidebar with links like 'Getting Started', 'Deployments', 'Virtual Networks' (which is selected and highlighted in grey), 'Virtual Hubs', 'Security', 'Azure Firewall Policies', 'Security Partner Providers', and 'DDoS Protection Plans'. The main area has a header with 'Search (Ctrl+J)', '+ Create new Secured Virtual Network', 'Refresh', and 'Manage Security'. Below the header, there's a filter bar with 'Filter by name' and 'Clear all filters', and a dropdown for 'subscription : VEH Doc Test'. The main table lists virtual networks with columns: 'Virtual Networks' (containing 'Hub-vnet-01'), 'Azure Firewall Policy' (containing 'fw-pol-01'), 'DDoS Protection Plan' (containing 'DDoS-plan-01' which is highlighted with a red box), 'Resource Group' (containing 'Ddos-Test-rg'), and 'Location' (containing 'westus2').

## Enable DDoS protection for all virtual networks

This [built-in policy](#) will detect any virtual networks in a defined scope that don't have DDoS Protection Standard enabled. This policy will then optionally create a remediation task that will create the association to protect the Virtual Network. See [Azure Policy built-in definitions for Azure DDoS Protection Standard](#) for full list of built-in policies.

## Validate and test

First, check the details of your DDoS protection plan:

1. Select **All services** on the top, left of the portal.
2. Enter **DDoS** in the **Filter** box. When **DDoS protection plans** appear in the results, select it.
3. Select your DDoS protection plan from the list.

The *MyVnet* virtual network should be listed.

## View protected resources

Under **Protected resources**, you can view your protected virtual networks and public IP addresses, or add more virtual networks to your DDoS protection plan:

The screenshot shows the Azure portal interface for managing a DDoS protection plan. The left sidebar has a tree view with 'Protected resources' selected under 'ddosplanav | Protected resources'. The main area displays a table of resources with columns: Public IP address, Virtual network, Application gateway, and Subscription. The table shows four entries: myAppGatewayDDoSCTest, NewDDoSvNET, myAppGatewayDDoS, Azure DDoS Protection Demo Sub; newddosappgwip, ddostest, ddosbillingappgw, Azure DDoS Protection Demo Sub; ddostest, appgw-vnet-wcu, appgw-wcu, Azure DDoS Protection Demo Sub; and appgw-wcu, appgw-wcu, appgw-wcu, Azure DDoS Protection Demo Sub.

## Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* resource group. When you delete the resource group, you also delete the DDoS protection plan and all its related resources. If you don't intend to use this DDoS protection plan, you should remove resources to avoid unnecessary charges.

### WARNING

This action is irreversible.

1. In the Azure portal, search for and select **Resource groups**, or select **Resource groups** from the Azure portal menu.
2. Filter or scroll down to find the *MyResourceGroup* resource group.
3. Select the resource group, then select **Delete resource group**.
4. Type the resource group name to verify, and then select **Delete**.

To disable DDoS protection for a virtual network:

1. Enter the name of the virtual network you want to disable DDoS protection standard for in the **Search resources, services, and docs** box at the top of the portal. When the name of the virtual network appears in the search results, select it.
2. Under **DDoS Protection Standard**, select **Disable**.

### NOTE

If you want to delete a DDoS protection plan, you must first dissociate all virtual networks from it.

## Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

[View and configure DDoS protection telemetry](#)

# Quickstart: Create and configure Azure DDoS Protection Standard using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Get started with Azure DDoS Protection Standard by using Azure PowerShell.

A DDoS protection plan defines a set of virtual networks that have DDoS protection standard enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.

In this quickstart, you'll create a DDoS protection plan and link it to a virtual network.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- Azure PowerShell installed locally or Azure Cloud Shell

### NOTE

To interact with Azure, the Azure Az PowerShell module is recommended. See [Install Azure PowerShell](#) to get started. To learn how to migrate to the Az PowerShell module, see [Migrate Azure PowerShell from AzureRM to Az](#).

## Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

OPTION	EXAMPLE/LINK
Select Try It in the upper-right corner of a code or command block. Selecting Try It doesn't automatically copy the code or command to Cloud Shell.	
Go to <a href="https://shell.azure.com">https://shell.azure.com</a> , or select the Launch Cloud Shell button to open Cloud Shell in your browser.	
Select the Cloud Shell button on the menu bar at the upper right in the <a href="#">Azure portal</a> .	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl+Shift+V** on Windows and Linux, or by selecting **Cmd+Shift+V** on macOS.

4. Select Enter to run the code or command.

## Create a DDoS Protection plan

In Azure, you allocate related resources to a resource group. You can either use an existing resource group or create a new one.

To create a resource group, use [New-AzResourceGroup](#). In this example, we'll name our resource group *MyResourceGroup* and use the *East US* location:

```
New-AzResourceGroup -Name MyResourceGroup -Location "East US"
```

Now create a DDoS protection plan named *MyDdosProtectionPlan*:

```
New-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name MyDdosProtectionPlan -Location "East US"
```

## Enable DDoS for a virtual network

### Enable DDoS for a new virtual network

You can enable DDoS protection when creating a virtual network. In this example, we'll name our virtual network *MyVnet*.

```
#Gets the DDoS protection plan ID  
$ddosProtectionPlanID = Get-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name  
MyDdosProtectionPlan  
  
#Creates the virtual network  
New-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup -Location "East US" -AddressPrefix  
10.0.0.0/16 -DdosProtectionPlan $ddosProtectionPlanID -EnableDdosProtection
```

### Enable DDoS for an existing virtual network

You can associate an existing virtual network when creating a DDoS protection plan:

```
#Gets the DDoS protection plan ID  
$ddosProtectionPlanID = Get-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name  
MyDdosProtectionPlan  
  
# Gets the most updated version of the virtual network  
$vnet = Get-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup  
$vnet.DdosProtectionPlan = New-Object Microsoft.Azure.Commands.Network.Models.PSResourceId  
  
# Update the properties and enable DDoS protection  
$vnet.DdosProtectionPlan.Id = $ddosProtectionPlanID.Id  
$vnet.EnableDdosProtection = $true  
$vnet | Set-AzVirtualNetwork
```

## Validate and test

Check the details of your DDoS protection plan and verify that the command returns the correct details of your DDoS protection plan.

```
Get-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name MyDdosProtectionPlan
```

Check the details of your vNet and verify the DDoS protection plan is enabled.

```
Get-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup
```

## Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* resource group. When you delete the resource group, you also delete the DDoS protection plan and all its related resources.

```
Remove-AzResourceGroup -Name MyResourceGroup
```

To disable DDoS protection for a virtual network:

```
# Gets the most updated version of the virtual network
$vnet = Get-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup
$vnet.DdosProtectionPlan = $null
$vnet.EnableDdosProtection = $false
$vnet | Set-AzVirtualNetwork
```

If you want to delete a DDoS protection plan, you must first dissociate all virtual networks from it.

## Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

[View and configure DDoS protection telemetry](#)

# Quickstart: Create and configure Azure DDoS Protection Standard using Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

Get started with Azure DDoS Protection Standard by using Azure CLI.

A DDoS protection plan defines a set of virtual networks that have DDoS protection standard enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.

In this quickstart, you'll create a DDoS protection plan and link it to a virtual network.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- Azure CLI installed locally or Azure Cloud Shell

## Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

OPTION	EXAMPLE/LINK
Select Try It in the upper-right corner of a code or command block. Selecting Try It doesn't automatically copy the code or command to Cloud Shell.	
Go to <a href="https://shell.azure.com">https://shell.azure.com</a> , or select the Launch Cloud Shell button to open Cloud Shell in your browser.	
Select the Cloud Shell button on the menu bar at the upper right in the <a href="#">Azure portal</a> .	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl+Shift+V** on Windows and Linux, or by selecting **Cmd+Shift+V** on macOS.
4. Select **Enter** to run the code or command.

If you choose to install and use the CLI locally, this quickstart requires Azure CLI version 2.0.56 or later. To find the version, run `az --version`. If you need to install or upgrade, see [Install the Azure CLI](#).

# Create a DDoS Protection plan

In Azure, you allocate related resources to a resource group. You can either use an existing resource group or create a new one.

To create a resource group, use [az group create](#). In this example, we'll name our resource group *MyResourceGroup* and use the *East US* location:

```
az group create \
--name MyResourceGroup \
--location eastus
```

Now create a DDoS protection plan named *MyDdosProtectionPlan*:

```
az network ddos-protection create \
--resource-group MyResourceGroup \
--name MyDdosProtectionPlan
```

## Enable DDoS protection for a virtual network

### Enable DDoS protection for a new virtual network

You can enable DDoS protection when creating a virtual network. In this example, we'll name our virtual network *MyVnet*.

```
az network vnet create \
--resource-group MyResourceGroup \
--name MyVnet \
--location eastus \
--ddos-protection-plan MyDdosProtectionPlan \
--ddos-protection true
```

#### NOTE

You cannot move a virtual network to another resource group or subscription when DDoS Standard is enabled for the virtual network. If you need to move a virtual network with DDoS Standard enabled, disable DDoS Standard first, move the virtual network, and then enable DDoS standard. After the move, the auto-tuned policy thresholds for all the protected public IP addresses in the virtual network are reset.

### Enable DDoS protection for an existing virtual network

When [creating a DDoS protection plan](#), you can associate one or more virtual networks to the plan. To add more than one virtual network, simply list the names or IDs, space-separated. In this example, we'll add *MyVnet*.

```
az group create \
--name MyResourceGroup \
--location eastus

az network ddos-protection create \
--resource-group MyResourceGroup \
--name MyDdosProtectionPlan \
--vnets MyVnet
```

Alternatively, you can enable DDoS protection for a given virtual network:

```
az network vnet update \
--resource-group MyResourceGroup \
--name MyVnet \
--ddos-protection-plan MyDdosProtectionPlan \
--ddos-protection true
```

## Validate and test

First, check the details of your DDoS protection plan:

```
az network ddos-protection show \
--resource-group MyResourceGroup \
--name MyDdosProtectionPlan
```

Verify that the command returns the correct details of your DDoS protection plan.

## Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* resource group. When you delete the resource group, you also delete the DDoS protection plan and all its related resources.

To delete the resource group use [az group delete](#):

```
az group delete \
--name MyResourceGroup
```

Update a given virtual network to disable DDoS protection:

```
az network vnet update \
--resource-group MyResourceGroup \
--name MyVnet \
--ddos-protection-plan MyDdosProtectionPlan \
--ddos-protection false
```

If you want to delete a DDoS protection plan, you must first dissociate all virtual networks from it.

## Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

[View and configure DDoS protection telemetry](#)

# Quickstart: Create an Azure DDoS Protection Standard using ARM template

9/21/2022 • 3 minutes to read • [Edit Online](#)

This quickstart describes how to use an Azure Resource Manager template (ARM template) to create a distributed denial of service (DDoS) protection plan and virtual network (VNet), then enables the protection plan for the VNet. An Azure DDoS Protection Standard plan defines a set of virtual networks that have DDoS protection enabled across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.

An [ARM template](#) is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

## Prerequisites

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Review the template

The template used in this quickstart is from [Azure Quickstart Templates](#).

```
{  
  "$schema": "https://schema.management.azure.com/schemas/2019-04-01/deploymentTemplate.json#",  
  "contentVersion": "1.0.0.0",  
  "metadata": {

            "metadata": {
                "description": "Specify the virtual network subnet prefix"
            }
        },
        "ddosProtectionPlanEnabled": {
            "type": "bool",
            "defaultValue": true,
            "metadata": {
                "description": "Enable DDoS protection plan."
            }
        }
    },
    "resources": [
        {
            "type": "Microsoft.Network/ddosProtectionPlans",
            "apiVersion": "2021-05-01",
            "name": "[parameters('ddosProtectionPlanName')]",
            "location": "[parameters('location')]"
        },
        {
            "type": "Microsoft.Network/virtualNetworks",
            "apiVersion": "2021-05-01",
            "name": "[parameters('virtualNetworkName')]",
            "location": "[parameters('location')]",
            "properties": {
                "addressSpace": {
                    "addressPrefixes": [
                        "[parameters('vnetAddressPrefix')]"
                    ]
                },
                "subnets": [
                    {
                        "name": "default",
                        "properties": {
                            "addressPrefix": "[parameters('subnetPrefix')]"
                        }
                    }
                ],
                "enableDdosProtection": "[parameters('ddosProtectionPlanEnabled')]",
                "ddosProtectionPlan": {
                    "id": "[resourceId('Microsoft.Network/ddosProtectionPlans',
parameters('ddosProtectionPlanName'))]"
                }
            },
            "dependsOn": [
                "[resourceId('Microsoft.Network/ddosProtectionPlans', parameters('ddosProtectionPlanName'))]"
            ]
        }
    ]
}

```

The template defines two resources:

- [Microsoft.Network/ddosProtectionPlans](#)
- [Microsoft.Network/virtualNetworks](#)

# Deploy the template

In this example, the template creates a new resource group, a DDoS protection plan, and a VNet.

1. To sign in to Azure and open the template, select the **Deploy to Azure** button.

2. Enter the values to create a new resource group, DDoS protection plan, and VNet name.

The screenshot shows the 'Create and enable a DDOS protection plan' template in the Azure portal. It's a 'Template' type with 2 resources. The 'Subscription' dropdown is set to 'Azure subscription name'. The 'Resource group' dropdown is set to '(New) MyResourceGroup', which is highlighted with a red box. The 'Region' dropdown is set to 'East US'. The 'Ddos Protection Plan Name' dropdown is set to 'MyDdosProtectionPlan'. The 'Virtual Network Name' dropdown is set to 'MyVNet'. Other fields like 'Location', 'Vnet Address Prefix', 'Subnet Prefix', and 'Ddos Protection Plan Enabled' are also visible. At the bottom, there are 'Review + create' and 'Next : Review + create >' buttons.

- **Subscription:** Name of the Azure subscription where the resources will be deployed.
- **Resource group:** Select an existing resource group or create a new resource group.
- **Region:** The region where the resource group is deployed, such as East US.
- **Ddos Protection Plan Name:** The name of for the new DDoS protection plan.
- **Virtual Network Name:** Creates a name for the new VNet.
- **Location:** Function that uses the same region as the resource group for resource deployment.
- **Vnet Address Prefix:** Use the default value or enter your VNet address.
- **Subnet Prefix:** Use the default value or enter your VNet subnet.
- **Ddos Protection Plan Enabled:** Default is `true` to enable the DDoS protection plan.

3. Select **Review + create**.

4. Verify that template validation passed and select **Create** to begin the deployment.

## Review deployed resources

To copy the Azure CLI or Azure PowerShell command, select the **Copy** button. The **Try it** button opens Azure Cloud Shell to run the command.

- [CLI](#)
- [PowerShell](#)

```
az network ddos-protection show \
--resource-group MyResourceGroup \
--name MyDdosProtectionPlan
```

The output shows the new resources.

- [CLI](#)
- [PowerShell](#)

```
{
  "etag": "W/\"abcdefg-1111-2222-bbbb-987654321098\"",
  "id": "/subscriptions/b1111111-2222-3333-aaaa-
012345678912/resourceGroups/MyResourceGroup/providers/Microsoft.Network/ddosProtectionPlans/MyDdosProtection
Plan",
  "location": "eastus",
  "name": "MyDdosProtectionPlan",
  "provisioningState": "Succeeded",
  "resourceGroup": "MyResourceGroup",
  "resourceGuid": null,
  "tags": null,
  "type": "Microsoft.Network/ddosProtectionPlans",
  "virtualNetworks": [
    {
      "id": "/subscriptions/b1111111-2222-3333-aaaa-
012345678912/resourceGroups/MyResourceGroup/providers/Microsoft.Network/virtualNetworks/MyVNet",
      "resourceGroup": "MyResourceGroup"
    }
  ]
}
```

## Clean up resources

When you're finished you can delete the resources. The command deletes the resource group and all the resources it contains.

- [CLI](#)
- [PowerShell](#)

```
az group delete --name MyResourceGroup
```

## Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

[View and configure DDoS protection telemetry](#)

# Open ports and endpoints to a VM with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You open a port, or create an endpoint, to a virtual machine (VM) in Azure by creating a network filter on a subnet or VM network interface. You place these filters, which control both inbound and outbound traffic, on a Network Security Group attached to the resource that receives the traffic. Let's use a common example of web traffic on port 80. This article shows you how to open a port to a VM with the Azure CLI.

To create a Network Security Group and rules you need the latest [Azure CLI](#) installed and logged in to an Azure account using [az login](#).

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myNetworkSecurityGroup*, and *myVnet*.

## Quickly open a port for a VM

If you need to quickly open a port for a VM in a dev/test scenario, you can use the [az vm open-port](#) command. This command creates a Network Security Group, adds a rule, and applies it to a VM or subnet. The following example opens port *80* on the VM named *myVM* in the resource group named *myResourceGroup*.

```
az vm open-port --resource-group myResourceGroup --name myVM --port 80
```

For more control over the rules, such as defining a source IP address range, continue with the additional steps in this article.

## Create a Network Security Group and rules

Create the network security group with [az network nsg create](#). The following example creates a network security group named *myNetworkSecurityGroup* in the *eastus* location:

```
az network nsg create \
--resource-group myResourceGroup \
--location eastus \
--name myNetworkSecurityGroup
```

Add a rule with [az network nsg rule create](#) to allow HTTP traffic to your webserver (or adjust for your own scenario, such as SSH access or database connectivity). The following example creates a rule named *myNetworkSecurityGroupRule* to allow TCP traffic on port 80:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name myNetworkSecurityGroupRule \
--protocol tcp \
--priority 1000 \
--destination-port-range 80
```

## Apply Network Security Group to VM

Associate the Network Security Group with your VM's network interface (NIC) with [az network nic update](#). The following example associates an existing NIC named *myNic* with the Network Security Group named *myNetworkSecurityGroup*.

```
az network nic update \
--resource-group myResourceGroup \
--name myNic \
--network-security-group myNetworkSecurityGroup
```

Alternatively, you can associate your Network Security Group with a virtual network subnet with [az network vnet subnet update](#) rather than just to the network interface on a single VM. The following example associates an existing subnet named *mySubnet* in the *myVnet* virtual network with the Network Security Group named *myNetworkSecurityGroup*.

```
az network vnet subnet update \
--resource-group myResourceGroup \
--vnet-name myVnet \
--name mySubnet \
--network-security-group myNetworkSecurityGroup
```

## More information on Network Security Groups

The quick commands here allow you to get up and running with traffic flowing to your VM. Network Security Groups provide many great features and granularity for controlling access to your resources. You can read more about [creating a Network Security Group and ACL rules here](#).

For highly available web applications, you should place your VMs behind an Azure Load Balancer. The load balancer distributes traffic to VMs, with a Network Security Group that provides traffic filtering. For more information, see [How to load balance Linux virtual machines in Azure to create a highly available application](#).

## Next steps

In this example, you created a simple rule to allow HTTP traffic. You can find information on creating more detailed environments in the following articles:

- [Azure Resource Manager overview](#)
- [What is a Network Security Group \(NSG\)?](#)

# How to open ports and endpoints to a VM using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

You open a port, or create an endpoint, to a virtual machine (VM) in Azure by creating a network filter on a subnet or a VM network interface. You place these filters, which control both inbound and outbound traffic, on a network security group attached to the resource that receives the traffic.

The example in this article demonstrates how to create a network filter that uses the standard TCP port 80 (it's assumed you've already started the appropriate services and opened any OS firewall rules on the VM).

After you've created a VM that's configured to serve web requests on the standard TCP port 80, you can:

1. Create a network security group.
2. Create an inbound security rule allowing traffic and assign values to the following settings:
  - **Destination port ranges:** 80
  - **Source port ranges:** \* (allows any source port)
  - **Priority value:** Enter a value that is less than 65,500 and higher in priority than the default catch-all deny inbound rule.
3. Associate the network security group with the VM network interface or subnet.

Although this example uses a simple rule to allow HTTP traffic, you can also use network security groups and rules to create more complex network configurations.

## Quick commands

To create a Network Security Group and ACL rules you need [the latest version of Azure PowerShell installed](#). You can also [perform these steps using the Azure portal](#).

Log in to your Azure account:

```
Connect-AzAccount
```

In the following examples, replace parameter names with your own values. Example parameter names included *myResourceGroup*, *myNetworkSecurityGroup*, and *myVnet*.

Create a rule with [New-AzNetworkSecurityRuleConfig](#). The following example creates a rule named *myNetworkSecurityGroupRule* to allow *tcp* traffic on port *80*:

```
$httprule = New-AzNetworkSecurityRuleConfig `  
    -Name "myNetworkSecurityGroupRule" `  
    -Description "Allow HTTP" `  
    -Access "Allow" `  
    -Protocol "Tcp" `  
    -Direction "Inbound" `  
    -Priority 100 `  
    -SourceAddressPrefix "Internet" `  
    -SourcePortRange * `  
    -DestinationAddressPrefix * `  
    -DestinationPortRange "80"
```

Next, create your Network Security group with [New-AzNetworkSecurityGroup](#) and assign the HTTP rule you just created as follows. The following example creates a Network Security Group named *myNetworkSecurityGroup*:

```
$nsg = New-AzNetworkSecurityGroup `  
    -ResourceGroupName "myResourceGroup" `  
    -Location "EastUS" `  
    -Name "myNetworkSecurityGroup" `  
    -SecurityRules $httprule
```

Now let's assign your Network Security Group to a subnet. The following example assigns an existing virtual network named *myVnet* to the variable `$vnet` with [Get-AzVirtualNetwork](#):

```
$vnet = Get-AzVirtualNetwork `  
    -ResourceGroupName "myResourceGroup" `  
    -Name "myVnet"
```

Associate your Network Security Group with your subnet with [Set-AzVirtualNetworkSubnetConfig](#). The following example associates the subnet named *mySubnet* with your Network Security Group:

```
$subnetPrefix = $vnet.Subnets | ?{$_ . Name -eq 'mySubnet'}`  
  
Set-AzVirtualNetworkSubnetConfig `  
    -VirtualNetwork $vnet `  
    -Name "mySubnet" `  
    -AddressPrefix $subnetPrefix.AddressPrefix `  
    -NetworkSecurityGroup $nsg
```

Finally, update your virtual network with [Set-AzVirtualNetwork](#) in order for your changes to take effect:

```
Set-AzVirtualNetwork -VirtualNetwork $vnet
```

## More information on Network Security Groups

The quick commands here allow you to get up and running with traffic flowing to your VM. Network Security Groups provide many great features and granularity for controlling access to your resources. You can read more about [creating a Network Security Group and ACL rules here](#).

For highly available web applications, you should place your VMs behind an Azure Load Balancer. The load balancer distributes traffic to VMs, with a Network Security Group that provides traffic filtering. For more information, see [How to load balance Linux virtual machines in Azure to create a highly available application](#).

## Next steps

In this example, you created a simple rule to allow HTTP traffic. You can find information on creating more detailed environments in the following articles:

- [Azure Resource Manager overview](#)
- [What is a network security group?](#)
- [Azure Load Balancer Overview](#)

# How to open ports to a virtual machine with the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

You open a port, or create an endpoint, to a virtual machine (VM) in Azure by creating a network filter on a subnet or a VM network interface. You place these filters, which control both inbound and outbound traffic, on a network security group attached to the resource that receives the traffic.

The example in this article demonstrates how to create a network filter that uses the standard TCP port 80 (it's assumed you've already started the appropriate services and opened any OS firewall rules on the VM).

After you've created a VM that's configured to serve web requests on the standard TCP port 80, you can:

1. Create a network security group.
2. Create an inbound security rule allowing traffic and assign values to the following settings:
  - **Destination port ranges:** 80
  - **Source port ranges:** \* (allows any source port)
  - **Priority value:** Enter a value that is less than 65,500 and higher in priority than the default catch-all deny inbound rule.
3. Associate the network security group with the VM network interface or subnet.

Although this example uses a simple rule to allow HTTP traffic, you can also use network security groups and rules to create more complex network configurations.

## Sign in to Azure

Sign in to the Azure portal at <https://portal.azure.com>.

## Create a network security group

1. Search for and select the resource group for the VM, choose **Add**, then search for and select **Network security group**.
2. Select **Create**.

The **Create network security group** window opens.

## Create network security group

Basics Tags Review + create

Project details

Subscription \* myAzureSubscription

Resource group \* myresourcegroup [Create new](#)

[Review + create](#) [< Previous](#) [Next : Tags >](#) [Download a template for automation](#)

3. Enter a name for your network security group.
4. Select or create a resource group, then select a location.
5. Select **Create** to create the network security group.

## Create an inbound security rule

1. Select your new network security group.
2. Select **Inbound security rules** from the left menu, then select **Add**.

## Add inbound security rule

Description

**Add** **Cancel**

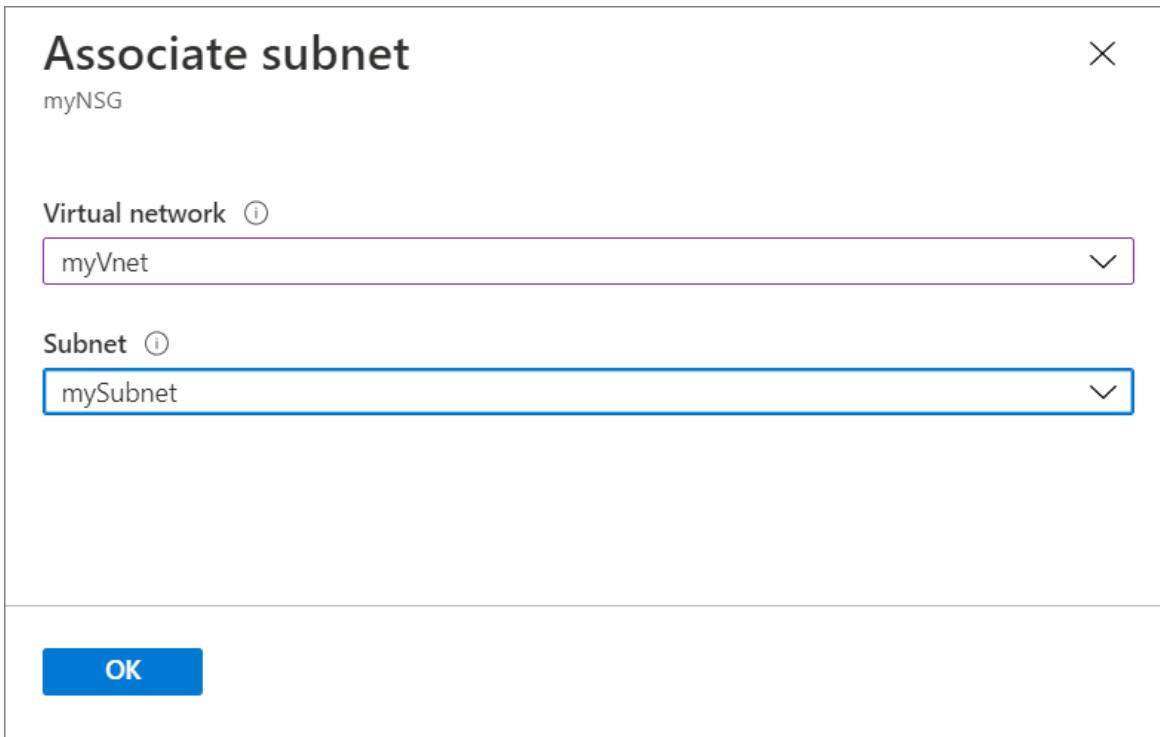

3. You can limit the **Source** and **Source port ranges** as needed or leave the default of *Any*.
4. You can limit the **Destination** as needed or leave the default of *Any*.
5. Choose a common **Service** from the drop-down menu, such as **HTTP**. You can also select **Custom** if you want to provide a specific port to use.
6. Optionally, change the **Priority** or **Name**. The priority affects the order in which rules are applied: the lower the numerical value, the earlier the rule is applied.
7. Select **Add** to create the rule.

## Associate your network security group with a subnet

Your final step is to associate your network security group with a subnet or a specific network interface. For this example, we'll associate the network security group with a subnet.

1. Select **Subnets** from the left menu, then select **Associate**.

2. Select your virtual network, and then select the appropriate subnet.

3. When you are done, select OK.

## Additional information

You can also [perform the steps in this article by using Azure PowerShell](#).

The commands described in this article allow you to quickly get traffic flowing to your VM. Network security groups provide many great features and granularity for controlling access to your resources. For more information, see [Filter network traffic with a network security group](#).

For highly available web applications, consider placing your VMs behind an Azure load balancer. The load balancer distributes traffic to VMs, with a network security group that provides traffic filtering. For more information, see [Load balance Windows virtual machines in Azure to create a highly available application](#).

## Next steps

In this article, you created a network security group, created an inbound rule that allows HTTP traffic on port 80, and then associated that rule with a subnet.

You can find information on creating more detailed environments in the following articles:

- [Azure Resource Manager overview](#)
- [Security groups](#)

# Tutorial: Migrate a virtual machine public IP address to Azure Virtual Network NAT

9/21/2022 • 4 minutes to read • [Edit Online](#)

In this article, you'll learn how to migrate your virtual machine's public IP address to a NAT gateway. You'll learn how to remove the IP address from the virtual machine. You'll reuse the IP address from the virtual machine for the NAT gateway.

Azure Virtual Network NAT is the recommended method for outbound connectivity. A NAT gateway is a fully managed and highly resilient Network Address Translation (NAT) service. A NAT gateway doesn't have the same limitations of SNAT port exhaustion as default outbound access. A NAT gateway replaces the need for a virtual machine to have a public IP address to have outbound connectivity.

For more information about Azure Virtual Network NAT, see [What is Azure Virtual Network NAT](#)

In this tutorial, you learn how to:

- Remove the public IP address from the virtual machine.
- Associate the public IP address from the virtual machine with a NAT gateway.

## Prerequisites

- An Azure account with an active subscription. [Create an account for free](#).
- An Azure Virtual Machine with a public IP address assigned to its network interface. For more information on creating a virtual machine with a public IP, see [Quickstart: Create a Windows virtual machine in the Azure portal](#).
  - For the purposes of this article, the example virtual machine is named **myVM**. The example public IP address is named **myPublicIP**.

### NOTE

Removal of the public IP address prevents direct connections to the virtual machine from the internet. RDP or SSH access won't function to the virtual machine after you complete this migration. To securely manage virtual machines in your subscription, use Azure Bastion. For more information on Azure Bastion, see [What is Azure Bastion?](#)

## Remove public IP from virtual machine

In this section, you'll learn how to remove the public IP address from the virtual machine.

1. Sign in to the [Azure portal](#).
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines**.
3. In **Virtual machines**, select **myVM** or your virtual machine.
4. In the **Overview** of **myVM**, select **Public IP address**.

7. Select **Yes** in **Dissociate public IP address**.

#### (Optional) Upgrade IP address

The NAT gateway resource in Azure Virtual Network NAT requires a standard SKU public IP address. In this section, you'll upgrade the IP you removed from the virtual machine in the previous section. If the IP address you removed is already a standard SKU public IP, you can proceed to the next section.

1. In the search box at the top of the portal, enter **Public IP**. Select **Public IP addresses**.
2. In **Public IP addresses**, select **myPublicIP** or your basic SKU IP address.
3. In the **Overview** of **myPublicIP**, select the IP address upgrade banner.

Upgrade to Standard SKU

You won't be able to revert the Standard Public IP address back to Basic SKU once you upgrade it. There is a cost associated with Standard Public IP address whereas Basic Public IP address is free. For comparison and pricing, [Learn more](#).

I acknowledge.

Upgrade Cancel

- When the upgrade is complete, proceed to the next section.

## Create NAT gateway

In this section, you'll create a NAT gateway with the IP address you previously removed from the virtual machine. You'll assign the NAT gateway to your pre-created subnet within your virtual network. The subnet name for this example is **default**.

- In the search box at the top of the portal, enter **NAT gateway**. Select **NAT gateways**.
- In **NAT gateways**, select **+ Create**.
- In **Create network address translation (NAT) gateway**, enter or select the following information in the **Basics** tab.

SETTING	VALUE
<b>Project details</b>	
Subscription	Select your subscription.
Resource group	Select <b>Create new</b> . Enter <b>myResourceGroup</b> . Select <b>OK</b> .
<b>Instance details</b>	
NAT gateway name	Enter <b>myNATgateway</b> .
Region	Select the region of your virtual network. In this example, it's <b>West US 2</b> .

SETTING	VALUE
Availability zone	Leave the default of <b>None</b> .
Idle timeout (minutes)	Enter <b>10</b> .

4. Select the **Outbound IP** tab, or select **Next: Outbound IP** at the bottom of the page.
5. In **Public IP addresses** in the **Outbound IP** tab, select the IP address from the previous section in **Public IP addresses**. In this example, it's **myPublicIP**.
6. Select the **Subnet** tab, or select **Next: Subnet** at the bottom of the page.
7. In the pull-down box for **Virtual network**, select your virtual network.
8. In **Subnet name**, select the checkbox for your subnet. In this example, it's **default**.
9. Select the **Review + create** tab, or select **Review + create** at the bottom of the page.
10. Select **Create**.

## Clean up resources

If you're not going to continue to use this application, delete the NAT gateway with the following steps:

1. From the left-hand menu, select **Resource groups**.
2. Select the **myResourceGroup** resource group.
3. Select **Delete resource group**.
4. Enter **myResourceGroup** and select **Delete**.

## Next steps

In this article, you learned how to:

- Remove a public IP address from a virtual machine.
- Create a NAT gateway and use the public IP address from the virtual machine for the NAT gateway resource.

Any virtual machine created within this subnet won't require a public IP address and will automatically have outbound connectivity. For more information about NAT gateway and the connectivity benefits it provides, see [Design virtual networks with NAT gateway](#).

Advance to the next article to learn how to migrate default outbound access to Azure Virtual Network NAT:

[Migrate outbound access to NAT gateway](#)

# Create a virtual machine with a static public IP address using the Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

In this article, you'll create a VM with a static public IP address. A public IP address enables communication to a virtual machine from the internet. Assign a static public IP address, instead of a dynamic address, to ensure the address never changes.

Public IP addresses have a [nominal charge](#). There's a [limit](#) to the number of public IP addresses that you can use per subscription.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the [az login](#) command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run [az version](#) to find the version and dependent libraries that are installed. To upgrade to the latest version, run [az upgrade](#).
- An Azure account with an active subscription. [Create an account for free](#).
- This tutorial requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with [az group create](#) named **myResourceGroup** in the **eastus2** location.

```
az group create \
--name myResourceGroup \
--location eastus2
```

## Create a public IP address

Use [az network public-ip create](#) to create a standard public IPv4 address.

The following command creates a zone-redundant public IP address named **myPublicIP** in

myResourceGroup.

```
az network public-ip create \
--resource-group myResourceGroup \
--name myPublicIP \
--version IPv4 \
--sku Standard \
--zone 1 2 3
```

## Create a virtual machine

Create a virtual machine with [az vm create](#).

The following command creates a Windows Server virtual machine. You'll enter the name of the public IP address created previously in the `-PublicIPAddressName` parameter. When prompted, provide a username and password to be used as the credentials for the virtual machine:

```
az vm create \
--name myVM \
--resource-group TutorVMRoutePref-rg \
--public-ip-address myPublicIP \
--size Standard_A2 \
--image MicrosoftWindowsServer:WindowsServer:2019-Datacenter:latest \
--admin-username azureuser
```

For more information on public IP SKUs, see [Public IP address SKUs](#). A virtual machine can be added to the backend pool of an Azure Load Balancer. The SKU of the public IP address must match the SKU of a load balancer's public IP. For more information, see [Azure Load Balancer](#).

View the public IP address assigned and confirm that it was created as a static address, with [az network public-ip show](#):

```
az network public-ip show \
--resource-group myResourceGroup \
--name myPublicIP \
--query [ipAddress,publicIpAllocationMethod,sku] \
--output table
```

### WARNING

Do not modify the IP address settings within the virtual machine's operating system. The operating system is unaware of Azure public IP addresses. Though you can add private IP address settings to the operating system, we recommend not doing so unless necessary, and not until after reading [Add a private IP address to an operating system](#).

#### NOTE

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the back-end pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

For more information, see [Default outbound access in Azure](#).

The default outbound access IP is disabled when either a public IP address is assigned to the VM or the VM is placed in the back-end pool of a standard load balancer, with or without outbound rules. If an [Azure Virtual Network network address translation \(NAT\) gateway](#) resource is assigned to the subnet of the virtual machine, the default outbound access IP is disabled.

VMs that are created by virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see [Use source network address translation \(SNAT\) for outbound connections](#).

## Clean up resources

When no longer needed, you can use `az group delete` to remove the resource group and all of the resources it contains:

```
az group delete --name myResourceGroup --yes
```

## Next steps

- Learn more about [public IP addresses](#) in Azure.
- Learn more about all [public IP address settings](#).
- Learn more about [private IP addresses](#) and assigning a [static private IP address](#) to an Azure virtual machine.
- Learn more about creating [Linux](#) and [Windows](#) virtual machines.

# Add Custom Domain to Azure VM or resource

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

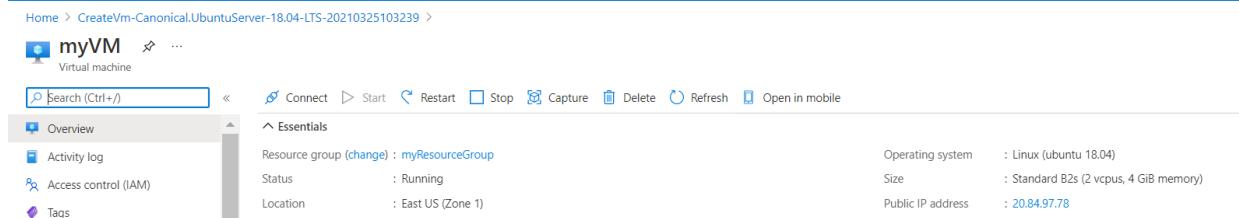

In Azure there are multiple ways to connect a custom domain to your VM or resource. For any resource with a public IP (Virtual Machine, Load Balancer, Application Gateway) the most straight-forward way is to create an A record set in your corresponding domain registrar.

## Prerequisites

- You need a VM with a web server running. You can use the [Quickstart](#) to create a VM and add NGINX.
- The VM must be accessible to the web (open port 80, or 443). For a more secure deployment place your VM behind a load balancer or Application Gateway first. For more information, see [Quickstart: Load Balancer](#).
- Have an existing domain and access to DNS settings. For more information, see [Buy a custom domain for Azure App Service](#).

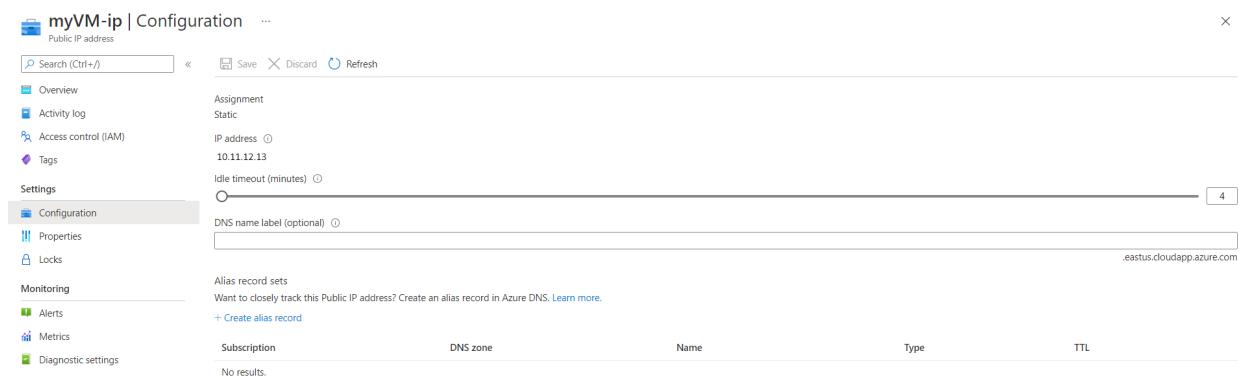

## Add custom domain to VM public IP address

When you create a virtual machine in the Azure portal, a public IP resource for the virtual machine is automatically created. Your public IP address is shown in VM overview page.

The screenshot shows the Azure portal interface for a virtual machine named 'myVM'. In the top navigation bar, the URL is 'Home > CreateVm-Canonical.UbuntuServer-18.04-LTS-20210325103239 >'. Below the navigation bar, there's a search bar and a toolbar with options like 'Connect', 'Start', 'Stop', 'Capture', 'Delete', 'Refresh', and 'Open in mobile'. On the left, a sidebar menu includes 'Overview', 'Activity log', 'Access control (IAM)', and 'Tags'. The main content area is titled 'Essentials' and displays the following details:  
Resource group (change) : myResourceGroup  
Status : Running  
Location : East US (Zone 1)  
Operating system : Linux (ubuntu 18.04)  
Size : Standard B2s (2 vcpus, 4 GiB memory)  
Public IP address : 20.84.97.78

If you select the IP address you can see more information on it. Check to make sure your **IP Assignment** is set to **Static**. A static IP address will not change if the VM or resource reboots or shuts down.

The screenshot shows the 'Configuration' page for the public IP address 'myVM-ip'. The left sidebar includes 'Overview', 'Activity log', 'Access control (IAM)', 'Tags', 'Settings' (with 'Configuration' selected), 'Monitoring', 'Alerts', 'Metrics', and 'Diagnostic settings'. The main content area has tabs for 'Configuration' and 'Properties'. Under 'Configuration', there are fields for 'Assignment' (set to 'Static'), 'IP address' (10.11.12.13), 'Idle timeout (minutes)' (set to 4), and 'DNS name label (optional)' (eastus.cloudapp.azure.com). Below these fields, there's a note about alias record sets and a link to create one. At the bottom, there's a table for 'Subscription', 'DNS zone', 'Name', 'Type', and 'TTL', with a note 'No results.'

If your IP Address is not static, you will need to create an FQDN.

1. Select your VM in the portal.
2. In the left menu, select **Properties**
3. Under **Public IP address\DNS name label**, select your IP address.
4. Under **DNS name label**, enter the prefix you want to use.

5. Select **Save** at the top of the page.
6. Select **Overview** in the left menu to return to the VM overview blade.
7. Verify that the *DNS name* appears correctly.

Open a browser and enter your IP address or FQDN and verify that it shows the web content running on your VM.

After verifying your static IP or FQDN, go to your domain provider and navigate to DNS settings.

Once there add an *A record* pointing to your Public IP Address or FQDN. For example, the procedure for the GoDaddy domain registrar is as follows:

1. Sign in and select the custom domain you want to use.
2. In the **Domains** section, select **Manage All**, then select **DNS | Manage Zones**.
3. For **Domain Name**, enter your custom domain, then select **Search**.
4. From the DNS Management page, select **Add**, then select **A** in the Type list.
5. Complete the fields of the A entry:
  - Type: Leave **A** selected.
  - Host: Enter **@**
  - Points to: Enter the Public IP Address or FQDN of your VM.
  - TTL: Leave one hour selected.
6. Select **Save**.

The A record entry is added to the DNS records table.

After the record is created it usually takes about an hour for DNS propagate, but it can sometimes take up to 48 hours.

## Next steps

# How to create a Linux virtual machine in Azure with multiple network interface cards

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article details how to create a VM with multiple NICs with the Azure CLI.

## Create supporting resources

Install the latest [Azure CLI](#) and log in to an Azure account using [az login](#).

In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *mystorageaccount*, and *myVM*.

First, create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name myResourceGroup --location eastus
```

Create the virtual network with [az network vnet create](#). The following example creates a virtual network named *myVnet* and subnet named *mySubnetFrontEnd*.

```
az network vnet create \
--resource-group myResourceGroup \
--name myVnet \
--address-prefix 10.0.0.0/16 \
--subnet-name mySubnetFrontEnd \
--subnet-prefix 10.0.1.0/24
```

Create a subnet for the back-end traffic with [az network vnet subnet create](#). The following example creates a subnet named *mySubnetBackEnd*.

```
az network vnet subnet create \
--resource-group myResourceGroup \
--vnet-name myVnet \
--name mySubnetBackEnd \
--address-prefix 10.0.2.0/24
```

Create a network security group with [az network nsg create](#). The following example creates a network security group named *myNetworkSecurityGroup*.

```
az network nsg create \
--resource-group myResourceGroup \
--name myNetworkSecurityGroup
```

## Create and configure multiple NICs

Create two NICs with [az network nic create](#). The following example creates two NICs, named *myNic1* and *myNic2*, connected the network security group, with one NIC connecting to each subnet:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic1 \
--vnet-name myVnet \
--subnet mySubnetFrontEnd \
--network-security-group myNetworkSecurityGroup
az network nic create \
--resource-group myResourceGroup \
--name myNic2 \
--vnet-name myVnet \
--subnet mySubnetBackEnd \
--network-security-group myNetworkSecurityGroup
```

## Create a VM and attach the NICs

When you create the VM, specify the NICs you created with `--nics`. You also need to take care when you select the VM size. There are limits for the total number of NICs that you can add to a VM. Read more about [Linux VM sizes](#).

Create a VM with [az vm create](#). The following example creates a VM named *myVM*:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image UbuntuLTS \
--size Standard_DS3_v2 \
--admin-username azureuser \
--generate-ssh-keys \
--nics myNic1 myNic2
```

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Add a NIC to a VM

The previous steps created a VM with multiple NICs. You can also add NICs to an existing VM with the Azure CLI. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly. If needed, you can [resize a VM](#).

Create another NIC with [az network nic create](#). The following example creates a NIC named *myNic3* connected to the back-end subnet and network security group created in the previous steps:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic3 \
--vnet-name myVnet \
--subnet mySubnetBackEnd \
--network-security-group myNetworkSecurityGroup
```

To add a NIC to an existing VM, first deallocate the VM with [az vm deallocate](#). The following example deallocates the VM named *myVM*:

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Add the NIC with [az vm nic add](#). The following example adds *myNic3* to *myVM*:

```
az vm nic add \
--resource-group myResourceGroup \
--vm-name myVM \
--nics myNic3
```

Start the VM with [az vm start](#):

```
az vm start --resource-group myResourceGroup --name myVM
```

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Remove a NIC from a VM

To remove a NIC from an existing VM, first deallocate the VM with [az vm deallocate](#). The following example deallocates the VM named *myVM*.

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Remove the NIC with [az vm nic remove](#). The following example removes *myNic3* from *myVM*.

```
az vm nic remove \
--resource-group myResourceGroup \
--vm-name myVM \
--nics myNic3
```

Start the VM with [az vm start](#):

```
az vm start --resource-group myResourceGroup --name myVM
```

## Create multiple NICs using Resource Manager templates

Azure Resource Manager templates use declarative JSON files to define your environment. You can read an [overview of Azure Resource Manager](#). Resource Manager templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. You use *copy* to specify the number of instances to create:

```
"copy": {
  "name": "multiplenics"
  "count": "[parameters('count')]"
}
```

Read more about [creating multiple instances using copy](#).

You can also use a `copyIndex()` to then append a number to a resource name, which allows you to create `myNic1`, `myNic2`, etc. The following shows an example of appending the index value:

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of [creating multiple NICs using Resource Manager templates](#).

Add routing tables to the guest OS by completing the steps in [Configure the guest OS for multiple NICs](#).

## Configure guest OS for multiple NICs

The previous steps created a virtual network and subnet, attached NICs, then created a VM. A public IP address and network security group rules that allow SSH traffic were not created. To configure the guest OS for multiple NICs, you need to allow remote connections and run commands locally on the VM.

To allow SSH traffic, create a network security group rule with [az network nsg rule create](#) as follows:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name allow_ssh \
--priority 101 \
--destination-port-ranges 22
```

Create a public IP address with [az network public-ip create](#) and assign it to the first NIC with [az network nic ip-config update](#):

```
az network public-ip create --resource-group myResourceGroup --name myPublicIP

az network nic ip-config update \
--resource-group myResourceGroup \
--nic-name myNic1 \
--name ipconfig1 \
--public-ip myPublicIP
```

To view the public IP address of the VM, use [az vm show](#) as follows::

```
az vm show --resource-group myResourceGroup --name myVM -d --query publicIps -o tsv
```

Now SSH to the public IP address of your VM. The default username provided in a previous step was *azureuser*. Provide your own username and public IP address:

```
ssh azureuser@137.117.58.232
```

To send to or from a secondary network interface, you have to manually add persistent routes to the operating system for each secondary network interface. In this article, *eth1* is the secondary interface. Instructions for adding persistent routes to the operating system vary by distro. See documentation for your distro for instructions.

When adding the route to the operating system, the gateway address is the first address of the subnet the network interface is in. For example, if the subnet has been assigned the range *10.0.2.0/24*, the gateway you specify for the route is *10.0.2.1* or if the subnet has been assigned the range *10.0.2.128/25*, the gateway you specify for the route is *10.0.2.129*. You can define a specific network for the route's destination, or specify a destination of *0.0.0.0*, if you want all traffic for the interface to go through the specified gateway. The gateway for each subnet is managed by the virtual network.

Once you've added the route for a secondary interface, verify that the route is in your route table with `route -n`. The following example output is for the route table that has the two network interfaces added to the VM in this article:

Kernel IP routing table							
Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
0.0.0.0	10.0.1.1	0.0.0.0	UG	0	0	0	eth0
0.0.0.0	10.0.2.1	0.0.0.0	UG	0	0	0	eth1
10.0.1.0	0.0.0.0	255.255.255.0	U	0	0	0	eth0
10.0.2.0	0.0.0.0	255.255.255.0	U	0	0	0	eth1
168.63.129.16	10.0.1.1	255.255.255.255	UGH	0	0	0	eth0
169.254.169.254	10.0.1.1	255.255.255.255	UGH	0	0	0	eth0

Confirm that the route you added persists across reboots by checking your route table again after a reboot. To test connectivity, you can enter the following command, for example, where *eth1* is the name of a secondary network interface:

```
ping bing.com -c 4 -I eth1
```

## Next steps

Review [Linux VM sizes](#) when trying to creating a VM with multiple NICs. Pay attention to the maximum number of NICs each VM size supports.

To further secure your VMs, use just in time VM access. This feature opens network security group rules for SSH traffic when needed, and for a defined period of time. For more information, see [Manage virtual machine access using just in time](#).

# Create and manage a Windows virtual machine that has multiple NICs

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Virtual machines (VMs) in Azure can have multiple virtual network interface cards (NICs) attached to them. A common scenario is to have different subnets for front-end and back-end connectivity. You can associate multiple NICs on a VM to multiple subnets, but those subnets must all reside in the same virtual network (vNet). This article details how to create a VM that has multiple NICs attached to it. You also learn how to add or remove NICs from an existing VM. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly.

## NOTE

If multiple subnets are not required for a scenario, it may be more straightforward to utilize multiple IP configurations on a single NIC. Instructions for this setup can be found [here](#).

## Prerequisites

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

## Create a VM with multiple NICs

First, create a resource group. The following example creates a resource group named *myResourceGroup* in the *EastUs* location:

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

### Create virtual network and subnets

A common scenario is for a virtual network to have two or more subnets. One subnet may be for front-end traffic, the other for back-end traffic. To connect to both subnets, you then use multiple NICs on your VM.

1. Define two virtual network subnets with [New-AzVirtualNetworkSubnetConfig](#). The following example defines the subnets for *mySubnetFrontEnd* and *mySubnetBackEnd*.

```
$mySubnetFrontEnd = New-AzVirtualNetworkSubnetConfig -Name "mySubnetFrontEnd" `  
    -AddressPrefix "192.168.1.0/24"  
$mySubnetBackEnd = New-AzVirtualNetworkSubnetConfig -Name "mySubnetBackEnd" `  
    -AddressPrefix "192.168.2.0/24"
```

2. Create your virtual network and subnets with [New-AzVirtualNetwork](#). The following example creates a virtual network named *myVnet*.

```
$myVnet = New-AzVirtualNetwork -ResourceGroupName "myResourceGroup" `  
    -Location "EastUs" `  
    -Name "myVnet" `  
    -AddressPrefix "192.168.0.0/16" `  
    -Subnet $mySubnetFrontEnd,$mySubnetBackEnd
```

## Create multiple NICs

Create two NICs with [New-AzNetworkInterface](#). Attach one NIC to the front-end subnet and one NIC to the back-end subnet. The following example creates NICs named *myNic1* and *myNic2*:

```
$frontEnd = $myVnet.Subnets | ?{$_ . Name -eq 'mySubnetFrontEnd'}  
$myNic1 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `  
    -Name "myNic1" `  
    -Location "EastUs" `  
    -SubnetId $frontEnd.Id  
  
$backEnd = $myVnet.Subnets | ?{$_ . Name -eq 'mySubnetBackEnd'}  
$myNic2 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `  
    -Name "myNic2" `  
    -Location "EastUs" `  
    -SubnetId $backEnd.Id
```

Typically you also create a [network security group](#) to filter network traffic to the VM and a [load balancer](#) to distribute traffic across multiple VMs.

## Create the virtual machine

Now start to build your VM configuration. Each VM size has a limit for the total number of NICs that you can add to a VM. For more information, see [Windows VM sizes](#).

1. Set your VM credentials to the `$cred` variable as follows:

```
$cred = Get-Credential
```

2. Define your VM with [New-AzVMConfig](#). The following example defines a VM named *myVM* and uses a VM size that supports more than two NICs (*Standard\_DS3\_v2*):

```
$vmConfig = New-AzVMConfig -VMName "myVM" -VMSize "Standard_DS3_v2"
```

3. Create the rest of your VM configuration with [Set-AzVMOperatingSystem](#) and [Set-AzVMSourceImage](#). The following example creates a Windows Server 2016 VM:

```
$vmConfig = Set-AzVMOperatingSystem -VM $vmConfig `  
    -Windows `  
    -ComputerName "myVM" `  
    -Credential $cred `  
    -ProvisionVMAgent `  
    -EnableAutoUpdate  
$vmConfig = Set-AzVMSourceImage -VM $vmConfig `  
    -PublisherName "MicrosoftWindowsServer" `  
    -Offer "WindowsServer" `  
    -Skus "2016-Datacenter" `  
    -Version "latest"
```

4. Attach the two NICs that you previously created with [Add-AzVMNetworkInterface](#):

```
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic1.Id -Primary  
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic2.Id
```

5. Create your VM with [New-AzVM](#):

```
New-AzVM -VM $vmConfig -ResourceGroupName "myResourceGroup" -Location "EastUs"
```

6. Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Add a NIC to an existing VM

To add a virtual NIC to an existing VM, you deallocate the VM, add the virtual NIC, then start the VM. Different [VM sizes](#) support a varying number of NICs, so size your VM accordingly. If needed, you can [resize a VM](#).

1. Deallocate the VM with [Stop-AzVM](#). The following example deallocates the VM named *myVM* in *myResourceGroup*:

```
Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

2. Get the existing configuration of the VM with [Get-AzVm](#). The following example gets information for the VM named *myVM* in *myResourceGroup*:

```
$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

3. The following example creates a virtual NIC with [New-AzNetworkInterface](#) named *myNic3* that is attached to *mySubnetBackEnd*. The virtual NIC is then attached to the VM named *myVM* in *myResourceGroup* with [Add-AzVMNetworkInterface](#):

```
# Get info for the back end subnet  
$myVnet = Get-AzVirtualNetwork -Name "myVnet" -ResourceGroupName "myResourceGroup"  
$backEnd = $myVnet.Subnets | ?{$_ . Name -eq 'mySubnetBackEnd' }  
  
# Create a virtual NIC  
$myNic3 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `  
    -Name "myNic3" `  
    -Location "EastUs" `  
    -SubnetId $backEnd.Id  
  
# Get the ID of the new virtual NIC and add to VM  
$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -Name "MyNic3").Id  
Add-AzVMNetworkInterface -VM $vm -Id $nicId | Update-AzVm -ResourceGroupName "myResourceGroup"
```

### Primary virtual NICs

One of the NICs on a multi-NIC VM needs to be primary. If one of the existing virtual NICs on the VM is already set as primary, you can skip this step. The following example assumes that two virtual NICs are now present on a VM and you wish to add the first NIC ([0]) as the primary:

```
# List existing NICs on the VM and find which one is primary  
$vm.NetworkProfile.NetworkInterfaces  
  
# Set NIC 0 to be primary  
$vm.NetworkProfile.NetworkInterfaces[0].Primary = $true  
$vm.NetworkProfile.NetworkInterfaces[1].Primary = $false  
  
# Update the VM state in Azure  
Update-AzVM -VM $vm -ResourceGroupName "myResourceGroup"
```

#### 4. Start the VM with [Start-AzVm](#):

```
Start-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM"
```

#### 5. Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Remove a NIC from an existing VM

To remove a virtual NIC from an existing VM, you deallocate the VM, remove the virtual NIC, then start the VM.

#### 1. Deallocation the VM with [Stop-AzVM](#). The following example deallocated the VM named *myVM* in *myResourceGroup*:

```
Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

#### 2. Get the existing configuration of the VM with [Get-AzVm](#). The following example gets information for the VM named *myVM* in *myResourceGroup*.

```
$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

#### 3. Get information about the NIC remove with [Get-AzNetworkInterface](#). The following example gets information about *myNic3*:

```
# List existing NICs on the VM if you need to determine NIC name  
$vm.NetworkProfile.NetworkInterfaces  
  
$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -Name "myNic3").Id
```

#### 4. Remove the NIC with [Remove-AzVMNetworkInterface](#) and then update the VM with [Update-AzVm](#). The following example removes *myNic3* as obtained by `$nicId` in the preceding step:

```
Remove-AzVMNetworkInterface -VM $vm -NetworkInterfaceIDs $nicId | `  
Update-AzVm -ResourceGroupName "myResourceGroup"
```

#### 5. Start the VM with [Start-AzVm](#):

```
Start-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

## Create multiple NICs with templates

Azure Resource Manager templates provide a way to create multiple instances of a resource during deployment,

such as creating multiple NICs. Resource Manager templates use declarative JSON files to define your environment. For more information, see [overview of Azure Resource Manager](#). You can use `copy` to specify the number of instances to create:

```
"copy": {  
    "name": "multiplenics",  
    "count": "[parameters('count')]"  
}
```

For more information, see [creating multiple instances by using `copy`](#).

You can also use `copyIndex()` to append a number to a resource name. You can then create `myNic1`, `MyNic2` and so on. The following code shows an example of appending the index value:

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of [creating multiple NICs by using Resource Manager templates](#).

Add routes for secondary NICs to the OS by completing the steps in [Configure the operating system for multiple NICs](#).

## Configure guest OS for multiple NICs

Azure assigns a default gateway to the first (primary) network interface attached to the virtual machine. Azure does not assign a default gateway to additional (secondary) network interfaces attached to a virtual machine. Therefore, you are unable to communicate with resources outside the subnet that a secondary network interface is in, by default. Secondary network interfaces can, however, communicate with resources outside their subnet, though the steps to enable communication are different for different operating systems.

- From a Windows command prompt, run the `route print` command, which returns output similar to the following output for a virtual machine with two attached network interfaces:

```
=====  
Interface List  
3...00 0d 3a 10 92 ce .....Microsoft Hyper-V Network Adapter #3  
7...00 0d 3a 10 9b 2a .....Microsoft Hyper-V Network Adapter #4  
=====
```

In this example, **Microsoft Hyper-V Network Adapter #4** (interface 7) is the secondary network interface that doesn't have a default gateway assigned to it.

- From a command prompt, run the `ipconfig` command to see which IP address is assigned to the secondary network interface. In this example, 192.168.2.4 is assigned to interface 7. No default gateway address is returned for the secondary network interface.
- To route all traffic destined for addresses outside the subnet of the secondary network interface to the gateway for the subnet, run the following command:

```
route add -p 0.0.0.0 MASK 0.0.0.0 192.168.2.1 METRIC 5015 IF 7
```

The gateway address for the subnet is the first IP address (ending in .1) in the address range defined for the subnet. If you don't want to route all traffic outside the subnet, you could add individual routes to specific destinations, instead. For example, if you only wanted to route traffic from the secondary network interface to the 192.168.3.0 network, you enter the command:

```
route add -p 192.168.3.0 MASK 255.255.255.0 192.168.2.1 METRIC 5015 IF 7
```

4. To confirm successful communication with a resource on the 192.168.3.0 network, for example, enter the following command to ping 192.168.3.4 using interface 7 (192.168.2.4):

```
ping 192.168.3.4 -S 192.168.2.4
```

You may need to open ICMP through the Windows firewall of the device you're pinging with the following command:

```
netsh advfirewall firewall add rule name=Allow-ping protocol=icmpv4 dir=in action=allow
```

5. To confirm the added route is in the route table, enter the `route print` command, which returns output similar to the following text:

```
=====
Active Routes:
Network Destination      Netmask          Gateway        Interface Metric
      0.0.0.0          0.0.0.0    192.168.1.1    192.168.1.4      15
      0.0.0.0          0.0.0.0    192.168.2.1    192.168.2.4    5015
```

The route listed with **192.168.1.1** under **Gateway**, is the route that is there by default for the primary network interface. The route with **192.168.2.1** under **Gateway**, is the route you added.

## Next steps

Review [Windows VM sizes](#) when you're trying to create a VM that has multiple NICs. Pay attention to the maximum number of NICs that each VM size supports.

# Create a fully qualified domain name for a VM in the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: Applies to: ✓ Linux VMs ✓ Windows VMs

When you create a virtual machine (VM) in the [Azure portal](#), a public IP resource for the virtual machine is automatically created. You use this public IP address to remotely access the VM. Although the portal does not create a [fully qualified domain name](#), or FQDN, you can add one once the VM is created. This article demonstrates the steps to create a DNS name or FQDN. If you create a VM without a public IP address, you can't create a FQDN.

## Create a FQDN

This article assumes that you have already created a VM. If needed, you can create a [Linux](#) or [Windows](#) VM in the portal. Follow these steps once your VM is up and running:

1. Select your VM in the portal.
2. In the left menu, select **Properties**
3. Under **Public IP address\DNS name label**, select your IP address.
4. Under **DNS name label**, enter the prefix you want to use.
5. Select **Save** at the top of the page.
6. Select **Overview** in the left menu to return to the VM overview blade.
7. Verify that the **DNS name** appears correctly.

## Next steps

You can also manage DNS using [Azure DNS zones](#).

# Create a fully qualified domain name for a VM in the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

# DNS Name Resolution options for Linux virtual machines in Azure

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure provides DNS name resolution by default for all virtual machines that are in a single virtual network. You can implement your own DNS name resolution solution by configuring your own DNS services on your virtual machines that Azure hosts. The following scenarios should help you choose the one that works for your situation.

- [Name resolution that Azure provides](#)
- [Name resolution using your own DNS server](#)

The type of name resolution that you use depends on how your virtual machines and role instances need to communicate with each other.

The following table illustrates scenarios and corresponding name resolution solutions:

SCENARIO	SOLUTION	SUFFIX
Name resolution between role instances or virtual machines in the same virtual network	Name resolution that Azure provides	hostname or fully-qualified domain name (FQDN)
Name resolution between role instances or virtual machines in different virtual networks	Customer-managed DNS servers that forward queries between virtual networks for resolution by Azure (DNS proxy). See <a href="#">Name resolution using your own DNS server</a> .	FQDN only
Resolution of on-premises computers and service names from role instances or virtual machines in Azure	Customer-managed DNS servers (for example, on-premises domain controller, local read-only domain controller, or a DNS secondary synced by using zone transfers). See <a href="#">Name resolution using your own DNS server</a> .	FQDN only
Resolution of Azure hostnames from on-premises computers	Forward queries to a customer-managed DNS proxy server in the corresponding virtual network. The proxy server forwards queries to Azure for resolution. See <a href="#">Name resolution using your own DNS server</a> .	FQDN only
Reverse DNS for internal IPs	<a href="#">Name resolution using your own DNS server</a>	n/a

## Name resolution that Azure provides

Along with resolution of public DNS names, Azure provides internal name resolution for virtual machines and role instances that are in the same virtual network. In virtual networks that are based on Azure Resource Manager, the DNS suffix is consistent across the virtual network; the FQDN is not needed. DNS names can be

assigned to both network interface cards (NICs) and virtual machines. Although the name resolution that Azure provides does not require any configuration, it is not the appropriate choice for all deployment scenarios, as seen on the preceding table.

## Features and considerations

### Features:

- No configuration is required to use name resolution that Azure provides.
- The name resolution service that Azure provides is highly available. You don't need to create and manage clusters of your own DNS servers.
- The name resolution service that Azure provides can be used along with your own DNS servers to resolve both on-premises and Azure hostnames.
- Name resolution is provided between virtual machines in virtual networks without need for the FQDN.
- You can use hostnames that best describe your deployments rather than working with auto-generated names.

### Considerations:

- The DNS suffix that Azure creates cannot be modified.
- You cannot manually register your own records.
- WINS and NetBIOS are not supported.
- Hostnames must be DNS-compatible. Names must use only 0-9, a-z, and '-', and they cannot start or end with a '-'. See RFC 3696 Section 2.
- DNS query traffic is throttled for each virtual machine. Throttling shouldn't impact most applications. If request throttling is observed, ensure that client-side caching is enabled. For more information, see [Getting the most from name resolution that Azure provides](#).

## Getting the most from name resolution that Azure provides

### Client-side caching:

Some DNS queries are not sent across the network. Client-side caching helps reduce latency and improve resilience to network inconsistencies by resolving recurring DNS queries from a local cache. DNS records contain a Time-To-Live (TTL), which enables the cache to store the record for as long as possible without impacting record freshness. As a result, client-side caching is suitable for most situations.

Some Linux distributions do not include caching by default. We recommend that you add a cache to each Linux virtual machine after you check that there isn't a local cache already.

Several different DNS caching packages, such as dnsmasq, are available. Here are the steps to install dnsmasq on the most common distributions:

### Ubuntu (uses resolvconf)

- Install the dnsmasq package ("sudo apt-get install dnsmasq").

### SUSE (uses netconf):

1. Install the dnsmasq package ("sudo zypper install dnsmasq").
2. Enable the dnsmasq service ("systemctl enable dnsmasq.service").
3. Start the dnsmasq service ("systemctl start dnsmasq.service").
4. Edit "/etc/sysconfig/network/config", and change NETCONFIG\_DNS\_FORWARDER="" to "dnsmasq".
5. Update resolv.conf ("netconfig update") to set the cache as the local DNS resolver.

### CentOS by Rogue Wave Software (formerly OpenLogic; uses NetworkManager)

1. Install the dnsmasq package ("sudo yum install dnsmasq").

2. Enable the dnsmasq service ("systemctl enable dnsmasq.service").
3. Start the dnsmasq service ("systemctl start dnsmasq.service").
4. Add "prepend domain-name-servers 127.0.0.1;" to "/etc/dhclient-eth0.conf".
5. Restart the network service ("service network restart") to set the cache as the local DNS resolver

**NOTE**

: The 'dnsmasq' package is only one of the many DNS caches that are available for Linux. Before you use it, check its suitability for your needs and that no other cache is installed.

## Client-side retries

DNS is primarily a UDP protocol. Because the UDP protocol doesn't guarantee message delivery, the DNS protocol itself handles retry logic. Each DNS client (operating system) can exhibit different retry logic depending on the creator's preference:

- Windows operating systems retry after one second and then again after another two, four, and another four seconds.
- The default Linux setup retries after five seconds. You should change this to retry five times at one-second intervals.

To check the current settings on a Linux virtual machine, 'cat /etc/resolv.conf', and look at the 'options' line, for example:

```
options timeout:1 attempts:5
```

The resolv.conf file is auto-generated and should not be edited. The specific steps that add the 'options' line vary by distribution:

### Ubuntu (uses resolvconf)

1. Add the options line to '/etc/resolvconf/resolv.conf.d/head'.
2. Run 'resolvconf -u' to update.

### SUSE (uses netconfig)

1. Add 'timeout:1 attempts:5' to the NETCONFIG\_DNS\_RESOLVER\_OPTIONS="" parameter in '/etc/sysconfig/network/config'.
2. Run 'netconfig update' to update.

### CentOS by Rogue Wave Software (formerly OpenLogic) (uses NetworkManager)

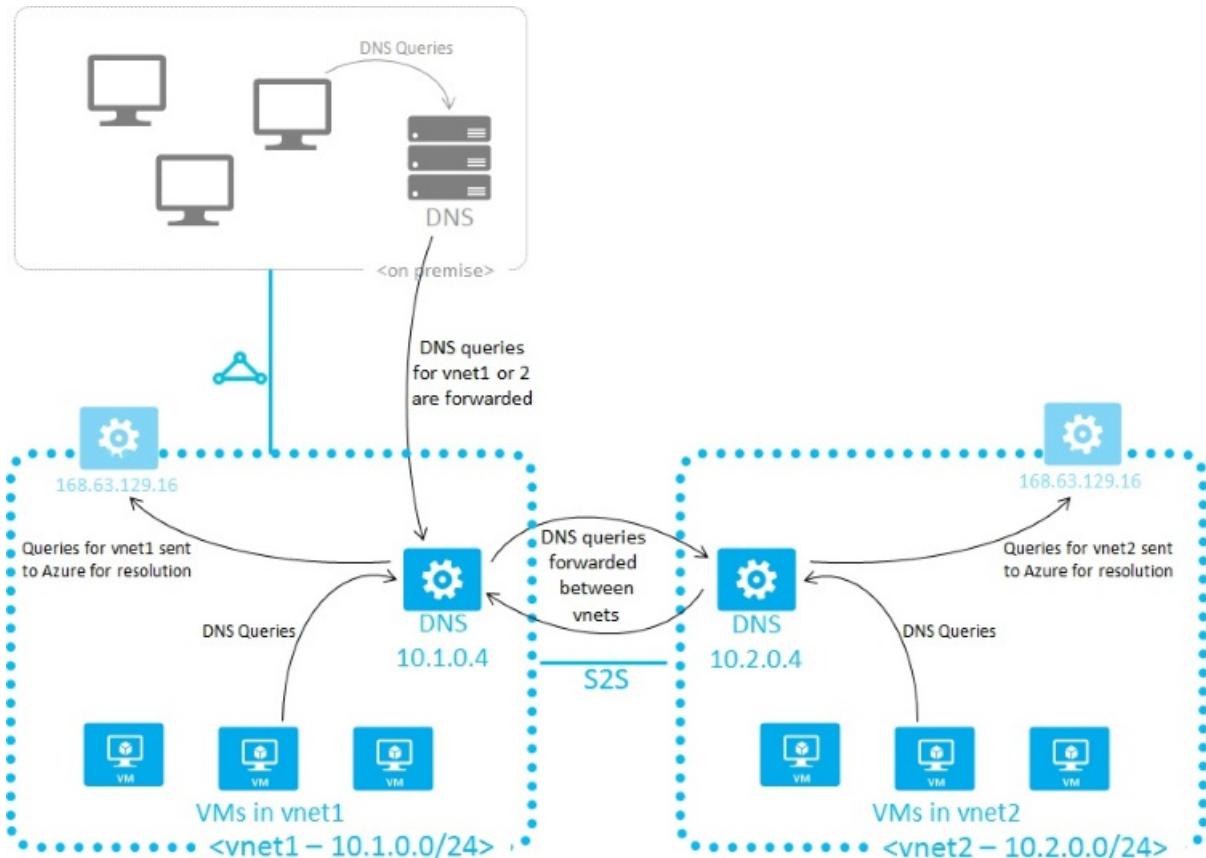

1. Add 'RES\_OPTIONS="timeout:1 attempts:5"' to '/etc/sysconfig/network'.
2. Run 'service network restart' to update.

## Name resolution using your own DNS server

Your name resolution needs may go beyond the features that Azure provides. For example, you might require DNS resolution between virtual networks. To cover this scenario, you can use your own DNS servers.

DNS servers within a virtual network can forward DNS queries to recursive resolvers of Azure to resolve hostnames that are in the same virtual network. For example, a DNS server that runs in Azure can respond to DNS queries for its own DNS zone files and forward all other queries to Azure. This functionality enables virtual machines to see both your entries in your zone files and hostnames that Azure provides (via the forwarder). Access to the recursive resolvers of Azure is provided via the virtual IP 168.63.129.16.

DNS forwarding also enables DNS resolution between virtual networks and enables your on-premises machines to resolve hostnames that Azure provides. To resolve a virtual machine's hostname, the DNS server virtual machine must reside in the same virtual network and be configured to forward hostname queries to Azure. Because the DNS suffix is different in each virtual network, you can use conditional forwarding rules to send DNS queries to the correct virtual network for resolution. The following image shows two virtual networks and an on-premises network doing DNS resolution between virtual networks by using this method:

When you use name resolution that Azure provides, the internal DNS suffix is provided to each virtual machine by using DHCP. When you use your own name resolution solution, this suffix is not supplied to virtual machines because the suffix interferes with other DNS architectures. To refer to machines by FQDN or to configure the suffix on your virtual machines, you can use PowerShell or the API to determine the suffix:

- For virtual networks that are managed by Azure Resource Manager, the suffix is available via the [network interface card](#) resource. You can also run the `azurerm network public-ip show <resource group> <ip name>` command to display the details of your public IP, which includes the FQDN of the NIC.

If forwarding queries to Azure doesn't suit your needs, you need to provide your own DNS solution. Your DNS solution needs to:

- Provide appropriate hostname resolution, for example via [DDNS](#). If you use DDNS, you might need to disable DNS record scavenging. DHCP leases of Azure are very long and scavenging may remove DNS records prematurely.
- Provide appropriate recursive resolution to allow resolution of external domain names.
- Be accessible (TCP and UDP on port 53) from the clients it serves and be able to access the Internet.
- Be secured against access from the Internet to mitigate threats posed by external agents.

#### NOTE

For best performance, when you use virtual machines in Azure DNS servers, disable IPv6 and assign an [Instance-Level Public IP](#) to each DNS server virtual machine.

# Create virtual network interface cards and use internal DNS for VM name resolution on Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article shows you how to set static internal DNS names for Linux VMs using virtual network interface cards (vNics) and DNS label names with the Azure CLI. Static DNS names are used for permanent infrastructure services like a Jenkins build server, which is used for this document, or a Git server.

The requirements are:

- [an Azure account](#)
- [SSH public and private key files](#)

## Quick commands

If you need to quickly accomplish the task, the following section details the commands needed. More detailed information and context for each step can be found in the rest of the document, [starting here](#). To perform these steps, you need the latest [Azure CLI](#) installed and logged in to an Azure account using [az login](#).

Pre-Requirements: Resource Group, virtual network and subnet, Network Security Group with SSH inbound.

### Create a virtual network interface card with a static internal DNS name

Create the vNic with [az network nic create](#). The `--internal-dns-name` CLI flag is for setting the DNS label, which provides the static DNS name for the virtual network interface card (vNic). The following example creates a vNic named `myNic`, connects it to the `myVnet` virtual network, and creates an internal DNS name record called `jenkins`:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic \
--vnet-name myVnet \
--subnet mySubnet \
--internal-dns-name jenkins
```

### Deploy a VM and connect the vNic

Create a VM with [az vm create](#). The `--nics` flag connects the vNic to the VM during the deployment to Azure. The following example creates a VM named `myVM` with Azure Managed Disks and attaches the vNic named `myNic` from the preceding step:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--nics myNic \
--image UbuntuLTS \
--admin-username azureuser \
--ssh-key-value ~/.ssh/id_rsa.pub
```

## Detailed walkthrough

A full continuous integration and continuous deployment (CiCd) infrastructure on Azure requires certain servers to be static or long-lived servers. It is recommended that Azure assets like the virtual networks and Network Security Groups are static and long lived resources that are rarely deployed. Once a virtual network has been deployed, it can be reused by new deployments without any adverse affects to the infrastructure. You can later add a Git repository server or a Jenkins automation server delivers CiCd to this virtual network for your development or test environments.

Internal DNS names are only resolvable inside an Azure virtual network. Because the DNS names are internal, they are not resolvable to the outside internet, providing additional security to the infrastructure.

In the following examples, replace example parameter names with your own values. Example parameter names include `myResourceGroup`, `myNic`, and `myVM`.

## Create the resource group

First, create the resource group with [az group create](#). The following example creates a resource group named `myResourceGroup` in the `westus` location:

```
az group create --name myResourceGroup --location westus
```

## Create the virtual network

The next step is to build a virtual network to launch the VMs into. The virtual network contains one subnet for this walkthrough. For more information on Azure virtual networks, see [Create a virtual network](#).

Create the virtual network with [az network vnet create](#). The following example creates a virtual network named `myVnet` and subnet named `mySubnet`:

```
az network vnet create \
--resource-group myResourceGroup \
--name myVnet \
--address-prefix 192.168.0.0/16 \
--subnet-name mySubnet \
--subnet-prefix 192.168.1.0/24
```

## Create the Network Security Group

Azure Network Security Groups are equivalent to a firewall at the network layer. For more information about Network Security Groups, see [How to create NSGs in the Azure CLI](#).

Create the network security group with [az network nsg create](#). The following example creates a network security group named `myNetworkSecurityGroup`:

```
az network nsg create \
--resource-group myResourceGroup \
--name myNetworkSecurityGroup
```

## Add an inbound rule to allow SSH

Add an inbound rule for the network security group with [az network nsg rule create](#). The following example creates a rule named `myRuleAllowSSH`:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name myRuleAllowSSH \
--protocol tcp \
--direction inbound \
--priority 1000 \
--source-address-prefix '*' \
--source-port-range '*' \
--destination-address-prefix '*' \
--destination-port-range 22 \
--access allow
```

## Associate the subnet with the Network Security Group

To associate the subnet with the Network Security Group, use [az network vnet subnet update](#). The following example associates the subnet name `mySubnet` with the Network Security Group named `myNetworkSecurityGroup`:

```
az network vnet subnet update \
--resource-group myResourceGroup \
--vnet-name myVnet \
--name mySubnet \
--network-security-group myNetworkSecurityGroup
```

## Create the virtual network interface card and static DNS names

Azure is very flexible, but to use DNS names for VM name resolution, you need to create virtual network interface cards (vNics) that include a DNS label. vNics are important as you can reuse them by connecting them to different VMs over the infrastructure lifecycle. This approach keeps the vNic as a static resource while the VMs can be temporary. By using DNS labeling on the vNic, we are able to enable simple name resolution from other VMs in the VNet. Using resolvable names enables other VMs to access the automation server by the DNS name `Jenkins` or the Git server as `gitrepo`.

Create the vNic with [az network nic create](#). The following example creates a vNic named `myNic`, connects it to the `myVnet` virtual network named `myVnet`, and creates an internal DNS name record called `jenkins`:

```
az network nic create \
--resource-group myResourceGroup \
--name myNic \
--vnet-name myVnet \
--subnet mySubnet \
--internal-dns-name jenkins
```

## Deploy the VM into the virtual network infrastructure

We now have a virtual network and subnet, a Network Security Group acting as a firewall to protect our subnet by blocking all inbound traffic except port 22 for SSH, and a vNic. You can now deploy a VM inside this existing network infrastructure.

Create a VM with [az vm create](#). The following example creates a VM named `myVM` with Azure Managed Disks and attaches the vNic named `myNic` from the preceding step:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--nics myNic \
--image UbuntuLTS \
--admin-username azureuser \
--ssh-key-value ~/.ssh/id_rsa.pub
```

By using the CLI flags to call out existing resources, we instruct Azure to deploy the VM inside the existing network. To reiterate, once a VNet and subnet have been deployed, they can be left as static or permanent resources inside your Azure region.

# Azure Virtual Machines security overview

9/21/2022 • 7 minutes to read • [Edit Online](#)

This article provides an overview of the core Azure security features that can be used with virtual machines.

You can use Azure Virtual Machines to deploy a wide range of computing solutions in an agile way. The service supports Microsoft Windows, Linux, Microsoft SQL Server, Oracle, IBM, SAP, and Azure BizTalk Services. So you can deploy any workload and any language on nearly any operating system.

An Azure virtual machine gives you the flexibility of virtualization without having to buy and maintain the physical hardware that runs the virtual machine. You can build and deploy your applications with the assurance that your data is protected and safe in highly secure datacenters.

With Azure, you can build security-enhanced, compliant solutions that:

- Protect your virtual machines from viruses and malware.
- Encrypt your sensitive data.
- Secure network traffic.
- Identify and detect threats.
- Meet compliance requirements.

## Antimalware

With Azure, you can use antimalware software from security vendors such as Microsoft, Symantec, Trend Micro, and Kaspersky. This software helps protect your virtual machines from malicious files, adware, and other threats.

Microsoft Antimalware for Azure Cloud Services and Virtual Machines is a real-time protection capability that helps identify and remove viruses, spyware, and other malicious software. Microsoft Antimalware for Azure provides configurable alerts when known malicious or unwanted software attempts to install itself or run on your Azure systems.

Microsoft Antimalware for Azure is a single-agent solution for applications and tenant environments. It's designed to run in the background without human intervention. You can deploy protection based on the needs of your application workloads, with either basic secure-by-default or advanced custom configuration, including antimalware monitoring.

Learn more about [Microsoft Antimalware for Azure](#) and the core features available.

Learn more about antimalware software to help protect your virtual machines:

- [Deploying Antimalware Solutions on Azure Virtual Machines](#)
- [How to install and configure Trend Micro Deep Security as a service on a Windows VM](#)
- [How to install and configure Symantec Endpoint Protection on a Windows VM](#)
- [Security solutions in the Azure Marketplace](#)

For even more powerful protection, consider using [Windows Defender Advanced Threat Protection](#). With Windows Defender ATP, you get:

- [Attack surface reduction](#)
- [Next generation protection](#)
- [Endpoint protection and response](#)
- [Automated investigation and remediation](#)

- [Secure score](#)
- [Advanced hunting](#)
- [Management and APIs](#)
- [Microsoft Threat Protection](#)

Learn more:

- [Get Started with WDATP](#)
- [Overview of WDATP capabilities](#)

## Hardware security module

Improving key security can enhance encryption and authentication protections. You can simplify the management and security of your critical secrets and keys by storing them in Azure Key Vault.

Key Vault provides the option to store your keys in hardware security modules (HSMs) certified to FIPS 140-2 Level 2 standards. Your SQL Server encryption keys for backup or [transparent data encryption](#) can all be stored in Key Vault with any keys or secrets from your applications. Permissions and access to these protected items are managed through [Azure Active Directory](#).

Learn more:

- [What is Azure Key Vault?](#)
- [Azure Key Vault blog](#)

## Virtual machine disk encryption

Azure Disk Encryption is a new capability for encrypting your Windows and Linux virtual machine disks. Azure Disk Encryption uses the industry-standard [BitLocker](#) feature of Windows and the [dm-crypt](#) feature of Linux to provide volume encryption for the OS and the data disks.

The solution is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets in your key vault subscription. It ensures that all data in the virtual machine disks are encrypted at rest in Azure Storage.

Learn more:

- [Azure Disk Encryption for Linux VMs](#) and [Azure Disk Encryption for Windows VMs](#)
- [Quickstart: Encrypt a Windows IaaS VM with Azure PowerShell](#)

## Virtual machine backup

Azure Backup is a scalable solution that helps protect your application data with zero capital investment and minimal operating costs. Application errors can corrupt your data, and human errors can introduce bugs into your applications. With Azure Backup, your virtual machines running Windows and Linux are protected.

Learn more:

- [What is Azure Backup?](#)
- [Azure Backup service FAQ](#)

## Azure Site Recovery

An important part of your organization's BCDR strategy is figuring out how to keep corporate workloads and apps running when planned and unplanned outages occur. Azure Site Recovery helps orchestrate replication, failover, and recovery of workloads and apps so that they're available from a secondary location if your primary

location goes down.

Site Recovery:

- **Simplifies your BCDR strategy:** Site Recovery makes it easy to handle replication, failover, and recovery of multiple business workloads and apps from a single location. Site Recovery orchestrates replication and failover but doesn't intercept your application data or have any information about it.
- **Provides flexible replication:** By using Site Recovery, you can replicate workloads running on Hyper-V virtual machines, VMware virtual machines, and Windows/Linux physical servers.
- **Supports failover and recovery:** Site Recovery provides test failovers to support disaster recovery drills without affecting production environments. You can also run planned failovers with a zero-data loss for expected outages, or unplanned failovers with minimal data loss (depending on replication frequency) for unexpected disasters. After failover, you can fail back to your primary sites. Site Recovery provides recovery plans that can include scripts and Azure Automation workbooks so that you can customize failover and recovery of multi-tier applications.
- **Eliminates secondary datacenters:** You can replicate to a secondary on-premises site, or to Azure. Using Azure as a destination for disaster recovery eliminates the cost and complexity of maintaining a secondary site. Replicated data is stored in Azure Storage.
- **Integrates with existing BCDR technologies:** Site Recovery partners with other applications' BCDR features. For example, you can use Site Recovery to help protect the SQL Server back end of corporate workloads. This includes native support for SQL Server Always On to manage the failover of availability groups.

Learn more:

- [What is Azure Site Recovery?](#)
- [How does Azure Site Recovery work?](#)
- [What workloads are protected by Azure Site Recovery?](#)

## Virtual networking

Virtual machines need network connectivity. To support that requirement, Azure requires virtual machines to be connected to an Azure virtual network.

An Azure virtual network is a logical construct built on top of the physical Azure network fabric. Each logical Azure virtual network is isolated from all other Azure virtual networks. This isolation helps ensure that network traffic in your deployments is not accessible to other Microsoft Azure customers.

Learn more:

- [Azure network security overview](#)
- [Virtual Network overview](#)
- [Networking features and partnerships for enterprise scenarios](#)

## Security policy management and reporting

Microsoft Defender for Cloud helps you prevent, detect, and respond to threats. Defender for Cloud gives you increased visibility into, and control over, the security of your Azure resources. It provides integrated security monitoring and policy management across your Azure subscriptions. It helps detect threats that might otherwise go unnoticed, and works with a broad ecosystem of security solutions.

Defender for Cloud helps you optimize and monitor the security of your virtual machines by:

- Providing [security recommendations](#) for the virtual machines. Example recommendations include: apply system updates, configure ACLs endpoints, enable antimalware, enable network security groups, and apply

disk encryption.

- Monitoring the state of your virtual machines.

Learn more:

- [Introduction to Microsoft Defender for Cloud](#)
- [Microsoft Defender for Cloud frequently asked questions](#)
- [Microsoft Defender for Cloud planning and operations](#)

## Compliance

Azure Virtual Machines is certified for FISMA, FedRAMP, HIPAA, PCI DSS Level 1, and other key compliance programs. This certification makes it easier for your own Azure applications to meet compliance requirements and for your business to address a wide range of domestic and international regulatory requirements.

Learn more:

- [Microsoft Trust Center: Compliance](#)
- [Trusted Cloud: Microsoft Azure Security, Privacy, and Compliance](#)

## Confidential Computing

While confidential computing is not technically part of virtual machine security, the topic of virtual machine security belongs to the higher-level subject of "compute" security. Confidential computing belongs within the category of "compute" security.

Confidential computing ensures that when data is "in the clear," which is required for efficient processing, the data is protected inside a Trusted Execution Environment

[https://en.wikipedia.org/wiki/Trusted\\_execution\\_environment](https://en.wikipedia.org/wiki/Trusted_execution_environment) (TEE - also known as an enclave), an example of which is shown in the figure below.

TEEs ensure there is no way to view data or the operations inside from the outside, even with a debugger. They even ensure that only authorized code is permitted to access data. If the code is altered or tampered, the operations are denied and the environment disabled. The TEE enforces these protections throughout the execution of code within it.

# Security recommendations for virtual machines in Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article contains security recommendations for Azure Virtual Machines. Follow these recommendations to help fulfill the security obligations described in our model for shared responsibility. The recommendations will also help you improve overall security for your web app solutions. For more information about what Microsoft does to fulfill service-provider responsibilities, see [Shared responsibilities for cloud computing](#).

Some of this article's recommendations can be automatically addressed by Microsoft Defender for Cloud. Microsoft Defender for Cloud is the first line of defense for your resources in Azure. It periodically analyzes the security state of your Azure resources to identify potential security vulnerabilities. It then recommends how to address the vulnerabilities. For more information, see [Security recommendations in Microsoft Defender for Cloud](#).

For general information about Microsoft Defender for Cloud, see [What is Microsoft Defender for Cloud?](#).

## General

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
When you build custom VM images, apply the latest updates.	Before you create images, install the latest updates for the operating system and for all applications that will be part of your image.	-
Keep your VMs current.	You can use the <a href="#">Update Management</a> solution in Azure Automation to manage operating system updates for your Windows and Linux computers in Azure.	Yes
Back up your VMs.	<a href="#">Azure Backup</a> helps protect your application data and has minimal operating costs. Application errors can corrupt your data, and human errors can introduce bugs into your applications. Azure Backup protects your VMs that run Windows and Linux.	-
Use multiple VMs for greater resilience and availability.	If your VM runs applications that must be highly available, use multiple VMs or <a href="#">availability sets</a> .	-

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Adopt a business continuity and disaster recovery (BCDR) strategy.	Azure Site Recovery allows you to choose from different options designed to support business continuity. It supports different replication and failover scenarios. For more information, see <a href="#">About Site Recovery</a> .	-

## Data security

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Encrypt operating system disks.	<a href="#">Azure Disk Encryption</a> helps you encrypt your Windows and Linux IaaS VM disks. Without the necessary keys, the contents of encrypted disks are unreadable. Disk encryption protects stored data from unauthorized access that would otherwise be possible if the disk were copied.	Yes
Encrypt data disks.	<a href="#">Azure Disk Encryption</a> helps you encrypt your Windows and Linux IaaS VM disks. Without the necessary keys, the contents of encrypted disks are unreadable. Disk encryption protects stored data from unauthorized access that would otherwise be possible if the disk were copied.	-
Limit installed software.	Limit installed software to what is required to successfully apply your solution. This guideline helps reduce your solution's attack surface.	-
Use antivirus or antimalware.	In Azure, you can use antimalware software from security vendors such as Microsoft, Symantec, Trend Micro, and Kaspersky. This software helps protect your VMs from malicious files, adware, and other threats. You can deploy Microsoft Antimalware based on your application workloads. Microsoft Antimalware is available for Windows machines only. Use either basic secure-by-default or advanced custom configuration. For more information, see <a href="#">Microsoft Antimalware for Azure Cloud Services and Virtual Machines</a> .	-

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Securely store keys and secrets.	Simplify the management of your secrets and keys by providing your application owners with a secure, centrally managed option. This management reduces the risk of an accidental compromise or leak. Azure Key Vault can securely store your keys in hardware security modules (HSMs) that are certified to FIPS 140-2 Level 2. If you need to use FIPs 140.2 Level 3 to store your keys and secrets, you can use <a href="#">Azure Dedicated HSM</a> .	-

## Identity and access management

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Centralize VM authentication.	You can centralize the authentication of your Windows and Linux VMs by using <a href="#">Azure Active Directory authentication</a> .	-

## Monitoring

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Monitor your VMs.	You can use <a href="#">Azure Monitor for VMs</a> to monitor the state of your Azure VMs and virtual machine scale sets. Performance issues with a VM can lead to service disruption, which violates the security principle of availability.	-

## Networking

RECOMMENDATION	COMMENTS	DEFENDER FOR CLOUD
Restrict access to management ports.	Attackers scan public cloud IP ranges for open management ports and attempt "easy" attacks like common passwords and known unpatched vulnerabilities. You can use <a href="#">just-in-time (JIT) VM access</a> to lock down inbound traffic to your Azure VMs, reducing exposure to attacks while providing easy connections to VMs when they're needed.	-
Limit network access.	Network security groups allow you to restrict network access and control the number of exposed endpoints. For more information, see <a href="#">Create, change, or delete a network security group</a> .	-

## Next steps

Check with your application provider to learn about additional security requirements. For more information about developing secure applications, see [Secure-development documentation](#).

# Trusted launch for Azure virtual machines

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure offers trusted launch as a seamless way to improve the security of [generation 2](#) VMs. Trusted launch protects against advanced and persistent attack techniques. Trusted launch is composed of several, coordinated infrastructure technologies that can be enabled independently. Each technology provides another layer of defense against sophisticated threats.

## IMPORTANT

Trusted launch requires the creation of new virtual machines. You can't enable trusted launch on existing virtual machines that were initially created without it.

## Benefits

- Securely deploy virtual machines with verified boot loaders, OS kernels, and drivers.
- Securely protect keys, certificates, and secrets in the virtual machines.
- Gain insights and confidence of the entire boot chain's integrity.
- Ensure workloads are trusted and verifiable.

## Limitations

### VM size support:

- B-series
- DCsv2-series
- DCsv3-series, DCdsv3-series
- Dv4-series, Dsv4-series, Dsv3-series, Dsv2-series
- Dav4-series, Dasv4-series
- Ddv4-series, Ddsv4-series
- Dv5-series, Dsv5-series
- Ddv5-series, Ddsv5-series
- Dasv5-series, Dadsv5-series
- Ev5-series, Esv5-series
- Edv5-series, Edsv5-series
- Easv5-series, Eadsv5-series
- Ebsv5-series, Ebdsv5-series
- Eav4-series, Easv4-series
- Ev4-series, Esv4-series, Esv3-series
- Edv4-series, Edsv4-series
- Fsv2-series
- Lsv2-series

### OS support:

- Redhat Enterprise Linux 8.3, 8.4, 8.5 LVM

- SUSE Enterprise Linux 15 SP3
- Ubuntu Server 22.04 LTS
- Ubuntu Server 20.04 LTS
- Ubuntu Server 18.04 LTS
- Debian 11
- CentOS 8.3, 8.4
- Oracle Linux 8.3 LVM
- CBL-Mariner
- Windows Server 2022
- Windows Server 2019
- Windows Server 2016
- Windows 11 Pro
- Windows 11 Enterprise
- Windows 11 Enterprise multi-session
- Windows 10 Pro
- Windows 10 Enterprise
- Windows 10 Enterprise multi-session

**Regions:**

- All public regions

**Pricing:** No additional cost to existing VM pricing.

**The following features are not supported:**

- Azure Site Recovery
- Shared disk
- Ultra disk
- Managed image
- Nested Virtualization

## Secure boot

At the root of trusted launch is Secure Boot for your VM. This mode, which is implemented in platform firmware, protects against the installation of malware-based rootkits and boot kits. Secure Boot works to ensure that only signed operating systems and drivers can boot. It establishes a "root of trust" for the software stack on your VM. With Secure Boot enabled, all OS boot components (boot loader, kernel, kernel drivers) must be signed by trusted publishers. Both Windows and select Linux distributions support Secure Boot. If Secure Boot fails to authenticate that the image was signed by a trusted publisher, the VM will not be allowed to boot. For more information, see [Secure Boot](#).

## vTPM

Trusted launch also introduces vTPM for Azure VMs. This is a virtualized version of a hardware [Trusted Platform Module](#), compliant with the TPM2.0 spec. It serves as a dedicated secure vault for keys and measurements.

Trusted launch provides your VM with its own dedicated TPM instance, running in a secure environment outside the reach of any VM. The vTPM enables [attestation](#) by measuring the entire boot chain of your VM (UEFI, OS, system, and drivers).

Trusted launch uses the vTPM to perform remote attestation by the cloud. This is used for platform health checks and for making trust-based decisions. As a health check, trusted launch can cryptographically certify that your

VM booted correctly. If the process fails, possibly because your VM is running an unauthorized component, Microsoft Defender for Cloud will issue integrity alerts. The alerts include details on which components failed to pass integrity checks.

## Virtualization-based security

[Virtualization-based Security \(VBS\)](#) uses the hypervisor to create a secure and isolated region of memory. Windows uses these regions to run various security solutions with increased protection against vulnerabilities and malicious exploits. Trusted launch lets you enable Hypervisor Code Integrity (HVCI) and Windows Defender Credential Guard.

HVCI is a powerful system mitigation that protects Windows kernel-mode processes against injection and execution of malicious or unverified code. It checks kernel mode drivers and binaries before they run, preventing unsigned files from loading into memory. This ensures such executable code can't be modified once it is allowed to load. For more information about VBS and HVCI, see [Virtualization Based Security \(VBS\) and Hypervisor Enforced Code Integrity \(HVCI\)](#).

With trusted launch and VBS you can enable Windows Defender Credential Guard. This feature isolates and protects secrets so that only privileged system software can access them. It helps prevent unauthorized access to secrets and credential theft attacks, like Pass-the-Hash (PtH) attacks. For more information, see [Credential Guard](#).

## Microsoft Defender for Cloud integration

Trusted launch is integrated with Azure Defender for Cloud to ensure your VMs are properly configured. Azure Defender for Cloud will continually assess compatible VMs and issue relevant recommendations.

- **Recommendation to enable Secure Boot** - This Recommendation only applies for VMs that support trusted launch. Azure Defender for Cloud will identify VMs that can enable Secure Boot, but have it disabled. It will issue a low severity recommendation to enable it.
- **Recommendation to enable vTPM** - If your VM has vTPM enabled, Azure Defender for Cloud can use it to perform Guest Attestation and identify advanced threat patterns. If Azure Defender for Cloud identifies VMs that support trusted launch and have vTPM disabled, it will issue a low severity recommendation to enable it.
- **Recommendation to install guest attestation extension** - If your VM has secure boot and vTPM enabled but it doesn't have the guest attestation extension installed, Azure Defender for Cloud will issue a low severity recommendation to install the guest attestation extension on it. This extension allows Azure Defender for Cloud to proactively attest and monitor the boot integrity of your VMs. Boot integrity is attested via remote attestation.
- **Attestation health assessment or Boot Integrity Monitoring** - If your VM has Secure Boot and vTPM enabled and attestation extension installed, Azure Defender for Cloud can remotely validate that your VM booted in a healthy way. This is known as boot integrity monitoring. Azure Defender for Cloud issues an assessment, indicating the status of remote attestation. Currently boot integrity monitoring is supported for both Windows and Linux single virtual machines and uniform scale sets.

If your VMs are properly set up with trusted launch, Microsoft Defender for Cloud can detect and alert you of VM health problems.

- **Alert for VM attestation failure:** Microsoft Defender for Cloud will periodically perform attestation on your VMs. This also happens after your VM boots. If the attestation fails, it will trigger a medium severity alert. VM attestation can fail for the following reasons:
  - The attested information, which includes a boot log, deviates from a trusted baseline. This can indicate that untrusted modules have been loaded, and the OS may be compromised.
  - The attestation quote could not be verified to originate from the vTPM of the attested VM. This can indicate that malware is present and may be intercepting traffic to the vTPM.

#### **NOTE**

This alert is available for VMs with vTPM enabled and the Attestation extension installed. Secure Boot must be enabled for attestation to pass. Attestation will fail if Secure Boot is disabled. If you must disable Secure Boot, you can suppress this alert to avoid false positives.

- **Alert for Untrusted Linux Kernel module:** For trusted launch with secure boot enabled, it's possible for a VM to boot even if a kernel driver fails validation and is prohibited from loading. If this happens, Microsoft Defender for Cloud will issue a low severity alert. While there is no immediate threat, because the untrusted driver has not been loaded, these events should be investigated. Consider the following:
  - Which kernel driver failed? Am I familiar with this driver and expect it to be loaded?
  - Is this the exact version of the driver I am expecting? Are the driver binaries intact? If this is a 3rd party driver, did the vendor pass the OS compliance tests to get it signed?

## FAQ

Frequently asked questions about trusted launch.

### **Why should I use trusted launch? What does trusted launch guard against?**

Trusted launch guards against boot kits, rootkits, and kernel-level malware. These sophisticated types of malware run in kernel mode and remain hidden from users. For example:

- Firmware rootkits: these kits overwrite the firmware of the virtual machine's BIOS, so the rootkit can start before the OS.
- Boot kits: these kits replace the OS's bootloader so that the virtual machine loads the boot kit before the OS.
- Kernel rootkits: these kits replace a portion of the OS kernel so the rootkit can start automatically when the OS loads.
- Driver rootkits: these kits pretend to be one of the trusted drivers that OS uses to communicate with the virtual machine's components.

### **What are the differences between secure boot and measured boot?**

In secure boot chain, each step in the boot process checks a cryptographic signature of the subsequent steps. For example, the BIOS will check a signature on the loader, and the loader will check signatures on all the kernel objects that it loads, and so on. If any of the objects are compromised, the signature won't match, and the VM will not boot. For more information, see [Secure Boot](#). Measured boot does not halt the boot process, it measures or computes the hash of the next objects in the chain and stores the hashes in the Platform Configuration Registers (PCRs) on the vTPM. Measured boot records are used for boot integrity monitoring.

### **What happens when an integrity fault is detected?**

Trusted launch for Azure virtual machines is monitored for advanced threats. If such threats are detected, an alert will be triggered. Alerts are only available if [Defender for Cloud's enhanced security features](#) are enabled.

Defender for Cloud periodically performs attestation. If the attestation fails, a medium severity alert will be triggered. Trusted launch attestation can fail for the following reasons:

Trusted launch for Azure virtual machines is monitored for advanced threats. If such threats are detected, an alert will be triggered. Alerts are only available in the [Standard Tier](#) of Azure Defender for Cloud. Azure Defender for Cloud periodically performs attestation. If the attestation fails, a medium severity alert will be triggered. Trusted launch attestation can fail for the following reasons:

- The attested information, which includes a log of the Trusted Computing Base (TCB), deviates from a trusted baseline (like when Secure Boot is enabled). This can indicate that untrusted modules have been loaded and the OS may be compromised.

- The attestation quote could not be verified to originate from the vTPM of the attested VM. This can indicate that malware is present and may be intercepting traffic to the TPM.
- The attestation extension on the VM is not responding. This can indicate a denial-of-service attack by malware, or an OS admin.

## How does trusted launch compare to Hyper-V Shielded VM?

Hyper-V Shielded VM is currently available on Hyper-V only. [Hyper-V Shielded VM](#) is typically deployed in conjunction with Guarded Fabric. A Guarded Fabric consists of a Host Guardian Service (HGS), one or more guarded hosts, and a set of Shielded VMs. Hyper-V Shielded VMs are intended for use in fabrics where the data and state of the virtual machine must be protected from both fabric administrators and untrusted software that might be running on the Hyper-V hosts. Trusted launch on the other hand can be deployed as a standalone virtual machine or virtual machine scale sets on Azure without additional deployment and management of HGS. All of the trusted launch features can be enabled with a simple change in deployment code or a checkbox on the Azure portal.

## Does trusted launch support Azure Compute Gallery?

Trusted launch now allows images to be created and shared through the Azure Compute Gallery (formerly Shared Image Gallery). The image source can be an existing Azure VM which is either generalized or specialized, an existing managed disk or a snapshot, a VHD or an image version from another gallery. To deploy a Trusted Launch VM from an Azure Compute Gallery image version see [trusted launch VM](#).

## Does trusted launch support Azure Backup?

Trusted launch now supports Azure Backup. For more information, see [Support matrix for Azure VM backup](#).

## Does trusted launch support ephemeral OS disks?

Trusted launch supports ephemeral OS disks. Note that, while using ephemeral disks for Trusted Launch VMs, keys and secrets generated or sealed by the vTPM after the creation of the VM may not be persisted across operations like reimaging and platform events like service healing. For more information, see [Trusted Launch for Ephemeral OS disks \(Preview\)](#).

## How can I find VM sizes that support Trusted launch?

See the list of [Generation 2 VM sizes supporting Trusted launch](#).

The following commands can be used to check if a [Generation 2 VM Size](#) does not support Trusted launch.

### CLI

```
subscription=<yourSubID>
region="westus"
vmSize="Standard_NC12s_v3"

az vm list-skus --resource-type virtualMachines --location $region --query "[?
name=='$vmSize'].capabilities" --subscription $subscription
```

### PowerShell

```
$region = "southeastasia"
$vmSize = "Standard_M64"
(Get-AzComputeResourceSku | where {$_.Locations.Contains($region) -and ($_.Name -eq $vmSize) })
[0].Capabilities
```

The response will be similar to the following form. `TrustedLaunchDisabled True` in the output indicates that the Generation 2 VM size does not support Trusted launch. If it's a Generation 2 VM size and `TrustedLaunchDisabled` is not part of the output, it implies that Trusted launch is supported for that VM size.

Name	Value
---	----
MaxResourceVolumeMB	8192000
OSVhdSizeMB	1047552
vCPUs	64
MemoryPreservingMaintenanceSupported	False
HyperVGenerations	V1,V2

RdmaEnabled	False
MaxNetworkInterfaces	8

## What is VM Guest State (VMGS)?

VM Guest State (VMGS) is specific to Trusted Launch VM. It is a blob that is managed by Azure and contains the unified extensible firmware interface (UEFI) secure boot signature databases and other security information. The lifecycle of the VMGS blob is tied to that of the OS Disk.

## Next steps

Deploy a [trusted launch VM](#).

# Deploy a VM with trusted launch enabled

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

**Trusted launch** is a way to improve the security of [generation 2](#) VMs. Trusted launch protects against advanced and persistent attack techniques by combining infrastructure technologies like vTPM and secure boot.

## Prerequisites

- You need to [onboard your subscription to Microsoft Defender for Cloud](#) if it isn't already. Microsoft Defender for Cloud has a free tier, which offers very useful insights for various Azure and Hybrid resources. Trusted launch leverages Defender for Cloud to surface multiple recommendations regarding VM health.
- Assign Azure policies initiatives to your subscription. These policy initiatives need to be assigned only once per subscription. This will automatically install all required extensions on all supported VMs.
  - Configure prerequisites to enable Guest Attestation on Trusted Launch enabled VMs
  - Configure machines to automatically install the Azure Monitor and Azure Security agents on virtual machines

## Deploy a trusted launch VM

Create a virtual machine with trusted launch enabled. Choose an option below:

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [Template](#)

1. Sign in to the Azure [portal](#).
2. Search for **Virtual Machines**.
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select **Add**, and then select **Virtual machine**.
5. Under **Project details**, make sure the correct subscription is selected.
6. Under **Resource group**, select **Create new** and type a name for your resource group or select an existing resource group from the dropdown.
7. Under **Instance details**, type a name for the virtual machine name and choose a region that supports [trusted launch](#).
8. For **Security type** select **Trusted launch virtual machines**. This will make two more options appear - **Secure boot** and **vTPM**. Select the appropriate options for your deployment.

Instance details

Virtual machine name *	myTVM
Region *	(US) East US
Availability options	Availability zone
Availability zone *	1
Security type	Trusted launch virtual machines
Secure boot	<input checked="" type="checkbox"/>
vTPM	<input checked="" type="checkbox"/>

- Under **Image**, select an image from the **Recommended Gen 2 images compatible with Trusted launch**. For a list, see [images that supports trusted launch](#).

**TIP**

If you don't see the Gen 2 version of the image you want in the drop-down, select **See all images** and then change the **Security type** filter to **Trusted Launch**.

- Select a VM size that supports trusted launch. See the list of [supported sizes](#).
- Fill in the **Administrator account** information and then **Inbound port rules**.
- At the bottom of the page, select **Review + Create**
- On the **Create a virtual machine** page, you can see the details about the VM you are about to deploy. Once validation shows as passed, select **Create**.

**Basics**

Subscription	myAzureSubscription
Resource group	myresourcegroup
Virtual machine name	myTrustedVM
Region	East US
Availability options	No infrastructure redundancy required
Security type	Trusted launch virtual machines
Secure boot	Yes
vTPM	Yes
Image	Windows Server 2019 Datacenter - Gen2
Size	Standard B2s (2 vcpus, 4 GiB memory)
Username	azureuser
Public inbound ports	RDP
Already have a Windows license?	No

It will take a few minutes for your VM to be deployed.

## Deploy a trusted launch VM from an Azure Compute Gallery image

- [Portal](#)
- [CLI](#)
- [PowerShell](#)

- Sign in to the Azure [portal](#).
- To create an Azure Compute Gallery Image from a VM, open an existing Trusted launch VM and select **Capture**.

3. In the Create an Image page that follows, allow the image to be shared to the gallery as a VM image version. Creation of Managed Images is not supported for Trusted Launch VMs.
4. Create a new target Azure Compute Gallery or select an existing gallery.
5. Select the **Operating system state** as either **Generalized** or **Specialized**. If you want to create a generalized image, ensure that you [generalize the VM to remove machine specific information](#) before selecting this option. If Bitlocker based encryption is enabled on your Trusted launch Windows VM, you may not be able to generalize the same.
6. Create a new image definition by providing a name, publisher, offer and SKU details. The **Security Type** of the image definition should already be set to **Trusted launch**.
7. Provide a version number for the image version.
8. Modify replication options if required.
9. At the bottom of the **Create an Image** page, select **Review + Create** and when validation shows as passed, select **Create**.
10. Once the image version is created, go the image version directly. Alternatively, you can navigate to the required image version through the image definition.
11. On the **VM image version** page, select the **+ Create VM** to land on the Create a virtual machine page.
12. In the Create a virtual machine page, under **Resource group**, select **Create new** and type a name for your resource group or select an existing resource group from the dropdown.
13. Under **Instance details**, type a name for the virtual machine name and choose a region that supports [trusted launch](#).
14. The image and the security type are already populated based on the selected image version. The **Secure Boot** and **vTPM** checkboxes are enabled by default.
15. Fill in the **Administrator account** information and then **Inbound port rules**.
16. At the bottom of the page, select **Review + Create**
17. On the **Create a virtual machine** page, you can see the details about the VM you are about to deploy. Once validation shows as passed, select **Create**.

In case you want to use either a managed disk or a managed disk snapshot as a source of the image version (instead of a trusted launch VM), then use the following steps

1. Sign in to the [portal](#)
2. Search for **VM Image Versions** and select **Create**
3. Provide the subscription, resource group, region and image version number
4. Select the source as **Disks and/or Snapshots**
5. Select the OS disk as a managed disk or a managed disk snapshot from the dropdown list
6. Select a **Target Azure Compute Gallery** to create and share the image. If no gallery exists, create a new gallery.
7. Select the **Operating system state** as either **Generalized** or **Specialized**. If you want to create a generalized image, ensure that you generalize the disk or snapshot to remove machine specific information.
8. For the **Target VM Image Definition** select **Create new**. In the window that opens, select an image definition name and ensure that the **Security type** is set to **Trusted launch**. Provide the publisher, offer and SKU information and select **OK**.
9. The **Replication** tab can be used to set the replica count and target regions for image replication, if required.
10. The **Encryption** tab can also be used to provide SSE encryption related information, if required.
11. Select **Create** in the **Review + create** tab to create the image
12. Once the image version is successfully created, select the **+ Create VM** to land on the Create a virtual machine page.
13. Please follow steps 12 to 17 as mentioned earlier to create a trusted launch VM using this image version

## Verify or update your settings

For VMs created with trusted launch enabled, you can view the trusted launch configuration by visiting the [Overview](#) page for the VM in the portal. The **Properties** tab will show the status of Trusted Launch features:

### Security type

Security type	Trusted launch
Secure boot	Enabled
vTPM	Enabled

To change the trusted launch configuration, in the left menu, select **Configuration** under the **Settings** section. You can enable or disable Secure Boot and vTPM from the **Trusted Launch Security types** section. Select **Save** at the top of the page when you are done.

#### Security type

The different levels of security available for your virtual machines. Standard offers basic protection at no extra costs. Trusted launch virtual machines provide additional security features on Gen 2 virtual machines to protect against persistent and advanced attacks. [Learn more about trusted launch](#) ↗

- Secure boot ⓘ
- vTPM ⓘ

If the VM is running, you will receive a message that the VM will be restarted. Select **Yes** then wait for the VM to restart for changes to take effect.

# Secure and use policies on virtual machines in Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

It's important to keep your virtual machine (VM) secure for the applications that you run. Securing your VMs can include one or more Azure services and features that cover secure access to your VMs and secure storage of your data. This article provides information that enables you to keep your VM and applications secure.

## Antimalware

The modern threat landscape for cloud environments is dynamic, increasing the pressure to maintain effective protection in order to meet compliance and security requirements. [Microsoft Antimalware for Azure](#) is a free real-time protection capability that helps identify and remove viruses, spyware, and other malicious software. Alerts can be configured to notify you when known malicious or unwanted software attempts to install itself or run on your VM. It is not supported on VMs running Linux or Windows Server 2008.

## Microsoft Defender for Cloud

[Microsoft Defender for Cloud](#) helps you prevent, detect, and respond to threats to your VMs. Defender for Cloud provides integrated security monitoring and policy management across your Azure subscriptions, helps detect threats that might otherwise go unnoticed, and works with a broad ecosystem of security solutions.

Defender for Cloud's just-in-time access can be applied across your VM deployment to lock down inbound traffic to your Azure VMs, reducing exposure to attacks while providing easy access to connect to VMs when needed. When just-in-time is enabled and a user requests access to a VM, Defender for Cloud checks what permissions the user has for the VM. If they have the correct permissions, the request is approved and Defender for Cloud automatically configures the Network Security Groups (NSGs) to allow inbound traffic to the selected ports for a limited amount of time. After the time has expired, Defender for Cloud restores the NSGs to their previous states.

## Encryption

Two encryption methods are offered for managed disks. Encryption at the OS-level, which is Azure Disk Encryption, and encryption at the platform-level, which is server-side encryption.

### Server-side encryption

Azure managed disks automatically encrypt your data by default when persisting it to the cloud. Server-side encryption protects your data and helps you meet your organizational security and compliance commitments. Data in Azure managed disks is encrypted transparently using 256-bit [AES encryption](#), one of the strongest block ciphers available, and is FIPS 140-2 compliant.

Encryption does not impact the performance of managed disks. There is no additional cost for the encryption.

You can rely on platform-managed keys for the encryption of your managed disk, or you can manage encryption using your own keys. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all data in managed disks.

To learn more about server-side encryption, refer to either the articles for [Windows](#) or [Linux](#).

### Azure Disk Encryption

For enhanced [Windows VM](#) and [Linux VM](#) security and compliance, virtual disks in Azure can be encrypted.

Virtual disks on Windows VMs are encrypted at rest using BitLocker. Virtual disks on Linux VMs are encrypted at rest using dm-crypt.

There is no charge for encrypting virtual disks in Azure. Cryptographic keys are stored in Azure Key Vault using software-protection, or you can import or generate your keys in Hardware Security Modules (HSMs) certified to FIPS 140-2 level 2 standards. These cryptographic keys are used to encrypt and decrypt virtual disks attached to your VM. You retain control of these cryptographic keys and can audit their use. An Azure Active Directory service principal provides a secure mechanism for issuing these cryptographic keys as VMs are powered on and off.

## Key Vault and SSH Keys

Secrets and certificates can be modeled as resources and provided by [Key Vault](#). You can use Azure PowerShell to create key vaults for [Windows VMs](#) and the Azure CLI for [Linux VMs](#). You can also create keys for encryption.

Key vault access policies grant permissions to keys, secrets, and certificates separately. For example, you can give a user access to only keys, but no permissions for secrets. However, permissions to access keys or secrets or certificates are at the vault level. In other words, [key vault access policy](#) does not support object level permissions.

When you connect to VMs, you should use public-key cryptography to provide a more secure way to sign in to them. This process involves a public and private key exchange using the secure shell (SSH) command to authenticate yourself rather than a username and password. Passwords are vulnerable to brute-force attacks, especially on Internet-facing VMs such as web servers. With a secure shell (SSH) key pair, you can create a [Linux VM](#) that uses SSH keys for authentication, eliminating the need for passwords to sign-in. You can also use SSH keys to connect from a [Windows VM](#) to a Linux VM.

## Managed identities for Azure resources

A common challenge when building cloud applications is how to manage the credentials in your code for authenticating to cloud services. Keeping the credentials secure is an important task. Ideally, the credentials never appear on developer workstations and aren't checked into source control. Azure Key Vault provides a way to securely store credentials, secrets, and other keys, but your code has to authenticate to Key Vault to retrieve them.

The managed identities for Azure resources feature in Azure Active Directory (Azure AD) solves this problem. The feature provides Azure services with an automatically managed identity in Azure AD. You can use the identity to authenticate to any service that supports Azure AD authentication, including Key Vault, without any credentials in your code. Your code that's running on a VM can request a token from two endpoints that are accessible only from within the VM. For more detailed information about this service, review the [managed identities for Azure resources](#) overview page.

## Policies

[Azure policies](#) can be used to define the desired behavior for your organization's [Windows VMs](#) and [Linux VMs](#). By using policies, an organization can enforce various conventions and rules throughout the enterprise. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization.

## Azure role-based access control

Using [Azure role-based access control \(Azure RBAC\)](#), you can segregate duties within your team and grant only the amount of access to users on your VM that they need to perform their jobs. Instead of giving everybody unrestricted permissions on the VM, you can allow only certain actions. You can configure access control for the VM in the [Azure portal](#), using the [Azure CLI](#), or [Azure PowerShell](#).

## Next steps

- Walk through the steps to monitor virtual machine security by using Microsoft Defender for Cloud for [Linux](#) or [Windows](#).

# Azure Policy Regulatory Compliance controls for Azure Virtual Machines

9/21/2022 • 158 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

[Regulatory Compliance in Azure Policy](#) provides Microsoft created and managed initiative definitions, known as *built-ins*, for the **compliance domains** and **security controls** related to different compliance standards. This page lists the **compliance domains** and **security controls** for Azure Virtual Machines. You can assign the built-ins for a **security control** individually to help make your Azure resources compliant with the specific standard.

The title of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Policy Version** column to view the source on the [Azure Policy GitHub repo](#).

## IMPORTANT

Each control is associated with one or more [Azure Policy](#) definitions. These policies might help you [assess compliance](#) with the control. However, there often isn't a one-to-one or complete match between a control and one or more policies. As such, **Compliant** in Azure Policy refers only to the policies themselves. This doesn't ensure that you're fully compliant with all requirements of a control. In addition, the compliance standard includes controls that aren't addressed by any Azure Policy definitions at this time. Therefore, compliance in Azure Policy is only a partial view of your overall compliance status. The associations between controls and Azure Policy Regulatory Compliance definitions for these compliance standards can change over time.

## Australian Government ISM PROTECTED

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see [Azure Policy Regulatory Compliance - Australian Government ISM PROTECTED](#). For more information about this compliance standard, see [Australian Government ISM PROTECTED](#).

## HIPAA HITRUST 9.2

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see [Azure Policy Regulatory Compliance - HIPAA HITRUST 9.2](#). For more information about this compliance standard, see [HIPAA HITRUST 9.2](#).

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY (AZURE PORTAL)	POLICY VERSION (GITHUB)
Privilege Management	11180.01c3System.6 - 01.c	Access to management functions or administrative consoles for systems hosting virtualized systems are restricted to personnel based upon the principle of least privilege and supported through technical controls.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Privilege Management	1143.01c1System.123 - 01.c	Privileges are formally authorized and controlled, allocated to users on a need-to-use and event-by-event basis for their functional role (e.g., user or administrator), and documented for each system product/element.	Management ports should be closed on your virtual machines	3.0.0
Privilege Management	1148.01c2System.78 - 01.c	The organization restricts access to privileged functions and all security-relevant information.	Windows machines should meet requirements for 'Security Options - Accounts'	3.0.0
Privilege Management	1150.01c2System.10 - 01.c	The access control system for the system components storing, processing or transmitting covered information is set with a default "deny-all" setting.	Management ports should be closed on your virtual machines	3.0.0
User Authentication for External Connections	1119.01j2Organizational.3 - 01.j	Network equipment is checked for unanticipated dial-up capabilities.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
User Authentication for External Connections	1175.01j1Organizational.8 - 01.j	Remote access to business information across public networks only takes place after successful identification and authentication.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
User Authentication for External Connections	1179.01j3Organizational.1 - 01.j	The information system monitors and controls remote access methods.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
Remote Diagnostic and Configuration Port Protection	1192.01l1Organizational.1 - 01.l	Access to network equipment is physically protected.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Remote Diagnostic and Configuration Port Protection	1193.01l2Organizational.13 - 01.l	Controls for the access to diagnostic and configuration ports include the use of a key lock and the implementation of supporting procedures to control physical access to the port.	<a href="#">Management ports should be closed on your virtual machines</a>	3.0.0
Remote Diagnostic and Configuration Port Protection	1197.01l3Organizational.3 - 01.l	The organization disables Bluetooth and peer-to-peer networking protocols within the information system determined to be unnecessary or non-secure.	<a href="#">Adaptive application controls for defining safe applications should be enabled on your machines</a>	3.0.0
Segregation in Networks	0805.01m1Organizational.12 - 01.m	The organization's security gateways (e.g. firewalls) enforce security policies and are configured to filter traffic between domains, block unauthorized access, and are used to maintain segregation between internal wired, internal wireless, and external network segments (e.g., the Internet) including DMZs and enforce access control policies for each of the domains.	<a href="#">Internet-facing virtual machines should be protected with network security groups</a>	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Segregation in Networks	0806.01m2Organizational.12356 - 01.m	The organizations network is logically and physically segmented with a defined security perimeter and a graduated set of controls, including subnetworks for publicly accessible system components that are logically separated from the internal network, based on organizational requirements; and traffic is controlled based on functionality required and classification of the data/systems based on a risk assessment and their respective security requirements.	Internet-facing virtual machines should be protected with network security groups	3.0.0
Segregation in Networks	0894.01m2Organizational.7 - 01.m	Networks are segregated from production-level networks when migrating physical servers, applications or data to virtualized servers.	Internet-facing virtual machines should be protected with network security groups	3.0.0
Network Connection Control	0809.01n2Organizational.1234 - 01.n	Network traffic is controlled in accordance with the organizations access control policy through firewall and other network-related restrictions for each network access point or external telecommunication service's managed interface.	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Network Connection Control	0809.01n2Organizational.1234 - 01.n	Network traffic is controlled in accordance with the organizations access control policy through firewall and other network-related restrictions for each network access point or external telecommunication service's managed interface.	<a href="#">Internet-facing virtual machines should be protected with network security groups</a>	3.0.0
Network Connection Control	0810.01n2Organizational.5 - 01.n	Transmitted information is secured and, at a minimum, encrypted over open, public networks.	<a href="#">Adaptive network hardening recommendations should be applied on internet facing virtual machines</a>	3.0.0
Network Connection Control	0810.01n2Organizational.5 - 01.n	Transmitted information is secured and, at a minimum, encrypted over open, public networks.	<a href="#">Internet-facing virtual machines should be protected with network security groups</a>	3.0.0
Network Connection Control	0811.01n2Organizational.6 - 01.n	Exceptions to the traffic flow policy are documented with a supporting mission/business need, duration of the exception, and reviewed at least annually; traffic flow policy exceptions are removed when no longer supported by an explicit mission/business need.	<a href="#">Adaptive network hardening recommendations should be applied on internet facing virtual machines</a>	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Network Connection Control	0811.01n2Organizational.6 - 01.n	Exceptions to the traffic flow policy are documented with a supporting mission/business need, duration of the exception, and reviewed at least annually; traffic flow policy exceptions are removed when no longer supported by an explicit mission/business need.	Internet-facing virtual machines should be protected with network security groups	3.0.0
Network Connection Control	0812.01n2Organizational.8 - 01.n	Remote devices establishing a non-remote connection are not allowed to communicate with external (remote) resources.	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
Network Connection Control	0812.01n2Organizational.8 - 01.n	Remote devices establishing a non-remote connection are not allowed to communicate with external (remote) resources.	Internet-facing virtual machines should be protected with network security groups	3.0.0
Network Connection Control	0814.01n1Organizational.12 - 01.n	The ability of users to connect to the internal network is restricted using a deny-by-default and allow-by-exception policy at managed interfaces according to the access control policy and the requirements of clinical and business applications.	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
Network Connection Control	0814.01n1Organizational.12 - 01.n	The ability of users to connect to the internal network is restricted using a deny-by-default and allow-by-exception policy at managed interfaces according to the access control policy and the requirements of clinical and business applications.	Internet-facing virtual machines should be protected with network security groups	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
User Identification and Authentication	11210.01q2Organizational.10 - 01.q	Electronic signatures and handwritten signatures executed to electronic records shall be linked to their respective electronic records.	Audit Windows machines that have the specified members in the Administrators group	2.0.0
User Identification and Authentication	11211.01q2Organizational.11 - 01.q	Signed electronic records shall contain information associated with the signing in human-readable format.	Audit Windows machines missing any of specified members in the Administrators group	2.0.0
User Identification and Authentication	1123.01q1System.2 - 01.q	Users who performed privileged functions (e.g., system administration) use separate accounts when performing those privileged functions.	Audit Windows machines that have extra accounts in the Administrators group	2.0.0
User Identification and Authentication	1125.01q2System.1 - 01.q	Multi-factor authentication methods are used in accordance with organizational policy, (e.g., for remote network access).	Audit Windows machines that have the specified members in the Administrators group	2.0.0
User Identification and Authentication	1127.01q2System.3 - 01.q	Where tokens are provided for multi-factor authentication, in-person verification is required prior to granting access.	Audit Windows machines missing any of specified members in the Administrators group	2.0.0
Audit Logging	1202.09aa1System.1 - 09.aa	A secure audit record is created for all activities on the system (create, read, update, delete) involving covered information.	System updates on virtual machine scale sets should be installed	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Audit Logging	1206.09aa2System.2 3 - 09.aa	Auditing is always available while the system is active and tracks key events, success/failed data access, system security configuration changes, privileged or utility use, any alarms raised, activation and deactivation of protection systems (e.g., A/V and IDS), activation and deactivation of identification and authentication mechanisms, and creation and deletion of system-level objects.	<a href="#">Resource logs in Virtual Machine Scale Sets should be enabled</a>	2.1.0
Monitoring System Use	12100.09ab2System. 15 - 09.ab	The organization monitors the information system to identify irregularities or anomalies that are indicators of a system malfunction or compromise and help confirm the system is functioning in an optimal, resilient and secure state.	<a href="#">Virtual machines should have the Log Analytics extension installed</a>	1.0.1
Monitoring System Use	12101.09ab1Organizational. 3 - 09.ab	The organization specifies how often audit logs are reviewed, how the reviews are documented, and the specific roles and responsibilities of the personnel conducting the reviews, including the professional certifications or other qualifications required.	<a href="#">The Log Analytics extension should be installed on Virtual Machine Scale Sets</a>	1.0.1

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Monitoring System Use	12102.09ab1Organizational.4 - 09.ab	The organization shall periodically test its monitoring and detection processes, remediate deficiencies, and improve its processes.	<a href="#">Audit Windows machines on which the Log Analytics agent is not connected as expected</a>	2.0.0
Monitoring System Use	1215.09ab2System.7 - 09.ab	Auditing and monitoring systems employed by the organization support audit reduction and report generation.	<a href="#">Virtual machines should have the Log Analytics extension installed</a>	1.0.1
Monitoring System Use	1216.09ab3System.12 - 09.ab	Automated systems are used to review monitoring activities of security systems (e.g., IPS/IDS) and system records on a daily basis, and identify and document anomalies.	<a href="#">The Log Analytics extension should be installed on Virtual Machine Scale Sets</a>	1.0.1
Monitoring System Use	1217.09ab3System.3 - 09.ab	Alerts are generated for technical personnel to analyze and investigate suspicious activity or suspected violations.	<a href="#">Audit Windows machines on which the Log Analytics agent is not connected as expected</a>	2.0.0
Segregation of Duties	1232.09c3Organizational.12 - 09.c	Access for individuals responsible for administering access controls is limited to the minimum necessary based upon each user's role and responsibilities and these individuals cannot access audit functions related to these controls.	<a href="#">Windows machines should meet requirements for 'User Rights Assignment'</a>	3.0.0
Segregation of Duties	1277.09c2Organizational.4 - 09.c	The initiation of an event is separated from its authorization to reduce the possibility of collusion.	<a href="#">Windows machines should meet requirements for 'Security Options - User Account Control'</a>	3.0.0

Control of Technical Vulnerabilities	0709.10m1Organizational.1 - 10.m	Technical vulnerabilities are identified, evaluated for risk and corrected in a timely manner.	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
Control of Technical Vulnerabilities	0709.10m1Organizational.1 - 10.m	Technical vulnerabilities are identified, evaluated for risk and corrected in a timely manner.	Windows machines should meet requirements for 'Security Options - Microsoft Network Server'	3.0.0
Control of Technical Vulnerabilities	0711.10m2Organizational.23 - 10.m	A technical vulnerability management program is in place to monitor, assess, rank, and remediate vulnerabilities identified in systems.	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Control of Technical Vulnerabilities	0713.10m2Organizational.5 - 10.m	Patches are tested and evaluated before they are installed.	Vulnerabilities in security configuration on your machines should be remediated	3.0.0
Control of Technical Vulnerabilities	0714.10m2Organizational.7 - 10.m	The technical vulnerability management program is evaluated on a quarterly basis.	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
Control of Technical Vulnerabilities	0715.10m2Organizational.8 - 10.m	Systems are appropriately hardened (e.g., configured with only necessary and secure services, ports and protocols enabled).	Vulnerabilities in container security configurations should be remediated	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Control of Technical Vulnerabilities	0717.10m3Organizational.2 - 10.m	Vulnerability scanning tools include the capability to readily update the information system vulnerabilities scanned.	<a href="#">Vulnerabilities in security configuration on your virtual machine scale sets should be remediated</a>	3.0.0
Control of Technical Vulnerabilities	0718.10m3Organizational.34 - 10.m	The organization scans for vulnerabilities in the information system and hosted applications to determine the state of flaw remediation monthly (automatically) and again (manually or automatically) when new vulnerabilities potentially affecting the systems and networked environments are identified and reported.	<a href="#">Vulnerabilities in security configuration on your machines should be remediated</a>	3.0.0
Business Continuity and Risk Assessment	1634.12b1Organizational.1 - 12.b	The organization identifies the critical business processes requiring business continuity.	<a href="#">Audit virtual machines without disaster recovery configured</a>	1.0.0
Business Continuity and Risk Assessment	1637.12b2Organizational.2 - 12.b	Business impact analysis are used to evaluate the consequences of disasters, security failures, loss of service, and service availability.	<a href="#">Windows machines should meet requirements for 'Security Options - Recovery console'</a>	3.0.0

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY	POLICY VERSION
Business Continuity and Risk Assessment	1638.12b2Organizational.345 - 12.b	Business continuity risk assessments (i) are carried out annually with full involvement from owners of business resources and processes; (ii) consider all business processes and is not limited to the information assets, but includes the results specific to information security; and (iii) identifies, quantifies, and prioritizes risks against key business objectives and criteria relevant to the organization, including critical resources, impacts of disruptions, allowable outage times, and recovery priorities.	<a href="#">Audit virtual machines without disaster recovery configured</a>	1.0.0

## IRS 1075 September 2016

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see [Azure Policy Regulatory Compliance - IRS 1075 September 2016](#). For more information about this compliance standard, see [IRS 1075 September 2016](#).

# Azure Policy built-in definitions for Azure Virtual Machines

9/21/2022 • 68 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This page is an index of [Azure Policy](#) built-in policy definitions for Azure Virtual Machines. For additional Azure Policy built-ins for other services, see [Azure Policy built-in definitions](#).

The name of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Version** column to view the source on the [Azure Policy GitHub repo](#).

## Microsoft.Compute

NAME (AZURE PORTAL)	DESCRIPTION	EFFECT(S)	VERSION (GITHUB)
[Preview]: [Preview]: Add user-assigned managed identity to enable Guest Configuration assignments on virtual machines	This policy adds a user-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration. A user-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit <a href="https://aka.ms/gcpol">https://aka.ms/gcpol</a> .	AuditIfNotExists, DeployIfNotExists, Disabled	<a href="#">2.0.0-preview</a>
[Preview]: [Preview]: Assign Built-In User-Assigned Managed Identity to Virtual Machine Scale Sets	Create and assign a built-in user-assigned managed identity or assign a pre-created user-assigned managed identity at scale to virtual machine scale sets. For more detailed documentation, visit <a href="http://aka.ms/managedidentitypolicy">aka.ms/managedidentitypolicy</a> .	AuditIfNotExists, DeployIfNotExists, Disabled	<a href="#">1.0.2-preview</a>
[Preview]: [Preview]: Assign Built-In User-Assigned Managed Identity to Virtual Machines	Create and assign a built-in user-assigned managed identity or assign a pre-created user-assigned managed identity at scale to virtual machines. For more detailed documentation, visit <a href="http://aka.ms/managedidentitypolicy">aka.ms/managedidentitypolicy</a> .	AuditIfNotExists, DeployIfNotExists, Disabled	<a href="#">1.0.2-preview</a>

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: Azure Security agent should be installed on your Linux virtual machine scale sets	Install the Azure Security agent on your Linux virtual machine scale sets in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can be seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Azure Security agent should be installed on your Linux virtual machines	Install the Azure Security agent on your Linux virtual machines in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can be seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Azure Security agent should be installed on your Windows virtual machine scale sets	Install the Azure Security agent on your Windows virtual machine scale sets in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can be seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Azure Security agent should be installed on your Windows virtual machines	Install the Azure Security agent on your Windows virtual machines in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can be seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: ChangeTracking extension should be installed on your Linux virtual machine	Install ChangeTracking Extension on Linux virtual machines to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	1.0.0-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: ChangeTracking extension should be installed on your Linux virtual machine scale sets	Install ChangeTracking Extension on Linux virtual machine scale sets to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: ChangeTracking extension should be installed on your Windows virtual machine	Install ChangeTracking Extension on Windows virtual machines to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: ChangeTracking extension should be installed on your Windows virtual machine scale sets	Install ChangeTracking Extension on Windows virtual machine scale sets to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	1.0.0-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: Configure Association to link virtual machines to default Microsoft Defender for Cloud Data Collection Rule	Configure machines to automatically create an association with the default data collection rule for Microsoft Defender for Cloud. Deleting this association will break the detection of security vulnerabilities for this virtual machine. Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	2.1.1-preview
[Preview]: [Preview]: Configure Association to link virtual machines to user-defined Microsoft Defender for Cloud Data Collection Rule	Configure machines to automatically create an association with the user-defined data collection rule for Microsoft Defender for Cloud. Deleting this association will break the detection of security vulnerabilities for this virtual machine. Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	1.1.1-preview
[Preview]: [Preview]: Configure Azure Defender for SQL agent on virtual machine	Configure Windows machines to automatically install the Azure Defender for SQL agent where the Azure Monitor Agent is installed. Security Center collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Creates a resource group and Log Analytics workspace in the same region as the machine. Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	1.0.0-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: Configure ChangeTracking Extension for Linux virtual machine scale sets	Configure Linux virtual machine scale sets to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitor Agent.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Configure ChangeTracking Extension for Linux virtual machines	Configure Linux virtual machines to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. [Preview]: [Preview]: Machines should be configured to periodically check for missing system updates	<p>To ensure periodic assessments for missing system updates are triggered automatically every 24 hours, the AssessmentMode property should be set to 'AutomaticByPlatform'. Learn more about AssessmentMode property for Windows: <a href="https://aka.ms/computevm-windowspatchassessmentmode">https://aka.ms/computevm-windowspatchassessmentmode</a>, for Linux: <a href="https://aka.ms/computevm-linuxpatchassessmentmode">https://aka.ms/computevm-linuxpatchassessmentmode</a>.</p>	Audit, Deny, Disabled	1.0.0-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: Machines should have ports closed that might expose attack vectors	Azure's Terms Of Use prohibit the use of Azure services in ways that could damage, disable, overburden, or impair any Microsoft server, or the network. The exposed ports identified by this recommendation need to be closed for your continued security. For each identified port, the recommendation also provides an explanation of the potential threat.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Network traffic data collection agent should be installed on Linux virtual machines	Security Center uses the Microsoft Dependency agent to collect network traffic data from your Azure virtual machines to enable advanced network protection features such as traffic visualization on the network map, network hardening recommendations and specific network threats.	AuditIfNotExists, Disabled	1.0.2-preview
[Preview]: [Preview]: Network traffic data collection agent should be installed on Windows virtual machines	Security Center uses the Microsoft Dependency agent to collect network traffic data from your Azure virtual machines to enable advanced network protection features such as traffic visualization on the network map, network hardening recommendations and specific network threats.	AuditIfNotExists, Disabled	1.0.2-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
[Preview]: [Preview]: Schedule recurring updates using Update Management Center	<p>You can use update management center (private preview) in Azure to save recurring deployment schedules to install operating system updates for your Windows Server and Linux machines in Azure, in on-premises environments, and in other cloud environments connected using Azure Arc-enabled servers. This policy will also change the patch mode for the Azure Virtual Machine to 'AutomaticByPlatform'. See more: <a href="https://aka.ms/umc-scheduled-patching">https://aka.ms/umc-scheduled-patching</a></p>	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: Secure Boot should be enabled on supported Windows virtual machines	<p>Enable Secure Boot on supported Windows virtual machines to mitigate against malicious and unauthorized changes to the boot chain. Once enabled, only trusted bootloaders, kernel and kernel drivers will be allowed to run. This assessment only applies to trusted launch enabled Windows virtual machines.</p>	Audit, Disabled	3.0.0-preview
[Preview]: [Preview]: System updates should be installed on your machines (powered by Update Center)	<p>Your machines are missing system, security, and critical updates. Software updates often include critical patches to security holes. Such holes are frequently exploited in malware attacks so it's vital to keep your software updated. To install all outstanding patches and secure your machines, follow the remediation steps.</p>	AuditIfExists, Disabled	1.0.0-preview

Name	Description	Effect(s)	Version
[Preview]: [Preview]: Virtual machines guest attestation status should be healthy	Guest attestation is performed by sending a trusted log (TCGLog) to an attestation server. The server uses these logs to determine whether boot components are trustworthy. This assessment is intended to detect compromises of the boot chain which might be the result of a bootkit or rootkit infection. This assessment only applies to Trusted Launch enabled virtual machines that have Guest Attestation extension installed.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: [Preview]: vTPM should be enabled on supported virtual machines	Enable virtual TPM device on supported virtual machines to facilitate Measured Boot and other OS security features that require a TPM. Once enabled, vTPM can be used to attest boot integrity. This assessment only applies to trusted launch enabled virtual machines.	Audit, Disabled	2.0.0-preview
[Preview]: [Preview]: Windows machines should meet STIG compliance requirements for Azure compute	Requires that prerequisites are deployed to the policy assignment scope. For details, visit <a href="https://aka.ms/gcpol">https://aka.ms/gcpol</a> . Machines are non-compliant if the machine is not configured correctly for one of the recommendations in STIG compliance requirements for Azure compute. DISA (Defense Information Systems Agency) provides technical guides STIG (Security Technical Implementation Guide) to secure compute OS as required by Department of Defense (DoD). For more details, <a href="https://public.cyber.mil/stigs/">https://public.cyber.mil/stigs/</a> .	AuditIfNotExists, Disabled	1.0.0-preview

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">A vulnerability assessment solution should be enabled on your virtual machines</a>	Audits virtual machines to detect whether they are running a supported vulnerability assessment solution. A core component of every cyber risk and security program is the identification and analysis of vulnerabilities. Azure Security Center's standard pricing tier includes vulnerability scanning for your virtual machines at no extra cost. Additionally, Security Center can automatically deploy this tool for you.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Adaptive application controls for defining safe applications should be enabled on your machines</a>	Enable application controls to define the list of known-safe applications running on your machines, and alert you when other applications run. This helps harden your machines against malware. To simplify the process of configuring and maintaining your rules, Security Center uses machine learning to analyze the applications running on each machine and suggest the list of known-safe applications.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Adaptive network hardening recommendations should be applied on internet facing virtual machines</a>	Azure Security Center analyzes the traffic patterns of Internet facing virtual machines and provides Network Security Group rule recommendations that reduce the potential attack surface	AuditIfNotExists, Disabled	3.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities</a>	This policy adds a system-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration but do not have any managed identities. A system-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit <a href="https://aka.ms/gcpol">https://aka.ms/gcpol</a> .	modify	4.0.0
<a href="#">Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity</a>	This policy adds a system-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration and have at least one user-assigned identity but do not have a system-assigned managed identity. A system-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit <a href="https://aka.ms/gcpol">https://aka.ms/gcpol</a> .	modify	4.0.0
<a href="#">All network ports should be restricted on network security groups associated to your virtual machine</a>	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Allowed virtual machine size SKUs</a>	This policy enables you to specify a set of virtual machine size SKUs that your organization can deploy.	Deny	1.0.1

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">Allowlist rules in your adaptive application control policy should be updated</a>	Monitor for changes in behavior on groups of machines configured for auditing by Azure Security Center's adaptive application controls. Security Center uses machine learning to analyze the running processes on your machines and suggest a list of known-safe applications. These are presented as recommended apps to allow in adaptive application control policies.	AuditIfNotExists, Disabled	3.0.0

<a href="#">Windows web servers should be configured to use secure communication protocols</a>	To protect the privacy of information communicated over the Internet, your web servers should use the latest version of the industry-standard cryptographic protocol, Transport Layer Security (TLS). TLS secures communications over a network by using security certificates to encrypt a connection between machines.	AuditIfNotExists, Disabled	4.0.0

## Microsoft.VirtualMachineImages

NAME (AZURE PORTAL)	DESCRIPTION	EFFECT(S)	VERSION (GITHUB)
<a href="#">VM Image Builder templates should use private link</a>	Azure Private Link lets you connect your virtual network to Azure services without a public IP address at the source or destination. The Private Link platform handles the connectivity between the consumer and services over the Azure backbone network. By mapping private endpoints to your VM Image Builder building resources, data leakage risks are reduced. Learn more about private links at: <a href="https://docs.microsoft.com/azure/virtual-machines/linux/image-builder-networking#deploy-using-an-existing-vnet">https://docs.microsoft.com/azure/virtual-machines/linux/image-builder-networking#deploy-using-an-existing-vnet</a> .	Audit, Disabled, Deny	1.1.0

# Microsoft.ClassicCompute

NAME (AZURE PORTAL)	DESCRIPTION	EFFECT(S)	VERSION (GITHUB)
<a href="#">A vulnerability assessment solution should be enabled on your virtual machines</a>	Audits virtual machines to detect whether they are running a supported vulnerability assessment solution. A core component of every cyber risk and security program is the identification and analysis of vulnerabilities. Azure Security Center's standard pricing tier includes vulnerability scanning for your virtual machines at no extra cost. Additionally, Security Center can automatically deploy this tool for you.	AuditIfNotExists, Disabled	<a href="#">3.0.0</a>
<a href="#">Adaptive application controls for defining safe applications should be enabled on your machines</a>	Enable application controls to define the list of known-safe applications running on your machines, and alert you when other applications run. This helps harden your machines against malware. To simplify the process of configuring and maintaining your rules, Security Center uses machine learning to analyze the applications running on each machine and suggest the list of known-safe applications.	AuditIfNotExists, Disabled	<a href="#">3.0.0</a>
<a href="#">All network ports should be restricted on network security groups associated to your virtual machine</a>	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	<a href="#">3.0.0</a>

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">Allowlist rules in your adaptive application control policy should be updated</a>	Monitor for changes in behavior on groups of machines configured for auditing by Azure Security Center's adaptive application controls. Security Center uses machine learning to analyze the running processes on your machines and suggest a list of known-safe applications. These are presented as recommended apps to allow in adaptive application control policies.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Audit virtual machines without disaster recovery configured</a>	Audit virtual machines which do not have disaster recovery configured. To learn more about disaster recovery, visit <a href="https://aka.ms/asr-doc">https://aka.ms/asr-doc</a> .	auditIfNotExists	1.0.0
<a href="#">Endpoint protection health issues should be resolved on your machines</a>	Resolve endpoint protection health issues on your virtual machines to protect them from latest threats and vulnerabilities. Azure Security Center supported endpoint protection solutions are documented here - <a href="https://docs.microsoft.com/azure/security-center/security-center-services?tabs=features-windows#supported-endpoint-protection-solutions">https://docs.microsoft.com/azure/security-center/security-center-services?tabs=features-windows#supported-endpoint-protection-solutions</a> . Endpoint protection assessment is documented here - <a href="https://docs.microsoft.com/azure/security-center/security-center-endpoint-protection">https://docs.microsoft.com/azure/security-center/security-center-endpoint-protection</a> .	AuditIfNotExists, Disabled	1.0.0
<a href="#">Endpoint protection should be installed on your machines</a>	To protect your machines from threats and vulnerabilities, install a supported endpoint protection solution.	AuditIfNotExists, Disabled	1.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">Internet-facing virtual machines should be protected with network security groups</a>	Protect your virtual machines from potential threats by restricting access to them with network security groups (NSG). Learn more about controlling traffic with NSGs at <a href="https://aka.ms/nsg-doc">https://aka.ms/nsg-doc</a>	AuditIfNotExists, Disabled	3.0.0
<a href="#">IP Forwarding on your virtual machine should be disabled</a>	Enabling IP forwarding on a virtual machine's NIC allows the machine to receive traffic addressed to other destinations. IP forwarding is rarely required (e.g., when using the VM as a network virtual appliance), and therefore, this should be reviewed by the network security team.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Log Analytics agent should be installed on your virtual machine for Azure Security Center monitoring</a>	This policy audits any Windows/Linux virtual machines (VMs) if the Log Analytics agent is not installed which Security Center uses to monitor for security vulnerabilities and threats	AuditIfNotExists, Disabled	1.0.0
<a href="#">Management ports should be closed on your virtual machines</a>	Open remote management ports are exposing your VM to a high level of risk from Internet-based attacks. These attacks attempt to brute force credentials to gain admin access to the machine.	AuditIfNotExists, Disabled	3.0.0
<a href="#">Monitor missing Endpoint Protection in Azure Security Center</a>	Servers without an installed Endpoint Protection agent will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.0.0
<a href="#">Non-internet-facing virtual machines should be protected with network security groups</a>	Protect your non-internet-facing virtual machines from potential threats by restricting access with network security groups (NSG). Learn more about controlling traffic with NSGs at <a href="https://aka.ms/nsg-doc">https://aka.ms/nsg-doc</a>	AuditIfNotExists, Disabled	3.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
<a href="#">System updates should be installed on your machines</a>	Missing security system updates on your servers will be monitored by Azure Security Center as recommendations	AuditIfExists, Disabled	4.0.0
<a href="#">Virtual machines should be migrated to new Azure Resource Manager resources</a>	Use new Azure Resource Manager for your virtual machines to provide security enhancements such as: stronger access control (RBAC), better auditing, Azure Resource Manager based deployment and governance, access to managed identities, access to key vault for secrets, Azure AD-based authentication and support for tags and resource groups for easier security management	Audit, Deny, Disabled	1.0.0
<a href="#">Virtual machines should encrypt temp disks, caches, and data flows between Compute and Storage resources</a>	By default, a virtual machine's OS and data disks are encrypted-at-rest using platform-managed keys. Temp disks, data caches and data flowing between compute and storage aren't encrypted. Disregard this recommendation if: 1. using encryption-at-host, or 2. server-side encryption on Managed Disks meets your security requirements. Learn more in: Server-side encryption of Azure Disk Storage: <a href="https://aka.ms/disksse">https://aka.ms/disksse</a> , Different disk encryption offerings: <a href="https://aka.ms/diskencryptioncomparison">https://aka.ms/diskencryptioncomparison</a>	AuditIfExists, Disabled	2.0.3
<a href="#">Vulnerabilities in container security configurations should be remediated</a>	Audit vulnerabilities in security configuration on machines with Docker installed and display as recommendations in Azure Security Center.	AuditIfExists, Disabled	3.0.0
<a href="#">Vulnerabilities in security configuration on your machines should be remediated</a>	Servers which do not satisfy the configured baseline will be monitored by Azure Security Center as recommendations	AuditIfExists, Disabled	3.0.0

# Apply policies to Linux VMs with Azure Resource Manager

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

By using policies, an organization can enforce various conventions and rules throughout the enterprise. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization. In this article, we describe how you can use Azure Resource Manager policies to define the desired behavior for your organization's Virtual Machines.

For an introduction to policies, see [What is Azure Policy?](#).

## Permitted Virtual Machines

To ensure that virtual machines for your organization are compatible with an application, you can restrict the permitted operating systems. In the following policy example, you allow only Ubuntu 14.04.2-LTS Virtual Machines to be created.

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "in": [
          "Microsoft.Compute/virtualMachines",
          "Microsoft.Compute/VirtualMachineScaleSets"
        ]
      },
      {
        "not": {
          "allOf": [
            {
              "field": "Microsoft.Compute/imagePublisher",
              "in": [
                "Canonical"
              ]
            },
            {
              "field": "Microsoft.Compute/imageOffer",
              "in": [
                "UbuntuServer"
              ]
            },
            {
              "field": "Microsoft.Compute/imageSku",
              "in": [
                "14.04.2-LTS"
              ]
            },
            {
              "field": "Microsoft.Compute/imageVersion",
              "in": [
                "latest"
              ]
            }
          ]
        }
      ],
      "then": {
        "effect": "deny"
      }
    }
  }
}
```

Use a wild card to modify the preceding policy to allow any Ubuntu LTS image:

```
{
  "field": "Microsoft.Compute/virtualMachines/imageSku",
  "like": "*LTS"
}
```

For information about policy fields, see [Policy aliases](#).

## Managed disks

To require the use of managed disks, use the following policy:

```
{
  "if": {
    "anyOf": [
      {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/virtualMachines"
          },
          {
            "field": "Microsoft.Compute/virtualMachines/osDisk.uri",
            "exists": true
          }
        ]
      },
      {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/VirtualMachineScaleSets"
          },
          {
            "anyOf": [
              {
                "field": "Microsoft.Compute/VirtualMachineScaleSets/osDisk.vhdContainers",
                "exists": true
              },
              {
                "field": "Microsoft.Compute/VirtualMachineScaleSets/osdisk.imageUrl",
                "exists": true
              }
            ]
          }
        ]
      }
    ],
    "then": {
      "effect": "deny"
    }
  }
}
```

## Images for Virtual Machines

For security reasons, you can require that only approved custom images are deployed in your environment. You can specify either the resource group that contains the approved images, or the specific approved images.

The following example requires images from an approved resource group:

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "in": [
          "Microsoft.Compute/virtualMachines",
          "Microsoft.Compute/VirtualMachineScaleSets"
        ]
      },
      {
        "not": {
          "field": "Microsoft.Compute/imageId",
          "contains": "resourceGroups/CustomImage"
        }
      }
    ],
    "then": {
      "effect": "deny"
    }
  }
}
```

The following example specifies the approved image IDs:

```
{
  "field": "Microsoft.Compute/imageId",
  "in": ["{imageId1}", "{imageId2}"]
}
```

## Virtual Machine extensions

You may want to forbid usage of certain types of extensions. For example, an extension may not be compatible with certain custom virtual machine images. The following example shows how to block a specific extension. It uses publisher and type to determine which extension to block.

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Compute/virtualMachines/extensions"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
        "equals": "Microsoft.Compute"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/type",
        "equals": "{extension-type}"
      }
    ],
    "then": {
      "effect": "deny"
    }
  }
}
```

## Next steps

- After defining a policy rule (as shown in the preceding examples), you need to create the policy definition and assign it to a scope. The scope can be a subscription, resource group, or resource. To assign policies, see [Use Azure portal to assign and manage resource policies](#), [Use PowerShell to assign policies](#), or [Use Azure CLI to assign policies](#).
- For an introduction to resource policies, see [What is Azure Policy?](#).
- For guidance on how enterprises can use Resource Manager to effectively manage subscriptions, see [Azure enterprise scaffold - prescriptive subscription governance](#).

# Apply policies to Windows VMs with Azure Resource Manager

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

By using policies, an organization can enforce various conventions and rules throughout the enterprise. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization. In this article, we describe how you can use Azure Resource Manager policies to define the desired behavior for your organization's Virtual Machines.

For an introduction to policies, see [What is Azure Policy?](#).

## Permitted Virtual Machines

To ensure that virtual machines for your organization are compatible with an application, you can restrict the permitted operating systems. In the following policy example, you allow only Windows Server 2012 R2 Datacenter Virtual Machines to be created:

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "in": [
          "Microsoft.Compute/virtualMachines",
          "Microsoft.Compute/VirtualMachineScaleSets"
        ]
      },
      {
        "not": {
          "allOf": [
            {
              "field": "Microsoft.Compute/imagePublisher",
              "in": [
                "MicrosoftWindowsServer"
              ]
            },
            {
              "field": "Microsoft.Compute/imageOffer",
              "in": [
                "WindowsServer"
              ]
            },
            {
              "field": "Microsoft.Compute/imageSku",
              "in": [
                "2012-R2-Datacenter"
              ]
            },
            {
              "field": "Microsoft.Compute/imageVersion",
              "in": [
                "latest"
              ]
            }
          ]
        }
      ],
      "then": {
        "effect": "deny"
      }
    }
  }
}
```

Use a wild card to modify the preceding policy to allow any Windows Server Datacenter image:

```
{
  "field": "Microsoft.Compute/imageSku",
  "like": "*Datacenter"
}
```

Use anyOf to modify the preceding policy to allow any Windows Server 2012 R2 Datacenter or higher image:

```
{
  "anyOf": [
    {
      "field": "Microsoft.Compute/imageSku",
      "like": "2012-R2-Datacenter*"
    },
    {
      "field": "Microsoft.Compute/imageSku",
      "like": "2016-Datacenter*"
    }
  ]
}
```

For information about policy fields, see [Policy aliases](#).

## Managed disks

To require the use of managed disks, use the following policy:

```
{
  "if": {
    "anyOf": [
      {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/virtualMachines"
          },
          {
            "field": "Microsoft.Compute/virtualMachines/osDisk.uri",
            "exists": true
          }
        ]
      },
      {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/VirtualMachineScaleSets"
          },
          {
            "anyOf": [
              {
                "field": "Microsoft.Compute/VirtualMachineScaleSets/osDisk.vhdContainers",
                "exists": true
              },
              {
                "field": "Microsoft.Compute/VirtualMachineScaleSets/osdisk.imageUrl",
                "exists": true
              }
            ]
          }
        ]
      }
    ],
    "then": {
      "effect": "deny"
    }
  }
}
```

## Images for Virtual Machines

For security reasons, you can require that only approved custom images are deployed in your environment. You can specify either the resource group that contains the approved images, or the specific approved images.

The following example requires images from an approved resource group:

```
{  
  "if": {  
    "allOf": [  
      {  
        "field": "type",  
        "in": [  
          "Microsoft.Compute/virtualMachines",  
          "Microsoft.Compute/VirtualMachineScaleSets"  
        ]  
      },  
      {  
        "not": {  
          "field": "Microsoft.Compute/imageId",  
          "contains": "resourceGroups/CustomImage"  
        }  
      }  
    ],  
    "then": {  
      "effect": "deny"  
    }  
  }  
}
```

The following example specifies the approved image IDs:

```
{  
  "field": "Microsoft.Compute/imageId",  
  "in": ["{imageId1}","{imageId2}"]  
}
```

## Virtual Machine extensions

You may want to forbid usage of certain types of extensions. For example, an extension may not be compatible with certain custom virtual machine images. The following example shows how to block a specific extension. It uses publisher and type to determine which extension to block.

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Compute/virtualMachines/extensions"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
        "equals": "Microsoft.Compute"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/type",
        "equals": "{extension-type}"
      }
    ]
  },
  "then": {
    "effect": "deny"
  }
}
```

## Azure Hybrid Use Benefit

When you have an on-premises license, you can save the license fee on your virtual machines. When you don't have the license, you should forbid the option. The following policy forbids usage of Azure Hybrid Use Benefit (AHUB):

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "in": [ "Microsoft.Compute/virtualMachines", "Microsoft.Compute/VirtualMachineScaleSets" ]
      },
      {
        "field": "Microsoft.Compute/licenseType",
        "exists": true
      }
    ]
  },
  "then": {
    "effect": "deny"
  }
}
```

## Next steps

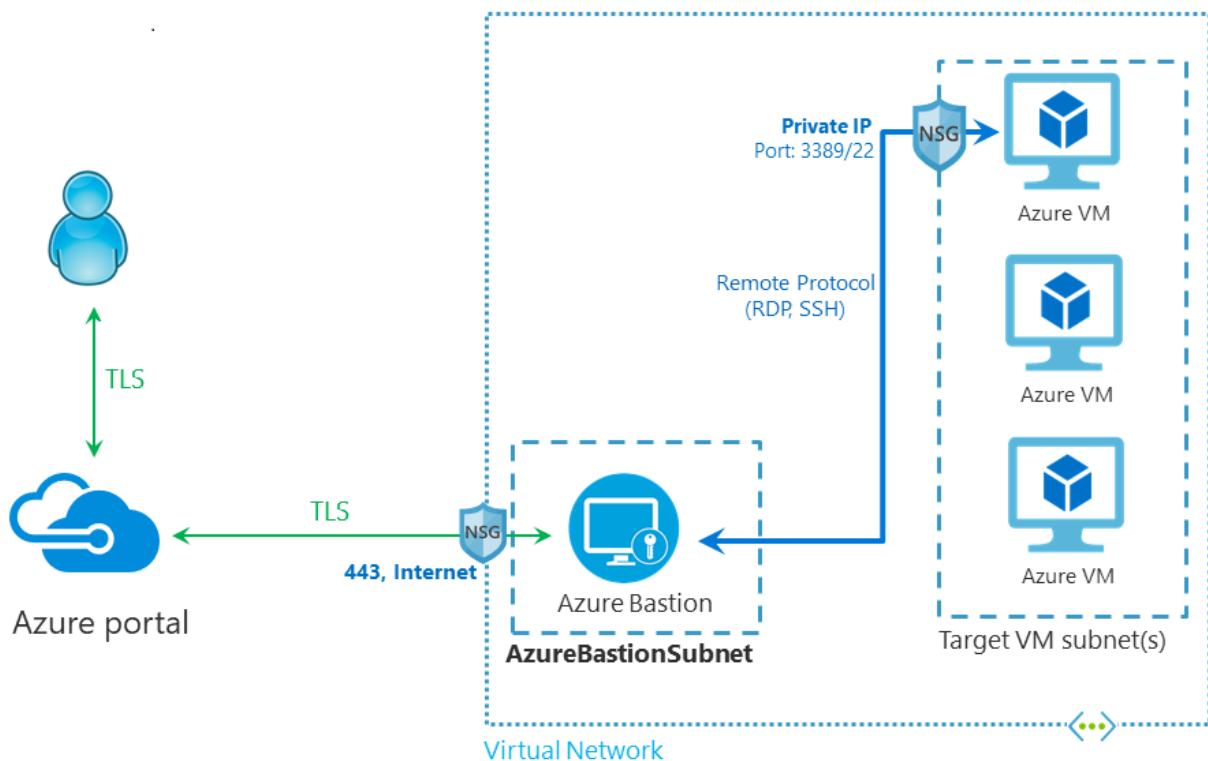

- After defining a policy rule (as shown in the preceding examples), you need to create the policy definition and assign it to a scope. The scope can be a subscription, resource group, or resource. To assign policies, see [Use Azure portal to assign and manage resource policies](#), [Use PowerShell to assign policies](#), or [Use Azure CLI to assign policies](#).
- For an introduction to resource policies, see [What is Azure Policy?](#).
- For guidance on how enterprises can use Resource Manager to effectively manage subscriptions, see [Azure enterprise scaffold - prescriptive subscription governance](#).

# What is Azure Bastion?

9/21/2022 • 4 minutes to read • [Edit Online](#)

Azure Bastion is a service you deploy that lets you connect to a virtual machine using your browser and the Azure portal, or via the native SSH or RDP client already installed on your local computer. The Azure Bastion service is a fully platform-managed PaaS service that you provision inside your virtual network. It provides secure and seamless RDP/SSH connectivity to your virtual machines directly from the Azure portal over TLS. When you connect via Azure Bastion, your virtual machines don't need a public IP address, agent, or special client software.

Bastion provides secure RDP and SSH connectivity to all of the VMs in the virtual network in which it is provisioned. Using Azure Bastion protects your virtual machines from exposing RDP/SSH ports to the outside world, while still providing secure access using RDP/SSH.

## Key benefits

BENEFIT	DESCRIPTION
RDP and SSH through the Azure portal	You can get to the RDP and SSH session directly in the Azure portal using a single-click seamless experience.
Remote Session over TLS and firewall traversal for RDP/SSH	Azure Bastion uses an HTML5 based web client that is automatically streamed to your local device. Your RDP/SSH session is over TLS on port 443. This enables the traffic to traverse firewalls more securely.

BENEFIT	DESCRIPTION
No Public IP address required on the Azure VM	Azure Bastion opens the RDP/SSH connection to your Azure VM by using the private IP address on your VM. You don't need a public IP address on your virtual machine.
No hassle of managing Network Security Groups (NSGs)	You don't need to apply any NSGs to the Azure Bastion subnet. Because Azure Bastion connects to your virtual machines over private IP, you can configure your NSGs to allow RDP/SSH from Azure Bastion only. This removes the hassle of managing NSGs each time you need to securely connect to your virtual machines. For more information about NSGs, see <a href="#">Network Security Groups</a> .
No need to manage a separate bastion host on a VM	Azure Bastion is a fully managed platform PaaS service from Azure that is hardened internally to provide you secure RDP/SSH connectivity.
Protection against port scanning	Your VMs are protected against port scanning by rogue and malicious users because you don't need to expose the VMs to the internet.
Hardening in one place only	Azure Bastion sits at the perimeter of your virtual network, so you don't need to worry about hardening each of the VMs in your virtual network.
Protection against zero-day exploits	The Azure platform protects against zero-day exploits by keeping the Azure Bastion hardened and always up to date for you.

## SKUs

Azure Bastion has two available SKUs, Basic and Standard. For more information, including how to upgrade a SKU, see the [Configuration settings](#) article.

The following table shows features and corresponding SKUs.

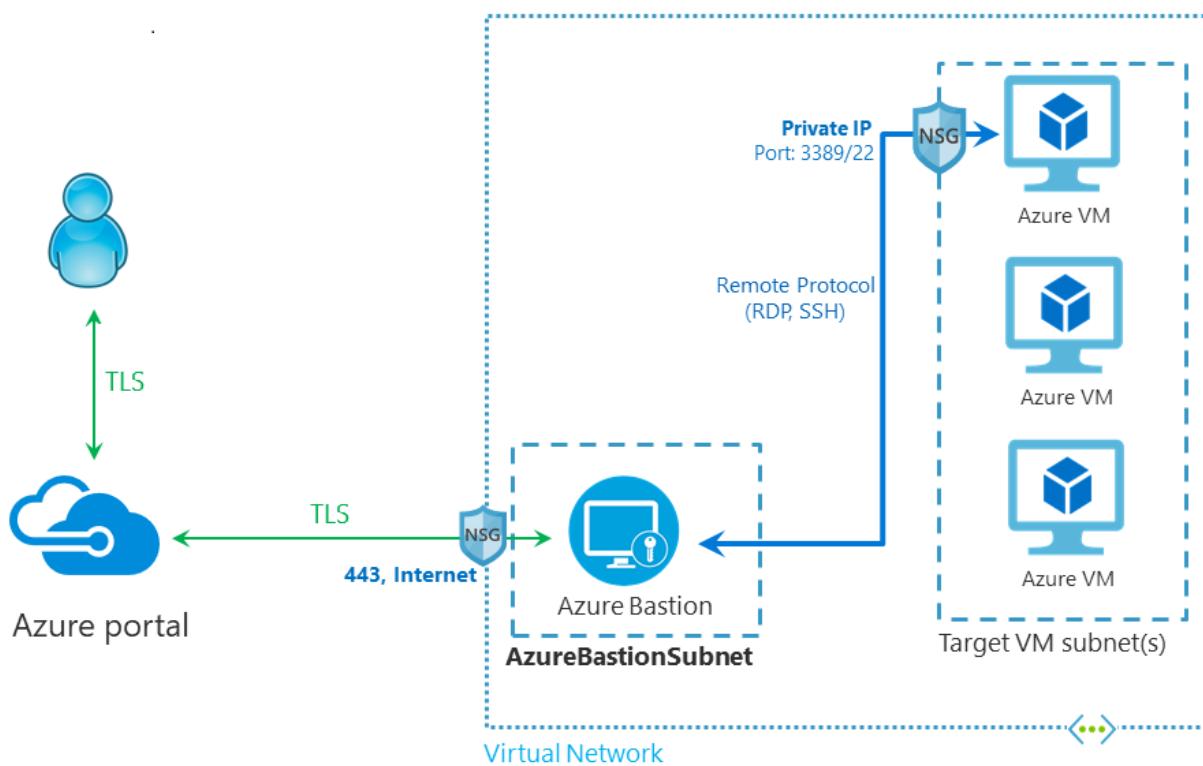

FEATURE	BASIC SKU	STANDARD SKU
Connect to target VMs in peered virtual networks	Yes	Yes
Access Linux VM Private Keys in Azure Key Vault (AKV)	Yes	Yes
Connect to Linux VM using SSH	Yes	Yes
Connect to Windows VM using RDP	Yes	Yes
VM audio output	Yes	Yes
Host scaling	Not available	Yes
Specify custom inbound port	Not available	Yes
Connect to Linux VM using RDP	Not available	Yes

FEATURE	BASIC SKU	STANDARD SKU
Connect to Windows VM using SSH	Not available	Yes
Upload or download files	Not available	Yes
Disable copy/paste (web-based clients)	Not available	Yes

## Architecture

Azure Bastion is deployed to a virtual network and supports virtual network peering. Specifically, Azure Bastion manages RDP/SSH connectivity to VMs created in the local or peered virtual networks.

RDP and SSH are some of the fundamental means through which you can connect to your workloads running in Azure. Exposing RDP/SSH ports over the Internet isn't desired and is seen as a significant threat surface. This is often due to protocol vulnerabilities. To contain this threat surface, you can deploy bastion hosts (also known as jump-servers) at the public side of your perimeter network. Bastion host servers are designed and configured to withstand attacks. Bastion servers also provide RDP and SSH connectivity to the workloads sitting behind the bastion, as well as further inside the network.

This figure shows the architecture of an Azure Bastion deployment. In this diagram:

- The Bastion host is deployed in the virtual network that contains the AzureBastionSubnet subnet that has a minimum /26 prefix.
- The user connects to the Azure portal using any HTML5 browser.
- The user selects the virtual machine to connect to.
- With a single click, the RDP/SSH session opens in the browser.
- No public IP is required on the Azure VM.

## Host scaling

Azure Bastion supports manual host scaling. You can configure the number of host instances (scale units) in order to manage the number of concurrent RDP/SSH connections that Azure Bastion can support. Increasing the number of host instances lets Azure Bastion manage more concurrent sessions. Decreasing the number of instances decreases the number of concurrent supported sessions. Azure Bastion supports up to 50 host instances. This feature is available for the Azure Bastion Standard SKU only.

For more information, see the [Configuration settings](#) article.

## Pricing

Azure Bastion pricing involves a combination of hourly pricing based on SKU, scale units, and data transfer rates. Pricing information can be found on the [Pricing](#) page.

## What's new?

Subscribe to the RSS feed and view the latest Azure Bastion feature updates on the [Azure Updates](#) page.

## Bastion FAQ

For frequently asked questions, see the Bastion [FAQ](#).

## Next steps

- [Learn module: Introduction to Azure Bastion](#).
- Learn about some of the other key [networking capabilities](#) of Azure.

# Tutorial: Deploy Bastion using specified settings

9/21/2022 • 9 minutes to read • [Edit Online](#)

This tutorial helps you deploy Azure Bastion from the Azure portal using your own specified manual settings. When you use manual settings, you can specify configuration values such as instance counts and the SKU at the time of deployment. After Bastion is deployed, you can connect (SSH/RDP) to virtual machines in the virtual network via Bastion using the private IP address of the VM. When you connect to a VM, it doesn't need a public IP address, client software, agent, or a special configuration.

In this tutorial, you deploy Bastion using the Standard SKU tier and adjust host scaling (instance count). After the deployment is complete, you connect to your VM via private IP address. If your VM has a public IP address that you don't need for anything else, you can remove it.

Azure Bastion is a PaaS service that's maintained for you, not a bastion host that you install on one of your VMs and maintain yourself. For more information about Azure Bastion, see [What is Azure Bastion?](#)

In this tutorial, you'll learn how to:

- Deploy Bastion to your VNet.
- Connect to a virtual machine.
- Remove the public IP address from a virtual machine.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Prerequisites

- A [virtual network](#). This will be the VNet to which you deploy Bastion.
- A virtual machine in the virtual network. This VM isn't a part of the Bastion configuration and doesn't become a bastion host. You connect to this VM later in this tutorial via Bastion. If you don't have a VM, create one using [Quickstart: Create a VM](#).
- **Required VM roles:**
  - Reader role on the virtual machine.
  - Reader role on the NIC with private IP of the virtual machine.
- **Required inbound ports:**
  - For Windows VMs - RDP (3389)
  - For Linux VMs - SSH (22)

### NOTE

The use of Azure Bastion with Azure Private DNS Zones is not supported at this time. Before you begin, please make sure that the virtual network where you plan to deploy your Bastion resource is not linked to a private DNS zone.

## Example values

You can use the following example values when creating this configuration, or you can substitute your own.

### Basic VNet and VM values:

NAME	VALUE
Virtual machine	TestVM
Resource group	TestRG1
Region	East US
Virtual network	VNet1
Address space	10.1.0.0/16
Subnets	FrontEnd: 10.1.0.0/24

#### Azure Bastion values:

NAME	VALUE
Name	VNet1-bastion
+ Subnet Name	AzureBastionSubnet
AzureBastionSubnet addresses	A subnet within your VNet address space with a subnet mask /26 or larger. For example, 10.1.1.0/26.
Tier/SKU	Standard
Instance count (host scaling)	3 or greater
Public IP address	Create new
Public IP address name	VNet1-ip
Public IP address SKU	Standard
Assignment	Static

#### IMPORTANT

For Azure Bastion resources deployed on or after November 2, 2021, the minimum AzureBastionSubnet size is /26 or larger (/25, /24, etc.). All Azure Bastion resources deployed in subnets of size /27 prior to this date are unaffected by this change and will continue to work, but we highly recommend increasing the size of any existing AzureBastionSubnet to /26 in case you choose to take advantage of [host scaling](#) in the future.

## Deploy Bastion

This section helps you deploy Bastion to your VNet. Once Bastion is deployed, you can connect securely to any VM in the VNet using its private IP address.

1. Sign in to the [Azure portal](#).
2. Go to your virtual network.

3. On the page for your virtual network, in the left pane, select **Bastion** to open the **Bastion** page.
4. On the Bastion page, select **Configure manually**. This lets you configure specific additional settings when deploying Bastion to your VNet.

Home > TestRG1 > VNet1

VNet1 | Bastion

Virtual network

Search (Ctrl+ /)

Diagnose and solve problems

**Settings**

- Address space
- Connected devices
- Subnets
- Bastion**
- DDoS protection
- Firewall
- Microsoft Defender for Cloud
- Network manager
- DNS servers
- Peerings

Azure Bastion protects your virtual machines by providing lightweight, browser-based connectivity without the need to expose them through public IP addresses. Deploying will automatically create a Bastion host on a subnet in your virtual network. [Learn more](#)

**Create Bastion**

Name ⓘ	VNet1-bastion
Resource group ⓘ	TestRG1
Virtual network ⓘ	VNet1
Public IP address ⓘ	VNet1-ip

Bastion pricing starts with an hourly base rate. [Learn more](#)

**Deploy Bastion**    **Configure manually**

5. On the **Create a Bastion** page, configure the settings for your bastion host. Project details are populated from your virtual network values. Configure the **Instance details** values.
  - **Name:** Type the name that you want to use for your bastion resource.
  - **Region:** The Azure public region in which the resource will be created. Choose the region in which your virtual network resides.
  - **Tier:** The tier is also known as the **SKU**. For this tutorial, select **Standard**. The Standard SKU lets you configure the instance count for host scaling and other features. For more information about features that require the Standard SKU, see [Configuration settings - SKU](#).
  - **Instance count:** This is the setting for **host scaling**. It's configured in scale unit increments. Use the slider or type a number to configure the instance count that you want. For this tutorial, you can select the instance count you'd prefer. For more information, see [Host scaling](#) and [Pricing](#).

**Instance details**

Name *	VNet1-bastion
Region *	East US
Tier *	Standard
Instance count *	3

6. Configure the **virtual networks** settings. Select your VNet from the dropdown. If you don't see your VNet in the dropdown list, make sure you selected the correct Region in the previous settings on this page.
7. To configure the AzureBastionSubnet, select **Manage subnet configuration**.

## Configure virtual networks

VNet1

Create new

To associate a virtual network with a Bastion, it must contain a subnet with name AzureBastionSubnet and a prefix of at least /26

Subnet \*

Manage subnet configuration

8. On the **Subnets** page, select **+ Subnet** to open the **Add subnet** page.
9. On the **Add subnet page**, create the 'AzureBastionSubnet' subnet using the following values. Leave the other values as default.
  - The subnet name must be **AzureBastionSubnet**.
  - The subnet must be at least **/26 or larger** (/26, /25, /24 etc.) to accommodate features available with the Standard SKU.Select **Save** at the bottom of the page to save your values.

10. At the top of the **Subnets** page, select **Create a Bastion** to return to the Bastion configuration page.

Home > TestRG1 > VNet1 | Bastion > **Create a Bastion** > VNet1

VNet1 | Subnets

Name	IPv4	IPv6	Available IPs	Delegated to
FrontEnd	10.1.0.0/24	-	249	-
AzureBastionSubnet	10.1.1.0/26	-	59	-

11. The **Public IP address** section is where you configure the public IP address of the Bastion host resource on which RDP/SSH will be accessed (over port 443). The public IP address must be in the same region as the Bastion resource you're creating. Create a new IP address. You can leave the default naming suggestion.
12. When you finish specifying the settings, select **Review + Create**. This validates the values.
13. Once validation passes, you can deploy Bastion. Select **Create**. You'll see a message letting you know that your deployment is in process. Status will display on this page as the resources are created. It takes about 10 minutes for the Bastion resource to be created and deployed.

## Connect to a VM

You can use any of the following detailed articles to connect to a VM. Some connection types require the Bastion **Standard SKU**.

- [Windows - RDP](#)
- [Windows - SSH](#)
- [Linux - SSH](#)
- [Linux - RDP](#)
- [Connect from a local computer using a native client](#)
- [Connect to a scale set](#)

You can also use the basic [Connection steps](#) in the section below to connect to your VM.

## Connection steps

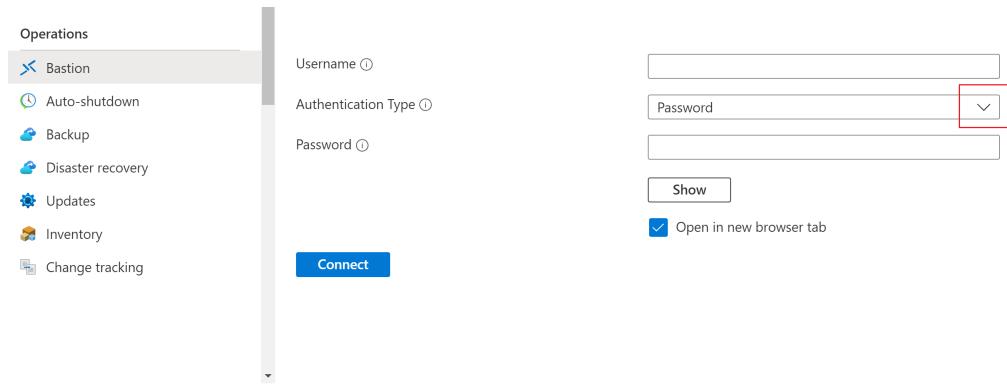

1. In the [Azure portal](#), go to the virtual machine to which you want to connect.
2. At the top of the page, select **Connect->Bastion** to go to the **Bastion** page. You can also go to the **Bastion** page using the left menu.
3. The options available on the **Bastion** page are dependant on the Bastion SKU tier. If you're using the **Basic SKU**, you connect to a Windows computer using RDP and port 3389, and to a Linux computer using SSH and port 22. You don't have options to change the port number or the protocol. However, you can change the keyboard language for RDP by expanding **Connection Settings**.

The screenshot shows the Azure portal interface for a 'TestVM' virtual machine. The left sidebar has 'Bastion' selected under 'Operations'. The main area displays the Bastion host information: 'Using Bastion: VNet1-bastion, Provisioning State: Succeeded'. It includes fields for 'Username', 'Authentication Type' (dropdown), 'Password', and a 'Show' button. A checked checkbox 'Open in new browser tab' is present. A large blue 'Connect' button is at the bottom. The 'Connection Settings' section is collapsed, indicated by a downward arrow icon.

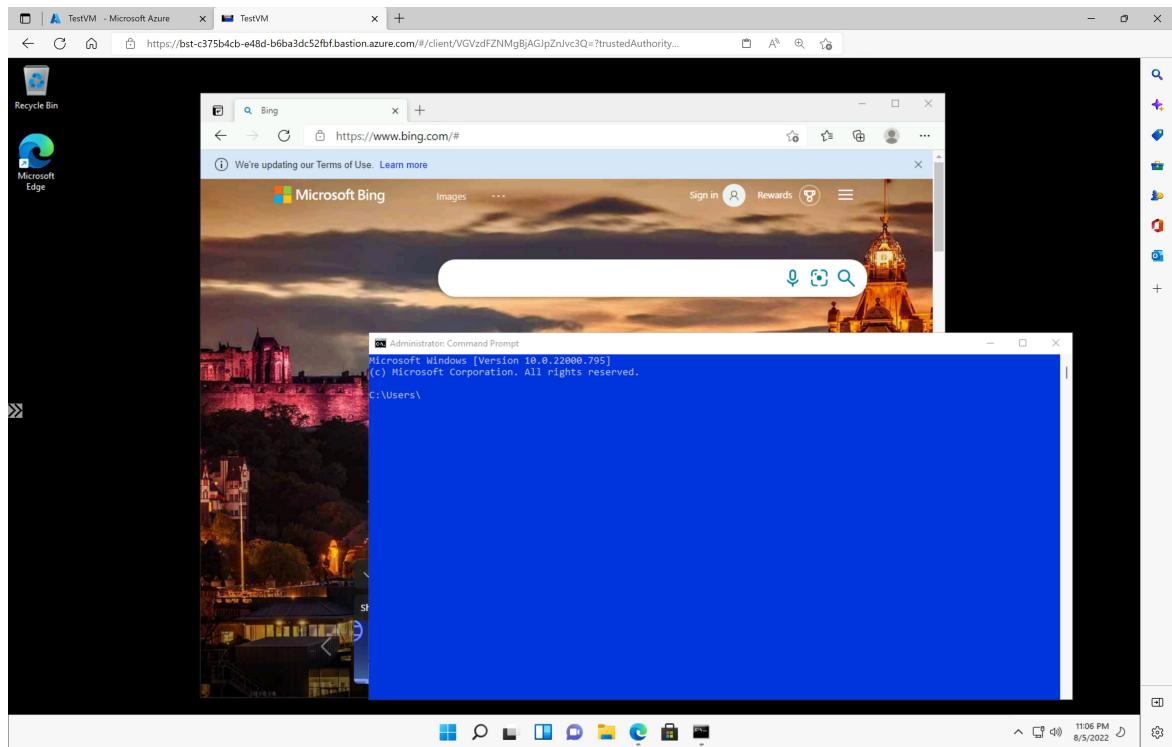

If you're using the **Standard SKU**, you have more connection protocol and port options available. Expand **Connection Settings** to see the options. Typically, unless you have configured different settings for your VM, you connect to a Windows computer using RDP and port 3389, and to a Linux computer using SSH and port 22.

The screenshot shows the same Azure portal interface for the 'TestVM' virtual machine, but with the 'Standard SKU' selected. The 'Connection Settings' section is now expanded, showing a radio button group for 'Protocol' (selected 'RDP') and 'SSH', a 'Port' field set to '3389' with a green checkmark, and a 'Keyboard Language' dropdown set to 'English (US)'.

4. Select the **Authentication Type** from the dropdown. The protocol determines the available authentication types. Complete the required authentication values.

5. To open the VM session in a new browser tab, leave **Open in a new browser tab** selected.
6. Click **Connect** to connect to the VM.
7. The connection to this virtual machine, via Bastion, will open directly in the Azure portal (over HTML5) using port 443 and the Bastion service.
  - When you connect, the desktop of the VM will look different than the example screenshot.
  - Using keyboard shortcut keys while connected to a VM may not result in the same behavior as shortcut keys on a local computer. For example, when connected to a Windows VM from a Windows client, CTRL+ALT+END is the keyboard shortcut for CTRL+ALT+Delete on a local computer. To do this from a Mac while connected to a Windows VM, the keyboard shortcut is Fn+CTRL+ALT+Backspace.

### To enable audio output

You can enable remote audio output for your VM. Some VMs automatically enable this setting, others require you to enable audio settings manually. The settings are changed on the VM itself. Your Bastion deployment doesn't need any special configuration settings to enable remote audio output.

#### NOTE

Audio output takes up bandwidth on your internet connection.

To enable remote audio output on a Windows VM:

1. After you're connected to the VM, on the right-hand bottom corner of the toolbar, you'll see an audio button.
2. Right-click the audio button and select "Sounds".
3. A pop-up appears asking if you would like to enable the Windows Audio Service. Select "Yes". You can configure more audio options in Sound preferences.
4. To verify sound output, hover your mouse over the audio button on the toolbar.

## Remove VM public IP address

When you connect to a VM using Azure Bastion, you don't need a public IP address for your VM. If you aren't using the public IP address for anything else, you can dissociate it from your VM. To dissociate a public IP address from your VM, use the following steps:

1. Go to your virtual machine and select **Networking**. Click the **NIC Public IP** to open the Public IP address page.

2. On the **Public IP address** page, you can see the VM network interface listed under **Associated to** on the lower right of the page. Click **Dissociate** at the top of the page.

3. Click **Yes** to dissociate the IP address from the network interface. Once the public IP address is dissociated from the VM network interface, you can see that it's no longer listed under **Associated to**.
4. After you dissociate the IP address, you can delete the public IP address resource. On the **Public IP address** page for the VM, select **Delete**.

The screenshot shows the Azure portal interface for managing a public IP address named 'TestVM-ip'. The left sidebar lists various navigation options like Overview, Activity log, Access control (IAM), Tags, Configuration, Properties, Locks, and Monitoring. The main content area is titled 'Essentials' and displays resource details: Resource group (TestRG1), Location (East US), Subscription (Content Development), Subscription ID, Tags, and Associated to. At the top right, there are buttons for Associate, Dissociate, Move, Delete (which is highlighted with a red box), Refresh, and a search bar.

5. Click **Yes** to delete the public IP address.

## Clean up resources

If you're not going to continue to use this application, delete your resources using the following steps:

1. Enter the name of your resource group in the **Search** box at the top of the portal. When you see your resource group in the search results, select it.
2. Select **Delete resource group**.
3. Enter the name of your resource group for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

## Next steps

In this tutorial, you deployed Bastion to a virtual network and connected to a VM. You then removed the public IP address from the VM. Next, learn about and configure additional Bastion features.

[Bastion features and configuration settings](#)

[Bastion - VM connections and features](#)

# Deploy Bastion using Azure PowerShell

9/21/2022 • 8 minutes to read • [Edit Online](#)

This article shows you how to deploy Azure Bastion with the Standard SKU using PowerShell. Azure Bastion is a PaaS service that's maintained for you, not a bastion host that you install on your VM and maintain yourself. An Azure Bastion deployment is per virtual network, not per subscription/account or virtual machine. For more information about Azure Bastion, see [What is Azure Bastion?](#)

Once you deploy Bastion to your virtual network, you can connect to your VMs via private IP address. This seamless RDP/SSH experience is available to all the VMs in the same virtual network. If your VM has a public IP address that you don't need for anything else, you can remove it.

You can also deploy Bastion by using the following other methods:

- [Azure portal](#)
- [Azure CLI](#)
- [Quickstart - deploy with default settings](#)

If you don't have an Azure subscription, create a [free account](#) before you begin.

## NOTE

The use of Azure Bastion with Azure Private DNS Zones is not supported at this time. Before you begin, please make sure that the virtual network where you plan to deploy your Bastion resource is not linked to a private DNS zone.

## Prerequisites

The following prerequisites are required.

### Azure PowerShell

This article uses PowerShell cmdlets. To run the cmdlets, you can use Azure Cloud Shell. Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open Cloud Shell, just select **Try it** from the upper-right corner of a code block. You can also open Cloud Shell on a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste them into Cloud Shell, and select the Enter key to run them.

You can also install and run the Azure PowerShell cmdlets locally on your computer. PowerShell cmdlets are updated frequently. If you have not installed the latest version, the values specified in the instructions may fail.

To find the versions of Azure PowerShell installed on your computer, use the `Get-Module -ListAvailable Az` cmdlet. To install or update, see [Install the Azure PowerShell module](#).

### Example values

You can use the following example values when creating this configuration, or you can substitute your own.

#### Basic VNet and VM values:

NAME	VALUE
Virtual machine	TestVM

NAME	VALUE
Resource group	TestRG1
Region	East US
Virtual network	VNet1
Address space	10.1.0.0/16
Subnets	FrontEnd: 10.1.0.0/24

#### Azure Bastion values:

NAME	VALUE
Name	VNet1-bastion
Subnet Name	FrontEnd
Subnet Name	AzureBastionSubnet
AzureBastionSubnet addresses	A subnet within your VNet address space with a subnet mask /26 or larger. For example, 10.1.1.0/26.
Tier/SKU	Standard
Public IP address	Create new
Public IP address name	VNet1-ip
Public IP address SKU	Standard
Assignment	Static

## Deploy Bastion

This section helps you create a virtual network, subnets, and deploy Azure Bastion using Azure PowerShell.

1. Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which Azure resources are deployed and managed. If you're running PowerShell locally, open your PowerShell console with elevated privileges and connect to Azure using the [Connect-AzAccount](#) command.

```
New-AzResourceGroup -Name TestRG1 -Location EastUS
```

2. Create a virtual network.

```
$virtualNetwork = New-AzVirtualNetwork `  
-ResourceGroupName TestRG1 `  
-Location EastUS `  
-Name VNet1 `  
-AddressPrefix 10.1.0.0/16
```

3. Set the configuration for the virtual network.

```
$virtualNetwork | Set-AzVirtualNetwork
```

4. Configure and set a subnet for your virtual network. This will be the subnet to which you'll deploy a VM. The variable used for `-VirtualNetwork` was set in the previous steps.

```
$subnetConfig = Add-AzVirtualNetworkSubnetConfig `  
-Name 'FrontEnd' `  
-AddressPrefix 10.1.0.0/24 `  
-VirtualNetwork $virtualNetwork
```

```
$virtualNetwork | Set-AzVirtualNetwork
```

5. Configure and set the Azure Bastion subnet for your virtual network. This subnet is reserved exclusively for Azure Bastion resources. You must create the Azure Bastion subnet using the name value `AzureBastionSubnet`. This value lets Azure know which subnet to deploy the Bastion resources to. The example below also helps you add an Azure Bastion subnet to an existing VNet.

**IMPORTANT**

For Azure Bastion resources deployed on or after November 2, 2021, the minimum AzureBastionSubnet size is /26 or larger (/25, /24, etc.). All Azure Bastion resources deployed in subnets of size /27 prior to this date are unaffected by this change and will continue to work, but we highly recommend increasing the size of any existing AzureBastionSubnet to /26 in case you choose to take advantage of [host scaling](#) in the future.

- The smallest subnet AzureBastionSubnet size you can create is /26. We recommend that you create a /26 or larger size to accommodate host scaling.
  - For more information about scaling, see [Configuration settings - Host scaling](#).
  - For more information about settings, see [Configuration settings - AzureBastionSubnet](#).
- Create the `AzureBastionSubnet` without any route tables or delegations.
- If you use Network Security Groups on the `AzureBastionSubnet`, refer to the [Work with NSGs](#) article.

Declare the variable.

```
$virtualNetwork = Get-AzVirtualNetwork -Name "VNet1" `  
-ResourceGroupName "TestRG1"
```

Add the configuration.

```
Add-AzVirtualNetworkSubnetConfig -Name "AzureBastionSubnet" `  
-VirtualNetwork $virtualNetwork -AddressPrefix "10.1.1.0/26" `
```

Set the configuration.

```
$virtualNetwork | Set-AzVirtualNetwork
```

6. Create a public IP address for Azure Bastion. The public IP is the public IP address the Bastion resource on which RDP/SSH will be accessed (over port 443). The public IP address must be in the same region as the Bastion resource you're creating.

```
$publicip = New-AzPublicIpAddress -ResourceGroupName "TestRG1" -name "VNet1-ip" -location "EastUS"  
-AllocationMethod Static -Sku Standard
```

7. Create a new Azure Bastion resource in the AzureBastionSubnet using the [New-AzBastion](#) command. The following example uses the **Standard SKU**. The Standard SKU lets you configure more Bastion features and connect to VMs using more connection types. For more information, see [Bastion SKUs](#). If you want to deploy using the Basic SKU, change the -Sku value to "Basic".

```
New-AzBastion -ResourceGroupName "TestRG1" -Name "VNet1-bastion" `  
-PublicIpAddressRgName "TestRG1" -PublicIpAddressName "VNet1-ip" `  
-VirtualNetworkRgName "TestRG1" -VirtualNetworkName "VNet1" `  
-Sku "Standard"
```

8. It takes about 10 minutes for the Bastion resources to deploy. You can create a VM in the next section while Bastion deploys to your virtual network.

## Create a VM

You can create a VM using the [Quickstart: Create a VM using PowerShell](#) or [Quickstart: Create a VM using the portal](#) articles. Be sure you deploy the VM to the virtual network to which you deployed Bastion. The VM you create in this section isn't a part of the Bastion configuration and doesn't become a bastion host. You connect to this VM later in this tutorial via Bastion.

The following required roles for your resources.

- Required VM roles:
  - Reader role on the virtual machine.
  - Reader role on the NIC with private IP of the virtual machine.
- Required inbound ports:
  - For Windows VMS - RDP (3389)
  - For Linux VMs - SSH (22)

## Connect to a VM

You can use the [Connection steps](#) in the section below to connect to your VM. You can also use any of the following articles to connect to a VM. Some connection types require the Bastion [Standard SKU](#).

- [Windows - RDP](#)
- [Windows - SSH](#)
- [Linux - SSH](#)
- [Linux - RDP](#)
- [Connect from a local computer using a native client](#)
- [Connect to a scale set](#)

### Connection steps

1. In the [Azure portal](#), go to the virtual machine to which you want to connect.
2. At the top of the page, select **Connect->Bastion** to go to the **Bastion** page. You can also go to the **Bastion** page using the left menu.
3. The options available on the **Bastion** page are dependant on the Bastion SKU tier. If you're using the **Basic SKU**, you connect to a Windows computer using RDP and port 3389, and to a Linux computer using SSH and port 22. You don't have options to change the port number or the protocol. However, you can change the keyboard language for RDP by expanding **Connection Settings**.

Home > TestVM

## TestVM | Bastion

Azure Bastion protects your virtual machines by providing lightweight, browser-based connectivity without the need to expose them through public IP addresses. Deploying will automatically create a Bastion host on a subnet in your virtual network. [Learn more](#)

Using Bastion: **VNet1-bastion**, Provisioning State: **Succeeded**

Please enter username and password to your virtual machine to connect using Bastion.

**Connection Settings**

Protocol \*  RDP  SSH

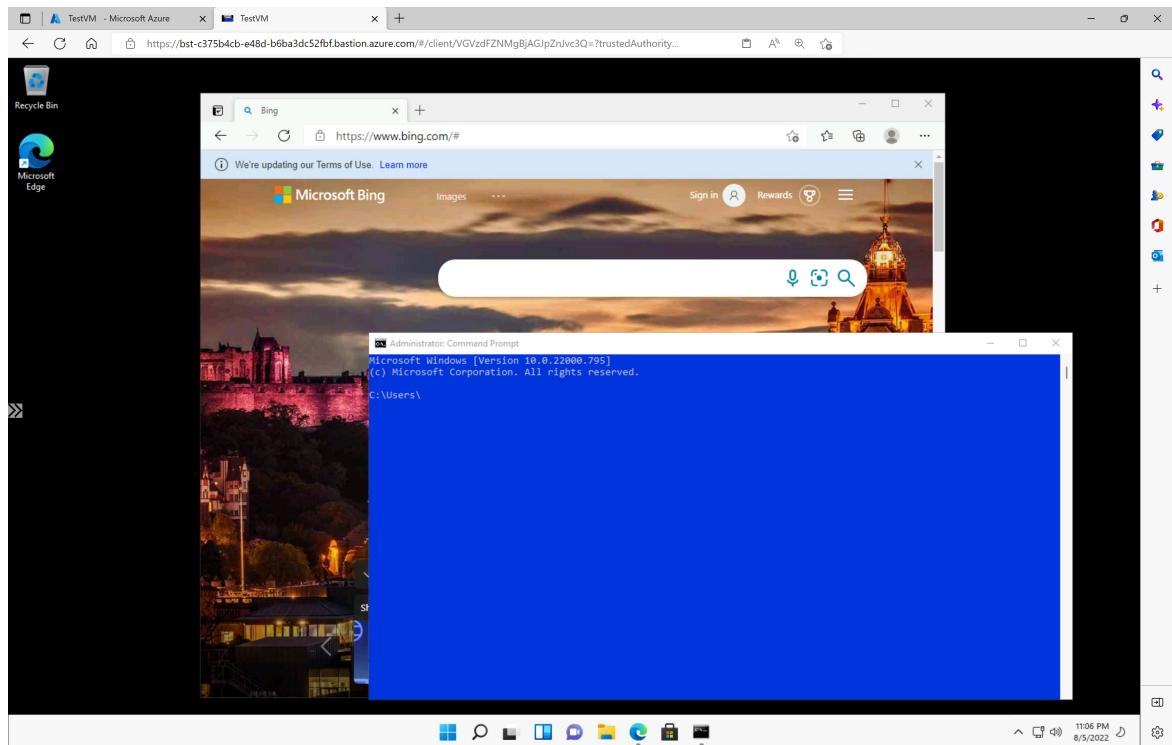

Port

Keyboard Language

4. Select the **Authentication Type** from the dropdown. The protocol determines the available authentication types. Complete the required authentication values.

5. To open the VM session in a new browser tab, leave **Open in a new browser tab** selected.
6. Click **Connect** to connect to the VM.
7. The connection to this virtual machine, via Bastion, will open directly in the Azure portal (over HTML5) using port 443 and the Bastion service.
  - When you connect, the desktop of the VM will look different than the example screenshot.
  - Using keyboard shortcut keys while connected to a VM may not result in the same behavior as shortcut keys on a local computer. For example, when connected to a Windows VM from a Windows client, CTRL+ALT+END is the keyboard shortcut for CTRL+ALT+Delete on a local computer. To do this from a Mac while connected to a Windows VM, the keyboard shortcut is Fn+CTRL+ALT+Backspace.

### To enable audio output

You can enable remote audio output for your VM. Some VMs automatically enable this setting, others require you to enable audio settings manually. The settings are changed on the VM itself. Your Bastion deployment doesn't need any special configuration settings to enable remote audio output.

#### NOTE

Audio output takes up bandwidth on your internet connection.

To enable remote audio output on a Windows VM:

1. After you're connected to the VM, on the right-hand bottom corner of the toolbar, you'll see an audio button.
2. Right-click the audio button and select "Sounds".
3. A pop-up appears asking if you would like to enable the Windows Audio Service. Select "Yes". You can configure more audio options in Sound preferences.
4. To verify sound output, hover your mouse over the audio button on the toolbar.

## Remove VM public IP address

Azure Bastion doesn't use the public IP address to connect to the client VM. If you don't need the public IP address for your VM, you can disassociate the public IP address. See [Dissociate a public IP address from an Azure VM](#).

## Next steps

- To use Network Security Groups with the Azure Bastion subnet, see [Work with NSGs](#).
- To understand VNet peering, see [VNet peering and Azure Bastion](#).

# Deploy Bastion using Azure CLI

9/21/2022 • 6 minutes to read • [Edit Online](#)

This article shows you how to deploy Azure Bastion using CLI. Azure Bastion is a PaaS service that's maintained for you, not a bastion host that you install on your VM and maintain yourself. An Azure Bastion deployment is per virtual network, not per subscription/account or virtual machine. For more information about Azure Bastion, see [What is Azure Bastion?](#)

Once you deploy Bastion to your virtual network, you can connect to your VMs via private IP address. This seamless RDP/SSH experience is available to all the VMs in the same virtual network. If your VM has a public IP address that you don't need for anything else, you can remove it.

You can also deploy Bastion by using the following other methods:

- [Azure portal](#)
- [Azure PowerShell](#)
- [Quickstart - deploy with default settings](#)

## Prerequisites

### Azure subscription

Verify that you have an Azure subscription. If you don't already have an Azure subscription, you can activate your [MSDN subscriber benefits](#) or sign up for a [free account](#).

### Azure CLI

This article uses the Azure CLI. To run commands, you can use Azure Cloud Shell. The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com> and toggle the dropdown in the left corner to reflect Bash or PowerShell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

#### NOTE

The use of Azure Bastion with Azure Private DNS Zones is not supported at this time. Before you begin, please make sure that the virtual network where you plan to deploy your Bastion resource is not linked to a private DNS zone.

## Deploy Bastion

This section helps you deploy Azure Bastion using Azure CLI.

#### NOTE

As shown in the examples, use the `--location` parameter with `--resource-group` for every command to ensure that the resources are deployed together.

1. Create a virtual network and an Azure Bastion subnet. You must create the Azure Bastion subnet using the name value **AzureBastionSubnet**. This value lets Azure know which subnet to deploy the Bastion

resources to. This is different than a VPN gateway subnet.

#### IMPORTANT

For Azure Bastion resources deployed on or after November 2, 2021, the minimum AzureBastionSubnet size is /26 or larger (/25, /24, etc.). All Azure Bastion resources deployed in subnets of size /27 prior to this date are unaffected by this change and will continue to work, but we highly recommend increasing the size of any existing AzureBastionSubnet to /26 in case you choose to take advantage of [host scaling](#) in the future.

- The smallest subnet AzureBastionSubnet size you can create is /26. We recommend that you create a /26 or larger size to accommodate host scaling.
  - For more information about scaling, see [Configuration settings - Host scaling](#).
  - For more information about settings, see [Configuration settings - AzureBastionSubnet](#).
- Create the **AzureBastionSubnet** without any route tables or delegations.
- If you use Network Security Groups on the **AzureBastionSubnet**, refer to the [Work with NSGs](#) article.

```
az network vnet create --resource-group MyResourceGroup --name MyVnet --address-prefix 10.0.0.0/16 --subnet-name AzureBastionSubnet --subnet-prefix 10.0.0.0/24 --location northeurope
```

2. Create a public IP address for Azure Bastion. The public IP is the public IP address the Bastion resource on which RDP/SSH will be accessed (over port 443). The public IP address must be in the same region as the Bastion resource you're creating.

The following example uses the **Standard SKU**. The Standard SKU lets you configure more Bastion features and connect to VMs using more connection types. For more information, see [Bastion SKUs](#).

```
az network public-ip create --resource-group MyResourceGroup --name MyIp --sku Standard --location northeurope
```

3. Create a new Azure Bastion resource in the AzureBastionSubnet of your virtual network. It takes about 10 minutes for the Bastion resource to create and deploy.

```
az network bastion create --name MyBastion --public-ip-address MyIp --resource-group MyResourceGroup --vnet-name MyVnet --location northeurope
```

## Connect to a VM

You can use the [Connection steps](#) in the section below to connect to your VM. You can also use any of the following articles to connect to a VM. Some connection types require the Bastion [Standard SKU](#).

- [Windows - RDP](#)
- [Windows - SSH](#)
- [Linux - SSH](#)
- [Linux - RDP](#)
- [Connect from a local computer using a native client](#)
- [Connect to a scale set](#)

### Connection steps

1. In the [Azure portal](#), go to the virtual machine to which you want to connect.
2. At the top of the page, select **Connect->Bastion** to go to the **Bastion** page. You can also go to the

Bastion page using the left menu.

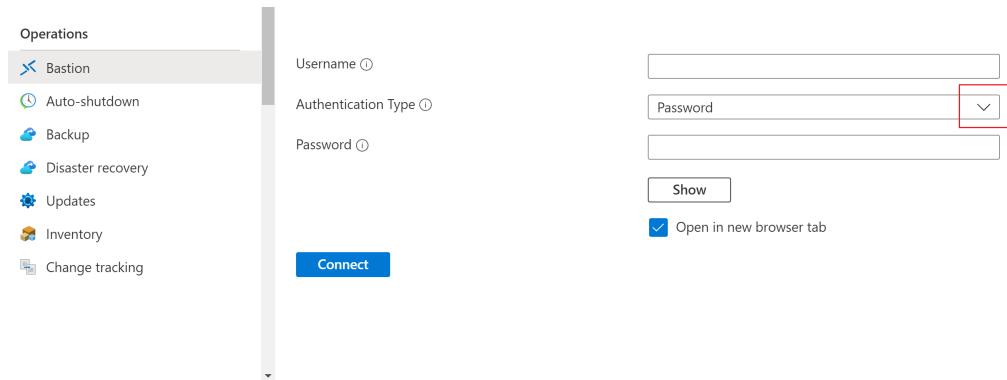

3. The options available on the **Bastion** page are dependant on the Bastion SKU tier. If you're using the **Basic SKU**, you connect to a Windows computer using RDP and port 3389, and to a Linux computer using SSH and port 22. You don't have options to change the port number or the protocol. However, you can change the keyboard language for RDP by expanding **Connection Settings**.

The screenshot shows the 'TestVM | Bastion' page. The left sidebar has a 'Bastion' section selected. The main area displays a message about Azure Bastion protecting virtual machines. Below it, it says 'Using Bastion: VNet1-bastion, Provisioning State: Succeeded'. A note asks to enter a username and password. Under 'Connection Settings', there are fields for 'Username', 'Authentication Type' (dropdown), 'Password', and a 'Show' button. A checked checkbox says 'Open in new browser tab'. At the bottom is a 'Connect' button.

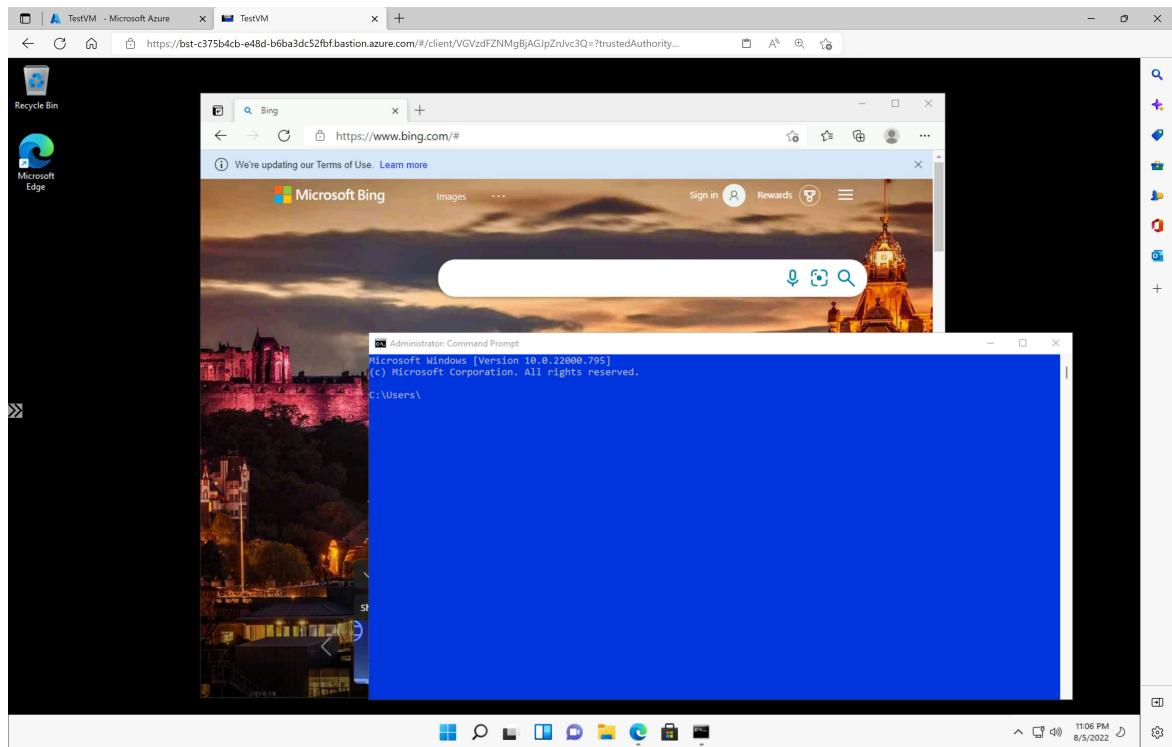

If you're using the **Standard SKU**, you have more connection protocol and port options available. Expand **Connection Settings** to see the options. Typically, unless you have configured different settings for your VM, you connect to a Windows computer using RDP and port 3389, and to a Linux computer using SSH and port 22.

The screenshot shows the same 'TestVM | Bastion' page, but the 'Bastion' section in the sidebar is not selected. The 'Connection Settings' section is expanded, showing 'Protocol' (radio buttons for 'RDP' and 'SSH', with 'RDP' selected), 'Port' (text input '3389'), and 'Keyboard Language' (dropdown 'English (US)').

4. Select the **Authentication Type** from the dropdown. The protocol determines the available authentication types. Complete the required authentication values.

5. To open the VM session in a new browser tab, leave **Open in a new browser tab** selected.
6. Click **Connect** to connect to the VM.
7. The connection to this virtual machine, via Bastion, will open directly in the Azure portal (over HTML5) using port 443 and the Bastion service.
  - When you connect, the desktop of the VM will look different than the example screenshot.
  - Using keyboard shortcut keys while connected to a VM may not result in the same behavior as shortcut keys on a local computer. For example, when connected to a Windows VM from a Windows client, CTRL+ALT+END is the keyboard shortcut for CTRL+ALT+Delete on a local computer. To do this from a Mac while connected to a Windows VM, the keyboard shortcut is Fn+CTRL+ALT+Backspace.

### To enable audio output

You can enable remote audio output for your VM. Some VMs automatically enable this setting, others require you to enable audio settings manually. The settings are changed on the VM itself. Your Bastion deployment doesn't need any special configuration settings to enable remote audio output.

#### NOTE

Audio output takes up bandwidth on your internet connection.

To enable remote audio output on a Windows VM:

1. After you're connected to the VM, on the right-hand bottom corner of the toolbar, you'll see an audio button.
2. Right-click the audio button and select "Sounds".
3. A pop-up appears asking if you would like to enable the Windows Audio Service. Select "Yes". You can configure more audio options in Sound preferences.
4. To verify sound output, hover your mouse over the audio button on the toolbar.

## Remove VM public IP address

Azure Bastion doesn't use the public IP address to connect to the client VM. If you don't need the public IP address for your VM, you can disassociate the public IP address. See [Dissociate a public IP address from an Azure VM](#).

## Next steps

- To use Network Security Groups with the Azure Bastion subnet, see [Work with NSGs](#).
- To understand VNet peering, see [VNet peering and Azure Bastion](#).

# Create an SSH connection to a Linux VM using Azure Bastion

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article shows you how to securely and seamlessly create an SSH connection to your Linux VMs located in an Azure virtual network directly through the Azure portal. When you use Azure Bastion, your VMs don't require a client, agent, or additional software. You can also connect to a Linux VM using RDP. For information, see [Create an RDP connection to a Linux VM](#).

Azure Bastion provides secure connectivity to all of the VMs in the virtual network in which it's provisioned. Using Azure Bastion protects your virtual machines from exposing RDP/SSH ports to the outside world, while still providing secure access using RDP/SSH. For more information, see the [What is Azure Bastion?](#) overview article.

When connecting to a Linux virtual machine using SSH, you can use both username/password and SSH keys for authentication.

The SSH private key must be in a format that begins with `"-----BEGIN RSA PRIVATE KEY-----"` and ends with `"-----END RSA PRIVATE KEY-----"`.

## Prerequisites

Make sure that you have set up an Azure Bastion host for the virtual network in which the VM resides. For more information, see [Create an Azure Bastion host](#). Once the Bastion service is provisioned and deployed in your virtual network, you can use it to connect to any VM in this virtual network.

### Required roles

In order to make a connection, the following roles are required:

- Reader role on the virtual machine
- Reader role on the NIC with private IP of the virtual machine
- Reader role on the Azure Bastion resource

### Ports

In order to connect to the Linux VM via SSH, you must have the following ports open on your VM:

- Inbound port: SSH (22) *or*
- Inbound port: Custom value (you'll then need to specify this custom port when you connect to the VM via Azure Bastion)

#### NOTE

If you want to specify a custom port value, Azure Bastion must be configured using the Standard SKU. The Basic SKU does not allow you to specify custom ports.

## Bastion connection page

1. In the [Azure portal](#), go to the virtual machine that you want to connect to. On the [Overview](#) page, select **Connect**, then select **Bastion** from the dropdown to open the Bastion connection page. You can also

select **Bastion** from the left pane.

The screenshot shows the Azure portal interface for a virtual machine named "TestVM". The left sidebar has a "Bastion" section selected. The main content area shows basic VM details: Status (Running), Location (East US), Subscription (Content Development), and Tags (Click here to add tags). At the top, there's a "Connect" dropdown menu with options: SSH, RDP, and Bastion (which is highlighted with a red box).

2. On the **Bastion** connection page, click the **Connection Settings** arrow to expand all the available settings. If you are using a Bastion **Standard** SKU, you have more available settings than a Basic SKU.

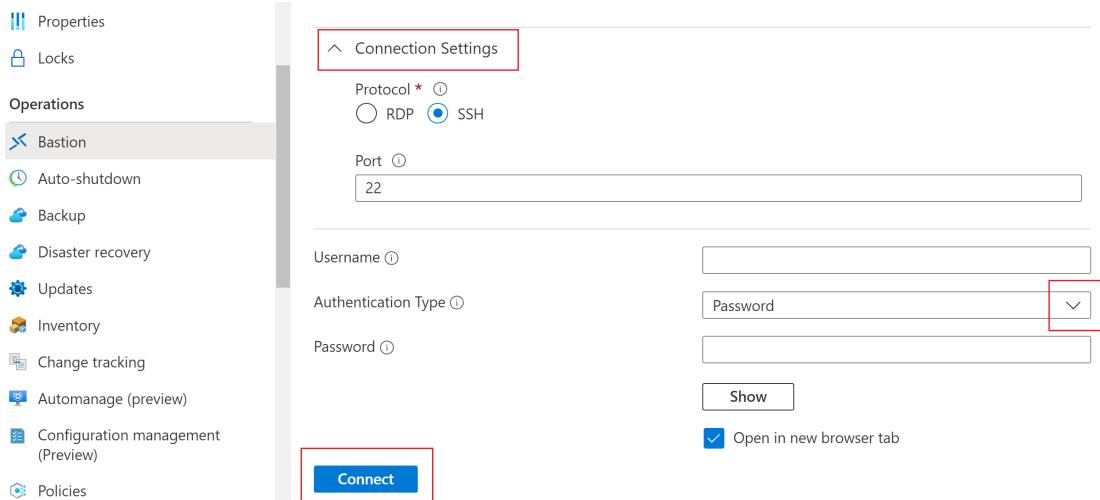

The screenshot shows the "TestVM | Bastion" page. The "Bastion" section in the left sidebar is selected. In the main content area, under "Connection Settings", the "Protocol" dropdown is set to "SSH" (radio button selected) and the "Port" input field contains "22". A note above says: "Please enter username and password to your virtual machine to connect using Bastion."

3. Authenticate and connect using one of the methods in the following sections.

- [Username and password](#)
- [Private key from local file](#)
- [Password - Azure Key Vault](#)
- [Private key - Azure Key Vault](#)

## Username and password

Use the following steps to authenticate using username and password.

1. To authenticate using a username and password, configure the following settings:

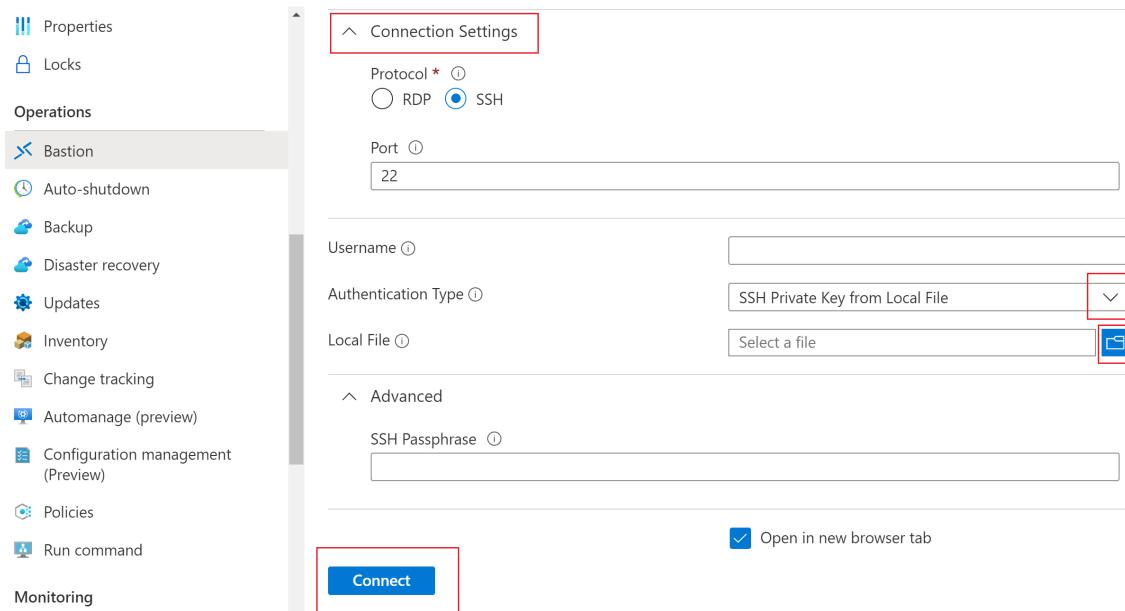

- **Protocol:** Select SSH.
- **Port:** Input the port number. Custom port connections are available for the Standard SKU only.
- **Authentication type:** Select **Password** from the dropdown.
- **Username:** Enter the username.
- **Password:** Enter the **Password**.

2. To work with the VM in a new browser tab, select **Open in new browser tab**.

3. Click **Connect** to connect to the VM.

## Private key from local file

Use the following steps to authenticate using an SSH private key from a local file.

1. To authenticate using a private key from a local file, configure the following settings:

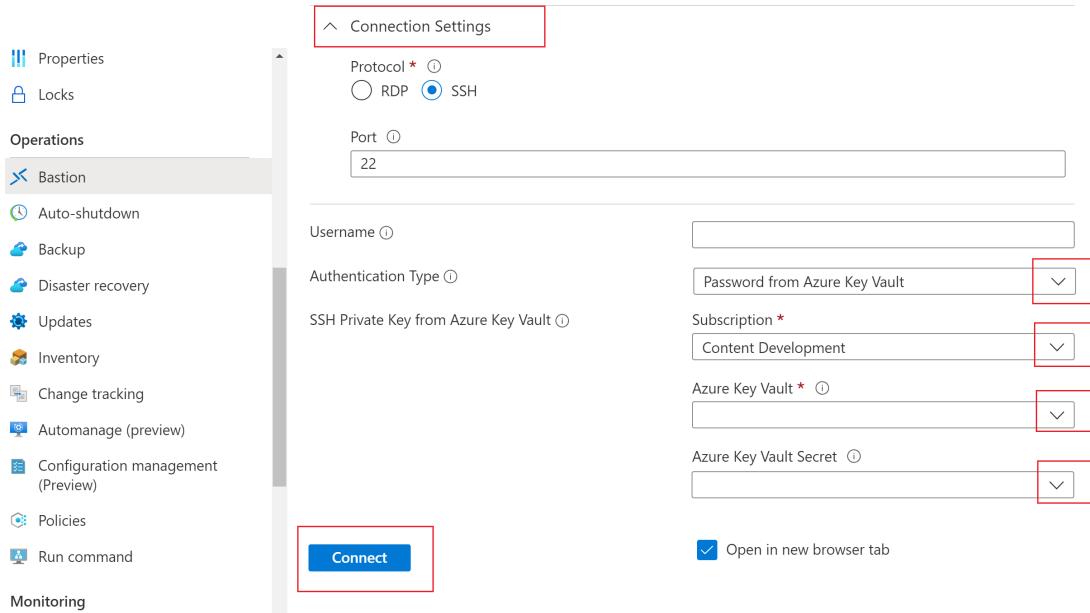

- **Protocol:** Select SSH.
- **Port:** Input the port number. Custom port connections are available for the Standard SKU only.
- **Authentication type:** Select **SSH Private Key from Local File** from the dropdown.
- **Local File:** Select the local file.
- **SSH Passphrase:** Enter the SSH passphrase if necessary.

2. To work with the VM in a new browser tab, select **Open in new browser tab**.

3. Click **Connect** to connect to the VM.

## Password - Azure Key Vault

Use the following steps to authenticate using a password from Azure Key Vault.

1. To authenticate using a password from Azure Key Vault, configure the following settings:

- **Protocol:** Select SSH.
- **Port:** Input the port number. Custom port connections are available for the Standard SKU only.
- **Authentication type:** Select **Password from Azure Key Vault** from the dropdown.
- **Username:** Enter the username.
- **Subscription:** Select the subscription.
- **Azure Key Vault:** Select the Key Vault.
- **Azure Key Vault Secret:** Select the Key Vault secret containing the value of your SSH private key.
  - If you didn't set up an Azure Key Vault resource, see [Create a key vault](#) and store your SSH private key as the value of a new Key Vault secret.
  - Make sure you have **List** and **Get** access to the secrets stored in the Key Vault resource. To assign and modify access policies for your Key Vault resource, see [Assign a Key Vault access policy](#).

### NOTE

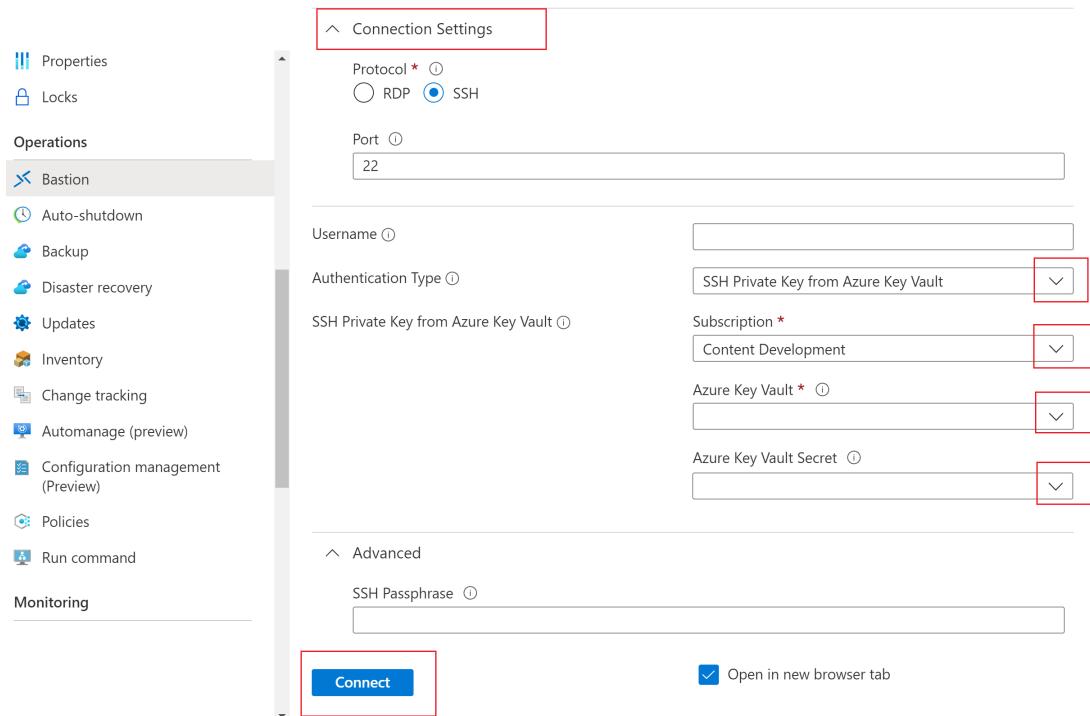

Please store your SSH private key as a secret in Azure Key Vault using the **PowerShell** or **Azure CLI** experience. Storing your private key via the Azure Key Vault portal experience will interfere with the formatting and result in unsuccessful login. If you did store your private key as a secret using the portal experience and no longer have access to the original private key file, see [Update SSH key](#) to update access to your target VM with a new SSH key pair.

2. To work with the VM in a new browser tab, select **Open in new browser tab**.

3. Click **Connect** to connect to the VM.

# Private key - Azure Key Vault

Use the following steps to authenticate using a private key stored in Azure Key Vault.

1. To authenticate using a private key stored in Azure Key Vault, configure the following settings:

- **Protocol:** Select SSH.
- **Port:** Input the port number. Custom port connections are available for the Standard SKU only.
- **Authentication type:** Select **SSH Private Key from Azure Key Vault** from the dropdown.
- **Username:** Enter the username.
- **Subscription:** Select the subscription.
- **Azure Key Vault:** Select the Key Vault.
  - If you didn't set up an Azure Key Vault resource, see [Create a key vault](#) and store your SSH private key as the value of a new Key Vault secret.
  - Make sure you have **List** and **Get** access to the secrets stored in the Key Vault resource. To assign and modify access policies for your Key Vault resource, see [Assign a Key Vault access policy](#).

#### NOTE

Please store your SSH private key as a secret in Azure Key Vault using the **PowerShell** or **Azure CLI** experience. Storing your private key via the Azure Key Vault portal experience will interfere with the formatting and result in unsuccessful login. If you did store your private key as a secret using the portal experience and no longer have access to the original private key file, see [Update SSH key](#) to update access to your target VM with a new SSH key pair.

- **Azure Key Vault Secret:** Select the Key Vault secret containing the value of your SSH private key.
2. To work with the VM in a new browser tab, select **Open in new browser tab**.
3. Click **Connect** to connect to the VM.

## Next steps

For more information about Azure Bastion, see the [Bastion FAQ](#).

# Create an RDP connection to a Windows VM using Azure Bastion

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article shows you how to securely and seamlessly create an RDP connection to your Windows VMs located in an Azure virtual network directly through the Azure portal. When you use Azure Bastion, your VMs don't require a client, agent, or additional software. You can also connect to a Windows VM using SSH. For information, see [Create an SSH connection to a Windows VM](#).

Azure Bastion provides secure connectivity to all of the VMs in the virtual network in which it's provisioned. Using Azure Bastion protects your virtual machines from exposing RDP/SSH ports to the outside world, while still providing secure access using RDP/SSH. For more information, see [What is Azure Bastion?](#)

## Prerequisites

Before you begin, verify that you've met the following criteria:

- A VNet with the Bastion host already installed.
  - Make sure that you have set up an Azure Bastion host for the virtual network in which the VM is located. Once the Bastion service is provisioned and deployed in your virtual network, you can use it to connect to any VM in the virtual network.
  - To set up an Azure Bastion host, see [Create a bastion host](#). If you plan to configure custom port values, be sure to select the Standard SKU when configuring Bastion.
- A Windows virtual machine in the virtual network.

## Required roles

- Reader role on the virtual machine.
- Reader role on the NIC with private IP of the virtual machine.
- Reader role on the Azure Bastion resource.

## Ports

To connect to the Windows VM, you must have the following ports open on your Windows VM:

- Inbound port: RDP (3389) *or*
- Inbound port: Custom value (you'll then need to specify this custom port when you connect to the VM via Azure Bastion)

### NOTE

If you want to specify a custom port value, Azure Bastion must be configured using the Standard SKU. The Basic SKU does not allow you to specify custom ports.

## Connect

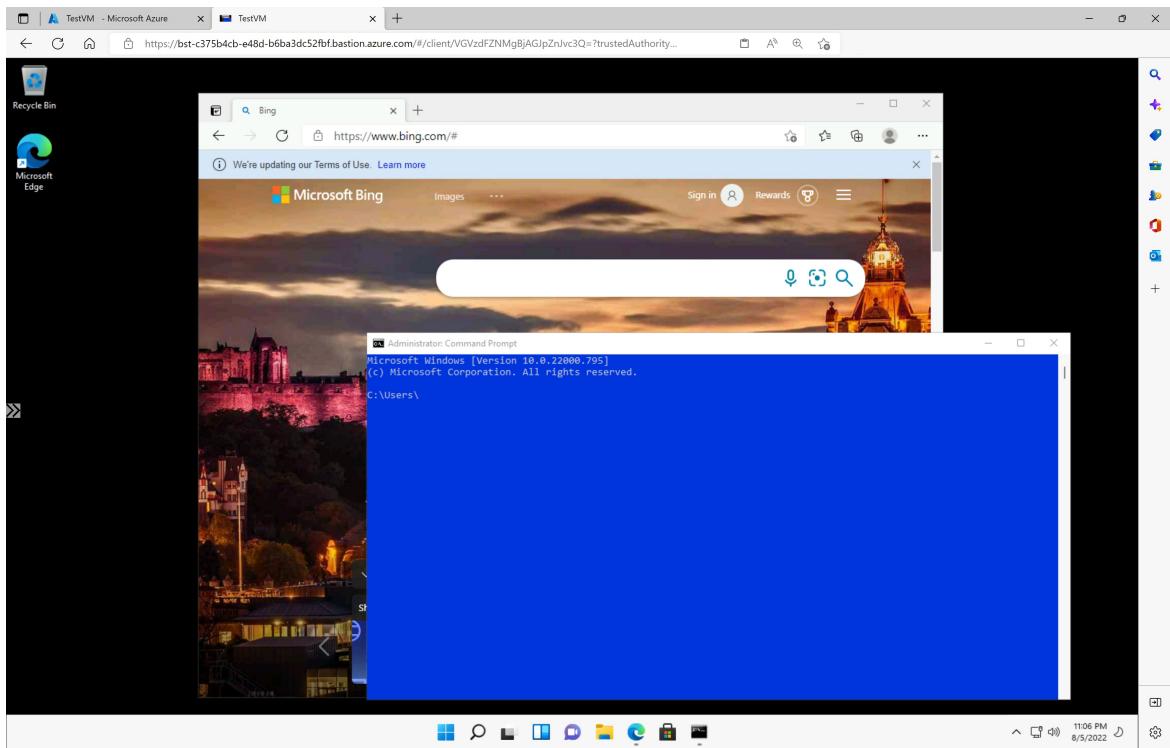

1. In the [Azure portal](#), go to the virtual machine that you want to connect to. On the **Overview** page, select **Connect**, then select **Bastion** from the dropdown to open the Bastion page. You can also select **Bastion** from the left pane.

The screenshot shows the Azure portal interface for a virtual machine named "TestVM". The left sidebar lists various operations like Availability + scaling, Configuration, Identity, Properties, Locks, and Bastion. The "Bastion" option is highlighted with a red box. The main content area displays the VM's properties: Resource group (TestRG1), Status (Running), Location (East US), Subscription (move), Operating system (Windows (Windows 11 Pro)), Size (Standard D2s v3 (2 vcpus, 8 GiB memory)), Public IP address, and Virtual network/subnet (VNet1/FrontEnd). A callout box points to the "Bastion" section in the top navigation bar.

2. On the **Bastion** page, enter the required authentication credentials, then click **Connect**. If you configured your bastion host using the Standard SKU, you'll see additional credential options on this page. If your VM is domain-joined, you must use the following format: **username@domain.com**.

The screenshot shows the "Bastion" page for "TestVM". The left sidebar includes options like Availability + scaling, Configuration, Identity, Properties, Locks, and Bastion (which is selected and highlighted with a red box). The main content area contains a brief description of Azure Bastion Service, provisioning state information (Using Bastion: VNet1-bastion, Provisioning State: Succeeded), and a form for entering connection details. The form includes fields for Username, Authentication Type (set to Password), Password, and a "Show" password toggle. A checkbox for "Open in new browser tab" is checked. A "Connect" button is at the bottom of the form.

3. When you click **Connect**, the RDP connection to this virtual machine via Bastion will open in your browser (over HTML5) using port 443 and the Bastion service. The following example shows a connection to a Windows 11 virtual machine in a new browser tab. The page you see depends on the VM you're connecting to.

When working with the VM, using keyboard shortcut keys may not result in the same behavior as shortcut keys on a local computer. For example, when connected to a Windows VM from a Windows client, CTRL+ALT+END is the keyboard shortcut for CTRL+ALT+Delete on a local computer. To do this from a Mac while connected to a Windows VM, the keyboard shortcut is Fn+CTRL+ALT+Backspace.

## Next steps

Read the [Bastion FAQ](#).

# What is Azure role-based access control (Azure RBAC)?

9/21/2022 • 6 minutes to read • [Edit Online](#)

Access management for cloud resources is a critical function for any organization that is using the cloud. Azure role-based access control (Azure RBAC) helps you manage who has access to Azure resources, what they can do with those resources, and what areas they have access to.

Azure RBAC is an authorization system built on [Azure Resource Manager](#) that provides fine-grained access management to Azure resources.

This video provides a quick overview of Azure RBAC.

## What can I do with Azure RBAC?

Here are some examples of what you can do with Azure RBAC:

- Allow one user to manage virtual machines in a subscription and another user to manage virtual networks
- Allow a DBA group to manage SQL databases in a subscription
- Allow a user to manage all resources in a resource group, such as virtual machines, websites, and subnets
- Allow an application to access all resources in a resource group

## How Azure RBAC works

The way you control access to resources using Azure RBAC is to assign Azure roles. This is a key concept to understand – it's how permissions are enforced. A role assignment consists of three elements: security principal, role definition, and scope.

### Security principal

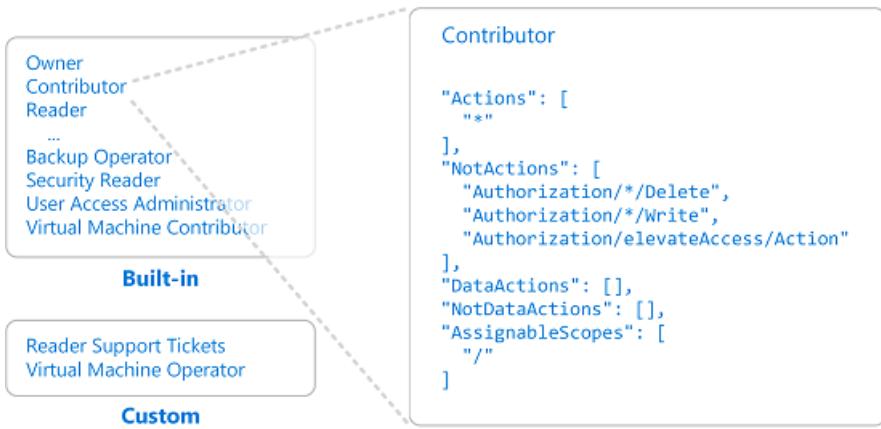

A *security principal* is an object that represents a user, group, service principal, or managed identity that is requesting access to Azure resources. You can assign a role to any of these security principals.

### Role definition

A *role definition* is a collection of permissions. It's typically just called a *role*. A role definition lists the actions that can be performed, such as read, write, and delete. Roles can be high-level, like owner, or specific, like virtual machine reader.

## 2 Role definition

Azure includes several [built-in roles](#) that you can use. For example, the [Virtual Machine Contributor](#) role allows a user to create and manage virtual machines. If the built-in roles don't meet the specific needs of your organization, you can create your own [Azure custom roles](#).

This video provides a quick overview of built-in roles and custom roles.

Azure has data actions that enable you to grant access to data within an object. For example, if a user has read data access to a storage account, then they can read the blobs or messages within that storage account.

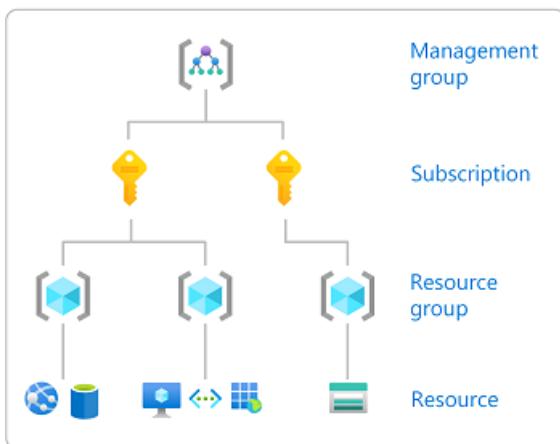

For more information, see [Understand Azure role definitions](#).

## Scope

**Scope** is the set of resources that the access applies to. When you assign a role, you can further limit the actions allowed by defining a scope. This is helpful if you want to make someone a [Website Contributor](#), but only for one resource group.

In Azure, you can specify a scope at four levels: [management group](#), subscription, [resource group](#), or [resource](#). Scopes are structured in a parent-child relationship. You can assign roles at any of these levels of scope.

## 3 Scope

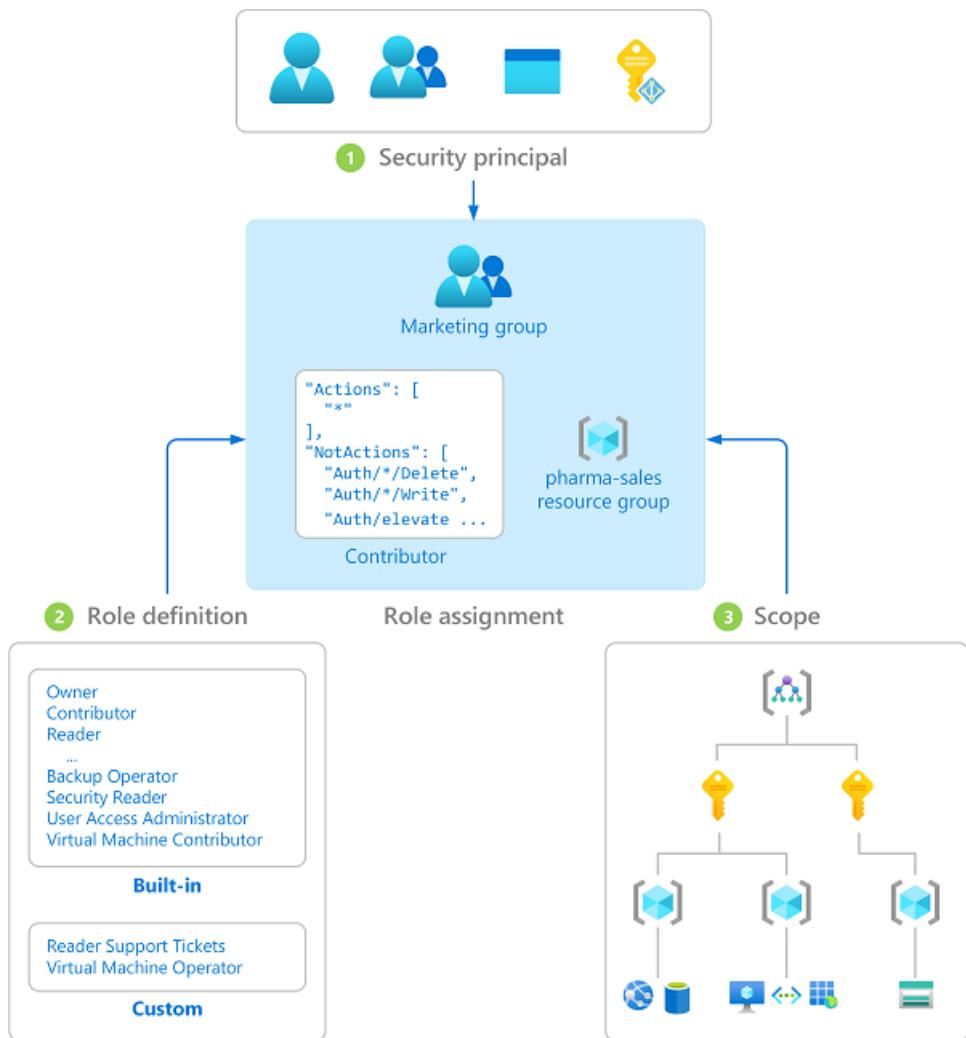

For more information about scope, see [Understand scope](#).

## Role assignments

A *role assignment* is the process of attaching a role definition to a user, group, service principal, or managed identity at a particular scope for the purpose of granting access. Access is granted by creating a role assignment, and access is revoked by removing a role assignment.

The following diagram shows an example of a role assignment. In this example, the Marketing group has been assigned the [Contributor](#) role for the pharma-sales resource group. This means that users in the Marketing

group can create or manage any Azure resource in the pharma-sales resource group. Marketing users do not have access to resources outside the pharma-sales resource group, unless they are part of another role assignment.

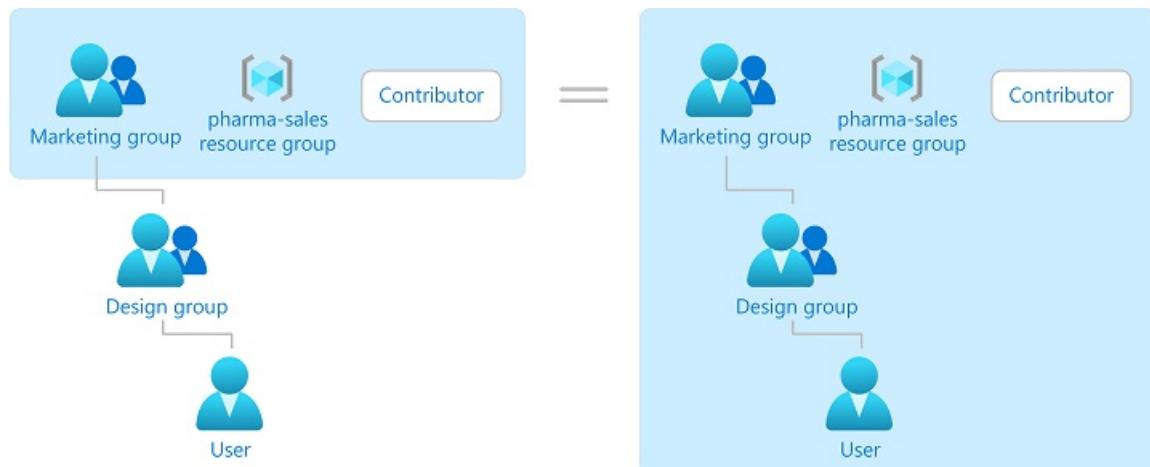

You can assign roles using the Azure portal, Azure CLI, Azure PowerShell, Azure SDKs, or REST APIs.

For more information, see [Steps to assign an Azure role](#).

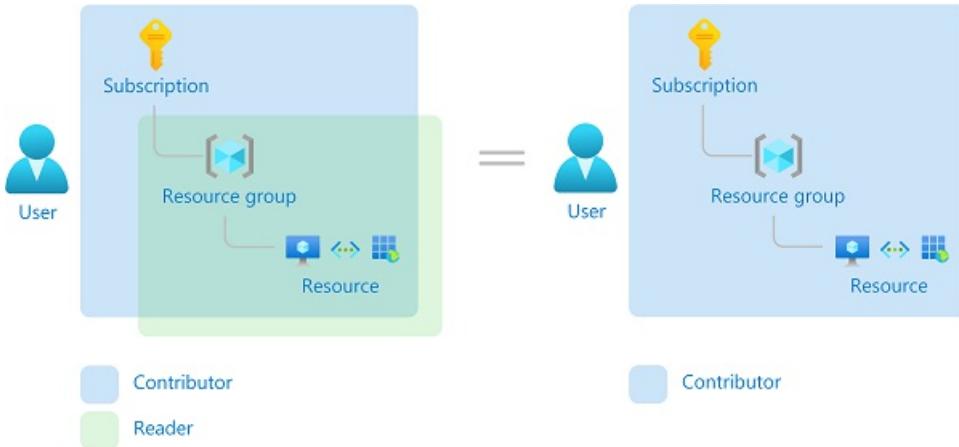

## Groups

Role assignments are transitive for groups which means that if a user is a member of a group and that group is a member of another group that has a role assignment, the user will have the permissions in the role assignment.

## Multiple role assignments

So what happens if you have multiple overlapping role assignments? Azure RBAC is an additive model, so your effective permissions are the sum of your role assignments. Consider the following example where a user is granted the Contributor role at the subscription scope and the Reader role on a resource group. The sum of the Contributor permissions and the Reader permissions is effectively the Contributor role for the subscription. Therefore, in this case, the Reader role assignment has no impact.

## Deny assignments

Previously, Azure RBAC was an allow-only model with no deny, but now Azure RBAC supports deny assignments in a limited way. Similar to a role assignment, a *deny assignment* attaches a set of deny actions to a user, group, service principal, or managed identity at a particular scope for the purpose of denying access. A role assignment defines a set of actions that are *allowed*, while a deny assignment defines a set of actions that are *not allowed*. In other words, deny assignments block users from performing specified actions even if a role assignment grants them access. Deny assignments take precedence over role assignments.

For more information, see [Understand Azure deny assignments](#).

## How Azure RBAC determines if a user has access to a resource

The following are the high-level steps that Azure RBAC uses to determine if you have access to a resource. These steps apply to Azure Resource Manager or data plane services integrated with Azure RBAC. This is helpful to understand if you are trying to troubleshoot an access issue.

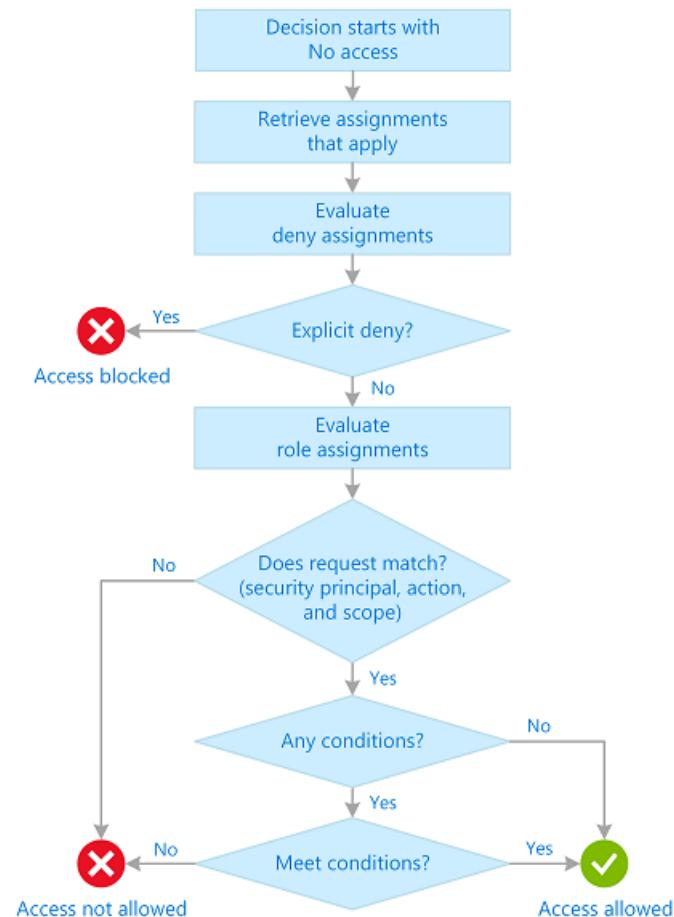

1. A user (or service principal) acquires a token for Azure Resource Manager.  
The token includes the user's group memberships (including transitive group memberships).
2. The user makes a REST API call to Azure Resource Manager with the token attached.
3. Azure Resource Manager retrieves all the role assignments and deny assignments that apply to the resource upon which the action is being taken.
4. If a deny assignment applies, access is blocked. Otherwise, evaluation continues.
5. Azure Resource Manager narrows the role assignments that apply to this user or their group and determines what roles the user has for this resource.
6. Azure Resource Manager determines if the action in the API call is included in the roles the user has for this resource. If the roles include `Actions` that have a wildcard (\*), the effective permissions are computed by subtracting the `NotActions` from the allowed `Actions`. Similarly, the same subtraction is done for any data actions.

Actions - NotActions = Effective management permissions

DataActions - NotDataActions = Effective data permissions

7. If the user doesn't have a role with the action at the requested scope, access is not allowed. Otherwise, any conditions are evaluated.
8. If the role assignment includes conditions, they are evaluated. Otherwise access is allowed.
9. If conditions are met, access is allowed. Otherwise access is not allowed.

The following diagram is a summary of the evaluation logic.

## Where is Azure RBAC data stored?

Role definitions, role assignments, and deny assignments are stored globally to ensure that you have access to your resources regardless of the region you created the resource.

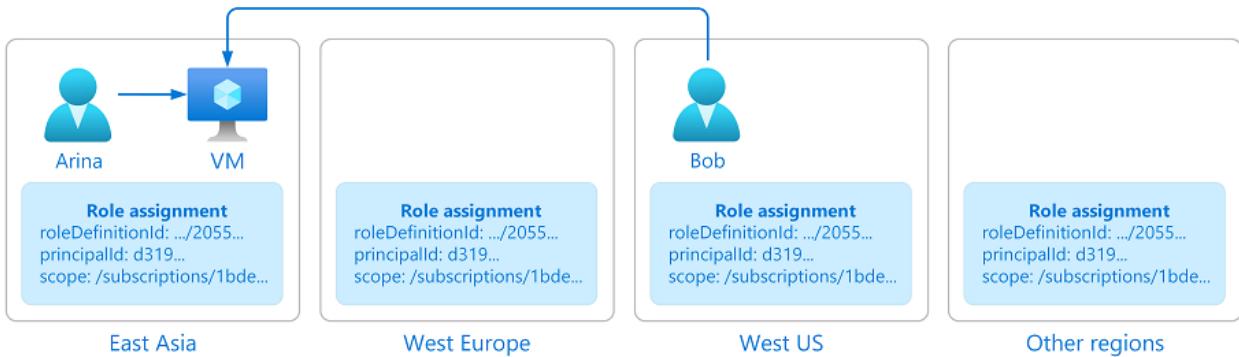

When a role assignment or any other Azure RBAC data is deleted, the data is globally deleted. Principals that had access to a resource via Azure RBAC data will lose their access.

## Why is Azure RBAC data global?

Azure RBAC data is global to ensure that customers can timely access resources regardless from where they are accessing. Azure RBAC is enforced by Azure Resource Manager, which has a global endpoint and requests are routed to the nearest region for speed and resilience. Therefore, Azure RBAC must be enforced in all regions and the data is replicated to all regions. For more information, see [Resiliency of Azure Resource Manager](#).

Consider the following example. Arina creates a virtual machine in East Asia. Bob, who is a member of Arina's team, works in the United States. Bob needs to access the virtual machine that was created in East Asia. To grant Bob timely access to the virtual machine, Azure needs to globally replicate the role assignment that grants Bob

access to the virtual machine from anywhere Bob is.

## License requirements

Using this feature is free and included in your Azure subscription.

# How to set up Key Vault for virtual machines with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In the Azure Resource Manager stack, secrets/certificates are modeled as resources that are provided by Key Vault. To learn more about Azure Key Vault, see [What is Azure Key Vault?](#) In order for Key Vault to be used with Azure Resource Manager VMs, the *EnabledForDeployment* property on Key Vault must be set to true. This article shows you how to set up Key Vault for use with Azure virtual machines (VMs) using the Azure CLI.

To perform these steps, you need the latest [Azure CLI](#) installed and logged in to an Azure account using [az login](#).

## Create a Key Vault

Create a key vault and assign the deployment policy with [az keyvault create](#). The following example creates a key vault named `myKeyVault` in the `myResourceGroup` resource group:

```
az keyvault create -l westus -n myKeyVault -g myResourceGroup --enabled-for-deployment true
```

## Update a Key Vault for use with VMs

Set the deployment policy on an existing key vault with [az keyvault update](#). The following updates the key vault named `myKeyVault` in the `myResourceGroup` resource group:

```
az keyvault update -n myKeyVault -g myResourceGroup --set properties.enabledForDeployment=true
```

## Use templates to set up Key Vault

When you use a template, you need to set the `enabledForDeployment` property to `true` for the Key Vault resource as follows:

```
{
  "type": "Microsoft.KeyVault/vaults",
  "name": "ContosoKeyVault",
  "apiVersion": "2015-06-01",
  "location": "<location-of-key-vault>",
  "properties": {
    "enabledForDeployment": "true",
    ...
    ...
  }
}
```

## Next steps

For other options that you can configure when you create a Key Vault by using templates, see [Create a key vault](#).

# Set up Key Vault for virtual machines using Azure PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

## NOTE

Azure has two different deployment models you can use to create and work with resources: [Azure Resource Manager](#) and [classic](#). This article covers the use of the Resource Manager deployment model. We recommend the Resource Manager deployment model for new deployments instead of the classic deployment model.

In Azure Resource Manager stack, secrets/certificates are modeled as resources that are provided by the resource provider of Key Vault. To learn more about Key Vault, see [What is Azure Key Vault?](#)

## NOTE

1. In order for Key Vault to be used with Azure Resource Manager virtual machines, the `EnabledForDeployment` property on Key Vault must be set to true. You can do this in various clients.
2. The Key Vault needs to be created in the same subscription and location as the Virtual Machine.

## Use PowerShell to set up Key Vault

To create a key vault by using PowerShell, see [Set and retrieve a secret from Azure Key Vault using PowerShell](#).

For new key vaults, you can use this PowerShell cmdlet:

```
New-AzKeyVault -VaultName 'ContosoKeyVault' -ResourceGroupName 'ContosoResourceGroup' -Location 'East Asia'  
-EnabledForDeployment
```

For existing key vaults, you can use this PowerShell cmdlet:

```
Set-AzKeyVaultAccessPolicy -VaultName 'ContosoKeyVault' -EnabledForDeployment
```

## Use CLI to set up Key Vault

To create a key vault by using the command-line interface (CLI), see [Manage Key Vault using CLI](#).

For CLI, you have to create the key vault before you assign the deployment policy. You can do this by using the following command:

```
az keyvault create --name "ContosoKeyVault" --resource-group "ContosoResourceGroup" --location "EastAsia"
```

Then to enable Key Vault for use with template deployment, run the following command:

```
az keyvault update --name "ContosoKeyVault" --resource-group "ContosoResourceGroup" --enabled-for-deployment  
"true"
```

## Use templates to set up Key Vault

While you use a template, you need to set the `enabledForDeployment` property to `true` for the Key Vault resource.

```
{  
  "type": "Microsoft.KeyVault/vaults",  
  "name": "ContosoKeyVault",  
  "apiVersion": "2015-06-01",  
  "location": "<location-of-key-vault>",  
  "properties": {  
    "enabledForDeployment": "true",  
    ....  
    ....  
  }  
}
```

For other options that you can configure when you create a key vault by using templates, see [Create a key vault](#).

# Guidance for mitigating silicon based micro-architectural and speculative execution side-channel vulnerabilities

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article provides guidance for a new class of silicon based micro-architectural and speculative execution side-channel vulnerabilities that affect many modern processors and operating systems. This includes Intel, AMD, and ARM. Specific details for these silicon-based vulnerabilities can be found in the following security advisories and CVEs:

- [ADV180002 - Guidance to mitigate speculative execution side-channel vulnerabilities](#)
- [ADV180012 - Microsoft Guidance for Speculative Store Bypass](#)
- [ADV180013 - Microsoft Guidance for Rogue System Register Read](#)
- [ADV180016 - Microsoft Guidance for Lazy FP State Restore](#)
- [ADV180018 - Microsoft Guidance to mitigate L1TF variant](#)
- [ADV190013 - Microsoft Guidance to mitigate Microarchitectural Data Sampling vulnerabilities](#)
- [ADV220002 - Microsoft Guidance on Intel Processor MMIO Stale Data Vulnerabilities](#)
- [CVE-2022-23816](<https://msrc.microsoft.com/update-guide/vulnerability/CVE-2022-23816> - AMD CPU Branch Type Confusion)
- [CVE-2022-21123](<https://msrc.microsoft.com/update-guide/vulnerability/CVE-2022-23825> - AMD CPU Branch Type Confusion)

The disclosure of these CPU vulnerabilities has resulted in questions from customers seeking more clarity.

Microsoft has deployed mitigations across all our cloud services. The infrastructure that runs Azure and isolates customer workloads from each other is protected. This means that a potential attacker using the same infrastructure can't attack your application using these vulnerabilities.

Azure is using [memory preserving maintenance](#) whenever possible, to minimize customer impact and eliminate the need for reboots. Azure will continue utilizing these methods when making systemwide updates to the host and protect our customers.

More information about how security is integrated into every aspect of Azure is available on the [Azure Security Documentation](#) site.

## NOTE

Since this document was first published, multiple variants of this vulnerability class have been disclosed. Microsoft continues to be heavily invested in protecting our customers and providing guidance. This page will be updated as we continue to release further fixes.

**Customers that are running untrusted code within their VM** need to take action to protect against these vulnerabilities by reading below for more guidance on all vulnerabilities.

Other customers should evaluate these vulnerabilities from a Defense in Depth perspective and consider the security and performance implications of their chosen configuration.

# Keeping your operating systems up-to-date

While an OS update is not required to isolate your applications running on Azure from other Azure customers, it is always a best practice to keep your software up-to-date. The latest Security Updates for Windows contain mitigations for these vulnerabilities. Similarly, Linux distributions have released multiple updates to address these vulnerabilities. Here are our recommended actions to update your operating system:

OFFERING	RECOMMENDED ACTION
Azure Cloud Services	Enable <a href="#">auto update</a> or ensure you're running the newest Guest OS.
Azure Linux Virtual Machines	Install updates from your operating system provider. For more information, see <a href="#">Linux</a> later in this document.
Azure Windows Virtual Machines	Install the latest security rollup.
Other Azure PaaS Services	There is no action needed for customers using these services. Azure automatically keeps your OS versions up-to-date.

## Additional guidance if you're running untrusted code

Customers who allow untrusted users to execute arbitrary code may wish to implement some extra security features inside their Azure Virtual Machines or Cloud Services. These features protect against the intra-process disclosure vectors that several speculative execution vulnerabilities describe.

Example scenarios where more security features are recommended:

- You allow code that you do not trust to run inside your VM.
  - *For example, you allow one of your customers to upload a binary or script that you then execute within your application.*
- You allow users that you do not trust to log into your VM using low privileged accounts.
  - *For example, you allow a low-privileged user to log into one of your VMs using remote desktop or SSH.*
- You allow untrusted users access to virtual machines implemented via nested virtualization.
  - *For example, you control the Hyper-V host, but allocate the VMs to untrusted users.*

Customers who do not implement a scenario involving untrusted code do not need to enable these extra security features.

## Enabling additional security

You can enable more security features inside your VM or Cloud Service if you're running untrusted code. In parallel, ensure your operating system is up-to-date to enable security features inside your VM or Cloud Service

### Windows

Your target operating system must be up-to-date to enable these extra security features. While numerous mitigations are enabled by default, the extra features described here must be enabled manually and may cause a performance impact.

#### Option 1

Step 1: Follow the instructions in [KB4072698](#) to verify protections are enabled using the [SpeculationControl](#) PowerShell module.

#### NOTE

If you previously downloaded this module, you will need to install the newest version.

To validate enabled protections against these vulnerabilities, see [Understanding Get-SpeculationControlSettings PowerShell script output](#).

If protections are not enabled, please [contact Azure Support](#) to enable additional controls on your Azure VM.

**Step 2:** To enable Kernel Virtual Address Shadowing (KVAS) and Branch Target Injection (BTI) OS support, follow the instructions in [KB4072698](#) to enable protections using the `Session Manager` registry keys. A reboot is required.

**Step 3:** For deployments that are using [nested virtualization](#) (D3 and E3 only): These instructions apply inside the VM you're using as a Hyper-V host.

1. Follow the instructions in [KB4072698](#) to enable protections using the `MinVmVersionForCpuBasedMitigations` registry keys.
2. Set the hypervisor scheduler type to `Core` by following the instructions [here](#).

#### Option 2

**Disable hyper-threading on the VM** - Customers running untrusted code on a hyper-threaded VM might choose to disable hyper-threading or move to a non-hyper-threaded VM size. Reference [this doc](#) for a list of hyper-threaded VM sizes (where ratio of vCPU to Core is 2:1). To check if your VM has hyper-threading enabled, refer to the below script using the Windows command line from within the VM.

Type `wmic` to enter the interactive interface. Then type the following command to view the amount of physical and logical processors on the VM.

```
CPU Get NumberOfCores,NumberOfLogicalProcessors /Format>List
```

If the number of logical processors is greater than physical processors (cores), then hyper-threading is enabled. If you're running a hyper-threaded VM, [contact Azure Support](#) to get hyper-threading disabled. Once hyper-threading is disabled, support will require a full VM reboot. Refer to [Core count](#) to understand why your VM core count decreased.

#### Option 3

For [CVE-2022-23816](#) and [CVE-2022-21123](#) (AMD CPU Branch Type Confusion), follow both **Option 1** and **Option 2** above.

#### Linux

Enabling the set of extra security features inside requires that the target operating system be fully up-to-date. Some mitigations will be enabled by default. The following section describes the features which are off by default and/or reliant on hardware support (microcode). Enabling these features may cause a performance impact. Reference your operating system provider's documentation for further instructions

**Step 1: Disable hyper-threading on the VM** - Customers running untrusted code on a hyper-threaded VM will need to disable hyper-threading or move to a non-hyper-threaded VM. Reference [this doc](#) for a list of hyper-threaded VM sizes (where ratio of vCPU to Core is 2:1). To check if you're running a hyper-threaded VM, run the `lscpu` command in the Linux VM.

If `Thread(s) per core = 2`, then hyper-threading has been enabled.

If `Thread(s) per core = 1`, then hyper-threading has been disabled.

Sample output for a VM with hyper-threading enabled:

```
CPU Architecture:      x86_64
CPU op-mode(s):       32-bit, 64-bit
Byte Order:           Little Endian
CPU(s):               8
On-line CPU(s) list: 0-7
Thread(s) per core:   2
Core(s) per socket:   4
Socket(s):            1
NUMA node(s):         1
```

If you're running a hyper-threaded VM, [contact Azure Support](#) to get hyper-threading disabled. Once hyper-threading is disabled, **support will require a full VM reboot**. Refer to [Core count](#) to understand why your VM core count decreased.

**Step 2:** To mitigate against any of the below CPU based memory vulnerabilities, refer to your operating system provider's documentation:

- [Redhat and CentOS](#)
- [SUSE](#)
- [Ubuntu](#)

#### Core count

When a hyper-threaded VM is created, Azure allocates 2 threads per core - these are called vCPUs. When hyper-threading is disabled, Azure removes a thread and surfaces up single threaded cores (physical cores). The ratio of vCPU to CPU is 2:1, so once hyper-threading is disabled, the CPU count in the VM will appear to have decreased by half. For example, a D8\_v3 VM is a hyper-threaded VM running on 8 vCPUs (2 threads per core x 4 cores). When hyper-threading is disabled, CPUs will drop to 4 physical cores with 1 thread per core.

## Next steps

For more information about how security is integrated into every aspect of Azure, see [Azure Security Documentation](#).

# Join a Red Hat Enterprise Linux virtual machine to an Azure Active Directory Domain Services managed domain

9/21/2022 • 8 minutes to read • [Edit Online](#)

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to an Azure Active Directory Domain Services (Azure AD DS) managed domain. When you join a VM to an Azure AD DS managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join a Red Hat Enterprise Linux (RHEL) VM to a managed domain.

## Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, [create an account](#).
- An Azure Active Directory tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, [create an Azure Active Directory tenant](#) or [associate an Azure subscription with your account](#).
- An Azure Active Directory Domain Services managed domain enabled and configured in your Azure AD tenant.
  - If needed, the first tutorial [creates and configures an Azure Active Directory Domain Services managed domain](#).
- A user account that's a part of the managed domain.
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

## Create and connect to a RHEL Linux VM

If you have an existing RHEL Linux VM in Azure, connect to it using SSH, then continue on to the next step to [start configuring the VM](#).

If you need to create a RHEL Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- [Azure portal](#)
- [Azure CLI](#)
- [Azure PowerShell](#)

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Azure AD Domain Services.
- Deploy the VM into a different subnet than your Azure AD Domain Services managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

## Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the `/etc/hosts` file and set the hostname:

```
sudo vi /etc/hosts
```

In the `hosts` file, update the `localhost` address. In the following example:

- `aaddscontoso.com` is the DNS domain name of your managed domain.
- `rhel` is the hostname of your RHEL VM that you're joining to the managed domain.

Update these names with your own values:

```
127.0.0.1 rhel rhel.aaddscontoso.com
```

When done, save and exit the `hosts` file using the `:wq` command of the editor.

## Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `yum`. There are some differences between RHEL 7.x and RHEL 6.x, so use the appropriate commands for your distro version in the remaining sections of this article.

### RHEL 7

```
sudo yum install realmd sssd krb5-workstation krb5-libs oddjob oddjob-mkhomedir samba-common-tools
```

### RHEL 6

```
sudo yum install adcli sssd authconfig krb5-workstation
```

## Join VM to the managed domain

Now that the required packages are installed on the VM, join the VM to the managed domain. Again, use the appropriate steps for your RHEL distro version.

### RHEL 7

1. Use the `realm discover` command to discover the managed domain. The following example discovers the realm `AADDSCONTOSO.COM`. Specify your own managed domain name in ALL UPPERCASE:

```
sudo realm discover AADDSCONTOSO.COM
```

If the `realm discover` command can't find your managed domain, review the following troubleshooting steps:

- Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
- Check that the VM is deployed to the same, or a peered, virtual network in which the managed

domain is available.

- Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.
2. Now initialize Kerberos using the `kinit` command. Specify a user that's a part of the managed domain. If needed, [add a user account to a group in Azure AD](#).

Again, the managed domain name must be entered in ALL UPPERCASE. In the following example, the account named `contosoadmin@aaddscontoso.com` is used to initialize Kerberos. Enter your own user account that's a part of the managed domain:

```
kinit contosoadmin@AADDSCONTOSO.COM
```

3. Finally, join the VM to the managed domain using the `realm join` command. Use the same user account that's a part of the managed domain that you specified in the previous `kinit` command, such as `contosoadmin@AADDSCONTOSO.COM`:

```
sudo realm join --verbose AADDSCONTOSO.COM -U 'contosoadmin@AADDSCONTOSO.COM'
```

It takes a few moments to join the VM to the managed domain. The following example output shows the VM has successfully joined to the managed domain:

```
Successfully enrolled machine in realm
```

## RHEL 6

1. Use the `adcli info` command to discover the managed domain. The following example discovers the realm `AADDSCONTOSO.COM`. Specify your own managed domain name in ALL UPPERCASE:

```
sudo adcli info aaddscontoso.com
```

If the `adcli info` command can't find your managed domain, review the following troubleshooting steps:

- Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
  - Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
  - Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.
2. First, join the domain using the `adcli join` command, this command also creates the keytab to authenticate the machine. Use a user account that's a part of the managed domain.

```
sudo adcli join aaddscontoso.com -U contosoadmin
```

3. Now configure the `/etc/krb5.conf` and create the `/etc/sssd/sssd.conf` files to use the `aaddscontoso.com` Active Directory domain. Make sure that `AADDSCONTOSO.COM` is replaced by your own domain name:

Open the `/etc/krb5.conf` file with an editor:

```
sudo vi /etc/krb5.conf
```

Update the `krb5.conf` file to match the following sample:

```
[logging]
default = FILE:/var/log/krb5libs.log
kdc = FILE:/var/log/krb5kdc.log
admin_server = FILE:/var/log/kadmind.log

[libdefaults]
default_realm = AADDSCONTOSO.COM
dns_lookup_realm = true
dns_lookup_kdc = true
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true

[realms]
AADDSCONTOSO.COM = {
kdc = AADDSCONTOSO.COM
admin_server = AADDSCONTOSO.COM
}

[domain_realm]
.AADDSCONTOSO.COM = AADDSCONTOSO.COM
AADDSCONTOSO.COM = AADDSCONTOSO.COM
```

Create the `/etc/sssd/sssd.conf` file:

```
sudo vi /etc/sssd/sssd.conf
```

Update the `sssd.conf` file to match the following sample:

```
[sssd]
services = nss, pam, ssh, autofs
config_file_version = 2
domains = AADDSCONTOSO.COM

[domain/AADDSCONTOSO.COM]

id_provider = ad
```

4. Make sure `/etc/sssd/sssd.conf` permissions are 600 and is owned by root user:

```
sudo chmod 600 /etc/sssd/sssd.conf
sudo chown root:root /etc/sssd/sssd.conf
```

5. Use `authconfig` to instruct the VM about the AD Linux integration:

```
sudo authconfig --enablesssd --enablesssdauth --update
```

6. Start and enable the sssd service:

```
sudo service sssd start
sudo chkconfig sssd on
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed

domain.

Now check if you can query user AD information using `getent`

```
sudo getent passwd contosoadmin
```

## Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

1. Open the `sshd_config` file with an editor:

```
sudo vi /etc/ssh/sshd_config
```

2. Update the line for `PasswordAuthentication` to `yes`:

```
PasswordAuthentication yes
```

When done, save and exit the `sshd_config` file using the `:wq` command of the editor.

3. To apply the changes and let users sign in using a password, restart the SSH service for your RHEL distro version:

RHEL 7

```
sudo systemctl restart sshd
```

RHEL 6

```
sudo service sshd restart
```

## Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the `AAD DC Administrators` group administrative privileges on the RHEL VM, you add an entry to the `/etc/sudoers`. Once added, members of the `AAD DC Administrators` group can use the `sudo` command on the RHEL VM.

1. Open the `sudoers` file for editing:

```
sudo visudo
```

2. Add the following entry to the end of `/etc/sudoers` file. The `AAD DC Administrators` group contains whitespace in the name, so include the backslash escape character in the group name. Add your own domain name, such as `aaddscontoso.com`:

```
# Add 'AAD DC Administrators' group members as admins.  
%AAD\ DC\ Administrators@aaddscontoso.com ALL=(ALL) NOPASSWD:ALL
```

When done, save and exit the editor using the `:wq` command of the editor.

## Sign in to the VM using a domain account

To verify that the VM has been successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory has been created, and that group membership from the domain is applied.

1. Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as `rhel.aaddscontoso.com`. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

```
ssh -l contosoadmin@AADDSCONTOSO.com rhel.aaddscontoso.com
```

2. When you've successfully connected to the VM, verify that the home directory was initialized correctly:

```
pwd
```

You should be in the `/home` directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

```
id
```

You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

```
sudo yum update
```

## Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see [Troubleshooting domain join issues](#).

# Join a CentOS Linux virtual machine to an Azure Active Directory Domain Services managed domain

9/21/2022 • 6 minutes to read • [Edit Online](#)

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to an Azure Active Directory Domain Services (Azure AD DS) managed domain. When you join a VM to an Azure AD DS managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join a CentOS Linux VM to a managed domain.

## Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, [create an account](#).
- An Azure Active Directory tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, [create an Azure Active Directory tenant](#) or [associate an Azure subscription with your account](#).
- An Azure Active Directory Domain Services managed domain enabled and configured in your Azure AD tenant.
  - If needed, the first tutorial [creates and configures an Azure Active Directory Domain Services managed domain](#).
- A user account that's part of the managed domain.
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

## Create and connect to a CentOS Linux VM

If you have an existing CentOS Linux VM in Azure, connect to it using SSH, then continue on to the next step to [start configuring the VM](#).

If you need to create a CentOS Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- [Azure portal](#)
- [Azure CLI](#)
- [Azure PowerShell](#)

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Azure AD Domain Services.
- Deploy the VM into a different subnet than your managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

# Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the `/etc/hosts` file and set the hostname:

```
sudo vi /etc/hosts
```

In the `hosts` file, update the `localhost` address. In the following example:

- `aaddscontoso.com` is the DNS domain name of your managed domain.
- `centos` is the hostname of your CentOS VM that you're joining to the managed domain.

Update these names with your own values:

```
127.0.0.1 centos.aaddscontoso.com centos
```

When done, save and exit the `hosts` file using the `:wq` command of the editor.

## Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `yum`:

```
sudo yum install adcli realmd sssd krb5-workstation krb5-libs oddjob oddjob-mkhomedir samba-common-tools
```

## Join VM to the managed domain

Now that the required packages are installed on the VM, join the VM to the managed domain.

1. Use the `realm discover` command to discover the managed domain. The following example discovers the realm `AADDSCONTOSO.COM`. Specify your own managed domain name in ALL UPPERCASE:

```
sudo realm discover AADDSCONTOSO.COM
```

If the `realm discover` command can't find your managed domain, review the following troubleshooting steps:

- Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
  - Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
  - Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.
2. Now initialize Kerberos using the `kinit` command. Specify a user that's a part of the managed domain. If needed, [add a user account to a group in Azure AD](#).

Again, the managed domain name must be entered in ALL UPPERCASE. In the following example, the account named `contosoadmin@aaddscontoso.com` is used to initialize Kerberos. Enter your own user account that's a part of the managed domain:

```
kinit contosoadmin@AADDSCONTOSO.COM
```

3. Finally, join the VM to the managed domain using the `realm join` command. Use the same user account that's a part of the managed domain that you specified in the previous `kinit` command, such as

```
contosoadmin@AADDSCONTOSO.COM :
```

```
sudo realm join --verbose AADDSCONTOSO.COM -U 'contosoadmin@AADDSCONTOSO.COM' --membership-software=adcli
```

It takes a few moments to join the VM to the managed domain. The following example output shows the VM has successfully joined to the managed domain:

```
Successfully enrolled machine in realm
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed domain.

## Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

1. Open the `sshd_config` file with an editor:

```
sudo vi /etc/ssh/sshd_config
```

2. Update the line for `PasswordAuthentication` to `yes`:

```
PasswordAuthentication yes
```

When done, save and exit the `sshd_config` file using the `:wq` command of the editor.

3. To apply the changes and let users sign in using a password, restart the SSH service:

```
sudo systemctl restart sshd
```

## Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the `AAD DC Administrators` group administrative privileges on the CentOS VM, you add an entry to the `/etc/sudoers`. Once added, members of the `AAD DC Administrators` group can use the `sudo` command on the CentOS VM.

1. Open the `sudoers` file for editing:

```
sudo visudo
```

2. Add the following entry to the end of `/etc/sudoers` file. The `AAD DC Administrators` group contains whitespace in the name, so include the backslash escape character in the group name. Add your own domain name, such as `aaddscontoso.com`:

```
# Add 'AAD DC Administrators' group members as admins.  
%AAD\ DC\ Administrators@aaddscontoso.com ALL=(ALL) NOPASSWD:ALL
```

When done, save and exit the editor using the `:wq` command of the editor.

## Sign in to the VM using a domain account

To verify that the VM has been successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory has been created, and that group membership from the domain is applied.

1. Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as `centos.aaddscontoso.com`. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

```
ssh -l contosoadmin@AADDSCONTOSO.com centos.aaddscontoso.com
```

2. When you've successfully connected to the VM, verify that the home directory was initialized correctly:

```
pwd
```

You should be in the `/home` directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

```
id
```

You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

```
sudo yum update
```

## Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see [Troubleshooting domain join issues](#).

# Join an Ubuntu Linux virtual machine to an Azure Active Directory Domain Services managed domain

9/21/2022 • 8 minutes to read • [Edit Online](#)

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to an Azure Active Directory Domain Services (Azure AD DS) managed domain. When you join a VM to an Azure AD DS managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join an Ubuntu Linux VM to a managed domain.

## Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, [create an account](#).
- An Azure Active Directory tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, [create an Azure Active Directory tenant](#) or [associate an Azure subscription with your account](#).
- An Azure Active Directory Domain Services managed domain enabled and configured in your Azure AD tenant.
  - If needed, the first tutorial [creates and configures an Azure Active Directory Domain Services managed domain](#).
- A user account that's a part of the managed domain. Make sure the SAMAccountName attribute for the user is not autogenerated. If multiple user accounts in the Azure AD tenant have the same mailNickname attribute, the SAMAccountName attribute for each user is autogenerated. For more information, see [How objects and credentials are synchronized in an Azure Active Directory Domain Services managed domain](#).
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

## Create and connect to an Ubuntu Linux VM

If you have an existing Ubuntu Linux VM in Azure, connect to it using SSH, then continue on to the next step to [start configuring the VM](#).

If you need to create an Ubuntu Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- [Azure portal](#)
- [Azure CLI](#)
- [Azure PowerShell](#)

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Azure AD Domain

Services.

- Deploy the VM into a different subnet than your Azure AD Domain Services managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

## Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the `/etc/hosts` file and set the hostname:

```
sudo vi /etc/hosts
```

In the `hosts` file, update the `localhost` address. In the following example:

- `aaddscontoso.com` is the DNS domain name of your managed domain.
- `ubuntu` is the hostname of your Ubuntu VM that you're joining to the managed domain.

Update these names with your own values:

```
127.0.0.1 ubuntu.aaddscontoso.com ubuntu
```

When done, save and exit the `hosts` file using the `:wq` command of the editor.

## Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `apt-get`

During the Kerberos installation, the `krb5-user` package prompts for the realm name in ALL UPPERCASE. For example, if the name of your managed domain is `aaddscontoso.com`, enter `AADDSCONTOSO.COM` as the realm. The installation writes the `[realm]` and `[domain_realm]` sections in `/etc krb5.conf` configuration file. Make sure that you specify the realm an ALL UPPERCASE:

```
sudo apt-get update
sudo apt-get install krb5-user samba sssd sssd-tools libnss-sss libpam-sss ntp ntpdate realmd adcli
```

## Configure Network Time Protocol (NTP)

For domain communication to work correctly, the date and time of your Ubuntu VM must synchronize with the managed domain. Add your managed domain's NTP hostname to the `/etc/ntp.conf` file.

1. Open the `ntp.conf` file with an editor:

```
sudo vi /etc/ntp.conf
```

2. In the `ntp.conf` file, create a line to add your managed domain's DNS name. In the following example, an entry for `aaddscontoso.com` is added. Use your own DNS name:

```
server aaddscontoso.com
```

When done, save and exit the `ntp.conf` file using the `:wq` command of the editor.

3. To make sure that the VM is synchronized with the managed domain, the following steps are needed:

- Stop the NTP server
- Update the date and time from the managed domain
- Start the NTP service

Run the following commands to complete these steps. Use your own DNS name with the `ntpd` command:

```
sudo systemctl stop ntp
sudo ntpdate aaddscontoso.com
sudo systemctl start ntp
```

## Join VM to the managed domain

Now that the required packages are installed on the VM and NTP is configured, join the VM to the managed domain.

1. Use the `realm discover` command to discover the managed domain. The following example discovers the realm `AADDSCONTOSO.COM`. Specify your own managed domain name in ALL UPPERCASE:

```
sudo realm discover AADDSCONTOSO.COM
```

If the `realm discover` command can't find your managed domain, review the following troubleshooting steps:

- Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
- Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
- Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.

2. Now initialize Kerberos using the `kinit` command. Specify a user that's a part of the managed domain. If needed, [add a user account to a group in Azure AD](#).

Again, the managed domain name must be entered in ALL UPPERCASE. In the following example, the account named `contosoadmin@aaddscontoso.com` is used to initialize Kerberos. Enter your own user account that's a part of the managed domain:

```
kinit -V contosoadmin@AADDSCONTOSO.COM
```

3. Finally, join the VM to the managed domain using the `realm join` command. Use the same user account that's a part of the managed domain that you specified in the previous `kinit` command, such as `contosoadmin@AADDSCONTOSO.COM`:

```
sudo realm join --verbose AADDSCONTOSO.COM -U 'contosoadmin@AADDSCONTOSO.COM' --install=/
```

It takes a few moments to join the VM to the managed domain. The following example output shows the VM has successfully joined to the managed domain:

```
Successfully enrolled machine in realm
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed domain.

If you received the error *Unspecified GSS failure. Minor code may provide more information (Server not found in Kerberos database)*, open the file `/etc/krb5.conf` and add the following code in `[libdefaults]` section and try again:

```
rdns=false
```

## Update the SSSD configuration

One of the packages installed in a previous step was for System Security Services Daemon (SSSD). When a user tries to sign in to a VM using domain credentials, SSSD relays the request to an authentication provider. In this scenario, SSSD uses Azure AD DS to authenticate the request.

1. Open the `sssd.conf` file with an editor:

```
sudo vi /etc/sssd/sssd.conf
```

2. Comment out the line for `use_fully_qualified_names` as follows:

```
# use_fully_qualified_names = True
```

When done, save and exit the `sssd.conf` file using the `:wq` command of the editor.

3. To apply the change, restart the SSSD service:

```
sudo systemctl restart sssd
```

## Configure user account and group settings

With the VM joined to the managed domain and configured for authentication, there are a few user configuration options to complete. These configuration changes include allowing password-based authentication, and automatically creating home directories on the local VM when domain users first sign in.

### Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

1. Open the `sshd_config` file with an editor:

```
sudo vi /etc/ssh/sshd_config
```

2. Update the line for `PasswordAuthentication` to `yes`:

```
PasswordAuthentication yes
```

When done, save and exit the `sshd_config` file using the `:wq` command of the editor.

- To apply the changes and let users sign in using a password, restart the SSH service:

```
sudo systemctl restart ssh
```

### Configure automatic home directory creation

To enable automatic creation of the home directory when a user first signs in, complete the following steps:

- Open the `/etc/pam.d/common-session` file in an editor:

```
sudo vi /etc/pam.d/common-session
```

- Add the following line in this file below the line `session optional pam_sss.so`:

```
session required pam_mkhomedir.so skel=/etc/skel/ umask=0077
```

When done, save and exit the `common-session` file using the `:wq` command of the editor.

### Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the `AAD DC Administrators` group administrative privileges on the Ubuntu VM, you add an entry to the `/etc/sudoers`. Once added, members of the `AAD DC Administrators` group can use the `sudo` command on the Ubuntu VM.

- Open the `sudoers` file for editing:

```
sudo visudo
```

- Add the following entry to the end of `/etc/sudoers` file:

```
# Add 'AAD DC Administrators' group members as admins.  
%AAD\ DC\ Administrators ALL=(ALL) NOPASSWD:ALL
```

When done, save and exit the editor using the `ctrl-X` command.

## Sign in to the VM using a domain account

To verify that the VM has been successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory has been created, and that group membership from the domain is applied.

- Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as `ubuntu.aaddscontoso.com`. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

```
ssh -l contosoadmin@AADDSCONTOSO.com ubuntu.aaddscontoso.com
```

- When you've successfully connected to the VM, verify that the home directory was initialized correctly:

```
pwd
```

You should be in the `/home` directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

```
id
```

You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

```
sudo apt-get update
```

## Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see [Troubleshooting domain join issues](#).

# Configure managed identities for Azure resources on a VM using the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provides Azure services with an automatically managed identity in Azure Active Directory. You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, you learn how to enable and disable system and user-assigned managed identities for an Azure Virtual Machine (VM), using the Azure portal.

## Prerequisites

- If you're unfamiliar with managed identities for Azure resources, check out the [overview section](#).
- If you don't already have an Azure account, [sign up for a free account](#) before continuing.

## System-assigned managed identity

In this section, you learn how to enable and disable the system-assigned managed identity for VM using the Azure portal.

### **Enable system-assigned managed identity during creation of a VM**

To enable system-assigned managed identity on a VM during its creation, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

- Under the **Management** tab in the **Identity** section, switch **Managed service identity** to **On**.

## Create a virtual machine

Basics Disks Networking **Management** Guest config Tags Review + create

Configure monitoring and management options for your VM.

**MONITORING**

Boot diagnostics [i](#)  On  Off

OS guest diagnostics [i](#)  On  Off

\* Diagnostics storage account [i](#)  [Create new](#)

**IDENTITY**

Managed service identity [i](#)  On  Off

**AUTO-SHUTDOWN**

Enable auto-shutdown [i](#)  On  Off

**BACKUP**

Enable backup [i](#)  On  Off

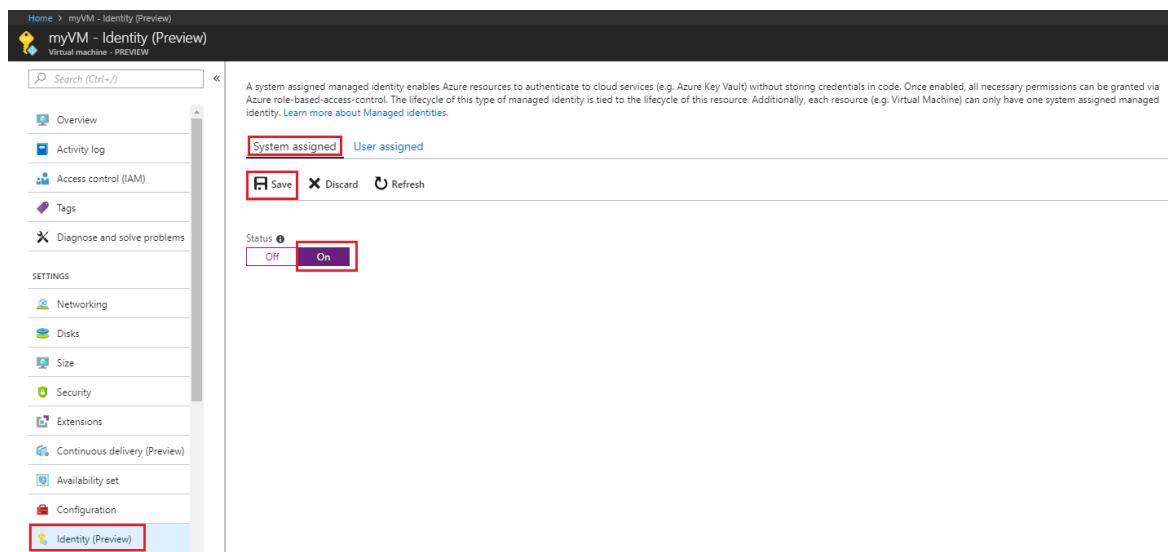

Refer to the following Quickstarts to create a VM:

- [Create a Windows virtual machine with the Azure portal](#)
- [Create a Linux virtual machine with the Azure portal](#)

### Enable system-assigned managed identity on an existing VM

To enable system-assigned managed identity on a VM that was originally provisioned without it, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Sign in to the [Azure portal](#) using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and select **Identity**.
3. Under **System assigned, Status**, select **On** and then click **Save**:

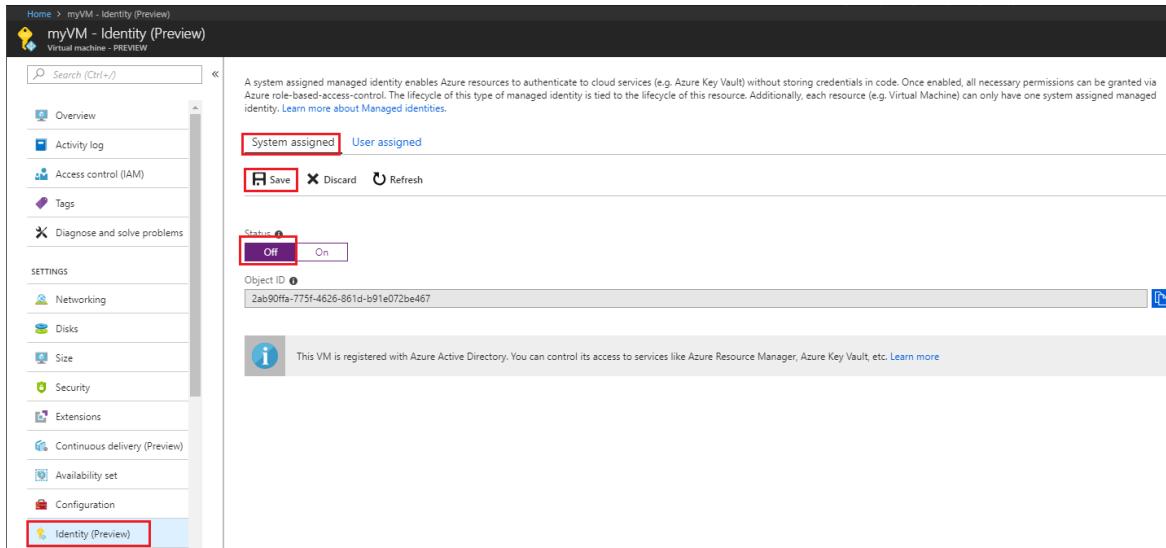

### Remove system-assigned managed identity from a VM

To remove system-assigned managed identity from a VM, your account needs the [Virtual Machine Contributor](#)

role assignment. No other Azure AD directory role assignments are required.

If you have a Virtual Machine that no longer needs system-assigned managed identity:

1. Sign in to the [Azure portal](#) using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and select **Identity**.
3. Under **System assigned, Status**, select **Off** and then click **Save**:

## User-assigned managed identity

In this section, you learn how to add and remove a user-assigned managed identity from a VM using the Azure portal.

### Assign a user-assigned identity during the creation of a VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

Currently, the Azure portal does not support assigning a user-assigned managed identity during the creation of a VM. Instead, refer to one of the following VM creation Quickstart articles to first create a VM, and then proceed to the next section for details on assigning a user-assigned managed identity to the VM:

- [Create a Windows virtual machine with the Azure portal](#)
- [Create a Linux virtual machine with the Azure portal](#)

### Assign a user-assigned managed identity to an existing VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Sign in to the [Azure portal](#) using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired VM and click **Identity, User assigned** and then **+ Add**.

User assigned managed identities enable Azure resources to authenticate to cloud services (e.g. Azure Key Vault) without storing credentials in code. This type of managed identities are created as standalone Azure resources, and have their own lifecycle. A single resource (e.g. Virtual Machine) can utilize multiple user assigned managed identities. Similarly, a single user assigned managed identity can be shared across multiple resources (e.g. Virtual Machine). [Learn more about Managed identities.](#)

## Remove a user-assigned managed identity from a VM

To remove a user-assigned identity from a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Sign in to the [Azure portal](#) using an account associated with the Azure subscription that contains the VM.

2. Navigate to the desired VM and click **Identity**, **User assigned**, the name of the user-assigned managed identity you want to delete and then click **Remove** (click **Yes** in the confirmation pane).

The screenshot shows the Azure portal interface for managing identities on a virtual machine. The left sidebar has a 'Identity' section with several options: Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, Networking, Disks, Size, Security, Extensions, Continuous delivery (Preview), Availability set, Configuration, and Identity. The 'Identity' option is highlighted with a red box. The main content area is titled 'myVM - Identity' and shows the 'Virtual machine - PREVIEW' section. It displays information about user-assigned managed identities, mentioning they enable authentication to cloud services without storing credentials in code. Below this, there are tabs for 'System assigned' and 'User assigned', with 'User assigned' being the active tab. A table lists managed identities with columns for NAME, RESOURCE GROUP, and SUBSCRIPTION. One entry, 'ID1', is selected and has a checkmark in the first column. The 'Remove' button in the table header is also highlighted with a red box.

NAME	RESOURCE GROUP	SUBSCRIPTION
ID1	TestRG	<SUBSCRIPTION ID>

## Next steps

- Using the Azure portal, give an Azure VM's managed identity [access to another Azure resource](#).

# Configure managed identities for Azure resources on an Azure VM using Azure CLI

9/21/2022 • 7 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provide Azure services with an automatically managed identity in Azure Active Directory. You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, using the Azure CLI, you learn how to perform the following managed identities for Azure resources operations on an Azure VM:

- Enable and disable the system-assigned managed identity on an Azure VM
- Add and remove a user-assigned managed identity on an Azure VM

If you don't already have an Azure account, [sign up for a free account](#) before continuing.

## Prerequisites

- If you're unfamiliar with managed identities for Azure resources, see [What are managed identities for Azure resources?](#). To learn about system-assigned and user-assigned managed identity types, see [Managed identity types](#).

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## System-assigned managed identity

In this section, you learn how to enable and disable the system-assigned managed identity on an Azure VM using Azure CLI.

### Enable system-assigned managed identity during creation of an Azure VM

To create an Azure VM with the system-assigned managed identity enabled, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Create a [resource group](#) for containment and deployment of your VM and its related resources, using `az group create`. You can skip this step if you already have resource group you would like to use instead:

```
az group create --name myResourceGroup --location westus
```

2. Create a VM using `az vm create`. The following example creates a VM named *myVM* with a system-

assigned managed identity, as requested by the `--assign-identity` parameter, with the specified `--role` and `--scope`. The `--admin-username` and `--admin-password` parameters specify the administrative user name and password account for virtual machine sign-in. Update these values as appropriate for your environment:

```
az vm create --resource-group myResourceGroup --name myVM --image win2016datacenter --generate-ssh-keys --assign-identity --role contributor --scope mySubscription --admin-username azureuser --admin-password myPassword12
```

### Enable system-assigned managed identity on an existing Azure VM

To enable system-assigned managed identity on a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. If you're using the Azure CLI in a local console, first sign in to Azure using `az login`. Use an account that is associated with the Azure subscription that contains the VM.

```
az login
```

2. Use `az vm identity assign` with the `identity assign` command enable the system-assigned identity to an existing VM:

```
az vm identity assign -g myResourceGroup -n myVm
```

### Disable system-assigned identity from an Azure VM

To disable system-assigned managed identity on a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

If you have a Virtual Machine that no longer needs the system-assigned identity, but still needs user-assigned identities, use the following command:

```
az vm update -n myVM -g myResourceGroup --set identity.type='UserAssigned'
```

If you have a virtual machine that no longer needs system-assigned identity and it has no user-assigned identities, use the following command:

#### NOTE

The value `none` is case sensitive. It must be lowercase.

```
az vm update -n myVM -g myResourceGroup --set identity.type="none"
```

## User-assigned managed identity

In this section, you will learn how to add and remove a user-assigned managed identity from an Azure VM using Azure CLI. If you create your user-assigned managed identity in a different RG than your VM. You'll have to use the URL of your managed identity to assign it to your VM. For example:

```
--identities  
"/subscriptions/<SUBID>/resourcegroups/<RESOURCEGROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER_ASSIGNED_IDENTITY_NAME>"
```

### Assign a user-assigned managed identity during the creation of an Azure VM

To assign a user-assigned identity to a VM during its creation, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. You can skip this step if you already have a resource group you would like to use. Create a [resource group](#) for containment and deployment of your user-assigned managed identity, using `az group create`. Be sure to replace the `<RESOURCE GROUP>` and `<LOCATION>` parameter values with your own values.:

```
az group create --name <RESOURCE GROUP> --location <LOCATION>
```

2. Create a user-assigned managed identity using [az identity create](#). The `-g` parameter specifies the resource group where the user-assigned managed identity is created, and the `-n` parameter specifies its name.

**IMPORTANT**

When you create user-assigned managed identities, only alphanumeric characters (0-9, a-z, and A-Z) and the hyphen (-) are supported. For the assignment to a virtual machine or virtual machine scale set to work properly, the name is limited to 24 characters. For more information, see [FAQs and known issues](#).

```
az identity create -g myResourceGroup -n myUserAssignedIdentity
```

The response contains details for the user-assigned managed identity created, similar to the following. The resource ID value assigned to the user-assigned managed identity is used in the following step.

```
{  
    "clientId": "73444643-8088-4d70-9532-c3a0fdc190fz",  
    "clientSecretUrl": "https://control-westcentralus.identity.azure.net/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESOURCE GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<myUserAssignedIdentity>/credential s?tid=5678&oid=9012&aid=73444643-8088-4d70-9532-c3a0fdc190fz",  
    "id": "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESOURCE GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER ASSIGNED IDENTITY NAME>",  
    "location": "westcentralus",  
    "name": "<USER ASSIGNED IDENTITY NAME>",  
    "principalId": "e5fdfdc1-ed84-4d48-8551-fe9fb9dedf11",  
    "resourceGroup": "<RESOURCE GROUP>",  
    "tags": {},  
    "tenantId": "733a8f0e-ec41-4e69-8ad8-971fc4b533b1",  
    "type": "Microsoft.ManagedIdentity/userAssignedIdentities"  
}
```

3. Create a VM using [az vm create](#). The following example creates a VM associated with the new user-assigned identity, as specified by the `--assign-identity` parameter, with the specified `--role` and `--scope`. Be sure to replace the `<RESOURCE GROUP>`, `<VM NAME>`, `<USER NAME>`, `<PASSWORD>`, `<USER ASSIGNED IDENTITY NAME>`, `<ROLE>`, and `<SUBSCRIPTION>` parameter values with your own values.

```
az vm create --resource-group <RESOURCE GROUP> --name <VM NAME> --image UbuntuLTS --admin-username <USER NAME> --admin-password <PASSWORD> --assign-identity <USER ASSIGNED IDENTITY NAME> --role <ROLE> --scope <SUBSCRIPTION>
```

### Assign a user-assigned managed identity to an existing Azure VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Create a user-assigned identity using [az identity create](#). The `-g` parameter specifies the resource group where the user-assigned identity is created, and the `-n` parameter specifies its name. Be sure to replace the `<RESOURCE GROUP>` and `<USER ASSIGNED IDENTITY NAME>` parameter values with your own values:

**IMPORTANT**

Creating user-assigned managed identities with special characters (i.e. underscore) in the name is not currently supported. Please use alphanumeric characters. Check back for updates. For more information, see [FAQs and known issues](#)

```
az identity create -g <RESOURCE GROUP> -n <USER ASSIGNED IDENTITY NAME>
```

The response contains details for the user-assigned managed identity created, similar to the following.

```
{
  "clientId": "73444643-8088-4d70-9532-c3a0fdc190fz",
  "clientSecretUrl": "https://control-westcentralus.identity.azure.net/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESOURCE GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER ASSIGNED IDENTITY NAME>/credentials?tid=5678&oid=9012&aid=73444643-8088-4d70-9532-c3a0fdc190fz",
  "id": "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESOURCE GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER ASSIGNED IDENTITY NAME>",
  "location": "westcentralus",
  "name": "<USER ASSIGNED IDENTITY NAME>",
  "principalId": "e5fdfdc1-ed84-4d48-8551-fe9fb9dedf11",
  "resourceGroup": "<RESOURCE GROUP>",
  "tags": {},
  "tenantId": "733a8f0e-ec41-4e69-8ad8-971fc4b533b1",
  "type": "Microsoft.ManagedIdentity/userAssignedIdentities"
}
```

- Assign the user-assigned identity to your VM using `az vm identity assign`. Be sure to replace the `<RESOURCE GROUP>` and `<VM NAME>` parameter values with your own values. The `<USER ASSIGNED IDENTITY NAME>` is the user-assigned managed identity's resource `name` property, as created in the previous step. If you created your user-assigned managed identity in a different RG than your VM. You'll have to use the URL of your managed identity.

```
az vm identity assign -g <RESOURCE GROUP> -n <VM NAME> --identities <USER ASSIGNED IDENTITY>
```

### Remove a user-assigned managed identity from an Azure VM

To remove a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) role assignment.

If this is the only user-assigned managed identity assigned to the virtual machine, `UserAssigned` will be removed from the identity type value. Be sure to replace the `<RESOURCE GROUP>` and `<VM NAME>` parameter values with your own values. The `<USER ASSIGNED IDENTITY>` will be the user-assigned identity's `name` property, which can be found in the identity section of the virtual machine using `az vm identity show`:

```
az vm identity remove -g <RESOURCE GROUP> -n <VM NAME> --identities <USER ASSIGNED IDENTITY>
```

If your VM does not have a system-assigned managed identity and you want to remove all user-assigned identities from it, use the following command:

#### NOTE

The value `none` is case sensitive. It must be lowercase.

```
az vm update -n myVM -g myResourceGroup --set identity.type="none" identity.userAssignedIdentities=null
```

If your VM has both system-assigned and user-assigned identities, you can remove all the user-assigned identities by switching to use only system-assigned. Use the following command:

```
az vm update -n myVM -g myResourceGroup --set identity.type='SystemAssigned'
identity.userAssignedIdentities=null
```

  - [Create a Linux virtual machine with CLI](#)

# Configure managed identities for Azure resources on an Azure VM using PowerShell

9/21/2022 • 6 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provide Azure services with an automatically managed identity in Azure Active Directory. You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, using PowerShell, you learn how to perform the following managed identities for Azure resources operations on an Azure VM.

## NOTE

To interact with Azure, the Azure Az PowerShell module is recommended. See [Install Azure PowerShell](#) to get started. To learn how to migrate to the Az PowerShell module, see [Migrate Azure PowerShell from AzureRM to Az](#).

## Prerequisites

- If you're unfamiliar with managed identities for Azure resources, check out the [overview section](#). Be sure to review the [difference between a system-assigned and user-assigned managed identity](#).
- If you don't already have an Azure account, [sign up for a free account](#) before continuing.
- To run the example scripts, you have two options:
  - Use the [Azure Cloud Shell](#), which you can open using the Try It button on the top-right corner of code blocks.
  - Run scripts locally by installing the latest version of [Azure PowerShell](#), then sign in to Azure using `Connect-AzAccount`.

## System-assigned managed identity

In this section, you'll learn how to enable and disable the system-assigned managed identity using Azure PowerShell.

### Enable system-assigned managed identity during creation of an Azure VM

To create an Azure VM with the system-assigned managed identity enabled, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Refer to one of the following Azure VM Quickstarts, completing only the necessary sections ("Sign in to Azure", "Create resource group", "Create networking group", "Create the VM").

When you get to the "Create the VM" section, make a slight modification to the `New-AzVMConfig` cmdlet syntax. Be sure to add a `-IdentityType SystemAssigned` parameter to provision the VM with the system-assigned identity enabled, for example:

```
$vmConfig = New-AzVMConfig -VMName myVM -IdentityType SystemAssigned ...
```

- Create a Windows virtual machine using PowerShell
- Create a Linux virtual machine using PowerShell

## Enable system-assigned managed identity on an existing Azure VM

To enable system-assigned managed identity on a VM that was originally provisioned without it, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Retrieve the VM properties using the `Get-AzVM` cmdlet. Then to enable a system-assigned managed identity, use the `-IdentityType` switch on the `Update-AzVM` cmdlet:

```
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Update-AzVM -ResourceGroupName myResourceGroup -VM $vm -IdentityType SystemAssigned
```

## Add VM system assigned identity to a group

After you have enabled system assigned identity on a VM, you can add it to a group. The following procedure adds a VM's system assigned identity to a group.

1. Retrieve and note the `ObjectId` (as specified in the `Id` field of the returned values) of the VM's service principal:

```
Get-AzADServicePrincipal -displayname "myVM"
```

2. Retrieve and note the `ObjectId` (as specified in the `Id` field of the returned values) of the group:

```
Get-AzADGroup -searchstring "myGroup"
```

3. Add the VM's service principal to the group:

```
Add-AzureADGroupMember -ObjectId "<objectId of group>" -RefObjectId "<object id of VM service principal>"
```

## Disable system-assigned managed identity from an Azure VM

To disable system-assigned managed identity on a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

If you have a Virtual Machine that no longer needs the system-assigned managed identity but still needs user-assigned managed identities, use the following cmdlet:

1. Retrieve the VM properties using the `Get-AzVM` cmdlet and set the `-IdentityType` parameter to `UserAssigned`:

```
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Update-AzVm -ResourceGroupName myResourceGroup -VM $vm -IdentityType "UserAssigned"
```

If you have a virtual machine that no longer needs system-assigned managed identity and it has no user-assigned managed identities, use the following commands:

```
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Update-AzVm -ResourceGroupName myResourceGroup -VM $vm -IdentityType None
```

# User-assigned managed identity

In this section, you learn how to add and remove a user-assigned managed identity from a VM using Azure PowerShell.

## Assign a user-assigned managed identity to a VM during creation

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Refer to one of the following Azure VM Quickstarts, completing only the necessary sections ("Sign in to Azure", "Create resource group", "Create networking group", "Create the VM").

When you get to the "Create the VM" section, make a slight modification to the `New-AzVMConfig` cmdlet syntax. Add the `-IdentityType UserAssigned` and `-IdentityID` parameters to provision the VM with a user-assigned identity. Replace `<VM NAME>`, `<SUBSCRIPTION ID>`, `<RESOURCE GROUP>`, and `<USER ASSIGNED IDENTITY NAME>` with your own values. For example:

```
$vmConfig = New-AzVMConfig -VMName <VM NAME> -IdentityType UserAssigned -IdentityID  
"/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESOURCE  
GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER ASSIGNED IDENTITY NAME>..."
```

- [Create a Windows virtual machine using PowerShell](#)
- [Create a Linux virtual machine using PowerShell](#)

## Assign a user-assigned managed identity to an existing Azure VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Create a user-assigned managed identity using the `New-AzUserAssignedIdentity` cmdlet. Note the `Id` in the output because you'll need this information in the next step.

### IMPORTANT

Creating user-assigned managed identities only supports alphanumeric, underscore and hyphen (0-9 or a-z or A-Z, \_ or -) characters. Additionally, name should be limited from 3 to 128 character length for the assignment to VM/VMSS to work properly. For more information, see [FAQs and known issues](#)

```
New-AzUserAssignedIdentity -ResourceGroupName <RESOURCEGROUP> -Name <USER ASSIGNED IDENTITY NAME>
```

2. Retrieve the VM properties using the `Get-AzVM` cmdlet. Then to assign a user-assigned managed identity to the Azure VM, use the `-IdentityType` and `-IdentityID` switch on the `Update-AzVM` cmdlet. The value for the `-IdentityId` parameter is the `Id` you noted in the previous step. Replace `<VM NAME>`, `<SUBSCRIPTION ID>`, `<RESOURCE GROUP>`, and `<USER ASSIGNED IDENTITY NAME>` with your own values.

### WARNING

To retain any previously user-assigned managed identities assigned to the VM, query the `Identity` property of the VM object (for example, `$vm.Identity`). If any user assigned managed identities are returned, include them in the following command along with the new user assigned managed identity you would like to assign to the VM.

```
$vm = Get-AzVM -ResourceGroupName <RESOURCE GROUP> -Name <VM NAME>
Update-AzVM -ResourceGroupName <RESOURCE GROUP> -VM $vm -IdentityType UserAssigned -IdentityID
"/subscriptions/<SUBSCRIPTION ID>/resourcegroups/<RESROUCE
GROUP>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<USER ASSIGNED IDENTITY NAME>"
```

## Remove a user-assigned managed identity from an Azure VM

To remove a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) role assignment.

If your VM has multiple user-assigned managed identities, you can remove all but the last one using the following commands. Be sure to replace the `<RESOURCE GROUP>` and `<VM NAME>` parameter values with your own values. The `<USER ASSIGNED IDENTITY NAME>` is the user-assigned managed identity's name property, which should remain on the VM. This information can be found by querying the `Identity` property of the VM object. For example, `$vm.Identity`:

```
$vm = Get-AzVm -ResourceGroupName myResourceGroup -Name myVm
Update-AzVm -ResourceGroupName myResourceGroup -VirtualMachine $vm -IdentityType UserAssigned -IdentityID
<USER ASSIGNED IDENTITY NAME>
```

If your VM doesn't have a system-assigned managed identity and you want to remove all user-assigned managed identities from it, use the following command:

```
$vm = Get-AzVm -ResourceGroupName myResourceGroup -Name myVm
Update-AzVm -ResourceGroupName myResourceGroup -VM $vm -IdentityType None
```

If your VM has both system-assigned and user-assigned managed identities, you can remove all the user-assigned managed identities by switching to use only system-assigned managed identities.

```
$vm = Get-AzVm -ResourceGroupName myResourceGroup -Name myVm
Update-AzVm -ResourceGroupName myResourceGroup -VirtualMachine $vm -IdentityType "SystemAssigned"
```

## Next steps

  - [Create a Windows virtual machine with PowerShell](#)
  - [Create a Linux virtual machine with PowerShell](#)

# Configure managed identities for Azure resources on an Azure VM using templates

9/21/2022 • 6 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provide Azure services with an automatically managed identity in Azure Active Directory. You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, using the Azure Resource Manager deployment template, you learn how to perform the following managed identities for Azure resources operations on an Azure VM:

## Prerequisites

- If you're unfamiliar with using Azure Resource Manager deployment template, check out the [overview section](#). Be sure to review the [difference between a system-assigned and user-assigned managed identity](#).
- If you don't already have an Azure account, [sign up for a free account](#) before continuing.

## Azure Resource Manager templates

As with the Azure portal and scripting, [Azure Resource Manager](#) templates allow you to deploy new or modified resources defined by an Azure resource group. Several options are available for template editing and deployment, both local and portal-based, including:

- Using a [custom template from the Azure Marketplace](#), which allows you to create a template from scratch, or base it on an existing common or [quickstart template](#).
- Deriving from an existing resource group, by exporting a template from either [the original deployment](#), or from the [current state of the deployment](#).
- Using a local [JSON editor](#) (such as VS Code), and then uploading and deploying by using PowerShell or CLI.
- Using the Visual Studio [Azure Resource Group project](#) to both create and deploy a template.

Regardless of the option you choose, template syntax is the same during initial deployment and redeployment. Enabling a system or user-assigned managed identity on a new or existing VM is done in the same manner. Also, by default, Azure Resource Manager does an [incremental update](#) to deployments.

## System-assigned managed identity

In this section, you will enable and disable a system-assigned managed identity using an Azure Resource Manager template.

### **Enable system-assigned managed identity during creation of an Azure VM or on an existing VM**

To enable system-assigned managed identity on a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Whether you sign in to Azure locally or via the Azure portal, use an account that is associated with the Azure subscription that contains the VM.

2. To enable system-assigned managed identity, load the template into an editor, locate the `Microsoft.Compute/virtualMachines` resource of interest within the `resources` section and add the `"identity"` property at the same level as the `"type": "Microsoft.Compute/virtualMachines"` property. Use the following syntax:

```
"identity": {  
    "type": "SystemAssigned"  
},
```

3. When you're done, the following sections should be added to the `resource` section of your template and it should resemble the following:

```
"resources": [  
    {  
        //other resource provider properties...  
        "apiVersion": "2018-06-01",  
        "type": "Microsoft.Compute/virtualMachines",  
        "name": "[variables('vmName')]",  
        "location": "[resourceGroup().location]",  
        "identity": {  
            "type": "SystemAssigned",  
        }  
    }  
]
```

## Assign a role the VM's system-assigned managed identity

After you enable a system-assigned managed identity on your VM, you may want to grant it a role such as **Reader** access to the resource group in which it was created. You can find detailed information to help you with this step in the [Assign Azure roles using Azure Resource Manager templates](#) article.

## Disable a system-assigned managed identity from an Azure VM

To remove system-assigned managed identity from a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Whether you sign in to Azure locally or via the Azure portal, use an account that is associated with the Azure subscription that contains the VM.
2. Load the template into an [editor](#) and locate the `Microsoft.Compute/virtualMachines` resource of interest within the `resources` section. If you have a VM that only has system-assigned managed identity, you can disable it by changing the identity type to `None`.

### Microsoft.Compute/virtualMachines API version 2018-06-01

If your VM has both system and user-assigned managed identities, remove `SystemAssigned` from the identity type and keep `UserAssigned` along with the `userAssignedIdentities` dictionary values.

### Microsoft.Compute/virtualMachines API version 2018-06-01

If your `apiVersion` is `2017-12-01` and your VM has both system and user-assigned managed identities, remove `SystemAssigned` from the identity type and keep `UserAssigned` along with the `identityIds` array of the user-assigned managed identities.

The following example shows you how to remove a system-assigned managed identity from a VM with no user-assigned managed identities:

```
{  
    "apiVersion": "2018-06-01",  
    "type": "Microsoft.Compute/virtualMachines",  
    "name": "[parameters('vmName')]",  
    "location": "[resourceGroup().location]",  
    "identity": {  
        "type": "None"  
    }  
}
```

## User-assigned managed identity

In this section, you assign a user-assigned managed identity to an Azure VM using Azure Resource Manager template.

### NOTE

To create a user-assigned managed identity using an Azure Resource Manager Template, see [Create a user-assigned managed identity](#).

### Assign a user-assigned managed identity to an Azure VM

To assign a user-assigned identity to a VM, your account needs the [Managed Identity Operator](#) role assignment. No other Azure AD directory role assignments are required.

- Under the `resources` element, add the following entry to assign a user-assigned managed identity to your VM. Be sure to replace `<USERASSIGNEDIDENTITY>` with the name of the user-assigned managed identity you created.

#### Microsoft.Compute/virtualMachines API version 2018-06-01

If your `apiVersion` is `2018-06-01`, your user-assigned managed identities are stored in the `userAssignedIdentities` dictionary format and the `<USERASSIGNEDIDENTITYNAME>` value must be stored in a variable defined in the `variables` section of your template.

```
{  
    "apiVersion": "2018-06-01",  
    "type": "Microsoft.Compute/virtualMachines",  
    "name": "[variables('vmName')]",  
    "location": "[resourceGroup().location]",  
    "identity": {  
        "type": "userAssigned",  
        "userAssignedIdentities": {  
            "  
[resourceID('Microsoft.ManagedIdentity/userAssignedIdentities/',variables('<USERASSIGNEDIDENTITYNAME>  
''))]": {}  
        }  
    }  
}
```

#### Microsoft.Compute/virtualMachines API version 2017-12-01

If your `apiVersion` is `2017-12-01`, your user-assigned managed identities are stored in the `identityIds` array and the `<USERASSIGNEDIDENTITYNAME>` value must be stored in a variable defined in the `variables` section of your template.

```
{
    "apiVersion": "2017-12-01",
    "type": "Microsoft.Compute/virtualMachines",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "identity": {
        "type": "userAssigned",
        "identityIds": [
            ""
        ]
    }
}
```

2. When you're done, the following sections should be added to the `resource` section of your template and it should resemble the following:

#### **Microsoft.Compute/virtualMachines API version 2018-06-01**

```
"resources": [
{
    //other resource provider properties...
    "apiVersion": "2018-06-01",
    "type": "Microsoft.Compute/virtualMachines",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "identity": {
        "type": "userAssigned",
        "userAssignedIdentities": {
            ""
        }
    }
}
]
```

#### **Microsoft.Compute/virtualMachines API version 2017-12-01**

```
"resources": [
{
    //other resource provider properties...
    "apiVersion": "2017-12-01",
    "type": "Microsoft.Compute/virtualMachines",
    "name": "[variables('vmName')]",
    "location": "[resourceGroup().location]",
    "identity": {
        "type": "userAssigned",
        "identityIds": [
            ""
        ]
    }
}
]
```

### **Remove a user-assigned managed identity from an Azure VM**

To remove a user-assigned identity from a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Whether you sign in to Azure locally or via the Azure portal, use an account that is associated with the Azure subscription that contains the VM.
2. Load the template into an [editor](#) and locate the `Microsoft.Compute/virtualMachines` resource of interest within the `resources` section. If you have a VM that only has user-assigned managed identity, you can disable it by changing the identity type to `None`.

The following example shows you how to remove all user-assigned managed identities from a VM with no system-assigned managed identities:

```
{  
    "apiVersion": "2018-06-01",  
    "type": "Microsoft.Compute/virtualMachines",  
    "name": "[parameters('vmName')]",  
    "location": "[resourceGroup().location]",  
    "identity": {  
        "type": "None"  
    },  
}
```

#### **Microsoft.Compute/virtualMachines API version 2018-06-01**

To remove a single user-assigned managed identity from a VM, remove it from the `userAssignedIdentities` dictionary.

If you have a system-assigned managed identity, keep it in the `type` value under the `identity` value.

#### **Microsoft.Compute/virtualMachines API version 2017-12-01**

To remove a single user-assigned managed identity from a VM, remove it from the `identityIds` array.

If you have a system-assigned managed identity, keep it in the `type` value under the `identity` value.

## Next steps

- [Managed identities for Azure resources overview](#).

# Configure Managed identities for Azure resources on an Azure VM using REST API calls

9/21/2022 • 14 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provide Azure services with an automatically managed system identity in Azure Active Directory. You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, using CURL to make calls to the Azure Resource Manager REST endpoint, you learn how to perform the following managed identities for Azure resources operations on an Azure VM:

- Enable and disable the system-assigned managed identity on an Azure VM
- Add and remove a user-assigned managed identity on an Azure VM

If you don't already have an Azure account, [sign up for a free account](#) before continuing.

## Prerequisites

- If you're unfamiliar with managed identities for Azure resources, see [What are managed identities for Azure resources?](#). To learn about system-assigned and user-assigned managed identity types, see [Managed identity types](#).

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## System-assigned managed identity

In this section, you learn how to enable and disable system-assigned managed identity on an Azure VM using CURL to make calls to the Azure Resource Manager REST endpoint.

### **Enable system-assigned managed identity during creation of an Azure VM**

To create an Azure VM with the system-assigned managed identity enabled, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Create a [resource group](#) for containment and deployment of your VM and its related resources, using [az group create](#). You can skip this step if you already have resource group you would like to use instead:

```
az group create --name myResourceGroup --location westus
```

2. Create a [network interface](#) for your VM:

```
az network nic create -g myResourceGroup --vnet-name myVnet --subnet mySubnet -n myNic
```

3. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

4. Using Azure Cloud Shell, create a VM using CURL to call the Azure Resource Manager REST endpoint. The following example creates a VM named *myVM* with a system-assigned managed identity, as identified in the request body by the value `"identity": {"type": "SystemAssigned"}`. Replace `<ACCESS TOKEN>` with the value you received in the previous step when you requested a Bearer access token and the `<SUBSCRIPTION ID>` value as appropriate for your environment.

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01' -X PUT -d '{"location": "westus", "name": "myVM", "identity": {"type": "SystemAssigned"}, "properties": {"hardwareProfile": {"vmSize": "Standard_D2_v2"}, "storageProfile": {"imageReference": {"sku": "2016-Datacenter", "publisher": "MicrosoftWindowsServer", "version": "latest", "offer": "WindowsServer"}, "osDisk": {"caching": "ReadWrite", "managedDisk": {"storageAccountType": "StandardSSD_LRS"}, "name": "myVM3osdisk", "createOption": "FromImage"}, "dataDisks": [{"diskSizeGB": 1023, "createOption": "Empty", "lun": 0}, {"diskSizeGB": 1023, "createOption": "Empty", "lun": 1}], "osProfile": {"adminUsername": "azureuser", "computerName": "myVM", "adminPassword": "<SECURE PASSWORD STRING>"}, "networkProfile": {"networkInterfaces": [{"id": "/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myNic", "properties": {"primary": true}}]} }' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PUT https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "location": "westus",
  "name": "myVM",
  "identity": {
    "type": "SystemAssigned"
  },
  "properties": {
    "hardwareProfile": {
      "vmSize": "Standard_D2_v2"
    },
    "storageProfile": {
      "imageReference": {
        "sku": "2016-Datacenter",
        "publisher": "MicrosoftWindowsServer",
        "version": "latest",
        "offer": "WindowsServer"
      },
      "osDisk": {
        "caching": "ReadWrite",
        "managedDisk": {
          "storageAccountType": "StandardSSD_LRS"
        },
        "name": "myVM3osdisk",
        "createOption": "FromImage"
      },
      "dataDisks": [
        {
          "lun": 0,
          "createOption": "Empty",
          "diskSizeGB": 1023
        },
        {
          "lun": 1,
          "createOption": "Empty",
          "diskSizeGB": 1023
        }
      ]
    },
    "osProfile": {
      "adminUsername": "azureuser",
      "computerName": "myVM",
      "adminPassword": "myPassword12"
    },
    "networkProfile": {
      "networkInterfaces": [
        {
          "id": "/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myNic",
          "properties": {
            "primary": true
          }
        }
      ]
    }
  }
}
```

## Enable system-assigned identity on an existing Azure VM

To enable system-assigned managed identity on a VM that was originally provisioned without it, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

2. Use the following CURL command to call the Azure Resource Manager REST endpoint to enable system-assigned managed identity on your VM as identified in the request body by the value

`{"identity": {"type": "SystemAssigned"}}` for a VM named *myVM*. Replace `<ACCESS TOKEN>` with the value you received in the previous step when you requested a Bearer access token and the `<SUBSCRIPTION ID>` value as appropriate for your environment.

#### IMPORTANT

To ensure you don't delete any existing user-assigned managed identities that are assigned to the VM, you need to list the user-assigned managed identities by using this CURL command:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01' -H "Authorization: Bearer <ACCESS TOKEN>"
```

If you have any user-assigned managed identities assigned to the VM as identified in the `identity` value in the response, skip to step 3 that shows you how to retain user-assigned managed identities while enabling system-assigned managed identity on your VM.

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01' -X PATCH -d '{"identity": {"type": "SystemAssigned" }}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01 HTTP/1.1
```

#### Request headers

REQUEST HEADER	DESCRIPTION
<code>Content-Type</code>	Required. Set to <code>application/json</code> .
<code>Authorization</code>	Required. Set to a valid <code>Bearer</code> access token.

#### Request body

```
{  
  "identity": {  
    "type": "SystemAssigned"  
  }  
}
```

3. To enable system-assigned managed identity on a VM with existing user-assigned managed identities, you need to add `SystemAssigned` to the `type` value.

For example, if your VM has the user-assigned managed identities `ID1` and `ID2` assigned to it, and you would like to add system-assigned managed identity to the VM, use the following CURL call. Replace `<ACCESS TOKEN>` and `<SUBSCRIPTION ID>` with values appropriate to your environment.

API version `2018-06-01` stores user-assigned managed identities in the `userAssignedIdentities` value in a dictionary format as opposed to the `identityIds` value in an array format used in API version

2017-12-01 .

## API VERSION 2018-06-01

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01' -X PATCH -d '{"identity": {"type": "SystemAssigned, UserAssigned", "userAssignedIdentities": [
{}], "/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1": [
{}], "/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2": [
{}]} }' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01 HTTP/1.1
```

### Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

### Request body

```
{
  "identity": {
    "type": "SystemAssigned, UserAssigned",
    "userAssignedIdentities": [
      "/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1": {

      },
      "/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2": {

      }
    ]
  }
}
```

## API VERSION 2017-12-01

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01' -X PATCH -d '{"identity": {"type": "SystemAssigned, UserAssigned", "identityIds": [
"/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1", "/subscriptions/<>SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2"]}}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{  
    "identity":{  
        "type":"SystemAssigned, UserAssigned",  
        "identityIds": [  
            "/subscriptions/<>SUBSCRIPTION  
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1",  
            "/subscriptions/<>SUBSCRIPTION  
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2"  
        ]  
    }  
}
```

## Disable system-assigned managed identity from an Azure VM

To disable system-assigned managed identity on a VM, your account needs the [Virtual Machine Contributor](#) role assignment. No other Azure AD directory role assignments are required.

1. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

2. Update the VM using CURL to call the Azure Resource Manager REST endpoint to disable system-assigned managed identity. The following example disables system-assigned managed identity as identified in the request body by the value `{"identity":{"type":"None"}}` from a VM named *myVM*. Replace `<ACCESS TOKEN>` with the value you received in the previous step when you requested a Bearer access token and the `<SUBSCRIPTION ID>` value as appropriate for your environment.

### IMPORTANT

To ensure you don't delete any existing user-assigned managed identities that are assigned to the VM, you need to list the user-assigned managed identities by using this CURL command:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE  
GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01' -H  
"Authorization: Bearer <ACCESS TOKEN>"
```

- If you have any user-assigned managed identities assigned to the VM as identified in the `identity` value in the response, skip to step 3 that shows you how to retain user-assigned managed identities while disabling system-assigned managed identity on your VM.

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION  
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-  
06-01' -X PATCH -d '{"identity":{"type":"None"}}' -H "Content-Type: application/json" -H  
"Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{  
    "identity":{  
        "type":"None"  
    }  
}
```

To remove system-assigned managed identity from a virtual machine that has user-assigned managed identities, remove `SystemAssigned` from the `{"identity": {"type: " "}}` value while keeping the `UserAssigned` value and the `userAssignedIdentities` dictionary values if you are using API version `2018-06-01`. If you are using API version `2017-12-01` or earlier, keep the `identityIds` array.

## User-assigned managed identity

In this section, you learn how to add and remove user-assigned managed identity on an Azure VM using CURL to make calls to the Azure Resource Manager REST endpoint.

### Assign a user-assigned managed identity during the creation of an Azure VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

2. Create a [network interface](#) for your VM:

```
az network nic create -g myResourceGroup --vnet-name myVnet --subnet mySubnet -n myNic
```

3. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

4. Create a user-assigned managed identity using the instructions found here: [Create a user-assigned managed identity](#).

5. Create a VM using CURL to call the Azure Resource Manager REST endpoint. The following example

creates a VM named *myVM* in the resource group *myResourceGroup* with a user-assigned managed identity `ID1`, as identified in the request body by the value `"identity": {"type": "UserAssigned"}`. Replace `<ACCESS TOKEN>` with the value you received in the previous step when you requested a Bearer access token and the `<SUBSCRIPTION ID>` value as appropriate for your environment.

## API VERSION 2018-06-01

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01' -X PUT -d '{"location": "westus", "name": "myVM", "identity": {"type": "UserAssigned", "identityIds": [
"/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1"]}, "properties": {"hardwareProfile": {"vmSize": "Standard_D2_v2"}, "storageProfile": {"imageReference": {"sku": "2016-
Datacenter", "publisher": "MicrosoftWindowsServer", "version": "latest", "offer": "WindowsServer"}, "osDisk": {"caching": "ReadWrite", "managedDisk": {"storageAccountType": "StandardSSD_LRS"}, "name": "myVM3osdisk", "createOption": "FromImage"}, "dataDisks": [{"diskSizeGB": 1023, "createOption": "Empty", "lun": 0}, {"diskSizeGB": 1023, "createOption": "Empty", "lun": 1}], "osProfile": {"adminUsername": "azureuser", "computerName": "myVM", "adminPassword": "myPassword12"}, "networkProfile": {"networkInterfaces": [{"id": "/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/myNic", "properties": {"primary": true}}]}]]}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PUT https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01 HTTP/1.1
```

### Request headers

REQUEST HEADER	DESCRIPTION
<code>Content-Type</code>	Required. Set to <code>application/json</code> .
<code>Authorization</code>	Required. Set to a valid <code>Bearer</code> access token.

### Request body

```
{
  "location": "westus",
  "name": "myVM",
  "identity": {
    "type": "UserAssigned",
    "identityIds": [
      "/subscriptions/<SUBSCRIPTION

          }
        }
      ]
    }
  }
}
```

## Assign a user-assigned managed identity to an existing Azure VM

To assign a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) and [Managed Identity Operator](#) role assignments. No other Azure AD directory role assignments are required.

1. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

2. Create a user-assigned managed identity using the instructions found here, [Create a user-assigned managed identity](#).
3. To ensure you don't delete existing user or system-assigned managed identities that are assigned to the VM, you need to list the identity types assigned to the VM by using the following CURL command. If you have managed identities assigned to the virtual machine scale set, they are listed under in the `identity` value.

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01' -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
GET https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<code>Authorization</code>	Required. Set to a valid <code>Bearer</code> access token.

If you have any user or system-assigned managed identities assigned to the VM as identified in the `identity` value in the response, skip to step 5 that shows you how to retain the system-assigned managed identity while adding a user-assigned managed identity on your VM.

4. If you don't have any user-assigned managed identities assigned to your VM, use the following CURL command to call the Azure Resource Manager REST endpoint to assign the first user-assigned managed identity to the VM.

The following example assigns a user-assigned managed identity, `ID1` to a VM named `myVM` in the resource group `myResourceGroup`. Replace `<ACCESS TOKEN>` with the value you received in the previous step when you requested a Bearer access token and the `<SUBSCRIPTION ID>` value as appropriate for your environment.

## API VERSION 2018-06-01

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01' -X PATCH -d '{"identity":{"type":"UserAssigned", "userAssignedIdentities": [{""/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1": {}}}}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity":{
    "type":"UserAssigned",
    "userAssignedIdentities":{
      "/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1":{

        }
      }
    }
}
```

API VERSION 2017-12-01

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01' -X PATCH -d '{"identity":{"type":"userAssigned", "identityIds":["/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1"]}}'
  -H "Content-Type: application/json" -H "Authorization:Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity":{
    "type":"userAssigned",
    "identityIds":[
      "/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1"
    ]
  }
}
```

5. If you have an existing user-assigned or system-assigned managed identity assigned to your VM:

API VERSION 2018-06-01

Add the user-assigned managed identity to the `userAssignedIdentities` dictionary value.

For example, if you have system-assigned managed identity and the user-assigned managed identity `ID1` currently assigned to your VM and would like to add the user-assigned managed identity `ID2` to it:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01' -X PATCH -d '{"identity":{"type":"SystemAssigned, UserAssigned", "userAssignedIdentities":"
"/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1":{},"/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2":{}}}}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-
06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<code>Content-Type</code>	Required. Set to <code>application/json</code> .
<code>Authorization</code>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity": {
    "type": "SystemAssigned, UserAssigned",
    "userAssignedIdentities": {
      "/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1": {

      },
      "/subscriptions/<SUBSCRIPTION
ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2": {

      }
    }
  }
}
```

## API VERSION 2017-12-01

Retain the user-assigned managed identities you would like to keep in the `identityIds` array value while adding the new user-assigned managed identity.

For example, if you have system-assigned managed identity and the user-assigned managed identity `ID1` currently assigned to your VM and would like to add the user-assigned managed identity `ID2` to it:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-12-01' -X PATCH -d '{"identity":{"type":"SystemAssigned,UserAssigned", "identityIds": ["/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1", "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2"]}}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-12-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity":{
    "type":"SystemAssigned,UserAssigned",
    "identityIds":[
      "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1",
      "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2"
    ]
  }
}
```

## Remove a user-assigned managed identity from an Azure VM

To remove a user-assigned identity to a VM, your account needs the [Virtual Machine Contributor](#) role assignment.

1. Retrieve a Bearer access token, which you will use in the next step in the Authorization header to create your VM with a system-assigned managed identity.

```
az account get-access-token
```

2. To ensure you don't delete any existing user-assigned managed identities that you would like to keep assigned to the VM or remove the system-assigned managed identity, you need to list the managed identities by using the following CURL command:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01' -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
GET https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/<RESOURCE GROUP>/providers/Microsoft.Compute/virtualMachines/<VM NAME>?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

If you have managed identities assigned to the VM, they are listed in the response in the `identity` value.

For example, if you have user-assigned managed identities `ID1` and `ID2` assigned to your VM, and you only want to keep `ID1` assigned and retain the system-assigned identity:

## API VERSION 2018-06-01

Add `null` to the user-assigned managed identity you would like to remove:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01' -X PATCH -d '{"identity": {"type": "SystemAssigned, UserAssigned", "userAssignedIdentities": {"/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2": null}}}' -H "Content-Type: application/json" -H "Authorization: Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity": {
    "type": "SystemAssigned, UserAssigned",
    "userAssignedIdentities": {
      "/subscriptions/<SUBSCRIPTION ID>/resourcegroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID2": null
    }
  }
}
```

## API VERSION 2017-12-01

Retain only the user-assigned managed identity(s) you would like to keep in the `identityIds` array:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01' -X PATCH -d '{"identity":{"type":"SystemAssigned, UserAssigned", "identityIds":
["/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1"]}}'
-H "Content-Type: application/json" -H "Authorization:Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2017-
12-01 HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{
  "identity":{
    "type":"SystemAssigned, UserAssigned",
    "identityIds":[
      "/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.ManagedIdentity/userAssignedIdentities/ID1"
    ]
  }
}
```

If your VM has both system-assigned and user-assigned managed identities, you can remove all the user-assigned managed identities by switching to use only system-assigned managed identity using the following command:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01'
-X PATCH -d '{"identity":{"type":"SystemAssigned"}}' -H "Content-Type: application/json" -H
"Authorization:Bearer <ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01
HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{  
  "identity":{  
    "type":"SystemAssigned"  
  }  
}
```

If your VM has only user-assigned managed identities and you would like to remove them all, use the following command:

```
curl 'https://management.azure.com/subscriptions/<SUBSCRIPTION  
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01'  
-X PATCH -d '{"identity":{"type":"None"}}' -H "Content-Type: application/json" -H Authorization:"Bearer  
<ACCESS TOKEN>"
```

```
PATCH https://management.azure.com/subscriptions/<SUBSCRIPTION  
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM?api-version=2018-06-01  
HTTP/1.1
```

## Request headers

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i>	Required. Set to <code>application/json</code> .
<i>Authorization</i>	Required. Set to a valid <code>Bearer</code> access token.

## Request body

```
{  
  "identity":{  
    "type":"None"  
  }  
}
```

## Next steps

For information on how to create, list, or delete user-assigned managed identities using REST see:

- [Create, list, or delete a user-assigned managed identities using REST API calls](#)

# Configure a VM with managed identities for Azure resources using an Azure SDK

9/21/2022 • 2 minutes to read • [Edit Online](#)

Managed identities for Azure resources is a feature of Azure Active Directory. Each of the [Azure services that support managed identities for Azure resources](#) are subject to their own timeline. Make sure you review the [availability](#) status of managed identities for your resource and [known issues](#) before you begin.

Managed identities for Azure resources provide Azure services with an automatically managed identity in Azure Active Directory (AD). You can use this identity to authenticate to any service that supports Azure AD authentication, without having credentials in your code.

In this article, you learn how to enable and remove managed identities for Azure resources for an Azure VM, using an Azure SDK.

## Prerequisites

- If you're not familiar with the managed identities for Azure resources feature, see this [overview](#). If you don't have an Azure account, [sign up for a free account](#) before you continue.

## Azure SDKs with managed identities for Azure resources support

Azure supports multiple programming platforms through a series of [Azure SDKs](#). Several of them have been updated to support managed identities for Azure resources, and provide corresponding samples to demonstrate usage. This list is updated as other support is added:

SDK	SAMPLE
.NET	<a href="#">Manage resource from a VM enabled with managed identities for Azure resources enabled</a>
Java	<a href="#">Manage storage from a VM enabled with managed identities for Azure resources</a>
Node.js	<a href="#">Create a VM with system-assigned managed identity enabled</a>
Python	<a href="#">Create a VM with system-assigned managed identity enabled</a>
Ruby	<a href="#">Create Azure VM with a system-assigned identity enabled</a>

## Next steps

- See related articles under [Configure Identity for an Azure VM](#), to learn how you can also use the Azure portal, PowerShell, CLI, and resource templates.

# Log in to a Linux virtual machine in Azure by using Azure AD and OpenSSH

9/21/2022 • 21 minutes to read • [Edit Online](#)

To improve the security of Linux virtual machines (VMs) in Azure, you can integrate with Azure Active Directory (Azure AD) authentication. You can now use Azure AD as a core authentication platform and a certificate authority to SSH into a Linux VM by using Azure AD and OpenSSH certificate-based authentication. This functionality allows organizations to manage access to VMs with Azure role-based access control (RBAC) and Conditional Access policies.

This article shows you how to create and configure a Linux VM and log in with Azure AD by using OpenSSH certificate-based authentication.

## IMPORTANT

This capability is now generally available. The previous version that made use of device code flow was [deprecated on August 15, 2021](#). To migrate from the old version to this version, see the section [Migrate from the previous \(preview\) version](#).

There are many security benefits of using Azure AD with OpenSSH certificate-based authentication to log in to Linux VMs in Azure. They include:

- Use your Azure AD credentials to log in to Azure Linux VMs.
- Get SSH key-based authentication without needing to distribute SSH keys to users or provision SSH public keys on any Azure Linux VMs that you deploy. This experience is much simpler than having to worry about sprawl of stale SSH public keys that could cause unauthorized access.
- Reduce reliance on local administrator accounts, credential theft, and weak credentials.
- Help secure Linux VMs by configuring password complexity and password lifetime policies for Azure AD.
- With RBAC, specify who can log in to a VM as a regular user or with administrator privileges. When users join your team, you can update the Azure RBAC policy for the VM to grant access as appropriate. When employees leave your organization and their user accounts are disabled or removed from Azure AD, they no longer have access to your resources.
- With Conditional Access, configure policies to require multifactor authentication or to require that your client device is managed (for example, compliant or hybrid Azure AD joined) before you can use it SSH into Linux VMs.
- Use Azure deploy and audit policies to require Azure AD login for Linux VMs and flag unapproved local accounts.

Login to Linux VMs with Azure Active Directory works for customers who use Active Directory Federation Services.

## Supported Linux distributions and Azure regions

The following Linux distributions are currently supported for deployments in a supported region:

DISTRIBUTION	VERSION
Common Base Linux Mariner (CBL-Mariner)	CBL-Mariner 1, CBL-Mariner 2

DISTRIBUTION	VERSION
CentOS	CentOS 7, CentOS 8
Debian	Debian 9, Debian 10, Debian 11
openSUSE	openSUSE Leap 42.3, openSUSE Leap 15.1+
RedHat Enterprise Linux (RHEL)	RHEL 7.4 to RHEL 7.10, RHEL 8.3+
SUSE Linux Enterprise Server (SLES)	SLES 12, SLES 15.1+
Ubuntu Server	Ubuntu Server 16.04 to Ubuntu Server 22.04

The following Azure regions are currently supported for this feature:

- Azure Global
- Azure Government
- Azure China 21Vianet

Use of the SSH extension for Azure CLI on Azure Kubernetes Service (AKS) clusters is not supported. For more information, see [Support policies for AKS](#).

If you choose to install and use the Azure CLI locally, it must be version 2.22.1 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install the Azure CLI](#).

#### NOTE

This functionality is also available for [Azure Arc-enabled servers](#).

## Meet requirements for login with Azure AD using OpenSSH certificate-based authentication

To enable Azure AD login through SSH certificate-based authentication for Linux VMs in Azure, be sure to meet the following network, virtual machine, and client (SSH client) requirements.

### Network

VM network configuration must permit outbound access to the following endpoints over TCP port 443.

Azure Global:

- `https://packages.microsoft.com` : For package installation and upgrades.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.com` : For PAM-based (pluggable authentication modules) authentication flows.
- `https://pas.windows.net` : For Azure RBAC flows.

Azure Government:

- `https://packages.microsoft.com` : For package installation and upgrades.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.us` : For PAM-based authentication flows.
- `https://pasff.usgovcloudapi.net` : For Azure RBAC flows.

Azure China 21Vianet:

- `https://packages.microsoft.com` : For package installation and upgrades.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.chinacloudapi.cn` : For PAM-based authentication flows.
- `https://pas.chinacloudapi.cn` : For Azure RBAC flows.

## Virtual machine

Ensure that your VM is configured with the following functionality:

- System-assigned managed identity. This option is automatically selected when you use the Azure portal to create VMs and select the Azure AD login option. You can also enable system-assigned managed identity on a new or existing VM by using the Azure CLI.
- `aadsshlogin` and `aadsshlogin-selinux` (as appropriate). These packages are installed with the `AADSSHLoginForLinux` VM extension. The extension is installed when you use the Azure portal or the Azure CLI to create VMs and enable Azure AD login (**Management** tab).

## Client

Ensure that your client meets the following requirements:

- SSH client support for OpenSSH-based certificates for authentication. You can use Azure CLI (2.21.1 or later) with OpenSSH (included in Windows 10 version 1803 or later) or Azure Cloud Shell to meet this requirement.
- SSH extension for Azure CLI. You can install this extension by using `az extension add --name ssh`. You don't need to install this extension when you're using Azure Cloud Shell, because it comes preinstalled.

If you're using any SSH client other than the Azure CLI or Azure Cloud Shell that supports OpenSSH certificates, you'll still need to use the Azure CLI with the SSH extension to retrieve ephemeral SSH certificates and optionally a configuration file. You can then use the configuration file with your SSH client.

- TCP connectivity from the client to either the public or private IP address of the VM. (ProxyCommand or SSH forwarding to a machine with connectivity also works.)

### IMPORTANT

SSH clients based on PuTTY don't support OpenSSH certificates and can't be used to log in with Azure AD OpenSSH certificate-based authentication.

## Enable Azure AD login for a Linux VM in Azure

To use Azure AD login for a Linux VM in Azure, you need to first enable the Azure AD login option for your Linux VM. You then configure Azure role assignments for users who are authorized to log in to the VM. Finally, you use the SSH client that supports OpenSSH, such as the Azure CLI or Azure Cloud Shell, to SSH into your Linux VM.

There are two ways to enable Azure AD login for your Linux VM:

- The Azure portal experience when you're creating a Linux VM
- The Azure Cloud Shell experience when you're creating a Linux VM or using an existing one

### Azure portal

You can enable Azure AD login for any of the [supported Linux distributions](#) by using the Azure portal.

For example, to create an Ubuntu Server 18.04 Long Term Support (LTS) VM in Azure with Azure AD login:

1. Sign in to the Azure portal by using an account that has access to create VMs, and then select + **Create a**

resource.

2. Select **Create** under **Ubuntu Server 18.04 LTS** in the **Popular** view.
3. On the **Management** tab:
  - a. Select the **Login with Azure Active Directory** checkbox.
  - b. Ensure that the **System assigned managed identity** checkbox is selected.
4. Go through the rest of the experience of creating a virtual machine. You'll have to create an administrator account with username and password or SSH public key.

## Azure Cloud Shell

Azure Cloud Shell is a free, interactive shell that you can use to run the steps in this article. Common Azure tools are preinstalled and configured in Cloud Shell for you to use with your account. Just select the **Copy** button to copy the code, paste it in Cloud Shell, and then select the **Enter** key to run it.

There are a few ways to open Cloud Shell:

- Select **Try It** in the upper-right corner of a code block.
- Open Cloud Shell in your browser.
- Select the Cloud Shell button on the menu in the upper-right corner of the Azure portal.

If you choose to install and use the Azure CLI locally, this article requires you to use version 2.22.1 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install the Azure CLI](#).

1. Create a resource group by running [az group create](#).
2. Create a VM by running [az vm create](#). Use a supported distribution in a supported region.
3. Install the Azure AD login VM extension by using [az vm extension set](#).

The following example deploys a VM and then installs the extension to enable Azure AD login for a Linux VM. VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure virtual machines. Customize the example as needed to support your testing requirements.

```
az group create --name AzureADLinuxVM --location southcentralus
az vm create \
    --resource-group AzureADLinuxVM \
    --name myVM \
    --image UbuntuLTS \
    --assign-identity \
    --admin-username azureuser \
    --generate-ssh-keys
az vm extension set \
    --publisher Microsoft.Azure.ActiveDirectory \
    --name AADSSHLoginForLinux \
    --resource-group AzureADLinuxVM \
    --vm-name myVM
```

It takes a few minutes to create the VM and supporting resources.

The AADSSHLoginForLinux extension can be installed on an existing (supported distribution) Linux VM with a running VM agent to enable Azure AD authentication. If you're deploying this extension to a previously created VM, the VM must have at least 1 GB of memory allocated or the installation will fail.

The `provisioningState` value of `Succeeded` appears when the extension is successfully installed on the VM. The VM must have a running [VM agent](#) to install the extension.

## Configure role assignments for the VM

Now that you've created the VM, you need to configure an Azure RBAC policy to determine who can log in to the VM. Two Azure roles are used to authorize VM login:

- **Virtual Machine Administrator Login:** Users who have this role assigned can log in to an Azure virtual machine with administrator privileges.
- **Virtual Machine User Login:** Users who have this role assigned can log in to an Azure virtual machine with regular user privileges.

To allow a user to log in to a VM over SSH, you must assign the Virtual Machine Administrator Login or Virtual Machine User Login role on the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resources.

An Azure user who has the Owner or Contributor role assigned for a VM doesn't automatically have privileges to Azure AD login to the VM over SSH. There's an intentional (and audited) separation between the set of people who control virtual machines and the set of people who can access virtual machines.

There are two ways to configure role assignments for a VM:

- Azure AD portal experience
- Azure Cloud Shell experience

#### NOTE

The Virtual Machine Administrator Login and Virtual Machine User Login roles use `dataActions` and can be assigned at the management group, subscription, resource group, or resource scope. We recommend that you assign the roles at the management group, subscription, or resource level and not at the individual VM level. This practice avoids the risk of reaching the [Azure role assignments limit](#) per subscription.

## Azure AD portal

To configure role assignments for your Azure AD-enabled Linux VMs:

1. For **Resource Group**, select the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resource.
2. Select **Access control (IAM)**.
3. Select **Add > Add role assignment** to open the **Add role assignment** page.
4. Assign the following role. For detailed steps, see [Assign Azure roles by using the Azure portal](#).

SETTING	VALUE
Role	Virtual Machine Administrator Login or Virtual Machine User Login
Assign access to	User, group, service principal, or managed identity

A role definition is a collection of permissions. You can use the built-in roles or you can create your own custom roles. [Learn more](#)

Name ↑↓	Description ↑↓	Type ↑↓	Category ↑↓	Details
Owner	Grants full access to manage all resources, including the ability to a...	BuiltinRole	General	<a href="#">View</a>
Contributor	Grants full access to manage all resources, but does not allow you ...	BuiltinRole	General	<a href="#">View</a>
Reader	View all resources, but does not allow you to make any changes.	BuiltinRole	General	<a href="#">View</a>
AcrDelete	acr delete	BuiltinRole	Containers	<a href="#">View</a>
AcrImageSigner	acr image signer	BuiltinRole	Containers	<a href="#">View</a>
AcrPull	acr pull	BuiltinRole	Containers	<a href="#">View</a>
AcrPush	acr push	BuiltinRole	Containers	<a href="#">View</a>
AcrQuarantineReader	acr quarantine data reader	BuiltinRole	Containers	<a href="#">View</a>
AcrQuarantineWriter	acr quarantine data writer	BuiltinRole	Containers	<a href="#">View</a>

After a few moments, the security principal is assigned the role at the selected scope.

## Azure Cloud Shell

The following example uses `az role assignment create` to assign the Virtual Machine Administrator Login role to the VM for your current Azure user. You obtain the username of your current Azure account by using `az account show`, and you set the scope to the VM created in a previous step by using `az vm show`.

You can also assign the scope at a resource group or subscription level. Normal Azure RBAC inheritance permissions apply.

```
username=$(az account show --query user.name --output tsv)
rg=$(az group show --resource-group myResourceGroup --query id -o tsv)

az role assignment create \
    --role "Virtual Machine Administrator Login" \
    --assignee $username \
    --scope $rg
```

### NOTE

If your Azure AD domain and login username domain don't match, you must specify the object ID of your user account by using `--assignee-object-id`, not just the username for `--assignee`. You can obtain the object ID for your user account by using `az ad user list`.

For more information on how to use Azure RBAC to manage access to your Azure subscription resources, see [Steps to assign an Azure role](#).

## Install the SSH extension for Azure CLI

If you're using Azure Cloud Shell, no other setup is needed because both the minimum required version of the Azure CLI and the SSH extension for Azure CLI are already included in the Cloud Shell environment.

Run the following command to add the SSH extension for Azure CLI:

```
az extension add --name ssh
```

The minimum version required for the extension is 0.1.4. Check the installed version by using the following command:

```
az extension show --name ssh
```

## Enforce Conditional Access policies

You can enforce Conditional Access policies that are enabled with Azure AD login, such as:

- Requiring multifactor authentication.
- Requiring a compliant or hybrid Azure AD-joined device for the device running the SSH client.
- Checking for risks before authorizing access to Linux VMs in Azure.

The application that appears in the Conditional Access policy is called *Azure Linux VM Sign-In*.

### NOTE

Conditional Access policy enforcement that requires device compliance or hybrid Azure AD join on the device that's running the SSH client works only with the Azure CLI that's running on Windows and macOS. It's not supported when you're using the Azure CLI on Linux or Azure Cloud Shell.

### Missing application

If the Azure Linux VM Sign-In application is missing from Conditional Access, make sure the application isn't in the tenant:

1. Sign in to the Azure portal.
2. Browse to **Azure Active Directory > Enterprise applications**.
3. Remove the filters to see all applications, and search for **VM**. If you don't see Azure Linux VM Sign-In as a result, the service principal is missing from the tenant.

Another way to verify it is via Graph PowerShell:

1. [Install the Graph PowerShell SDK](#) if you haven't already done so.
2. Enter the command  

```
Connect-MgGraph -Scopes "ServicePrincipalEndpoint.ReadWrite.All","Application.ReadWrite.All"
```
3. Sign in with a Global Admin account.
4. Consent to the prompt that asks for your permission.
5. Enter the command  

```
Get-MgServicePrincipal -ConsistencyLevel eventual -Search '"DisplayName:Azure Linux VM Sign-In"'
```

If this command results in no output and returns you to the PowerShell prompt, you can create the service principal by using the following Graph PowerShell command:

```
New-MgServicePrincipal -AppId ce6ff14a-7fdc-4685-bbe0-f6afdfcfa8e0
```

Successful output will show that the app ID and the application name Azure Linux VM Sign-In were created.

6. Sign out of Graph PowerShell by using the following command: `Disconnect-MgGraph`.

# Log in by using an Azure AD user account to SSH into the Linux VM

## Log in by using the Azure CLI

Enter `az login`. This command opens a browser window, where you can sign in by using your Azure AD account.

```
az login
```

Then enter `az ssh vm`. The following example automatically resolves the appropriate IP address for the VM.

```
az ssh vm -n myVM -g AzureADLinuxVM
```

If you're prompted, enter your Azure AD login credentials at the login page, perform multifactor authentication, and/or satisfy device checks. You'll be prompted only if your Azure CLI session doesn't already meet any required Conditional Access criteria. Close the browser window, return to the SSH prompt, and you'll be automatically connected to the VM.

You're now signed in to the Linux virtual machine with the role permissions as assigned, such as VM User or VM Administrator. If your user account is assigned the Virtual Machine Administrator Login role, you can use sudo to run commands that require root privileges.

## Log in by using Azure Cloud Shell

You can use Azure Cloud Shell to connect to VMs without needing to install anything locally to your client machine. Start Cloud Shell by selecting the shell icon in the upper-right corner of the Azure portal.

Cloud Shell automatically connects to a session in the context of the signed-in user. Now run `az login` again and go through the interactive sign-in flow:

```
az login
```

Then you can use the normal `az ssh vm` commands to connect by using the name and resource group or IP address of the VM:

```
az ssh vm -n myVM -g AzureADLinuxVM
```

### NOTE

Conditional Access policy enforcement that requires device compliance or hybrid Azure AD join is not supported when you're using Azure Cloud Shell.

# Log in by using the Azure AD service principal to SSH into the Linux VM

The Azure CLI supports authenticating with a service principal instead of a user account. Because service principals aren't tied to any particular user, customers can use them to SSH into a VM to support any automation scenarios they might have. The service principal must have VM Administrator or VM User rights assigned. Assign permissions at the subscription or resource group level.

The following example will assign VM Administrator rights to the service principal at the resource group level. Replace the placeholders for service principal object ID, subscription ID, and resource group name.

```
az role assignment create \
--role "Virtual Machine Administrator Login" \
--assignee-object-id <service-principal-objectid> \
--assignee-principal-type ServicePrincipal \
--scope "/subscriptions/<subscription-id>/resourceGroups/<resourcegroup-name>"
```

Use the following example to authenticate to the Azure CLI by using the service principal. For more information, see the article [Sign in to the Azure CLI with a service principal](#).

```
az login --service-principal -u <sp-app-id> -p <password-or-cert> --tenant <tenant-id>
```

When authentication with a service principal is complete, use the normal Azure CLI SSH commands to connect to the VM:

```
az ssh vm -n myVM -g AzureADLinuxVM
```

## Export the SSH configuration for use with SSH clients that support OpenSSH

Login to Azure Linux VMs with Azure AD supports exporting the OpenSSH certificate and configuration. That means you can use any SSH clients that support OpenSSH-based certificates to sign in through Azure AD. The following example exports the configuration for all IP addresses assigned to the VM:

```
az ssh config --file ~/.ssh/config -n myVM -g AzureADLinuxVM
```

Alternatively, you can export the configuration by specifying just the IP address. Replace the IP address in the following example with the public or private IP address for your VM. (You must bring your own connectivity for private IPs.) Enter `az ssh config -h` for help with this command.

```
az ssh config --file ~/.ssh/config --ip 10.11.123.456
```

You can then connect to the VM through normal OpenSSH usage. Connection can be done through any SSH client that uses OpenSSH.

## Run sudo with Azure AD login

After users who are assigned the VM Administrator role successfully SSH into a Linux VM, they'll be able to run sudo with no other interaction or authentication requirement. Users who are assigned the VM User role won't be able to run sudo.

## Connect to VMs in virtual machine scale sets

Virtual machine scale sets are supported, but the steps are slightly different for enabling and connecting to VMs in a virtual machine scale set:

1. Create a virtual machine scale set or choose one that already exists. Enable a system-assigned managed identity for your virtual machine scale set:

```
az vmss identity assign --name myVMSS --resource-group AzureADLinuxVM
```

## 2. Install the Azure AD extension on your virtual machine scale set:

```
az vmss extension set --publisher Microsoft.Azure.ActiveDirectory --name AADSSHLoginForLinux --resource-group AzureADLinuxVM --vmss-name myVMSS
```

Virtual machine scale sets usually don't have public IP addresses. You must have connectivity to them from another machine that can reach their Azure virtual network. This example shows how to use the private IP of a VM in a virtual machine scale set to connect from a machine in the same virtual network:

```
az ssh vm --ip 10.11.123.456
```

### NOTE

You can't automatically determine the virtual machine scale set VM's IP addresses by using the `--resource-group` and `--name` switches.

## Migrate from the previous (preview) version

If you're using the previous version of Azure AD login for Linux that was based on device code flow, complete the following steps by using the Azure CLI:

### 1. Uninstall the AADLoginForLinux extension on the VM:

```
az vm extension delete -g MyResourceGroup --vm-name MyVm -n AADLoginForLinux
```

### NOTE

Uninstallation of the extension can fail if there are any Azure AD users currently logged in on the VM. Make sure all users are logged out first.

### 2. Enable system-assigned managed identity on your VM:

```
az vm identity assign -g myResourceGroup -n myVm
```

### 3. Install the AADSSHLoginForLinux extension on the VM:

```
az vm extension set \
--publisher Microsoft.Azure.ActiveDirectory \
--name AADSSHLoginForLinux \
--resource-group myResourceGroup \
--vm-name myVm
```

## Use Azure Policy to meet standards and assess compliance

Use Azure Policy to:

- Ensure that Azure AD login is enabled for your new and existing Linux virtual machines.
- Assess compliance of your environment at scale on a compliance dashboard.

With this capability, you can use many levels of enforcement. You can flag new and existing Linux VMs within your environment that don't have Azure AD login enabled. You can also use Azure Policy to deploy the Azure AD

extension on new Linux VMs that don't have Azure AD login enabled, as well as remediate existing Linux VMs to the same standard.

In addition to these capabilities, you can use Azure Policy to detect and flag Linux VMs that have unapproved local accounts created on their machines. To learn more, review [Azure Policy](#).

## Troubleshoot sign-in issues

Use the following sections to correct common errors that can happen when you try to SSH with Azure AD credentials.

### Couldn't retrieve token from local cache

If you get a message that says the token couldn't be retrieved from the local cache, you must run `az login` again and go through an interactive sign-in flow. Review the section about [logging in by using Azure Cloud Shell](#).

### Access denied: Azure role not assigned

If you see an "Azure role not assigned" error on your SSH prompt, verify that you've configured Azure RBAC policies for the VM that grants the user either the Virtual Machine Administrator Login role or the Virtual Machine User Login role. If you're having problems with Azure role assignments, see the article [Troubleshoot Azure RBAC](#).

### Problems deleting the old (AADLoginForLinux) extension

If the uninstallation scripts fail, the extension might get stuck in a transitioning state. When this happens, the extension can leave packages that it's supposed to uninstall during its removal. In such cases, it's better to manually uninstall the old packages and then try to run the `az vm extension delete` command.

To uninstall old packages:

1. Log in as a local user with admin privileges.
2. Make sure there are no logged-in Azure AD users. Call the `who -u` command to see who is logged in. Then use `sudo kill <pid>` for all session processes that the previous command reported.
3. Run `sudo apt remove --purge aadlogin` (Ubuntu/Debian), `sudo yum erase aadlogin` (RHEL or CentOS), or `sudo zypper remove aadlogin` (openSUSE or SLES).
4. If the command fails, try the low-level tools with scripts disabled:
  - a. For Ubuntu/Debian, run `sudo dpkg --purge aadlogin`. If it's still failing because of the script, delete the `/var/lib/dpkg/info/aadlogin.prerm` file and try again.
  - b. For everything else, run `rpm -e --noscripts aadlogin`.
5. Repeat steps 3-4 for package `aadlogin-selinux`.

### Extension installation errors

Installation of the AADSSHLoginForLinux VM extension to existing computers might fail with one of the following known error codes.

#### Non-zero exit code 22

If you get exit code 22, the status of the AADSSHLoginForLinux VM extension shows as **Transitioning** in the portal.

This failure happens because a system-assigned managed identity is required.

The solution is to:

1. Uninstall the failed extension.
2. Enable a system-assigned managed identity on the Azure VM.
3. Run the extension installation command again.

## Non-zero exit code 23

If you get exit code 23, the status of the AADSSHLoginForLinux VM extension shows as **Transitioning** in the portal.

This failure happens when the older AADLoginForLinux VM extension is still installed.

The solution is to uninstall the older AADLoginForLinux VM extension from the VM. The status of the new AADSSHLoginForLinux VM extension will then change to **Provisioning succeeded** in the portal.

## The az ssh vm command fails with KeyError access\_token

If the `az ssh vm` command fails, you're using an outdated version of the Azure CLI client.

The solution is to upgrade the Azure CLI client to version 2.21.0 or later.

## SSH connection is closed

After a user successfully signs in by using `az login`, connection to the VM through `az ssh vm -ip <address>` or `az ssh vm --name <vm_name> -g <resource_group>` might fail with "Connection closed by <ip\_address> port 22."

One cause for this error is that the user isn't assigned to the Virtual Machine Administrator Login or Virtual Machine User Login role within the scope of this VM. In that case, the solution is to add the user to one of those Azure RBAC roles within the scope of this VM.

This error can also happen if the user is in a required Azure RBAC role, but the system-assigned managed identity has been disabled on the VM. In that case, perform these actions:

1. Enable the system-assigned managed identity on the VM.
2. Allow several minutes to pass before the user tries to connect by using `az ssh vm --ip <ip_address>`.

## Connection problems with virtual machine scale sets

VM connections with virtual machine scale sets can fail if the scale set instances are running an old model.

Upgrading scale set instances to the latest model might resolve the problem, especially if an upgrade hasn't been done since the Azure AD Login extension was installed. Upgrading an instance applies a standard scale set configuration to the individual instance.

## AllowGroups or DenyGroups statements in sshd\_config cause the first login to fail for Azure AD users

If `sshd_config` contains either `AllowGroups` or `DenyGroups` statements, the first login fails for Azure AD users. If the statement was added after users have already had a successful login, they can log in.

One solution is to remove `AllowGroups` and `DenyGroups` statements from `sshd_config`.

Another solution is to move `AllowGroups` and `DenyGroups` to a `match user` section in `sshd_config`. Make sure the match template excludes Azure AD users.

- [Common Conditional Access policies](#)

# Log in to a Windows virtual machine in Azure by using Azure AD

9/21/2022 • 19 minutes to read • [Edit Online](#)

Organizations can improve the security of Windows virtual machines (VMs) in Azure by integrating with Azure Active Directory (Azure AD) authentication. You can now use Azure AD as a core authentication platform to RDP into *Windows Server 2019 Datacenter edition* and later, or *Windows 10 1809* and later. You can then centrally control and enforce Azure role-based access control (RBAC) and Conditional Access policies that allow or deny access to the VMs.

This article shows you how to create and configure a Windows VM and log in by using Azure AD-based authentication.

There are many security benefits of using Azure AD-based authentication to log in to Windows VMs in Azure. They include:

- Use Azure AD credentials to log in to Windows VMs in Azure. The result is federated and managed domain users.
- Reduce reliance on local administrator accounts.
- Password complexity and password lifetime policies that you configure for Azure AD also help secure Windows VMs.
- With Azure RBAC:
  - Specify who can log in to a VM as a regular user or with administrator privileges.
  - When users join or leave your team, you can update the Azure RBAC policy for the VM to grant access as appropriate.
  - When employees leave your organization and their user accounts are disabled or removed from Azure AD, they no longer have access to your resources.
- Configure Conditional Access policies to require multifactor authentication (MFA) and other signals, such as user sign-in risk, before you can RDP into Windows VMs.
- Use Azure deploy and audit policies to require Azure AD login for Windows VMs and to flag the use of unapproved local accounts on the VMs.
- Use Intune to automate and scale Azure AD join with mobile device management (MDM) auto-enrollment of Azure Windows VMs that are part of your virtual desktop infrastructure (VDI) deployments.

MDM auto-enrollment requires Azure AD Premium P1 licenses. Windows Server VMs don't support MDM enrollment.

## NOTE

After you enable this capability, your Windows VMs in Azure will be Azure AD joined. You cannot join them to another domain, like on-premises Active Directory or Azure Active Directory Domain Services. If you need to do so, disconnect the VM from Azure AD by uninstalling the extension.

## Requirements

## Supported Azure regions and Windows distributions

This feature currently supports the following Windows distributions:

- Windows Server 2019 Datacenter and later
- Windows 10 1809 and later

### IMPORTANT

Remote connection to VMs that are joined to Azure AD is allowed only from Windows 10 or later PCs that are Azure AD registered (starting with Windows 10 20H1), Azure AD joined, or hybrid Azure AD joined to the *same* directory as the VM.

This feature is now available in the following Azure clouds:

- Azure Global
- Azure Government
- Azure China 21Vianet

## Network requirements

To enable Azure AD authentication for your Windows VMs in Azure, you need to ensure that your VM's network configuration permits outbound access to the following endpoints over TCP port 443.

Azure Global:

- `https://enterpriseregistration.windows.net` : For device registration.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.com` : For authentication flows.
- `https://pas.windows.net` : For Azure RBAC flows.

Azure Government:

- `https://enterpriseregistration.microsoftonline.us` : For device registration.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.us` : For authentication flows.
- `https://pasff.usgovcloudapi.net` : For Azure RBAC flows.

Azure China 21Vianet:

- `https://enterpriseregistration.partner.microsoftonline.cn` : For device registration.
- `http://169.254.169.254` : Azure Instance Metadata Service endpoint.
- `https://login.chinacloudapi.cn` : For authentication flows.
- `https://pas.chinacloudapi.cn` : For Azure RBAC flows.

## Enable Azure AD login for a Windows VM in Azure

To use Azure AD login for a Windows VM in Azure, you must:

1. Enable the Azure AD login option for the VM.
2. Configure Azure role assignments for users who are authorized to log in to the VM.

There are two ways to enable Azure AD login for your Windows VM:

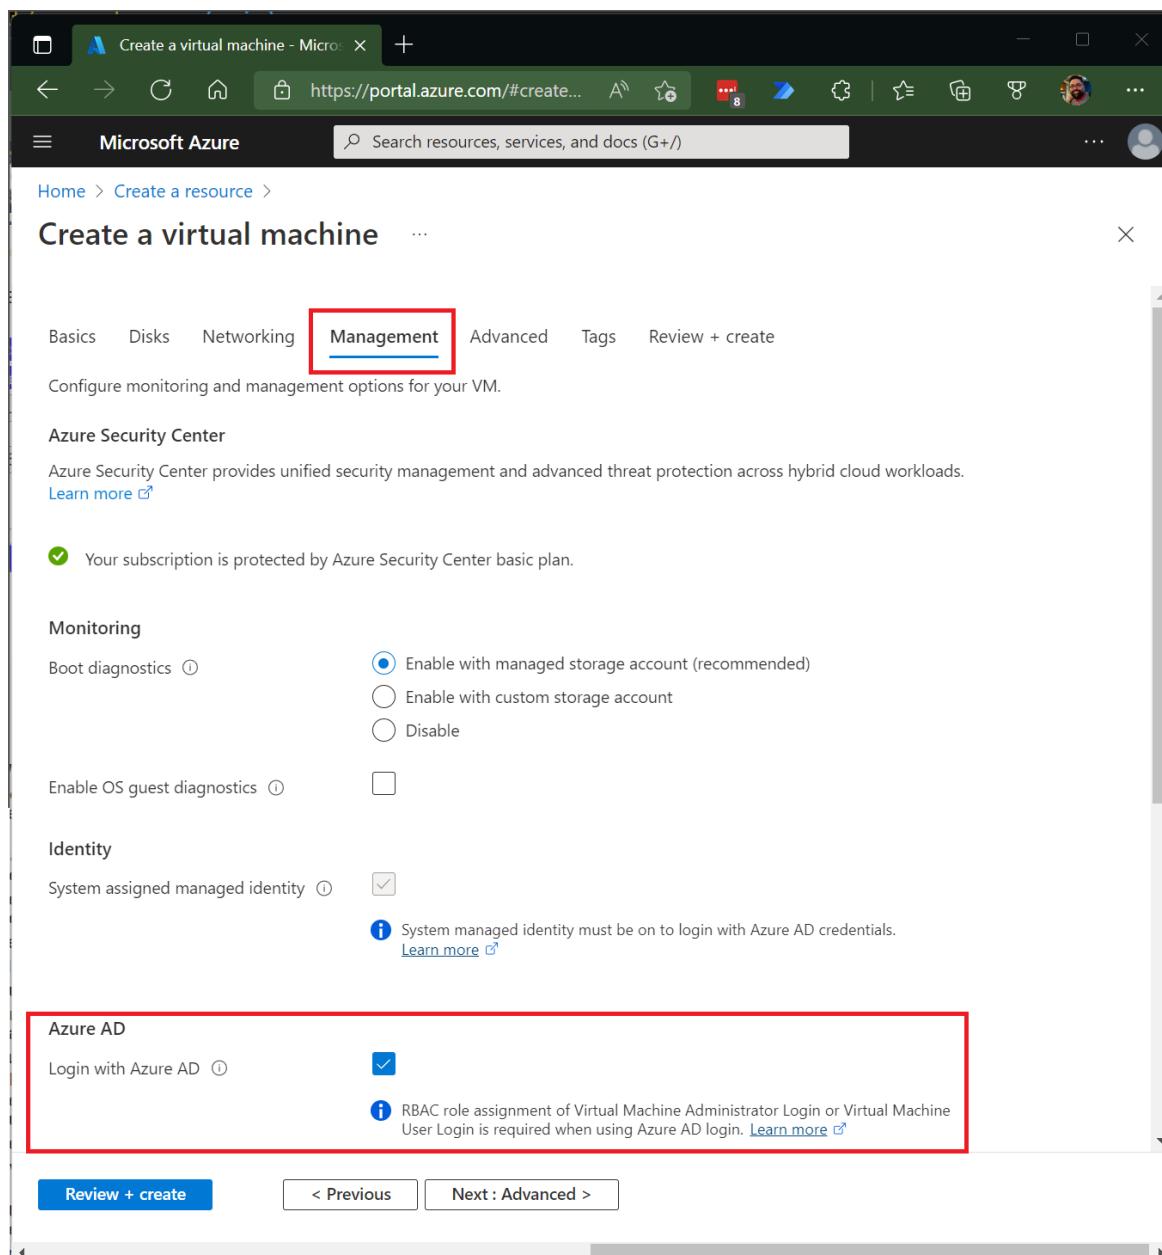

- The Azure portal, when you're creating a Windows VM.
- Azure Cloud Shell, when you're creating a Windows VM or using an existing Windows VM.

## Azure portal

You can enable Azure AD login for VM images in Windows Server 2019 Datacenter or Windows 10 1809 and later.

To create a Windows Server 2019 Datacenter VM in Azure with Azure AD login:

1. Sign in to the [Azure portal](#) by using an account that has access to create VMs, and select + **Create a resource**.
2. In the **Search the Marketplace** search bar, type **Windows Server**.
3. Select **Windows Server**, and then choose **Windows Server 2019 Datacenter** from the **Select a software plan** dropdown list.
4. Select **Create**.
5. On the **Management** tab, select the **Login with Azure AD** checkbox in the **Azure AD** section.

6. Make sure that **System assigned managed identity** in the **Identity** section is selected. This action should happen automatically after you enable login with Azure AD.
7. Go through the rest of the experience of creating a virtual machine. You'll have to create an administrator username and password for the VM.

## NOTE

To log in to the VM by using your Azure AD credentials, you first need to [configure role assignments](#) for the VM.

## Azure Cloud Shell

Azure Cloud Shell is a free, interactive shell that you can use to run the steps in this article. Common Azure tools are preinstalled and configured in Cloud Shell for you to use with your account. Just select the **Copy** button to copy the code, paste it in Cloud Shell, and then select the Enter key to run it. There are a few ways to open Cloud Shell:

- Select **Try It** in the upper-right corner of a code block.
- Open Cloud Shell in your browser.
- Select the Cloud Shell button on the menu in the upper-right corner of the [Azure portal](#).

This article requires you to run Azure CLI version 2.0.31 or later. Run `az --version` to find the version. If you need to install or upgrade, see the article [Install the Azure CLI](#).

1. Create a resource group by running `az group create`.
2. Create a VM by running `az vm create`. Use a supported distribution in a supported region.
3. Install the Azure AD login VM extension.

The following example deploys a VM named `myVM` (that uses `Win2019Datacenter`) into a resource group named `myResourceGroup`, in the `southcentralus` region. In this example and the next one, you can provide your own resource group and VM names as needed.

```
az group create --name myResourceGroup --location southcentralus

az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image Win2019Datacenter \
    --assign-identity \
    --admin-username azureuser \
    --admin-password yourpassword
```

## NOTE

You must enable system-assigned managed identity on your virtual machine before you install the Azure AD login VM extension.

It takes a few minutes to create the VM and supporting resources.

Finally, install the Azure AD login VM extension to enable Azure AD login for Windows VMs. VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure virtual machines. Use `az vm extension` set to install the `AADLoginForWindows` extension on the VM named `myVM` in the `myResourceGroup` resource group.

You can install the `AADLoginForWindows` extension on an existing Windows Server 2019 or Windows 10 1809 and later VM to enable it for Azure AD authentication. The following example uses the Azure CLI to install the extension:

```
az vm extension set \
--publisher Microsoft.Azure.ActiveDirectory \
--name AADLoginForWindows \
--resource-group myResourceGroup \
--vm-name myVM
```

After the extension is installed on the VM, `provisioningState` shows `Succeeded`.

## Configure role assignments for the VM

Now that you've created the VM, you need to configure an Azure RBAC policy to determine who can log in to the VM. Two Azure roles are used to authorize VM login:

- **Virtual Machine Administrator Login:** Users who have this role assigned can log in to an Azure virtual machine with administrator privileges.
- **Virtual Machine User Login:** Users who have this role assigned can log in to an Azure virtual machine with regular user privileges.

To allow a user to log in to the VM over RDP, you must assign the Virtual Machine Administrator Login or Virtual Machine User Login role to the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resources.

An Azure user who has the Owner or Contributor role assigned for a VM does not automatically have privileges to log in to the VM over RDP. The reason is to provide audited separation between the set of people who control virtual machines and the set of people who can access virtual machines.

There are two ways to configure role assignments for a VM:

- Azure AD portal experience
- Azure Cloud Shell experience

### NOTE

The Virtual Machine Administrator Login and Virtual Machine User Login roles use `dataActions`, so they can't be assigned at the management group scope. Currently, you can assign these roles only at the subscription, resource group, or resource scope.

### Azure AD portal

To configure role assignments for your Azure AD-enabled Windows Server 2019 Datacenter VMs:

1. For **Resource Group**, select the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resource.
2. Select **Access control (IAM)**.
3. Select **Add > Add role assignment** to open the **Add role assignment** page.
4. Assign the following role. For detailed steps, see [Assign Azure roles by using the Azure portal](#).

SETTING	VALUE
Role	Virtual Machine Administrator Login or Virtual Machine User Login
Assign access to	User, group, service principal, or managed identity

A role definition is a collection of permissions. You can use the built-in roles or you can create your own custom roles. [Learn more](#)

Name ↑↓	Description ↑↓	Type ↑↓	Category ↑↓	Details
Owner	Grants full access to manage all resources, including the ability to a...	BuiltinRole	General	<a href="#">View</a>
Contributor	Grants full access to manage all resources, but does not allow you ...	BuiltinRole	General	<a href="#">View</a>
Reader	View all resources, but does not allow you to make any changes.	BuiltinRole	General	<a href="#">View</a>
AcrDelete	acr delete	BuiltinRole	Containers	<a href="#">View</a>
AcrImageSigner	acr image signer	BuiltinRole	Containers	<a href="#">View</a>
AcrPull	acr pull	BuiltinRole	Containers	<a href="#">View</a>
AcrPush	acr push	BuiltinRole	Containers	<a href="#">View</a>
AcrQuarantineReader	acr quarantine data reader	BuiltinRole	Containers	<a href="#">View</a>
AcrQuarantineWriter	acr quarantine data writer	BuiltinRole	Containers	<a href="#">View</a>

## Azure Cloud Shell

The following example uses [az role assignment create](#) to assign the Virtual Machine Administrator Login role to the VM for your current Azure user. You obtain the username of your current Azure account by using [az account show](#), and you set the scope to the VM created in a previous step by using [az vm show](#).

You can also assign the scope at a resource group or subscription level. Normal Azure RBAC inheritance permissions apply. For more information, see [Log in to a Linux virtual machine in Azure by using Azure Active Directory authentication](#).

```
$username=$(az account show --query user.name --output tsv)
$rg=$(az group show --resource-group myResourceGroup --query id -o tsv)

az role assignment create \
    --role "Virtual Machine Administrator Login" \
    --assignee $username \
    --scope $rg
```

### NOTE

If your Azure AD domain and login username domain don't match, you must specify the object ID of your user account by using `--assignee-object-id`, not just the username for `--assignee`. You can obtain the object ID for your user account by using [az ad user list](#).

For more information about how to use Azure RBAC to manage access to your Azure subscription resources, see the following articles:

- [Assign Azure roles by using the Azure CLI](#)
- [Assign Azure roles by using the Azure portal](#)
- [Assign Azure roles by using Azure PowerShell](#)

## Enforce Conditional Access policies

You can enforce Conditional Access policies, such as multifactor authentication or user sign-in risk check, before

you authorize access to Windows VMs in Azure that are enabled with Azure AD login. To apply a Conditional Access policy, you must select the **Azure Windows VM Sign-In** app from the cloud apps or actions assignment option. Then use sign-in risk as a condition and/or require MFA as a control for granting access.

#### NOTE

If you require MFA as a control for granting access to the Azure Windows VM Sign-In app, then you must supply an MFA claim as part of the client that initiates the RDP session to the target Windows VM in Azure. The only way to achieve this on a Windows 10 or later client is to use a Windows Hello for Business PIN or biometric authentication with the RDP client. Support for biometric authentication was added to the RDP client in Windows 10 version 1809.

Remote desktop using Windows Hello for Business authentication is available only for deployments that use a certificate trust model. It's currently not available for a key trust model.

## Log in by using Azure AD credentials to a Windows VM

#### IMPORTANT

Remote connection to VMs that are joined to Azure AD is allowed only from Windows 10 or later PCs that are either Azure AD registered (minimum required build is 20H1) or Azure AD joined or hybrid Azure AD joined to the *same* directory as the VM. Additionally, to RDP by using Azure AD credentials, users must belong to one of the two Azure roles, Virtual Machine Administrator Login or Virtual Machine User Login.

If you're using an Azure AD-registered Windows 10 or later PC, you must enter credentials in the `AzureAD\UPN` format (for example, `AzureAD\john@contoso.com`). At this time, you can use Azure Bastion to log in with Azure AD authentication [via the Azure CLI and the native RDP client mstsc](#).

To log in to your Windows Server 2019 virtual machine by using Azure AD:

1. Go to the overview page of the virtual machine that has been enabled with Azure AD login.
2. Select **Connect** to open the **Connect to virtual machine** pane.
3. Select **Download RDP File**.
4. Select **Open** to open the Remote Desktop Connection client.
5. Select **Connect** to open the Windows login dialog.
6. Log in by using your Azure AD credentials.

You're now logged in to the Windows Server 2019 Azure virtual machine with the role permissions as assigned, such as VM User or VM Administrator.

#### NOTE

You can save the .rdp file locally on your computer to start future remote desktop connections to your virtual machine, instead of going to the virtual machine overview page in the Azure portal and using the connect option.

## Use Azure Policy to meet standards and assess compliance

Use Azure Policy to:

- Ensure that Azure AD login is enabled for your new and existing Windows virtual machines.
- Assess compliance of your environment at scale on a compliance dashboard.

With this capability, you can use many levels of enforcement. You can flag new and existing Windows VMs within your environment that don't have Azure AD login enabled. You can also use Azure Policy to deploy the Azure AD extension on new Windows VMs that don't have Azure AD login enabled, and remediate existing

Windows VMs to the same standard.

In addition to these capabilities, you can use Azure Policy to detect and flag Windows VMs that have unapproved local accounts created on their machines. To learn more, review [Azure Policy](#).

## Troubleshoot deployment problems

The AADLoginForWindows extension must be installed successfully for the VM to complete the Azure AD join process. If the VM extension fails to be installed correctly, perform the following steps:

1. RDP to the VM by using the local administrator account and examine the *CommandExecution.log* file under *C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.ActiveDirectoryAADLoginForWindows\1.0.0.1*.

### NOTE

If the extension restarts after the initial failure, the log with the deployment error will be saved as *CommandExecution\_YYYYMMDDHHMMSSSS.log*.

2. Open a PowerShell window on the VM. Verify that the following queries against the Azure Instance Metadata Service endpoint running on the Azure host return the expected output:

COMMAND TO RUN	EXPECTED OUTPUT
<pre>curl -H Metadata:true "http://169.254.169.254/metadata/instance?api-version=2017-08-01"</pre>	Correct information about the Azure VM
<pre>curl -H Metadata:true "http://169.254.169.254/metadata/identity/info?api-version=2018-02-01"</pre>	Valid tenant ID associated with the Azure subscription
<pre>curl -H Metadata:true "http://169.254.169.254/metadata/identity/oauth2/token?resource=urn:ms-drivers:enterpriseregistration.windows.net&amp;api-version=2018-02-01"</pre>	Valid access token issued by Azure Active Directory for the managed identity that is assigned to this VM

### NOTE

You can decode the access token by using a tool like [calebb.net](#). Verify that the `oid` value in the access token matches the managed identity that's assigned to the VM.

3. Ensure that the required endpoints are accessible from the VM via PowerShell:

- curl.exe https://login.microsoftonline.com/ -D -
- curl.exe https://login.microsoftonline.com/<TenantID>/ -D -
- curl.exe https://enterpriseregistration.windows.net/ -D -
- curl.exe https://device.login.microsoftonline.com/ -D -
- curl.exe https://pas.windows.net/ -D -

### NOTE

Replace `<TenantID>` with the Azure AD tenant ID that's associated with the Azure subscription.

`login.microsoftonline.com/<TenantID>`, `enterpriseregistration.windows.net`, and `pas.windows.net` should return 404 Not Found, which is expected behavior.

4. View the device state by running `dsregcmd /status`. The goal is for the device state to show as

`AzureAdJoined : YES`.

#### NOTE

Azure AD join activity is captured in Event Viewer under the *User Device Registration\Admin* log at *Event Viewer (local)\Applications and Services Logs\Windows\Microsoft\User Device Registration\Admin*.

If the AADLoginForWindows extension fails with an error code, you can perform the following steps.

#### Terminal error code 1007 and exit code -2145648574.

Terminal error code 1007 and exit code -2145648574 translate to `DSREG_E_MSI_TENANTID_UNAVAILABLE`. The extension can't query the Azure AD tenant information.

Connect to the VM as a local administrator and verify that the endpoint returns a valid tenant ID from Azure Instance Metadata Service. Run the following command from an elevated PowerShell window on the VM:

```
curl -H Metadata:true http://169.254.169.254/metadata/identity/info?api-version=2018-02-01
```

This problem can also happen when the VM admin attempts to install the AADLoginForWindows extension, but a system-assigned managed identity hasn't enabled the VM first. In that case, go to the **Identity** pane of the VM. On the **System assigned** tab, verify that the **Status** toggle is set to **On**.

#### Exit code -2145648607

Exit code -2145648607 translates to `DSREG_AUTOJOIN_DISC_FAILED`. The extension can't reach the `https://enterpriseregistration.windows.net` endpoint.

1. Verify that the required endpoints are accessible from the VM via PowerShell:

- `curl https://login.microsoftonline.com/ -D -`
- `curl https://login.microsoftonline.com/<TenantID>/ -D -`
- `curl https://enterpriseregistration.windows.net/ -D -`
- `curl https://device.login.microsoftonline.com/ -D -`
- `curl https://pas.windows.net/ -D -`

#### NOTE

Replace `<TenantID>` with the Azure AD tenant ID that's associated with the Azure subscription. If you need to find the tenant ID, you can hover over your account name or select **Azure Active Directory > Properties > Directory ID** in the Azure portal.

Attempts to connect to `enterpriseregistration.windows.net` might return 404 Not Found, which is expected behavior. Attempts to connect to `pas.windows.net` might prompt for PIN credentials or might return 404 Not Found. (You don't need to enter the PIN.) Either one is sufficient to verify that the URL is reachable.

2. If any of the commands fails with "Could not resolve host `<URL>`," try running this command to determine which DNS server the VM is using:

```
nslookup <URL>
```

#### NOTE

Replace `<URL>` with the fully qualified domain names that the endpoints use, such as `login.microsoftonline.com`.

3. See whether specifying a public DNS server allows the command to succeed:

```
nslookup <URL> 208.67.222.222
```

4. If necessary, change the DNS server that's assigned to the network security group that the Azure VM belongs to.

### Exit code 51

Exit code 51 translates to "This extension is not supported on the VM's operating system."

The AADLoginForWindows extension is intended to be installed only on Windows Server 2019 or Windows 10 (Build 1809 or later). Ensure that your version or build of Windows is supported. If it isn't supported, uninstall the extension.

## Troubleshoot sign-in problems

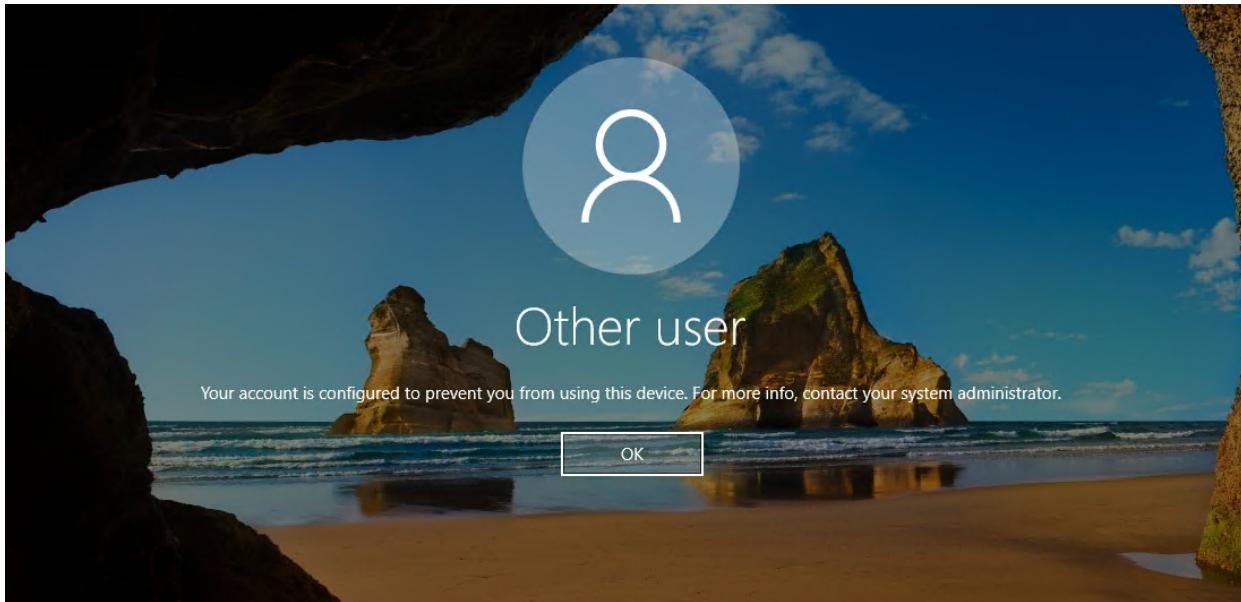

Use the following information to correct sign-in problems.

You can view the device and single sign-on (SSO) state by running `dsregcmd /status`. The goal is for the device state to show as `AzureAdJoined : YES` and for the SSO state to show `AzureAdPrt : YES`.

RDP sign-in via Azure AD accounts is captured in Event Viewer under the *AAD\Operational* event logs.

### Azure role not assigned

You might get the following error message when you initiate a remote desktop connection to your VM: "Your account is configured to prevent you from using this device. For more info, contact your system administrator."

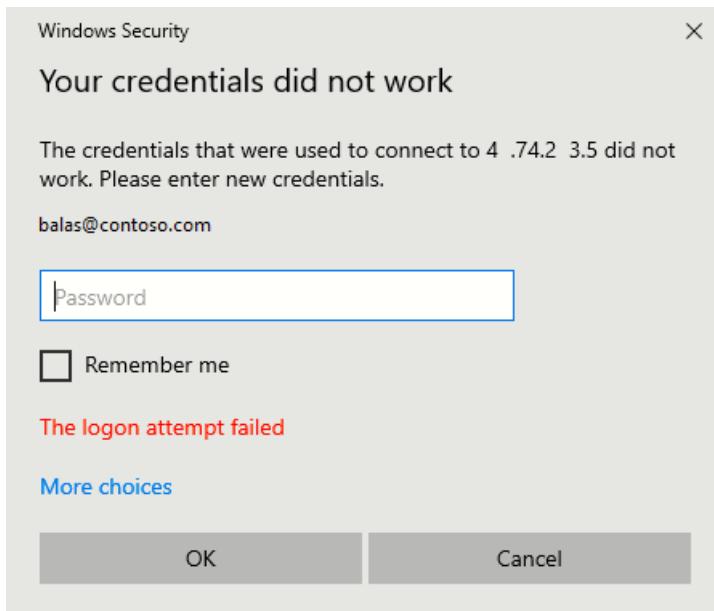

Verify that you've [configured Azure RBAC policies](#) for the VM that grant the user the Virtual Machine Administrator Login or Virtual Machine User Login role.

#### NOTE

If you're having problems with Azure role assignments, see [Troubleshoot Azure RBAC](#).

### Unauthorized client or password change required

You might get the following error message when you initiate a remote desktop connection to your VM: "Your credentials did not work."

Try these solutions:

- The Windows 10 or later PC that you're using to initiate the remote desktop connection must be Azure AD joined, or hybrid Azure AD joined to the same Azure AD directory. For more information about device identity, see the article [What is a device identity?](#).

**NOTE**

Windows 10 Build 20H1 added support for an Azure AD-registered PC to initiate an RDP connection to your VM.

When you're using a PC that's Azure AD registered (not Azure AD joined or hybrid Azure AD joined) as the RDP client to initiate connections to your VM, you must enter credentials in the format

AzureAD\UPN

(for example,

AzureAD\john@contoso.com).

Verify that the AADLoginForWindows extension wasn't uninstalled after the Azure AD join finished.

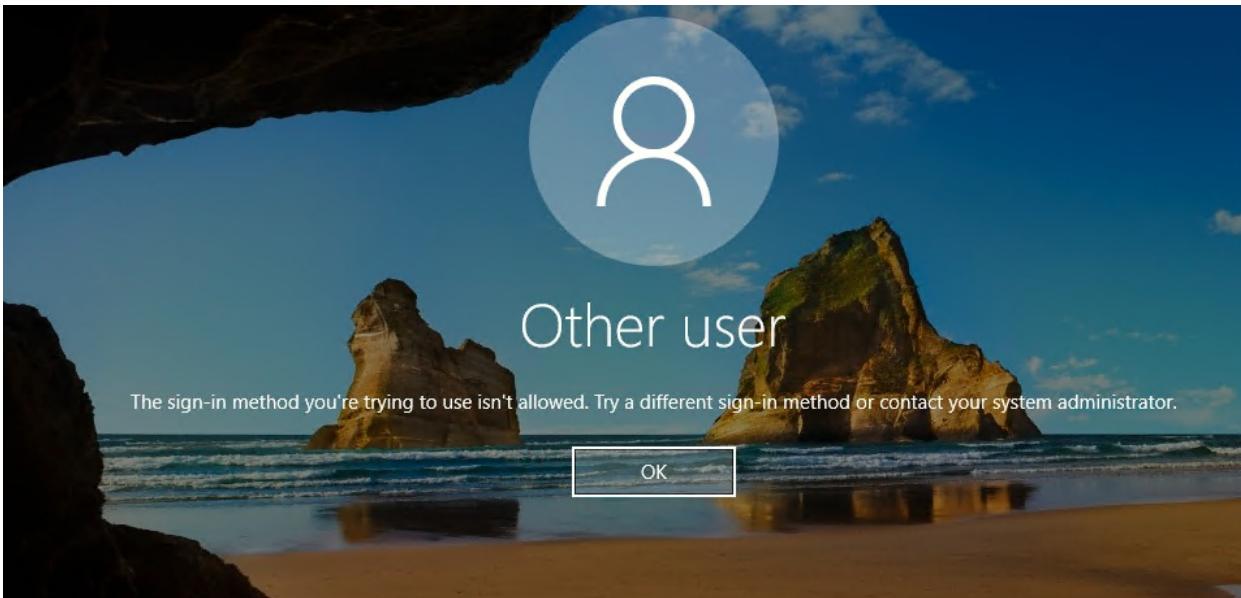

Also, make sure that the security policy **Network security: Allow PKU2U authentication requests to this computer to use online identities** is enabled on both the server *and* the client.

- Verify that the user doesn't have a temporary password. Temporary passwords can't be used to log in to a remote desktop connection.

Sign in with the user account in a web browser. For instance, open the [Azure portal](#) in a private browsing window. If you're prompted to change the password, set a new password. Then try connecting again.

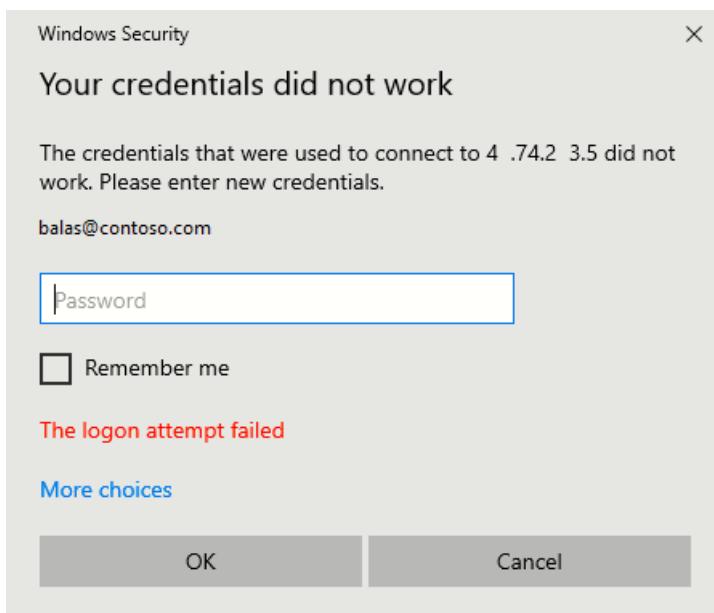

**MFA sign-in method required**

You might see the following error message when you initiate a remote desktop connection to your VM: "The sign-in method you're trying to use isn't allowed. Try a different sign-in method or contact your system administrator."

If you've configured a Conditional Access policy that requires MFA or legacy per-user Enabled/Enforced Azure AD MFA before you can access the resource, you need to ensure that the Windows 10 or later PC that's initiating the remote desktop connection to your VM signs in by using a strong authentication method such as Windows Hello. If you don't use a strong authentication method for your remote desktop connection, you'll see the error.

Another MFA-related error message is the one described previously: "Your credentials did not work."

If you've configured a legacy per-user Enabled/Enforced Azure AD Multi-Factor Authentication setting and you see the error above, you can resolve the problem by removing the per-user MFA setting through these commands:

```
# Get StrongAuthenticationRequirements configure on a user
(Get-MsolUser -UserPrincipalName username@contoso.com).StrongAuthenticationRequirements

# Clear StrongAuthenticationRequirements from a user
$mfa = @()
Set-MsolUser -UserPrincipalName username@contoso.com -StrongAuthenticationRequirements $mfa

# Verify StrongAuthenticationRequirements are cleared from the user
(Get-MsolUser -UserPrincipalName username@contoso.com).StrongAuthenticationRequirements
```

If you haven't deployed Windows Hello for Business and if that isn't an option for now, you can configure a Conditional Access policy that excludes the Azure Windows VM Sign-In app from the list of cloud apps that

require MFA. To learn more about Windows Hello for Business, see [Windows Hello for Business overview](#).

#### NOTE

Windows Hello for Business PIN authentication with RDP has been supported for several versions of Windows 10. Support for biometric authentication with RDP was added in Windows 10 version 1809. Using Windows Hello for Business authentication during RDP is available only for deployments that use a certificate trust model. It's currently not available for a key trust model.

Share your feedback about this feature or report problems with using it on the [Azure AD feedback forum](#).

#### Missing application

If the Azure Windows VM Sign-In application is missing from Conditional Access, make sure that the application isn't in the tenant:

1. Sign in to the Azure portal.
2. Browse to **Azure Active Directory > Enterprise applications**.
3. Remove the filters to see all applications, and search for VM. If you don't see **Azure Windows VM Sign-In** as a result, the service principal is missing from the tenant.

Another way to verify it is via Graph PowerShell:

1. [Install the Graph PowerShell SDK](#) if you haven't already done so.
2. Run `Connect-MgGraph -Scopes "ServicePrincipalEndpoint.ReadWrite.All"`, followed by `"Application.ReadWrite.All"`.
3. Sign in with a Global Admin account.
4. Consent to the permission prompt.
5. Run `Get-MgServicePrincipal -ConsistencyLevel eventual -Search '"DisplayName:Azure Windows VM Sign-In"'`.
  - If this command results in no output and returns you to the PowerShell prompt, you can create the service principal with the following Graph PowerShell command:

```
New-MgServicePrincipal -AppId 372140e0-b3b7-4226-8ef9-d57986796201
```
  - Successful output will show that the Azure Windows VM Sign-In app and its ID were created.
6. Sign out of Graph PowerShell by using the `Disconnect-MgGraph` command.

## Next steps

For more information about Azure AD, see [What is Azure Active Directory?](#).

# Updates and maintenance overview

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article provides an overview of the various update and maintenance options for Azure virtual machines (VMs).

## Automatic OS image upgrade

Enabling [automatic OS image upgrades](#) on your scale set helps ease update management by safely and automatically upgrading the OS disk for all instances in the scale set.

[Automatic OS upgrade](#) has the following characteristics:

- Once configured, the latest OS image published by image publishers is automatically applied to the scale set without user intervention.
- Upgrades batches of instances in a rolling manner each time a new image is published by the publisher.
- Integrates with application health probes and [Application Health extension](#).
- Works for all VM sizes, and for both Windows and Linux images.
- You can opt out of automatic upgrades at any time (OS Upgrades can be initiated manually as well).
- The OS Disk of a VM is replaced with the new OS Disk created with latest image version. Configured extensions and custom data scripts are run, while persisted data disks are retained.
- [Extension sequencing](#) is supported.
- Automatic OS image upgrade can be enabled on a scale set of any size.

## Automatic VM guest patching

Enabling [automatic VM guest patching](#) for your Azure VMs helps ease update management by safely and automatically patching virtual machines to maintain security compliance.

[Automatic VM guest patching](#) has the following characteristics:

- Patches classified as *Critical* or *Security* are automatically downloaded and applied on the VM.
- Patches are applied during off-peak hours in the VM's time zone.
- Patch orchestration is managed by Azure and patches are applied following [availability-first principles](#).
- Virtual machine health, as determined through platform health signals, is monitored to detect patching failures.
- Works for all VM sizes.

## Automatic extension upgrade

[Automatic Extension Upgrade](#) is available for Azure VMs and Azure Virtual Machine Scale Sets. When Automatic Extension Upgrade is enabled on a VM or scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that extension.

Automatic Extension Upgrade has the following features:

- Supported for Azure VMs and Azure Virtual Machine Scale Sets.
- Upgrades are applied in an availability-first deployment model.
- For a Virtual Machine Scale Set, no more than 20% of the scale set virtual machines will be upgraded in a

single batch. The minimum batch size is one virtual machine.

- Works for all VM sizes, and for both Windows and Linux extensions.
- You can opt out of automatic upgrades at any time.
- Automatic extension upgrade can be enabled on a Virtual Machine Scale Sets of any size.
- Each supported extension is enrolled individually, and you can choose which extensions to upgrade automatically.
- Supported in all public cloud regions.

## Hotpatch

[Hotpatching](#) is a new way to install updates on new Windows Server Azure Edition virtual machines (VMs) that doesn't require a reboot after installation. Hotpatch for Windows Server Azure Edition VMs, has the following benefits:

- Lower workload impact with less reboots
- Faster deployment of updates as the packages are smaller, install faster, and have easier patch orchestration with Azure Update Manager
- Better protection, as the Hotpatch update packages are scoped to Windows security updates that install faster without rebooting

## Azure update management

You can use [Update Management in Azure Automation](#) to manage operating system updates for your Windows and Linux virtual machines in Azure, in on-premises environments, and in other cloud environments. You can quickly assess the status of available updates on all agent machines and manage the process of installing required updates for servers.

## Update management center (preview)

[Update management center \(preview\)](#) is a new-age unified service in Azure to manage and govern updates (Windows and Linux), both on-premises and other cloud platforms, across hybrid environments from a single dashboard. The new functionality provides native and out-of-the-box experience, granular access controls, flexibility to create schedules or take action now, ability to check updates automatically and much more. The enhanced functionality ensures that the administrators have visibility into the health of all systems in the environment. For more information, see [key benefits](#).

## Maintenance control

Manage platform updates, that don't require a reboot, using [maintenance control](#). Azure frequently updates its infrastructure to improve reliability, performance, security or launch new features. Most updates are transparent to users. Some sensitive workloads, like gaming, media streaming, and financial transactions, can't tolerate even few seconds of a VM freezing or disconnecting for maintenance. Maintenance control gives you the option to wait on platform updates and apply them within a 35-day rolling window.

Maintenance control lets you decide when to apply updates to your isolated VMs and Azure dedicated hosts.

With [maintenance control](#), you can:

- Batch updates into one update package.
- Wait up to 35 days to apply updates for Host machines.
- Automate platform updates by configuring a maintenance schedule or by using [Azure Functions](#).
- Maintenance configurations work across subscriptions and resource groups.

## Scheduled events

Scheduled Events is an Azure Metadata Service that gives your application time to prepare for virtual machine (VM) maintenance. It provides information about upcoming maintenance events (for example, reboot) so that your application can prepare for them and limit disruption. It's available for all Azure Virtual Machines types, including PaaS and IaaS on both Windows and Linux.

For information on Scheduled Events, see [Scheduled Events for Windows VMs](#) and [Scheduled Events for Linux](#)

## Next steps

Review the [Availability and scale](#) documentation for more ways to increase the uptime of your applications and services.

# Azure virtual machine scale set automatic OS image upgrades

9/21/2022 • 15 minutes to read • [Edit Online](#)

Enabling automatic OS image upgrades on your scale set helps ease update management by safely and automatically upgrading the OS disk for all instances in the scale set.

Automatic OS upgrade has the following characteristics:

- Once configured, the latest OS image published by image publishers is automatically applied to the scale set without user intervention.
- Upgrades batches of instances in a rolling manner each time a new image is published by the publisher.
- Integrates with application health probes and [Application Health extension](#).
- Works for all VM sizes, and for both Windows and Linux images including custom images through [Azure Compute Gallery](#).
- You can opt out of automatic upgrades at any time (OS Upgrades can be initiated manually as well).
- The OS Disk of a VM is replaced with the new OS Disk created with latest image version. Configured extensions and custom data scripts are run, while persisted data disks are retained.
- [Extension sequencing](#) is supported.
- Can be enabled on a scale set of any size.

## NOTE

Before enabling automatic OS image upgrades, check [requirements section](#) of this documentation.

## How does automatic OS image upgrade work?

An upgrade works by replacing the OS disk of a VM with a new disk created using the latest image version. Any configured extensions and custom data scripts are run on the OS disk, while data disks are retained. To minimize the application downtime, upgrades take place in batches, with no more than 20% of the scale set upgrading at any time.

You can integrate an Azure Load Balancer application health probe or [Application Health extension](#) to track the health of the application after an upgrade. We recommended incorporating an application heartbeat to validate upgrade success.

### Availability-first Updates

The availability-first model for platform orchestrated updates described below ensures that availability configurations in Azure are respected across multiple availability levels.

#### Across regions:

- An update will move across Azure globally in a phased manner to prevent Azure-wide deployment failures.
- A 'phase' can have one or more regions, and an update moves across phases only if eligible VMs in the previous phase update successfully.
- Geo-paired regions will not be updated concurrently and cannot be in the same regional phase.
- The success of an update is measured by tracking the health of a VM post update.

#### Within a region:

- VMs in different Availability Zones are not updated concurrently with the same update.

#### Within a 'set':

- All VMs in a common scale set are not updated concurrently.
- VMs in a common virtual machine scale set are grouped in batches and updated within Update Domain boundaries as described below.

The platform orchestrated updates process is followed for rolling out supported OS platform image upgrades every month. For custom images through Azure Compute Gallery, an image upgrade is only kicked off for a particular Azure region when the new image is published and [replicated](#) to the region of that scale set.

#### Upgrading VMs in a scale set

The region of a scale set becomes eligible to get image upgrades either through the availability-first process for platform images or replicating new custom image versions for Share Image Gallery. The image upgrade is then applied to an individual scale set in a batched manner as follows:

- Before you begin the upgrade process, the orchestrator will ensure that no more than 20% of instances in the entire scale set are unhealthy (for any reason).
- The upgrade orchestrator identifies the batch of VM instances to upgrade, with any one batch having a maximum of 20% of the total instance count, subject to a minimum batch size of one virtual machine. There is no minimum scale set size requirement and scale sets with 5 or fewer instances will have 1 VM per upgrade batch (minimum batch size).
- The OS disk of every VM in the selected upgrade batch is replaced with a new OS disk created from the latest image. All specified extensions and configurations in the scale set model are applied to the upgraded instance.
- For scale sets with configured application health probes or Application Health extension, the upgrade waits up to 5 minutes for the instance to become healthy, before moving on to upgrade the next batch. If an instance does not recover its health in 5 minutes after an upgrade, then by default the previous OS disk for the instance is restored.
- The upgrade orchestrator also tracks the percentage of instances that become unhealthy post an upgrade. The upgrade will stop if more than 20% of upgraded instances become unhealthy during the upgrade process.
- The above process continues until all instances in the scale set have been upgraded.

The scale set OS upgrade orchestrator checks for the overall scale set health before upgrading every batch. While you're upgrading a batch, there could be other concurrent planned or unplanned maintenance activities that could impact the health of your scale set instances. In such cases if more than 20% of the scale set's instances become unhealthy, then the scale set upgrade stops at the end of current batch.

#### NOTE

Automatic OS upgrade does not upgrade the reference image Sku on the scale set. To change the Sku (such as Ubuntu 16.04-LTS to 18.04-LTS), you must update the [scale set model](#) directly with the desired image Sku. Image publisher and offer can't be changed for an existing scale set.

## Supported OS images

Only certain OS platform images are currently supported. Custom images [are supported](#) if the scale set uses custom images through [Azure Compute Gallery](#).

The following platform SKUs are currently supported (and more are added periodically):

PUBLISHER	OS OFFER	SKU
Canonical	UbuntuServer	18.04-LTS
Canonical	UbuntuServer	18.04-LTS-Gen2
Canonical	0001-com-ubuntu-server-focal	20.04-LTS

MicrosoftWindowsServer	WindowsServer	2022-Datacenter-g2

## Requirements for configuring automatic OS image upgrade

- The *version* property of the image must be set to *latest*.
- Must use application health probes or [Application Health extension](#) for non-Service Fabric scale sets. For Service Fabric requirements, see [Service Fabric requirement](#).
- Use Compute API version 2018-10-01 or higher.
- Ensure that external resources specified in the scale set model are available and updated. Examples include SAS URI for bootstrapping payload in VM extension properties, payload in storage account, reference to secrets in the model, and more.
- For scale sets using Windows virtual machines, starting with Compute API version 2019-03-01, the property *virtualMachineProfile.osProfile.windowsConfiguration.enableAutomaticUpdates* property must set to *false* in the scale set model definition. The *enableAutomaticUpdates* property enables in-VM patching where "Windows Update" applies operating system patches without replacing the OS disk. With automatic OS image upgrades enabled on your scale set, an extra patching process through Windows Update is not required.

### Service Fabric requirements

If you are using Service Fabric, ensure the following conditions are met:

- Service Fabric [durability level](#) is Silver or Gold. If Service Fabric durability is Bronze, only Stateless-only node types supports automatic OS image upgrades).
- The Service Fabric extension on the scale set model definition must have TypeHandlerVersion 1.1 or above.
- Durability level should be the same at the Service Fabric cluster and Service Fabric extension on the scale set model definition.
- An additional health probe or use of application health extension is not required for Silver or Gold durability. Bronze durability with Stateless-only node types requires an additional health probe.
- The property *virtualMachineProfile.osProfile.windowsConfiguration.enableAutomaticUpdates* property must set to *false* in the scale set model definition. The *enableAutomaticUpdates* property enables in-VM patching using "Windows Update" and is not supported on Service Fabric scale sets.

Ensure that durability settings are not mismatched on the Service Fabric cluster and Service Fabric extension, as a mismatch will result in upgrade errors. Durability levels can be modified per the guidelines outlined on [this page](#).

## Automatic OS image upgrade for custom images

Automatic OS image upgrade is supported for custom images deployed through [Azure Compute Gallery](#). Other custom images are not supported for automatic OS image upgrades.

### Additional requirements for custom images

- The setup and configuration process for automatic OS image upgrade is the same for all scale sets as detailed in the [configuration section](#) of this page.
- Scale sets instances configured for automatic OS image upgrades will be upgraded to the latest version of the Azure Compute Gallery image when a new version of the image is published and [replicated](#) to the region of that scale set. If the new image is not replicated to the region where the scale is deployed, the scale set instances will not be upgraded to the latest version. Regional image replication allows you to control the rollout of the new image for your scale sets.
- The new image version should not be excluded from the latest version for that gallery image. Image versions excluded from the gallery image's latest version are not rolled out to the scale set through automatic OS image upgrade.

#### **NOTE**

It can take up to 3 hours for a scale set to trigger the first image upgrade rollout after the scale set is first configured for automatic OS upgrades. This is a one-time delay per scale set. Subsequent image rollouts are triggered on the scale set within 30-60 minutes.

## Configure automatic OS image upgrade

To configure automatic OS image upgrade, ensure that the `automaticOSUpgradePolicy.enableAutomaticOSUpgrade` property is set to `true` in the scale set model definition.

#### **NOTE**

**Upgrade Policy mode** and **Automatic OS Upgrade Policy** are separate settings and control different aspects of the scale set. When there are changes in the scale set template, the Upgrade Policy `mode` will determine what happens to existing instances in the scale set. However, Automatic OS Upgrade Policy `enableAutomaticOSUpgrade` is specific to the OS image and tracks changes the image publisher has made and determines what happens when there is an update to the image.

## REST API

The following example describes how to set automatic OS upgrades on a scale set model:

```
PUT or PATCH on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachineScaleSets/myScaleSet?api-version=2021-03-01`
```

```
{
  "properties": {
    "upgradePolicy": {
      "automaticOSUpgradePolicy": {
        "enableAutomaticOSUpgrade": true
      }
    }
  }
}
```

## Azure PowerShell

Use the [Update-AzVmss](#) cmdlet to configure automatic OS image upgrades for your scale set. The following example configures automatic upgrades for the scale set named `myScaleSet` in the resource group named `myResourceGroup`.

```
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet" -AutomaticOSUpgrade $true
```

## Azure CLI 2.0

Use [az vmss update](#) to configure automatic OS image upgrades for your scale set. Use Azure CLI 2.0.47 or above. The following example configures automatic upgrades for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

```
az vmss update --name myScaleSet --resource-group myResourceGroup --set  
UpgradePolicy.AutomaticOSUpgradePolicy.EnableAutomaticOSUpgrade=true
```

### NOTE

After configuring automatic OS image upgrades for your scale set, you must also bring the scale set VMs to the latest scale set model if your scale set uses the 'Manual' [upgrade policy](#).

## Using Application Health Probes

During an OS Upgrade, VM instances in a scale set are upgraded one batch at a time. The upgrade should continue only if the customer application is healthy on the upgraded VM instances. We recommend that the application provides health signals to the scale set OS Upgrade engine. By default, during OS Upgrades the platform considers VM power state and extension provisioning state to determine if a VM instance is healthy after an upgrade. During the OS Upgrade of a VM instance, the OS disk on a VM instance is replaced with a new disk based on latest image version. After the OS Upgrade has completed, the configured extensions are run on these VMs. The application is considered healthy only when all the extensions on the instance are successfully provisioned.

A scale set can optionally be configured with Application Health Probes to provide the platform with accurate information on the ongoing state of the application. Application Health Probes are Custom Load Balancer Probes that are used as a health signal. The application running on a scale set VM instance can respond to external HTTP or TCP requests indicating whether it's healthy. For more information on how Custom Load Balancer Probes work, see to [Understand load balancer probes](#). Application Health Probes are not supported for Service Fabric scale sets. Non-Service Fabric scale sets require either Load Balancer application health probes or [Application Health extension](#).

If the scale set is configured to use multiple placement groups, probes using a [Standard Load Balancer](#) need to be used.

### Configuring a Custom Load Balancer Probe as Application Health Probe on a scale set

As a best practice, create a load balancer probe explicitly for scale set health. The same endpoint for an existing HTTP probe or TCP probe can be used, but a health probe could require different behavior from a traditional load-balancer probe. For example, a traditional load balancer probe could return unhealthy if the load on the instance is too high, but that would not be appropriate for determining the instance health during an automatic OS upgrade. Configure the probe to have a high probing rate of less than two minutes.

The load-balancer probe can be referenced in the *networkProfile* of the scale set and can be associated with either an internal or public facing load-balancer as follows:

```
"networkProfile": {  
    "healthProbe" : {  
        "id": "[concat(variables('lbId'), '/probes/', variables('sshProbeName'))]"  
    },  
    "networkInterfaceConfigurations":  
    ...  
}
```

#### NOTE

When using Automatic OS Upgrades with Service Fabric, the new OS image is rolled out Update Domain by Update Domain to maintain high availability of the services running in Service Fabric. To utilize Automatic OS Upgrades in Service Fabric your cluster node type must be configured to use the Silver Durability Tier or higher. For Bronze Durability tier, automatic OS image upgrade is only supported for Stateless node types. For more information on the durability characteristics of Service Fabric clusters, please see [this documentation](#).

#### Keep credentials up to date

If your scale set uses any credentials to access external resources, such as a VM extension configured to use a SAS token for storage account, then ensure that the credentials are updated. If any credentials, including certificates and tokens, have expired, the upgrade will fail and the first batch of VMs will be left in a failed state.

The recommended steps to recover VMs and re-enable automatic OS upgrade if there's a resource authentication failure are:

- Regenerate the token (or any other credentials) passed into your extension(s).
- Ensure that any credential used from inside the VM to talk to external entities is up to date.
- Update extension(s) in the scale set model with any new tokens.
- Deploy the updated scale set, which will update all VM instances including the failed ones.

## Using Application Health extension

The Application Health extension is deployed inside a virtual machine scale set instance and reports on VM health from inside the scale set instance. You can configure the extension to probe on an application endpoint and update the status of the application on that instance. This instance status is checked by Azure to determine whether an instance is eligible for upgrade operations.

As the extension reports health from within a VM, the extension can be used in situations where external probes such as Application Health Probes (that utilize custom Azure Load Balancer [probes](#)) can't be used.

There are multiple ways of deploying the Application Health extension to your scale sets as detailed in the examples in [this article](#).

## Get the history of automatic OS image upgrades

You can check the history of the most recent OS upgrade performed on your scale set with Azure PowerShell, Azure CLI 2.0, or the REST APIs. You can get history for the last five OS upgrade attempts within the past two months.

#### REST API

The following example uses [REST API](#) to check the status for the scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
GET on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachineScaleSets/myScaleSet/osUpgradeHistory?api-version=2021-03-01`
```

The GET call returns properties similar to the following example output:

```
{  
  "value": [  
    {  
      "properties": {  
        "runningStatus": {  
          "code": "RollingForward",  
          "startTime": "2018-07-24T17:46:06.1248429+00:00",  
          "completedTime": "2018-04-21T12:29:25.0511245+00:00"  
        },  
        "progress": {  
          "successfulInstanceCount": 16,  
          "failedInstanceCount": 0,  
          "inProgressInstanceCount": 4,  
          "pendingInstanceCount": 0  
        },  
        "startedBy": "Platform",  
        "targetImageReference": {  
          "publisher": "MicrosoftWindowsServer",  
          "offer": "WindowsServer",  
          "sku": "2016-Datacenter",  
          "version": "2016.127.20180613"  
        },  
        "rollbackInfo": {  
          "successfullyRolledbackInstanceCount": 0,  
          "failedRolledbackInstanceCount": 0  
        }  
      },  
      "type": "Microsoft.Compute/virtualMachineScaleSets/rollingUpgrades",  
      "location": "westeurope"  
    }  
  ]  
}
```

## Azure PowerShell

Use the [Get-AzVmss](#) cmdlet to check OS upgrade history for your scale set. The following example details how you review the OS upgrade status for a scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet" -OSUpgradeHistory
```

## Azure CLI 2.0

Use [az vmss get-os-upgrade-history](#) to check the OS upgrade history for your scale set. Use Azure CLI 2.0.47 or above. The following example details how you review the OS upgrade status for a scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
az vmss get-os-upgrade-history --resource-group myResourceGroup --name myScaleSet
```

# How to get the latest version of a platform OS image?

You can get the available image versions for automatic OS upgrade supported SKUs using the below examples:

## REST API

```
GET on  
`/subscriptions/subscription_id/providers/Microsoft.Compute/locations/{location}/publishers/{publisherName}/  
artifacttypes/vmimage/offers/{offer}/skus/{skus}/versions?api-version=2021-03-01`
```

## Azure PowerShell

```
Get-AzVmImage -Location "westus" -PublisherName "Canonical" -Offer "UbuntuServer" -Skus "16.04-LTS"
```

## Azure CLI 2.0

```
az vm image list --location "westus" --publisher "Canonical" --offer "UbuntuServer" --sku "16.04-LTS" --all
```

# Manually trigger OS image upgrades

With automatic OS image upgrade enabled on your scale set, you do not need to manually trigger image updates on your scale set. The OS upgrade orchestrator will automatically apply the latest available image version to your scale set instances without any manual intervention.

For specific cases where you do not want to wait for the orchestrator to apply the latest image, you can trigger an OS image upgrade manually using the below examples.

### NOTE

Manual trigger of OS image upgrades does not provide automatic rollback capabilities. If an instance does not recover its health after an upgrade operation, its previous OS disk can't be restored.

## REST API

Use the [Start OS Upgrade](#) API call to start a rolling upgrade to move all virtual machine scale set instances to the latest available image OS version. Instances that are already running the latest available OS version are not affected. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
POST on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachineSca  
leSets/myScaleSet/osRollingUpgrade?api-version=2021-03-01`
```

## Azure PowerShell

Use the [Start-AzVmssRollingOSUpgrade](#) cmdlet to check OS upgrade history for your scale set. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
Start-AzVmssRollingOSUpgrade -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet"
```

## Azure CLI 2.0

Use [az vmss rolling-upgrade start](#) to check the OS upgrade history for your scale set. Use Azure CLI 2.0.47 or above. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*.

```
az vmss rolling-upgrade start --resource-group "myResourceGroup" --name "myScaleSet" --subscription  
"subscriptionId"
```

[Learn about the Application Health Extension](#)

# Maintenance control for Azure virtual machine scale sets

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Uniform scale sets

Manage [automatic OS image upgrades](#) for your virtual machine scale sets using maintenance control.

Maintenance control lets you decide when to apply updates to OS disks in your virtual machine scale sets through an easier and more predictable experience.

Maintenance configurations work across subscriptions and resource groups.

The entire workflow comes down to these steps:

- Create a maintenance configuration.
- Associate a virtual machine scale set to a maintenance configuration.
- Enable automatic OS upgrades.

## Limitations

- VMs must be in a scale set.
- User must have **Resource Contributor** access.
- Maintenance duration must be 5 hours or longer in the maintenance configuration.
- Maintenance recurrence must be set to 'Day' in the maintenance configuration

## Management options

You can create and manage maintenance configurations using any of the following options:

- [Azure PowerShell](#)
- [Azure CLI](#)
- [Azure portal](#)

## Next steps

[Virtual machine scale set maintenance control by using PowerShell](#)

# Maintenance control for OS image upgrades on Azure virtual machine scale sets using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Uniform scale sets

Maintenance control lets you decide when to apply automatic guest OS image upgrades to your virtual machine scale sets. This topic covers the Azure PowerShell options for Maintenance control. For more information on using Maintenance control, see [Maintenance control for Azure virtual machine scale sets](#).

## Enable the PowerShell module

Make sure `PowerShellGet` is up to date.

```
Install-Module -Name PowerShellGet -Repository PSGallery -Force
```

Install the `Az.Maintenance` PowerShell module.

```
Install-Module -Name Az.Maintenance
```

If you're installing locally, make sure you open your PowerShell prompt as an administrator.

You may also be asked to confirm that you want to install from an *untrusted repository*. Type `y` or select Yes to All to install the module.

## Connect to an Azure account

Connect to your desired Azure account using `Connect-AzAccount` and `Set-AzAccount`.

```
Connect-AzAccount  
Set-AzContext 00a000aa-0a00-0a0a-00aa-a00a000aaa00  
  
$RGName="myMaintenanceRG"  
$MaintenanceConfig="myMaintenanceConfig"  
$location="eastus2"  
$vmss="myMaintenanceVMSS"
```

## Create a maintenance configuration

Create a resource group as a container for your configuration. In this example, a resource group named `myMaintenanceRG` is created in `eastus2`. If you already have a resource group that you want to use, you can skip this part. Just replace the resource group name with your own in the rest of the examples.

```
New-AzResourceGroup `  
-Location $location `  
-Name $RGName
```

Use `New-AzMaintenanceConfiguration` to create a maintenance configuration. This example creates a maintenance configuration named `myConfig` scoped to the OS image.

```
$config = New-AzMaintenanceConfiguration ` 
    -ResourceGroup $RGName ` 
    -Name $MaintenanceConfig ` 
    -MaintenanceScope OSImage ` 
    -Location $location ` 
    -StartTime "2020-10-01 00:00" ` 
    -TimeZone "Pacific Standard Time" ` 
    -Duration "05:00" ` 
    -RecurEvery "Day"
```

### IMPORTANT

Maintenance **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to *Day*.

Using `-MaintenanceScope OSImage` ensures that the maintenance configuration is used for controlling updates to the guest OS.

If you try to create a configuration with the same name, but in a different location, you'll get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using [Get-AzMaintenanceConfiguration](#).

```
Get-AzMaintenanceConfiguration | Format-Table -Property Name,Id
```

## Associate your virtual machine scale set to the maintenance configuration

A virtual machine scale set can be associated to any Maintenance configuration regardless of the region and subscription of the Maintenance configuration. By opting in to the Maintenance configuration, new OS image updates for the scale set will be automatically scheduled on the next available maintenance window.

Use [New-AzConfigurationAssignment](#) to associate your virtual machine scale set the maintenance configuration.

```
New-AzConfigurationAssignment ` 
    -ResourceGroupName $RGName ` 
    -Location $location ` 
    -ResourceName $vmss ` 
    -ResourceType VirtualMachineScaleSets ` 
    -ProviderName Microsoft.Compute ` 
    -ConfigurationAssignmentName $config.Name ` 
    -MaintenanceConfigurationId $config.Id
```

## Enable automatic OS upgrade

You can enable automatic OS upgrades for each virtual machine scale set that is going to use maintenance control. For more information about enabling automatic OS upgrades on your virtual machine scale set, see [Azure virtual machine scale set automatic OS image upgrades](#).

## Next steps

[Learn about Maintenance and updates for virtual machines running in Azure](#)

# Maintenance control for OS image upgrades on Azure virtual machine scale sets using Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Maintenance control lets you decide when to apply automatic guest OS image upgrades to your virtual machine scale sets. This topic covers the Azure CLI options for Maintenance control. For more information on using Maintenance control, see [Maintenance control for Azure virtual machine scale sets](#).

## Create a maintenance configuration

Use `az maintenance configuration create` to create a maintenance configuration. This example creates a maintenance configuration named *myConfig* scoped to the osimage.

```
az group create \
--location eastus \
--name myMaintenanceRG
az maintenance configuration create \
-g myMaintenanceRG \
--resource-name myConfig \
--maintenance-scope osimage \
--location eastus
```

Copy the configuration ID from the output to use later.

Using `--maintenance-scope osimage` ensures that the maintenance configuration is used for controlling updates to the guest OS.

If you try to create a configuration with the same name, but in a different location, you will get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using `az maintenance configuration list`.

```
az maintenance configuration list --query "[].{Name:name, ID:id}" -o table
```

### Create a maintenance configuration with a scheduled window

You can also declare a scheduled window when Azure will apply the updates on your resources. This example creates a maintenance configuration named *myConfig* with a scheduled window of 5 hours on the fourth Monday of every month. Once you create a scheduled window, you no longer have to apply the updates manually.

#### IMPORTANT

Maintenance **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to *Day*.

```
az maintenance configuration create \
-g myMaintenanceRG \
--resource-name myConfig \
--maintenance-scope osimage \
--location eastus \
--maintenance-window-duration "05:00" \
--maintenance-window-recur-every "Day" \
--maintenance-window-start-date-time "2020-12-30 08:00" \
--maintenance-window-time-zone "Pacific Standard Time"
```

## Assign the configuration

Use `az maintenance assignment create` to assign the configuration to your virtual machine scale set.

## Enable automatic OS upgrade

You can enable automatic OS upgrades for each virtual machine scale set that is going to use maintenance control. For more information about enabling automatic OS upgrades on your virtual machine scale set, see [Azure virtual machine scale set automatic OS image upgrades](#).

## Next steps

[Learn about Maintenance and updates for virtual machines running in Azure](#)

# Maintenance control for OS image upgrades on Azure virtual machine scale sets using Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Maintenance control lets you decide when to apply automatic guest OS image upgrades to your virtual machine scale sets. This topic covers the Azure portal options for Maintenance control. For more information on using Maintenance control, see [Maintenance control for Azure virtual machine scale sets](#).

## Create a maintenance configuration

1. Sign in to the Azure portal.
2. Search for **Maintenance Configurations**.

The screenshot shows the Azure search bar with the text "maintenance" typed into it. Below the search bar, the "Services" tab is selected, and the "Maintenance Configurations" item is highlighted with a blue background and white text. The "Services" tab has a blue underline, while other tabs like "Compute" and "Storage" are in grey.

3. Select **Add**.

## Maintenance Configurations

Microsoft (microsoft.onmicrosoft.com)

 Add  Manage view  Refresh  Export to CSV

4. In the Basics tab, choose a subscription and resource group, provide a name for the configuration, choose a region, and select *OS image upgrade* for the scope. Select **Next**.

## Create a maintenance configuration

Basics Schedule Assignments Tags Review + create

Maintenance configurations allow you to batch and delay updates to Azure infrastructure like virtual machines. [Learn more](#)

### Project details

Select a subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	Contoso
Resource group *	myMaintenanceRG
	<a href="#">Create new</a>

### Instance details

Configuration name *	Demo_Maintenance
Region *	(US) East US 2
Scope *	OS image upgrade

5. In the Schedule tab, declare a scheduled window when Azure will apply the updates on your resources. Set a start date, maintenance window, and recurrence. Once you create a scheduled window, you no longer have to apply the updates manually. Select **Next**.

#### IMPORTANT

Maintenance window **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to repeat at least once a day.

## Create a maintenance configuration

Basics **Schedule** Assignments Tags Review + create

You can specify a schedule to have granular control over when the updates can happen.

Start date *	06/05/2021	12:00 AM
	(UTC-08:00) Pacific Time (US & Canada)	
Maintenance window	5	Hours
Repeats every *	1	Day
End	<input type="checkbox"/>	

6. In the Assignment tab, assign resources now or skip this step and assign resources after the maintenance configuration deployment. Select **Next**.

7. Add tags and values. Select **Next**.

## Create a maintenance configuration

Basics Schedule Assignments **Tags** Review + create

Tags are name/value pairs that enable you to categorize resources and view consolidated billing by applying the same tag to multiple resources and resource groups. [Learn more about tags ↗](#)

Note that if you create tags and then change resource settings on other tabs, your tags will be automatically updated.

Name ⓘ	Value ⓘ
project	: Infra
	:

8. Review the summary. Select **Create**.

9. After the deployment is complete, select **Go to resource**.

## Assign the configuration

On the details page of the maintenance configuration, select **Assignments** and then select **Assign resource**.

The screenshot shows the Azure portal interface for managing maintenance configurations. On the left, there's a sidebar with navigation links: Overview, Activity log, Access control (IAM), Tags, Settings, Assignments (which is highlighted in grey), Properties, Locks, and Export template. The main content area has a title 'VM\_Maintenance | Assignments' and a subtitle 'Maintenance Configuration'. At the top right of this area are several buttons: 'Search (Ctrl+ /)', 'Assign resource' (which is highlighted with a red box), 'Unassign resource', 'Run maintenance now', and 'Refresh'. Below these buttons, a message says 'Manage resources assigned to this maintenance configuration. You can assign new resources, see remove them from this configuration.' Underneath is a table with three columns: 'Name ↑↓', 'Type', and 'Maintenance status ↑↓'. The table currently displays 'No results.'

Select the virtual machine scale set resources that you want the maintenance configuration assigned to and select **Ok**.

# Maintenance control for OS image upgrades on Azure virtual machine scale sets using an ARM template

9/21/2022 • 2 minutes to read • [Edit Online](#)

Maintenance control lets you decide when to apply automatic OS image upgrades to your virtual machine scale sets. For more information on using Maintenance control, see [Maintenance control for Azure virtual machine scale sets](#).

This article explains how you can use an Azure Resource Manager (ARM) template to create a maintenance configuration. You will learn how to:

- Create the configuration
- Assign the configuration to a virtual machine

An [ARM template](#) is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

## Create the configuration

While creating the configuration, it is important to note that there are different scopes and each will have unique properties in their creation template. Make sure you are using the right one.

For more information about this Maintenance Configuration template, see [maintenanceConfigurations](#).

### Host and OS image

```
{  
    "type": "Microsoft.Maintenance/maintenanceConfigurations",  
    "apiVersion": "2021-09-01-preview",  
    "name": "string",  
    "location": "string",  
    "tags": {  
        "tagName1": "tagValue1",  
        "tagName2": "tagValue2"  
    },  
    "properties": {  
        "extensionProperties": {},  
        "installPatches": {  
            "linuxParameters": {  
                "classificationsToInclude": [ "string" ],  
                "packageNameMasksToExclude": [ "string" ],  
                "packageNameMasksToInclude": [ "string" ]  
            },  
            "rebootSetting": "string",  
            "tasks": {  
                "postTasks": [  
                    {  
                        "parameters": {},  
                        "source": "string",  
                        "taskScope": "string"  
                    }  
                ],  
                "preTasks": [  
                    {  
                        "parameters": {},  
                        "source": "string",  
                        "taskScope": "string"  
                    }  
                ]  
            },  
            "windowsParameters": {  
                "classificationsToInclude": [ "string" ],  
                "excludeKbsRequiringReboot": "bool",  
                "kbNumbersToExclude": [ "string" ],  
                "kbNumbersToInclude": [ "string" ]  
            }  
        },

# Automatic VM guest patching for Azure VMs

9/21/2022 • 15 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

Enabling automatic VM guest patching for your Azure VMs helps ease update management by safely and automatically patching virtual machines to maintain security compliance.

Automatic VM guest patching has the following characteristics:

- Patches classified as *Critical* or *Security* are automatically downloaded and applied on the VM.
- Patches are applied during off-peak hours in the VM's time zone.
- Patch orchestration is managed by Azure and patches are applied following [availability-first principles](#).
- Virtual machine health, as determined through platform health signals, is monitored to detect patching failures.
- Works for all VM sizes.

## How does automatic VM guest patching work?

If automatic VM guest patching is enabled on a VM, then the available *Critical* and *Security* patches are downloaded and applied automatically on the VM. This process kicks off automatically every month when new patches are released. Patch assessment and installation are automatic, and the process includes rebooting the VM as required.

The VM is assessed periodically every few days and multiple times within any 30-day period to determine the applicable patches for that VM. The patches can be installed any day on the VM during off-peak hours for the VM. This automatic assessment ensures that any missing patches are discovered at the earliest possible opportunity.

Patches are installed within 30 days of the monthly patch releases, following availability-first orchestration described below. Patches are installed only during off-peak hours for the VM, depending on the time zone of the VM. The VM must be running during the off-peak hours for patches to be automatically installed. If a VM is powered off during a periodic assessment, the VM will be automatically assessed and applicable patches will be installed automatically during the next periodic assessment (usually within a few days) when the VM is powered on.

Definition updates and other patches not classified as *Critical* or *Security* will not be installed through automatic VM guest patching. To install patches with other patch classifications or schedule patch installation within your own custom maintenance window, you can use [Update Management](#).

### Availability-first Updates

The patch installation process is orchestrated globally by Azure for all VMs that have automatic VM guest patching enabled. This orchestration follows availability-first principles across different levels of availability provided by Azure.

For a group of virtual machines undergoing an update, the Azure platform will orchestrate updates:

#### Across regions:

- A monthly update is orchestrated across Azure globally in a phased manner to prevent global deployment failures.
- A phase can have one or more regions, and an update moves to the next phases only if eligible VMs in a

phase update successfully.

- Geo-paired regions are not updated concurrently and can't be in the same regional phase.
- The success of an update is measured by tracking the VM's health post update. VM Health is tracked through platform health indicators for the VM.

#### Within a region:

- VMs in different Availability Zones are not updated concurrently with the same update.
- VMs that are not part of an availability set are batched on a best effort basis to avoid concurrent updates for all VMs in a subscription.

#### Within an availability set:

- All VMs in a common availability set are not updated concurrently.
- VMs in a common availability set are updated within Update Domain boundaries and VMs across multiple Update Domains are not updated concurrently.

The patch installation date for a given VM may vary month-to-month, as a specific VM may be picked up in a different batch between monthly patching cycles.

#### Which patches are installed?

The patches installed depend on the rollout stage for the VM. Every month, a new global rollout is started where all security and critical patches assessed for an individual VM are installed for that VM. The rollout is orchestrated across all Azure regions in batches (described in the availability-first patching section above).

The exact set of patches to be installed vary based on the VM configuration, including OS type, and assessment timing. It is possible for two identical VMs in different regions to get different patches installed if there are more or less patches available when the patch orchestration reaches different regions at different times. Similarly, but less frequently, VMs within the same region but assessed at different times (due to different Availability Zone or Availability Set batches) might get different patches.

As the Automatic VM Guest Patching does not configure the patch source, two similar VMs configured to different patch sources, such as public repository vs private repository, may also see a difference in the exact set of patches installed.

For OS types that release patches on a fixed cadence, VMs configured to the public repository for the OS can expect to receive the same set of patches across the different rollout phases in a month. For example, Windows VMs configured to the public Windows Update repository.

As a new rollout is triggered every month, a VM will receive at least one patch rollout every month if the VM is powered on during off-peak hours. This process ensures that the VM is patched with the latest available security and critical patches on a monthly basis. To ensure consistency in the set of patches installed, you can configure your VMs to assess and download patches from your own private repositories.

## Supported OS images

#### IMPORTANT

Automatic VM guest patching, on-demand patch assessment and on-demand patch installation are supported only on VMs created from images with the exact combination of publisher, offer and sku from the below supported OS images list. Custom images or any other publisher, offer, sku combinations are not supported. More images are added periodically.

## Patch orchestration modes

VMs on Azure now support the following patch orchestration modes:

### **AutomaticByPlatform (Azure-orchestrated patching):**

- This mode is supported for both Linux and Windows VMs.
- This mode enables automatic VM guest patching for the virtual machine and subsequent patch installation is orchestrated by Azure.
- This mode is required for availability-first patching.
- This mode is only supported for VMs that are created using the supported OS platform images above.

- For Windows VMs, setting this mode also disables the native Automatic Updates on the Windows virtual machine to avoid duplication.
- To use this mode on Linux VMs, set the property `osProfile.linuxConfiguration.patchSettings.patchMode=AutomaticByPlatform` in the VM template.
- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByPlatform` in the VM template.

#### AutomaticByOS:

- This mode is supported only for Windows VMs.
- This mode enables Automatic Updates on the Windows virtual machine, and patches are installed on the VM through Automatic Updates.
- This mode does not support availability-first patching.
- This mode is set by default if no other patch mode is specified for a Windows VM.
- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.enableAutomaticUpdates=true`, and set the property `osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByOS` in the VM template.

#### Manual:

- This mode is supported only for Windows VMs.
- This mode disables Automatic Updates on the Windows virtual machine. When deploying a VM using CLI or PowerShell, setting `--enable-auto-updates` to `false` will also set `patchMode` to `manual` and will disable Automatic Updates.
- This mode does not support availability-first patching.
- This mode should be set when using custom patching solutions.
- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.enableAutomaticUpdates=false`, and set the property `osProfile.windowsConfiguration.patchSettings.patchMode=Manual` in the VM template.

#### ImageDefault:

- This mode is supported only for Linux VMs.
- This mode does not support availability-first patching.
- This mode honors the default patching configuration in the image used to create the VM.
- This mode is set by default if no other patch mode is specified for a Linux VM.
- To use this mode on Linux VMs, set the property `osProfile.linuxConfiguration.patchSettings.patchMode=ImageDefault` in the VM template.

#### NOTE

For Windows VMs, the property `osProfile.windowsConfiguration.enableAutomaticUpdates` can only be set when the VM is first created. This impacts certain patch mode transitions. Switching between AutomaticByPlatform and Manual modes is supported on VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=false`. Similarly switching between AutomaticByPlatform and AutomaticByOS modes is supported on VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=true`. Switching between AutomaticByOS and Manual modes is not supported.

## Requirements for enabling automatic VM guest patching

- The virtual machine must have the Azure VM Agent for [Windows](#) or [Linux](#) installed.
- For Linux VMs, the Azure Linux agent must be version 2.2.53.1 or higher. [Update the Linux agent](#) if the

current version is lower than the required version.

- For Windows VMs, the Windows Update service must be running on the virtual machine.
- The virtual machine must be able to access the configured update endpoints. If your virtual machine is configured to use private repositories for Linux or Windows Server Update Services (WSUS) for Windows VMs, the relevant update endpoints must be accessible.
- Use Compute API version 2021-03-01 or higher to access all functionality including on-demand assessment and on-demand patching.
- Custom images are not currently supported.

## Enable automatic VM guest patching

Automatic VM guest patching can be enabled on any Windows or Linux VM that is created from a supported platform image. To enable automatic VM guest patching on a Windows VM, ensure that the property `osProfile.windowsConfiguration.enableAutomaticUpdates` is set to `true` in the VM template definition. This property can only be set when creating the VM. This additional property is not applicable for Linux VMs.

### REST API for Linux VMs

The following example describes how to enable automatic VM guest patching:

```
PUT on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/m  
yVirtualMachine?api-version=2020-12-01`
```

```
{  
    "location": "<location>",  
    "properties": {  
        "osProfile": {  
            "linuxConfiguration": {  
                "provisionVMAgent": true,  
                "patchSettings": {  
                    "patchMode": "AutomaticByPlatform"  
                }  
            }  
        }  
    }  
}
```

### REST API for Windows VMs

The following example describes how to enable automatic VM guest patching:

```
PUT on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/m  
yVirtualMachine?api-version=2020-12-01`
```

```
{  
  "location": "<location>",  
  "properties": {  
    "osProfile": {  
      "windowsConfiguration": {  
        "provisionVMAgent": true,  
        "enableAutomaticUpdates": true,  
        "patchSettings": {  
          "patchMode": "AutomaticByPlatform"  
        }  
      }  
    }  
  }  
}
```

## Azure PowerShell for Windows VMs

Use the [Set-AzVMOperatingSystem](#) cmdlet to enable automatic VM guest patching when creating or updating a VM.

```
Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -ComputerName $ComputerName -Credential $Credential -  
ProvisionVMAgent -EnableAutoUpdate -PatchMode "AutomaticByPlatform"
```

## Azure CLI for Windows VMs

Use [az vm create](#) to enable automatic VM guest patching when creating a new VM. The following example configures automatic VM guest patching for a VM named *myVM* in the resource group named *myResourceGroup*.

```
az vm create --resource-group myResourceGroup --name myVM --image Win2019Datacenter --enable-agent --enable-  
auto-update --patch-mode AutomaticByPlatform
```

To modify an existing VM, use [az vm update](#)

```
az vm update --resource-group myResourceGroup --name myVM --set  
osProfile.windowsConfiguration.enableAutomaticUpdates=true  
osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByPlatform
```

## Azure portal

When creating a VM using the Azure portal, patch orchestration modes can be set under the **Management** tab for both Linux and Windows.

Auto-shutdown

Enable auto-shutdown

Shutdown time

Time zone

Notification before shutdown

Email \*

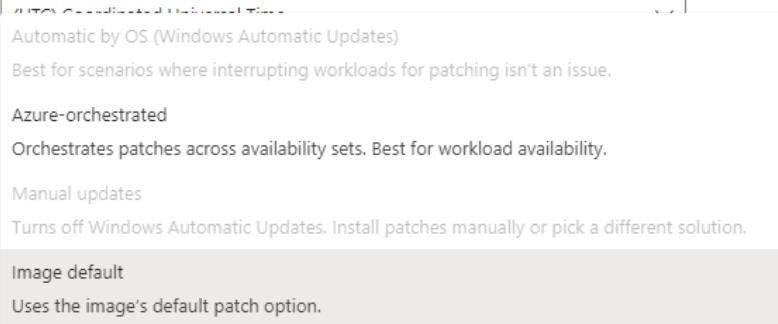

**Backup**

Enable backup

**Guest OS updates**

Patch orchestration options

Some patch orchestration options are not available for this image. [Learn more](#)

[Review + create](#)

[< Previous](#)

[Next : Advanced >](#)

## Enablement and assessment

### NOTE

It can take more than three hours to enable automatic VM guest updates on a VM, as the enablement is completed during the VM's off-peak hours. As assessment and patch installation occur only during off-peak hours, your VM must be also be running during off-peak hours to apply patches.

When automatic VM guest patching is enabled for a VM, a VM extension of type

`Microsoft.CPlat.Core.LinuxPatchExtension` is installed on a Linux VM or a VM extension of type

`Microsoft.CPlat.Core.WindowsPatchExtension` is installed on a Windows VM. This extension does not need to be manually installed or updated, as this extension is managed by the Azure platform as part of the automatic VM guest patching process.

It can take more than three hours to enable automatic VM guest updates on a VM, as the enablement is completed during the VM's off-peak hours. The extension is also installed and updated during off-peak hours for the VM. If the VM's off-peak hours end before enablement can be completed, the enablement process will resume during the next available off-peak time.

Automatic updates are disabled in most scenarios, and patch installation is done through the extension going forward. The following conditions apply.

- If a Windows VM previously had Automatic Windows Update turned on through the AutomaticByOS patch mode, then Automatic Windows Update is turned off for the VM when the extension is installed.
- For Ubuntu VMs, the default automatic updates are disabled automatically when Automatic VM Guest Patching completes enablement.
- For RHEL, automatic updates need to be manually disabled. Execute:

```
systemctl stop packagekit
```

```
systemctl mask packagekit
```

To verify whether automatic VM guest patching has completed and the patching extension is installed on the

VM, you can review the VM's instance view. If the enablement process is complete, the extension will be installed and the assessment results for the VM will be available under `patchStatus`. The VM's instance view can be accessed through multiple ways as described below.

## REST API

```
GET on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/m  
yVirtualMachine/instanceView?api-version=2020-12-01`
```

## Azure PowerShell

Use the [Get-AzVM](#) cmdlet with the `-Status` parameter to access the instance view for your VM.

```
Get-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM" -Status
```

PowerShell currently only provides information on the patch extension. Information about `patchStatus` will also be available soon through PowerShell.

## Azure CLI

Use [az vm get-instance-view](#) to access the instance view for your VM.

```
az vm get-instance-view --resource-group myResourceGroup --name myVM
```

## Understanding the patch status for your VM

The `patchStatus` section of the instance view response provides details on the latest assessment and the last patch installation for your VM.

The assessment results for your VM can be reviewed under the `availablePatchSummary` section. An assessment is periodically conducted for a VM that has automatic VM guest patching enabled. The count of available patches after an assessment is provided under `criticalAndSecurityPatchCount` and `otherPatchCount` results. Automatic VM guest patching will install all patches assessed under the *Critical* and *Security* patch classifications. Any other assessed patch is skipped.

The patch installation results for your VM can be reviewed under the `lastPatchInstallationSummary` section. This section provides details on the last patch installation attempt on the VM, including the number of patches that were installed, pending, failed or skipped. Patches are installed only during the off-peak hours maintenance window for the VM. Pending and failed patches are automatically retried during the next off-peak hours maintenance window.

## Disable automatic VM guest patching

Automatic VM guest patching can be disabled by changing the [patch orchestration mode](#) for the VM.

To disable automatic VM guest patching on a Linux VM, change the patch mode to `ImageDefault`.

To enable automatic VM guest patching on a Windows VM, the property `osProfile.windowsConfiguration.enableAutomaticUpdates` determines which patch modes can be set on the VM and this property can only be set when the VM is first created. This impacts certain patch mode transitions:

- For VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=false`, disable automatic VM guest patching by changing the patch mode to `Manual`.
- For VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=true`, disable automatic VM guest patching by changing the patch mode to `AutomaticByOS`.

- Switching between AutomaticByOS and Manual modes is not supported.

Use the examples from the [enablement](#) section above in this article for API, PowerShell and CLI usage examples to set the required patch mode.

## On-demand patch assessment

If automatic VM guest patching is already enabled for your VM, a periodic patch assessment is performed on the VM during the VM's off-peak hours. This process is automatic and the results of the latest assessment can be reviewed through the VM's instance view as described earlier in this document. You can also trigger an on-demand patch assessment for your VM at any time. Patch assessment can take a few minutes to complete and the status of the latest assessment is updated on the VM's instance view.

### NOTE

On-demand patch assessment does not automatically trigger patch installation. If you have enabled automatic VM guest patching then the assessed and applicable patches for the VM will be installed during the VM's off-peak hours, following the availability-first patching process described earlier in this document.

### REST API

Use the [Assess Patches](#) API to assess available patches for your virtual machine.

```
POST on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/m  
yVirtualMachine/assessPatches?api-version=2020-12-01`
```

### Azure PowerShell

Use the [Invoke-AzVmPatchAssessment](#) cmdlet to assess available patches for your virtual machine.

```
Invoke-AzVmPatchAssessment -ResourceGroupName "myResourceGroup" -VMName "myVM"
```

### Azure CLI

Use [az vm assess-patches](#) to assess available patches for your virtual machine.

```
az vm assess-patches --resource-group myResourceGroup --name myVM
```

## On-demand patch installation

If automatic VM guest patching is already enabled for your VM, a periodic patch installation of Security and Critical patches is performed on the VM during the VM's off-peak hours. This process is automatic and the results of the latest installation can be reviewed through the VM's instance view as described earlier in this document.

You can also trigger an on-demand patch installation for your VM at any time. Patch installation can take a few minutes to complete and the status of the latest installation is updated on the VM's instance view.

You can use on-demand patch installation to install all patches of one or more patch classifications. You can also choose to include or exclude specific packages for Linux or specific KB IDs for Windows. When triggering an on-demand patch installation, ensure that you specify at least one patch classification or at least one patch (package for Linux, KB ID for Windows) in the inclusion list.

### REST API

Use the [Install Patches](#) API to install patches on your virtual machine.

```
POST on  
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/mVirtualMachine/installPatches?api-version=2020-12-01`
```

Example request body for Linux:

```
{  
    "maximumDuration": "PT1H",  
    "rebootSetting": "IfRequired",  
    "linuxParameters": {  
        "classificationsToInclude": [  
            "Critical",  
            "Security"  
        ]  
    }  
}
```

Example request body for Windows:

```
{  
    "maximumDuration": "PT1H",  
    "rebootSetting": "IfRequired",  
    "windowsParameters": {  
        "classificationsToInclude": [  
            "Critical",  
            "Security"  
        ]  
    }  
}
```

## Azure PowerShell

Use the [Invoke-AzVmInstallPatch](#) cmdlet to install patches on your virtual machine.

Example to install certain packages on a Linux VM:

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -MaximumDuration "PT90M" -  
RebootSetting "Always" -Linux -ClassificationToIncludeForLinux "Security" -PackageNameMaskToInclude  
["package123"] -PackageNameMaskToExclude ["package567"]
```

Example to install all Critical patches on a Windows VM:

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -MaximumDuration "PT2H" -  
RebootSetting "Never" -Windows -ClassificationToIncludeForWindows Critical
```

Example to install all Security patches on a Windows VM, while including and excluding patches with specific KB IDs and excluding any patch that requires a reboot:

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -MaximumDuration "PT90M" -  
RebootSetting "Always" -Windows -ClassificationToIncludeForWindows "Security" -KBNumberToInclude  
["KB1234567", "KB123567"] -KBNumberToExclude ["KB1234702", "KB1234802"] -ExcludeKBsRequiringReboot
```

## Azure CLI

Use [az vm install-patches](#) to install patches on your virtual machine.

Example to install all Critical patches on a Linux VM:

```
az vm install-patches --resource-group myResourceGroup --name myVM --maximum-duration PT2H --reboot-setting IfRequired --classifications-to-include-linux Critical
```

Example to install all Critical and Security patches on a Windows VM, while excluding any patch that requires a reboot:

```
az vm install-patches --resource-group myResourceGroup --name myVM --maximum-duration PT2H --reboot-setting IfRequired --classifications-to-include-win Critical Security --exclude-kbs-requiring-reboot true
```

## Next steps

[Learn more about creating and managing Windows virtual machines](#)

# Hotpatch for new virtual machines

9/21/2022 • 8 minutes to read • [Edit Online](#)

## IMPORTANT

Hotpatch is supported on *Windows Server 2022 Datacenter: Azure Edition (Server Core)*.

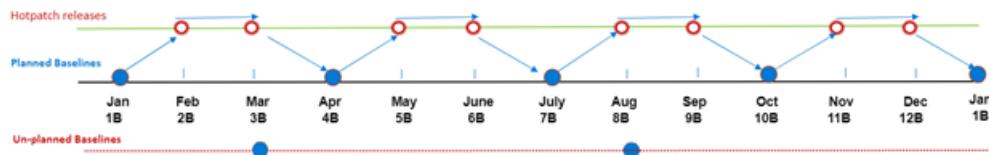

Hotpatching is a new way to install updates on supported *Windows Server Azure Edition* virtual machines (VMs) that doesn't require a reboot after installation. This article covers information about Hotpatch for supported *Windows Server Azure Edition* VMs, which has the following benefits:

- Lower workload impact with less reboots
- Faster deployment of updates as the packages are smaller, install faster, and have easier patch orchestration with Azure Update Manager
- Better protection, as the Hotpatch update packages are scoped to Windows security updates that install faster without rebooting

## How hotpatch works

Hotpatch works by first establishing a baseline with a Windows Update Latest Cumulative Update. Hotpatches are periodically released (for example, on the second Tuesday of the month) that build on that baseline.

Hotpatches will contain updates that don't require a reboot. Periodically (starting at every three months), the baseline is refreshed with a new Latest Cumulative Update.

There are two types of baselines: **Planned baselines** and **unplanned baselines**.

- **Planned baselines** are released on a regular cadence, with hotpatch releases in between. Planned baselines include all the updates in a comparable *Latest Cumulative Update* for that month, and require a reboot.
  - The sample schedule above illustrates four planned baseline releases in a calendar year (five total in the diagram), and eight hotpatch releases.
- **Unplanned baselines** are released when an important update (such as a zero-day fix) is released, and that particular update can't be released as a Hotpatch. When unplanned baselines are released, a hotpatch release will be replaced with an unplanned baseline in that month. Unplanned baselines also include all the updates in a comparable *Latest Cumulative Update* for that month, and also require a reboot.
  - The sample schedule above illustrates two unplanned baselines that would replace the hotpatch releases for those months (the actual number of unplanned baselines in a year isn't known in advance).

## Regional availability

Hotpatch is available in all global Azure regions.

## How to get started

#### NOTE

You can preview onboarding Automanage machine best practices during VM creation in the Azure portal using [this link](#).

To start using Hotpatch on a new VM, follow these steps:

1. Start creating a new VM from the Azure portal

- You can preview onboarding Automanage machine best practices during VM creation in the Azure portal using [this link](#).

2. Supply details during VM creation

- Ensure that a supported *Windows Server Azure Edition* image is selected in the Image dropdown. Use [this guide](#) to determine which images are supported.
- On the Management tab under section 'Guest OS updates', the checkbox for 'Enable hotpatch' will be selected. Patch orchestration options will be set to 'Azure-orchestrated'.
- If you create a VM using [this link](#), on the Management tab under section 'Azure Automanage', select 'Dev/Test' or 'Production' for 'Azure Automanage environment' to evaluate Automanage machine best practices while in preview.

3. Create your new VM

## Patch installation

[Automatic VM Guest Patching](#) is enabled automatically for all VMs created with a supported *Windows Server Azure Edition* image. With automatic VM guest patching enabled:

- Patches classified as Critical or Security are automatically downloaded and applied on the VM.
- Patches are applied during off-peak hours in the VM's time zone.
- Patch orchestration is managed by Azure and patches are applied following [availability-first principles](#).
- Virtual machine health, as determined through platform health signals, is monitored to detect patching failures.

## How does automatic VM guest patching work?

When [Automatic VM Guest Patching](#) is enabled on a VM, the available Critical and Security patches are downloaded and applied automatically. This process kicks off automatically every month when new patches are released. Patch assessment and installation are automatic, and the process includes rebooting the VM as required.

With Hotpatch enabled on supported *Windows Server Azure Edition* VMs, most monthly security updates are delivered as hotpatches that don't require reboots. Latest Cumulative Updates sent on planned or unplanned baseline months will require VM reboots. Additional Critical or Security patches may also be available periodically which may require VM reboots.

The VM is assessed automatically every few days and multiple times within any 30-day period to determine the applicable patches for that VM. This automatic assessment ensures that any missing patches are discovered at the earliest possible opportunity.

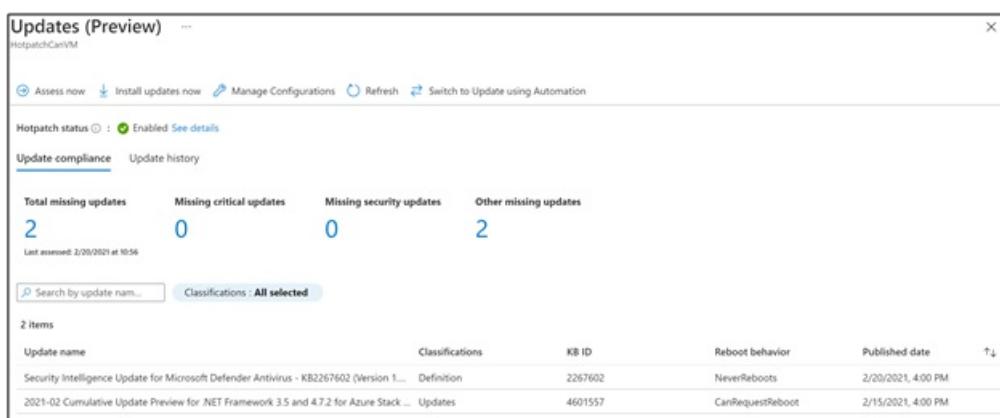

Patches are installed within 30 days of the monthly patch releases, following [availability-first principles](#). Patches are installed only during off-peak hours for the VM, depending on the time zone of the VM. The VM must be running during the off-peak hours for patches to be automatically installed. If a VM is powered off during a periodic assessment, the VM will be assessed and applicable patches will be installed automatically during the next periodic assessment when the VM is powered on. The next periodic assessment usually happens within a few days.

Definition updates and other patches not classified as Critical or Security won't be installed through automatic VM guest patching.

## Understanding the patch status for your VM

To view the patch status for your VM, navigate to the **Guest + host updates** section for your VM in the Azure portal. Under the **Guest OS updates** section, click on 'Go to Hotpatch (Preview)' to view the latest patch status for your VM.

On this screen, you'll see the Hotpatch status for your VM. You can also review if there are any available patches for your VM that haven't been installed. As described in the 'Patch installation' section above, all security and critical updates will be automatically installed on your VM using [Automatic VM Guest Patching](#) and no extra actions are required. Patches with other update classifications aren't automatically installed. Instead, they're viewable in the list of available patches under the 'Update compliance' tab. You can also view the history of update deployments on your VM through the 'Update history'. Update history from the past 30 days is displayed, along with patch installation details.

The screenshot shows the 'Updates (Preview)' window for a VM named 'HotpatchCanVM'. At the top, there are buttons for 'Assess now', 'Install updates now', 'Manage Configurations', 'Refresh', and 'Switch to Update using Automation'. Below this, the 'Hotpatch status' is shown as 'Enabled' with a green checkmark and a 'See details' link. There are two tabs: 'Update compliance' (selected) and 'Update history'. Under 'Update compliance', it shows 'Total missing updates' as 2, with breakdowns: 'Missing critical updates' (0), 'Missing security updates' (0), and 'Other missing updates' (2). The last assessment was on 2/20/2021 at 10:56. A search bar and a classification filter ('All selected') are present. The 'Update history' section shows 2 items:

Update name	Classifications	KB ID	Reboot behavior	Published date
Security Intelligence Update for Microsoft Defender Antivirus - KB2267602 (Version 1...)	Definition	2267602	NeverReboots	2/20/2021, 4:00 PM
2021-02 Cumulative Update Preview for .NET Framework 3.5 and 4.7.2 for Azure Stack ...	Updates	4601557	CanRequestReboot	2/15/2021, 4:00 PM

With automatic VM guest patching, your VM is periodically and automatically assessed for available updates. These periodic assessments ensure that available patches are detected. You can view the results of the assessment on the Updates screen above, including the time of the last assessment. You can also choose to trigger an on-demand patch assessment for your VM at any time using the 'Assess now' option and review the results after assessment completes.

Similar to on-demand assessment, you can also install patches on-demand for your VM using the 'Install updates now' option. Here you can choose to install all updates under specific patch classifications. You can also specify updates to include or exclude by providing a list of individual knowledge base articles. Patches installed on-demand aren't installed using availability-first principles and may require more reboots and VM downtime for update installation.

## Supported updates

Hotpatch covers Windows Security updates and maintains parity with the content of security updates issued to in the regular (non-Hotpatch) Windows update channel.

There are some important considerations to running a supported *Windows Server Azure Edition* VM with Hotpatch enabled. Reboots are still required to install updates that aren't included in the Hotpatch program. Reboots are also required periodically after a new baseline has been installed. These reboots keep the VM in sync with non-security patches included in the latest cumulative update.

- Patches that are currently not included in the Hotpatch program include non-security updates released for Windows, and non-Windows updates (such as .NET patches). These types of patches need to be installed during a baseline month, and will require a reboot.

# Frequently asked questions

## What is hotpatching?

- Hotpatching is a new way to install updates on a supported *Windows Server Azure Edition* VM in Azure that doesn't require a reboot after installation. It works by patching the in-memory code of running processes without the need to restart the process.

## How does hotpatching work?

- Hotpatching works by establishing a baseline with a Windows Update Latest Cumulative Update, then builds upon that baseline with updates that don't require a reboot to take effect. The baseline is updated periodically with a new cumulative update. The cumulative update includes all security and quality updates and requires a reboot.

## Why should I use Hotpatch?

- When you use Hotpatch on a supported *Windows Server Azure Edition* image, your VM will have higher availability (fewer reboots), and faster updates (smaller packages that are installed faster without the need to restart processes). This process results in a VM that is always up to date and secure.

## What types of updates are covered by Hotpatch?

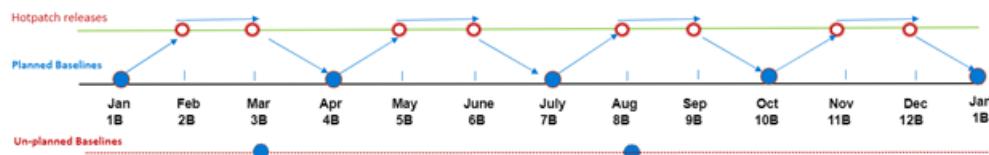

- Hotpatch currently covers Windows security updates.

## When will I receive the first Hotpatch update?

- Hotpatch updates are typically released on the second Tuesday of each month. For more information, see below.

## What will the Hotpatch schedule look like?

- Hotpatching works by establishing a baseline with a Windows Update Latest Cumulative Update, then builds upon that baseline with Hotpatch updates released monthly. Baselines will be released starting out every three months. See the image below for an example of an annual three-month schedule (including example unplanned baselines due to zero-day fixes).

## Are reboots still needed for a VM enrolled in Hotpatch?

- Reboots are still required to install updates not included in the Hotpatch program, and are required periodically after a baseline (Windows Update Latest Cumulative Update) has been installed. This reboot will keep your VM in sync with all the patches included in the cumulative update. Baselines (which require a reboot) will start out on a three-month cadence and increase over time.

## Are my applications affected when a Hotpatch update is installed?

- Because Hotpatch patches the in-memory code of running processes without the need to restart the process, your applications will be unaffected by the patching process. Note that this is separate from any potential performance and functionality implications of the patch itself.

## Can I turn off Hotpatch on my VM?

- You can turn off Hotpatch on a VM via the Azure portal. Turning off Hotpatch will unenroll the VM from Hotpatch, which reverts the VM to typical update behavior for Windows Server. Once you unenroll from Hotpatch on a VM, you can re-enroll that VM when the next Hotpatch baseline is released.

## Can I upgrade from my existing Windows Server OS?

- Yes, upgrading from existing versions of Windows Server (such as Windows Server 2016 or Windows Server

2019) to *Windows Server 2022 Datacenter: Azure Edition* is supported.

### How can I get troubleshooting support for Hotpatching?

- You can file a [technical support case ticket](#). For the Service option, search for and select **Virtual Machine running Windows** under Compute. Select **Azure Features** for the problem type and **Automatic VM Guest Patching** for the problem subtype.

# Automatic Extension Upgrade for VMs and Scale Sets in Azure

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Automatic Extension Upgrade is available for Azure VMs and Azure Virtual Machine Scale Sets. When Automatic Extension Upgrade is enabled on a VM or scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that extension.

Automatic Extension Upgrade has the following features:

- Supported for Azure VMs and Azure Virtual Machine Scale Sets.
- Upgrades are applied in an availability-first deployment model (detailed below).
- For a Virtual Machine Scale Set, no more than 20% of the scale set virtual machines will be upgraded in a single batch. The minimum batch size is one virtual machine.
- Works for all VM sizes, and for both Windows and Linux extensions.
- You can opt out of automatic upgrades at any time.
- Automatic extension upgrade can be enabled on a Virtual Machine Scale Sets of any size.
- Each supported extension is enrolled individually, and you can choose which extensions to upgrade automatically.
- Supported in all public cloud regions.

## How does Automatic Extension Upgrade work?

The extension upgrade process replaces the existing extension version on a VM with a new version of the same extension when published by the extension publisher. The health of the VM is monitored after the new extension is installed. If the VM is not in a healthy state within 5 minutes of the upgrade completion, the extension version is rolled back to the previous version.

A failed extension update is automatically retried. A retry is attempted every few days automatically without user intervention.

### Availability-first Updates

The availability-first model for platform orchestrated updates ensures that availability configurations in Azure are respected across multiple availability levels.

For a group of virtual machines undergoing an update, the Azure platform will orchestrate updates:

#### Across regions:

- An update will move across Azure globally in a phased manner to prevent Azure-wide deployment failures.
- A 'phase' can have one or more regions, and an update moves across phases only if eligible VMs in the previous phase update successfully.
- Geo-paired regions will not be updated concurrently and cannot be in the same regional phase.
- The success of an update is measured by tracking the health of a VM post update. VM health is tracked through platform health indicators for the VM. For Virtual Machine Scale Sets, the VM health is tracked through application health probes or the Application Health extension, if applied to the scale set.

#### Within a region:

- VMs in different Availability Zones are not updated concurrently with the same update.
- Single VMs that are not part of an availability set are batched on a best effort basis to avoid concurrent updates for all VMs in a subscription.

#### Within a 'set':

- All VMs in a common availability set or scale set are not updated concurrently.
- VMs in a common availability set are updated within Update Domain boundaries and VMs across multiple Update Domains are not updated concurrently.
- VMs in a common virtual machine scale set are grouped in batches and updated within Update Domain boundaries.

#### Upgrade process for Virtual Machine Scale Sets

1. Before beginning the upgrade process, the orchestrator will ensure that no more than 20% of VMs in the entire scale set are unhealthy (for any reason).
2. The upgrade orchestrator identifies the batch of VM instances to upgrade. An upgrade batch can have a maximum of 20% of the total VM count, subject to a minimum batch size of one virtual machine.
3. For scale sets with configured application health probes or Application Health extension, the upgrade waits up to 5 minutes (or the defined health probe configuration) for the VM to become healthy before upgrading the next batch. If a VM does not recover its health after an upgrade, then by default the previous extension version on the VM is reinstalled.
4. The upgrade orchestrator also tracks the percentage of VMs that become unhealthy after an upgrade. The upgrade will stop if more than 20% of upgraded instances become unhealthy during the upgrade process.

The above process continues until all instances in the scale set have been upgraded.

The scale set upgrade orchestrator checks for the overall scale set health before upgrading every batch. While upgrading a batch, there could be other concurrent planned or unplanned maintenance activities that could impact the health of your scale set virtual machines. In such cases, if more than 20% of the scale set's instances become unhealthy, then the scale set upgrade stops at the end of current batch.

## Supported extensions

Automatic Extension Upgrade supports the following extensions (and more are added periodically):

- Dependency Agent – [Linux](#) and [Windows](#)
- [Application Health Extension](#) – Linux and Windows
- [Guest Configuration Extension](#) – Linux and Windows
- Key Vault – [Linux](#) and [Windows](#)
- [Azure Monitor Agent](#)
- [DSC extension for Linux](#)

## Enabling Automatic Extension Upgrade

To enable Automatic Extension Upgrade for an extension, you must ensure the property `enableAutomaticUpgrade` is set to `true` and added to every extension definition individually.

#### REST API for Virtual Machines

To enable automatic extension upgrade for an extension (in this example the Dependency Agent extension) on an Azure VM, use the following:

```
PUT on  
`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachi  
nes/<vmName>/extensions/<extensionName>?api-version=2019-12-01`
```

```
{  
    "name": "extensionName",  
    "type": "Microsoft.Compute/virtualMachines/extensions",  
    "location": "<location>",  
    "properties": {  
        "autoUpgradeMinorVersion": true,  
        "enableAutomaticUpgrade": true,  
        "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",  
        "type": "DependencyAgentWindows",  
        "typeHandlerVersion": "9.5"  
    }  
}
```

## REST API for Virtual Machine Scale Sets

Use the following to add the extension to the scale set model:

```
PUT on  
`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachi  
neScaleSets/<vmssName>?api-version=2019-12-01`
```

```
{  
    "location": "<location>",  
    "properties": {  
        "virtualMachineProfile": {  
            "extensionProfile": {  
                "extensions": [  
                    {  
                        "name": "<extensionName>",  
                        "properties": {  
                            "autoUpgradeMinorVersion": true,  
                            "enableAutomaticUpgrade": true,  
                            "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",  
                            "type": "DependencyAgentWindows",  
                            "typeHandlerVersion": "9.5"  
                        }  
                    }  
                ]  
            }  
        }  
    }  
}
```

## Azure PowerShell for Virtual Machines

Use the [Set-AzVMExtension](#) cmdlet:

```
Set-AzVMExtension -ExtensionName "Microsoft.Azure.Monitoring.DependencyAgent" `  
    -ResourceGroupName "myResourceGroup" `  
    -VMName "myVM" `  
    -Publisher "Microsoft.Azure.Monitoring.DependencyAgent" `  
    -ExtensionType "DependencyAgentWindows" `  
    -TypeHandlerVersion 9.5 `  
    -Location WestUS `  
    -EnableAutomaticUpgrade $true
```

## Azure PowerShell for Virtual Machine Scale Sets

Use the [Add-AzVmssExtension](#) cmdlet to add the extension to the scale set model:

```
Add-AzVmssExtension -VirtualMachineScaleSet $vmss  
-Name "Microsoft.Azure.Monitoring.DependencyAgent"  
-Publisher "Microsoft.Azure.Monitoring.DependencyAgent"  
-Type "DependencyAgentWindows"  
-TypeHandlerVersion 9.5  
-EnableAutomaticUpgrade $true
```

Update the scale set using [Update-AzVmss](#) after adding the extension.

## Azure CLI for Virtual Machines

Use the [az vm extension set](#) cmdlet:

```
az vm extension set \  
--resource-group myResourceGroup \  
--vm-name myVM \  
--name DependencyAgentLinux \  
--publisher Microsoft.Azure.Monitoring.DependencyAgent \  
--version 9.5 \  
--enable-auto-upgrade true
```

## Azure CLI for Virtual Machine Scale Sets

Use the [az vmss extension set](#) cmdlet to add the extension to the scale set model:

```
az vmss extension set \  
--resource-group myResourceGroup \  
--vmss-name myVMSS \  
--name DependencyAgentLinux \  
--publisher Microsoft.Azure.Monitoring.DependencyAgent \  
--version 9.5 \  
--enable-auto-upgrade true
```

## Extension upgrades with multiple extensions

A VM or Virtual Machine Scale Set can have multiple extensions with automatic extension upgrade enabled. The same VM or scale set can also have other extensions without automatic extension upgrade enabled.

If multiple extension upgrades are available for a virtual machine, the upgrades may be batched together, but each extension upgrade is applied individually on a virtual machine. A failure on one extension does not impact the other extension(s) that may be upgrading. For example, if two extensions are scheduled for an upgrade, and the first extension upgrade fails, the second extension will still be upgraded.

Automatic Extension Upgrades can also be applied when a VM or virtual machine scale set has multiple extensions configured with [extension sequencing](#). Extension sequencing is applicable for the first-time deployment of the VM, and any future extension upgrades on an extension are applied independently.

# Update Management overview

9/21/2022 • 12 minutes to read • [Edit Online](#)

You can use Update Management in Azure Automation to manage operating system updates for your Windows and Linux virtual machines in Azure, physical or VMs in on-premises environments, and in other cloud environments. You can quickly assess the status of available updates and manage the process of installing required updates for your machines reporting to Update Management.

As a service provider, you may have onboarded multiple customer tenants to [Azure Lighthouse](#). Update Management can be used to assess and schedule update deployments to machines in multiple subscriptions in the same Azure Active Directory (Azure AD) tenant, or across tenants using Azure Lighthouse.

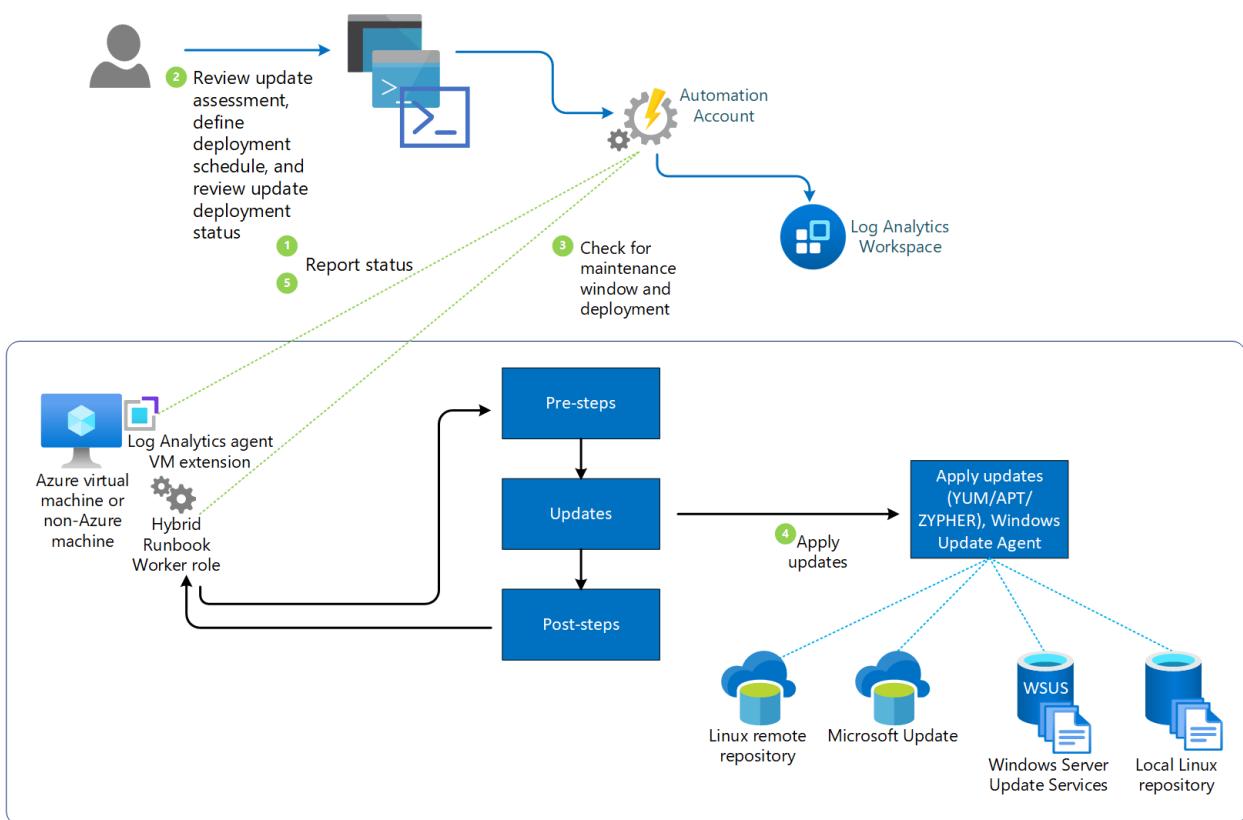

Microsoft offers other capabilities to help you manage updates for your Azure VMs or Azure virtual machine scale sets that you should consider as part of your overall update management strategy.

- If you are interested in automatically assessing and updating your Azure virtual machines to maintain security compliance with *Critical* and *Security* updates released each month, review [Automatic VM guest patching](#). This is an alternative update management solution for your Azure VMs to auto-update them during off-peak hours, including VMs within an availability set, compared to managing update deployments to those VMs from Update Management in Azure Automation.
- If you manage Azure virtual machine scale sets, review how to perform [automatic OS image upgrades](#) to safely and automatically upgrade the OS disk for all instances in the scale set.

Before deploying Update Management and enabling your machines for management, make sure that you understand the information in the following sections.

## About Update Management

The following diagram illustrates how Update Management assesses and applies security updates to all connected Windows Server and Linux servers.

Update Management integrates with Azure Monitor Logs to store update assessments and update deployment results as log data, from assigned Azure and non-Azure machines. To collect this data, the Automation Account and Log Analytics workspace are linked together, and the Log Analytics agent for Windows and Linux is required on the machine and configured to report to this workspace.

Update Management supports collecting information about system updates from agents in a System Center Operations Manager management group connected to the workspace. Having a machine registered for Update Management in more than one Log Analytics workspace (also referred to as multihoming) isn't supported.

The following table summarizes the supported connected sources with Update Management.

CONNECTED SOURCE	SUPPORTED	DESCRIPTION
Windows	Yes	<p>Update Management collects information about system updates from Windows machines with the Log Analytics agent and installation of required updates.</p> <p>Machines need to report to Microsoft Update or Windows Server Update Services (WSUS).</p>
Linux	Yes	<p>Update Management collects information about system updates from Linux machines with the Log Analytics agent and installation of required updates on supported distributions.</p> <p>Machines need to report to a local or remote repository.</p>

CONNECTED SOURCE	SUPPORTED	DESCRIPTION
Operations Manager management group	Yes	<p>Update Management collects information about software updates from agents in a connected management group.</p> <p>A direct connection from the Operations Manager agent to Azure Monitor logs isn't required. Log data is forwarded from the management group to the Log Analytics workspace.</p>

The machines assigned to Update Management report how up to date they are based on what source they are configured to synchronize with. Windows machines need to be configured to report to either [Windows Server Update Services](#) or [Microsoft Update](#), and Linux machines need to be configured to report to a local or public repository. You can also use Update Management with Microsoft Endpoint Configuration Manager, and to learn more see [Integrate Update Management with Windows Endpoint Configuration Manager](#).

If the Windows Update Agent (WUA) on the Windows machine is configured to report to WSUS, depending on when WSUS last synchronized with Microsoft Update, the results might differ from what Microsoft Update shows. This behavior is the same for Linux machines that are configured to report to a local repo instead of a public repo. On a Windows machine, the compliance scan is run every 12 hours by default. For a Linux machine, the compliance scan is performed every hour by default. If the Log Analytics agent is restarted, a compliance scan is started within 15 minutes. When a machine completes a scan for update compliance, the agent forwards the information in bulk to Azure Monitor Logs.

You can deploy and install software updates on machines that require the updates by creating a scheduled deployment. Updates classified as *Optional* aren't included in the deployment scope for Windows machines. Only required updates are included in the deployment scope.

The scheduled deployment defines which target machines receive the applicable updates. It does so either by explicitly specifying certain machines or by selecting a [computer group](#) that's based on log searches of a specific set of machines (or based on an [Azure query](#) that dynamically selects Azure VMs based on specified criteria). These groups differ from [scope configuration](#), which is used to control the targeting of machines that receive the configuration to enable Update Management. This prevents them from performing and reporting update compliance, and install approved required updates.

While defining a deployment, you also specify a schedule to approve and set a time period during which updates can be installed. This period is called the maintenance window. A 10-minute span of the maintenance window is reserved for reboots, assuming one is needed and you selected the appropriate reboot option. If patching takes longer than expected and there's less than 10 minutes in the maintenance window, a reboot won't occur.

After an update package is scheduled for deployment, it takes 2 to 3 hours for the update to show up for Linux machines for assessment. For Windows machines, it takes 12 to 15 hours for the update to show up for assessment after it's been released. Before and after update installation, a scan for update compliance is performed and the log data results is forwarded to the workspace.

Updates are installed by runbooks in Azure Automation. You can't view these runbooks, and they don't require any configuration. When an update deployment is created, it creates a schedule that starts a master update runbook at the specified time for the included machines. The master runbook starts a child runbook on each agent that initiates the installation of the required updates with the Windows Update agent on Windows, or the applicable command on supported Linux distro.

At the date and time specified in the update deployment, the target machines execute the deployment in parallel. Before installation, a scan is run to verify that the updates are still required. For WSUS client machines, if the

updates aren't approved in WSUS, update deployment fails.

## Limits

For limits that apply to Update Management, see [Azure Automation service limits](#).

## Permissions

To create and manage update deployments, you need specific permissions. To learn about these permissions, see [Role-based access - Update Management](#).

## Update Management components

Update Management uses the resources described in this section. These resources are automatically added to your Automation account when you enable Update Management.

### Hybrid Runbook Worker groups

After you enable Update Management, any Windows machine that's directly connected to your Log Analytics workspace is automatically configured as a system Hybrid Runbook Worker to support the runbooks that support Update Management.

Each Windows machine that's managed by Update Management is listed in the Hybrid worker groups pane as a System hybrid worker group for the Automation account. The groups use the `Hostname_FQDN_GUID` naming convention. You can't target these groups with runbooks in your account. If you try, the attempt fails. These groups are intended to support only Update Management. To learn more about viewing the list of Windows machines configured as a Hybrid Runbook Worker, see [view Hybrid Runbook Workers](#).

You can add the Windows machine to a user Hybrid Runbook Worker group in your Automation account to support Automation runbooks if you use the same account for Update Management and the Hybrid Runbook Worker group membership. This functionality was added in version 7.2.12024.0 of the Hybrid Runbook Worker.

### External dependencies

Azure Automation Update Management depends on the following external dependencies to deliver software updates.

- Windows Server Update Services (WSUS) or Microsoft Update is needed for software updates packages and for the software updates applicability scan on Windows-based machines.
- The Windows Update Agent (WUA) client is required on Windows-based machines so that they can connect to the WSUS server or Microsoft Update.
- A local or remote repository to retrieve and installs OS updates on Linux-based machines.

### Management packs

The following management packs are installed on the machines managed by Update Management. If your Operations Manager management group is [connected to a Log Analytics workspace](#), the management packs are installed in the Operations Manager management group. You don't need to configure or manage these management packs.

- Microsoft System Center Advisor Update Assessment Intelligence Pack  
(`Microsoft.IntelligencePacks.UpdateAssessment`)
- `Microsoft.IntelligencePack.UpdateAssessment.Configuration`  
(`Microsoft.IntelligencePack.UpdateAssessment.Configuration`)
- Update Deployment MP

#### **NOTE**

If you have an Operations Manager 1807 or 2019 management group connected to a Log Analytics workspace with agents configured in the management group to collect log data, you need to override the parameter `IsAutoRegistrationEnabled` and set it to `True` in the `Microsoft.IntelligencePacks.AzureAutomation.HybridAgent.Init` rule.

For more information about updates to management packs, see [Connect Operations Manager to Azure Monitor logs](#).

#### **NOTE**

For Update Management to fully manage machines with the Log Analytics agent, you must update to the Log Analytics agent for Windows or the Log Analytics agent for Linux. To learn how to update the agent, see [How to upgrade an Operations Manager agent](#). In environments that use Operations Manager, you must be running System Center Operations Manager 2012 R2 UR 14 or later.

## Data collection frequency

Update Management scans managed machines for data using the following rules. It can take between 30 minutes and 6 hours for the dashboard to display updated data from managed machines.

- Each Windows machine - Update Management does a scan twice per day for each machine.
- Each Linux machine - Update Management does a scan every hour.

The average data usage by Azure Monitor logs for a machine using Update Management is approximately 25 MB per month. This value is only an approximation and is subject to change, depending on your environment. We recommend that you monitor your environment to keep track of your exact usage. For more information about analyzing Azure Monitor Logs data usage, see [Azure Monitor Logs pricing details](#).

## Update classifications

The following table defines the classifications that Update Management supports for Windows updates.

CLASSIFICATION	DESCRIPTION
Critical updates	An update for a specific problem that addresses a critical, non-security-related bug.
Security updates	An update for a product-specific, security-related issue.
Update rollups	A cumulative set of hotfixes that are packaged together for easy deployment.
Feature packs	New product features that are distributed outside a product release.
Service packs	A cumulative set of hotfixes that are applied to an application.
Definition updates	An update to virus or other definition files.
Tools	A utility or feature that helps complete one or more tasks.

Classification	Description
Updates	An update to an application or file that currently is installed.

The next table defines the supported classifications for Linux updates.

Classification	Description
Critical and security updates	Updates for a specific problem or a product-specific, security-related issue.
Other updates	All other updates that aren't critical in nature or that aren't security updates.

#### NOTE

Update classification for Linux machines is only available when used in supported Azure public cloud regions. There is no classification of Linux updates when using Update Management in the following national cloud regions:

- Azure US Government
- 21Vianet in China

Instead of being classified, updates are reported under the **Other updates** category.

Update Management uses data published by the supported distributions, specifically their released [OVAL](#) (Open Vulnerability and Assessment Language) files. Because internet access is restricted from these national clouds, Update Management cannot access the files.

For Linux, Update Management can distinguish between critical updates and security updates in the cloud under classification **Security** and **Others**, while displaying assessment data due to data enrichment in the cloud. For patching, Update Management relies on classification data available on the machine. Unlike other distributions, CentOS does not have this information available in the RTM version. If you have CentOS machines configured to return security data for the following command, Update Management can patch based on classifications.

```
sudo yum -q --security check-update
```

There's currently no supported method to enable native classification-data availability on CentOS. At this time, limited support is provided to customers who might have enabled this feature on their own.

To classify updates on Red Hat Enterprise version 6, you need to install the yum-security plugin. On Red Hat Enterprise Linux 7, the plugin is already a part of yum itself and there's no need to install anything. For more information, see the following Red Hat [knowledge article](#).

When you schedule an update to run on a Linux machine, that for example is configured to install only updates matching the **Security** classification, the updates installed might be different from, or are a subset of, the updates matching this classification. When an assessment of OS updates pending for your Linux machine is performed, [Open Vulnerability and Assessment Language](#) (OVAL) files provided by the Linux distro vendor is used by Update Management for classification.

Categorization is done for Linux updates as **Security** or **Others** based on the OVAL files, which includes updates addressing security issues or vulnerabilities. But when the update schedule is run, it executes on the Linux machine using the appropriate package manager like YUM, APT, or ZYPPER to install them. The package manager for the Linux distro may have a different mechanism to classify updates, where the results may differ from the ones obtained from OVAL files by Update Management. To manually check the machine and understand which updates are security relevant by your package manager, see [Troubleshoot Linux update](#)

deployment.

#### NOTE

During update assessment, the classification of missing updates as Security and Critical may not work correctly for Linux distros supported by Update Management. This is a result of an issue identified with the naming schema of the OVAL files, which the Update Management uses to classify updates during the assessment. This prevents Update Management from properly matching classifications based on filtering rules during the assessment of missing updates.

This doesn't affect the deployment of updates. As a different logic is used in security update assessments, results might differ from the security updates applied during deployment. If you have classification set as **Critical** and **Security**, the update deployment will function as expected. Only the *classification of updates* during an assessment is affected.

**Update Management for Windows Server machines is unaffected; update classification and deployments are unchanged.**

## Integrate Update Management with Configuration Manager

Customers who have invested in Microsoft Endpoint Configuration Manager for managing PCs, servers, and mobile devices also rely on the strength and maturity of Configuration Manager to help manage software updates. To learn how to integrate Update Management with Configuration Manager, see [Integrate Update Management with Windows Endpoint Configuration Manager](#).

## Third-party updates on Windows

Update Management relies on the locally configured update repository to update supported Windows systems, either WSUS or Windows Update. Tools such as [System Center Updates Publisher](#) allow you to import and publish custom updates with WSUS. This scenario allows Update Management to update machines that use Configuration Manager as their update repository with third-party software. To learn how to configure Updates Publisher, see [Install Updates Publisher](#).

## Next steps

- Before enabling and using Update Management, review [Plan your Update Management deployment](#).
- Review commonly asked questions about Update Management in the [Azure Automation frequently asked questions](#).

# Maintenance for virtual machines in Azure

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure periodically updates its platform to improve the reliability, performance, and security of the host infrastructure for virtual machines. The purpose of these updates ranges from patching software components in the hosting environment to upgrading networking components or decommissioning hardware.

Updates rarely affect the hosted VMs. When updates do have an effect, Azure chooses the least impactful method for updates:

- If the update doesn't require a reboot, the VM is paused while the host is updated, or the VM is live-migrated to an already updated host.
- If maintenance requires a reboot, you're notified of the planned maintenance. Azure also provides a time window in which you can start the maintenance yourself, at a time that works for you. The self-maintenance window is typically 35 days (for Host machines) unless the maintenance is urgent. Azure is investing in technologies to reduce the number of cases in which planned platform maintenance requires the VMs to be rebooted. For instructions on managing planned maintenance, see [Handling planned maintenance notifications using the Azure CLI, PowerShell or portal](#).

This page describes how Azure performs both types of maintenance. For more information about unplanned events (outages), see [Manage the availability of VMs for Windows](#) or the corresponding article for [Linux](#).

Within a VM, you can get notifications about upcoming maintenance by [using Scheduled Events for Windows](#) or for [Linux](#).

## Maintenance that doesn't require a reboot

Most platform updates don't affect customer VMs. When a no-impact update isn't possible, Azure chooses the update mechanism that's least impactful to customer VMs.

Most nonzero-impact maintenance pauses the VM for less than 10 seconds. In certain cases, Azure uses memory-preserving maintenance mechanisms. These mechanisms pause the VM, typically for about 30 seconds, and preserve the memory in RAM. The VM is then resumed, and its clock is automatically synchronized.

Memory-preserving maintenance works for more than 90 percent of Azure VMs. It doesn't work for G, L, M, N, and H series. Azure increasingly uses live-migration technologies and improves memory-preserving maintenance mechanisms to reduce the pause durations.

These maintenance operations that don't require a reboot are applied one fault domain at a time. They stop if they receive any warning health signals from platform monitoring tools. Maintenance operations that do not require a reboot may occur simultaneously in paired regions or Availability Zones. For a given change, the deployment are mostly sequenced across Availability Zones and across Region pairs, but there can be overlap at the tail.

These types of updates can affect some applications. When the VM is live-migrated to a different host, some sensitive workloads might show a slight performance degradation in the few minutes leading up to the VM pause. To prepare for VM maintenance and reduce impact during Azure maintenance, try [using Scheduled Events for Windows](#) or [Linux](#) for such applications.

For greater control on all maintenance activities including zero-impact and rebootless updates, you can create a

Maintenance Configuration feature. Creating a Maintenance Configuration gives you the option to skip all platform updates and apply the updates at your choice of time. For more information, see [Managing platform updates with Maintenance Configurations](#).

## Live migration

Live migration is an operation that doesn't require a reboot and that preserves memory for the VM. It causes a pause or freeze, typically lasting no more than 5 seconds. Except for G, M, N, and H series, all infrastructure as a service (IaaS) VMs, are eligible for live migration. Eligible VMs represent more than 90 percent of the IaaS VMs that are deployed to the Azure fleet.

### NOTE

You won't receive a notification in the Azure portal for live migration operations that don't require a reboot. To see a list of live migrations that don't require a reboot, [query for scheduled events](#).

The Azure platform starts live migration in the following scenarios:

- Planned maintenance
- Hardware failure
- Allocation optimizations

Some planned-maintenance scenarios use live migration, and you can use Scheduled Events to know in advance when live migration operations will start.

Live migration can also be used to move VMs when Azure Machine Learning algorithms predict an impending hardware failure or when you want to optimize VM allocations. For more information about predictive modeling that detects instances of degraded hardware, see [Improving Azure VM resiliency with predictive machine learning and live migration](#). Live-migration notifications appear in the Azure portal in the Monitor and Service Health logs as well as in Scheduled Events if you use these services.

## Maintenance that requires a reboot

In the rare case where VMs need to be rebooted for planned maintenance, you'll be notified in advance. Planned maintenance has two phases: the self-service phase and a scheduled maintenance phase.

During the *self-service phase*, which typically lasts four weeks, you start the maintenance on your VMs. As part of the self-service, you can query each VM to see its status and the result of your last maintenance request.

### NOTE

For VM-series that do not support [Live Migration](#), local (ephemeral) disks data can be lost during the maintenance events. See each individual VM-series for information on if Live Migration is supported.

When you start self-service maintenance, your VM is redeployed to an already updated node. Because the VM is redeployed, the temporary disk is lost and dynamic IP addresses associated with the virtual network interface are updated.

If an error arises during self-service maintenance, the operation stops, the VM isn't updated, and you get the option to retry the self-service maintenance.

When the self-service phase ends, the *scheduled maintenance phase* begins. During this phase, you can still query for the maintenance phase, but you can't start the maintenance yourself.

For more information on managing maintenance that requires a reboot, see [Handling planned maintenance notifications](#) using the Azure [CLI](#), [PowerShell](#) or [portal](#).

## Availability considerations during scheduled maintenance

If you decide to wait until the scheduled maintenance phase, there are a few things you should consider to maintain the highest availability of your VMs.

### Paired regions

Each Azure region is paired with another region within the same geographical vicinity. Together, they make a region pair. During the scheduled maintenance phase, Azure updates only the VMs in a single region of a region pair. For example, while updating the VM in North Central US, Azure doesn't update any VM in South Central US at the same time. However, other regions such as North Europe can be under maintenance at the same time as East US. Understanding how region pairs work can help you better distribute your VMs across regions. For more information, see [Azure region pairs](#).

### Availability zones

Availability zones are unique physical locations within an Azure region. Each zone is made up of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there's a minimum of three separate zones in all enabled regions.

An availability zone is a combination of a fault domain and an update domain. If you create three or more VMs across three zones in an Azure region, your VMs are effectively distributed across three fault domains and three update domains. The Azure platform recognizes this distribution across update domains to make sure that VMs in different zones are not updated at the same time.

Each infrastructure update rolls out zone by zone, within a single region. But, you can have deployment going on in Zone 1, and different deployment going in Zone 2, at the same time. Deployments are not all serialized. But, a single deployment that requires a reboot only rolls out one zone at a time to reduce risk. In general, updates that require a reboot are avoided when possible, and Azure attempts to use Live Migration or provide customers control.

### Virtual machine scale sets

Virtual machine scale sets in **Flexible** orchestration mode are an Azure compute resource allow you to combine the scalability of virtual machine scale sets in **Uniform** orchestration mode with the regional availability guarantees of availability sets.

With Flexible orchestration, you can choose whether your instances are spread across multiple zones, or spread across fault domains within a single region.

### Availability sets and Uniform scale sets

When deploying a workload on Azure VMs, you can create the VMs within an *availability set* to provide high availability to your application. Using availability sets, you can ensure that during either an outage or maintenance events that require a reboot, at least one VM is available.

Within an availability set, individual VMs are spread across up to 20 update domains. During scheduled maintenance, only one update domain is updated at any given time. Update domains aren't necessarily updated sequentially.

Virtual machine *scale sets* in **Uniform** orchestration mode are an Azure compute resource that you can use to deploy and manage a set of identical VMs as a single resource. The scale set is automatically deployed across UDs, like VMs in an availability set. As with availability sets, when you use Uniform scale sets, only one UD is updated at any given time during scheduled maintenance.

For more information about setting up your VMs for high availability, see [Manage the availability of your VMs for Windows](#) or the corresponding article for [Linux](#).

## Next steps

You can use the [Azure CLI](#), [Azure PowerShell](#), or the [portal](#) to manage planned maintenance.

# Handling planned maintenance notifications

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure periodically performs updates to improve the reliability, performance, and security of the host infrastructure for virtual machines. Updates are changes like patching the hosting environment or upgrading and decommissioning hardware. A majority of these updates are completed without any impact to the hosted virtual machines. However, there are cases where updates do have an impact:

- If the maintenance does not require a reboot, Azure pauses the VM for few seconds while the host is updated. These types of maintenance operations are applied fault domain by fault domain. Progress is stopped if any warning health signals are received.
- If maintenance requires a reboot, you get a notice of when the maintenance is planned. You are given a time window of about 35 days where you can start the maintenance yourself, when it works for you.

Planned maintenance that requires a reboot is scheduled in waves. Each wave has different scope (regions).

- A wave starts with a notification to customers. By default, the notification is sent to the subscription admin and co-admins. You can add more recipients and messaging options like email, SMS, and webhooks, using [Activity Log Alerts](#).
- Once a notification goes out, a *self-service window* is made available. During this window, you can query which of your virtual machines are affected and start maintenance based on your own scheduling needs. The self-service window is typically about 35 days.
- After the self-service window, a *scheduled maintenance window* begins. At some point during this window, Azure schedules and applies the required maintenance to your virtual machine.

The goal in having two windows is to give you enough time to start maintenance and reboot your virtual machine while knowing when Azure will automatically start maintenance.

You can use the Azure portal, PowerShell, REST API, and CLI to query for the maintenance windows for your VMs and start self-service maintenance.

## Should you start maintenance using during the self-service window?

The following guidelines should help you decide whether to use this capability and start maintenance at your own time.

### NOTE

Self-service maintenance might not be available for all of your VMs. To determine if proactive redeploy is available for your VM, look for the **Start now** in the maintenance status. Self-service maintenance is currently not available for Cloud Services (Web/Worker Role) and Service Fabric.

Self-service maintenance is not recommended for deployments using **availability sets**. Availability sets are already only updated one update domain at a time.

- Let Azure trigger the maintenance. For maintenance that requires reboot, maintenance will be done update domain by update domain. The update domains do not necessarily receive the maintenance sequentially, and that there is a 30-minute pause between update domains.
- If a temporary loss of some capacity (1 update domain) is a concern, you can add instances during the

maintenance period.

- For maintenance that does not require reboot, updates are applied at the fault domain level.

**Don't** use self-service maintenance in the following scenarios:

- If you shut down your VMs frequently, either manually, using DevTest Labs, using auto-shutdown, or following a schedule, it could revert the maintenance status and therefore cause additional downtime.
- On short-lived VMs that you know will be deleted before the end of the maintenance wave.
- For workloads with a large state stored in the local (ephemeral) disk that is desired to be maintained upon update.
- For cases where you resize your VM often, as it could revert the maintenance status.
- If you have adopted scheduled events that enable proactive failover or graceful shutdown of your workload, 15 minutes before start of maintenance shutdown

**Use** self-service maintenance, if you are planning to run your VM uninterrupted during the scheduled maintenance phase and none of the counter-indications mentioned above are applicable.

It is best to use self-service maintenance in the following cases:

- You need to communicate an exact maintenance window to your management or end-customer.
- You need to complete the maintenance by a given date.
- You need to control the sequence of maintenance, for example, multi-tier application to guarantee safe recovery.
- More than 30 minutes of VM recovery time is needed between two update domains (UDs). To control the time between update domains, you must trigger maintenance on your VMs one update domain (UD) at a time.

## FAQ

**Q: Why do you need to reboot my virtual machines now?**

**A:** While the majority of updates and upgrades to the Azure platform do not impact virtual machine's availability, there are cases where we can't avoid rebooting virtual machines hosted in Azure. We have accumulated several changes that require us to restart our servers that will result in virtual machines reboot.

**Q: If I follow your recommendations for High Availability by using an Availability Set, am I safe?**

**A:** Virtual machines deployed in an availability set or virtual machine scale sets have the notion of Update Domains (UD). When performing maintenance, Azure honors the UD constraint and will not reboot virtual machines from different UD (within the same availability set). Azure also waits for at least 30 minutes before moving to the next group of virtual machines.

For more information about high availability, see [Availability for virtual machines in Azure](#).

**Q: How do I get notified about planned maintenance?**

**A:** A planned maintenance wave starts by setting a schedule to one or more Azure regions. Soon after, an email notification is sent to the subscription admins, co-admins, owners, and contributors (One email per subscription with all recipients added). Additional channels and recipients for this notification could be configured using Activity Log Alerts. In case you deploy a virtual machine to a region where planned maintenance is already scheduled, you will not receive the notification but rather need to check the maintenance state of the VM.

**Q: I don't see any indication of planned maintenance in the portal, PowerShell, or CLI. What is wrong?**

**A:** Information related to planned maintenance is available during a planned maintenance wave only for the VMs that are going to be impacted by it. In other words, if you see no data, it could be that the maintenance

wave has already completed (or not started) or that your virtual machine is already hosted in an updated server.

**Q: Is there a way to know exactly when my virtual machine will be impacted?**

**A:** When setting the schedule, we define a time window of several days. However, the exact sequencing of servers (and VMs) within this window is unknown. Customers who would like to know the exact time for their VMs can use [scheduled events](#) and query from within the virtual machine and receive a 15-minute notification before a VM reboot.

**Q: How long will it take you to reboot my virtual machine?**

**A:** Depending on the size of your VM, reboot may take up to several minutes during the self-service maintenance window. During the Azure initiated reboots in the scheduled maintenance window, the reboot will typically take about 25 minutes. Note that in case you use Cloud Services (Web/Worker Role), Virtual Machine Scale Sets, or availability sets, you will be given 30 minutes between each group of VMs (UD) during the scheduled maintenance window.

**Q: What is the experience in the case of Virtual Machine Scale Sets?**

**A:** Planned maintenance is now available for Virtual Machine Scale Sets. For instructions on how to initiate self-service maintenance refer [planned maintenance for virtual machine scale sets](#) document.

**Q: What is the experience in the case of Cloud Services (Web/Worker Role) and Service Fabric?**

**A:** While these platforms are impacted by planned maintenance, customers using these platforms are considered safe given that only VMs in a single Upgrade Domain (UD) will be impacted at any given time. Self-service maintenance is currently not available for Cloud Services (Web/Worker Role) and Service Fabric.

**Q: I don't see any maintenance information on my VMs. What went wrong?**

**A:** There are several reasons why you're not seeing any maintenance information on your VMs:

1. You are using a subscription marked as Microsoft internal.
2. Your VMs are not scheduled for maintenance. It could be that the maintenance wave has ended, canceled, or modified so that your VMs are no longer impacted by it.
3. You have deallocated VM and then started it. This can cause VM to move to a location which does not have planned maintenance wave scheduled. So the VM will not show maintenance information any more.
4. You don't have the **Maintenance** column added to your VM list view. While we have added this column to the default view, customers who configured to see non-default columns must manually add the **Maintenance** column to their VM list view.

**Q: My VM is scheduled for maintenance for the second time. Why?**

**A:** There are several use cases where you will see your VM scheduled for maintenance after you have already completed your maintenance-redeploy:

1. We have canceled the maintenance wave and restarted it with a different payload. It could be that we've detected faulted payload and we simply need to deploy an additional payload.
2. Your VM was *service healed* to another node due to a hardware fault.
3. You have selected to stop (deallocate) and restart the VM.
4. You have **auto shutdown** turned on for the VM.

## Next steps

You can handle planned maintenance using the [Azure CLI](#), [Azure PowerShell](#) or [portal](#).

# Handling planned maintenance notifications using the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can use the CLI to see when VMs are scheduled for [maintenance](#). Planned maintenance information is available from [az vm get-instance-view](#).

Maintenance information is returned only if there is maintenance planned.

```
az vm get-instance-view -n myVM -g myResourceGroup --query instanceView.maintenanceRedeployStatus
```

Output

```
"maintenanceRedeployStatus": {  
    "additionalProperties": {},  
    "isCustomerInitiatedMaintenanceAllowed": true,  
    "lastOperationMessage": null,  
    "lastOperationResultCode": "None",  
    "maintenanceWindowEndTime": "2018-06-04T16:30:00+00:00",  
    "maintenanceWindowStartTime": "2018-05-21T16:30:00+00:00",  
    "preMaintenanceWindowEndTime": "2018-05-19T12:30:00+00:00",  
    "preMaintenanceWindowStartTime": "2018-05-14T12:30:00+00:00"
```

## Start maintenance

The following call will start maintenance on a VM if `IsCustomerInitiatedMaintenanceAllowed` is set to true.

```
az vm perform-maintenance -g myResourceGroup -n myVM
```

## Classic deployments

### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

If you still have legacy VMs that were deployed using the classic deployment model, you can use the Azure classic CLI to query for VMs and initiate maintenance.

Make sure you are in the correct mode to work with classic VM by typing:

```
azure config mode asm
```

To get the maintenance status of a VM named *myVM*, type:

```
azure vm show myVM
```

To start maintenance on your classic VM named *myVM* in the *myService* service and *myDeployment* deployment, type:

```
azure compute virtual-machine initiate-maintenance --service-name myService --name myDeployment --virtual-machine-name myVM
```

## Next steps

You can also handle planned maintenance using the [Azure PowerShell](#) or [portal](#).

# Handling planned maintenance notifications using the portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Once a [planned maintenance](#) wave is scheduled, you can check for a list of virtual machines that are impacted.

You can use the Azure portal and look for VMs scheduled for maintenance.

1. Sign in to the [Azure portal](#).
2. In the left navigation, click **Virtual Machines**.
3. In the Virtual Machines pane, select **Maintenance -> Virtual machine maintenance** button to open the list with maintenance columns.

**Maintenance status:** Shows the maintenance status for the VM. The following are the potential values:

VALUE	DESCRIPTION
Start now	The VM is in the self-service maintenance window that lets you initiate the maintenance yourself. See below on how to start maintenance on your VM.
Scheduled	The VM is scheduled for maintenance with no option for you to initiate maintenance. You can learn of the maintenance window by selecting the Maintenance - Scheduled window in this view or by clicking on the VM.
Already updated	Your VM is already updated and no further action is required at this time.
Retry later	You have initiated maintenance with no success. You will be able to use the self-service maintenance option at a later time.
Retry now	You can retry a previously unsuccessful self-initiated maintenance.
-	Your VM is not part of a planned maintenance wave.

**Maintenance - Self-service window:** Shows the time window when you can self-start maintenance on your VMs.

**Maintenance - Scheduled window:** Shows the time window when Azure will maintain your VM in order to complete maintenance.

## Notification and alerts in the portal

Azure communicates a schedule for planned maintenance by sending an email to the subscription owner and co-owners group. You can add additional recipients and channels to this communication by creating Azure activity log alerts. For more information, see [Create activity log alerts on service notifications](#).

Make sure you set the **Event type** as **Planned maintenance**, and **Services** as **Virtual Machine Scale Sets** and/or **Virtual Machines**.

## Start Maintenance on your VM from the portal

While looking at the VM details, you will be able to see more maintenance-related details.

At the top of the VM details view, a new notification ribbon will be added if your VM is included in a planned maintenance wave. In addition, a new option is added to start maintenance when possible.

Click on the maintenance notification to see the maintenance page with more details on the planned maintenance. From there, you will be able to **start maintenance** on your VM.

Once you start maintenance, your virtual machine will be maintained and the maintenance status will be updated to reflect the result within few minutes.

If you missed the self-service window, you will still be able to see the window when your VM will be maintained by Azure.

## Next steps

You can also handle planned maintenance using the [Azure CLI](#) or [PowerShell](#).

# Handling planned maintenance using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can use Azure PowerShell to see when VMs are scheduled for [maintenance](#). Planned maintenance information is available from the [Get-AzVM](#) cmdlet when you use the `-status` parameter.

Maintenance information is returned only if there is maintenance planned. If no maintenance is scheduled that impacts the VM, the cmdlet does not return any maintenance information.

```
Get-AzVM -ResourceGroupName myResourceGroup -Name myVM -Status
```

## Output

```
MaintenanceRedeployStatus      :  
IsCustomerInitiatedMaintenanceAllowed : True  
PreMaintenanceWindowStartTime    : 5/14/2018 12:30:00 PM  
PreMaintenanceWindowEndTime     : 5/19/2018 12:30:00 PM  
MaintenanceWindowStartTime      : 5/21/2018 4:30:00 PM  
MaintenanceWindowEndTime        : 6/4/2018 4:30  
LastOperationResultCode         : None
```

The following properties are returned under MaintenanceRedeployStatus:

VALUE	DESCRIPTION
IsCustomerInitiatedMaintenanceAllowed	Indicates whether you can start maintenance on the VM at this time
PreMaintenanceWindowStartTime	The beginning of the maintenance self-service window when you can initiate maintenance on your VM
PreMaintenanceWindowEndTime	The end of the maintenance self-service window when you can initiate maintenance on your VM
MaintenanceWindowStartTime	The beginning of the maintenance scheduled in which Azure initiates maintenance on your VM
MaintenanceWindowEndTime	The end of the maintenance scheduled window in which Azure initiates maintenance on your VM
LastOperationResultCode	The result of the last attempt to initiate maintenance on the VM

You can also get the maintenance status for all VMs in a resource group by using [Get-AzVM](#) and not specifying a VM.

```
Get-AzVM -ResourceGroupName myResourceGroup -Status
```

The following PowerShell example takes your subscription ID and returns a list of VMs that are scheduled for

maintenance.

```
function MaintenanceIterator
{
    Select-AzSubscription -SubscriptionId $args[0]

    $rgList= Get-AzResourceGroup

    for ($rgIdx=0; $rgIdx -lt $rgList.Length ; $rgIdx++)
    {
        $rg = $rgList[$rgIdx]
        $vmList = Get-AzVM -ResourceGroupName $rg.ResourceGroupName
        for ($vmIdx=0; $vmIdx -lt $vmList.Length ; $vmIdx++)
        {
            $vm = $vmList[$vmIdx]
            $vmDetails = Get-AzVM -ResourceGroupName $rg.ResourceGroupName -Name $vm.Name -Status
            if ($vmDetails.MaintenanceRedeployStatus )
            {
                Write-Output "VM: $($vmDetails.Name) IsCustomerInitiatedMaintenanceAllowed:
$($vmDetails.MaintenanceRedeployStatus.IsCustomerInitiatedMaintenanceAllowed)
 $($vmDetails.MaintenanceRedeployStatus.LastOperationMessage)"
            }
        }
    }
}
```

## Start maintenance on your VM using PowerShell

Using information from the function in the previous section, the following starts maintenance on a VM if **IsCustomerInitiatedMaintenanceAllowed** is set to true.

```
Restart-AzVM -PerformMaintenance -name $vm.Name -ResourceGroupName $rg.ResourceGroupName
```

## Classic deployments

### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

If you still have legacy VMs that were deployed using the classic deployment model, you can use PowerShell to query for VMs and initiate maintenance.

To get the maintenance status of a VM, type:

```
Get-AzureVM -ServiceName <Service name> -Name <VM name>
```

To start maintenance on your classic VM, type:

```
Restart-AzureVM -InitiateMaintenance -ServiceName <service name> -Name <VM name>
```

## Next steps

You can also handle planned maintenance using the [Azure CLI](#) or [portal](#).

# Managing VM updates with Maintenance Configurations

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Maintenance Configurations give you the ability to control and manage updates for many Azure virtual machine resources since Azure frequently updates its infrastructure to improve reliability, performance, security or launch new features. Most updates are transparent to users, but some sensitive workloads, like gaming, media streaming, and financial transactions, can't tolerate even few seconds of a VM freezing or disconnecting for maintenance. Maintenance configurations is integrated with Azure Resource Graph (ARG) for low latency and high scale customer experience.

## IMPORTANT

Users are required to have a role of at least contributor in order to use maintenance configurations.

## Scopes

Maintenance Configurations currently supports three (3) scopes: Host, OS image, and Guest. While each scope allows scheduling and managing updates, the major difference lies in the resource they each support. This section outlines the details on the various scopes and their supported types:

SCOPE	SUPPORT RESOURCES
Host	Isolated Virtual Machines, Isolated Virtual Machine Scale Sets, Dedicated Hosts
OS Image	Virtual Machine Scale Sets
Guest	Virtual Machines, Azure Arc Servers

### Host

With this scope, you can manage platform updates that do not require a reboot on your *isolated VMs*, *isolated Virtual Machine Scale Set instances* and *dedicated hosts*. Some features and limitations unique to the host scope are:

- Schedules can be set anytime within 35 days. After 35 days, updates are automatically applied.
- A minimum of a 2 hour maintenance window is required for this scope.

[Learn more about Azure Dedicated Hosts](#)

### OS image

Using this scope with maintenance configurations lets you decide when to apply upgrades to OS disks in your *virtual machine scale sets* through an easier and more predictable experience. An upgrade works by replacing the OS disk of a VM with a new disk created using the latest image version. Any configured extensions and custom data scripts are run on the OS disk, while data disks are retained. Some features and limitations unique to this scope are:

- Scale sets need to have [automatic OS upgrades](#) enabled in order to use maintenance configurations.
- Schedule recurrence is defaulted to daily
- A minimum of 5 hours is required for the maintenance window

## Guest

This scope is integrated with [update management center](#) which allows you to save recurring deployment schedules to install updates for your Windows Server and Linux machines in Azure, in on-premises environments, and in other cloud environments connected using Azure Arc-enabled servers. Some features and limitations unique to this scope include:

- [Patch orchestration](#) for virtual machines need to be set to AutomaticByPlatform
- A minimum of 1 hour and 10 minutes is required for the maintenance window.
- There is no limit to the recurrence of your schedule

To learn more about this topic, checkout [update management center and scheduled patching](#)

## Management options

You can create and manage maintenance configurations using any of the following options:

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Azure portal](#)

For an Azure Functions sample, see [Scheduling Maintenance Updates with Maintenance Configurations and Azure Functions](#).

## Next steps

To learn more, see [Maintenance and updates](#).

# Control updates with Maintenance Configurations and the Azure CLI

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Maintenance Configurations lets you decide when to apply platform updates to various Azure resources. This topic covers the Azure CLI options for Dedicated Hosts and Isolated VMs. For more about benefits of using Maintenance Configurations, its limitations, and other management options, see [Managing platform updates with Maintenance Configurations](#).

## IMPORTANT

There are different **scopes** which support certain machine types and schedules, so please ensure you are selecting the right scope for your virtual machine.

## Create a maintenance configuration

Use `az maintenance configuration create` to create a maintenance configuration. This example creates a maintenance configuration named *myConfig* scoped to the host.

```
az group create \
--location eastus \
--name myMaintenanceRG
az maintenance configuration create \
-g myMaintenanceRG \
--resource-name myConfig \
--maintenance-scope host\
--location eastus
```

Copy the configuration ID from the output to use later.

Using `--maintenance-scope host` ensures that the maintenance configuration is used for controlling updates to the host infrastructure.

If you try to create a configuration with the same name, but in a different location, you will get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using `az maintenance configuration list`.

```
az maintenance configuration list --query "[].{Name:name, ID:id}" -o table
```

## Create a maintenance configuration with scheduled window

You can also declare a scheduled window when Azure will apply the updates on your resources. This example creates a maintenance configuration named *myConfig* with a scheduled window of 5 hours on the fourth Monday of every month. Once you create a scheduled window you no longer have to apply the updates manually.

```
az maintenance configuration create \
-g myMaintenanceRG \
--resource-name myConfig \
--maintenance-scope host \
--location eastus \
--maintenance-window-duration "05:00" \
--maintenance-window-recur-every "Month Fourth Monday" \
--maintenance-window-start-date-time "2020-12-30 08:00" \
--maintenance-window-time-zone "Pacific Standard Time"
```

#### IMPORTANT

Maintenance **duration** must be *2 hours* or longer.

Maintenance recurrence can be expressed as daily, weekly or monthly. Some examples are:

- **daily**- maintenance-window-recur-every: "Day" **or** "3Days"
- **weekly**- maintenance-window-recur-every: "3Weeks" **or** "Week Saturday,Sunday"
- **monthly**- maintenance-window-recur-every: "Month day23,day24" **or** "Month Last Sunday" **or** "Month Fourth Monday"

## Assign the configuration

Use `az maintenance assignment create` to assign the configuration to your machine.

#### Isolated VM

Apply the configuration to a VM using the ID of the configuration. Specify `--resource-type virtualMachines` and supply the name of the VM for `--resource-name`, and the resource group for to the VM in `--resource-group`, and the location of the VM for `--location`.

```
az maintenance assignment create \
--resource-group myMaintenanceRG \
--location eastus \
--resource-name myVM \
--resource-type virtualMachines \
--provider-name Microsoft.Compute \
--configuration-assignment-name myConfig \
--maintenance-configuration-id "/subscriptions/1111abcd-1a11-1a2b-1a12-123456789abc/resourcegroups/myMaintenanceRG/providers/Microsoft.Maintenance/maintenanceConfigurations/myConfig"
```

#### Dedicated host

To apply a configuration to a dedicated host, you need to include `--resource-type hosts`, `--resource-parent-name` with the name of the host group, and `--resource-parent-type hostGroups`.

The parameter `--resource-id` is the ID of the host. You can use [az-vm-host-get-instance-view](#) to get the ID of your dedicated host.

```
az maintenance assignment create \
    -g myDHResourceGroup \
    --resource-name myHost \
    --resource-type hosts \
    --provider-name Microsoft.Compute \
    --configuration-assignment-name myConfig \
    --maintenance-configuration-id "/subscriptions/1111abcd-1a11-1a2b-1a12-
123456789abc/resourcegroups/myDHResourceGroup/providers/Microsoft.Maintenance/maintenanceConfigurations/myCo
nfig" \
    -l eastus \
    --resource-parent-name myHostGroup \
    --resource-parent-type hostGroups
```

## Check configuration

You can verify that the configuration was applied correctly, or check to see what configuration is currently applied using `az maintenance assignment list`.

### Isolated VM

```
az maintenance assignment list \
    --provider-name Microsoft.Compute \
    --resource-group myMaintenanceRG \
    --resource-name myVM \
    --resource-type virtualMachines \
    --query "[].{resource:resourceGroup, configName:name}" \
    --output table
```

### Dedicated host

```
az maintenance assignment list \
    --resource-group myDHResourceGroup \
    --resource-name myHost \
    --resource-type hosts \
    --provider-name Microsoft.Compute \
    --resource-parent-name myHostGroup \
    --resource-parent-type hostGroups \
    --query "[].{ResourceGroup:resourceGroup,configName:name}" \
    -o table
```

## Check for pending updates

Use `az maintenance update list` to see if there are pending updates. Update `--subscription` to be the ID for the subscription that contains the VM.

If there are no updates, the command will return an error message, which will contain the text:

```
Resource not found...StatusCode: 404 .
```

If there are updates, only one will be returned, even if there are multiple updates pending. The data for this update will be returned in an object:

```
[  
 {  
   "impactDurationInSec": 9,  
   "impactType": "Freeze",  
   "maintenanceScope": "Host",  
   "notBefore": "2020-03-03T07:23:04.905538+00:00",  
   "resourceId": "/subscriptions/9120c5ff-e78e-4bd0-b29f-  
75c19cadd078/resourcegroups/DemoRG/providers/Microsoft.Compute/hostGroups/demoHostGroup/hosts/myHost",  
   "status": "Pending"  
 }  
]
```

## Isolated VM

Check for pending updates for an isolated VM. In this example, the output is formatted as a table for readability.

```
az maintenance update list \  
-g myMaintenanceRg \  
--resource-name myVM \  
--resource-type virtualMachines \  
--provider-name Microsoft.Compute \  
-o table
```

## Dedicated host

To check for pending updates for a dedicated host. In this example, the output is formatted as a table for readability. Replace the values for the resources with your own.

```
az maintenance update list \  
--subscription 1111abcd-1a11-1a2b-1a12-123456789abc \  
-g myHostResourceGroup \  
--resource-name myHost \  
--resource-type hosts \  
--provider-name Microsoft.Compute \  
--resource-parentname myHostGroup \  
--resource-parent-type hostGroups \  
-o table
```

## Apply updates

Use `az maintenance apply update` to apply pending updates. On success, this command will return JSON containing the details of the update. Apply update calls can take upto 2 hours to complete.

### Isolated VM

Create a request to apply updates to an isolated VM.

```
az maintenance applyupdate create \  
--subscription 1111abcd-1a11-1a2b-1a12-123456789abc \  
--resource-group myMaintenanceRG \  
--resource-name myVM \  
--resource-type virtualMachines \  
--provider-name Microsoft.Compute
```

### Dedicated host

Apply updates to a dedicated host.

```
az maintenance applyupdate create \
--subscription 1111abcd-1a11-1a2b-1a12-123456789abc \
--resource-group myHostResourceGroup \
--resource-name myHost \
--resource-type hosts \
--provider-name Microsoft.Compute \
--resource-parent-name myHostGroup \
--resource-parent-type hostGroups
```

## Check the status of applying updates

You can check on the progress of the updates using `az maintenance applyupdate get`.

You can use `default` as the update name to see results for the last update, or replace `myUpdateName` with the name of the update that was returned when you ran `az maintenance applyupdate create`.

```
Status      : Completed
ResourceId   : /subscriptions/12ae7457-4a34-465c-94c1-
               17c058c2bd25/resourcegroups/TestShants/providers/Microsoft.Com-
               pute/virtualMachines/DXT-test-04-iso
LastUpdateTime : 1/1/2020 12:00:00 AM
Id          : /subscriptions/12ae7457-4a34-465c-94c1-
               17c058c2bd25/resourcegroups/TestShants/providers/Microsoft.Com-
               pute/virtualMachines/DXT-test-04-iso/providers/Microsoft.Mainten-
               ance/applyUpdates/default
Name        : default
Type        : Microsoft.Maintenance/applyUpdates
```

LastUpdateTime will be the time when the update got complete, either initiated by you or by the platform in case self-maintenance window was not used. If there has never been an update applied through maintenance control it will show default value.

### Isolated VM

```
az maintenance applyupdate get \
--resource-group myMaintenanceRG \
--resource-name myVM \
--resource-type virtualMachines \
--provider-name Microsoft.Compute \
--apply-update-name default
```

### Dedicated host

```
az maintenance applyupdate get \
--subscription 1111abcd-1a11-1a2b-1a12-123456789abc \
--resource-group myMaintenanceRG \
--resource-name myHost \
--resource-type hosts \
--provider-name Microsoft.Compute \
--resource-parent-name myHostGroup \
--resource-parent-type hostGroups \
--apply-update-name myUpdateName \
--query "{LastUpdate:lastUpdateTime, Name:name, ResourceGroup:resourceGroup, Status:status}" \
--output table
```

## Delete a maintenance configuration

Use `az maintenance configuration delete` to delete a maintenance configuration. Deleting the configuration removes the maintenance control from the associated resources.

```
az maintenance configuration delete \
--subscription 1111abcd-1a11-1a2b-1a12-123456789abc \
-g myResourceGroup \
--resource-name myConfig
```

## Next steps

To learn more, see [Maintenance and updates](#).

# Control updates with Maintenance Configurations and Azure PowerShell

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Creating a Maintenance Configurations lets you decide when to apply platform updates to various Azure resources. This topic covers the Azure PowerShell options for Dedicated Hosts and Isolated VMs. For more about benefits of using Maintenance Configurations, its limitations, and other management options, see [Managing platform updates with Maintenance Configurations](#).

If you are looking for information about Maintenance Configurations for scale sets, see [Maintenance Control for virtual machine scale sets](#).

## IMPORTANT

There are different **scopes** which support certain machine types and schedules, so please ensure you are selecting the right scope for your virtual machine.

## Enable the PowerShell module

Make sure `PowerShellGet` is up to date.

```
Install-Module -Name PowerShellGet -Repository PSGallery -Force
```

Install the `Az.Maintenance` PowerShell module.

```
Install-Module -Name Az.Maintenance
```

If you are installing locally, make sure you open your PowerShell prompt as an administrator.

You may also be asked to confirm that you want to install from an *untrusted repository*. Type `y` or select **Yes to All** to install the module.

## Create a maintenance configuration

Create a resource group as a container for your configuration. In this example, a resource group named `myMaintenanceRG` is created in `eastus`. If you already have a resource group that you want to use, you can skip this part and replace the resource group name with your own in the rest of the examples.

```
New-AzResourceGroup  
-Location eastus  
-Name myMaintenanceRG
```

Use `New-AzMaintenanceConfiguration` to create a maintenance configuration. This example creates a maintenance configuration named `myConfig` scoped to the host.

```
$config = New-AzMaintenanceConfiguration `  
    -ResourceGroup myMaintenanceRG `  
    -Name myConfig `  
    -MaintenanceScope host `  
    -Location eastus
```

Using `-MaintenanceScope host` ensures that the maintenance configuration is used for controlling updates to the host.

If you try to create a configuration with the same name, but in a different location, you will get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using [Get-AzMaintenanceConfiguration](#).

```
Get-AzMaintenanceConfiguration | Format-Table -Property Name,Id
```

### Create a maintenance configuration with scheduled window

You can also declare a scheduled window when Azure will apply the updates on your resources. This example creates a maintenance configuration named myConfig with a scheduled window of 5 hours on the fourth Monday of every month. Once you create a scheduled window you no longer have to apply the updates manually.

```
$config = New-AzMaintenanceConfiguration `  
    -ResourceGroup $RGName `  
    -Name $MaintenanceConfig `  
    -MaintenanceScope Host `  
    -Location $location `  
    -StartTime "2020-10-01 00:00" `  
    -TimeZone "Pacific Standard Time" `  
    -Duration "05:00" `  
    -RecurEvery "Month Fourth Monday"
```

#### IMPORTANT

Maintenance **duration** must be *2 hours* or longer.

Maintenance **recurrence** can be expressed as daily, weekly or monthly. Some examples are:

- **daily**- RecurEvery "Day" **or** "3Days"
- **weekly**- RecurEvery "3Weeks" **or** "Week Saturday,Sunday"
- **monthly**- RecurEvery "Month day23,day24" **or** "Month Last Sunday" **or** "Month Fourth Monday"

## Assign the configuration

Use [New-AzConfigurationAssignment](#) to assign the configuration to your isolated VM or Azure Dedicated Host.

### Isolated VM

Apply the configuration to a VM using the ID of the configuration. Specify `-ResourceType VirtualMachines` and supply the name of the VM for `-ResourceName`, and the resource group of the VM for `-ResourceGroupName`.

```
New-AzConfigurationAssignment ` 
-ResourceGroupName myResourceGroup ` 
-Location eastus ` 
-ResourceName myVM ` 
-ResourceType VirtualMachines ` 
-ProviderName Microsoft.Compute ` 
-ConfigurationAssignmentName $config.Name ` 
-MaintenanceConfigurationId $config.Id
```

## Dedicated host

To apply a configuration to a dedicated host, you also need to include `-ResourceType hosts`, `-ResourceParentName` with the name of the host group, and `-ResourceParentType hostGroups`.

```
New-AzConfigurationAssignment ` 
-ResourceGroupName myResourceGroup ` 
-Location eastus ` 
-ResourceName myHost ` 
-ResourceType hosts ` 
-ResourceParentName myHostGroup ` 
-ResourceParentType hostGroups ` 
-ProviderName Microsoft.Compute ` 
-ConfigurationAssignmentName $config.Name ` 
-MaintenanceConfigurationId $config.Id
```

## Check for pending updates

Use [Get-AzMaintenanceUpdate](#) to see if there are pending updates. Use `-subscription` to specify the Azure subscription of the VM if it is different from the one that you are logged into.

If there are no updates to show, this command will return nothing. Otherwise, it will return a `PSApplyUpdate` object:

```
{
  "maintenanceScope": "Host",
  "impactType": "Freeze",
  "status": "Pending",
  "impactDurationInSec": 9,
  "notBefore": "2020-02-21T16:47:44.8728029Z",
  "properties": {
    "resourceId": "/subscriptions/39c6cced-4d6c-4dd5-af86-57499cd3f846/resourcegroups/Ignite2019/providers/Microsoft.Compute/virtualMachines/MCDemo3"
  }
}
```

## Isolated VM

Check for pending updates for an isolated VM. In this example, the output is formatted as a table for readability.

```
Get-AzMaintenanceUpdate ` 
-ResourceGroupName myResourceGroup ` 
-ResourceName myVM ` 
-ResourceType VirtualMachines ` 
-ProviderName Microsoft.Compute | Format-Table
```

## Dedicated host

To check for pending updates for a dedicated host. In this example, the output is formatted as a table for readability. Replace the values for the resources with your own.

```
Get-AzMaintenanceUpdate ` 
-ResourceGroupName myResourceGroup ` 
-ResourceName myHost ` 
-ResourceType hosts ` 
-ResourceParentName myHostGroup ` 
-ResourceParentType hostGroups ` 
-ProviderName Microsoft.Compute | Format-Table
```

## Apply updates

Use [New-AzApplyUpdate](#) to apply pending updates. Apply update calls can take upto 2 hours to complete.

### Isolated VM

Create a request to apply updates to an isolated VM.

```
New-AzApplyUpdate ` 
-ResourceGroupName myResourceGroup ` 
-ResourceName myVM ` 
-ResourceType VirtualMachines ` 
-ProviderName Microsoft.Compute
```

On success, this command will return a `PSApplyUpdate` object. You can use the `Name` attribute in the [Get-AzApplyUpdate](#) command to check the update status. See [Check update status](#).

### Dedicated host

Apply updates to a dedicated host.

```
New-AzApplyUpdate ` 
-ResourceGroupName myResourceGroup ` 
-ResourceName myHost ` 
-ResourceType hosts ` 
-ResourceParentName myHostGroup ` 
-ResourceParentType hostGroups ` 
-ProviderName Microsoft.Compute
```

## Check update status

Use [Get-AzApplyUpdate](#) to check on the status of an update. The commands shown below show the status of the latest update by using `default` for the `-ApplyUpdateName` parameter. You can substitute the name of the update (returned by the [New-AzApplyUpdate](#) command) to get the status of a specific update.

```
Status      : Completed
ResourceId   : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShants/providers/Microsoft.Com-
pute/virtualMachines/DXT-test-04-iso
LastUpdateTime : 1/1/2020 12:00:00 AM
Id          : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShants/providers/Microsoft.Com-
pute/virtualMachines/DXT-test-04-iso/providers/Microsoft.Mainten-
ance/applyUpdates/default
Name        : default
Type        : Microsoft.Maintenance/applyUpdates
```

`LastUpdateTime` will be the time when the update got complete, either initiated by you or by the platform in case self-maintenance window was not used. If there has never been an update applied through maintenance configurations it will show `default` value.

## Isolated VM

Check for updates to a specific virtual machine.

```
Get-AzApplyUpdate ` 
    -ResourceGroupName myResourceGroup ` 
    -ResourceName myVM ` 
    -ResourceType VirtualMachines ` 
    -ProviderName Microsoft.Compute ` 
    -ApplyUpdateName default
```

## Dedicated host

Check for updates to a dedicated host.

```
Get-AzApplyUpdate ` 
    -ResourceGroupName myResourceGroup ` 
    -ResourceName myHost ` 
    -ResourceType hosts ` 
    -ResourceParentName myHostGroup ` 
    -ResourceParentType hostGroups ` 
    -ProviderName Microsoft.Compute ` 
    -ApplyUpdateName myUpdateName
```

## Remove a maintenance configuration

Use [Remove-AzMaintenanceConfiguration](#) to delete a maintenance configuration.

```
Remove-AzMaintenanceConfiguration ` 
    -ResourceGroupName myResourceGroup ` 
    -Name $config.Name
```

## Next steps

To learn more, see [Maintenance and updates](#).

# Control updates with Maintenance Configurations and the Azure portal

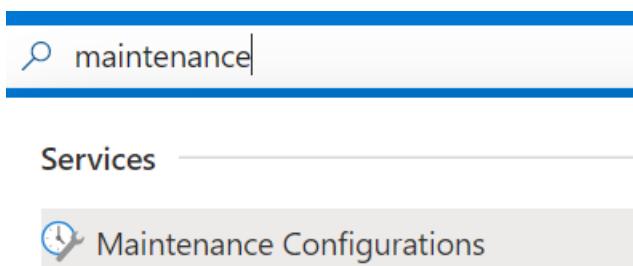

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

With Maintenance Configurations, you can now take more control over when to apply updates to various Azure resources. This topic covers the Azure portal options for creating Maintenance Configurations. For more about benefits of using Maintenance Configurations, its limitations, and other management options, see [Managing platform updates with Maintenance Configurations](#).

## Create a Maintenance Configuration

1. Sign in to the Azure portal.
2. Search for **Maintenance Configurations**.

3. Click **Create**.

### Maintenance Configurations

Microsoft (microsoft.onmicrosoft.com)

[+ Create](#) [Manage view](#) [Refresh](#) [Export to CSV](#)

4. In the Basics tab, choose a subscription and resource group, provide a name for the configuration, choose a region, and select one of the scopes we offer which you wish to apply updates for. Click **Add a schedule** to add or modify the schedule for your configuration.

#### IMPORTANT

Certain virtual machine types and schedules will require a specific kind of scope. Check out [maintenance configuration scopes](#) to find the right one for your virtual machine.

## Create a maintenance configuration ...

Basics Machines Tags Review + create

Schedule your recurring updates by creating a maintenance configuration. Set your schedule first, then add your resources.  
[Learn more](#)

### Project details

Select a subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	AISC-DEV-02
Resource group *	<input type="text"/> <a href="#">Create new</a>

### Instance details

Configuration name *	<input type="text"/>
Region *	(US) East US
Maintenance scope *	Host (isolated/dedicated hardware)
Schedule	<a href="#">Add a schedule</a>

5. In the Schedule tab, declare a scheduled window when Azure will apply the updates on your resources.

Set a start date, maintenance window, and recurrence if your resource requires it. Once you create a scheduled window you no longer have to apply the updates manually. Click **Next**.

#### IMPORTANT

Maintenance window duration must be *2 hours* or longer.

## Add/Modify schedule

X

Start on	<input type="text"/> MM/DD/YYYY <input type="button"/> h:mm A <input type="text"/> (UTC-08:00) Pacific Time (US & Canada) <input type="button"/>
Maintenance window (hours) *	<input type="text"/> 2
Repeats	<input type="text"/> 1 <input type="button"/> Day <input type="button"/>
Add end date	<input checked="" type="checkbox"/>
Ends on *	<input type="text"/> MM/DD/YYYY <input type="button"/> h:mm A
Schedule summary	Starts on: - Maintenance window: 2 hours Repeats: Does not repeat Ends on: -

6. In the Machines tab, assign resources now or skip this step and assign resources later after maintenance configuration deployment. Click **Next**.

7. Add tags and values. Click **Next**.

## Create a maintenance configuration

Basics Schedule Assignments Tags Review + create

Tags are name/value pairs that enable you to categorize resources and view consolidated billing by applying the same tag to multiple resources and resource groups. [Learn more about tags ↗](#)

Note that if you create tags and then change resource settings on other tabs, your tags will be automatically updated.

Name ⓘ	Value ⓘ
project	: Infra
	:

8. Review the summary. Click **Create**.

9. After the deployment is complete, click **Go to resource**.

## Assign the configuration

On the details page of the maintenance configuration, click Machines and then click **Add Machine**.

The screenshot shows the Azure portal interface for managing a maintenance configuration named 'test'. The top navigation bar includes 'Home > test' and tabs for 'Machines', 'Schedule', 'Updates', 'Properties', and 'Locks'. On the left, there's a sidebar with 'Overview', 'Activity log', 'Access control (IAM)', 'Tags', and 'Automation' sections. The main content area has a search bar, a 'Add machine' button (which is highlighted with a red box), and a 'Remove machines' button. A message below the buttons says: 'Manage resources assigned to this maintenance configuration. You can assign new resources, see the status of all resources currently assigned to the configuration, and by selecting resources below either apply pending maintenance or remove them from this configuration.' Below this message is a table with columns for 'Name ↑↓' and 'Type'. The 'Machines' section of the sidebar is currently selected.

Select the resources that you want the maintenance configuration assigned to and click **Ok**. The VM needs to be running to assign the configuration. An error occurs if you try to assign a configuration to a VM that is stopped.

Select resources

Select resources to assign to this maintenance configuration. Only resources that are not already assigned to a maintenance configuration are shown below. Currently, only dedicated hosts and isolated virtual machines are supported.

[Learn more about isolated virtual machines](#) [Learn more about dedicated hosts](#)

# Azure Metadata Service: Scheduled Events for Linux VMs

9/21/2022 • 12 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

Scheduled Events is an Azure Metadata Service that gives your application time to prepare for virtual machine (VM) maintenance. It provides information about upcoming maintenance events (for example, reboot) so that your application can prepare for them and limit disruption. It's available for all Azure Virtual Machines types, including PaaS and IaaS on both Windows and Linux.

For information about Scheduled Events on Windows, see [Scheduled Events for Windows VMs](#).

## NOTE

Scheduled Events is generally available in all Azure Regions. See [Version and Region Availability](#) for latest release information.

## Why use Scheduled Events?

Many applications can benefit from time to prepare for VM maintenance. The time can be used to perform application-specific tasks that improve availability, reliability, and serviceability, including:

- Checkpoint and restore.
- Connection draining.
- Primary replica failover.
- Removal from a load balancer pool.
- Event logging.
- Graceful shutdown.

With Scheduled Events, your application can discover when maintenance will occur and trigger tasks to limit its impact.

Scheduled Events provides events in the following use cases:

- [Platform initiated maintenance](#) (for example, VM reboot, live migration or memory preserving updates for host).
- Virtual machine is running on [degraded host hardware](#) that is predicted to fail soon.
- Virtual machine was running on a host that suffered a hardware failure.
- User-initiated maintenance (for example, a user restarts or redeploys a VM).
- [Spot VM](#) and [Spot scale set](#) instance evictions.

## The Basics

Metadata Service exposes information about running VMs by using a REST endpoint that's accessible from within the VM. The information is available via a nonroutable IP so that it's not exposed outside the VM.

### Scope

Scheduled events are delivered to:

- Standalone Virtual Machines.
- All the VMs in a cloud service.
- All the VMs in an availability set.
- All the VMs in an availability zone.
- All the VMs in a scale set placement group.

#### **NOTE**

Scheduled Events for all virtual machines (VMs) in a Fabric Controller (FC) tenant are delivered to all VMs in a FC tenant. FC tenant equates to a standalone VM, an entire Cloud Service, an entire Availability Set, and a Placement Group for a VM Scale Set (VMSS) regardless of Availability Zone usage. For example, if you have 100 VMs in a availability set and there is an update to one of them, the scheduled event will go to all 100, whereas if there are 100 single VMs in a zone, then event will only go to the VM which is getting impacted.

As a result, check the `Resources` field in the event to identify which VMs are affected.

#### **Endpoint discovery**

For VNET enabled VMs, Metadata Service is available from a static nonroutable IP, `169.254.169.254`. The full endpoint for the latest version of Scheduled Events is:

```
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

If the VM is not created within a Virtual Network, the default cases for cloud services and classic VMs, additional logic is required to discover the IP address to use. To learn how to [discover the host endpoint](#), see this sample.

#### **Version and Region Availability**

The Scheduled Events service is versioned. Versions are mandatory; the current version is `2020-07-01`.

VERSION	RELEASE TYPE	REGIONS	RELEASE NOTES
2020-07-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for Event Duration</li> </ul>
2019-08-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for EventSource</li> </ul>
2019-04-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for Event Description</li> </ul>
2019-01-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for virtual machine scale sets EventType 'Terminate'</li> </ul>
2017-11-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for Spot VM eviction EventType 'Preempt'</li> </ul>
2017-08-01	General Availability	All	<ul style="list-style-type: none"> <li>Removed prepended underscore from resource names for IaaS VMs</li> <li>Metadata header requirement enforced for all requests</li> </ul>

VERSION	RELEASE TYPE	REGIONS	RELEASE NOTES
2017-03-01	Preview	All	<ul style="list-style-type: none"> <li>Initial release</li> </ul>

#### NOTE

Previous preview releases of Scheduled Events supported {latest} as the api-version. This format is no longer supported and will be deprecated in the future.

## Enabling and Disabling Scheduled Events

Scheduled Events is enabled for your service the first time you make a request for events. You should expect a delayed response in your first call of up to two minutes.

Scheduled Events is disabled for your service if it does not make a request for 24 hours.

### User-initiated Maintenance

User-initiated VM maintenance via the Azure portal, API, CLI, or PowerShell results in a scheduled event. You then can test the maintenance preparation logic in your application, and your application can prepare for user-initiated maintenance.

If you restart a VM, an event with the type `Reboot` is scheduled. If you redeploy a VM, an event with the type `Redeploy` is scheduled. Typically events with a user event source can be immediately approved to avoid a delay on user-initiated actions.

## Use the API

### Headers

When you query Metadata Service, you must provide the header `Metadata:true` to ensure the request wasn't unintentionally redirected. The `Metadata:true` header is required for all scheduled events requests. Failure to include the header in the request results in a "Bad Request" response from Metadata Service.

### Query for events

You can query for scheduled events by making the following call:

#### Bash sample

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

#### Python sample

```
import json
import requests

metadata_url ="http://169.254.169.254/metadata/scheduledevents"
header = {'Metadata' : 'true'}
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data
```

A response contains an array of scheduled events. An empty array means that currently no events are scheduled. In the case where there are scheduled events, the response contains an array of events.

```
{
  "DocumentIncarnation": {IncarnationID},
  "Events": [
    {
      "EventId": {eventID},
      "EventType": "Reboot" | "Redeploy" | "Freeze" | "Preempt" | "Terminate",
      "ResourceType": "VirtualMachine",
      "Resources": [{resourceName}],
      "EventStatus": "Scheduled" | "Started",
      "NotBefore": {timeInUTC},
      "Description": {eventDescription},
      "EventSource" : "Platform" | "User",
      "DurationInSeconds" : {timeInSeconds},
    }
  ]
}
```

## Event Properties

PROPERTY	DESCRIPTION
Document Incarnation	<p>Integer that increases when the events array changes.</p> <p>Documents with the same incarnation contain the same event information, and the incarnation will be incremented when an event changes.</p>
EventId	<p>Globally unique identifier for this event.</p> <p>Example:</p> <ul style="list-style-type: none"> <li>• 602d9444-d2cd-49c7-8624-8643e7171297</li> </ul>
EventType	<p>Impact this event causes.</p> <p>Values:</p> <ul style="list-style-type: none"> <li>• <code>Freeze</code> : The Virtual Machine is scheduled to pause for a few seconds. CPU and network connectivity may be suspended, but there is no impact on memory or open files.</li> <li>• <code>Reboot</code> : The Virtual Machine is scheduled for reboot (non-persistent memory is lost). ## Event Scheduling

Each event is scheduled a minimum amount of time in the future based on the event type. This time is reflected in an event's `NotBefore` property.

EVENT TYPE	MINIMUM NOTICE
Freeze	15 minutes
Reboot	15 minutes
Redeploy	10 minutes
Preempt	30 seconds

EVENT TYPE	MINIMUM NOTICE
Terminate	User Configurable: 5 to 15 minutes

#### NOTE

In some cases, Azure is able to predict host failure due to degraded hardware and will attempt to mitigate disruption to your service by scheduling a migration. Affected virtual machines will receive a scheduled event with a `NotBefore` that is typically a few days in the future. The actual time varies depending on the predicted failure risk assessment. Azure tries to give 7 days' advance notice when possible, but the actual time varies and might be smaller if the prediction is that there is a high chance of the hardware failing imminently. To minimize risk to your service in case the hardware fails before the system-initiated migration, we recommend that you self-redeploy your virtual machine as soon as possible.

#### NOTE

In the case the host node experiences a hardware failure Azure will bypass the minimum notice period and immediately begin the recovery process for affected virtual machines. This reduces recovery time in the case that the affected VMs are unable to respond. During the recovery process an event will be created for all impacted VMs with `EventType = Reboot` and `EventStatus = Started`.

## Polling frequency

You can poll the endpoint for updates as frequently or infrequently as you like. However, the longer the time between requests, the more time you potentially lose to react to an upcoming event. Most events have 5 to 15 minutes of advance notice, although in some cases advance notice might be as little as 30 seconds. To ensure that you have as much time as possible to take mitigating actions, we recommend that you poll the service once per second.

## Start an event

After you learn of an upcoming event and finish your logic for graceful shutdown, you can approve the outstanding event by making a `POST` call to Metadata Service with `EventId`. This call indicates to Azure that it can shorten the minimum notification time (when possible). The event may not start immediately upon approval, in some cases Azure will require the approval of all the VMs hosted on the node before proceeding with the event.

The following JSON sample is expected in the `POST` request body. The request should contain a list of `StartRequests`. Each `StartRequest` contains `EventId` for the event you want to expedite:

```
{
  "StartRequests" : [
    {
      "EventId": {EventId}
    }
  ]
}
```

The service will always return a 200 success code in the case of a valid event ID, even if it was already approved by a different VM. A 400 error code indicates that the request header or payload was malformed.

## Bash sample

```
curl -H Metadata:true -X POST -d '{"StartRequests": [{"EventId": "f020ba2e-3bc0-4c40-a10b-86575a9eabd5"}]}' http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

## Python sample

```
import json
import requests

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    payload = json.dumps({"StartRequests": [{"EventId": event_id }]}))
    response = requests.post("http://169.254.169.254/metadata/scheduledevents",
                             headers = {'Metadata' : 'true'},
                             params = {'api-version':'2020-07-01'},
                             data = payload)
    return response.status_code
```

### NOTE

Acknowledging an event allows the event to proceed for all `Resources` in the event, not just the VM that acknowledges the event. Therefore, you can choose to elect a leader to coordinate the acknowledgement, which might be as simple as the first machine in the `Resources` field.

## Example Responses

The following is an example of a series of events that were seen by two VMs that were live migrated to another node.

The `DocumentIncarnation` is changing every time there is new information in `Events`. An approval of the event would allow the freeze to proceed for both WestNO\_0 and WestNO\_1. The `DurationInSeconds` of -1 indicates that the platform does not know how long the operation will take.

```
{
  "DocumentIncarnation": 1,
  "Events": [
    []
  }
}

{
  "DocumentIncarnation": 2,
  "Events": [
    {
      "EventId": "C7061BAC-AFDC-4513-B24B-AA5F13A16123",
      "EventStatus": "Scheduled",
      "EventType": "Freeze",
      "ResourceType": "VirtualMachine",
      "Resources": [
        "WestNO_0",
        "WestNO_1"
      ],
      "NotBefore": "Mon, 11 Apr 2022 22:26:58 GMT",
      "Description": "Virtual machine is being paused because of a memory-preserving Live Migration operation.",
      "EventSource": "Platform",
      "DurationInSeconds": -1
    }
  ]
}

{
  "DocumentIncarnation": 3,
  "Events": [
    {
      "EventId": "C7061BAC-AFDC-4513-B24B-AA5F13A16123",
      "EventStatus": "Started",
      "EventType": "Freeze",
      "ResourceType": "VirtualMachine",
      "Resources": [
        "WestNO_0",
        "WestNO_1"
      ],
      "NotBefore": "",
      "Description": "Virtual machine is being paused because of a memory-preserving Live Migration operation.",
      "EventSource": "Platform",
      "DurationInSeconds": -1
    }
  ]
}

{
  "DocumentIncarnation": 4,
  "Events": [
    []
  }
}
```

## Python Sample

The following sample queries Metadata Service for scheduled events and approves each outstanding event:

```
#!/usr/bin/python
import json
import requests
from time import sleep

# The URL to access the metadata service
```

```

metadata_url ="http://169.254.169.254/metadata/scheduledevents"
# This must be sent otherwise the request will be ignored
header = {'Metadata' : 'true'}
# Current version of the API
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    # You can confirm multiple events in a single request if needed
    payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
    response = requests.post(metadata_url,
                            headers= header,
                            params = query_params,
                            data = payload)
    return response.status_code

def log(event):
    # This is an optional placeholder for logging events to your system
    print(event["Description"])
    return

def advanced_sample(last_document_incarnation):
    # Poll every second to see if there are new scheduled events to process
    # Since some events may have necessarily short warning periods, it is
    # recommended to poll frequently
    found_document_incarnation = last_document_incarnation
    while (last_document_incarnation == found_document_incarnation):
        sleep(1)
        payload = get_scheduled_events()
        found_document_incarnation = payload["DocumentIncarnation"]

        # We recommend processing all events in a document together,
        # even if you won't be actioning on them right away
        for event in payload["Events"]:

            # Events that have already started, logged for tracking
            if (event["EventStatus"] == "Started"):
                log(event)

            # Approve all user initiated events. These are typically created by an
            # administrator and approving them immediately can help to avoid delays
            # in admin actions
            elif (event["EventSource"] == "User"):
                confirm_scheduled_event(event["EventId"])

            # For this application, freeze events less than 9 seconds are considered
            # no impact. This will immediately approve them
            elif (event["EventType"] == "Freeze" and
                  int(event["DurationInSeconds"]) >= 0 and
                  int(event["DurationInSeconds"]) < 9):
                confirm_scheduled_event(event["EventId"])

            # Events that may be impactful (eg. Reboot or redeploy) may need custom
            # handling for your application
            else:
                #TODO Custom handling for impactful events
                log(event)
        print("Processed events from document: " + str(found_document_incarnation))
        return found_document_incarnation

def main():
    # This will track the last set of events seen
    last_document_incarnation = "-1"

```

```
input_text = "\n    Press 1 to poll for new events \n\n    Press 2 to exit \n\n"
program_exit = False

while program_exit == False:
    user_input = input(input_text)
    if (user_input == "1"):
        last_document_incarnation = advanced_sample(last_document_incarnation)
    elif (user_input == "2"):
        program_exit = True

if __name__ == '__main__':
    main()
```

# Azure Metadata Service: Scheduled Events for Windows VMs

9/21/2022 • 12 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Scheduled Events is an Azure Metadata Service that gives your application time to prepare for virtual machine (VM) maintenance. It provides information about upcoming maintenance events (for example, reboot) so that your application can prepare for them and limit disruption. It's available for all Azure Virtual Machines types, including PaaS and IaaS on both Windows and Linux.

For information about Scheduled Events on Linux, see [Scheduled Events for Linux VMs](#).

## NOTE

Scheduled Events is generally available in all Azure Regions. See [Version and Region Availability](#) for latest release information.

## Why use Scheduled Events?

Many applications can benefit from time to prepare for VM maintenance. The time can be used to perform application-specific tasks that improve availability, reliability, and serviceability, including:

- Checkpoint and restore.
- Connection draining.
- Primary replica failover.
- Removal from a load balancer pool.
- Event logging.
- Graceful shutdown.

With Scheduled Events, your application can discover when maintenance will occur and trigger tasks to limit its impact.

Scheduled Events provides events in the following use cases:

- [Platform initiated maintenance](#) (for example, VM reboot, live migration or memory preserving updates for host).
- Virtual machine is running on [degraded host hardware](#) that is predicted to fail soon.
- Virtual machine was running on a host that suffered a hardware failure.
- User-initiated maintenance (for example, a user restarts or redeploys a VM).
- [Spot VM](#) and [Spot scale set](#) instance evictions.

## The Basics

Metadata Service exposes information about running VMs by using a REST endpoint that's accessible from within the VM. The information is available via a nonroutable IP so that it's not exposed outside the VM.

### Scope

Scheduled events are delivered to:

- Standalone Virtual Machines.
- All the VMs in a cloud service.
- All the VMs in an availability set.
- All the VMs in an availability zone.
- All the VMs in a scale set placement group.

#### **NOTE**

Scheduled Events for all virtual machines (VMs) in a Fabric Controller (FC) tenant are delivered to all VMs in a FC tenant. FC tenant equates to a standalone VM, an entire Cloud Service, an entire Availability Set, and a Placement Group for a VM Scale Set (VMSS) regardless of Availability Zone usage.

As a result, check the `Resources` field in the event to identify which VMs are affected.

#### **Endpoint discovery**

For VNET enabled VMs, Metadata Service is available from a static nonroutable IP, `169.254.169.254`. The full endpoint for the latest version of Scheduled Events is:

```
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

If the VM is not created within a Virtual Network, the default cases for cloud services and classic VMs, additional logic is required to discover the IP address to use. To learn how to [discover the host endpoint](#), see this sample.

#### **Version and region availability**

The Scheduled Events service is versioned. Versions are mandatory; the current version is `2020-07-01`.

VERSION	RELEASE TYPE	REGIONS	RELEASE NOTES
2020-07-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for Event Duration</li> </ul>
2019-08-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for EventSource</li> </ul>

2019-01-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for virtual machine scale sets EventType 'Terminate'</li> </ul>
2017-11-01	General Availability	All	<ul style="list-style-type: none"> <li>Added support for Spot VM eviction EventType 'Preempt'</li> </ul>
2017-08-01	General Availability	All	<ul style="list-style-type: none"> <li>Removed prepended underscore from resource names for IaaS VMs</li> <li>Metadata header requirement enforced for all requests</li> </ul>
2017-03-01	Preview	All	<ul style="list-style-type: none"> <li>Initial release</li> </ul>

#### **NOTE**

Previous preview releases of Scheduled Events supported {latest} as the api-version. This format is no longer supported and will be deprecated in the future.

## **Enabling and disabling Scheduled Events**

Scheduled Events is enabled for your service the first time you make a request for events. You should expect a delayed response in your first call of up to two minutes.

Scheduled Events is disabled for your service if it does not make a request for 24 hours.

### **User-initiated maintenance**

User-initiated VM maintenance via the Azure portal, API, CLI, or PowerShell results in a scheduled event. You then can test the maintenance preparation logic in your application, and your application can prepare for user-initiated maintenance.

If you restart a VM, an event with the type `Reboot` is scheduled. If you redeploy a VM, an event with the type `Redeploy` is scheduled. Typically events with a user event source can be immediately approved to avoid a delay on user-initiated actions.

## **Use the API**

### **Headers**

When you query Metadata Service, you must provide the header `Metadata:true` to ensure the request wasn't unintentionally redirected. The `Metadata:true` header is required for all scheduled events requests. Failure to include the header in the request results in a "Bad Request" response from Metadata Service.

### **Query for events**

You can query for scheduled events by making the following call:

#### **Bash sample**

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

#### **PowerShell sample**

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -Uri "http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01" | ConvertTo-Json -Depth 64
```

#### **Python sample**

```
import json
import requests

metadata_url = "http://169.254.169.254/metadata/scheduledevents"
header = {'Metadata' : 'true'}
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data
```

A response contains an array of scheduled events. An empty array means that currently no events are scheduled. In the case where there are scheduled events, the response contains an array of events.

```
{
  "DocumentIncarnation": {IncarnationID},
  "Events": [
    {
      "EventId": {eventID},
      "EventType": "Reboot" | "Redeploy" | "Freeze" | "Preempt" | "Terminate",
      "ResourceType": "VirtualMachine",
      "Resources": [{resourceName}],
      "EventStatus": "Scheduled" | "Started",
      "NotBefore": {timeInUTC},
      "Description": {eventDescription},
      "EventSource" : "Platform" | "User",
      "DurationInSeconds" : {timeInSeconds},
    }
  ]
}
```

## Event scheduling

Each event is scheduled a minimum amount of time in the future based on the event type. This time is reflected in an event's `NotBefore` property.

EVENT TYPE	MINIMUM NOTICE
Freeze	15 minutes
Reboot	15 minutes
Redeploy	10 minutes
Preempt	30 seconds

EVENT TYPE	MINIMUM NOTICE
Terminate	User Configurable: 5 to 15 minutes

#### NOTE

In some cases, Azure is able to predict host failure due to degraded hardware and will attempt to mitigate disruption to your service by scheduling a migration. Affected virtual machines will receive a scheduled event with a `NotBefore` that is typically a few days in the future. The actual time varies depending on the predicted failure risk assessment. Azure tries to give 7 days' advance notice when possible, but the actual time varies and might be smaller if the prediction is that there is a high chance of the hardware failing imminently. To minimize risk to your service in case the hardware fails before the system-initiated migration, we recommend that you self-redeploy your virtual machine as soon as possible.

#### NOTE

In the case the host node experiences a hardware failure Azure will bypass the minimum notice period and immediately begin the recovery process for affected virtual machines. This reduces recovery time in the case that the affected VMs are unable to respond. During the recovery process an event will be created for all impacted VMs with `EventType = Reboot` and `EventStatus = Started`.

## Polling frequency

You can poll the endpoint for updates as frequently or infrequently as you like. However, the longer the time between requests, the more time you potentially lose to react to an upcoming event. Most events have 5 to 15 minutes of advance notice, although in some cases advance notice might be as little as 30 seconds. To ensure that you have as much time as possible to take mitigating actions, we recommend that you poll the service once per second.

## Start an event

After you learn of an upcoming event and finish your logic for graceful shutdown, you can approve the outstanding event by making a `POST` call to Metadata Service with `EventId`. This call indicates to Azure that it can shorten the minimum notification time (when possible). The event may not start immediately upon approval, in some cases Azure will require the approval of all the VMs hosted on the node before proceeding with the event.

The following JSON sample is expected in the `POST` request body. The request should contain a list of `StartRequests`. Each `StartRequest` contains `EventId` for the event you want to expedite:

```
{
  "StartRequests" : [
    {
      "EventId": {EventId}
    }
  ]
}
```

The service will always return a 200 success code in the case of a valid event ID, even if it was already approved by a different VM. A 400 error code indicates that the request header or payload was malformed.

## Bash sample

```
curl -H Metadata:true -X POST -d '{"StartRequests": [{"EventId": "f020ba2e-3bc0-4c40-a10b-86575a9eabd5"}]}' http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

## PowerShell sample

```
Invoke-RestMethod -Headers @{"Metadata" = "true"} -Method POST -body '{"StartRequests": [{"EventId": "5DD55B64-45AD-49D3-BBC9-F57D4EA97BD7"}]}' -Uri http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01 | ConvertTo-Json -Depth 64
```

## Python sample

```
import json
import requests

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    payload = json.dumps({"StartRequests": [{"EventId": event_id}]})
    response = requests.post("http://169.254.169.254/metadata/scheduledevents",
                             headers = {'Metadata' : 'true'},
                             params = {'api-version':'2020-07-01'},
                             data = payload)
    return response.status_code
```

### NOTE

Acknowledging an event allows the event to proceed for all `Resources` in the event, not just the VM that acknowledges the event. Therefore, you can choose to elect a leader to coordinate the acknowledgement, which might be as simple as the first machine in the `Resources` field.

## Example responses

The following is an example of a series of events that were seen by two VMs that were live migrated to another node.

The `DocumentIncarnation` is changing every time there is new information in `Events`. An approval of the event would allow the freeze to proceed for both WestNO\_0 and WestNO\_1. The `DurationInSeconds` of -1 indicates that the platform does not know how long the operation will take.

```
{
  "DocumentIncarnation": 1,
  "Events": [
    []
  }
}

{
  "DocumentIncarnation": 2,
  "Events": [
    {
      "EventId": "C7061BAC-AFDC-4513-B24B-AA5F13A16123",
      "EventStatus": "Scheduled",
      "EventType": "Freeze",
      "ResourceType": "VirtualMachine",
      "Resources": [
        "WestNO_0",
        "WestNO_1"
      ],
      "NotBefore": "Mon, 11 Apr 2022 22:26:58 GMT",
      "Description": "Virtual machine is being paused because of a memory-preserving Live Migration operation.",
      "EventSource": "Platform",
      "DurationInSeconds": -1
    }
  ]
}

{
  "DocumentIncarnation": 3,
  "Events": [
    {
      "EventId": "C7061BAC-AFDC-4513-B24B-AA5F13A16123",
      "EventStatus": "Started",
      "EventType": "Freeze",
      "ResourceType": "VirtualMachine",
      "Resources": [
        "WestNO_0",
        "WestNO_1"
      ],
      "NotBefore": "",
      "Description": "Virtual machine is being paused because of a memory-preserving Live Migration operation.",
      "EventSource": "Platform",
      "DurationInSeconds": -1
    }
  ]
}

{
  "DocumentIncarnation": 4,
  "Events": [
    []
  }
}
```

## Python Sample

The following sample queries Metadata Service for scheduled events and approves each outstanding event:

```
#!/usr/bin/python
import json
import requests
from time import sleep

# The URL to access the metadata service
```

```

metadata_url ="http://169.254.169.254/metadata/scheduledevents"
# This must be sent otherwise the request will be ignored
header = {'Metadata' : 'true'}
# Current version of the API
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    # You can confirm multiple events in a single request if needed
    payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
    response = requests.post(metadata_url,
                            headers= header,
                            params = query_params,
                            data = payload)
    return response.status_code

def log(event):
    # This is an optional placeholder for logging events to your system
    print(event["Description"])
    return

def advanced_sample(last_document_incarnation):
    # Poll every second to see if there are new scheduled events to process
    # Since some events may have necessarily short warning periods, it is
    # recommended to poll frequently
    found_document_incarnation = last_document_incarnation
    while (last_document_incarnation == found_document_incarnation):
        sleep(1)
        payload = get_scheduled_events()
        found_document_incarnation = payload["DocumentIncarnation"]

        # We recommend processing all events in a document together,
        # even if you won't be actioning on them right away
        for event in payload["Events"]:

            # Events that have already started, logged for tracking
            if (event["EventStatus"] == "Started"):
                log(event)

            # Approve all user initiated events. These are typically created by an
            # administrator and approving them immediately can help to avoid delays
            # in admin actions
            elif (event["EventSource"] == "User"):
                confirm_scheduled_event(event["EventId"])

            # For this application, freeze events less than 9 seconds are considered
            # no impact. This will immediately approve them
            elif (event["EventType"] == "Freeze" and
                  int(event["DurationInSeconds"]) >= 0 and
                  int(event["DurationInSeconds"]) < 9):
                confirm_scheduled_event(event["EventId"])

            # Events that may be impactful (eg. Reboot or redeploy) may need custom
            # handling for your application
            else:
                #TODO Custom handling for impactful events
                log(event)
        print("Processed events from document: " + str(found_document_incarnation))
        return found_document_incarnation

def main():
    # This will track the last set of events seen
    last_document_incarnation = "-1"

```

```
input_text = "\n    Press 1 to poll for new events \n\n    Press 2 to exit \n\n"
program_exit = False

while program_exit == False:
    user_input = input(input_text)
    if (user_input == "1"):
        last_document_incarnation = advanced_sample(last_document_incarnation)
    elif (user_input == "2"):
        program_exit = True

if __name__ == '__main__':
    main()
```

# Monitor scheduled events for your Azure VMs

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

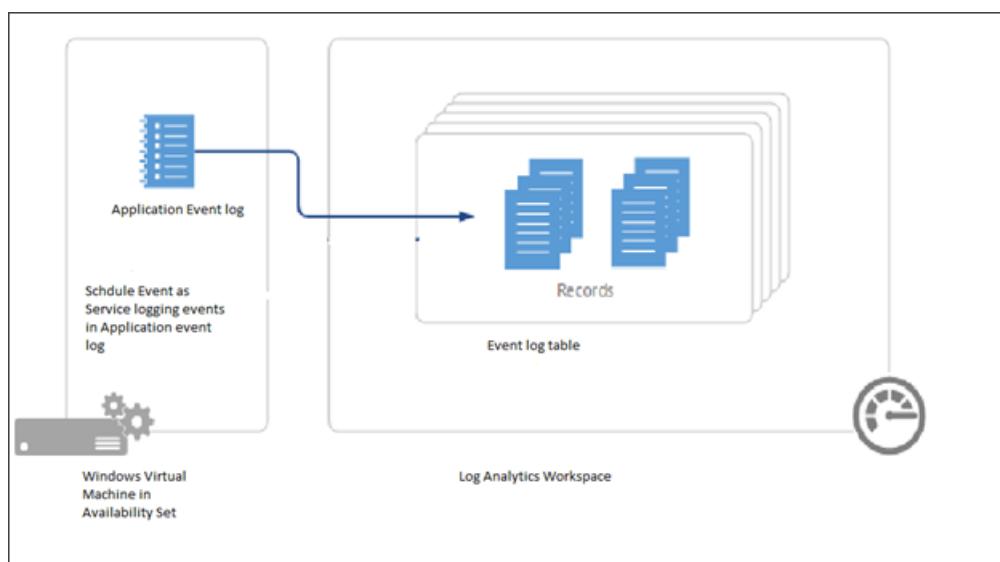

Updates are applied to different parts of Azure every day, to keep the services running on them secure, and up-to-date. In addition to planned updates, unplanned events may also occur. For example, if any hardware degradation or fault is detected, Azure services may need to perform unplanned maintenance. Using live migration, memory preserving updates and generally keeping a strict bar on the impact of updates, in most cases these events are almost transparent to customers, and they have no impact or at most cause a few seconds of virtual machine freeze. However, for some applications, even a few seconds of virtual machine freeze could cause an impact. Knowing in advance about upcoming Azure maintenance is important, to ensure the best experience for those applications. [Scheduled Events service](#) provides you a programmatic interface to be notified about upcoming maintenance, and enables you to gracefully handle the maintenance.

In this article, we will show how you can use scheduled events to be notified about maintenance events that could be affecting your VMs and build some basic automation that can help with monitoring and analysis.

## Routing scheduled events to Log Analytics

Scheduled Events is available as part of the [Azure Instance Metadata Service](#), which is available on every Azure virtual machine. Customers can write automation to query the endpoint of their virtual machines to find scheduled maintenance notifications and perform mitigations, like saving the state and taking the virtual machine out of rotation. We recommend building automation to record the Scheduled Events so you can have an auditing log of Azure maintenance events.

In this article, we will walk you through how to capture maintenance Scheduled Events to Log Analytics. Then, we will trigger some basic notification actions, like sending an email to your team and getting a historical view of all events that have affected your virtual machines. For the event aggregation and automation we will use [Log Analytics](#), but you can use any monitoring solution to collect these logs and trigger automation.

## Prerequisites

For this example, you will need to create a [Windows Virtual Machine in an Availability Set](#). Scheduled Events provide notifications about changes that can affect any of the virtual machines in your availability set, Cloud

Service, Virtual Machine Scale Set or standalone VMs. We will be running a [service](#) that polls for scheduled events on one of the VMs that will act as a collector, to get events for all of the other VMs in the availability set.

Don't delete the group resource group at the end of the tutorial.

You will also need to [create a Log Analytics workspace](#) that we will use to aggregate information from the VMs in the availability set.

## Set up the environment

You should now have 2 initial VMs in an availability set. Now we need to create a 3rd VM, called `myCollectorVM`, in the same availability set.

```
New-AzVm ` 
  -ResourceGroupName "myResourceGroupAvailability" ` 
  -Name "myCollectorVM" ` 
  -Location "East US" ` 
  -VirtualNetworkName "myVnet" ` 
  -SubnetName "mySubnet" ` 
  -SecurityGroupName "myNetworkSecurityGroup" ` 
  -OpenPorts 3389 ` 
  -PublicIpAddressName "myPublicIpAddress3" ` 
  -AvailabilitySetName "myAvailabilitySet" ` 
  -Credential $cred
```

Download the installation .zip file of the project from [GitHub](#).

Connect to `myCollectorVM` and copy the .zip file to the virtual machine and extract all of the files. On your VM, open a PowerShell prompt. Move your prompt into the folder containing `SchService.ps1`, for example:

```
PS C:\Users\azureuser\AzureScheduledEventsService-master\AzureScheduledEventsService-master\Powershell>, and
set up the service.
```

```
.\SchService.ps1 -Setup
```

Start the service.

```
.\SchService.ps1 -Start
```

The service will now start polling every 10 seconds for any scheduled events and approve the events to expedite the maintenance. Freeze, Reboot, Redeploy, and Preempt are the events captured by Schedule events. Note that you can extend the script to trigger some mitigations prior to approving the event.

Validate the service status and make sure it is running.

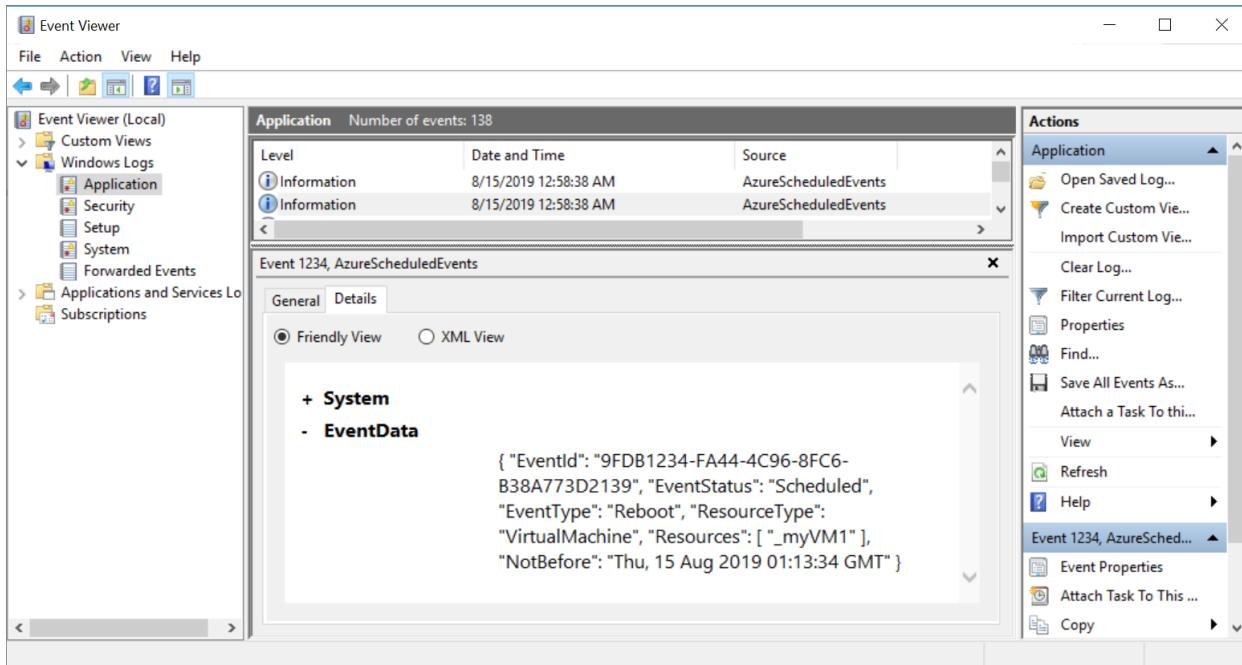

```
.\SchService.ps1 -status
```

This should return `Running`.

The service will now start polling every 10 seconds for any scheduled events and approve the events to expedite the maintenance. Freeze, Reboot, Redeploy and Preempt are the events captured by Schedule events. You can extend the script to trigger some mitigations prior to approving the event.

When any of the above events are captured by Schedule Event service, it will get logged in the Application Event Log Event Status, Event Type, Resources (Virtual machine names) and NotBefore (minimum notice period). You can locate the events with ID 1234 in the Application Event Log.

Once the service is set up and started, it will log events in the Windows Application logs. To verify this works, restart one of the virtual machines in the availability set and you should see an event being logged in Event viewer in Windows Logs > Application log showing the VM restarted.

When events are captured by the Schedule Event service, it will get logged in the application even log with Event Status, Event Type, Resources (VM name) and NotBefore (minimum notice period). You can locate the events with ID 1234 in the Application Event Log.

#### NOTE

In this example, the virtual machines were are in an availability set, which enabled us to designate a single virtual machine as the collector to listen and route scheduled events to our log analytics works space. If you have standalone virtual machines, you can run the service on every virtual machine, and then connect them individually to your log analytics workspace.

For our set up, we chose Windows, but you can design a similar solution on Linux.

At any point you can stop/remove the Scheduled Event Service by using the switches `-stop` and `-remove`.

## Connect to the workspace

We now want to connect a Log Analytics Workspace to the collector VM. The Log Analytics workspace acts as a repository and we will configure event log collection to capture the application logs from the collector VM.

To route the Scheduled Events to the Events Log, which will be saved as Application log by our service, you will need to connect your virtual machine to your Log Analytics workspace.

1. Open the page for the workspace you created.
2. Under Connect to a data source select **Azure virtual machines (VMs)**.

## Get started with Log Analytics

Log Analytics collects data from a variety of sources and uses a powerful query language to give you insights into the operation of your applications and resources. Use Azure Monitor to access the complete set of tools for monitoring all of your Azure resources.

### 1 Connect a data source

Select one or more data sources to connect to the workspace

[Azure virtual machines \(VMs\)](#)

[Windows, Linux and other sources](#)

[Azure Activity logs](#)

3. Search for and select **myCollectorVM**.

4. On the new page for **myCollectorVM**, select **Connect**.

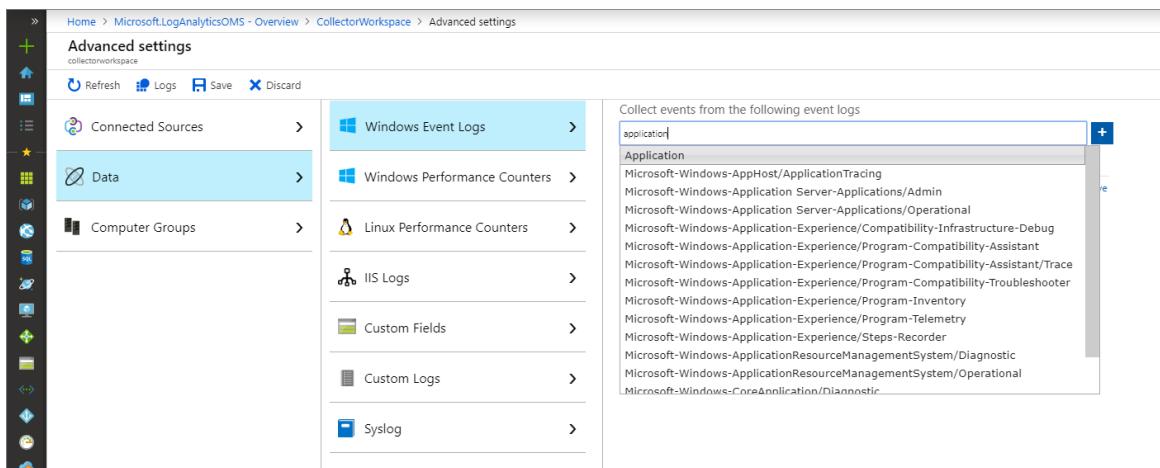

This will install the [Microsoft Monitoring agent](#) in your virtual machine. It will take a few minutes to connect your VM to the workspace and install the extension.

## Configure the workspace

1. Open the page for your workspace and select **Advanced settings**.

2. Select **Data** from the left menu, then select **Windows Event Logs**.

3. In **Collect from the following event logs**, start typing *application* and then select **Application** from the list.

4. Leave **ERROR**, **WARNING**, and **INFORMATION** selected and then select **Save** to save the settings.

### NOTE

There will be some delay, and it may take up to 10 minutes before the log is available.

## Creating an alert rule with Azure Monitor

Once the events are pushed to Log Analytics, you can run the following [query](#) to look for the schedule Events.

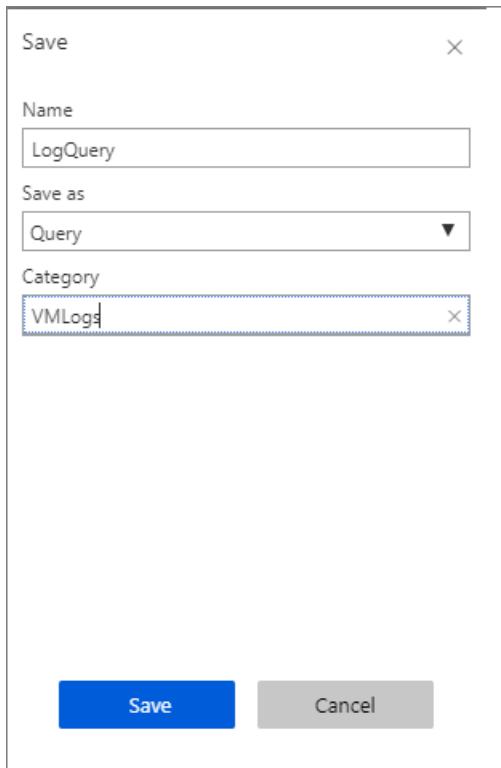

1. At the top of the page, select **Logs** and paste the following into the text box:

```

Event
| where EventLog == "Application" and Source contains "AzureScheduledEvents" and RenderedDescription
contains "Scheduled" and RenderedDescription contains "EventStatus"
| project TimeGenerated, RenderedDescription
| extend ReqJson= parse_json(RenderedDescription)
| extend EventId = ReqJson["EventId"]
,EventStatus = ReqJson["EventStatus"]
,EventType = ReqJson["EventType"]
,NotBefore = ReqJson["NotBefore"]
,ResourceType = ReqJson["ResourceType"]
,Resources = ReqJson["Resources"]
| project-away RenderedDescription,ReqJson

```

2. Select **Save**, and then type `LogQuery` for the name, leave **Query** as the type, type `VMLogs` as the **Category**, and then select **Save**.

3. Select **New alert rule**.
4. In the **Create rule** page, leave `collectorworkspace` as the **Resource**.
5. Under **Condition**, select the entry *Whenever the customer log search is <login undefined>*. The **Configure signal logic** page will open.
6. Under **Threshold value**, enter *0* and then select **Done**.
7. Under **Actions**, select **Create action group**. The **Add action group** page will open.
8. In **Action group name**, type *myActionGroup*.
9. In **Short name**, type *myActionGroup*.
10. In **Resource group**, select **myResourceGroupAvailability**.
11. Under **Actions**, in **ACTION NAME** type **Email**, and then select **Email/SMS/Push/Voice**. The **Email/SMS/Push/Voice** page will open.
12. Select **Email**, type in your e-mail address, then select **OK**.
13. In the **Add action group** page, select **OK**.

14. In the **Create rule** page, under **ALERT DETAILS**, type *myAlert* for the **Alert rule name**, and then type *Email alert rule* for the **Description**.
15. When you are finished, select **Create alert rule**.
16. Restart one of the VMs in the availability set. Within a few minutes, you should get an e-mail that the alert has been triggered.

To manage your alert rules, go to the resource group, select **Alerts** from the left menu, and then select **Manage alert rules** from the top of the page.

## Next steps

To learn more, see the [Scheduled events service](#) page on GitHub.

# Tutorial: Monitor changes and update a Linux virtual machine in Azure

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure [Change Tracking](#) allows you to easily identify changes and [Update Management](#) allows you to manage operating system updates for your Azure Linux VMs.

In this tutorial, you learn how to:

- Manage Linux updates
- Monitor changes and inventory

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This tutorial requires version 2.0.30 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create VM

To see diagnostics and metrics in action, you need a VM. First, create a resource group with `az group create`. The following example creates a resource group named `myResourceGroupMonitor` in the `eastus` location.

```
az group create --name myResourceGroupMonitor --location eastus
```

Now create a VM with `az vm create`. The following example creates a VM named `myVM` and generates SSH keys if they do not already exist in `~/.ssh/`.

```
az vm create \
--resource-group myResourceGroupMonitor \
--name myVM \
--image UbuntuLTS \
--admin-username azureuser \
--generate-ssh-keys
```

## Manage software updates

Update management allows you to manage updates and patches for your Azure Linux VMs. Directly from your VM, you can quickly assess the status of available updates, schedule installation of required updates, and review deployment results to verify updates were applied successfully to the VM.

For pricing information, see [Automation pricing for Update management](#)

### Enable Update management

Enable Update management for your VM:

1. On the left-hand side of the screen, select **Virtual machines**.
2. From the list, select a VM.
3. On the VM screen, in the **Operations** section, select **Update management**. The **Enable Update Management** screen opens.

Validation is performed to determine if Update management is enabled for this VM. The validation includes checks for a Log Analytics workspace and linked Automation account, and if the solution is in the workspace.

A [Log Analytics](#) workspace is used to collect data that is generated by features and services such as Update management. The workspace provides a single location to review and analyze data from multiple sources. To perform additional actions on VMs that require updates, Azure Automation allows you to run runbooks against VMs, such as download and apply updates.

The validation process also checks to see if the VM is provisioned with the Log Analytics agent and Automation hybrid runbook worker. This agent is used to communicate with the VM and obtain information about the update status.

Choose the Log Analytics workspace and automation account and select **Enable** to enable the solution. The solution takes up to 15 minutes to enable.

If any of the following prerequisites were found to be missing during onboarding, they're automatically added:

- [Log Analytics workspace](#)
- [Automation account](#)
- A [Hybrid runbook worker](#) is enabled on the VM

The **Update Management** screen opens. Configure the location, Log Analytics workspace and Automation account to use and select **Enable**. If the fields are grayed out, that means another automation solution is enabled for the VM and the same workspace and Automation account must be used.

Enabling the solution can take up to 15 minutes. During this time, you shouldn't close the browser window. After the solution is enabled, information about missing updates on the VM flows to Azure Monitor logs. It can take between 30 minutes and 6 hours for the data to be available for analysis.

## View update assessment

After **Update management** is enabled, the **Update management** screen appears. After the evaluation of updates is complete, you see a list of missing updates on the **Missing updates** tab.

UPDATE NAME	CLASSIFICATION	INFORMATION LINK
apport	critical	<a href="#">View details</a>
sudo	critical	<a href="#">View details</a>
linux-firmware	critical	<a href="#">View details</a>
dosfstools	security	<a href="#">View details</a>
bash	security	<a href="#">View details</a>
cpio	security	<a href="#">View details</a>
curl	security	<a href="#">View details</a>
patch	security	<a href="#">View details</a>

## Schedule an update deployment

To install updates, schedule a deployment that follows your release schedule and service window. You can choose which update types to include in the deployment. For example, you can include critical or security updates and exclude update rollups.

Schedule a new Update Deployment for the VM by clicking **Schedule update deployment** at the top of the **Update management** screen. In the **New update deployment** screen, specify the following information:

To create a new update deployment, select **Schedule update deployment**. The **New update deployment**

page opens. Enter values for the properties described in the following table and then click **Create**:

PROPERTY	DESCRIPTION
Name	Unique name to identify the update deployment.
Operating System	Linux or Windows
Groups to update	<p>For Azure machines, define a query based on a combination of subscription, resource groups, locations, and tags to build a dynamic group of Azure VMs to include in your deployment.</p> <p>For Non-Azure machines, select an existing saved search to select a group of Non-Azure machines to include in the deployment.</p> <p>To learn more, see <a href="#">Dynamic Groups</a></p>
Machines to update	<p>Select a Saved search, Imported group, or pick Machine from the drop-down and select individual machines. If you choose <b>Machines</b>, the readiness of the machine is shown in the <b>UPDATE AGENT READINESS</b> column.</p> <p>To learn about the different methods of creating computer groups in Azure Monitor logs, see <a href="#">Computer groups in Azure Monitor logs</a></p>
Update classifications	Select all the update classifications that you need
Include/exclude updates	This opens the <b>Include/Exclude</b> page. Updates to be included or excluded are on separate tabs. For more information on how inclusion is handled, see <a href="#">Schedule an Update Deployment</a>
Schedule settings	Select the time to start, and select either Once or recurring for the recurrence
Pre-scripts + Post-scripts	Select the scripts to run before and after your deployment
Maintenance window	Number of minutes set for updates. The value can't be less than 30 minutes and no more than 6 hours
Reboot control	<p>Determines how reboots should be handled. Available options are:</p> <ul style="list-style-type: none"> <li>Reboot if required (Default)</li> <li>Always reboot</li> <li>Never reboot</li> <li>Only reboot - will not install updates</li> </ul>

Update Deployments can also be created programmatically. To learn how to create an Update Deployment with the REST API, see [Software Update Configurations - Create](#). There is also a sample runbook that can be used to create a weekly Update Deployment. To learn more about this runbook, see [Create a weekly update deployment for one or more VMs in a resource group](#).

After you have completed configuring the schedule, click **Create** button and you return to the status dashboard. Notice that the **Scheduled** table shows the deployment schedule you created.

#### **View results of an update deployment**

After the scheduled deployment starts, you can see the status for that deployment on the **Update deployments** tab on the **Update management** screen. If it is currently running, its status shows as **In progress**. After it completes, if successful, it changes to **Succeeded**. If there is a failure with one or more updates in the deployment, the status is **Partially failed**. Select the completed update deployment to see the dashboard for that update deployment.

The screenshot shows the Update management dashboard for a VM named Marketing10. The deployment run has completed successfully. The deployment results summary indicates 89 Updates, all of which were Succeeded. The detailed updates status table lists five specific updates, each with a green checkmark indicating success. Below the table, there are navigation links for page numbers 1 through 18. The bottom section of the dashboard features three tabs: All Logs, Output, and Errors. The Errors tab is selected, showing 0 errors.

UPDATE NAME	STATUS
NetworkManager-libnm.x86_64	Succeeded
NetworkManager-tui.x86_64	Succeeded
NetworkManager-team.x86_64	Succeeded
NetworkManager.x86_64	Succeeded
WALinuxAgent.noarch	Succeeded

In **Update results** tile is a summary of the total number of updates and deployment results on the VM. In the table to the right is a detailed breakdown of each update and the installation results, which could be one of the following values:

- **Not attempted** - the update was not installed because there was insufficient time available based on the maintenance window duration defined.
- **Succeeded** - the update succeeded
- **Failed** - the update failed

Select **All logs** to see all log entries that the deployment created.

Select the **Output** tile to see job stream of the runbook responsible for managing the update deployment on the target VM.

Select **Errors** to see detailed information about any errors from the deployment.

## Monitor changes and inventory

You can collect and view inventory for software, files, Linux daemons, Windows Services, and Windows registry keys on your computers. Tracking the configurations of your machines can help you pinpoint operational issues across your environment and better understand the state of your machines.

### Enable Change and Inventory management

Enable Change and Inventory management for your VM:

1. On the left-hand side of the screen, select **Virtual machines**.
2. From the list, select a VM.
3. On the VM screen, in the **Operations** section, select **Inventory or Change tracking**. The **Enable Change Tracking and Inventory** screen opens.

Configure the location, Log Analytics workspace and Automation account to use and select **Enable**. If the fields are grayed out, that means another automation solution is enabled for the VM and the same workspace and Automation account must be used. Even though the solutions are separate on the menu, they are the same.

solution. Enabling one enables both for your VM.

The screenshot shows the Azure portal interface for a virtual machine named 'myVM'. The left sidebar has a search bar and several navigation items: Auto-shutdown, Backup, Disaster recovery (Preview), Update management, Inventory (which is selected and highlighted in blue), and Change tracking. Below these are sections for MONITORING: Metrics, Alert rules, Diagnostics settings, Advisor recommendations, and Diagram. The main content area is titled 'Inventory' and contains the following text:  
Enable consistent control and compliance of this VM with Change Tracking and Inventory.  
This service is included with Azure virtual machines. You only pay for logs stored in Log Analytics.  
This service requires a Log Analytics workspace and an Automation account. You can use your existing workspace and account or let us configure the nearest workspace and account for use.  
Below this are three dropdown menus: Location (set to East US), Log Analytics workspace (set to defaultworkspace), and Automation account (set to Automate). A large blue 'Enable' button is at the bottom.

After the solution has been enabled, it may take some time while inventory is being collected on the VM before data appears.

## Track changes

On your VM, select **Change Tracking** under **OPERATIONS**. Select **Edit Settings**, the **Change Tracking** page is displayed. Select the type of setting you want to track and then select **+ Add** to configure the settings. The available option Linux is **Linux Files**

For detailed information on Change Tracking see, [Troubleshoot changes on a VM](#)

## View inventory

On your VM, select **Inventory** under **OPERATIONS**. On the **Software** tab, there is a table list the software that had been found. The high-level details for each software record are viewable in the table. These details include the software name, version, publisher, last refreshed time.

The screenshot shows the 'Software' tab of the 'Inventory' configuration page. At the top, there is a summary: 'New software 1' (with a '7' icon), 'Last 24 hours', and links to 'Learn more', 'Inventory', and 'Provide feedback'. Below this is a navigation bar with tabs: Software (which is selected and highlighted in blue), Files, and Linux Daemons. There is also a search bar: 'Search to filter items...'. The main area is a table with the following columns: NAME, VERSION, PUBLISHER, and LAST REFRESHED TIME. The table lists the following software packages:

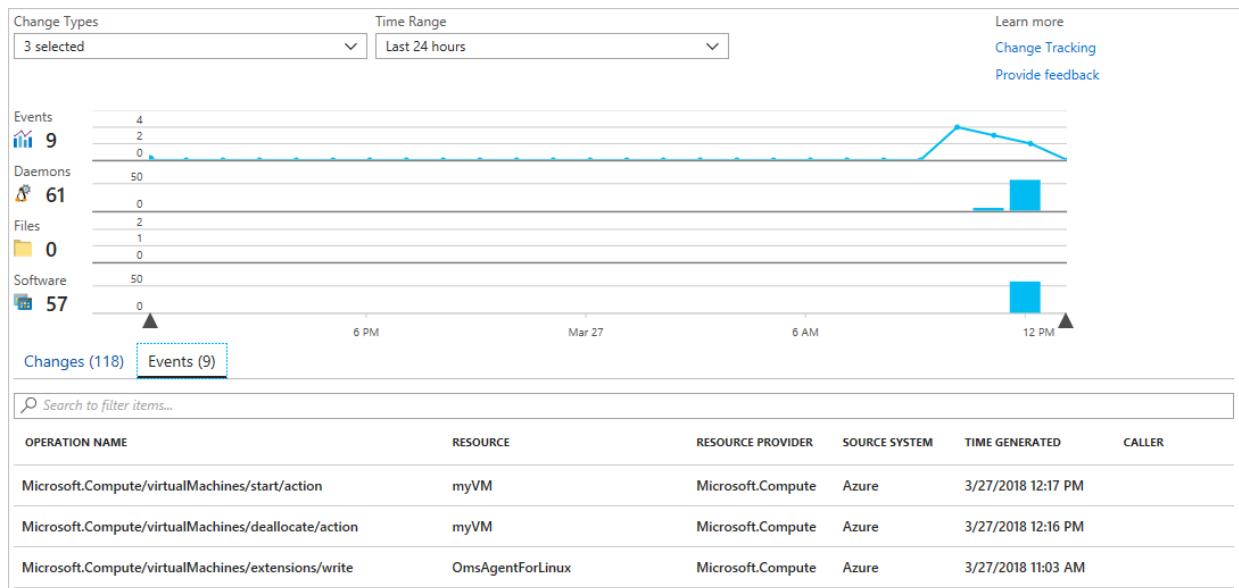

NAME	VERSION	PUBLISHER	LAST REFRESHED TIME	...
accountsservice	0.6.40-2ubuntu11.3	Ubuntu Developers <ubun...	3/27/2018 11:51 AM	...

## Monitor Activity logs and changes

From the **Change tracking** page on your VM, select **Manage Activity Log Connection**. This task opens the **Azure Activity log** page. Select **Connect** to connect Change tracking to the Azure activity log for your VM.

With this setting enabled, navigate to the **Overview** page for your VM and select **Stop** to stop your VM. When prompted, select **Yes** to stop the VM. When it is deallocated, select **Start** to restart your VM.

Stopping and starting a VM logs an event in its activity log. Navigate back to the **Change tracking** page. Select the **Events** tab at the bottom of the page. After a while, the events shown in the chart and the table. Each event can be selected to view detailed information on the event.

The chart shows changes that have occurred over time. After you have added an Activity Log connection, the line graph at the top displays Azure Activity Log events. Each row of bar graphs represents a different trackable Change type. These types are Linux daemons, files, and software. The change tab shows the details for the changes shown in the visualization in descending order of time that the change occurred (most recent first).

## Next steps

In this tutorial, you configured and reviewed Change Tracking and Update Management for your VM. You learned how to:

- Create a resource group and VM
- Manage Linux updates
- Monitor changes and inventory

Advance to the next tutorial to learn about monitoring your VM.

[Monitor virtual machines](#)

# Tutorial: Monitor changes and update a Windows virtual machine in Azure

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

With Azure [Change Tracking](#) and [Update Management](#), you can easily identify changes in your Windows virtual machines in Azure and manage operating system updates for those VMs.

In this tutorial, you learn how to:

- Manage Windows updates.
- Monitor changes and inventory.

## Open Azure Cloud Shell

Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your Azure account.

To open any code block in Cloud Shell, just select Try it from the upper-right corner of that code block.

You can also open Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select Copy to copy code blocks, paste them into the Cloud Shell tab, and select the Enter key to run the code.

## Create a virtual machine

To configure Azure monitoring and update management in this tutorial, you need a Windows VM in Azure.

First, set an administrator username and password for the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Next, create the VM with [New-AzVM](#). The following example creates a VM named myVM in the East US location. If they don't already exist, the resource group myResourceGroupMonitor and supporting network resources are created:

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroupMonitor" ` 
    -Name "myVM" ` 
    -Location "East US" ` 
    -Credential $cred
```

It takes a few minutes for the resources and VM to be created.

## Manage Windows updates

Update Management helps you manage updates and patches for your Azure Windows VMs. Directly from your VM, you can quickly:

- Assess the status of available updates.
- Schedule installation of required updates.

- Review deployment results to verify updates were successfully applied to the VM.

For pricing information, see [Automation pricing for Update management](#).

## Enable Update Management

To enable Update Management for your VM:

1. Navigate to your VM in the Azure portal (search for **Virtual machines** in the search bar, then choose a VM from the list).
2. Select **Updates** under Operations.
3. Click on **Go to Updates using automation**.
4. The **Enable Update Management** window opens.

Validation is done to determine if Update Management is enabled for this VM. Validation includes checks for a Log Analytics workspace, for a linked Automation account, and for whether the solution is in the workspace.

You use a [Log Analytics](#) workspace to collect data that is generated by features and services such as Update Management. The workspace provides a single location to review and analyze data from multiple sources.

To perform additional actions on VMs that require updates, you can use Azure Automation to run runbooks against VMs. Such actions include downloading or applying updates.

The validation process also checks to see if the VM is provisioned with the Microsoft Monitoring Agent (MMA) and Automation Hybrid Runbook Worker. You use the agent to communicate with the VM and obtain information about the update status.

In the **Enable Update Management** window, choose the Log Analytics workspace and automation account, and then select **Enable**. The solution takes up to 15 minutes to become enabled.

Any of the following prerequisites that are missing during onboarding are automatically added:

- [Log Analytics](#) workspace
- [Automation](#)
- A [Hybrid runbook worker](#), which is enabled on the VM

After the solution is enabled, the **Update management** window opens. Configure the location, Log Analytics workspace and Automation account to use, and then select **Enable**. If these options appear dimmed, another automation solution is enabled for the VM, and that solution's workspace and Automation account must be used.

The Update Management solution can take up to 15 minutes to become enabled. During this time, don't close the browser window. After the solution is enabled, information about missing updates on the VM flows to Azure Monitor logs. It can take from 30 minutes to 6 hours for the data to become available for analysis.

## View an update assessment

After Update Management is enabled, the **Update management** window appears. After the evaluation of updates is finished, you see a list of missing updates on the **Missing updates** tab.

UPDATE NAME	CLASSIFICATION	PUBLISHED DATE	INFORMATION LINK
2019-05 Cumulative Update for Windows Server 2016 for ...	Updates	5/22/2019	<a href="#">KB4499177</a>
Definition Update for Windows Defender Antivirus - KB22...	Definition updates	6/2/2019	<a href="#">KB2267602</a>
Definition Update for Windows Defender Antivirus - KB22...	Definition updates	6/2/2019	<a href="#">KB2267602</a>

## Schedule an update deployment

To install updates, schedule a deployment that follows your release schedule and service window. You choose which update types to include in the deployment. For example, you can include critical or security updates and exclude update rollups.

To schedule a new update deployment for the VM, select **Schedule update deployment** at the top of the **Update management** window. In the **New update deployment** window, specify the following information:

OPTION	DESCRIPTION
Name	Enter a unique name to identify the update deployment.
Operating system	Select either <b>Linux</b> or <b>Windows</b> .

OPTION	DESCRIPTION
<b>Groups to update</b>	<p>For VMs hosted on Azure, define a query based on a combination of subscription, resource groups, locations, and tags. This query builds a dynamic group of Azure-hosted VMs to include in your deployment.</p> <p>For VMs not hosted on Azure, select an existing saved search. With this search, you can select a group of these VMs to include in the deployment.</p> <p>To learn more, see <a href="#">Dynamic Groups</a>.</p>
<b>Machines to update</b>	<p>Select <b>Saved search</b>, <b>Imported group</b>, or <b>Machines</b>.</p> <p>If you select <b>Machines</b>, you can choose individual machines from the drop-down list. The readiness of each machine is shown in the <b>UPDATE AGENT READINESS</b> column of the table.</p> <p>To learn about the different methods of creating computer groups in Azure Monitor logs, see <a href="#">Computer groups in Azure Monitor logs</a></p>
<b>Update classifications</b>	Choose all necessary update classifications.
<b>Include/exclude updates</b>	Select this option to open the <b>Include/Exclude</b> pane. Updates to be included and those to be excluded are on separate tabs. For more information on how inclusion is handled, see <a href="#">Schedule an Update Deployment</a> .
<b>Schedule settings</b>	Choose the time to start, and select either <b>Once</b> or <b>Recurring</b> .
<b>Pre-scripts + Post-scripts</b>	Choose the scripts to run before and after your deployment.
<b>Maintenance window</b>	Enter the number of minutes set for updates. Valid values range from 30 to 360 minutes.
<b>Reboot control</b>	<p>Select how reboots are handled. Available selections are:</p> <ul style="list-style-type: none"> <li>• <b>Reboot if required</b></li> <li>• <b>Always reboot</b></li> <li>• <b>Never reboot</b></li> <li>• <b>Only reboot</b></li> </ul> <p><b>Reboot if required</b> is the default selection. If you select <b>Only reboot</b>, updates aren't installed.</p>

After you have finished configuring the schedule, click **Create** to return to the status dashboard. The **Scheduled** table shows the deployment schedule you created.

You can also create update deployments programmatically. To learn how to create an update deployment with the REST API, see [Software Update Configurations - Create](#). There's also a sample runbook that you can use to create a weekly update deployment. To learn more about this runbook, see [Create a weekly update deployment for one or more VMs in a resource group](#).

### View results of an update deployment

After the scheduled deployment starts, you can see the deployment status in the **Update deployments** tab of the **Update management** window.

If the deployment is currently running, its status shows as "In progress." After successful completion, the status changes to "Succeeded." But if any updates in the deployment fail, the status is "Partially failed."

Select the completed update deployment to see the dashboard for that deployment.

UPDATE NAME	STATUS
2019-05 Cumulative Update for Windows Server 2016 for x64-based Systems (KB4505052)	Succeeded
Definition Update for Windows Defender Antivirus - KB2267602 (Definition 1.293.1980.0)	Succeeded
2019-05 Servicing Stack Update for Windows Server 2016 for x64-based Systems (KB4498947)	Succeeded
Definition Update for Windows Defender Antivirus - KB2267602 (Definition 1.293.1982.0)	Succeeded
Windows Malicious Software Removal Tool x64 - May 2019 (KB890830)	Succeeded

The **Update results** tile shows a summary of the total number of updates and deployment results on the VM. The table to the right shows a detailed breakdown of each update and the installation results. Each result has one of the following values:

- **Not attempted:** The update isn't installed. There wasn't enough time available based on the defined maintenance-window duration.
- **Succeeded:** The update succeeded.
- **Failed:** The update failed.

Select **All logs** to see all log entries that the deployment created.

Select the **Output** tile to see the job stream of the runbook responsible for managing the update deployment on the target VM.

Select **Errors** to see detailed information about any deployment errors.

## Monitor changes and inventory

You can collect and view an inventory of the software, files, Linux daemons, Windows services, and Windows registry keys on your computers. Tracking the configurations of your machines helps you pinpoint operational issues across your environment and better understand the state of your machines.

### Enable change and inventory management

To enable change and inventory management for your VM:

1. On the leftmost side of the window, select **Virtual machines**.
2. Choose a VM from the list.
3. Under **Operations** in the VM window, select either **Inventory** or **Change tracking**.
4. The **Enable Change Tracking and Inventory** pane opens.

Configure the location, Log Analytics workspace, and Automation account to use, and then select **Enable**. If the options appear dimmed, an automation solution is already enabled for the VM. In that case, the already enabled workspace and Automation account must be used.

Even though the solutions appear separately in the menu, they're the same solution. Enabling one enables both for your VM.

The screenshot shows the Azure portal interface for managing a virtual machine named 'myVM'. On the left, there's a sidebar with various operational services: Auto-shutdown, Backup, Disaster recovery (Preview), Update management, Inventory (which is selected and highlighted in blue), and Change tracking. Under MONITORING, there are options for Metrics, Alert rules, Diagnostics settings, and Advisor recommendations. The main pane is titled 'Inventory' and contains descriptive text about enabling consistent control and compliance using Change Tracking and Inventory. It mentions that this service is included with Azure virtual machines and requires a Log Analytics workspace and an Automation account. Below this, there are dropdown menus for 'Location' (set to 'East US'), 'Log Analytics workspace' (set to 'defaultworkspace'), and 'Automation account' (set to 'Automate'). A large blue 'Enable' button is located at the bottom of the configuration area.

After the solution has been enabled, it might take some time for inventory to be collected on the VM before data appears.

## Track changes

On your VM under **OPERATIONS**, select **Change Tracking** and then select **Edit Settings**. The **Change Tracking** pane opens. Select the type of setting you want to track and then select **+ Add** to configure the settings.

The available settings options for Windows are:

- Windows Registry
- Windows Files

For detailed information on Change Tracking, see [Troubleshoot changes on a VM](#).

## View inventory

On your VM select **Inventory** under **OPERATIONS**. On the **Software** tab, there's a table that shows the software that had been found. The high-level details for each software record appear in the table. These details include the software name, version, publisher, and last refreshed time.

The screenshot shows the 'Software' tab for the 'Inventory' service in the Azure portal. At the top, there are links for 'New software', 'Learn more', 'Inventory', and 'Provide feedback'. Below this, a message says 'Last 24 hours' with a '0' icon. There are tabs for 'Software', 'Files', 'Windows Registry', and 'Windows Services', with 'Software' being the active tab. A search bar is present. The main area is a table with columns: NAME, VERSION, PUBLISHER, and LAST REFRESHED TIME. The table lists several software packages, all of which are 'Installed' and published by Microsoft Corporation, with the last refresh time being 3/22/2018, 9:08 AM.

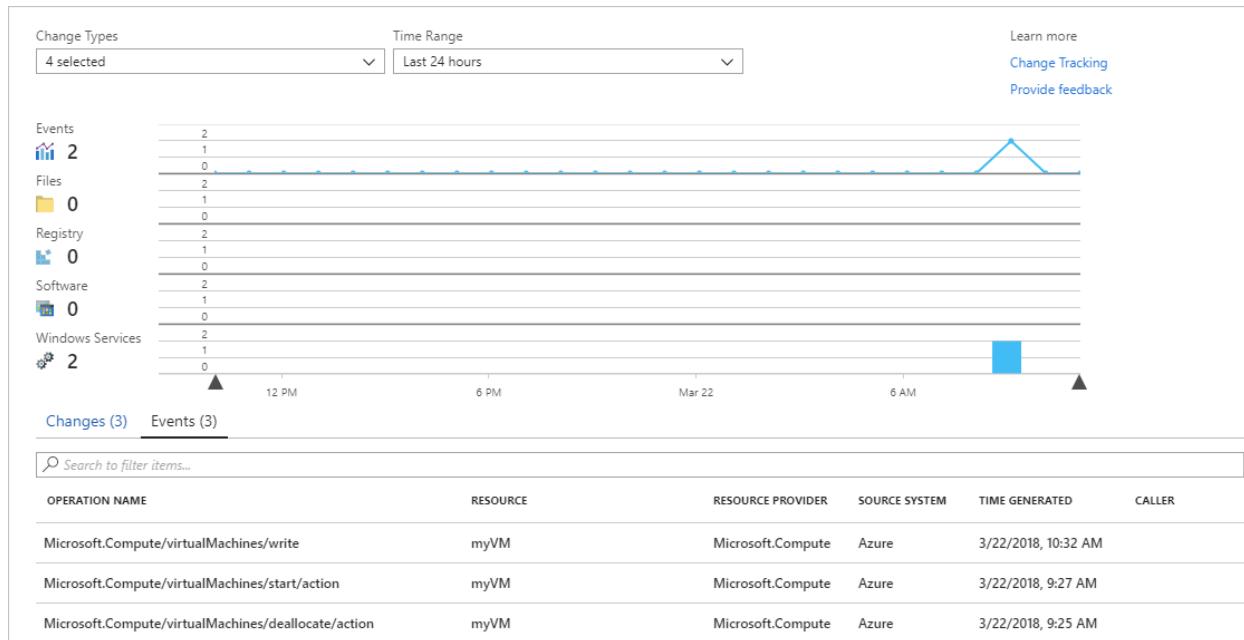

NAME	VERSION	PUBLISHER	LAST REFRESHED TIME
2018-03 Cumulative Update for Windows Server 2016 for x64-based Systems (KB4088787)	Installed	Microsoft Corporation	3/22/2018, 9:08 AM
Definition Update for Windows Defender Antivirus - KB2267602 (Definition 1.263.954.0)	Installed	Microsoft Corporation	3/22/2018, 9:08 AM
Microsoft Monitoring Agent	8.0.11081.0	Microsoft Corporation	3/22/2018, 9:08 AM
Update for Windows Defender antimalware platform - KB4052623 (Version 4.12.17007.18022)	Installed	Microsoft Corporation	3/22/2018, 9:08 AM
Windows Malicious Software Removal Tool x64 - March 2018 (KB890830)	Installed	Microsoft Corporation	3/22/2018, 9:08 AM

## Monitor activity logs and changes

From the **Change tracking** window on your VM, select **Manage Activity Log Connection** to open the **Azure Activity log** pane. Select **Connect** to connect Change Tracking to the Azure activity log for your VM.

After Change Tracking is enabled, go to the **Overview** pane for your VM and select **Stop** to stop your VM. When prompted, select **Yes** to stop the VM. After the VM is deallocated, select **Start** to restart your VM.

Stopping and restarting a VM logs an event in its activity log. Go back to the **Change tracking** pane and select the **Events** tab at the bottom of the pane. After a while, the events appear in the chart and the table. You can select each event to view detailed information for that event.

The previous chart shows changes that have occurred over time. After you add an Azure Activity Log connection, the line graph at the top displays Azure Activity Log events.

Each row of bar graphs represents a different trackable change type. These types are Linux daemons, files, Windows registry keys, software, and Windows services. The **Change** tab shows the change details. Changes appear in the order of when each occurred, with the most recent change shown first.

## Next steps

In this tutorial, you configured and reviewed Change Tracking and Update Management for your VM. You learned how to:

- Create a resource group and VM.
- Manage Windows updates.
- Monitor changes and inventory.

Go to the next tutorial to learn about monitoring your VM.

[Monitor virtual machines](#)

# Monitor Azure virtual machines

9/21/2022 • 6 minutes to read • [Edit Online](#)

When you have critical applications and business processes that rely on Azure resources, it's important to monitor those resources for their availability, performance, and operation. This article describes the monitoring data that's generated by Azure virtual machines (VMs), and it discusses how to use the features of [Azure Monitor](#) to analyze and alert you about this data.

## NOTE

This article provides basic information to help you get started with monitoring your VMs. For a complete guide to monitoring your entire environment of Azure and hybrid virtual machines, see [Monitor virtual machines with Azure Monitor](#).

## What is Azure Monitor?

[Azure Monitor](#) is a full stack monitoring service that provides a complete set of features to monitor your Azure resources. You don't need to directly interact with Azure Monitor, though, to perform a variety of monitoring tasks, because its features are integrated with the Azure portal for the Azure services that it monitors. For a tutorial with an overview of how Azure Monitor works with Azure resources, see [Monitor Azure resources by using Azure Monitor](#).

## Monitoring virtual machine data

Azure virtual machines collect the same kinds of monitoring data as other Azure resources, which are described in [Monitoring data from Azure resources](#). For detailed information about the metrics and logs that are created by Azure virtual machines, see [Reference: Monitoring Azure virtual machine data](#).

## Overview page

To begin exploring Azure Monitor, go to the [Overview](#) page for your virtual machine, and then select the [Monitoring](#) tab. You can see the number of active alerts on the tab.

The [Alerts](#) pane shows you the alerts fired in the last 24 hours, along with important statistics about those alerts. If there are no alerts configured for your VM, there is a link to help you quickly create new alerts for your VM.

## Activity log

The [Activity log](#) displays recent activity by the virtual machine, including any configuration changes and when it was stopped and started. View the Activity log in the Azure portal, or create a [diagnostic setting to send it to a Log Analytics workspace](#), where you can view events over time or analyze them with other collected data.

The screenshot shows the Azure portal's Activity log for a virtual machine named "srv-win-01". The left sidebar includes options like Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, Networking, Connect, Windows Admin Center (preview), Disks, Size, Security, Advisor recommendations, Extensions + applications, Continuous delivery, Availability + scaling, Configuration, Identity, Properties, and Locks.

The main area displays the Activity log with the following details:

- Filtering:** Management Group: None, Subscription: my-subscription, Event severity: All, Timespan: Last 24 hours, Resource: srv-win-01.
- Table Headers:** Operation name, Status, Time, Time stamp, Subscription, Event initiated by.
- Events:** A list of 13 items, including:

  - Deallocate Virtual Machine (Accepted, 4 minutes ago)
  - Health Event Resolved (Resolved, 13 hours ago)
  - Start Virtual Machine (Succeeded, 14 hours ago)
  - Health Event Updated (Updated, 14 hours ago)
  - Health Event Updated (Updated, 14 hours ago)

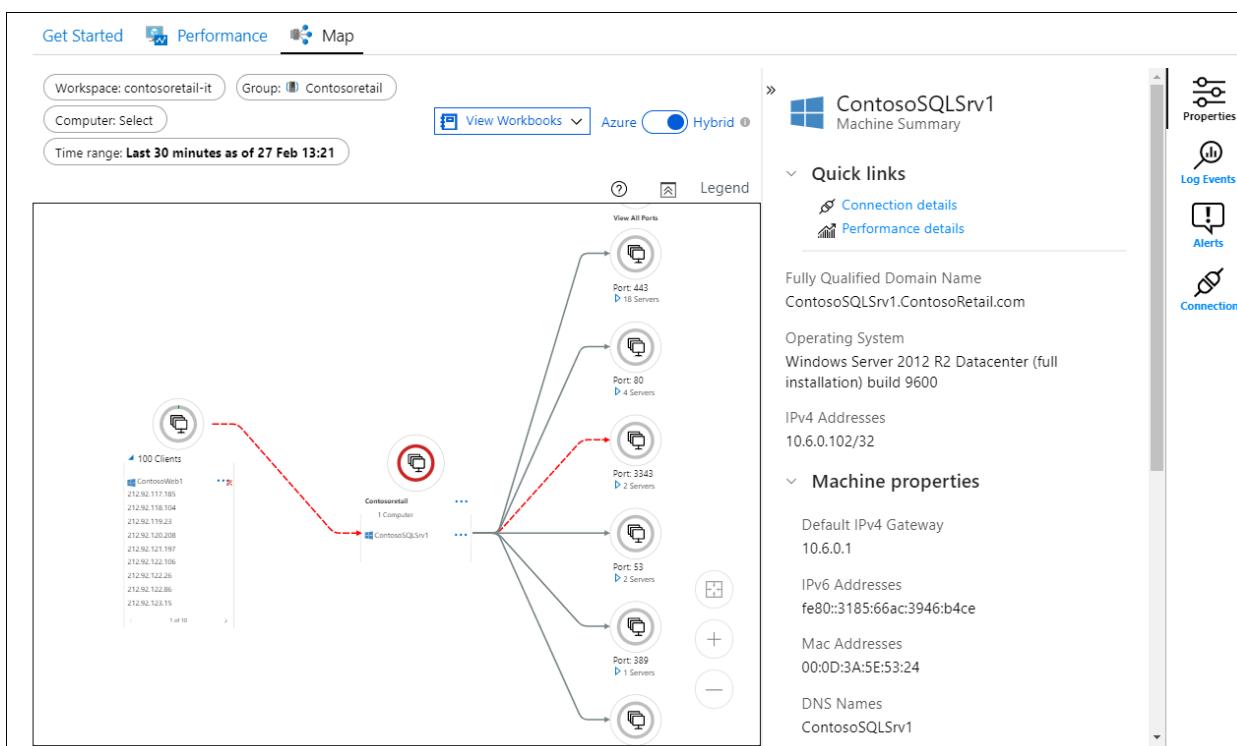

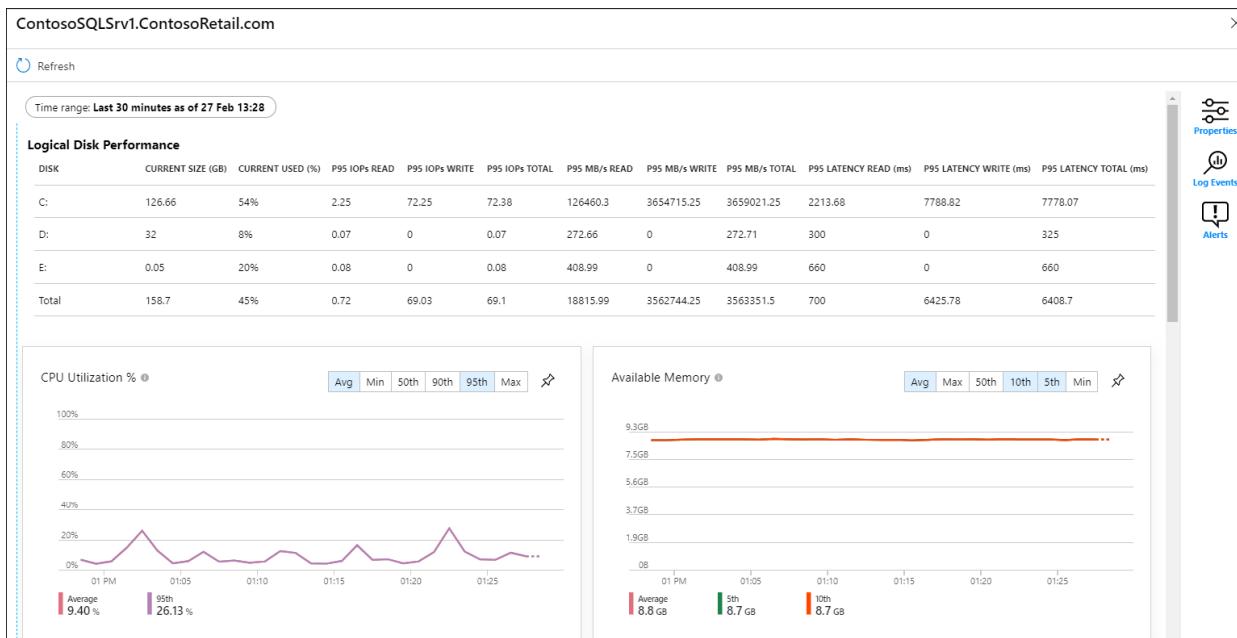

## VM insights

Some services in Azure display customized monitoring experiences in Azure Monitor. These experiences are called *insights*, and they include pre-built workbooks and other specialized features for that particular service.

VM insights are designed to monitor your entire set of Azure and hybrid virtual machines in a single interface.

When you start monitoring multiple virtual machines in your Azure environment, you might want to consider enabling VM insights for the following features:

- Simplified onboarding of the Log Analytics agent and the Dependency agent, so that you can monitor a virtual machine guest operating system and workloads.
- Pre-defined trending performance charts and workbooks, so that you can analyze core performance metrics from the virtual machine's guest operating system.
- The Dependency map, which displays processes that run on each virtual machine and the interconnected components with other machines and external sources.

For quick steps for configuring VM insights and enabling monitoring for a virtual machine, see [Enable Azure Monitor for a single virtual machine or virtual machine scale set in the Azure portal](#).

For general information about enabling insights and a variety of methods for onboarding virtual machines, see [Enable VM insights overview](#).

# Collect guest metrics and logs

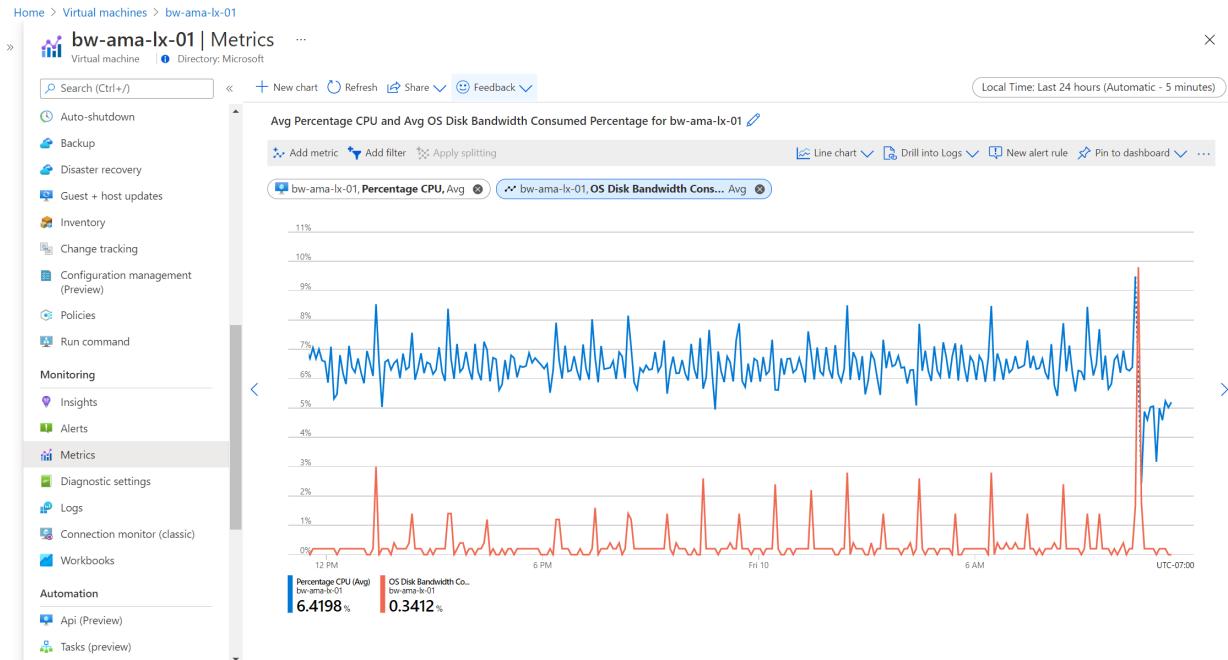

Azure Monitor starts automatically collecting metric data for your virtual machine host when you create the VM. To collect metrics from the guest operating system of the virtual machine, though, you must install an agent. When you enable [VM insights](#), the Log Analytics agent is installed and starts sending performance data to Azure Monitor Logs, which then enables the **Performance** and **Map** views. For a tutorial on enabling VM insights for a virtual machine, see [Enable monitoring for Azure virtual machines](#).

After you've enabled VM insights, install the [Azure Monitor agent](#) so that you can collect guest logs from your virtual machine and send guest metrics to the Azure Monitor **Metrics** pane. By doing so, you can also [analyze metrics on the Metrics pane](#). To learn how to install the Azure Monitor agent and create a data collection rule that defines the data to collect, see [Tutorial: Collect guest logs and metrics from an Azure virtual machine](#).

## Analyze metrics

Metrics are numerical values that describe some aspect of a system at a particular point in time. Although platform metrics for the virtual machine host are collected automatically, you must [install the Azure Monitor agent](#) to collect guest metrics.

The **Overview** pane includes the most common host metrics, and you can access others by using the **Metrics** pane. With this tool, you can create charts from metric values and visually correlate trends. You can also create a metric alert rule or pin a chart to an Azure dashboard. For a tutorial on using this tool, see [Analyze metrics for an Azure resource](#).

For a list of the available metrics, see [Reference: Monitoring Azure virtual machine data](#).

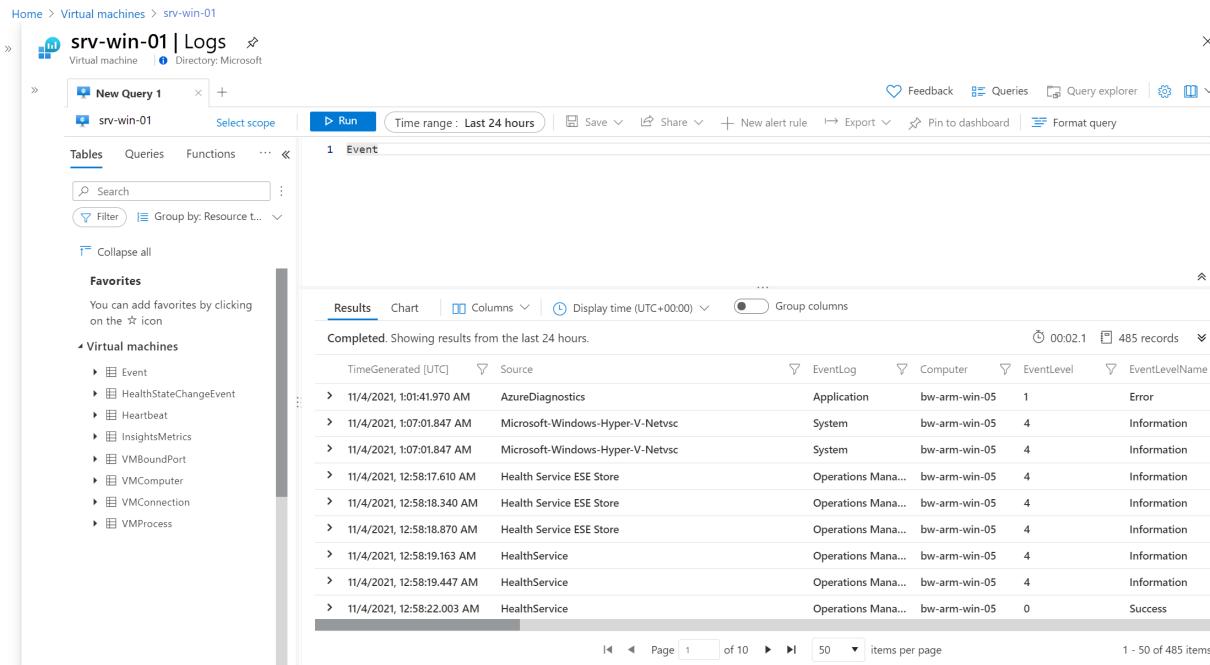

## Analyze logs

Data in Azure Monitor Logs is stored in a Log Analytics workspace, where it's separated into tables, each with its own set of unique properties.

VM insights store the collected data in logs, and the insights provide performance and map views that you can use to interactively analyze the data. You can work directly with this data to drill down further or perform custom analyses. For more information and to get sample queries for this data, see [How to query logs from VM insights](#).

To analyze other log data that you collect from your virtual machines, use [log queries in Log Analytics](#). Several

[built-in queries](#) for virtual machines are available to use, or you can create your own. You can interactively work with the results of these queries, include them in a workbook to make them available to other users, or generate alerts based on their results.

The screenshot shows the Azure Log Analytics interface for a virtual machine named 'srv-win-01'. The left sidebar shows 'Virtual machines' under 'Favorites'. The main area displays a table of events from the last 24 hours. The table has columns: TimeGenerated [UTC], Source, EventLog, Computer, EventLevel, and EventLevelName. The data shows various system events, such as HealthStateChangeEvent, Heartbeat, InsightsMetrics, and VM-related events, with levels ranging from Error to Success.

TimeGenerated [UTC]	Source	EventLog	Computer	EventLevel	EventLevelName
11/4/2021, 1:01:41.970 AM	AzureDiagnostics	Application	bw-arm-win-05	1	Error

## Alerts

Azure Monitor alerts proactively notify you when important conditions are found in your monitoring data. These alerts can help you identify and address issues in your system before your customers notice them. You can set alerts on [metrics](#), [logs](#), and the [activity log](#).

For more information about the various alerts for Azure virtual machines, see the following resources:

- See [Create an alert when an Azure virtual machine is unavailable](#) for a tutorial on creating a log query alert for when a virtual machine is unresponsive.
- See [Monitor virtual machines with Azure Monitor: Alerts](#) for common alert rules for virtual machines.
- See [Monitor virtual machines with Azure Monitor: Workloads](#) for data you can collect from VM workloads that you can use to create alerts.
- See [Create a log query alert for an Azure resource](#) for a tutorial on creating a log query alert rule.
- For common log alert rules, go to the [Queries](#) pane in Log Analytics. For **Resource type**, enter **Virtual machines**, and for **Type**, enter **Alerts**.

## Next steps

For documentation about the logs and metrics that are generated by Azure virtual machines, see [Reference: Monitoring Azure virtual machine data](#).

# Reference: Monitoring Azure virtual machine data

9/21/2022 • 2 minutes to read • [Edit Online](#)

For more information about collecting and analyzing monitoring data for Azure virtual machines (VMs), see [Monitoring Azure virtual machines](#).

## Metrics

This section lists the platform metrics that are collected for Azure virtual machines and virtual machine scale sets.

METRIC TYPE	RESOURCE PROVIDER / TYPE NAMESPACE AND LINK TO INDIVIDUAL METRICS
Virtual machines	<a href="#">Microsoft.Compute/virtualMachines</a>
Virtual machine scale sets	<a href="#">Microsoft.Compute/virtualMachineScaleSets</a>
Virtual machine scale sets and virtual machines	<a href="#">Microsoft.Compute/virtualMachineScaleSets/virtualMachines</a>

For more information, see a list of [platform metrics that are supported in Azure Monitor](#).

## Metric dimensions

For more information about metric dimensions, see [Multi-dimensional metrics](#).

Azure virtual machines and virtual machine scale sets have the following dimensions that are associated with their metrics.

DIMENSION NAME	DESCRIPTION
LUN	Logical unit number
VMName	Used with virtual machine scale sets

## Azure Monitor Logs tables

This section refers to all the Azure Monitor Logs tables that are relevant to virtual machines and virtual machine scale sets and available for query by Log Analytics.

RESOURCE TYPE	NOTES
<a href="#">Virtual machines</a>	
<a href="#">Virtual machine scale sets</a>	

For reference documentation about Azure Monitor Logs and Log Analytics tables, see the [Azure Monitor Logs](#)

[table reference](#).

## Activity log

The following table lists a few example operations that relate to creating virtual machines in the activity log. For a complete list of possible log entries, see [Microsoft.Compute Resource Provider options](#).

OPERATION	DESCRIPTION
Microsoft.Compute/virtualMachines/start/action	Starts the virtual machine
Microsoft.Compute/virtualMachines/restart/action	Deletes a managed cluster
Microsoft.Compute/virtualMachines/write	Creates a new virtual machine or updates an existing one
Microsoft.Compute/virtualMachines/deallocate/action	Powers off the virtual machine and releases the compute resources
Microsoft.Compute/virtualMachines/extensions/write	Creates a new virtual machine extension or updates an existing one
Microsoft.Compute/virtualMachineScaleSets/write	Starts the instances of the virtual machine scale set

For more information about the schema of activity log entries, see [Activity log schema](#).

## See also

For a description of monitoring Azure virtual machines, see [Monitoring Azure virtual machines](#).

# Tutorial: Enable monitoring for Azure virtual machine

9/21/2022 • 3 minutes to read • [Edit Online](#)

To monitor the health and performance of an Azure virtual machine, you need to install an agent to collect data from its guest operating system. VM insights is a feature of Azure Monitor for monitoring the guest operating system and workloads running on Azure virtual machines. When you enable monitoring for an Azure virtual machine, it installs the necessary agents and starts collecting performance, process, and dependency information from the guest operating system.

## NOTE

If you're completely new to Azure Monitor, you should start with [Tutorial: Monitor Azure resources with Azure Monitor](#). Azure virtual machines generate similar monitoring data as other Azure resources such as platform metrics and Activity log. This tutorial describes how to enable additional monitoring unique to virtual machines.

In this tutorial, you learn how to:

- Create a Log Analytics workspace to collect performance and log data from the virtual machine.
- Enable VM insights for the virtual machine which installs the required agents and begins data collection.
- Inspect graphs analyzing performance data collected from the virtual machine.
- Inspect map showing processes running on the virtual machine and dependencies with other systems.

## NOTE

VM insights installs the Log Analytics agent which collects performance data from the guest operating system of virtual machines. It doesn't collect logs from the guest operating system and doesn't send performance data to Azure Monitor Metrics. For this functionality, see [Tutorial: Collect guest logs and metrics from Azure virtual machine](#).

## Prerequisites

To complete this tutorial you need the following:

- An Azure virtual machine to monitor.

## Create a Log Analytics workspace

Log data in Azure Monitor is stored in a Log Analytics workspace. If you already created a workspace in your subscription, then you can use that one. You can also choose to use the default workspace that's created in each Azure subscription.

If you want to create a new Log Analytics, then you can use the following procedure. If you're going to use an existing one, then move on to the next section.

From **All services** in the Azure portal, select **Log Analytics workspaces**.

The screenshot shows the Microsoft Azure portal's search interface. The search bar at the top contains the text "log analytics workspaces". Below the search bar, the "Services" section is expanded, showing several options: Log Analytics workspaces, Activity log, Azure Synapse Analytics (workspaces preview), Workspaces, Logic Apps, and Data Catalog. To the right of the services, there are sections for "Marketplace" (Log Analytics Workspace) and "Documentation" (links to workspace creation and management). A "See all" link is located at the top right of the services list.

Click **Create** to create a new workspace.

This screenshot shows the "Log Analytics workspaces" list page. At the top left is the breadcrumb navigation "Home > Log Analytics workspaces". Below it is a toolbar with buttons for "+ Create", "Open recycle bin", "Manage view", "Refresh", "Export to CSV", "Open query", "Assign tags", and "Feedback". There are also filters for "Subscription", "Resource group", and "Location". A message at the bottom of the toolbar says "Filter for any field...". The main area displays a list of workspaces, with the first item, "Log Analytics workspace", being the one currently selected.

On the **Basics** tab, select a **Subscription**, **Resource group**, and **Region** for the workspace. These do not need to be the same as the resource being monitored. Provide a **Name** that must be globally unique across all Azure Monitor subscriptions.

This screenshot shows the "Create Log Analytics workspace" wizard on the "Basics" tab. The top navigation bar includes "Home > Log Analytics workspaces > Create Log Analytics workspace". Below the tabs "Basics", "Tags", and "Review + Create", the "Basics" tab is active. A callout box provides information about what a Log Analytics workspace is and links to learn more. The "Project details" section asks for a subscription and resource group. The "Subscription" dropdown is set to "AzureMonitor\_Docs" and the "Resource group" dropdown is set to "my-resource-group". The "Instance details" section asks for a name and region. The "Name" input field is filled with "my-workspace" and the "Region" dropdown is set to "East US". At the bottom are buttons for "Review + Create", "Previous", and "Next : Pricing tier >".

Click **Review + Create** to create the workspace.

## Enable monitoring

Select **Insights** from your virtual machine's menu in the Azure portal. If VM insights hasn't yet been enabled for it, you should see a screen similar to the following allowing you to enable monitoring. Click **Enable**.

### NOTE

If you selected the option to **Enable detailed monitoring** when you created your virtual machine, VM insights may already be enabled. Select your workspace and click **Enable** again. This is the workspace where data collected by VM insights will be sent.

t

## Get more visibility into the health and performance of your virtual machine

With an Azure virtual machine you get host CPU, disk and up/down state of your VMs out of the box. Enabling additional monitoring capabilities provides insights into the performance and dependencies for your virtual machines.

You will be billed based on the amount of data ingested and your data retention settings. It can take between 5-10 minutes to configure the virtual machine and the monitoring data to appear.

The VM is not connected to any workspace. Please select the monitoring workspace where you will store your data

Workspace Subscription \* ⓘ

AzureMonitor\_Docs

Choose a Log Analytics Workspace ⓘ

DefaultWorkspace-00000000-0000-0000-0000-000000000000-EUS [eastus]

Note: If the virtual machine already has either SCOM or OMS agent installed locally, the Microsoft Monitoring Agent (MMA) extension will still be installed and connected to the configured workspace.

The map data set collected with Azure Monitor for VMs is intended to be infrastructure data about the resources being deployed and monitored. For details on data collected please [click here](#).

**Enable**

⚠️ Having difficulties enabling Azure Monitors for VM? [Troubleshoot](#)

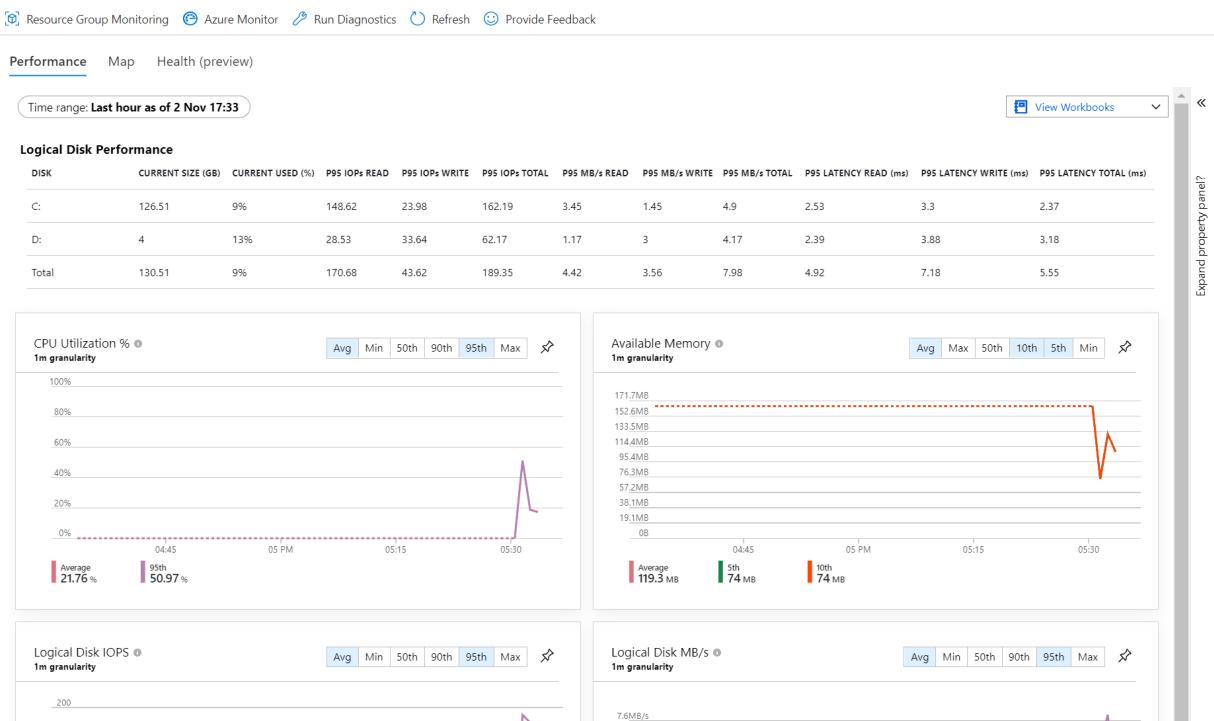

You'll see a message saying that monitoring is being enabled. It may take several minutes for the agent to be installed and for data collection to begin.

### NOTE

You may receive a message about an upgrade being available for VM insights. If so, select the option to perform the upgrade before proceeding.

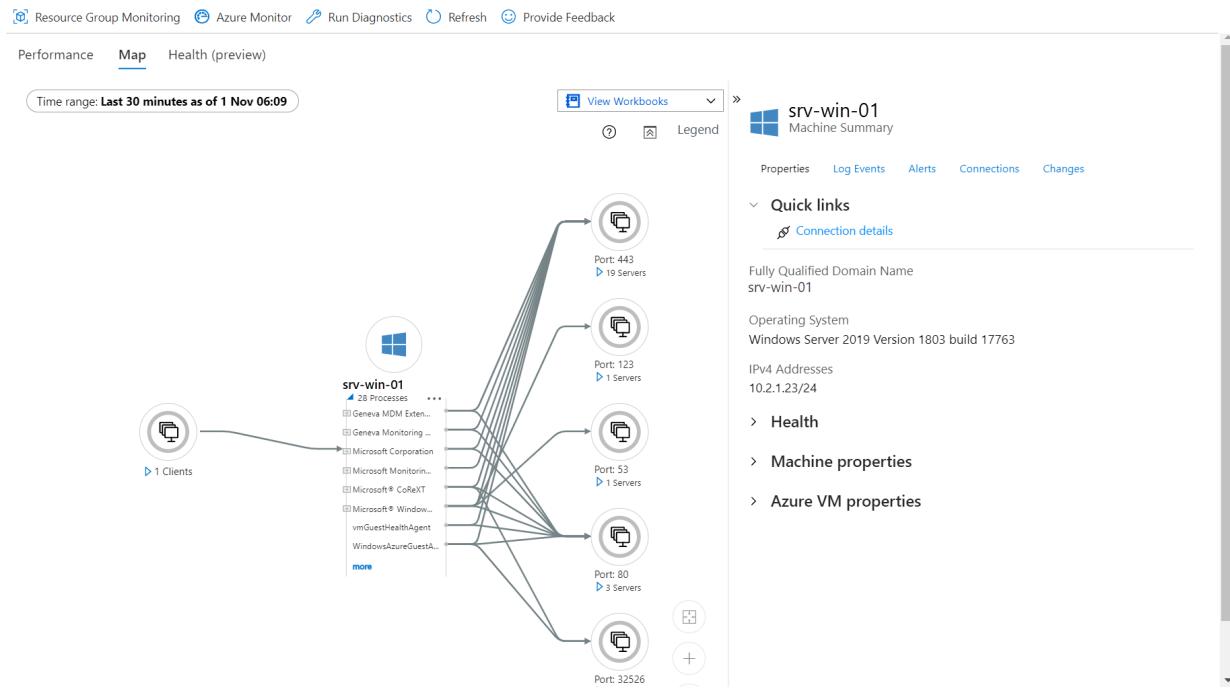

## View performance

When the deployment is complete, you'll see views in the **Performance** tab in VM insights with performance data for the machine. This shows you the values of key guest metrics over time.

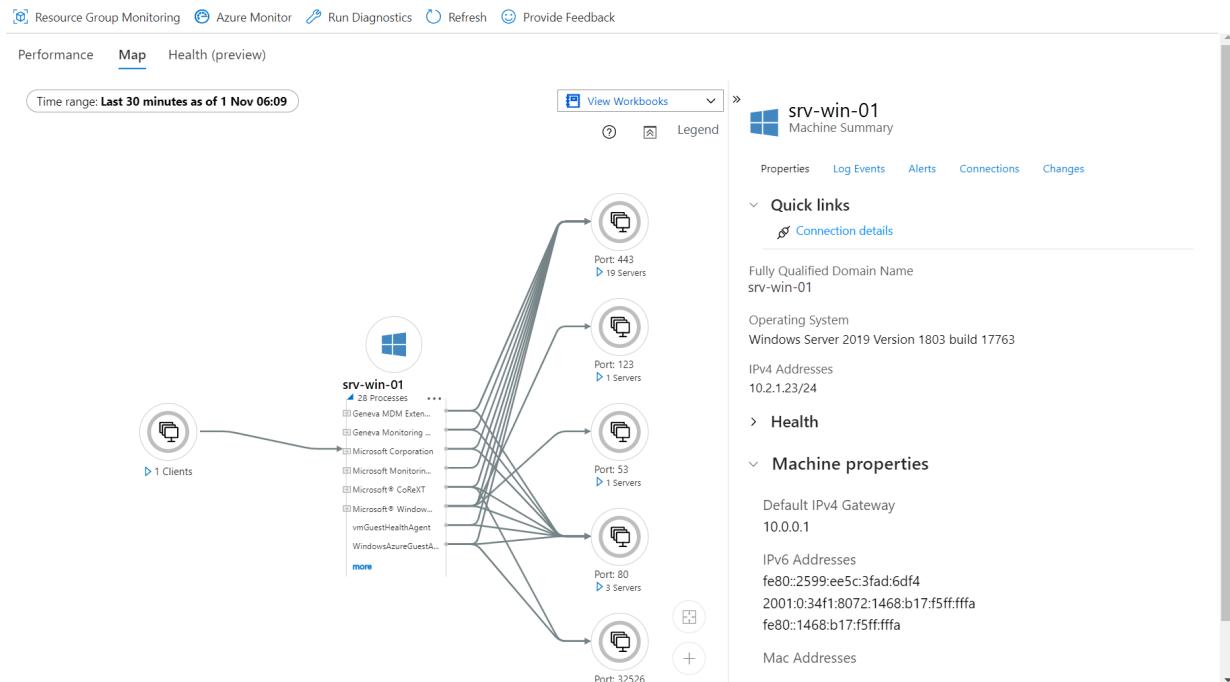

# View processes and dependencies

Select the **Maps** tab to view processes and dependencies for the virtual machine. The current machine is at the center of the view. View the processes running on it by expanding **Processes**.

## View machine details

The **Maps** view provides different tabs with information collected about the virtual machine. Click through the tabs to see what's available.

## Next steps

Now that you're collecting data from the virtual machine, you can use that data to create alerts to proactively notify you when issues are detected.

[Create alert when Azure virtual machine is unavailable](#)

# Tutorial: Create alert when Azure virtual machine is unavailable

9/21/2022 • 4 minutes to read • [Edit Online](#)

One of the most common alerting conditions for a virtual machine is whether the virtual machine is running. Once you enable monitoring with VM insights in Azure Monitor for the virtual machine, a heartbeat is sent to Azure Monitor every minute. You can create a log query alert rule that sends an alert if a heartbeat isn't detected. This method not only alerts if the virtual machine isn't running, but also if it's not responsive.

In this tutorial, you learn how to:

- View log data collected by VM insights in Azure Monitor for a virtual machine.
- Create an alert rule from log data that will proactively notify you if the virtual machine is unavailable.

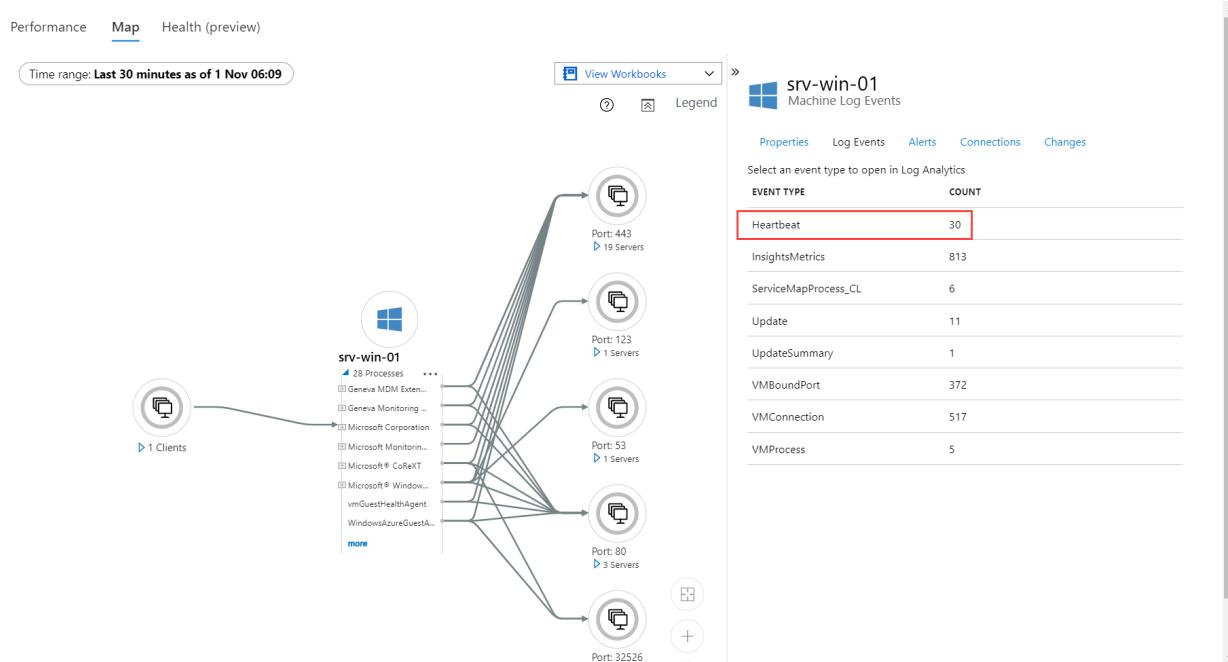

## Prerequisites

To complete this tutorial you need the following:

- An Azure virtual machine to monitor.
- Monitoring with VM insights enabled for the virtual machine. See [Tutorial: Enable monitoring for Azure virtual machine](#).

## Create a heartbeat query

There are multiple ways to create a log query alert rule. For this tutorial, we'll start from the **Logs Events** tab in the **Map** view. This gives a summary of the log data that's been collected for the virtual machine.

Click on **Heartbeat**. This opens Log Analytics, which is the primary tool to analyze log data collected from the virtual machine, with a simple query for heartbeat events. If you click on **TimeGenerated** to sort by that column, you can see that a heartbeat is created each minute.

For the alert, you want to return only heartbeat records in the last 5 minutes. If no records are returned, then you can assume the virtual machine is down.

Add a line to the query to filter the results to only records created in the last 5 minutes. This uses the [ago function](#) that subtracts a particular time span from the current time.

```
Heartbeat  
| where Computer == 'computer-name'  
| where TimeGenerated > ago(5m)
```

Click **Run** to see the results of this query, which should now include just the heartbeats in the last 5 minutes.

The screenshot shows the Azure Log Analytics workspace interface. The top navigation bar includes 'Home > Virtual machines > srv-win-01' and a 'Logs' icon. Below the navigation is a search bar with 'New Query \*' and a red box highlighting the 'Run' button. The query editor contains the following code:

```
1 Heartbeat
2 | where Computer == 'srv-win-01'
3 | where TimeGenerated > ago(5m)
```

The results table has columns: TimeGenerated (UTC), SourceComputerId, ComputerIP, Computer, Category, OSType, OSMajorVersion, OSMinorVersion, and Version. The table displays six rows of completed heartbeat data for the 'srv-win-01' computer. The last row is highlighted with a red box.

TimeGenerated (UTC)	SourceComputerId	ComputerIP	Computer	Category	OSType	OSMajorVersion	OSMinorVersion	Version
11/2/2021, 9:12:40.053 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:13:40.060 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:14:40.067 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:15:40.083 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:16:40.090 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18

## Create alert rule

Now that you have the log query, you can create an alert rule that will send an alert when that query doesn't return any records. If no heartbeat records are returned from the last 5 minutes, then we can assume that machine hasn't been responsive in that time.

Click **New alert rule** to create a rule from the current query.

The screenshot shows the Azure Log Analytics workspace for a workspace named "my-workspace". A query titled "New Query 1" is running, displaying the following log entries:

TimeGenerated [UTC]	SourceComputerId	ComputerIP	Computer	Category	OSType	OSMajorVersion	OSMinorVersion	Version
11/2/2021, 9:12:40.053 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:13:40.060 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:14:40.067 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:15:40.083 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18
11/2/2021, 9:16:40.090 PM	19de8c1d-e6b4-4c0f-9904-c198f653...	20.106.171.133	srv-win-01	Direct Agent	Windows	10	0	10.20.18

At the top right of the query editor, there is a red box around the "New alert rule" button.

The alert rule will already have the **Log query** filled in. The **Measurement** is also already correct since we want to count the number of table rows returned from the query. If the number of rows is zero, then we want to create an alert.

The screenshot shows the "Create alert rule (preview)" configuration page. The "Condition" tab is selected. The "Log query" section contains the same query as the previous screenshot:

```
Heartbeat
| where Computer == 'win-srv-01'
| where TimeGenerated > ago(5m)
```

The "Measurement" section shows the following settings:

Measure:	Table rows
Aggregation type:	Count
Aggregation granularity:	5 minutes

At the bottom, there are "Review + create", "Previous", and "Next: Actions >" buttons.

Scroll down to **Alert logic** and change **Operator** to **Equal to** and provide a **Threshold value** of 0. This means that we want to create an alert when no records are returned, or when the record count from the query equals zero.

## Configure details

The **Details** page allows you to configure different settings for the alert rule.

- **Subscription and Resource group** where the alert rule will be stored. This doesn't need to be in the same resource group as the resource that you're monitoring.
- **Severity** for the alert. The severity allows you to group alerts with a similar relative importance. A severity of **Error** is appropriate for an unresponsive virtual machine.
- Keep the box checked to **Enable alert upon creation**.
- Keep the box checked to **Automatically resolve alerts**. This will automatically resolve the alert when the virtual machine comes back online and heartbeat records are seen again.

## Next steps

Now that you know how to create an alert from log data, collect additional logs and performance data from the virtual machine with a data collection rule.

[Collect guest logs and metrics from Azure virtual machine](#)

# Tutorial: Collect guest logs and metrics from Azure virtual machine

9/21/2022 • 5 minutes to read • [Edit Online](#)

When you [enable monitoring with VM insights](#), it collects performance data using the Log Analytics agent. To collect logs from the guest operating system and to send performance data to Azure Monitor Metrics, install the [Azure Monitor agent](#) and create a [data collection rule](#) (DCR) that defines the data to collect and where to send it.

## NOTE

Prior to the Azure Monitor agent, guest metrics for Azure virtual machines were collected with the [Azure diagnostic extension](#) for Windows (WAD) and Linux (LAD). These agents are still available and can be configured with the **Diagnostic settings** menu item for the virtual machine, but they are in the process of being replaced with Azure Monitor agent.

In this tutorial, you learn how to:

- Create a data collection rule that send guest performance data to Azure Monitor metrics and log events to Azure Monitor Logs.
- View guest metrics in metrics explorer.
- View guest logs in Log Analytics.

## Prerequisites

To complete this tutorial you need the following:

- An Azure virtual machine to monitor.

## Create data collection rule

[Data collection rules](#) in Azure Monitor define data to collect and where it should be sent. When you define the data collection rule using the Azure portal, you specify the virtual machines it should be applied to. The Azure Monitor agent will automatically be installed on any virtual machines that don't already have it.

## NOTE

You must currently install the Azure Monitor agent from **Monitor** menu in the Azure portal. This functionality is not yet available from the virtual machine's menu.

From the **Monitor** menu in the Azure portal, select **Data Collection Rules** and then **Create** to create a new data collection rule.

Home > Monitor

## Monitor | Data Collection Rules

Platform Type \* Windows

Review + create < Previous Next : Resources >

## Select resources

On the **Resources** tab, identify one or more virtual machines that the data collection rule will apply to. The Azure Monitor agent will be installed on any that don't already have it. Click **Add resources** and select either your virtual machines or the resource group or subscription where your virtual machine is located. The data collection rule will apply to all virtual machines in the selected scope.

## Select data sources

A single data collection rule can have multiple data sources. For this tutorial, we'll use the same rule to collect both guest metrics and guest logs. We'll send metrics to both to Azure Monitor Metrics and to Azure Monitor Logs so that they can be analyzed both with metrics explorer and Log Analytics.

On the **Collect and deliver** tab, click **Add data source**. For the **Data source type**, select **Performance counters**. Leave the **Basic** setting and select the counters that you want to collect. **Custom** allows you to select individual metric values.

Select the **Destination** tab. **Azure Monitor Metrics** should already be listed. Click **Add destination** to add another. Select **Azure Monitor Logs** for the **Destination type**. Select your Log Analytics workspace for the **Account or namespace**. Click **Add data source** to save the data source.

Click **Add data source** again to add logs to the data collection rule. For the **Data source type**, select **Windows event logs** or **Linux syslog**. Select the types of log data that you want to collect.

Select the **Destination** tab. **Azure Monitor Logs** should already be selected for the **Destination type**. Select your Log Analytics workspace for the **Account or namespace**. If you don't already have a workspace, then you can select the default workspace for your subscription, which will automatically be created. Click **Add data source** to save the data source.

Click **Review + create** to create the data collection rule and install the Azure Monitor agent on the selected virtual machines.

Home > Monitor >

## Viewing logs

Data is retrieved from a Log Analytics workspace using a log query written in Kusto Query Language (KQL). While a set of pre-created queries are available for virtual machines, we'll use a simple query to have a look at the events that we're collecting.

Select **Logs** from your virtual machine's menu. Log Analytics opens with an empty query window with the scope set to that machine. Any queries will include only records collected from that machine.

### NOTE

The **Queries** window may open when you open Log Analytics. This includes pre-created queries that you can use. For now, close this window since we're going to manually create a simple query.

Home > Virtual machines > srv-win-01

Queries History

No queries history

You haven't run any queries yet. To start, go to Queries on the side pane or type a query in the query editor.

In the empty query window, type either **Event** or **Syslog** depending on whether your machine is running Windows or Linux and then click **Run**. The events collected within the **Time range** are displayed.

### NOTE

If the query doesn't return any data, then you may need to wait a few minutes until events are created on the virtual machine to be collected. You may also need to modify the data source in the data collection rule to include additional categories of events.

The screenshot shows the Azure Log Analytics interface for the virtual machine 'srv-win-01'. The left sidebar has a 'Favorites' section with 'Virtual machines' expanded, showing various event types like 'Event', 'HealthStateChangeEvent', 'Heartbeat', etc. The main area is titled 'Logs' and shows a table of events. The table has the following columns: TimeGenerated [UTC], Source, EventLog, Computer, EventLevel, and EventLevelName. The data in the table includes:

TimeGenerated [UTC]	Source	EventLog	Computer	EventLevel	EventLevelName
11/4/2021, 1:01:41.970 AM	AzureDiagnostics	Application	bw-arm-win-05	1	Error
11/4/2021, 1:07:01.847 AM	Microsoft-Windows-Hyper-V-Netvsc	System	bw-arm-win-05	4	Information
11/4/2021, 1:07:01.847 AM	Microsoft-Windows-Hyper-V-Netvsc	System	bw-arm-win-05	4	Information

11/4/2021, 12:58:18.870 AM	Health Service ESE Store	Operations Mana...	bw-arm-win-05	4	Information
11/4/2021, 12:58:19.163 AM	HealthService	Operations Mana...	bw-arm-win-05	4	Information
11/4/2021, 12:58:19.447 AM	HealthService	Operations Mana...	bw-arm-win-05	4	Information
11/4/2021, 12:58:22.003 AM	HealthService	Operations Mana...	bw-arm-win-05	0	Success

For a tutorial on using Log Analytics to analyze log data, see [Log Analytics tutorial](#). For a tutorial on creating alert rules from log data, see [Tutorial: Create a log query alert for an Azure resource](#).

## View guest metrics

You can view metrics for your host virtual machine with metrics explorer without a data collection rule just like [any other Azure resource](#). With the data collection rule though, you can use metrics explorer to view guest metrics in addition to host metrics.

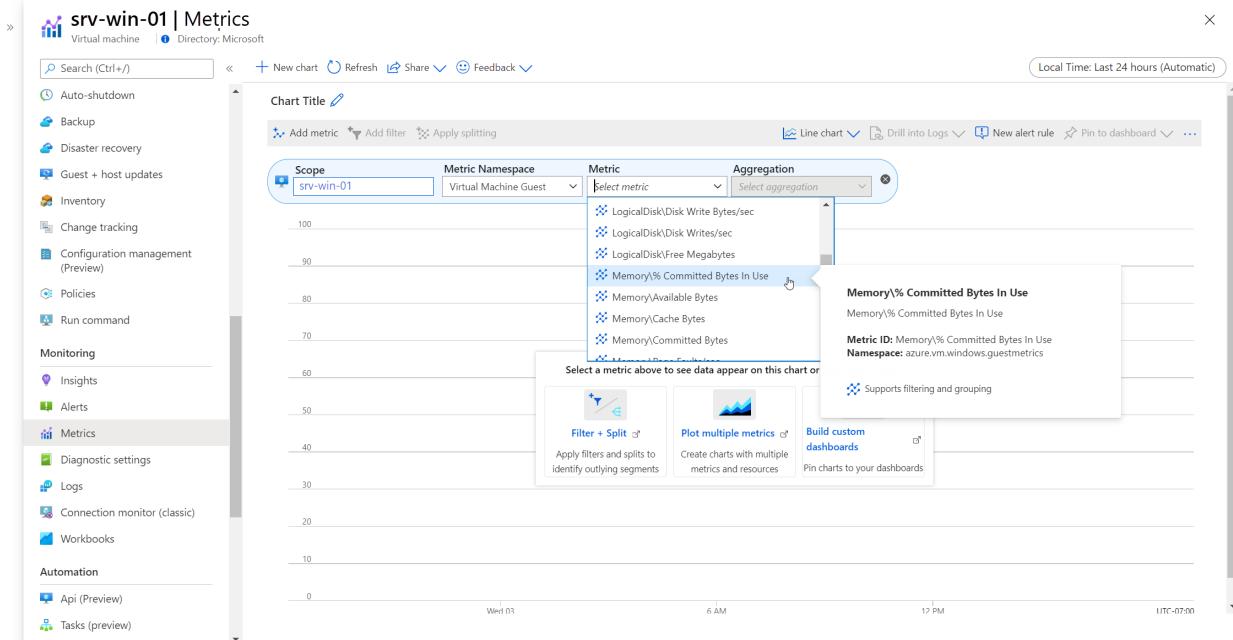

Select **Metrics** from your virtual machine's menu. Metrics explorer opens with the scope set to your virtual machine. Click **Metric Namespace**, and select **Virtual Machine Guest**.

### NOTE

If you don't see **Virtual Machine Guest**, you may just need to wait a few more minutes for the agent to be deployed and data to begin collecting.

The screenshot shows the Azure Metrics Explorer interface for the virtual machine 'srv-win-01'. The left sidebar has a 'Metrics' section selected. The main area shows a chart with a dropdown menu for 'Metric Namespace'. The dropdown menu has two options: 'Virtual Machine Host' (which is selected) and 'Virtual Machine Guest'. Below the chart are three buttons: 'Filter + Split', 'Plot multiple metrics', and 'Build custom dashboards'.

The available guest metrics are displayed. Select a **Metric** to add to the chart.

You can get a complete tutorial on viewing and analyzing metric data using metrics explorer in [Tutorial: Analyze metrics for an Azure resource](#) and on creating metrics alerts in [Tutorial: Create a metric alert for an Azure resource](#).

## Next steps

Now that you're collecting guest metrics for the virtual machine, you can create metric alerts based on guest metrics such as available memory and logical disk space.

[Create a metric alert in Azure Monitor](#)

# Azure Monitor Agent overview

9/21/2022 • 8 minutes to read • [Edit Online](#)

Azure Monitor Agent (AMA) collects monitoring data from the guest operating system of Azure and hybrid virtual machines and delivers it to Azure Monitor for use by features, insights, and other services, such as [Microsoft Sentinel](#) and [Microsoft Defender for Cloud](#). Azure Monitor Agent replaces all of Azure Monitor's legacy monitoring agents. This article provides an overview of Azure Monitor Agent's capabilities and supported use cases.

Here's a short [introduction to Azure Monitor video](#), which includes a quick demo of how to set up the agent from the Azure portal: [ITOps Talk: Azure Monitor Agent](#)

## Consolidating legacy agents

Deploy Azure Monitor Agent on all new virtual machines, scale sets and on-premises servers to collect data for [supported services and features](#).

If you have machines already deployed with legacy Log Analytics agents, we recommend you [migrate to Azure Monitor Agent](#) as soon as possible. The legacy Log Analytics agent will not be supported after August 2024.

Azure Monitor Agent replaces the Azure Monitor legacy monitoring agents:

- [Log Analytics Agent](#): Sends data to a Log Analytics workspace and supports monitoring solutions. This is fully consolidated into Azure Monitor agent.
- [Telegraf agent](#): Sends data to Azure Monitor Metrics (Linux only). Only basic Telegraf plugins are supported today in Azure Monitor agent.
- [Diagnostics extension](#): Sends data to Azure Monitor Metrics (Windows only), Azure Event Hubs, and Azure Storage. This is not consolidated yet.

## Install the agent and configure data collection

Azure Monitor Agent uses [data collection rules](#), using which you define which data you want each agent to collect. Data collection rules let you manage data collection settings at scale and define unique, scoped configurations for subsets of machines. The rules are independent of the workspace and the virtual machine, which means you can define a rule once and reuse it across machines and environments.

### To collect data using Azure Monitor Agent:

1. Install the agent on the resource.

RESOURCE TYPE	INSTALLATION METHOD	MORE INFORMATION
Virtual machines, scale sets	<a href="#">Virtual machine extension</a>	Installs the agent by using Azure extension framework.
On-premises servers (Azure Arc-enabled servers)	<a href="#">Virtual machine extension</a> (after installing the <a href="#">Azure Arc agent</a> )	Installs the agent by using Azure extension framework, provided for on-premises by first installing <a href="#">Azure Arc agent</a> .
Windows 10, 11 desktops, workstations	<a href="#">Client installer (Public preview)</a>	Installs the agent by using a Windows MSI installer.

RESOURCE TYPE	INSTALLATION METHOD	MORE INFORMATION
Windows 10, 11 laptops	<a href="#">Client installer (Public preview)</a>	Installs the agent by using a Windows MSI installer. The installer works on laptops, but the agent <i>isn't optimized yet</i> for battery or network consumption.

2. Define a data collection rule and associate the resource to the rule.

The table below lists the types of data you can currently collect with the Azure Monitor Agent and where you can send that data.

DATA SOURCE	DESTINATIONS	DESCRIPTION
Performance	Azure Monitor Metrics (Public preview) <sup>1</sup> - Insights.virtualmachine namespace Log Analytics workspace - <a href="#">Perf</a> table	Numerical values measuring performance of different aspects of operating system and workloads
Windows event logs (including sysmon events)	Log Analytics workspace - <a href="#">Event</a> table	Information sent to the Windows event logging system
Syslog	Log Analytics workspace - <a href="#">Syslog</a> <sup>2</sup> table	Information sent to the Linux event logging system
Text logs	Log Analytics workspace - custom table	Events sent to log file on agent machine

<sup>1</sup> On Linux, using Azure Monitor Metrics as the only destination is supported in v1.10.9.0 or higher.

<sup>2</sup> Azure Monitor Linux Agent v1.15.2 or higher supports syslog RFC formats including Cisco Meraki, Cisco ASA, Cisco FTD, Sophos XG, Juniper Networks, Corelight Zeek, CipherTrust, NXLog, McAfee, and Common Event Format (CEF).

## Supported services and features

In addition to the generally available data collection listed above, Azure Monitor Agent also supports these Azure Monitor features in preview:

AZURE MONITOR FEATURE	CURRENT SUPPORT	OTHER EXTENSIONS INSTALLED	MORE INFORMATION
Text logs and Windows IIS logs	Public preview	None	<a href="#">Collect text logs with Azure Monitor Agent (Public preview)</a>
Windows client installer	Public preview	None	<a href="#">Set up Azure Monitor Agent on Windows client devices</a>
<a href="#">VM insights</a>	Public preview	Dependency Agent extension, if you're using the Map Services feature	<a href="#">Enable VM Insights overview</a>

In addition to the generally available data collection listed above, Azure Monitor Agent also supports these Azure services in preview:

AZURE SERVICE	CURRENT SUPPORT	OTHER EXTENSIONS INSTALLED	MORE INFORMATION
Microsoft Defender for Cloud	Public preview	<ul style="list-style-type: none"> <li>Azure Security Agent extension</li> <li>SQL Advanced Threat Protection extension</li> <li>SQL Vulnerability Assessment extension</li> </ul>	<a href="#">Auto-deployment of Azure Monitor Agent (Preview)</a>
Microsoft Sentinel	<ul style="list-style-type: none"> <li>Windows Security Events: <a href="#">Generally available</a></li> <li>Windows Forwarding Event (WEF): <a href="#">Public preview</a></li> <li>Windows DNS logs: <a href="#">Public preview</a></li> <li>Linux Syslog CEF: Preview</li> </ul>	Sentinel DNS extension, if you're collecting DNS logs. For all other data types, you just need the Azure Monitor Agent extension.	<ul style="list-style-type: none"> <li><a href="#">Sign-up link for Linux Syslog CEF</a></li> <li>No sign-up needed for Windows Forwarding Event (WEF), Windows Security Events and Windows DNS events</li> </ul>
Change Tracking	Change Tracking: Preview.	Change Tracking extension	<a href="#">Sign-up link</a>
Update Management (available without Azure Monitor Agent)	Use Update Management v2 - Public preview	None	<a href="#">Update management center (Public preview) documentation</a>
Network Watcher	Connection Monitor: Preview	Azure NetworkWatcher extension	<a href="#">Sign-up link</a>

## Supported regions

Azure Monitor Agent is available in all public regions and Azure Government clouds. It's not yet supported in air-gapped clouds. For more information, see [Product availability by region](#).

## Costs

There's no cost for the Azure Monitor Agent, but you might incur charges for the data ingested. For information on Log Analytics data collection and retention and for customer metrics, see [Azure Monitor pricing](#).

## Compare to legacy agents

The tables below provide a comparison of Azure Monitor Agent with the legacy the Azure Monitor telemetry agents for Windows and Linux.

### Windows agents

		AZURE MONITOR AGENT	LOG ANALYTICS AGENT	DIAGNOSTICS EXTENSION (WAD)
Environments supported				

		AZURE MONITOR AGENT	LOG ANALYTICS AGENT	DIAGNOSTICS EXTENSION (WAD)
	Azure	X	X	X
	Other cloud (Azure Arc)	X	X	
	On-premises (Azure Arc)	X	X	
	Windows Client OS	X (Public preview)

		AZURE MONITOR AGENT	LOG ANALYTICS AGENT	DIAGNOSTICS EXTENSION (LAD)	TELEGRAF AGENT
	Microsoft Defender for Cloud	X (Public preview)	X		
	Update Management	X (Public preview, independent of monitoring agents)	X		
	Change Tracking		X		

<sup>1</sup> To review other limitations of using Azure Monitor Metrics, see [quotas and limits](#). On Linux, using Azure Monitor Metrics as the only destination is supported in v.1.10.9.0 or higher.

## Supported operating systems

The following tables list the operating systems that Azure Monitor Agent and the legacy agents support. All operating systems are assumed to be x64. x86 isn't supported for any operating system.

### Windows

OPERATING SYSTEM	AZURE MONITOR AGENT	LOG ANALYTICS AGENT	DIAGNOSTICS EXTENSION
Windows Server 2022	X		
Windows Server 2022 Core	X		
Windows Server 2019	X	X	X
Windows Server 2019 Core	X		
Windows Server 2016	X	X	X
Windows Server 2016 Core	X		X
Windows Server 2012 R2	X	X	X
Windows Server 2012	X	X	X
Windows Server 2008 R2 SP1	X	X	X
Windows Server 2008 R2			X
Windows Server 2008 SP2		X	
Windows 11 Client Enterprise and Pro	X <sup>2, 3</sup>		
Windows 10 1803 (RS4) and higher	X <sup>2</sup>		

OPERATING SYSTEM	AZURE MONITOR AGENT	LOG ANALYTICS AGENT	DIAGNOSTICS EXTENSION
Windows 10 Enterprise (including multi-session) and Pro (Server scenarios only <sup>1</sup> )	X	X	X
Windows 8 Enterprise and Pro (Server scenarios only <sup>1</sup> )		X	
Windows 7 SP1 (Server scenarios only <sup>1</sup> )		X	
Azure Stack HCI		X	

<sup>1</sup> Running the OS on server hardware, for example, machines that are always connected, always turned on, and not running other workloads (PC, office, browser).

<sup>2</sup> Using the Azure Monitor agent [client installer \(Public preview\)](#).

<sup>3</sup> Also supported on Arm64-based machines.

#### Linux

OPERATING SYSTEM	AZURE MONITOR AGENT <sup>1</sup>	LOG ANALYTICS AGENT <sup>1</sup>	DIAGNOSTICS EXTENSION <sup>2</sup>
AlmaLinux 8.5	X <sup>3</sup>

Rocky Linux 8	X	X	
SUSE Linux Enterprise Server 15 SP4	X <sup>3</sup>		
SUSE Linux Enterprise Server 15 SP2	X		
SUSE Linux Enterprise Server 15 SP1	X	X	
SUSE Linux Enterprise Server 15	X	X	
SUSE Linux Enterprise Server 12	X	X	X
Ubuntu 22.04 LTS	X		
Ubuntu 20.04 LTS	X <sup>3</sup>	X	X
Ubuntu 18.04 LTS	X <sup>3</sup>	X	X
Ubuntu 16.04 LTS	X	X	X
Ubuntu 14.04 LTS		X	X

<sup>1</sup> Requires Python (2 or 3) to be installed on the machine.

<sup>2</sup> Requires Python 2 to be installed on the machine and aliased to the `python` command.

<sup>3</sup> Also supported on Arm64-based machines.

## Next steps

- [Install the Azure Monitor Agent](#) on Windows and Linux virtual machines.
- [Create a data collection rule](#) to collect data from the agent and send it to Azure Monitor.

# Manage the Azure Monitor agent

9/21/2022 • 11 minutes to read • [Edit Online](#)

This article provides the different options currently available to install, uninstall, and update the [Azure Monitor agent](#). This agent extension can be installed on Azure virtual machines, scale sets, and Azure Arc-enabled servers. It also lists the options to create [associations with data collection rules](#) that define which data the agent should collect. Installing, upgrading, or uninstalling the Azure Monitor agent won't require you to restart your server.

## Virtual machine extension details

The Azure Monitor agent is implemented as an [Azure VM extension](#) with the details in the following table. You can install it by using any of the methods to install virtual machine extensions including the methods described in this article.

PROPERTY	WINDOWS	LINUX
Publisher	Microsoft.Azure.Monitor	Microsoft.Azure.Monitor
Type	AzureMonitorWindowsAgent	AzureMonitorLinuxAgent
TypeHandlerVersion	See <a href="#">Azure Monitor agent extension versions</a>	<a href="#">Azure Monitor agent extension versions</a>

## Extension versions

View [Azure Monitor agent extension versions](#).

## Prerequisites

The following prerequisites must be met prior to installing the Azure Monitor agent.

- **Permissions:** For methods other than using the Azure portal, you must have the following role assignments to install the agent:

BUILT-IN ROLE	SCOPES	REASON
• <a href="#">Virtual Machine Contributor</a> • <a href="#">Azure Connected Machine Resource Administrator</a>	• Virtual machines, scale sets, • Azure Arc-enabled servers	To deploy the agent
Any role that includes the action <code>Microsoft.Resources/deployments/*</code>	• Subscription and/or • Resource group and/or	To deploy Azure Resource Manager templates

- **Non-Azure:** To install the agent on physical servers and virtual machines hosted *outside* of Azure (that is, on-premises) or in other clouds, you must [install the Azure Arc Connected Machine agent](#) first, at no added cost.
- **Authentication:** [Managed identity](#) must be enabled on Azure virtual machines. Both user-assigned and

system-assigned managed identities are supported.

- **User-assigned:** This managed identity is recommended for large-scale deployments, configurable via [built-in Azure policies](#). You can create a user-assigned managed identity once and share it across multiple VMs, which means it's more scalable than a system-assigned managed identity. If you use a user-assigned managed identity, you must pass the managed identity details to the Azure Monitor agent via extension settings:

```
{  
  "authentication": {  
    "managedIdentity": {  
      "identifier-name": "mi_res_id" or "object_id" or "client_id",  
      "identifier-value": "<resource-id-of-uai>" or "<guid-object-or-client-id>"  
    }  
  }  
}
```

We recommend that you use `mi_res_id` as the `identifier-name`. The following sample commands only show usage with `mi_res_id` for the sake of brevity. For more information on `mi_res_id`, `object_id`, and `client_id`, see the [Managed identity documentation](#).

- **System-assigned:** This managed identity is suited for initial testing or small deployments. When used at scale, for example, for all VMs in a subscription, it results in a substantial number of identities created (and deleted) in Azure Active Directory. To avoid this churn of identities, use user-assigned managed identities instead. *For Azure Arc-enabled servers, system-assigned managed identity is enabled automatically as soon as you install the Azure Arc agent. It's the only supported type for Azure Arc-enabled servers.*
- **Not required for Azure Arc-enabled servers:** The system identity is enabled automatically if the agent is installed via [creating and assigning a data collection rule by using the Azure portal](#).
- **Networking:** If you use network firewalls, the [AzureResourceManager service tag](#) must be enabled on the virtual network for the virtual machine. The virtual machine must also have access to the following HTTPS endpoints:
  - `global.handler.control.monitor.azure.com`
  - `<virtual-machine-region-name>.handler.control.monitor.azure.com` (example: `westus.handler.control.azure.com`)
  - `<log-analytics-workspace-id>.ods.opinsights.azure.com` (example: `12345a01-b1cd-1234-e1f2-1234567g8h99.ods.opinsights.azure.com`)  
(If you use private links on the agent, you must also add the [dce endpoints](#)).

#### NOTE

This article only pertains to agent installation or management. After you install the agent, you must review the next article to [configure data collection rules and associate them with the machines](#) with agents installed. *The Azure Monitor agents can't function without being associated with data collection rules.*

## Use the Azure portal

Follow these instructions to use the Azure portal.

### Install

To install the Azure Monitor agent by using the Azure portal, follow the process to [create a data collection rule](#) in the Azure portal. This process creates the rule, associates it to the selected resources, and installs the Azure

Monitor agent on them if it's not already installed.

## Uninstall

To uninstall the Azure Monitor agent by using the Azure portal, go to your virtual machine, scale set, or Azure Arc-enabled server. Select the **Extensions** tab and select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Uninstall**.

## Update

To perform a one-time update of the agent, you must first uninstall the existing agent version. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature. Go to your virtual machine or scale set, select the **Extensions** tab and select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Enable automatic upgrade**.

# Use Resource Manager templates

Follow these instructions to use Azure Resource Manager templates.

## Install

You can use Resource Manager templates to install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers and to create an association with data collection rules. You must create any data collection rule prior to creating the association.

Get sample templates for installing the agent and creating the association from the following resources:

- [Template to install Azure Monitor agent \(Azure and Azure Arc\)](#)
- [Template to create association with data collection rule](#)

Install the templates by using [any deployment method for Resource Manager templates](#), such as the following commands.

- [PowerShell](#)
- [CLI](#)

```
New-AzResourceGroupDeployment -ResourceGroupName "<resource-group-name>" -TemplateFile "<template-filename.json>" -TemplateParameterFile "<parameter-filename.json>"
```

# Use PowerShell

You can install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers by using the PowerShell command for adding a virtual machine extension.

## Install on Azure virtual machines

Use the following PowerShell commands to install the Azure Monitor agent on Azure virtual machines. Choose the appropriate command based on your chosen authentication method.

### User-assigned managed identity

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Location <location> -TypeHandlerVersion <version-number> -SettingString '{"authentication":{"managedIdentity":{"identifier-name":"mi_res_id","identifier-value":/subscriptions/<my-subscription-id>/resourceGroups/<my-resource-group>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<my-user-assigned-identity>"}}}'
```

### System-assigned managed identity

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Location <location> -TypeHandlerVersion <version-number>
```

### Uninstall on Azure virtual machines

Use the following PowerShell commands to uninstall the Azure Monitor agent on Azure virtual machines.

- [Windows](#)
- [Linux](#)

```
Remove-AzVMExtension -Name AzureMonitorWindowsAgent -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name>
```

### Update on Azure virtual machines

To perform a one-time update of the agent, you must first uninstall the existing agent version,. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -ExtensionName AzureMonitorWindowsAgent -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Publisher Microsoft.Azure.Monitor -ExtensionType AzureMonitorWindowsAgent -TypeHandlerVersion <version-number> -Location <location> -EnableAutomaticUpgrade $true
```

### Install on Azure Arc-enabled servers

Use the following PowerShell commands to install the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
New-AzConnectedMachineExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -MachineName <arc-server-name> -Location <arc-server-location>
```

### Uninstall on Azure Arc-enabled servers

Use the following PowerShell commands to uninstall the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
Remove-AzConnectedMachineExtension -MachineName <arc-server-name> -ResourceGroupName <resource-group-name> -Name AzureMonitorWindowsAgent
```

## Upgrade on Azure Arc-enabled servers

To perform a one-time upgrade of the agent, use the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
$target = @{"Microsoft.Azure.Monitor.AzureMonitorWindowsAgent" = @{"targetVersion"=<target-version-number>}}
Update-AzConnectedExtension -ResourceGroupName $env.ResourceGroupName -MachineName <arc-server-name> -ExtensionTarget $target
```

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade \(preview\)](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
Update-AzConnectedMachineExtension -ResourceGroup <resource-group-name> -MachineName <arc-server-name> -Name AzureMonitorWindowsAgent -EnableAutomaticUpgrade
```

# Use the Azure CLI

You can install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers by using the Azure CLI command for adding a virtual machine extension.

## Install on Azure virtual machines

Use the following CLI commands to install the Azure Monitor agent on Azure virtual machines. Choose the appropriate command based on your chosen authentication method.

### User-assigned managed identity

- [Windows](#)
- [Linux](#)

```
az vm extension set --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --ids <vm-resource-id> --settings '{"authentication":{"managedIdentity":{"identifier-name":"mi_res_id","identifier-value":/subscriptions/<my-subscription-id>/resourceGroups/<my-resource-group>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<my-user-assigned-identity>"}}}'
```

### System-assigned managed identity

- [Windows](#)
- [Linux](#)

```
az vm extension set --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --ids <vm-resource-id>
```

## Uninstall on Azure virtual machines

Use the following CLI commands to uninstall the Azure Monitor agent on Azure virtual machines.

- [Windows](#)
- [Linux](#)

```
az vm extension delete --resource-group <resource-group-name> --vm-name <virtual-machine-name> -name AzureMonitorWindowsAgent
```

## Update on Azure virtual machines

To perform a one-time update of the agent, you must first uninstall the existing agent version,. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature by using the following CLI commands.

- [Windows](#)
- [Linux](#)

```
az vm extension set -name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --vm-name <virtual-machine-name> --resource-group <resource-group-name> --enable-auto-upgrade true
```

## Install on Azure Arc-enabled servers

Use the following CLI commands to install the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension create --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --type AzureMonitorWindowsAgent --machine-name <arc-server-name> --resource-group <resource-group-name> --location <arc-server-location>
```

## Uninstall on Azure Arc-enabled servers

Use the following CLI commands to uninstall the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension delete --name AzureMonitorWindowsAgent --machine-name <arc-server-name> --resource-group <resource-group-name>
```

## Upgrade on Azure Arc-enabled servers

To perform a one-time upgrade of the agent, use the following CLI commands.

- [Windows](#)
- [Linux](#)

```
az connectedmachine upgrade-extension --extension-targets "  
{\"Microsoft.Azure.Monitor.AzureMonitorWindowsAgent\":{\"targetVersion\":\"<target-version-number>\"},\"}  
--machine-name <arc-server-name> --resource-group <resource-group-name>
```

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade \(preview\)](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension update --name AzureMonitorWindowsAgent --machine-name <arc-server-name> --  
resource-group <resource-group-name> --enable-auto-upgrade true
```

## Use Azure Policy

Use the following policies and policy initiatives to automatically install the agent and associate it with a data collection rule every time you create a virtual machine, scale set, or Azure Arc-enabled server.

### NOTE

As per Microsoft Identity best practices, policies for installing the Azure Monitor agent on virtual machines and scale sets rely on user-assigned managed identity. This option is the more scalable and resilient managed identity for these resources. For Azure Arc-enabled servers, policies rely on system-assigned managed identity as the only supported option today.

### Built-in policy initiatives

Before you proceed, review [prerequisites for agent installation](#).

Policy initiatives for Windows and Linux virtual machines, scale sets consist of individual policies that:

- (Optional) Create and assign built-in user-assigned managed identity, per subscription, per region. [Learn more](#).
  - **Bring Your Own User-Assigned Identity** : If set to `true`, it creates the built-in user-assigned managed identity in the predefined resource group and assigns it to all machines that the policy is applied to. If set to `false`, you can instead use existing user-assigned identity that *you must assign* to the machines beforehand.
- Install the Azure Monitor agent extension on the machine, and configure it to use user-assigned identity as specified by the following parameters.
  - **Bring Your Own User-Assigned Managed Identity** : If set to `false`, it configures the agent to use the built-in user-assigned managed identity created by the preceding policy. If set to `true`, it configures the agent to use an existing user-assigned identity that *you must assign* to the machines in scope beforehand.
  - **User-Assigned Managed Identity Name** : If you use your own identity (selected `true`), specify the name of the identity that's assigned to the machines.
  - **User-Assigned Managed Identity Resource Group** : If you use your own identity (selected `true`), specify the resource group where the identity exists.
  - **Additional Virtual Machine Images** : Pass additional VM image names that you want to apply the policy to, if not already included.
- Create and deploy the association to link the machine to specified data collection rule.

- **Data Collection Rule Resource Id** : The Azure Resource Manager resourceId of the rule you want to associate via this policy to all machines the policy is applied to.

Home > Policy >

**Deploy Windows Azure Monitor Agent with user-assigned managed identity-based auth and associate with Data Collection Rule**

[?] Configure Windows Machines to be associated with a Data Collection Rule	[parameters('effect')]	Built-in	associateDataCollectionRuleV

## Known issues

- Managed Identity default behavior. [Learn more](#).
- Possible race condition with using built-in user-assigned identity creation policy. [Learn more](#).
- Assigning policy to resource groups. If the assignment scope of the policy is a resource group and not a subscription, the identity used by policy assignment (different from the user-assigned identity used by agent) must be manually granted [these roles](#) prior to assignment/remediation. Failing to do this step will result in *deployment failures*.
- Other [Managed Identity limitations](#).

## Built-in policies

You can choose to use the individual policies from the preceding policy initiative to perform a single action at scale. For example, if you *only* want to automatically install the agent, use the second agent installation policy from the initiative, as shown.

Home > Policy > Deploy Windows Azure Monitor Agent with user-assigned managed identity-based auth and associate with Data Collection Rule >

## Remediation

The initiatives or policies will apply to each virtual machine as it's created. A [remediation task](#) deploys the policy definitions in the initiative to existing resources, so you can configure the Azure Monitor agent for any resources that were already created.

When you create the assignment by using the Azure portal, you have the option of creating a remediation task at the same time. For information on the remediation, see [Remediate non-compliant resources with Azure Policy](#).

## Configure Azure Monitor Agent to Linux virtual machines and associate to Data Collection Rule

Assign initiative

Basics Parameters **Remediation** Non-compliance messages Review + create

By default, this assignment will only take effect on newly created resources. Existing resources can be updated via a remediation task after the policy is assigned. For deployIfNotExists policies, the remediation task will deploy the specified template. For modify policies, the remediation task will edit tags on the existing resources.

Create a remediation task ⓘ

Policy to remediate

Configure Linux virtual machines with Azure Monitor Agent

### Managed Identity

Policies with the deployIfNotExists and modify effect types need the ability to deploy resources and edit tags on existing resources respectively. To do this, a managed identity will be created for you.

[Learn more about Managed Identity.](#)

Create a Managed Identity ⓘ

Managed identity location \*

East US

### Permissions

This identity will also be given the following permissions:

Virtual Machine Contributor, Monitoring Contributor

 Role assignments (permissions) are created based on the role definitions specified in the policies.

## Next steps

[Create a data collection rule](#) to collect data from the agent and send it to Azure Monitor.

# Collect data from virtual machines with the Azure Monitor agent

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article describes how to collect events and performance counters from virtual machines using the Azure Monitor agent.

To collect data from virtual machines using the Azure Monitor agent, you'll:

1. Create [data collection rules \(DCR\)](#) that define which data Azure Monitor agent sends to which destinations.
2. Associate the data collection rule to specific virtual machines.

You can associate virtual machines to multiple data collection rules. This allows you to define each data collection rule to address a particular requirement, and associate the data collection rules to virtual machines based on the specific data you want to collect from each machine.

## Create data collection rule and association

To send data to Log Analytics, create the data collection rule in the **same region** as your Log Analytics workspace. You can still associate the rule to machines in other supported regions.

- [Portal](#)
- [API](#)
- [PowerShell](#)
- [Azure CLI](#)
- [Resource Manager template](#)

1. From the **Monitor** menu, select **Data Collection Rules**.
2. Select **Create** to create a new Data Collection Rule and associations.

The screenshot shows the Azure Monitor interface for Data Collection Rules. The left sidebar has a 'Data Collection Rules' section selected. The main area displays a table of existing rules:

Name	Subscription	Resource group	Location	Data sources	Destinations
central-it-default	my-subscription	my-resource-group	East US	Windows event logs	Azure Monitor Logs
lob-app	my-subscription	my-resource-group	East US	Performance counters	Azure Monitor Metrics
sql	my-subscription	my-resource-group	East US	Linux syslog	Azure Monitor Logs

3. Provide a **Rule name** and specify a **Subscription**, **Resource Group**, **Region**, and **Platform Type**.

**Region** specifies where the DCR will be created. The virtual machines and their associations can be in any subscription or resource group in the tenant.

**Platform Type** specifies the type of resources this rule can apply to. Custom allows for both Windows and Linux types.

Home > Monitor >

## Create Data Collection Rule

Data collection rule management

**Basics**   Resources   Collect and deliver   Review + create

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all of your resources.

**Rule details**

Rule Name \*  ✓

Subscription \*  ▼

Resource Group \*  ▼

Create new

Region \*  ▼

Platform Type \*  Windows  
 Linux  
 Custom

**Review + create**   < Previous   **Next : Resources >**

- On the **Resources** tab, add the resources (virtual machines, virtual machine scale sets, Arc for servers) to which to associate the data collection rule. The portal will install Azure Monitor Agent on resources that don't already have it installed, and will also enable Azure Managed Identity.

### IMPORTANT

The portal enables System-Assigned managed identity on the target resources, in addition to existing User-Assigned Identities (if any). For existing applications, unless you specify the User-Assigned identity in the request, the machine will default to using System-Assigned Identity instead.

If you need network isolation using private links, select existing endpoints from the same region for the respective resources, or [create a new endpoint](#).

Home > Monitor >

## Create Data Collection Rule

Data collection rule management

**Basics**   **Resources**   Collect and deliver   Review + create

Pick a set of machines to collect data from. The Azure Monitor Agent will be automatically installed on these machines.

This will also enable System Assigned Managed Identity on these machines, in addition to existing User Assigned Identities (if any). Note: Unless specified in the request, the machine will default to using System Assigned Identity for all other apps. [Learn More](#)

**+ Add Resource(s)**

⚠ Currently, only resources in the following region(s) are supported: Australia Southeast, Canada Central, Japan East, Australia East, Central India, Germany West Central, North Central US, South Central US, East US, Central US, West Europe, West US 2, Southeast Asia East US 2, UK South, North Europe, West US, Australia Central, West Central US, East Asia, UK West, Korea Central, France Central, South Africa North, Switzerland North, Brazil South, Australia Central 2, Brazil Southeast, Canada East, France South, Korea South, Norway West, UAE North, Japan West, Norway East, Switzerland West, East US 2, EUAP.

Name	Type	Location	Resource group	Subscription
my-vm-01	microsoft.compute/virtualmachines	westus	my-resource-grp	My subscription
my-vm-02	microsoft.compute/virtualmachines	westus	my-resource-grp	My subscription
my-vmss-01	microsoft.compute/virtualmachinescalesets	eastus	my-resource-grp	My subscription

**Review + create**   < Previous   **Next : Collect and deliver >**

- On the **Collect and deliver** tab, select **Add data source** to add a data source and set a destination.
- Select a **Data source type**.
- Select which data you want to collect. For performance counters, you can select from a predefined set of objects and their sampling rate. For events, you can select from a set of logs and severity levels.

Home > Monitor | Data Collection Rules >

## Create Data Collection Rule

Data collection rule management

**\*Basics**   Resources   **Collect and deliver**   Review + create

Configure which data sources to collect, and where to send the data to.

**+ Add data source**

No data sources and destination added

✖ This data collection rule doesn't have any data sources or destinations selected.

**Add data source**

**\* Data source**   Destination

Select which data source type and the data to collect for your virtual machine(s).

Data source type  ▼

**Configure Performance Counters**

Choose Basic to enable the collection of performance counters. Choose Custom if you want more control over which performance counters are collected.

None	Basic	Custom
<input checked="" type="checkbox"/> Performance counter	Sample rate (seconds)	
<input checked="" type="checkbox"/> CPU	10	
<input checked="" type="checkbox"/> Memory	10	
<input checked="" type="checkbox"/> Disk	10	
<input checked="" type="checkbox"/> Network	10	

**Review + create**   < Previous   **Next : Review + create >**

- Select **Custom** to collect logs and performance counters that are not [currently supported data sources](#) or to [filter events using XPath queries](#). You can then specify an [XPath](#) to collect any specific values. See [Sample DCR](#) for an example.

The screenshot shows the 'Add data source' dialog box. On the left, the 'Create Data Collection Rule' page is visible, showing the 'Collect and deliver' tab selected. On the right, the 'Add data source' dialog has the 'Data source' tab selected. Under 'Configure Performance Counters', there are tabs for 'None', 'Basic', and 'Custom'. The 'Custom' tab is selected, showing a list of performance counters with their sample rates:

Performance counter	Sample rate (seconds)
\Processor Information(_Total)\% Processor Time	10
\Processor Information(_Total)\% Privileged Time	10
\Processor Information(_Total)\% User Time	10
\Processor Information(_Total)\Processor Frequency	10
\System\Processes	10
\Process(_Total)\Thread Count	10
\Process(_Total)\Handle Count	10
\System\System Up Time	10
\System\Context Switches/sec	10
\System\Processor Queue Length	10

- On the **Destination** tab, add one or more destinations for the data source. You can select multiple destinations of the same or different types - for instance multiple Log Analytics workspaces (known as "multi-homing").

You can send Windows event and Syslog data sources to Azure Monitor Logs only. You can send performance counters to both Azure Monitor Metrics and Azure Monitor Logs.

The screenshot shows the 'Add data source' dialog box. On the left, the 'Create Data Collection Rule' page is visible, showing the 'Collect and deliver' tab selected. On the right, the 'Add data source' dialog has the 'Destination' tab selected. It shows two destination entries:

Destination type	Subscription	Account or namespace
Azure Monitor Metrics	my-subscription	No need to make a selection
Azure Monitor Logs	my-subscription	my-workspace

- Select **Add Data Source** and then **Review + create** to review the details of the data collection rule and association with the set of virtual machines.
- Select **Create** to create the data collection rule.

#### NOTE

It might take up to 5 minutes for data to be sent to the destinations after you create the data collection rule and associations.

## Filter events using XPath queries

Since you're charged for any data you collect in a Log Analytics workspace, collect only the data you need. The basic configuration in the Azure portal provides you with a limited ability to filter out events.

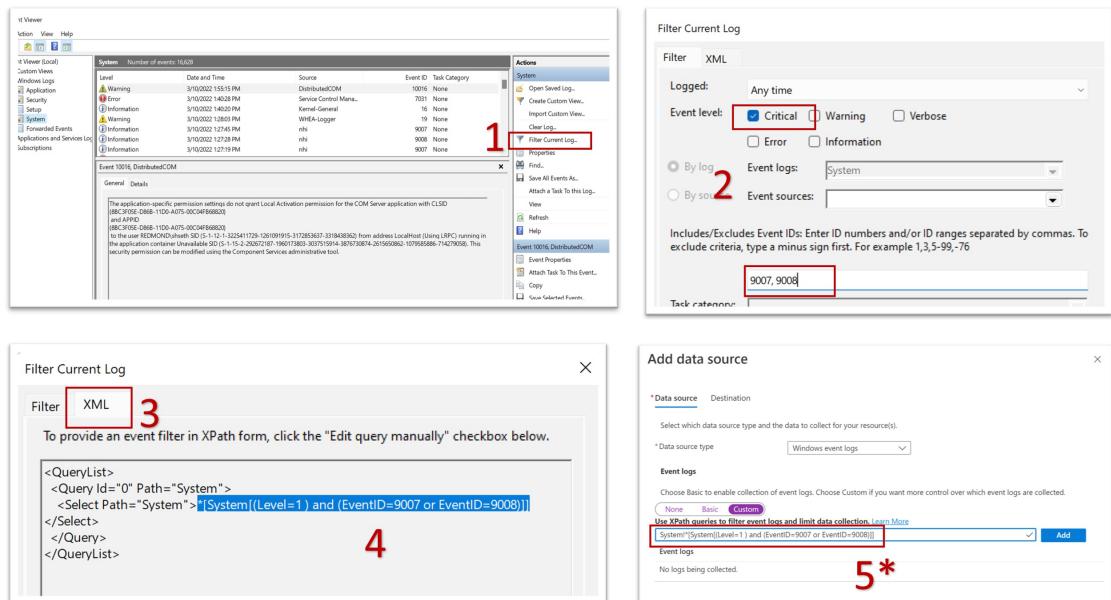

To specify additional filters, use Custom configuration and specify an XPath that filters out the events you don't need. XPath entries are written in the form `LogName!XPathQuery`. For example, you may want to return only events from the Application event log with an event ID of 1035. The XPathQuery for these events would be

`*[System[EventID=1035]]`. Since you want to retrieve the events from the Application event log, the XPath is `Application!*[System[EventID=1035]]`

## Extracting XPath queries from Windows Event Viewer

In Windows, you can use Event Viewer to extract XPath queries as shown below.

When you paste the XPath query into the field on the **Add data source** screen, (step 5 in the picture below), you must append the log type category followed by '!'.

See [XPath 1.0 limitations](#) for a list of limitations in the XPath supported by Windows event log.

### TIP

You can use the PowerShell cmdlet `Get-WinEvent` with the `FilterXPath` parameter to test the validity of an XPathQuery locally on your machine first. The following script shows an example.

```
$XPath = '*[System[EventID=1035]]'
Get-WinEvent -LogName 'Application' -FilterXPath $XPath
```

- In the cmdlet above, the value of the `-LogName` parameter is the initial part of the XPath query until the '!'. The rest of the XPath query goes into the `$XPath` parameter.
- If the script returns events, the query is valid.
- If you receive the message *No events were found that match the specified selection criteria.*, the query may be valid, but there are no matching events on the local machine.
- If you receive the message *The specified query is invalid*, the query syntax is invalid.

Examples of filtering events using a custom XPath:

DESCRIPTION	XPATH
Collect only System events with Event ID = 4648	<code>System!*[System[EventID=4648]]</code>
Collect Security Log events with Event ID = 4648 and a process name of consent.exe	<code>Security!*[System[(EventID=4648)]] and *[EventData[@Name='ProcessName']='C:\Windows\System32\consent.e</code>
Collect all Critical, Error, Warning, and Information events from the System event log except for Event ID = 6 (Driver loaded)	<code>System!*[System[(Level=1 or Level=2 or Level=3) and (EventID != 6)]]</code>

DESCRIPTION	XPATH
Collect all success and failure Security events except for Event ID 4624 (Successful logon)	<pre>Security!* [System[(band(Keywords,13510798882111488)) and (EventID != 4624)]]</pre>

# Migrate to Azure Monitor Agent from Log Analytics agent

9/21/2022 • 5 minutes to read • [Edit Online](#)

Azure Monitor Agent (AMA) replaces the Log Analytics agent (also known as MMA and OMS) for both Windows and Linux machines, in Azure and on premises. It introduces a simplified, flexible method of configuring collection configuration called [Data Collection Rules \(DCRs\)](#). This article outlines the benefits of migrating to Azure Monitor Agent (AMA) and provides guidance on how to implement a successful migration.

## IMPORTANT

The Log Analytics agent will be [retired on 31 August, 2024](#). If you are currently using the Log Analytics agent with Azure Monitor or other supported features and services, you should start planning your migration to Azure Monitor Agent using the information in this article.

## Benefits

Azure Monitor Agent provides the following benefits over legacy agents:

- **Security and performance**
  - Enhanced security through Managed Identity and Azure Active Directory (Azure AD) tokens (for clients).
  - A higher events per second (EPS) upload rate.
- **Cost savings** using data collection [using Data Collection Rules](#). Using Data Collection Rules is one of the most useful advantages of using Azure Monitor Agent.
  - DCRs lets you configure data collection for specific machines connected to a workspace as compared to the "all or nothing" approach of legacy agents.
  - Using DCRs you can define which data to ingest and which data to filter out to reduce workspace clutter and save on costs.
- **Simpler management** of data collection, including ease of troubleshooting
  - Easy [multihoming](#) on Windows and Linux.
  - Centralized, 'in the cloud' agent configuration makes every action simpler and more easily scalable throughout the data collection lifecycle, from onboarding to deployment to updates and changes over time.
  - Greater transparency and control of more capabilities and services, such as Sentinel, Defender for Cloud, and VM Insights.
- **A single agent** that consolidates all features necessary to address all telemetry data collection needs across servers and client devices (running Windows 10, 11). This is the goal, though Azure Monitor Agent currently converges with the Log Analytics agents.

## Migration plan considerations

Your migration plan to the Azure Monitor Agent should take into account:

- **Current and new feature requirements:** Review [Azure Monitor Agent's supported services and features](#) to ensure that Azure Monitor Agent has the features you require. If you currently use unsupported features you can temporarily do without, consider migrating to the new agent to benefit

from added security and reduced cost immediately. Use the [AMA Migration Helper](#) to discover what solutions and features you're using today that depend on the legacy agent.

If you use Microsoft Sentinel, see [Gap analysis for Microsoft Sentinel](#) for a comparison of the extra data collected by Microsoft Sentinel.

- **Installing Azure Monitor Agent alongside a legacy agent:** If you're setting up a **new environment** with resources, such as deployment scripts and onboarding templates, and you still need a legacy agent, assess the effort of migrating to Azure Monitor Agent later. If the setup will take a significant amount of rework, install Azure Monitor Agent together with a legacy agent in your new environment to decrease the migration effort.

Azure Monitor Agent can run alongside the legacy Log Analytics agents on the same machine so that you can continue to use existing functionality during evaluation or migration. While this allows you to begin the transition, ensure you understand the limitations:

- Be careful in collecting duplicate data from the same machine, which could skew query results and affect downstream features like alerts, dashboards or workbooks. For example, VM Insights uses the Log Analytics agent to send performance data to a Log Analytics workspace. You might also have configured the workspace to collect Windows events and Syslog events from agents. If you install Azure Monitor Agent and create a data collection rule for these events and performance data, you'll collect duplicate data. If you're using both agents to collect the same type of data, make sure the agents are **collecting data from different machines or sending the data to different destinations**. Collecting duplicate data also generates more charges for data ingestion and retention.
- Running two telemetry agents on the same machine consumes double the resources, including, but not limited to CPU, memory, storage space, and network bandwidth.

## Prerequisites

Review the [prerequisites](#) for use Azure Monitor Agent. For on-premises servers or other cloud managed servers, [installing the Azure Arc agent](#) is an important prerequisite that then helps to install the agent extension and other required extensions. Using Arc for this purpose comes at no added cost, and it's not mandatory to use Arc for server management overall (i.e. you can continue using your existing on-premises management solutions). Once Arc agent is installed, you can follow the same guidance below across Azure and on-premise for migration.

## Migration testing

To ensure safe deployment during migration, begin testing with few resources running Azure Monitor Agent in your nonproduction environment. After you validate the data collected on these test resources, roll out to production by following the same steps.

See [create new data collection rules](#) to start collecting some of the existing data types. Alternatively you can use the [DCR Config Generator](#) to convert existing legacy agent configuration into data collection rules. After you **validate** that data is flowing as expected with Azure Monitor Agent, check the **Category** column in the [Heartbeat](#) table for the value *Azure Monitor Agent* for AMA collected data. Ensure it matches data flowing through the existing Log Analytics agent.

## At-scale migration using Azure Policy

We recommend using [Azure Policy](#) to migrate a large number of agents. Start by analyzing your current monitoring setup with the Log Analytics agent using the [AMA Migration Helper](#) to find sources, such as virtual machines, virtual machine scale sets, and on-premises servers.

Use the [DCR Config Generator](#) to migrate legacy agent configuration, including data sources and destinations, from the workspace to the new DCRs.

**IMPORTANT**

Before you deploy a large number of agents, consider [configuring the workspace](#) to disable data collection for the Log Analytics agent. If you leave data collection for the Log Analytics agent enabled, you may collect duplicate data and increase your costs. You might choose to collect duplicate data for a short period during migration until you verify that you've deployed and configured Azure Monitor Agent correctly.

Validate that Azure Monitor Agent is collecting data as expected and all downstream dependencies, such as dashboards, alerts, and workbooks, function properly.

After you confirm that Azure Monitor Agent is collecting data properly, [uninstall the Log Analytics agent](#) from monitored resources. Clean up any configuration files, workspace keys, or certificates that were used previously by the Log Analytics agent.

**IMPORTANT**

Don't uninstall the legacy agent if you need to use it for System Center Operations Manager scenarios or others solutions not yet available on Azure Monitor Agent.

## Next steps

For more information, see:

- [Azure Monitor Agent overview](#)
- [Azure Monitor Agent migration for Microsoft Sentinel](#)
- [Frequently asked questions for Azure Monitor Agent migration](#)

# Log Analytics agent overview

9/21/2022 • 7 minutes to read • [Edit Online](#)

This article provides a detailed overview of the Log Analytics agent and the agent's system and network requirements and deployment methods.

## IMPORTANT

The Log Analytics agent is on a **deprecation path** and won't be supported after **August 31, 2024**. If you use the Log Analytics agent to ingest data to Azure Monitor, [migrate to the new Azure Monitor agent](#) prior to that date.

You might also see the Log Analytics agent referred to as Microsoft Monitoring Agent (MMA).

## Primary scenarios

Use the Log Analytics agent if you need to:

- Collect logs and performance data from Azure virtual machines or hybrid machines hosted outside of Azure.
- Send data to a Log Analytics workspace to take advantage of features supported by [Azure Monitor Logs](#), such as [log queries](#).
- Use [VM insights](#), which allows you to monitor your machines at scale and monitor their processes and dependencies on other resources and external processes.
- Manage the security of your machines by using [Microsoft Defender for Cloud](#) or [Microsoft Sentinel](#).
- Use [Azure Automation Update Management](#), [Azure Automation State Configuration](#), or [Azure Automation Change Tracking and Inventory](#) to deliver comprehensive management of your Azure and non-Azure machines.
- Use different [solutions](#) to monitor a particular service or application.

Limitations of the Log Analytics agent:

- Can't send data to Azure Monitor Metrics, Azure Storage, or Azure Event Hubs.
- Difficult to configure unique monitoring definitions for individual agents.
- Difficult to manage at scale because each virtual machine has a unique configuration.

## Comparison to other agents

For a comparison between the Log Analytics and other agents in Azure Monitor, see [Overview of Azure Monitor agents](#).

## Supported operating systems

For a list of the Windows and Linux operating system versions that are supported by the Log Analytics agent, see [Supported operating systems](#).

## Installation options

This section explains how to install the Log Analytics agent on different types of virtual machines and connect the machines to Azure Monitor.

**IMPORTANT**

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

**NOTE**

Cloning a machine with the Log Analytics Agent already configured is *not* supported. If the agent is already associated with a workspace, cloning won't work for "golden images."

**Azure virtual machine**

- Use [VM insights](#) to install the agent for a [single machine using the Azure portal](#) or for [multiple machines at scale](#). This installs the Log Analytics agent and [Dependency agent](#).
- Log Analytics VM extension for [Windows](#) or [Linux](#) can be installed with the Azure portal, Azure CLI, Azure PowerShell, or an Azure Resource Manager template.
- [Microsoft Defender for Cloud](#) can provision the Log Analytics agent on all supported Azure VMs and any new ones that are created if you enable it to monitor for security vulnerabilities and threats.
- Install for individual Azure virtual machines [manually from the Azure portal](#).
- Connect the machine to a workspace from the [Virtual machines](#) option in the [Log Analytics workspaces](#) menu in the Azure portal.

**Windows virtual machine on-premises or in another cloud**

- Use [Azure Arc-enabled servers](#) to deploy and manage the Log Analytics VM extension. Review the [deployment options](#) to understand the different deployment methods available for the extension on machines registered with Azure Arc-enabled servers.
- [Manually install](#) the agent from the command line.
- Automate the installation with [Azure Automation DSC](#).
- Use a [Resource Manager template with Azure Stack](#).

**Linux virtual machine on-premises or in another cloud**

- Use [Azure Arc-enabled servers](#) to deploy and manage the Log Analytics VM extension. Review the [deployment options](#) to understand the different deployment methods available for the extension on machines registered with Azure Arc-enabled servers.
- [Manually install](#) the agent calling a wrapper-script hosted on GitHub.
- Integrate [System Center Operations Manager](#) with Azure Monitor to forward collected data from Windows computers reporting to a management group.

## Data collected

The following table lists the types of data you can configure a Log Analytics workspace to collect from all connected agents. For a list of insights and solutions that use the Log Analytics agent to collect other kinds of data, see [What is monitored by Azure Monitor?](#).

DATA SOURCE	DESCRIPTION
<a href="#">Windows Event logs</a>	Information sent to the Windows event logging system
<a href="#">Syslog</a>	Information sent to the Linux event logging system

DATA SOURCE	DESCRIPTION
Performance	Numerical values measuring performance of different aspects of operating system and workloads
IIS logs	Usage information for IIS websites running on the guest operating system
Custom logs	Events from text files on both Windows and Linux computers

## Other services

The agent for Linux and Windows isn't only for connecting to Azure Monitor. Other services such as Microsoft Defender for Cloud and Microsoft Sentinel rely on the agent and its connected Log Analytics workspace. The agent also supports Azure Automation to host the Hybrid Runbook Worker role and other services such as [Change Tracking](#), [Update Management](#), and [Microsoft Defender for Cloud](#). For more information about the Hybrid Runbook Worker role, see [Azure Automation Hybrid Runbook Worker](#).

## Workspace and management group limitations

For details on connecting an agent to an Operations Manager management group, see [Configure agent to report to an Operations Manager management group](#).

- Windows agents can connect to up to four workspaces, even if they're connected to a System Center Operations Manager management group.
- The Linux agent doesn't support multi-homing and can only connect to a single workspace or management group.

## Security limitations

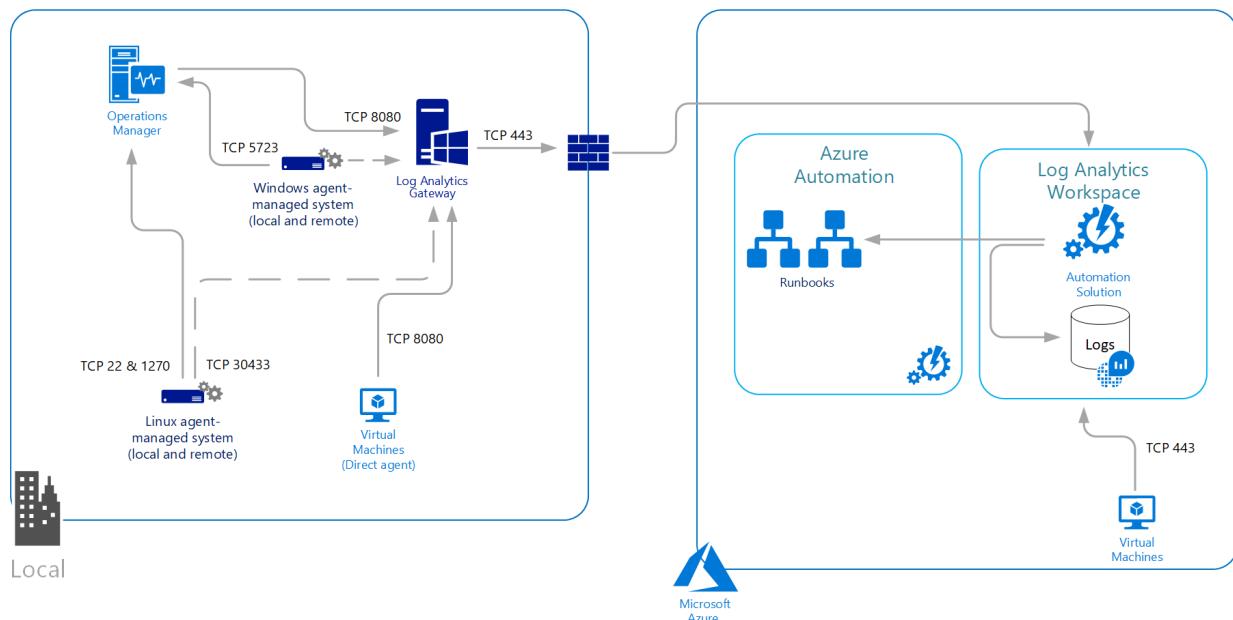

The Windows and Linux agents support the [FIPS 140 standard](#), but [other types of hardening might not be supported](#).

## TLS 1.2 protocol

To ensure the security of data in transit to Azure Monitor logs, we strongly encourage you to configure the agent to use at least Transport Layer Security (TLS) 1.2. Older versions of TLS/Secure Sockets Layer (SSL) have been found to be vulnerable. Although they still currently work to allow backward compatibility, they are *not recommended*. For more information, see [Sending data securely using TLS 1.2](#).

## Network requirements

The agent for Linux and Windows communicates outbound to the Azure Monitor service over TCP port 443. If the machine connects through a firewall or proxy server to communicate over the internet, review the following requirements to understand the network configuration required. If your IT security policies do not allow computers on the network to connect to the internet, set up a [Log Analytics gateway](#) and configure the agent to connect through the gateway to Azure Monitor. The agent can then receive configuration information and send data collected.

The following table lists the proxy and firewall configuration information required for the Linux and Windows agents to communicate with Azure Monitor logs.

### Firewall requirements

AGENT RESOURCE	POR TS	DIRECTION	BYPASS HTTPS INSPECTION
*.ods.opinsights.azure.com	Port 443	Outbound	Yes
*.oms.opinsights.azure.com	Port 443	Outbound	Yes
*.blob.core.windows.net	Port 443	Outbound	Yes
*.azure-automation.net	Port 443	Outbound	Yes

For firewall information required for Azure Government, see [Azure Government management](#).

#### IMPORTANT

If your firewall is doing CNAME inspections, you need to configure it to allow all domains in the CNAME.

If you plan to use the Azure Automation Hybrid Runbook Worker to connect to and register with the Automation service to use runbooks or management features in your environment, it must have access to the port number and the URLs described in [Configure your network for the Hybrid Runbook Worker](#).

### Proxy configuration

The Windows and Linux agent supports communicating either through a proxy server or Log Analytics gateway to Azure Monitor by using the HTTPS protocol. Both anonymous and basic authentication (username/password) are supported.

For the Windows agent connected directly to the service, the proxy configuration is specified during installation or [after deployment](#) from Control Panel or with PowerShell. Log Analytics Agent (MMA) doesn't use the system proxy settings. As a result, the user has to pass the proxy setting while installing MMA. These settings will be stored under MMA configuration (registry) on the virtual machine.

For the Linux agent, the proxy server is specified during installation or [after installation](#) by modifying the proxy.conf configuration file. The Linux agent proxy configuration value has the following syntax:

```
[protocol://][user:password@]proxyhost[:port]
```

PROPERTY	DESCRIPTION
Protocol	https
user	Optional username for proxy authentication
password	Optional password for proxy authentication
proxyhost	Address or FQDN of the proxy server/Log Analytics gateway
port	Optional port number for the proxy server/Log Analytics gateway

For example: `https://user01:password@proxy01.contoso.com:30443`

#### NOTE

If you use special characters such as "@" in your password, you'll receive a proxy connection error because the value is parsed incorrectly. To work around this issue, encode the password in the URL by using a tool like [URLDecode](#).

## Next steps

- Review [data sources](#) to understand the data sources available to collect data from your Windows or Linux system.
- Learn about [log queries](#) to analyze the data collected from data sources and solutions.
- Learn about [monitoring solutions](#) that add functionality to Azure Monitor and also collect data into the Log Analytics workspace.

# Install Log Analytics agent on Linux computers

9/21/2022 • 10 minutes to read • [Edit Online](#)

This article provides details on installing the Log Analytics agent on Linux computers hosted in other clouds or on-premises.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

The [installation methods described in this article](#) are:

- Install the agent for Linux using a wrapper-script hosted on GitHub. This is the recommended method to install and upgrade the agent when the computer has connectivity with the Internet, directly or through a proxy server.
- Manually download and install the agent. This is required when the Linux computer doesn't have access to the Internet and will be communicating with Azure Monitor or Azure Automation through the [Log Analytics gateway](#).

See [Installation options](#) for more efficient options you can use for Azure virtual machines.

## Requirements

### Supported operating systems

See [Overview of Azure Monitor agents](#) for a list of Linux distributions supported by the Log Analytics agent.

## NOTE

OpenSSL 1.1.0 is only supported on x86\_x64 platforms (64-bit) and OpenSSL earlier than 1.x is not supported on any platform.

## NOTE

The Log Analytics Linux Agent does not run in containers. To monitor containers, use the [Container Monitoring solution](#) for Docker hosts or [Container insights](#) for Kubernetes.

Starting with versions released after August 2018, we're making the following changes to our support model:

- Only the server versions are supported, not client.
- Focus support on any of the [Azure Linux Endorsed distros](#). There may be some delay between a new distro/version being Azure Linux Endorsed and it being supported for the Log Analytics Linux agent.
- All minor releases are supported for each major version listed.
- Versions that have passed their manufacturer's end-of-support date aren't supported.
- Only support VM images; containers, even those derived from official distro publishers' images, aren't supported.
- New versions of AMI aren't supported.
- Only versions that run OpenSSL 1.x by default are supported.

## NOTE

If you are using a distro or version that is not currently supported and doesn't align to our support model, we recommend that you fork this repo, acknowledging that Microsoft support will not provide assistance with forked agent versions.

## Python requirement

Starting from Agent version 1.13.27, the Linux Agent will support both Python 2 and 3. We always recommend using the latest agent.

If you're using an older version of the agent, you must have the Virtual Machine use Python 2 by default. If your virtual machine is using a distro that doesn't include Python 2 by default, then you must install it. The following sample commands will install Python 2 on different distros.

- Red Hat, CentOS, Oracle: `yum install -y python2`
- Ubuntu, Debian: `apt-get install -y python2`
- SUSE: `zypper install -y python2`

Again, only if you're using an older version of the agent, the `python2` executable must be aliased to `python`.

Following is one method that you can use to set this alias:

1. Run the following command to remove any existing aliases.

```
sudo update-alternatives --remove-all python
```

2. Run the following command to create the alias.

```
sudo update-alternatives --install /usr/bin/python python /usr/bin/python2 1
```

## Supported Linux hardening

The OMS Agent has limited customization and hardening support for Linux.

The following are currently supported:

- FIPS
- SELinux (Marketplace images for CentOS and RHEL with their default settings)

The following aren't supported:

- CIS
- SELinux (custom hardening like MLS)

CIS and SELinux hardening support is planned for [Azure Monitoring Agent](#). Further hardening and customization methods aren't supported nor planned for OMS Agent. For instance, OS images like GitHub Enterprise Server which include customizations such as limitations to user account privileges aren't supported.

## Agent prerequisites

The following table highlights the packages required for [supported Linux distros](#) that the agent will be installed on.

REQUIRED PACKAGE	DESCRIPTION	MINIMUM VERSION
Glibc	GNU C Library	2.5-12

REQUIRED PACKAGE	DESCRIPTION	MINIMUM VERSION
Openssl	OpenSSL Libraries	1.0.x or 1.1.x
Curl	cURL web client	7.15.5
Python		2.7 or 3.6+
Python-ctypes		
PAM	Pluggable Authentication Modules	

#### NOTE

Either rsyslog or syslog-ng are required to collect syslog messages. The default syslog daemon on version 5 of Red Hat Enterprise Linux, CentOS, and Oracle Linux version (sysklog) is not supported for syslog event collection. To collect syslog data from this version of these distributions, the rsyslog daemon should be installed and configured to replace sysklog.

## Network requirements

See [Log Analytics agent overview](#) for the network requirements for the Linux agent.

### Workspace ID and key

Regardless of the installation method used, you'll require the workspace ID and key for the Log Analytics workspace that the agent will connect to. Select the workspace from the **Log Analytics workspaces** menu in the Azure portal. Then select **Agents management** in the **Settings** section.

The screenshot shows the Azure Log Analytics workspace settings interface. On the left, there's a sidebar with options like 'Add', 'Open recycle bin', and 'Agents management'. The main area is titled 'CH-LA | Agents management' and shows '52 Windows computers connected'. It has sections for 'Download agent' (with links to 'Download Windows Agent (64 bit)' and 'Download Windows Agent (32 bit)'), 'Workspace ID' (a text input field containing '<GUID>'), 'Primary key' (a text input field containing '<GUID>'), and 'Secondary key' (a text input field containing '<GUID>'). Below these are links for 'Log Analytics Gateway' and 'Learn more about Log Analytics Gateway'.

## Agent install package

The Log Analytics agent for Linux is composed of multiple packages. The release file contains the following packages, which are available by running the shell bundle with the `--extract` parameter:

PACKAGE	VERSION	DESCRIPTION
omsagent	1.14.19	The Log Analytics Agent for Linux
omsconfig	1.1.1	Configuration agent for the Log Analytics agent

PACKAGE	VERSION	DESCRIPTION
omi	1.6.9	Open Management Infrastructure (OMI) -- a lightweight CIM Server. <i>Note that OMI requires root access to run a cron job necessary for the functioning of the service</i>
scx	1.6.9	OMI CIM Providers for operating system performance metrics
apache-cimprov	1.0.1	Apache HTTP Server performance monitoring provider for OMI. Only installed if Apache HTTP Server is detected.
mysql-cimprov	1.0.1	MySQL Server performance monitoring provider for OMI. Only installed if MySQL/MariaDB server is detected.
docker-cimprov	1.0.0	Docker provider for OMI. Only installed if Docker is detected.

## Agent installation details

### IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

Installing the Log Analytics agent for Linux packages also applies the system-wide configuration changes below. Uninstalling the `omsagent` package removes these artifacts.

- A non-privileged user named: `omsagent` is created. The daemon runs under this credential.
- A sudoers *include* file is created in `/etc/sudoers.d/omsagent`. This authorizes `omsagent` to restart the syslog and omsagent daemons. If sudo *include* directives aren't supported in the installed version of sudo, these entries will be written to `/etc/sudoers`.
- The syslog configuration is modified to forward a subset of events to the agent. For more information, see [Configure Syslog data collection](#).

On a monitored Linux computer, the agent is listed as `omsagent`. `omsconfig` is the Log Analytics agent for Linux configuration agent that looks for new portal side configuration every 5 minutes. The new and updated configuration is applied to the agent configuration files located at `/etc/opt/microsoft/omsagent/conf/omsagent.conf`.

## Install the agent

### IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

- [Wrapper script](#)

- [Shell](#)

The following steps configure setup of the agent for Log Analytics in Azure and Azure Government cloud using the wrapper script for Linux computers that can communicate directly or through a proxy server to download the agent hosted on GitHub and install the agent.

If your Linux computer needs to communicate through a proxy server to Log Analytics, this configuration can be specified on the command line by including `-p [protocol://][user:password@]proxyhost[:port]`. The *protocol* property accepts `http` or `https`, and the *proxyhost* property accepts a fully qualified domain name or IP address of the proxy server.

For example: `https://proxy01.contoso.com:30443`

If authentication is required in either case, you need to specify the username and password. For example:

`https://user01:password@proxy01.contoso.com:30443`

1. To configure the Linux computer to connect to a Log Analytics workspace, run the following command providing the workspace ID and primary key. The following command downloads the agent, validates its checksum, and installs it.

```
wget https://raw.githubusercontent.com/Microsoft/OMS-Agent-for-Linux/master/installer/scripts/onboard_agent.sh && sh onboard_agent.sh -w <YOUR WORKSPACE ID> -s <YOUR WORKSPACE PRIMARY KEY>
```

The following command includes the `-p` proxy parameter and example syntax when authentication is required by your proxy server:

```
wget https://raw.githubusercontent.com/Microsoft/OMS-Agent-for-Linux/master/installer/scripts/onboard_agent.sh && sh onboard_agent.sh -p [protocol://]<proxy user>:<proxy password>@<proxyhost>[:port] -w <YOUR WORKSPACE ID> -s <YOUR WORKSPACE PRIMARY KEY>
```

2. To configure the Linux computer to connect to Log Analytics workspace in Azure Government cloud, run the following command providing the workspace ID and primary key copied earlier. The following command downloads the agent, validates its checksum, and installs it.

```
wget https://raw.githubusercontent.com/Microsoft/OMS-Agent-for-Linux/master/installer/scripts/onboard_agent.sh && sh onboard_agent.sh -w <YOUR WORKSPACE ID> -s <YOUR WORKSPACE PRIMARY KEY> -d opinsights.azure.us
```

The following command includes the `-p` proxy parameter and example syntax when authentication is required by your proxy server:

```
wget https://raw.githubusercontent.com/Microsoft/OMS-Agent-for-Linux/master/installer/scripts/onboard_agent.sh && sh onboard_agent.sh -p [protocol://]<proxy user>:<proxy password>@<proxyhost>[:port] -w <YOUR WORKSPACE ID> -s <YOUR WORKSPACE PRIMARY KEY> -d opinsights.azure.us
```

3. Restart the agent by running the following command:

```
sudo /opt/microsoft/omsagent/bin/service_control restart [<workspace id>]
```

## Upgrade from a previous release

Upgrading from a previous version, starting with version 1.0.0-47, is supported in each release. Perform the installation with the `--upgrade` parameter to upgrade all components of the agent to the latest version.

#### NOTE

There will be a warning message during the upgrade "docker provider package installation skipped" since `--skip-docker-provider-install` flag is set. If you are installing over an existing omsagent install and wish to remove the docker provider, you should first purge the existing installation and then install using the `--skip-docker-provider-install` flag.

## Cache information

Data from the Log Analytics agent for Linux is cached on the local machine at `%STATE_DIR_WS%/out_oms_common.buffer*` before it's sent to Azure Monitor. Custom log data is buffered in `%STATE_DIR_WS%/out_oms_blob.buffer*`. The path may be different for some [solutions and data types](#).

The agent attempts to upload every 20 seconds. If it fails, it waits an exponentially increasing length of time until it succeeds: 30 seconds before the second attempt, 60 seconds before the third, 120 seconds, and so on, up to a maximum of 16 minutes between retries until it successfully connects again. The agent retries up to 6 times for a given chunk of data before discarding and moving to the next one. This continues until the agent can successfully upload again. This means that data may be buffered up to approximately 30 minutes before being discarded.

The default cache size is 10 MB but can be modified in the [omsagent.conf file](#).

## Next steps

- Review [Managing and maintaining the Log Analytics agent for Windows and Linux](#) to learn about how to reconfigure, upgrade, or remove the agent from the virtual machine.
- Review [Troubleshooting the Linux agent](#) if you encounter issues while installing or managing the agent.
- Review [Agent Data Sources](#) to learn about data source configuration.

# Connect computers without internet access by using the Log Analytics gateway in Azure Monitor

9/21/2022 • 21 minutes to read • [Edit Online](#)

This article describes how to configure communication with Azure Automation and Azure Monitor by using the Log Analytics gateway when computers that are directly connected or that are monitored by Operations Manager have no internet access.

The Log Analytics gateway is an HTTP forward proxy that supports HTTP tunneling using the HTTP CONNECT command. This gateway sends data to Azure Automation and a Log Analytics workspace in Azure Monitor on behalf of the computers that cannot directly connect to the internet. The gateway is only for log agent related connectivity and does not support Azure Automation features like runbook, DSC, and others.

The Log Analytics gateway supports:

- Reporting up to the same Log Analytics workspaces configured on each agent behind it and that are configured with Azure Automation Hybrid Runbook Workers.
- Windows computers on which either the [Azure Monitor Agent](#) or the legacy Microsoft Monitoring Agent is directly connected to a Log Analytics workspace in Azure Monitor. Both the source and the gateway server must be running the same agent. You can't stream events from a server running Azure Monitor agent through a server running the gateway with the Log Analytics agent.
- Linux computers on which either the [Azure Monitor Agent](#) or the legacy Log Analytics agent for Linux is directly connected to a Log Analytics workspace in Azure Monitor.
- System Center Operations Manager 2012 SP1 with UR7, Operations Manager 2012 R2 with UR3, or a management group in Operations Manager 2016 or later that is integrated with Log Analytics.

Some IT security policies don't allow internet connection for network computers. These unconnected computers could be point of sale (POS) devices or servers supporting IT services, for example. To connect these devices to Azure Automation or a Log Analytics workspace so you can manage and monitor them, configure them to communicate directly with the Log Analytics gateway. The Log Analytics gateway can receive configuration information and forward data on their behalf. If the computers are configured with the Log Analytics agent to directly connect to a Log Analytics workspace, the computers instead communicate with the Log Analytics gateway.

The Log Analytics gateway transfers data from the agents to the service directly. It doesn't analyze any of the data in transit and the gateway does not cache data when it loses connectivity with the service. When the gateway is unable to communicate with service, the agent continues to run and queues the collected data on the disk of the monitored computer. When the connection is restored, the agent sends the cached data collected to Azure Monitor.

When an Operations Manager management group is integrated with Log Analytics, the management servers can be configured to connect to the Log Analytics gateway to receive configuration information and send collected data, depending on the solution you have enabled. Operations Manager agents send some data to the management server. For example, agents might send Operations Manager alerts, configuration assessment data, instance space data, and capacity data. Other high-volume data, such as Internet Information Services (IIS) logs, performance data, and security events, is sent directly to the Log Analytics gateway.

If one or more Operations Manager Gateway servers are deployed to monitor untrusted systems in a perimeter network or an isolated network, those servers can't communicate with a Log Analytics gateway. Operations Manager Gateway servers can report only to a management server. When an Operations Manager management

group is configured to communicate with the Log Analytics gateway, the proxy configuration information is automatically distributed to every agent-managed computer that is configured to collect log data for Azure Monitor, even if the setting is empty.

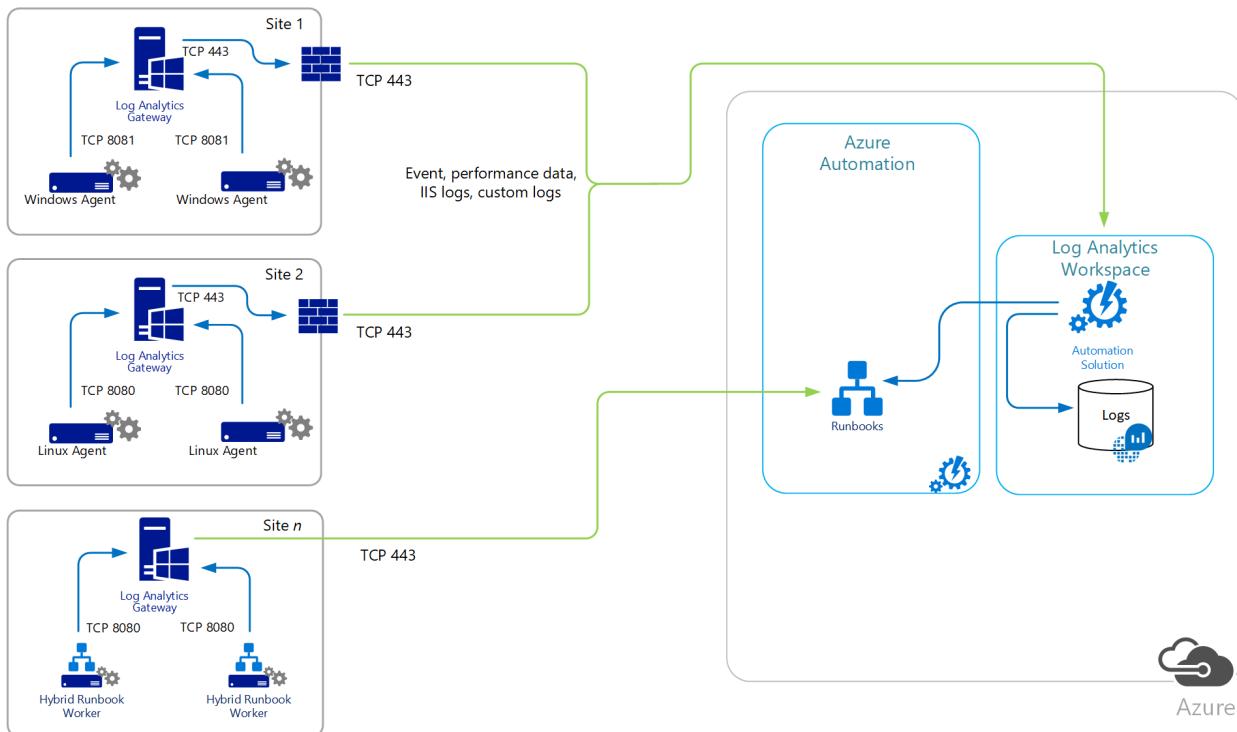

To provide high availability for directly connected or Operations Management groups that communicate with a Log Analytics workspace through the gateway, use network load balancing (NLB) to redirect and distribute traffic across multiple gateway servers. That way, if one gateway server goes down, the traffic is redirected to another available node.

The computer that runs the Log Analytics gateway requires the agent to identify the service endpoints that the gateway needs to communicate with. The agent also needs to direct the gateway to report to the same workspaces that the agents or Operations Manager management group behind the gateway are configured with. This configuration allows the gateway and the agent to communicate with their assigned workspace.

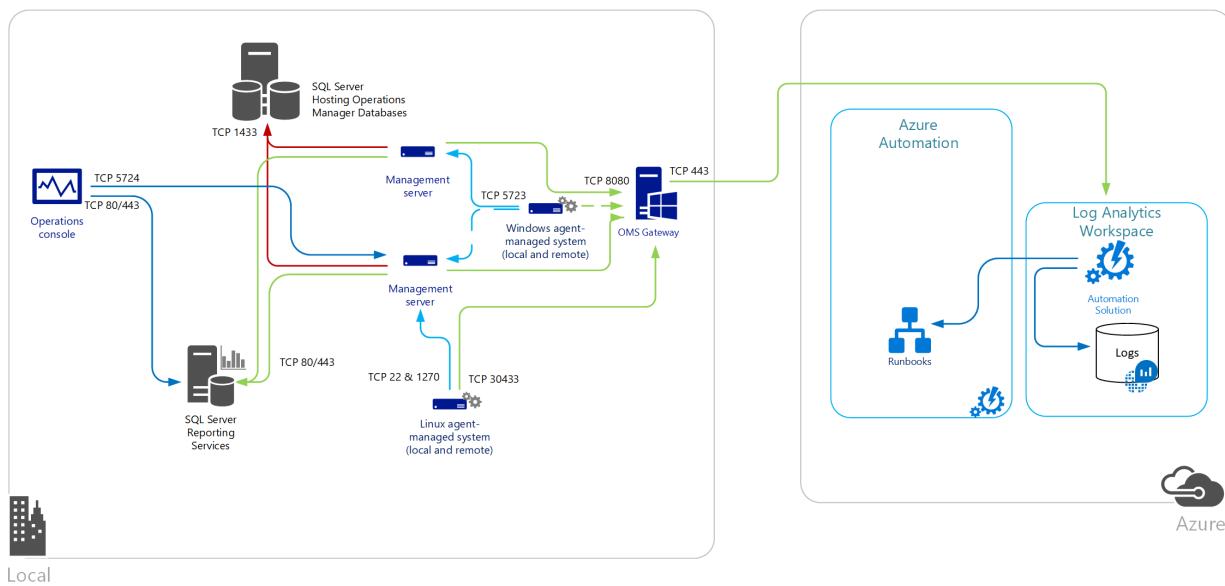

A gateway can be multihomed to up to ten workspaces using the Azure Monitor Agent and [data collection rules](#). Using the legacy Microsoft Monitor Agent, you can only multihome up to four workspaces as that is the total number of workspaces the legacy Windows agent supports.

Each agent must have network connectivity to the gateway so that agents can automatically transfer data to and from the gateway. Avoid installing the gateway on a domain controller. Linux computers that are behind a gateway server cannot use the [wrapper script installation](#) method to install the Log Analytics agent for Linux. The agent must be downloaded manually, copied to the computer, and installed manually because the gateway only supports communicating with the Azure services mentioned earlier.

The following diagram shows data flowing from direct agents, through the gateway, to Azure Automation and Log Analytics. The agent proxy configuration must match the port that the Log Analytics gateway is configured with.

The following diagram shows data flow from an Operations Manager management group to Log Analytics.

## Set up your system

Computers designated to run the Log Analytics gateway must have the following configuration:

- Windows 10, Windows 8.1, or Windows 7
- Windows Server 2019, Windows Server 2016, Windows Server 2012 R2, Windows Server 2012, Windows Server 2008 R2, or Windows Server 2008
- Microsoft .NET Framework 4.5
- At least a 4-core processor and 8 GB of memory
- An [Azure Monitor agent](#) installed with [data collection rule\(s\)](#) configured, or the [Log Analytics agent for Windows](#) configured to report to the same workspace as the agents that communicate through the gateway

### Language availability

The Log Analytics gateway is available in these languages:

- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- Dutch
- English
- French
- German
- Hungarian
- Italian
- Japanese
- Korean
- Polish
- Portuguese (Brazil)
- Portuguese (Portugal)
- Russian
- Spanish (International)

### Supported encryption protocols

The Log Analytics gateway supports only Transport Layer Security (TLS) 1.0, 1.1, and 1.2. It doesn't support Secure Sockets Layer (SSL). To ensure the security of data in transit to Log Analytics, configure the gateway to

use at least TLS 1.2. Older versions of TLS or SSL are vulnerable. Although they currently allow backward compatibility, avoid using them.

For additional information, review [Sending data securely using TLS 1.2](#).

**NOTE**

The gateway is a forwarding proxy that doesn't store any data. Once the agent establishes connection with Azure Monitor, it follows the same encryption flow with or without the gateway. The data is encrypted between the client and the endpoint. Since the gateway is just a tunnel, it doesn't have the ability to inspect what is being sent.

## Supported number of agent connections

The following table shows approximately how many agents can communicate with a gateway server. Support is based on agents that upload about 200 KB of data every 6 seconds. For each agent tested, data volume is about 2.7 GB per day.

GATEWAY	AGENTS SUPPORTED (APPROXIMATE)
CPU: Intel Xeon Processor E5-2660 v3 @ 2.6 GHz 2 Cores Memory: 4 GB Network bandwidth: 1 Gbps	600
CPU: Intel Xeon Processor E5-2660 v3 @ 2.6 GHz 4 Cores Memory: 8 GB Network bandwidth: 1 Gbps	1000

## Download the Log Analytics gateway

Get the latest version of the Log Analytics gateway Setup file from either Microsoft Download Center ([Download Link](#)) or the Azure portal.

To get the Log Analytics gateway from the Azure portal, follow these steps:

1. Browse the list of services, and then select **Log Analytics**.
2. Select a workspace.
3. In your workspace blade, under **General**, select **Quick Start**.
4. Under **Choose a data source to connect to the workspace**, select **Computers**.
5. In the **Direct Agent** blade, select **Download Log Analytics gateway**.

The screenshot shows the 'bandersfree - Quick Start' Log Analytics workspace. On the left, there's a sidebar with 'General' settings like Overview, Saved searches, Log Search, Solutions, Pricing tier, Log Analytics usage, and Properties. The 'Quick Start' button is highlighted with a red box. The main area displays options to 'Choose a data source to connect to the workspace' (Azure virtual machines (VMs), Storage account logs, Computers, System Center Operations Manager) and 'View collected data' (OMS Portal). Below that, there's a 'Learn more' section with 'Help documentation' and 'Give feedback' links.

**Direct Agent**

bandersfree

Download an agent for your operating system, then install and configure it using the keys for your workspace ID.

Windows Computers

[Download Windows Agent \(64 bit\)](#)  
[Download Windows Agent \(32 bit\)](#)

Linux Computers

Agent for Linux  
DOWNLOAD AND ONBOARD AGENT FOR LINUX  
`wget https://raw.githubusercontent.com/`

Workspace ID and Keys

WORKSPACE ID  
`d61b4bcf-0000-0000-0000-000000000000`

PRIMARY KEY  
`SgYGiixRFwT10nHv1Ow5oCSCWm80T5j`

SECONDARY KEY  
`6qra+9tGCKhnhMzL7y+TM99d9ZM6Aa`

OMS Gateway

If you have machines with no internet connectivity to OMS, download the OMS Gateway to act as a proxy. [Learn more](#).  
[Download OMS Gateway](#)

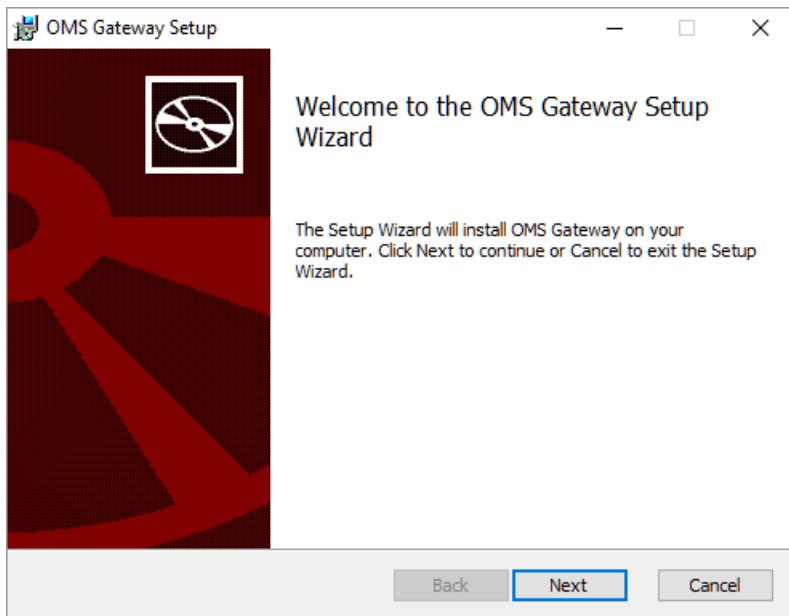

or

1. In your workspace blade, under Settings, select Advanced settings.
2. Go to Connected Sources > Windows Servers and select Download Log Analytics gateway.

## Install Log Analytics gateway using setup wizard

To install a gateway using the setup wizard, follow these steps.

1. From the destination folder, double-click Log Analytics gateway.msi.
2. On the Welcome page, select Next.

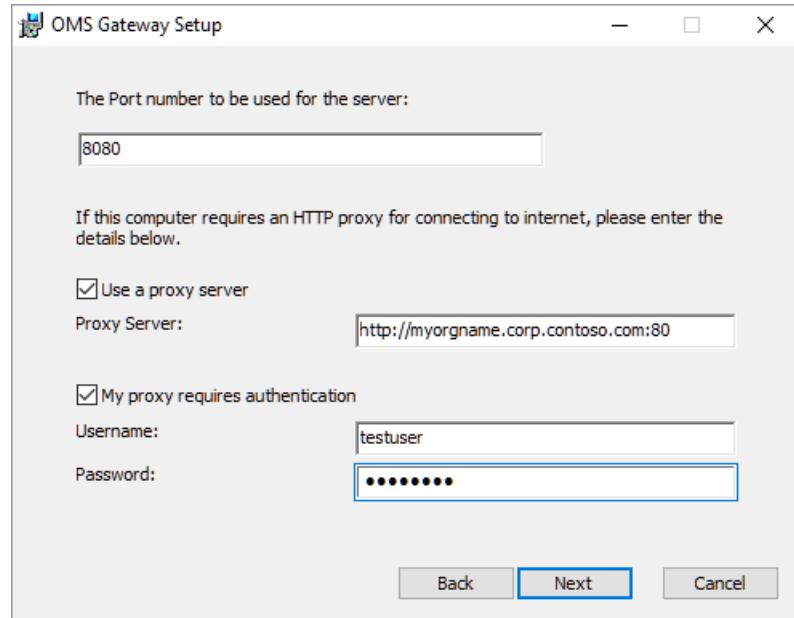

3. On the License Agreement page, select I accept the terms in the License Agreement to agree to the Microsoft Software License Terms, and then select Next.
4. On the Port and proxy address page:
  - a. Enter the TCP port number to be used for the gateway. Setup uses this port number to configure an

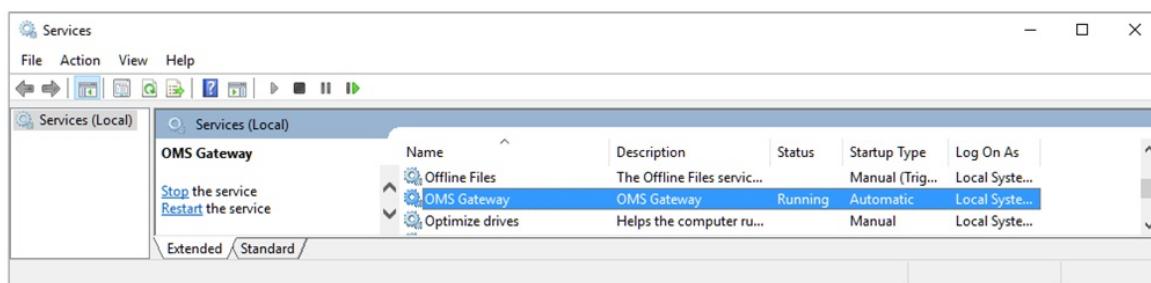

inbound rule on Windows Firewall. The default value is 8080. The valid range of the port number is 1 through 65535. If the input does not fall into this range, an error message appears.

b. If the server where the gateway is installed needs to communicate through a proxy, enter the proxy address where the gateway needs to connect. For example, enter `http://myorgname.corp.contoso.com:80`. If you leave this field blank, the gateway will try to connect to the internet directly. If your proxy server requires authentication, enter a username and password.

c. Select **Next**.

5. If you do not have Microsoft Update enabled, the Microsoft Update page appears, and you can choose to enable it. Make a selection and then select **Next**. Otherwise, continue to the next step.
6. On the **Destination Folder** page, either leave the default folder C:\Program Files\OMS Gateway or enter the location where you want to install the gateway. Then select **Next**.
7. On the **Ready to install** page, select **Install**. If User Account Control requests permission to install, select **Yes**.
8. After Setup finishes, select **Finish**. To verify that the service is running, open the services.msc snap-in and verify that **OMS Gateway** appears in the list of services and that its status is **Running**.

## Install the Log Analytics gateway using the command line

The downloaded file for the gateway is a Windows Installer package that supports silent installation from the command line or other automated method. If you are not familiar with the standard command-line options for Windows Installer, see [Command-line options](#).

The following table highlights the parameters supported by setup.

PARAMETERS	NOTES
PORNUMBER	TCP port number for gateway to listen on
PROXY	IP address of proxy server
INSTALLDIR	Fully qualified path to specify install directory of gateway software files
USERNAME	User ID to authenticate with proxy server
PASSWORD	Password of the user ID to authenticate with proxy
LicenseAccepted	Specify a value of 1 to verify you accept license agreement
HASAUTH	Specify a value of 1 when USERNAME/PASSWORD parameters are specified
HASPROXY	Specify a value of 1 when specifying IP address for PROXY parameter

To silently install the gateway and configure it with a specific proxy address, port number, type the following:

```
Msieexec.exe /I "oms_gateway.msi" /qn PORTNUMBER=8080 PROXY="10.80.2.200" HASPROXY=1 LicenseAccepted=1
```

Using the /qn command-line option hides setup, /qb shows setup during silent install.

If you need to provide credentials to authenticate with the proxy, type the following:

```
Msieexec.exe /I "oms_gateway.msi" /qn PORTNUMBER=8080 PROXY="10.80.2.200" HASPROXY=1 HASAUTH=1 USERNAME="  
<username>" PASSWORD="  
<password>" LicenseAccepted=1
```

After installation, you can confirm the settings are accepted (excluding the username and password) using the following PowerShell cmdlets:

- **Get-OMSGatewayConfig** – Returns the TCP Port the gateway is configured to listen on.
- **Get-OMSGatewayRelayProxy** – Returns the IP address of the proxy server you configured it to communicate with.

## Configure network load balancing

You can configure the gateway for high availability using network load balancing (NLB) using either Microsoft [Network Load Balancing \(NLB\)](#), [Azure Load Balancer](#), or hardware-based load balancers. The load balancer manages traffic by redirecting the requested connections from the Log Analytics agents or Operations Manager management servers across its nodes. If one Gateway server goes down, the traffic gets redirected to other nodes.

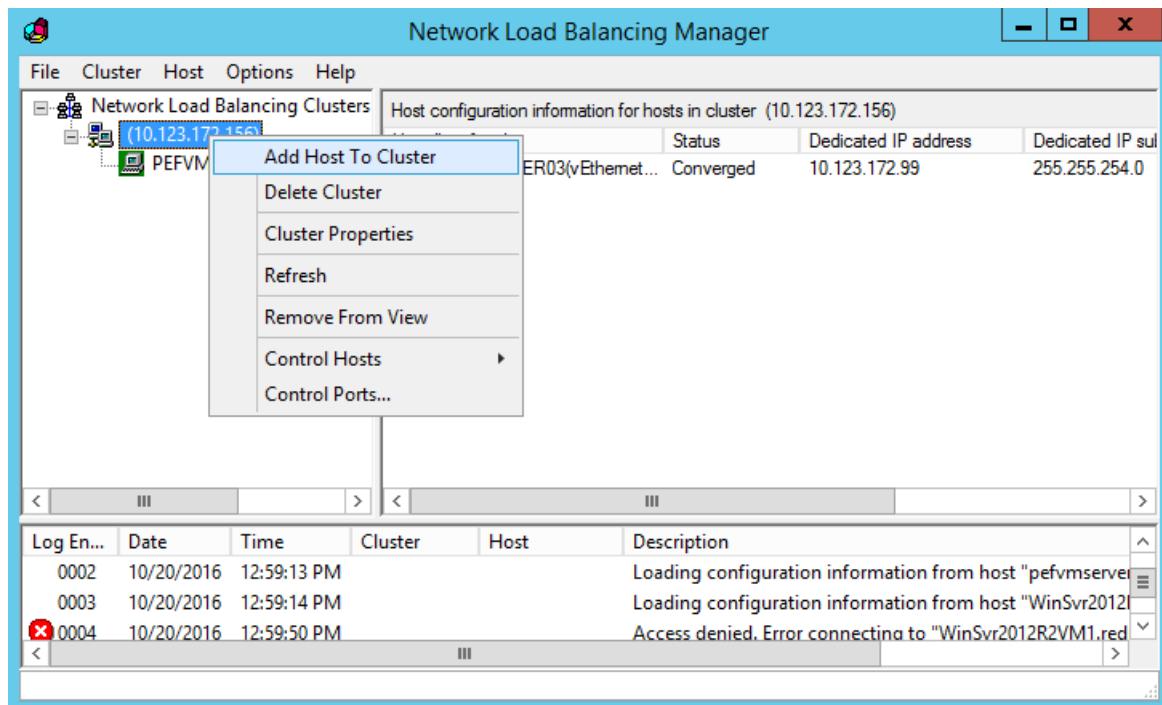

### Microsoft Network Load Balancing

To learn how to design and deploy a Windows Server 2016 network load balancing cluster, see [Network load balancing](#). The following steps describe how to configure a Microsoft network load balancing cluster.

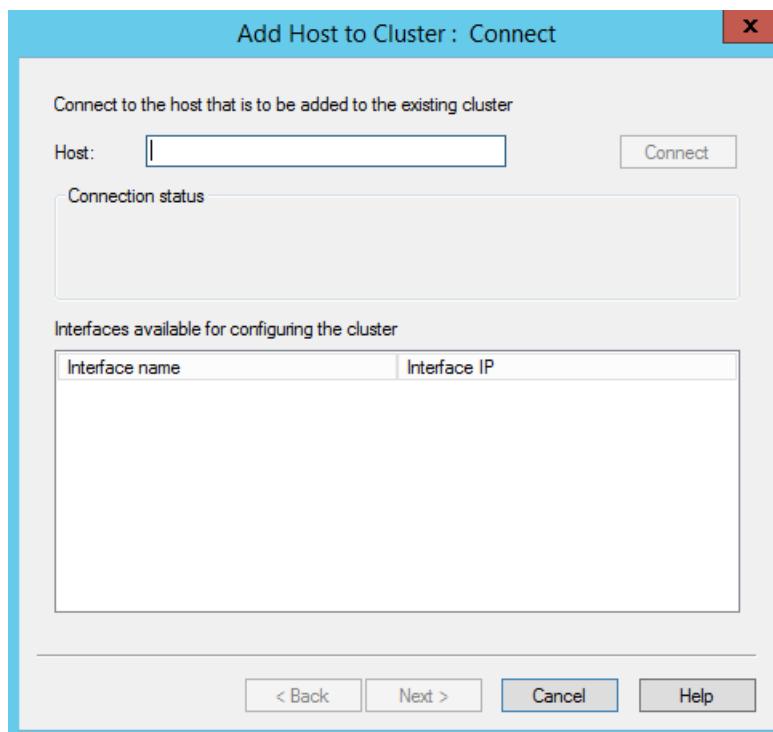

1. Sign onto the Windows server that is a member of the NLB cluster with an administrative account.
2. Open Network Load Balancing Manager in Server Manager, click **Tools**, and then click **Network Load**

## Balancing Manager.

- To connect a Log Analytics gateway server with the Microsoft Monitoring Agent installed, right-click the cluster's IP address, and then click **Add Host to Cluster**.

- Enter the IP address of the gateway server that you want to connect.

## Azure Load Balancer

To learn how to design and deploy an Azure Load Balancer, see [What is Azure Load Balancer?](#). To deploy a basic load balancer, follow the steps outlined in this [quickstart](#) excluding the steps outlined in the section **Create back-end servers**.

#### NOTE

Configuring the Azure Load Balancer using the **Basic SKU**, requires that Azure virtual machines belong to an Availability Set. To learn more about availability sets, see [Manage the availability of Windows virtual machines in Azure](#). To add existing virtual machines to an availability set, refer to [Set Azure Resource Manager VM Availability Set](#).

After the load balancer is created, a backend pool needs to be created, which distributes traffic to one or more gateway servers. Follow the steps described in the quickstart article section [Create resources for the load balancer](#).

#### NOTE

When configuring the health probe it should be configured to use the TCP port of the gateway server. The health probe dynamically adds or removes the gateway servers from the load balancer rotation based on their response to health checks.

## Configure the Azure Monitor agent to communicate using Log Analytics gateway

To configure the Azure Monitor agent (installed on the gateway server) to use the gateway to upload data for Windows or Linux:

1. Follow the instructions to [configure proxy settings on the agent](#) and provide the IP address and port number corresponding to the gateway server. If you have deployed multiple gateway servers behind a load balancer, the agent proxy configuration is the virtual IP address of the load balancer instead.
2. Add the **configuration endpoint URL** to fetch data collection rules to the allow list for the gateway  

```
Add-OMSGatewayAllowedHost -Host global.handler.control.monitor.azure.com
```

```
Add-OMSGatewayAllowedHost -Host <gateway-server-region-name>.handler.control.monitor.azure.com
```

(If using private links on the agent, you must also add the [dce endpoints](#))
3. Add the **data ingestion endpoint URL** to the allow list for the gateway  

```
Add-OMSGatewayAllowedHost -Host <log-analytics-workspace-id>.ods.opinsights.azure.com
```
4. Restart the **OMS Gateway** service to apply the changes  

```
Stop-Service -Name <gateway-name>
```

```
Start-Service -Name <gateway-name>
```

## Configure the Log Analytics agent and Operations Manager management group

In this section, you'll see how to configure directly connected legacy Log Analytics agents, an Operations Manager management group, or Azure Automation Hybrid Runbook Workers with the Log Analytics gateway to communicate with Azure Automation or Log Analytics.

### Configure a standalone Log Analytics agent

When configuring the legacy Log Analytics agent, replace the proxy server value with the IP address of the Log Analytics gateway server and its port number. If you have deployed multiple gateway servers behind a load balancer, the Log Analytics agent proxy configuration is the virtual IP address of the load balancer.

**NOTE**

To install the Log Analytics agent on the gateway and Windows computers that directly connect to Log Analytics, see [Connect Windows computers to the Log Analytics service in Azure](#). To connect Linux computers, see [Connect Linux computers to Azure Monitor](#).

After you install the agent on the gateway server, configure it to report to the workspace or workspace agents that communicate with the gateway. If the Log Analytics Windows agent is not installed on the gateway, event 300 is written to the OMS Gateway event log, indicating that the agent needs to be installed. If the agent is installed but not configured to report to the same workspace as the agents that communicate through it, event 105 is written to the same log, indicating that the agent on the gateway needs to be configured to report to the same workspace as the agents that communicate with the gateway.

After you complete configuration, restart the **OMS Gateway** service to apply the changes. Otherwise, the gateway will reject agents that attempt to communicate with Log Analytics and will report event 105 in the OMS Gateway event log. This will also happen when you add or remove a workspace from the agent configuration on the gateway server.

For information related to the Automation Hybrid Runbook Worker, see [Automate resources in your datacenter or cloud by using Hybrid Runbook Worker](#).

**Configure Operations Manager, where all agents use the same proxy server**

The Operations Manager proxy configuration is automatically applied to all agents that report to Operations Manager, even if the setting is empty.

To use OMS Gateway to support Operations Manager, you must have:

- Microsoft Monitoring Agent (version 8.0.10900.0 or later) installed on the OMS Gateway server and configured with the same Log Analytics workspaces that your management group is configured to report to.
- Internet connectivity. Alternatively, OMS Gateway must be connected to a proxy server that is connected to the internet.

**NOTE**

If you specify no value for the gateway, blank values are pushed to all agents.

If your Operations Manager management group is registering with a Log Analytics workspace for the first time, you won't see the option to specify the proxy configuration for the management group in the Operations console. This option is available only if the management group has been registered with the service.

To configure integration, update the system proxy configuration by using Netsh on the system where you're running the Operations console and on all management servers in the management group. Follow these steps:

1. Open an elevated command prompt:

- a. Select **Start** and enter **cmd**.
- b. Right-click **Command Prompt** and select **Run as administrator**.

2. Enter the following command:

```
netsh winhttp set proxy <proxy>:<port>
```

After completing the integration with Log Analytics, remove the change by running `netsh winhttp reset proxy`. Then, in the Operations console, use the **Configure proxy server** option to specify the Log Analytics gateway server.

1. On the Operations Manager console, under **Operations Management Suite**, select **Connection**, and then select **Configure Proxy Server**.

The screenshot shows the left navigation pane of the Operations Manager console. Under the 'Operations Management Suite' section, the 'Connection' item is highlighted. In the main content area, the title 'Operations Management Suite Overview' is displayed above an 'Introduction' section. Below the introduction, there is a 'Optional Configuration:' section containing a link to 'Configure Proxy Server'. The 'Configure Proxy Server' link is underlined and has a small blue arrow icon to its left.

2. Select **Use a proxy server to access the Operations Management Suite** and then enter the IP address of the Log Analytics gateway server or virtual IP address of the load balancer. Be careful to start with the prefix `http://`.

The screenshot shows the 'Operations Management Suite Settings Wizard: Proxy Server' window. The title bar says 'Wizard' and 'Operations Management Suite Settings Wizard: Proxy Server'. The left sidebar has a 'Proxy Server' tab selected. The main area contains the following text: 'Web Proxy Server: Define how the management server communicates with the service.' Below this is a checkbox labeled 'Use a proxy server to access the Operations Management Suite' which is checked. To its right is a 'Address:' label and a text input field containing 'http://10.123.173.30:8080'. At the bottom of the window are buttons for '< Previous', 'Next >', 'Finish' (which is highlighted in blue), and 'Cancel'.

3. Select **Finish**. Your Operations Manager management group is now configured to communicate through the gateway server to the Log Analytics service.

#### **Configure Operations Manager, where specific agents use a proxy server**

For large or complex environments, you might want only specific servers (or groups) to use the Log Analytics

gateway server. For these servers, you can't update the Operations Manager agent directly because this value is overwritten by the global value for the management group. Instead, override the rule used to push these values.

#### NOTE

Use this configuration technique if you want to allow for multiple Log Analytics gateway servers in your environment. For example, you can require specific Log Analytics gateway servers to be specified on a regional basis.

To configure specific servers or groups to use the Log Analytics gateway server:

1. Open the Operations Manager console and select the **Authoring** workspace.
2. In the Authoring workspace, select **Rules**.
3. On the Operations Manager toolbar, select the **Scope** button. If this button is not available, make sure you have selected an object, not a folder, in the **Monitoring** pane. The **Scope Management Pack Objects** dialog box displays a list of common targeted classes, groups, or objects.
4. In the **Look for** field, enter **Health Service** and select it from the list. Select **OK**.
5. Search for **Advisor Proxy Setting Rule**.
6. On the Operations Manager toolbar, select **Overrides** and then point to **Override the Rule\For a specific object of class: Health Service** and select an object from the list. Or create a custom group that contains the health service object of the servers you want to apply this override to. Then apply the override to your custom group.
7. In the **Override Properties** dialog box, add a check mark in the **Override** column next to the **WebProxyAddress** parameter. In the **Override Value** field, enter the URL of the Log Analytics gateway server. Be careful to start with the prefix `http://`.

#### NOTE

You don't need to enable the rule. It's already managed automatically with an override in the Microsoft System Center Advisor Secure Reference Override management pack that targets the Microsoft System Center Advisor Monitoring Server Group.

8. Select a management pack from the **Select destination management pack** list, or create a new unsealed management pack by selecting **New**.
9. When you finish, select **OK**.

### Configure for Automation Hybrid Runbook Workers

If you have Automation Hybrid Runbook Workers in your environment, follow these steps to configure the gateway to support the workers.

Refer to the [Configure your network](#) section of the Automation documentation to find the URL for each region.

If your computer is registered as a Hybrid Runbook Worker automatically, for example if the Update Management solution is enabled for one or more VMs, follow these steps:

1. Add the Job Runtime Data service URLs to the Allowed Host list on the Log Analytics gateway. For example:  
`Add-OMSGatewayAllowedHost we-jobruntimedata-prod-su1.azure-automation.net`
2. Restart the Log Analytics gateway service by using the following PowerShell cmdlet:  
`Restart-Service OMSGatewayService`

If your computer is joined to Azure Automation by using the Hybrid Runbook Worker registration cmdlet, follow

these steps:

1. Add the agent service registration URL to the Allowed Host list on the Log Analytics gateway. For example:

```
Add-OMSGatewayAllowedHost ncus-agentservice-prod-1.azure-automation.net
```

2. Add the Job Runtime Data service URLs to the Allowed Host list on the Log Analytics gateway. For example:

```
Add-OMSGatewayAllowedHost we-jobruntimedata-prod-su1.azure-automation.net
```

3. Restart the Log Analytics gateway service.

```
Restart-Service OMSGatewayService
```

## Useful PowerShell cmdlets

You can use cmdlets to complete the tasks to update the Log Analytics gateway's configuration settings. Before you use cmdlets, be sure to:

1. Install the Log Analytics gateway (Microsoft Windows Installer).
2. Open a PowerShell console window.
3. Import the module by typing this command:

```
Import-Module OMSGateway
```

4. If no error occurred in the previous step, the module was successfully imported and the cmdlets can be used.

Enter

```
Get-Module OMSGateway
```

5. After you use the cmdlets to make changes, restart the OMS Gateway service.

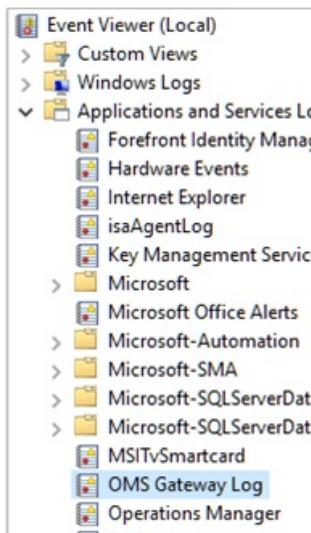

An error in step 3 means that the module wasn't imported. The error might occur when PowerShell can't find the module. You can find the module in the OMS Gateway installation path: *C:\Program Files\Microsoft OMS Gateway\PowerShell\OmsGateway*.

CMDLET	PARAMETERS	DESCRIPTION	EXAMPLE
<code>Get-OMSGatewayConfig</code>	Key	Gets the configuration of the service	<code>Get-OMSGatewayConfig</code>
<code>Set-OMSGatewayConfig</code>	Key (required) Value	Changes the configuration of the service	<code>Set-OMSGatewayConfig -Name ListenPort -Value 8080</code>
<code>Get-OMSGatewayRelayProxy</code>		Gets the address of relay (upstream) proxy	<code>Get-OMSGatewayRelayProxy</code>
<code>Set-OMSGatewayRelayProxy</code>	Address Username Password (secure string)	Sets the address (and credential) of relay (upstream) proxy	<ol style="list-style-type: none"><li>1. Set a relay proxy and credential: <pre>Set-OMSGatewayRelayProxy -Address http://www.myproxy.com:8080 -Username user1 - Password 123</pre></li><li>2. Set a relay proxy that doesn't need authentication: <pre>Set-OMSGatewayRelayProxy -Address http://www.myproxy.com:8080</pre></li><li>3. Clear the relay proxy setting: <pre>Set-OMSGatewayRelayProxy -Address ""</pre></li></ol>

CMDLET	PARAMETERS	DESCRIPTION	EXAMPLE
Get-OMSGatewayAllowedHost		Gets the currently allowed host (only the locally configured allowed host, not automatically downloaded allowed hosts)	Get-OMSGatewayAllowedHost
Add-OMSGatewayAllowedHost	Host (required)	Adds the host to the allowed list	Add-OMSGatewayAllowedHost -Host www.test.com
Remove-OMSGatewayAllowedHost	Host (required)	Removes the host from the allowed list	Remove-OMSGatewayAllowedHost -Host www.test.com
Add-OMSGatewayAllowedClientCertificate	Subject (required)	Adds the client certificate subject to the allowed list	Add-OMSGatewayAllowed ClientCertificate -Subject mycert
Remove-OMSGatewayAllowedClientCertificate	Subject (required)	Removes the client certificate subject from the allowed list	Remove-OMSGatewayAllowed ClientCertificate -Subject mycert
Get-OMSGatewayAllowedClientCertificate		Gets the currently allowed client certificate subjects (only the locally configured allowed subjects, not automatically downloaded allowed subjects)	Get-OMSGatewayAllowed ClientCertificate

## Troubleshooting

To collect events logged by the gateway, you should have the Log Analytics agent installed.

### Log Analytics gateway event IDs and descriptions

The following table shows the event IDs and descriptions for Log Analytics gateway log events.

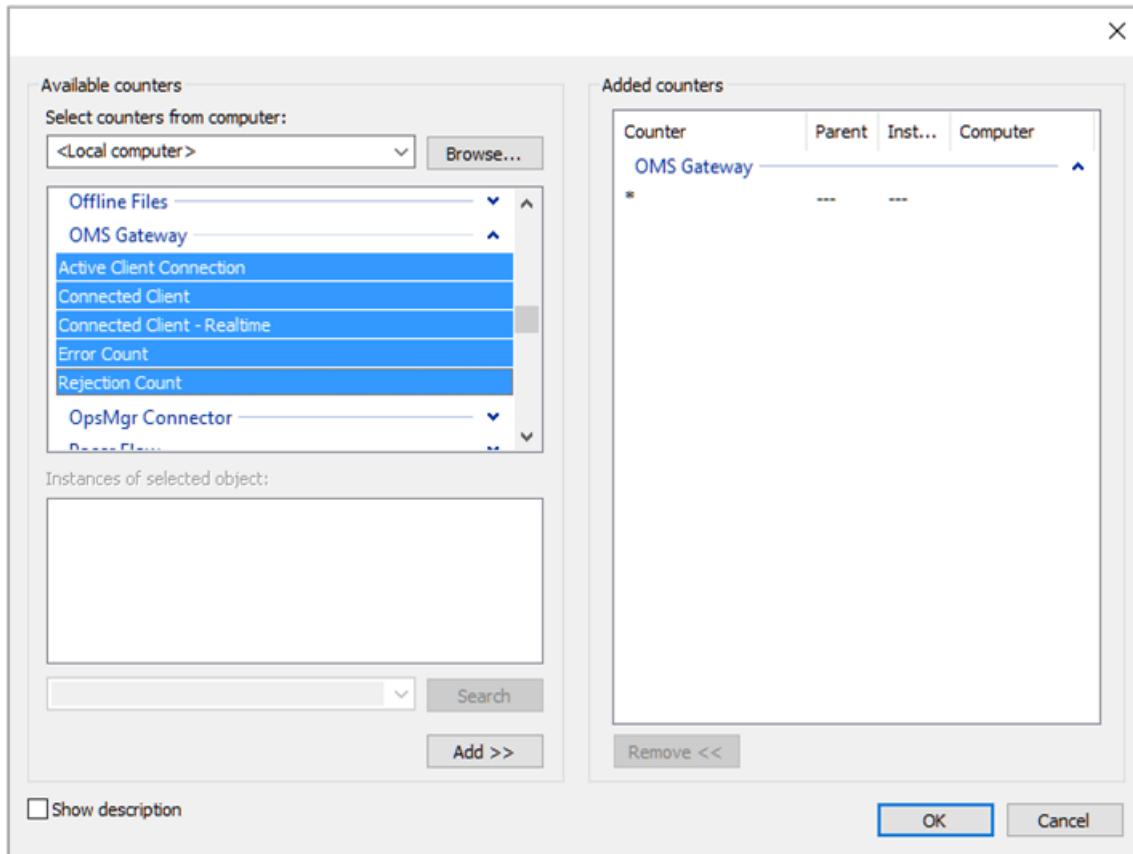

ID	DESCRIPTION
400	Any application error that has no specific ID.
401	Wrong configuration. For example, listenPort = "text" instead of an integer.
402	Exception in parsing TLS handshake messages.
403	Networking error. For example, cannot connect to target server.
100	General information.
101	Service has started.
102	Service has stopped.
103	An HTTP CONNECT command was received from client.
104	Not an HTTP CONNECT command.
105	Destination server is not in allowed list, or destination port is not secure (443).  Ensure that the MMA agent on your OMS Gateway server and the agents that communicate with OMS Gateway are connected to the same Log Analytics workspace.
105	ERROR TcpConnection – Invalid Client certificate: CN=Gateway.  Ensure that you're using OMS Gateway version 1.0.395.0 or greater. Also ensure that the MMA agent on your OMS Gateway server and the agents communicating with OMS Gateway are connected to the same Log Analytics workspace.
106	Unsupported TLS/SSL protocol version.  The Log Analytics gateway supports only TLS 1.0, TLS 1.1, and 1.2. It does not support SSL.
107	The TLS session has been verified.

### Performance counters to collect

The following table shows the performance counters available for the Log Analytics gateway. Use Performance Monitor to add the counters.

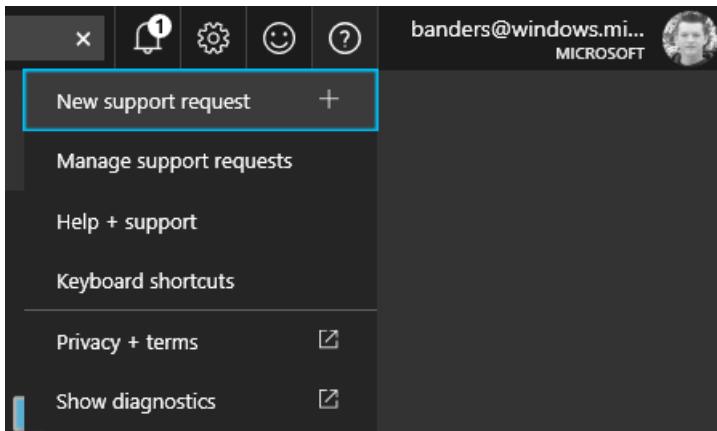

NAME	DESCRIPTION
Log Analytics Gateway/Active Client Connection	Number of active client network (TCP) connections
Log Analytics Gateway/Error Count	Number of errors

NAME	DESCRIPTION
Log Analytics Gateway/Connected Client	Number of connected clients
Log Analytics Gateway/Rejection Count	Number of rejections due to any TLS validation error

## Assistance

When you're signed in to the Azure portal, you can get help with the Log Analytics gateway or any other Azure service or feature. To get help, select the question mark icon in the upper-right corner of the portal and select **New support request**. Then complete the new support request form.

## Next steps

Add [data sources](#) to collect data from connected sources, and store the data in your Log Analytics workspace.

# Manage and maintain the Log Analytics agent for Windows and Linux

9/21/2022 • 11 minutes to read • [Edit Online](#)

After initial deployment of the Log Analytics Windows or Linux agent in Azure Monitor, you may need to reconfigure the agent, upgrade it, or remove it from the computer if it has reached the retirement stage in its lifecycle. You can easily manage these routine maintenance tasks manually or through automation, which reduces both operational error and expenses.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

## Upgrade the agent

Upgrade to the latest release of the Log Analytics agent for Windows and Linux manually or automatically based on your deployment scenario and the environment the VM is running in:

ENVIRONMENT	INSTALLATION METHOD	UPGRADE METHOD
Azure VM	Log Analytics agent VM extension for Windows/Linux	Agent is automatically upgraded <a href="#">after the VM model changes</a> , unless you configured your Azure Resource Manager template to opt out by setting the property <code>autoUpgradeMinorVersion</code> to <code>false</code> . Once deployed, however, the extension will not upgrade minor versions unless redeployed, even with this property set to true. Only Linux agent supports automatic update post deployment with <code>enableAutomaticUpgrade</code> property(See <a href="#">Enable Auto-Update for the Linux Agent</a> ). Major version upgrade is always manual(See <a href="#">VirtualMachineExtensionInner.AutoUpgradeMinorVersion Property</a> ).
Custom Azure VM images	Manual install of Log Analytics agent for Windows/Linux	Updating VMs to the newest version of the agent needs to be performed from the command line running the Windows installer package or Linux self-extracting and installable shell script bundle.
Non-Azure VMs	Manual install of Log Analytics agent for Windows/Linux	Updating VMs to the newest version of the agent needs to be performed from the command line running the Windows installer package or Linux self-extracting and installable shell script bundle.

## Upgrade Windows agent

To update the agent on a Windows VM to the latest version not installed using the Log Analytics VM extension, you either run from the Command Prompt, script or other automation solution, or by using the MMASetup-<platform>.msi Setup Wizard.

You can download the latest version of the Windows agent from your Log Analytics workspace, by performing the following steps.

1. Sign in to the [Azure portal](#).
2. In the Azure portal, click **All services**. In the list of resources, type **Log Analytics**. As you begin typing, the list filters based on your input. Select **Log Analytics workspaces**.
3. In your list of Log Analytics workspaces, select the workspace.
4. In your Log Analytics workspace, select **Agents Management** tile, and then **Windows Servers**.
5. From the **Windows Servers** page, select the appropriate **Download Windows Agent** version to download depending on the processor architecture of the Windows operating system.

### NOTE

During the upgrade of the Log Analytics agent for Windows, it does not support configuring or reconfiguring a workspace to report to. To configure the agent, you need to follow one of the supported methods listed under [Add or remove a workspace](#).

### To upgrade using the Setup Wizard

1. Sign on to the computer with an account that has administrative rights.
2. Execute **MMASetup-<platform>.exe** to start the Setup Wizard.
3. On the first page of the Setup Wizard, click **Next**.
4. In the **Microsoft Monitoring Agent Setup** dialog box, click **I agree** to accept the license agreement.
5. In the **Microsoft Monitoring Agent Setup** dialog box, click **Upgrade**. The status page displays the progress of the upgrade.
6. When the **Microsoft Monitoring Agent configuration completed successfully** page appears, click **Finish**.

### To upgrade from the command line

1. Sign on to the computer with an account that has administrative rights.
2. To extract the agent installation files, from an elevated command prompt run `MMASetup-<platform>.exe /c` and it will prompt you for the path to extract files to. Alternatively, you can specify the path by passing the arguments `MMASetup-<platform>.exe /c /t:<Full Path>`.
3. Run the following command, where D:\ is the location for the upgrade log file.

```
setup.exe /qn /l*v D:\logs\AgentUpgrade.log AcceptEndUserLicenseAgreement=1
```

## Upgrade Linux agent

Upgrade from prior versions (>1.0.0-47) is supported. Performing the installation with the `--upgrade` command will upgrade all components of the agent to the latest version.

Run the following command to upgrade the agent.

```
sudo sh ./omsagent-*.universal.x64.sh --upgrade
```

## Enable Auto-Update for the Linux Agent

We recommend enabling [Automatic Extension Upgrade](#) using these commands to update the agent automatically:

- [Powershell](#)
- [Azure CLI](#)

```
Set-AzVMExtension \
    -ResourceGroupName myResourceGroup \
    -VMName myVM \
    -ExtensionName OmsAgentForLinux \
    -ExtensionType OmsAgentForLinux \
    -Publisher Microsoft.EnterpriseCloud.Monitoring \
    -TypeHandlerVersion latestVersion \
    -ProtectedSettingString '{"workspaceKey":"myWorkspaceKey"}' \
    -SettingString '{"workspaceId":"myWorkspaceId","skipDockerProviderInstall": true}' \
    -EnableAutomaticUpgrade $true
```

## Add or remove a workspace

### Windows agent

The steps in this section are necessary when you want to not only reconfigure the Windows agent to report to a different workspace or to remove a workspace from its configuration, but also when you want to configure the agent to report to more than one workspace (commonly referred to as multi-homing). Configuring the Windows agent to report to multiple workspaces can only be performed after initial setup of the agent and using the methods described below.

#### Update settings from Control Panel

1. Sign on to the computer with an account that has administrative rights.
2. Open **Control Panel**.
3. Select **Microsoft Monitoring Agent** and then click the **Azure Log Analytics** tab.
4. If removing a workspace, select it and then click **Remove**. Repeat this step for any other workspace you want the agent to stop reporting to.
5. If adding a workspace, click **Add** and on the **Add a Log Analytics Workspace** dialog box, paste the Workspace ID and Workspace Key (Primary Key). If the computer should report to a Log Analytics workspace in Azure Government cloud, select Azure US Government from the Azure Cloud drop-down list.
6. Click **OK** to save your changes.

#### Remove a workspace using PowerShell

```
$workspaceId = "<Your workspace Id>"  
$mma = New-Object -ComObject 'AgentConfigManager.MgmtSvcCfg'  
$mma.RemoveCloudWorkspace($workspaceId)  
$mma.ReloadConfiguration()
```

#### Add a workspace in Azure commercial using PowerShell

```
$workspaceId = "<Your workspace Id>"  
$workspaceKey = "<Your workspace Key>"  
$mma = New-Object -ComObject 'AgentConfigManager.MgmtSvcCfg'  
$mma.AddCloudWorkspace($workspaceId, $workspaceKey)  
$mma.ReloadConfiguration()
```

### Add a workspace in Azure for US Government using PowerShell

```
$workspaceId = "<Your workspace Id>"  
$workspaceKey = "<Your workspace Key>"  
$mma = New-Object -ComObject 'AgentConfigManager.MgmtSvcCfg'  
$mma.AddCloudWorkspace($workspaceId, $workspaceKey, 1)  
$mma.ReloadConfiguration()
```

#### NOTE

If you've used the command line or script previously to install or configure the agent, `EnableAzureOperationalInsights` was replaced by `AddCloudWorkspace` and `RemoveCloudWorkspace`.

## Linux agent

The following steps demonstrate how to reconfigure the Linux agent if you decide to register it with a different workspace or to remove a workspace from its configuration.

1. To verify it is registered to a workspace, run the following command:

```
/opt/microsoft/omsagent/bin/omsadmin.sh -l
```

It should return a status similar to the following example:

```
Primary Workspace: <workspaceId> Status: Onboarded(OMSAgent Running)
```

It is important that the status also shows the agent is running, otherwise the following steps to reconfigure the agent will not complete successfully.

2. If it is already registered with a workspace, remove the registered workspace by running the following command. Otherwise if it is not registered, proceed to the next step.

```
/opt/microsoft/omsagent/bin/omsadmin.sh -X
```

3. To register with a different workspace, run the following command:

```
/opt/microsoft/omsagent/bin/omsadmin.sh -w <workspace id> -s <shared key> [-d <top level domain>]
```

4. To verify your changes took effect, run the following command:

```
/opt/microsoft/omsagent/bin/omsadmin.sh -l
```

It should return a status similar to the following example:

```
Primary Workspace: <workspaceId> Status: Onboarded(OMSAgent Running)
```

The agent service does not need to be restarted in order for the changes to take effect.

## Update proxy settings

Log Analytics Agent (MMA) does not use the system proxy settings. Hence, user has to pass proxy setting while installing MMA and these settings will be stored under MMA configuration(registry) on VM. To configure the agent to communicate to the service through a proxy server or [Log Analytics gateway](#) after deployment, use

one of the following methods to complete this task.

## Windows agent

### Update settings using Control Panel

1. Sign on to the computer with an account that has administrative rights.
2. Open **Control Panel**.
3. Select **Microsoft Monitoring Agent** and then click the **Proxy Settings** tab.
4. Click **Use a proxy server** and provide the URL and port number of the proxy server or gateway. If your proxy server or Log Analytics gateway requires authentication, type the username and password to authenticate and then click **OK**.

### Update settings using PowerShell

Copy the following sample PowerShell code, update it with information specific to your environment, and save it with a PS1 file name extension. Run the script on each computer that connects directly to the Log Analytics workspace in Azure Monitor.

```
param($ProxyDomainName="https://proxy.contoso.com:30443", $cred=(Get-Credential))

# First we get the Health Service configuration object. We need to determine if we
# have the right update rollup with the API we need. If not, no need to run the rest of the script.
$healthServiceSettings = New-Object -ComObject 'AgentConfigManager.MgmtSvcCfg'

$proxyMethod = $healthServiceSettings | Get-Member -Name 'SetProxyInfo'

if (!$proxyMethod)
{
    Write-Output 'Health Service proxy API not present, will not update settings.'
    return
}

Write-Output "Clearing proxy settings."
$healthServiceSettings.SetProxyInfo('', '', '')

$ProxyUserName = $cred.username

Write-Output "Setting proxy to $ProxyDomainName with proxy username $ProxyUserName."
$healthServiceSettings.SetProxyInfo($ProxyDomainName, $ProxyUserName, $cred.GetNetworkCredential().password)
```

## Linux agent

Perform the following steps if your Linux computers need to communicate through a proxy server or Log Analytics gateway. The proxy configuration value has the following syntax

[protocol://][user:password@]proxyhost[:port]. The *proxyhost* property accepts a fully qualified domain name or IP address of the proxy server.

1. Edit the file `/etc/opt/microsoft/omsagent/proxy.conf` by running the following commands and change the values to your specific settings.

```
proxyconf="https://proxyuser:proxypassword@proxyserver01:30443"
sudo echo $proxyconf >/etc/opt/microsoft/omsagent/proxy.conf
sudo chown omsagent:omiusers /etc/opt/microsoft/omsagent/proxy.conf
```

2. Restart the agent by running the following command:

```
sudo /opt/microsoft/omsagent/bin/service_control restart [<workspace id>]
```

If you see "cURL failed to perform on this base url" in the log, you can try removing '\n' in proxy.conf EOF to resolve the failure:

```
od -c /etc/opt/microsoft/omsagent/proxy.conf
cat /etc/opt/microsoft/omsagent/proxy.conf | tr -d '\n' > /etc/opt/microsoft/omsagent/proxy2.conf
rm /etc/opt/microsoft/omsagent/proxy.conf
mv /etc/opt/microsoft/omsagent/proxy2.conf /etc/opt/microsoft/omsagent/proxy.conf
sudo chown omsagent:omiusers /etc/opt/microsoft/omsagent/proxy.conf
sudo /opt/microsoft/omsagent/bin/service_control restart [<workspace id>]
```

## Uninstall agent

Use one of the following procedures to uninstall the Windows or Linux agent using the command line or setup wizard.

### Windows agent

#### Uninstall from Control Panel

1. Sign on to the computer with an account that has administrative rights.
2. In Control Panel, click **Programs and Features**.
3. In **Programs and Features**, click **Microsoft Monitoring Agent**, click **Uninstall**, and then click **Yes**.

#### NOTE

The Agent Setup Wizard can also be run by double-clicking **MMASetup-<platform>.exe**, which is available for download from a workspace in the Azure portal.

#### Uninstall from the command line

The downloaded file for the agent is a self-contained installation package created with IExpress. The setup program for the agent and supporting files are contained in the package and need to be extracted in order to properly uninstall using the command line shown in the following example.

1. Sign on to the computer with an account that has administrative rights.
2. To extract the agent installation files, from an elevated command prompt run `extract MMASetup-<platform>.exe` and it will prompt you for the path to extract files to. Alternatively, you can specify the path by passing the arguments `extract MMASetup-<platform>.exe /c:<Path> /t:<Path>`. For more information on the command-line switches supported by IExpress, see [Command-line switches for IExpress](#) and then update the example to suit your needs.
3. At the prompt, type `%WinDir%\System32\msiexec.exe /x <Path>:\MOMAgent.msi /qb`.

### Linux agent

To remove the agent, run the following command on the Linux computer. The `--purge` argument completely removes the agent and its configuration.

```
wget https://raw.githubusercontent.com/Microsoft/OMS-Agent-for-Linux/master/installer/scripts/onboard_agent.sh && sh onboard_agent.sh --purge
```

## Configure agent to report to an Operations Manager management group

### Windows agent

Perform the following steps to configure the Log Analytics agent for Windows to report to a System Center Operations Manager management group.

#### **NOTE**

As part of the ongoing transition from Microsoft Operations Management Suite to Azure Monitor, the Operations Management Suite Agent for Windows or Linux will be referred to as the Log Analytics agent for Windows and Log Analytics agent for Linux.

1. Sign on to the computer with an account that has administrative rights.
2. Open **Control Panel**.
3. Click **Microsoft Monitoring Agent** and then click the **Operations Manager** tab.
4. If your Operations Manager servers have integration with Active Directory, click **Automatically update management group assignments from AD DS**.
5. Click **Add** to open the **Add a Management Group** dialog box.
6. In **Management group name** field, type the name of your management group.
7. In the **Primary management server** field, type the computer name of the primary management server.
8. In the **Management server port** field, type the TCP port number.
9. Under **Agent Action Account**, choose either the Local System account or a local domain account.
10. Click **OK** to close the **Add a Management Group** dialog box and then click **OK** to close the **Microsoft Monitoring Agent Properties** dialog box.

#### **Linux agent**

Perform the following steps to configure the Log Analytics agent for Linux to report to a System Center Operations Manager management group.

#### **NOTE**

As part of the ongoing transition from Microsoft Operations Management Suite to Azure Monitor, the Operations Management Suite Agent for Windows or Linux will be referred to as the Log Analytics agent for Windows and Log Analytics agent for Linux.

1. Edit the file `/etc/opt/omi/conf/omiserver.conf`
2. Ensure that the line beginning with `httpsport=` defines the port 1270. Such as: `httpsport=1270`
3. Restart the OMI server: `sudo /opt/omi/bin/service_control restart`

## Next steps

- Review [Troubleshooting the Linux agent](#) if you encounter issues while installing or managing the Linux agent.
- Review [Troubleshooting the Windows agent](#) if you encounter issues while installing or managing the Windows agent.

# Agent Health solution in Azure Monitor

9/21/2022 • 5 minutes to read • [Edit Online](#)

The Agent Health solution in Azure helps you understand which monitoring agents are unresponsive and submitting operational data. That includes all the agents that report directly to the Log Analytics workspace in Azure Monitor or to a System Center Operations Manager management group connected to Azure Monitor.

You can also use the Agent Health solution to:

- Keep track of how many agents are deployed and where they're distributed geographically.
- Perform other queries to maintain awareness of the distribution of agents deployed in Azure, in other cloud environments, or on-premises.

## Prerequisites

Before you deploy this solution, confirm that you have supported [Windows agents](#) reporting to the Log Analytics workspace or reporting to an [Operations Manager management group](#) integrated with your workspace.

## Management packs

If your Operations Manager management group is connected to a Log Analytics workspace, the following management packs are installed in Operations Manager. These management packs are also installed on directly connected Windows computers after you add this solution.

- Microsoft System Center Advisor HealthAssessment Direct Channel Intelligence Pack  
(Microsoft.IntelligencePacks.HealthAssessmentDirect)
- Microsoft System Center Advisor HealthAssessment Server Channel Intelligence Pack  
(Microsoft.IntelligencePacks.HealthAssessmentViaServer).

There's nothing to configure or manage with these management packs. For more information on how solution management packs are updated, see [Connect Operations Manager to Log Analytics](#).

## Configuration

Add the Agent Health solution to your Log Analytics workspace by using the process described in [Add solutions](#). No further configuration is required.

## Supported agents

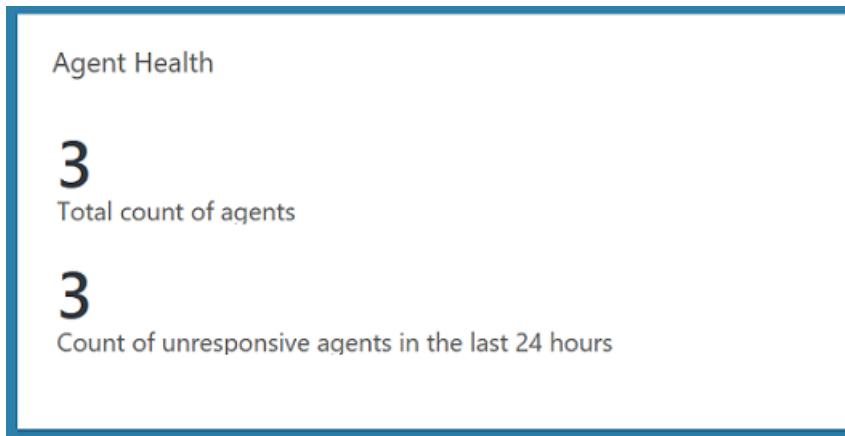

The following table describes the connected sources that this solution supports.

CONNECTED SOURCE	SUPPORTED	DESCRIPTION
Windows agents	Yes	Heartbeat events are collected from direct Windows agents.

CONNECTED SOURCE	SUPPORTED	DESCRIPTION
System Center Operations Manager management group	Yes	Heartbeat events are collected from agents that report to the management group every 60 seconds and then forwarded to Azure Monitor. A direct connection from Operations Manager agents to Azure Monitor is not required. Heartbeat event data is forwarded from the management group to the Log Analytics workspace.

## Using the solution

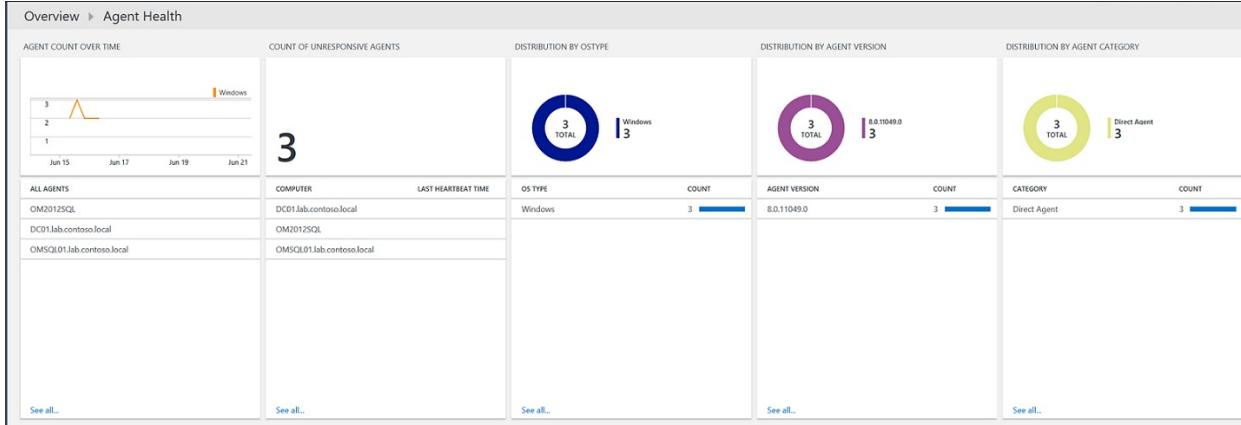

When you add the solution to your Log Analytics workspace, the **Agent Health** tile is added to your dashboard. This tile shows the total number of agents and the number of unresponsive agents in the last 24 hours.

Select the **Agent Health** tile to open the **Agent Health** dashboard. The dashboard includes the columns in the following table. Each column lists the top 10 events by count that match that column's criteria for the specified time range. You can run a log search that provides the entire list by selecting **See all** beneath each column, or by selecting the column heading.

COLUMN	DESCRIPTION
Agent count over time	A trend of your agent count over a period of seven days for both Linux and Windows agents
Count of unresponsive agents	A list of agents that haven't sent a heartbeat in the past 24 hours
Distribution by OS type	A partition of how many Windows and Linux agents you have in your environment
Distribution by agent version	A partition of the agent versions installed in your environment and a count of each one
Distribution by agent category	A partition of the categories of agents that are sending up heartbeat events: direct agents, Operations Manager agents, or the Operations Manager management server
Distribution by management group	A partition of the Operations Manager management groups in your environment

COLUMN	DESCRIPTION
Geo-location of agents	A partition of the countries/regions where you have agents, and a total count of the number of agents that have been installed in each country/region
Count of gateways installed	The number of servers that have the Log Analytics gateway installed, and a list of these servers

## Azure Monitor log records

The solution creates one type of record in the Log Analytics workspace: heartbeat. Heartbeat records have the properties in the following table.

PROPERTY	DESCRIPTION
Type	Heartbeat
Category	Direct Agent, SCOM Agent, or SCOM Management Server
Computer	Computer name
OSType	Windows or Linux operating system
OSMajorVersion	Operating system major version
OSMinorVersion	Operating system minor version
Version	Log Analytics agent or Operations Manager agent version
SCAgentChannel1	Direct and/or SCManagementServer
IsGatewayInstalled	true if the Log Analytics gateway is installed; otherwise false
ComputerIP	Public IP address for an Azure virtual machine, if one is available; Azure SNAT address (not the private IP address) for a virtual machine that uses a private IP

PROPERTY	DESCRIPTION
ComputerPrivateIPs	List of private IPs of the computer
RemoteIPCountry	Geographic location where the computer is deployed
ManagementGroupName	Name of the Operations Manager management group
SourceComputerId	Unique ID of the computer
RemoteIPLongitude	Longitude of the computer's geographic location
RemoteIPLatitude	Latitude of the computer's geographic location

Each agent that reports to an Operations Manager management server will send two heartbeats. The `SCAgentChannel1` property's value will include both `Direct` and `SCManagementServer`, depending on what data sources and monitoring solutions you've enabled in your subscription.

If you recall, data from solutions is sent either:

- Directly from an Operations Manager management server to Azure Monitor
- Directly from the agent to Azure Monitor, because of the volume of data collected on the agent

For heartbeat events that have the value `SCManagementServer`, the `ComputerIP` value is the IP address of the management server because it actually uploads the data. For heartbeats where `SCAgentChannel1` is set to `Direct`, it's the public IP address of the agent.

## Sample log searches

The following table provides sample log searches for records that the solution collects.

QUERY	DESCRIPTION
Heartbeat   distinct Computer	Total number of agents
Heartbeat   summarize LastCall = max(TimeGenerated) by Computer   where LastCall < ago(24h)	Count of unresponsive agents in the last 24 hours
Heartbeat   summarize LastCall = max(TimeGenerated) by Computer   where LastCall < ago(15m)	Count of unresponsive agents in the last 15 minutes
Heartbeat   where TimeGenerated > ago(24h) and Computer in ((Heartbeat   where TimeGenerated > ago(24h)   distinct Computer))   summarize LastCall = max(TimeGenerated) by Computer	Computers online in the last 24 hours
Heartbeat   where TimeGenerated > ago(24h) and Computer !in ((Heartbeat   where TimeGenerated > ago(30m)   distinct Computer))   summarize LastCall = max(TimeGenerated) by Computer	Total agents offline in the last 30 minutes (for the last 24 hours)
Heartbeat   summarize AggregatedValue = dcoun(Computer) by OSType	Trend of the number of agents over time by OS type

QUERY	DESCRIPTION
Heartbeat   summarize AggregatedValue = dcount(Computer) by OSType	Distribution by OS type
Heartbeat   summarize AggregatedValue = dcount(Computer) by Version	Distribution by agent version
Heartbeat   summarize AggregatedValue = count() by Category	Distribution by agent category
Heartbeat   summarize AggregatedValue = dcount(Computer) by ManagementGroupName	Distribution by management group
Heartbeat   summarize AggregatedValue = dcount(Computer) by RemoteIPCountry	Geo-location of agents
Heartbeat   where iff(isnotnull(toint(IsGatewayInstalled)), IsGatewayInstalled == true, IsGatewayInstalled == "true") == true   distinct Computer	Number of Log Analytics gateways installed

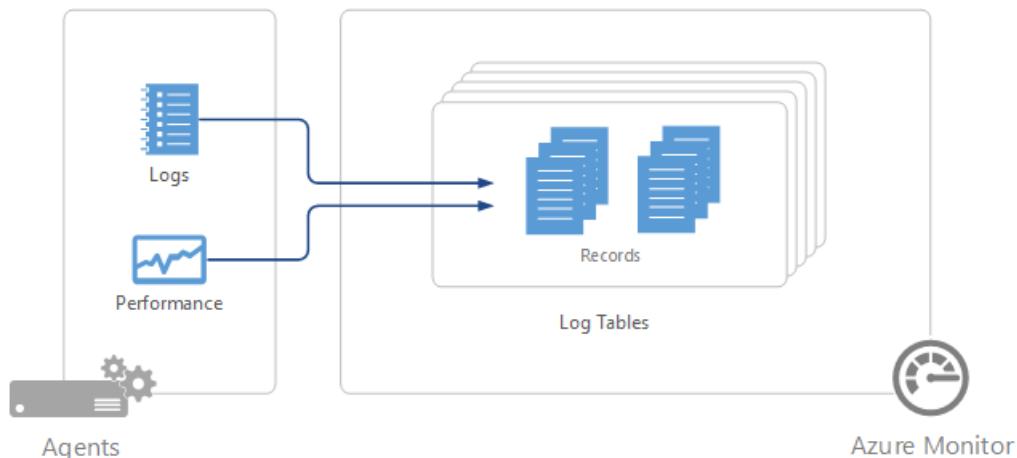

## Next steps

# Log Analytics agent data sources in Azure Monitor

9/21/2022 • 3 minutes to read • [Edit Online](#)

The data that Azure Monitor collects from virtual machines with the legacy [Log Analytics](#) agent is defined by the data sources that you configure on the [Log Analytics workspace](#). Each data source creates records of a particular type with each type having its own set of properties.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

## IMPORTANT

The data sources described in this article apply only to virtual machines running the Log Analytics agent.

## Summary of data sources

The following table lists the agent data sources that are currently available with the Log Analytics agent. Each has a link to a separate article providing detail for that data source. It also provides information on their method and frequency of collection.

DATA SOURCE	PLATFORM	LOG ANALYTICS AGENT	OPERATIONS MANAGER AGENT	AZURE STORAGE	OPERATIONS MANAGER REQUIRED?	OPERATIONS MANAGER AGENT DATA SENT VIA MANAGEMENT GROUP	COLLECTION FREQUENCY
Custom logs	Windows	•					on arrival
Custom logs	Linux	•					on arrival

DATA SOURCE	PLATFORM	LOG ANALYTICS AGENT	OPERATIONS MANAGER AGENT	AZURE STORAGE	OPERATIONS MANAGER REQUIRED?	OPERATIONS MANAGER DATA SENT VIA MANAGEMENT GROUP	COLLECTION FREQUENCY
IIS logs	Windows	•	•	•			depends on Log File Rollover setting
Performance counters	Windows	•	•				as scheduled, minimum of 10 seconds
Performance counters	Linux	•					as scheduled, minimum of 10 seconds
Syslog	Linux	•					from Azure storage: 10 minutes; from agent: on arrival
Windows Event logs	Windows	•	•	•		•	on arrival

## Configuring data sources

To configure data sources for Log Analytics agents, go to the **Log Analytics workspaces** menu in the Azure portal and select a workspace. Click on **Agents configuration**. Select the tab for the data source you want to configure. You can follow the links in the table above to documentation for each data source and details on their configuration.

Any configuration is delivered to all agents connected to that workspace. You cannot exclude any connected agents from this configuration.

## Data collection

Data source configurations are delivered to agents that are directly connected to Azure Monitor within a few minutes. The specified data is collected from the agent and delivered directly to Azure Monitor at intervals specific to each data source. See the documentation for each data source for these specifics.

For System Center Operations Manager agents in a connected management group, data source configurations are translated into management packs and delivered to the management group every 5 minutes by default. The agent downloads the management pack like any other and collects the specified data. Depending on the data source, the data will be either sent to a management server which forwards the data to the Azure Monitor, or the agent will send the data to Azure Monitor without going through the management server. See [Data collection details for monitoring solutions in Azure](#) for details. You can read about details of connecting Operations Manager and Azure Monitor and modifying the frequency that configuration is delivered at [Configure Integration with System Center Operations Manager](#).

If the agent is unable to connect to Azure Monitor or Operations Manager, it will continue to collect data that it will deliver when it establishes a connection. Data can be lost if the amount of data reaches the maximum cache size for the client, or if the agent is not able to establish a connection within 24 hours.

## Log records

All log data collected by Azure Monitor is stored in the workspace as records. Records collected by different data sources will have their own set of properties and be identified by their **Type** property. See the documentation for each data source and solution for details on each record type.

## Next steps

- Learn about [monitoring solutions](#) that add functionality to Azure Monitor and also collect data into the workspace.
- Learn about [log queries](#) to analyze the data collected from data sources and monitoring solutions.
- Configure [alerts](#) to proactively notify you of critical data collected from data sources and monitoring solutions.

# Collecting custom JSON data sources with the Log Analytics agent for Linux in Azure Monitor

9/21/2022 • 2 minutes to read • [Edit Online](#)

## NOTE

As part of the ongoing transition from Microsoft Operations Management Suite to Azure Monitor, the Operations Management Suite Agent for Windows or Linux will be referred to as the Log Analytics agent for Windows and Log Analytics agent for Linux.

Custom JSON data sources can be collected into [Azure Monitor](#) using the Log Analytics agent for Linux. These custom data sources can be simple scripts returning JSON such as `curl` or one of [FluentD's 300+ plugins](#). This article describes the configuration required for this data collection.

## NOTE

Log Analytics agent for Linux v1.1.0-217+ is required for Custom JSON Data.

## Configuration

### Configure input plugin

To collect JSON data in Azure Monitor, add `oms.api.` to the start of a FluentD tag in an input plugin.

For example, following is a separate configuration file `exec-json.conf` in `/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/`. This uses the FluentD plugin `exec` to run a `curl` command every 30 seconds. The output from this command is collected by the JSON output plugin.

```
<source>
  type exec
  command 'curl localhost/json.output'
  format json
  tag oms.api.httpresponse
  run_interval 30s
</source>

<match oms.api.httpresponse>
  type out_oms_api
  log_level info

  buffer_chunk_limit 5m
  buffer_type file
  buffer_path /var/opt/microsoft/omsagent/<workspace id>/state/out_oms_api_httpresponse*.buffer
  buffer_queue_limit 10
  flush_interval 20s
  retry_limit 10
  retry_wait 30s
</match>
```

The configuration file added under `/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/` will require to have its ownership changed with the following command.

```
sudo chown omsagent:omiusers /etc/opt/microsoft/omsagent/conf/omsagent.d/exec-json.conf
```

## Configure output plugin

Add the following output plugin configuration to the main configuration in

```
/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf or as a separate configuration file placed in  
/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/
```

```
<match oms.api.**>  
  type out_oms_api  
  log_level info  
  
  buffer_chunk_limit 5m  
  buffer_type file  
  buffer_path /var/opt/microsoft/omsagent/<workspace id>/state/out_oms_api*.buffer  
  buffer_queue_limit 10  
  flush_interval 20s  
  retry_limit 10  
  retry_wait 30s  
</match>
```

## Restart Log Analytics agent for Linux

Restart the Log Analytics agent for Linux service with the following command.

```
sudo /opt/microsoft/omsagent/bin/service_control restart
```

## Output

The data will be collected in Azure Monitor with a record type of `<FLUENTD_TAG>_CL`.

For example, the custom tag `tag oms.api.tomcat` in Azure Monitor with a record type of `tomcat_CL`. You could retrieve all records of this type with the following log query.

```
Type=tomcat_CL
```

Nested JSON data sources are supported, but are indexed based off of parent field. For example, the following JSON data is returned from a log query as `tag_s : "[{ "a":"1", "b":"2" }]`.

```
{  
  "tag": [{  
    "a":"1",  
    "b":"2"  
  }]  
}
```

## Next steps

- Learn about [log queries](#) to analyze the data collected from data sources and solutions.

# Collect data from CollectD on Linux agents in Azure Monitor

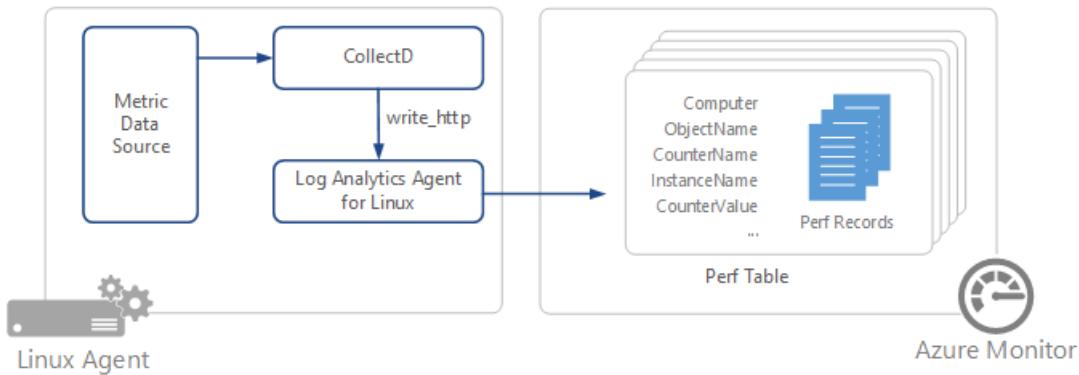

9/21/2022 • 3 minutes to read • [Edit Online](#)

CollectD is an open source Linux daemon that periodically collects performance metrics from applications and system level information. Example applications include the Java Virtual Machine (JVM), MySQL Server, and Nginx. This article provides information on collecting performance data from CollectD in Azure Monitor using the Log Analytics agent.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

A full list of available plugins can be found at [Table of Plugins](#).

The following CollectD configuration is included in the Log Analytics agent for Linux to route CollectD data to the Log Analytics agent for Linux.

## NOTE

As part of the ongoing transition from Microsoft Operations Management Suite to Azure Monitor, the Operations Management Suite Agent for Windows or Linux will be referred to as the Log Analytics agent for Windows and Log Analytics agent for Linux.

```
LoadPlugin write_http

<Plugin write_http>
  <Node "oms">
    URL "127.0.0.1:26000/oms.collectd"
    Format "JSON"
    StoreRates true
  </Node>
</Plugin>
```

Additionally, if using an versions of collectD before 5.5 use the following configuration instead.

```
LoadPlugin write_http

<Plugin write_http>
  <URL "127.0.0.1:26000/oms.collectd">
    Format "JSON"
    StoreRates true
  </URL>
</Plugin>
```

The CollectD configuration uses the default `write_http` plugin to send performance metric data over port 26000 to Log Analytics agent for Linux.

**NOTE**

This port can be configured to a custom-defined port if needed.

The Log Analytics agent for Linux also listens on port 26000 for CollectD metrics and then converts them to Azure Monitor schema metrics. The following is the Log Analytics agent for Linux configuration `collectd.conf`.

```
<source>
  type http
  port 26000
  bind 127.0.0.1
</source>

<filter oms.collectd>
  type filter_collectd
</filter>
```

**NOTE**

CollectD by default is set to read values at a 10-second `interval`. As this directly affects the volume of data sent to Azure Monitor Logs, you might need to tune this interval within the CollectD configuration to strike a good balance between the monitoring requirements and associated costs and usage for Azure Monitor Logs.

## Versions supported

- Azure Monitor currently supports CollectD version 4.8 and above.
- Log Analytics agent for Linux v1.1.0-217 or above is required for CollectD metric collection.

## Configuration

The following are basic steps to configure collection of CollectD data in Azure Monitor.

1. Configure CollectD to send data to the Log Analytics agent for Linux using the `write_http` plugin.
2. Configure the Log Analytics agent for Linux to listen for the CollectD data on the appropriate port.
3. Restart CollectD and Log Analytics agent for Linux.

### Configure CollectD to forward data

1. To route CollectD data to the Log Analytics agent for Linux, `oms.conf` needs to be added to CollectD's configuration directory. The destination of this file depends on the Linux distro of your machine.

If your CollectD config directory is located in /etc/collectd.d/:

```
sudo cp /etc/opt/microsoft/omsagent/sysconf/omsagent.d/oms.conf /etc/collectd.d/oms.conf
```

If your CollectD config directory is located in /etc/collectd/collectd.conf.d/:

```
sudo cp /etc/opt/microsoft/omsagent/sysconf/omsagent.d/oms.conf  
/etc/collectd/collectd.conf.d/oms.conf
```

**NOTE**

For CollectD versions before 5.5 you will have to modify the tags in `oms.conf` as shown above.

2. Copy collectd.conf to the desired workspace's omsagent configuration directory.

```
sudo cp /etc/opt/microsoft/omsagent/sysconf/omsagent.d/collectd.conf  
/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/  
sudo chown omsagent:omiusers /etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/collectd.conf
```

3. Restart CollectD and Log Analytics agent for Linux with the following commands.

```
sudo service collectd restart  
sudo /opt/microsoft/omsagent/bin/service_control restart
```

## CollectD metrics to Azure Monitor schema conversion

To maintain a familiar model between infrastructure metrics already collected by Log Analytics agent for Linux and the new metrics collected by CollectD the following schema mapping is used:

COLLECTD METRIC FIELD	AZURE MONITOR FIELD
<code>host</code>	Computer
<code>plugin</code>	None
<code>plugin_instance</code>	Instance Name If <code>plugin_instance</code> is <code>null</code> then <code>InstanceName=_Total</code>
<code>type</code>	ObjectName
<code>type_instance</code>	CounterName If <code>type_instance</code> is <code>null</code> then <code>CounterName=blank</code>
<code>dsnames[]</code>	CounterName
<code>dstypes</code>	None
<code>values[]</code>	CounterValue

## Next steps

- Learn about [log queries](#) to analyze the data collected from data sources and solutions.

- Use [Custom Fields](#) to parse data from syslog records into individual fields.

# Collect Syslog data sources with Log Analytics agent

9/21/2022 • 6 minutes to read • [Edit Online](#)

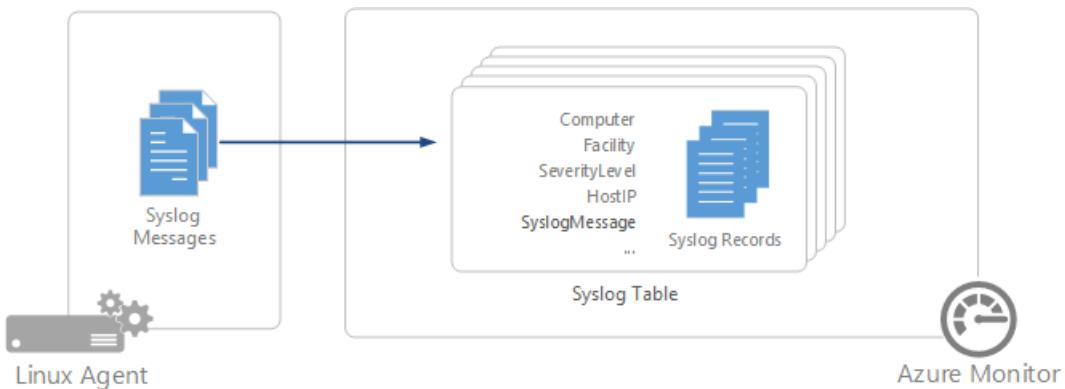

Syslog is an event logging protocol that is common to Linux. Applications will send messages that may be stored on the local machine or delivered to a Syslog collector. When the Log Analytics agent for Linux is installed, it configures the local Syslog daemon to forward messages to the agent. The agent then sends the message to Azure Monitor where a corresponding record is created.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

## NOTE

Azure Monitor supports collection of messages sent by rsyslog or syslog-ng, where rsyslog is the default daemon. The default syslog daemon on version 5 of Red Hat Enterprise Linux, CentOS, and Oracle Linux version (sysklog) is not supported for syslog event collection. To collect syslog data from this version of these distributions, the [rsyslog daemon](#) should be installed and configured to replace sysklog.

The following facilities are supported with the Syslog collector:

- kern
- user
- mail
- daemon
- auth
- syslog
- lpr
- news
- uucp
- cron
- authpriv
- ftp

- local0-local7

For any other facility, [configure a Custom Logs data source](#) in Azure Monitor.

## Configuring Syslog

The Log Analytics agent for Linux will only collect events with the facilities and severities that are specified in its configuration. You can configure Syslog through the Azure portal or by managing configuration files on your Linux agents.

### Configure Syslog in the Azure portal

Configure Syslog from the [Agent configuration menu](#) for the Log Analytics workspace. This configuration is delivered to the configuration file on each Linux agent.

You can add a new facility by clicking **Add facility**. For each facility, only messages with the selected severities will be collected. Check the severities for the particular facility that you want to collect. You cannot provide any additional criteria to filter messages.

Facility name	Emergency	Alert	Critical	Error	Warning	Notice	Info
cron	<input checked="" type="checkbox"/>						
syslog	<input checked="" type="checkbox"/>						
user	<input checked="" type="checkbox"/>						

By default, all configuration changes are automatically pushed to all agents. If you want to configure Syslog manually on each Linux agent, then uncheck the box *Apply below configuration to my machines*.

### Configure Syslog on Linux agent

When the [Log Analytics agent is installed on a Linux client](#), it installs a default syslog configuration file that defines the facility and severity of the messages that are collected. You can modify this file to change the configuration. The configuration file is different depending on the Syslog daemon that the client has installed.

#### NOTE

If you edit the syslog configuration, you must restart the syslog daemon for the changes to take effect.

#### rsyslog

The configuration file for rsyslog is located at `/etc/rsyslog.d/95-omsagent.conf`. Its default contents are shown below. This collects syslog messages sent from the local agent for all facilities with a level of warning or higher.

```
kern.warning      @127.0.0.1:25224
user.warning     @127.0.0.1:25224
daemon.warning   @127.0.0.1:25224
auth.warning     @127.0.0.1:25224
syslog.warning   @127.0.0.1:25224
uucp.warning     @127.0.0.1:25224
authpriv.warning @127.0.0.1:25224
ftp.warning      @127.0.0.1:25224
cron.warning     @127.0.0.1:25224
local0.warning   @127.0.0.1:25224
local1.warning   @127.0.0.1:25224
local2.warning   @127.0.0.1:25224
local3.warning   @127.0.0.1:25224
local4.warning   @127.0.0.1:25224
local5.warning   @127.0.0.1:25224
local6.warning   @127.0.0.1:25224
local7.warning   @127.0.0.1:25224
```

You can remove a facility by removing its section of the configuration file. You can limit the severities that are collected for a particular facility by modifying that facility's entry. For example, to limit the user facility to messages with a severity of error or higher you would modify that line of the configuration file to the following:

```
user.error      @127.0.0.1:25224
```

### **syslog-ng**

The configuration file for syslog-ng is located at **/etc/syslog-ng/syslog-ng.conf**. Its default contents are shown below. This collects syslog messages sent from the local agent for all facilities and all severities.

```

#
# Warnings (except iptables) in one file:
#
destination warn { file("/var/log/warn" fsync(yes)); };
log { source(src); filter(f_warn); destination(warn); };

#OMS_Destination
destination d_oms { udp("127.0.0.1" port(25224)); };

#OMS_facility = auth
filter f_auth_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(auth); };
log { source(src); filter(f_auth_oms); destination(d_oms); };

#OMS_facility = authpriv
filter f_authpriv_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(authpriv); };
log { source(src); filter(f_authpriv_oms); destination(d_oms); };

#OMS_facility = cron
filter f_cron_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(cron); };
log { source(src); filter(f_cron_oms); destination(d_oms); };

#OMS_facility = daemon
filter f_daemon_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(daemon); };
log { source(src); filter(f_daemon_oms); destination(d_oms); };

#OMS_facility = kern
filter f_kern_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(kern); };
log { source(src); filter(f_kern_oms); destination(d_oms); };

#OMS_facility = local0
filter f_local0_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(local0); };
log { source(src); filter(f_local0_oms); destination(d_oms); };

#OMS_facility = local1
filter f_local1_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(local1); };
log { source(src); filter(f_local1_oms); destination(d_oms); };

#OMS_facility = mail
filter f_mail_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(mail); };
log { source(src); filter(f_mail_oms); destination(d_oms); };

#OMS_facility = syslog
filter f_syslog_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(syslog); };
log { source(src); filter(f_syslog_oms); destination(d_oms); };

#OMS_facility = user
filter f_user_oms { level(alert,crit,debug,emerg,err,info,notice,warning) and facility(user); };
log { source(src); filter(f_user_oms); destination(d_oms); };

```

You can remove a facility by removing its section of the configuration file. You can limit the severities that are collected for a particular facility by removing them from its list. For example, to limit the user facility to just alert and critical messages, you would modify that section of the configuration file to the following:

```

#OMS_facility = user
filter f_user_oms { level(alert,crit) and facility(user); };
log { source(src); filter(f_user_oms); destination(d_oms); };

```

## Collecting data from additional Syslog ports

The Log Analytics agent listens for Syslog messages on the local client on port 25224. When the agent is installed, a default syslog configuration is applied and found in the following location:

- Rsyslog: /etc/rsyslog.d/95-omsagent.conf

- Syslog-**ng**: `/etc/syslog-ng/syslog-ng.conf`

You can change the port number by creating two configuration files: a FluentD config file and a rsyslog-or-syslog-**ng** file depending on the Syslog daemon you have installed.

- The FluentD config file should be a new file located in: `/etc/opt/microsoft/omsagent/conf/omsagent.d` and replace the value in the **port** entry with your custom port number.

```
<source>
  type syslog
  port %SYSLOG_PORT%
  bind 127.0.0.1
  protocol_type udp
  tag oms.syslog
</source>
<filter oms.syslog.**>
  type filter_syslog
```

- For rsyslog, you should create a new configuration file located in: `/etc/rsyslog.d/` and replace the value `%SYSLOG_PORT%` with your custom port number.

#### **NOTE**

If you modify this value in the configuration file `95-omsagent.conf`, it will be overwritten when the agent applies a default configuration.

```
# OMS Syslog collection for workspace %WORKSPACE_ID%
kern.warning      @127.0.0.1:%SYSLOG_PORT%
user.warning      @127.0.0.1:%SYSLOG_PORT%
daemon.warning    @127.0.0.1:%SYSLOG_PORT%
auth.warning      @127.0.0.1:%SYSLOG_PORT%
```

- The syslog-**ng** config should be modified by copying the example configuration shown below and adding the custom modified settings to the end of the `syslog-ng.conf` configuration file located in `/etc/syslog-ng/`. Do **not** use the default label `%WORKSPACE_ID%_oms` or `%WORKSPACE_ID_OMS`, define a custom label to help distinguish your changes.

#### **NOTE**

If you modify the default values in the configuration file, they will be overwritten when the agent applies a default configuration.

```
filter f_custom_filter { level(warning) and facility(auth); };
destination d_custom_dest { udp("127.0.0.1" port(%SYSLOG_PORT%)); };
log { source(s_src); filter(f_custom_filter); destination(d_custom_dest); };
```

After completing the changes, the Syslog and the Log Analytics agent service needs to be restarted to ensure the configuration changes take effect.

## Syslog record properties

Syslog records have a type of **Syslog** and have the properties in the following table.

PROPERTY	DESCRIPTION
Computer	Computer that the event was collected from.
Facility	Defines the part of the system that generated the message.
HostIP	IP address of the system sending the message.
HostName	Name of the system sending the message.
SeverityLevel	Severity level of the event.
SyslogMessage	Text of the message.
ProcessID	ID of the process that generated the message.
EventTime	Date and time that the event was generated.

## Log queries with Syslog records

The following table provides different examples of log queries that retrieve Syslog records.

QUERY	DESCRIPTION
Syslog	All Syslogs.
Syslog   where SeverityLevel == "error"	All Syslog records with severity of error.
Syslog   summarize AggregatedValue = count() by Computer	Count of Syslog records by computer.
Syslog   summarize AggregatedValue = count() by Facility	Count of Syslog records by facility.

## Next steps

- Learn about [log queries](#) to analyze the data collected from data sources and solutions.
- Use [Custom Fields](#) to parse data from syslog records into individual fields.
- [Configure Linux agents](#) to collect other types of data.

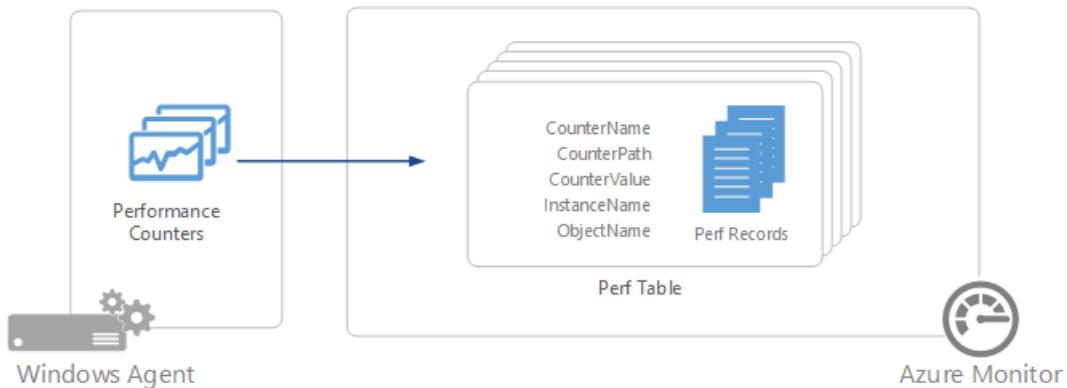

# Collect Windows and Linux performance data sources with Log Analytics agent

9/21/2022 • 7 minutes to read • [Edit Online](#)

Performance counters in Windows and Linux provide insight into the performance of hardware components, operating systems, and applications. Azure Monitor can collect performance counters from Log Analytics agents at frequent intervals for Near Real Time (NRT) analysis in addition to aggregating performance data for longer term analysis and reporting.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

## Configuring Performance counters

Configure Performance counters from the [Agents configuration menu](#) for the Log Analytics workspace.

When you first configure Windows or Linux Performance counters for a new workspace, you are given the option to quickly create several common counters. They are listed with a checkbox next to each. Ensure that any counters you want to initially create are checked and then click **Add the selected performance counters**.

For Windows performance counters, you can choose a specific instance for each performance counter. For Linux performance counters, the instance of each counter that you choose applies to all child counters of the parent counter. The following table shows the common instances available to both Linux and Windows performance counters.

INSTANCE NAME	DESCRIPTION
_Total	Total of all the instances
*	All instances
(/ /var)	Matches instances named: / or /var

### Windows performance counters

The screenshot shows the 'Windows performance counters' section of the Agents configuration page. It includes a search bar, tabs for Windows event logs, Windows performance counters (selected), Linux performance counters, Syslog, and IIS Logs. A descriptive text explains collecting performance counters from agents at custom intervals. Below is a table for adding performance counters:

Performance counter name	Sample rate (seconds)
LogicalDisk(*)\% Free Space	10
LogicalDisk(*)\Avg. Disk sec/Read	10
LogicalDisk(*)\Avg. Disk sec/Write	10
LogicalDisk(*)\Current Disk Queue Length	10
LogicalDisk(*)\Disk Reads/sec	10

Follow this procedure to add a new Windows performance counter to collect. Please note that V2 Windows Performance Counters are not supported.

1. Click **Add performance counter**.
2. Type the name of the counter in the text box in the format *object(instance)|counter*. When you start typing, you are presented with a matching list of common counters. You can either select a counter from the list or type in one of your own. You can also return all instances for a particular counter by specifying *object|counter*.  
When collecting SQL Server performance counters from named instances, all named instance counters start with *MSSQL\$* and followed by the name of the instance. For example, to collect the Log Cache Hit Ratio counter for all databases from the Database performance object for named SQL instance INST2, specify `MSSQL$INST2:Databases(*)\Log Cache Hit Ratio`.
3. When you add a counter, it uses the default of 10 seconds for its **Sample Interval**. You can change this to a higher value of up to 1800 seconds (30 minutes) if you want to reduce the storage requirements of the collected performance data.
4. When you're done adding counters, click the **Apply** button at the top of the screen to save the configuration.

## Linux performance counters

The screenshot shows the 'Linux performance counters' section of the Agents configuration page. It includes a search bar, tabs for Windows event logs, Windows performance counters, Linux performance counters (selected), Syslog, and IIS Logs. A descriptive text explains collecting performance counters from agents at custom intervals. Below is a table for adding performance counters:

Performance counter name	Instance	Sample rate (seconds)
Logical Disk	*	10
% Used Inodes		
% Used Space		
Disk Reads/sec		
Disk Transfers/sec		

Follow this procedure to add a new Linux performance counter to collect.

1. Click **Add performance counter**.
2. Type the name of the counter in the text box in the format *object(instance)|counter*. When you start typing,

you are presented with a matching list of common counters. You can either select a counter from the list or type in one of your own.

3. All counters for an object use the same **Sample Interval**. The default is 10 seconds. You change this to a higher value of up to 1800 seconds (30 minutes) if you want to reduce the storage requirements of the collected performance data.
4. When you're done adding counters, click the **Apply** button at the top of the screen to save the configuration.

#### Configure Linux performance counters in configuration file

Instead of configuring Linux performance counters using the Azure portal, you have the option of editing configuration files on the Linux agent. Performance metrics to collect are controlled by the configuration in `/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf`.

Each object, or category, of performance metrics to collect should be defined in the configuration file as a single `<source>` element. The syntax follows the pattern below.

```
<source>
  type oms_omi
  object_name "Processor"
  instance_regex ".*"
  counter_name_regex ".*"
  interval 30s
</source>
```

The parameters in this element are described in the following table.

PARAMETERS	DESCRIPTION
object_name	Object name for the collection.
instance_regex	A <i>regular expression</i> defining which instances to collect. The value: <code>.*</code> specifies all instances. To collect processor metrics for only the <code>_Total</code> instance, you could specify <code>_Total</code> . To collect process metrics for only the <code>crond</code> or <code>sshd</code> instances, you could specify: <code>(crond\ sshd)</code> .
counter_name_regex	A <i>regular expression</i> defining which counters (for the object) to collect. To collect all counters for the object, specify: <code>.*</code> . To collect only swap space counters for the memory object, for example, you could specify: <code>.+Swap.+</code>
interval	Frequency at which the object's counters are collected.

The following table lists the objects and counters that you can specify in the configuration file. There are additional counters available for certain applications as described in [Collect performance counters for Linux applications in Azure Monitor](#).

OBJECT NAME	COUNTER NAME
Logical Disk	% Free Inodes
Logical Disk	% Free Space
Logical Disk	% Used Inodes
Logical Disk	% Used Space

OBJECT NAME	COUNTER NAME
Logical Disk	Disk Read Bytes/sec
Logical Disk	Disk Reads/sec
Logical Disk	Disk Transfers/sec
Logical Disk	Disk Write Bytes/sec
Logical Disk	Disk Writes/sec
Logical Disk	Free Megabytes
Logical Disk	Logical Disk Bytes/sec
Memory	% Available Memory
Memory	% Available Swap Space
Memory	% Used Memory
Memory	% Used Swap Space
Memory	Available MBytes Memory
Memory	Available MBytes Swap
Memory	Page Reads/sec
Memory	Page Writes/sec
Memory	Pages/sec
Memory	Used MBytes Swap Space
Memory	Used Memory MBytes
Network	Total Bytes Transmitted
Network	Total Bytes Received
Network	Total Bytes
Network	Total Packets Transmitted
Network	Total Packets Received
Network	Total Rx Errors
Network	Total Tx Errors

OBJECT NAME	COUNTER NAME
Network	Total Collisions
Physical Disk	Avg. Disk sec/Read
Physical Disk	Avg. Disk sec/Transfer
Physical Disk	Avg. Disk sec/Write
Physical Disk	Physical Disk Bytes/sec
Process	Pct Privileged Time
Process	Pct User Time
Process	Used Memory kBytes
Process	Virtual Shared Memory
Processor	% DPC Time
Processor	% Idle Time
Processor	% Interrupt Time
Processor	% IO Wait Time
Processor	% Nice Time
Processor	% Privileged Time
Processor	% Processor Time
Processor	% User Time
System	Free Physical Memory
System	Free Space in Paging Files
System	Free Virtual Memory
System	Processes
System	Size Stored In Paging Files
System	Uptime
System	Users

Following is the default configuration for performance metrics.

```

<source>
  type oms_omi
  object_name "Physical Disk"
  instance_regex ".*"
  counter_name_regex ".*"

```

## Data collection

Azure Monitor collects all specified performance counters at their specified sample interval on all agents that have that counter installed. The data is not aggregated, and the raw data is available in all log query views for the duration specified by your log analytics workspace.

## Performance record properties

Performance records have a type of **Perf** and have the properties in the following table.

PROPERTY	DESCRIPTION
Computer	Computer that the event was collected from.
CounterName	Name of the performance counter
CounterPath	Full path of the counter in the form \\<Computer>\object(instance)\counter.
CounterValue	Numeric value of the counter.
InstanceName	Name of the event instance. Empty if no instance.
ObjectName	Name of the performance object

PROPERTY	DESCRIPTION
SourceSystem	Type of agent the data was collected from.  OpsManager – Windows agent, either direct connect or SCOM Linux – All Linux agents AzureStorage – Azure Diagnostics
TimeGenerated	Date and time the data was sampled.

## Sizing estimates

A rough estimate for collection of a particular counter at 10-second intervals is about 1 MB per day per instance. You can estimate the storage requirements of a particular counter with the following formula.

1 MB x (number of counters) x (number of agents) x (number of instances)
--

## Log queries with Performance records

The following table provides different examples of log queries that retrieve Performance records.

QUERY	DESCRIPTION
Perf	All Performance data
Perf   where Computer == "MyComputer"	All Performance data from a particular computer
Perf   where CounterName == "Current Disk Queue Length"	All Performance data for a particular counter
Perf   where ObjectName == "Processor" and CounterName == "% Processor Time" and InstanceName == "_Total"   summarize AVGCPU = avg(CounterValue) by Computer	Average CPU Utilization across all computers
Perf   where CounterName == "% Processor Time"   summarize AggregatedValue = max(CounterValue) by Computer	Maximum CPU Utilization across all computers
Perf   where ObjectName == "LogicalDisk" and CounterName == "Current Disk Queue Length" and Computer == "MyComputerName"   summarize AggregatedValue = avg(CounterValue) by InstanceName	Average Current Disk Queue length across all the instances of a given computer
Perf   where CounterName == "Disk Transfers/sec"   summarize AggregatedValue = percentile(CounterValue, 95) by Computer	95th Percentile of Disk Transfers/Sec across all computers
Perf   where CounterName == "% Processor Time" and InstanceName == "_Total"   summarize AggregatedValue = avg(CounterValue) by bin(TimeGenerated, 1h), Computer	Hourly average of CPU usage across all computers
Perf   where Computer == "MyComputer" and CounterName startswith_cs "%" and InstanceName == "_Total"   summarize AggregatedValue = percentile(CounterValue, 70) by bin(TimeGenerated, 1h), CounterName	Hourly 70 percentile of every % percent counter for a particular computer

QUERY	DESCRIPTION
<pre>Perf   where CounterName == "% Processor Time" and InstanceName == "_Total" and Computer == "MyComputer"   summarize ["min(CounterValue)"] = min(CounterValue), ["avg(CounterValue)"] = avg(CounterValue), ["percentile75(CounterValue)"] = percentile(CounterValue, 75), ["max(CounterValue)"] = max(CounterValue) by bin(TimeGenerated, 1h), Computer</pre>	Hourly average, minimum, maximum, and 75-percentile CPU usage for a specific computer
<pre>Perf   where ObjectName == "MSSQL\$INST2:Databases" and InstanceName == "master"</pre>	All Performance data from the Database performance object for the master database from the named SQL Server instance INST2.

# Collect performance counters for Linux applications in Azure Monitor

9/21/2022 • 6 minutes to read • [Edit Online](#)

This article provides details for configuring the [Log Analytics agent for Linux](#) to collect performance counters for specific applications into Azure Monitor. The applications included in this article are:

- [MySQL](#)
- [Apache HTTP Server](#)

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

## MySQL

If MySQL Server or MariaDB Server is detected on the computer when the Log Analytics agent is installed, a performance monitoring provider for MySQL Server will be automatically installed. This provider connects to the local MySQL/MariaDB server to expose performance statistics. MySQL user credentials must be configured so that the provider can access the MySQL Server.

### Configure MySQL credentials

The MySQL OMI provider requires a preconfigured MySQL user and installed MySQL client libraries in order to query the performance and health information from the MySQL instance. These credentials are stored in an authentication file that's stored on the Linux agent. The authentication file specifies what bind-address and port the MySQL instance is listening on and what credentials to use to gather metrics.

During installation of the Log Analytics agent for Linux the MySQL OMI provider will scan MySQL my.cnf configuration files (default locations) for bind-address and port and partially set the MySQL OMI authentication file.

The MySQL authentication file is stored at `/var/opt/microsoft/mysql-cimprov/auth/omsagent/mysql-auth`.

### Authentication file format

Following is the format for the MySQL OMI authentication file

```
[Port]=[Bind-Address], [username], [Base64 encoded Password]
(Port)=(Bind-Address), (username), (Base64 encoded Password)
(Port)=(Bind-Address), (username), (Base64 encoded Password)
AutoUpdate=[true|false]
```

The entries in the authentication file are described in the following table.

PROPERTY	DESCRIPTION
Port	Represents the current port the MySQL instance is listening on. Port 0 specifies that the properties following are used for default instance.

PROPERTY	DESCRIPTION
Bind-Address	Current MySQL bind-address.
username	MySQL user used to use to monitor the MySQL server instance.
Base64 encoded Password	Password of the MySQL monitoring user encoded in Base64.
AutoUpdate	Specifies whether to rescan for changes in the my.cnf file and overwrite the MySQL OMI Authentication file when the MySQL OMI Provider is upgraded.

## Default instance

The MySQL OMI authentication file can define a default instance and port number to make managing multiple MySQL instances on one Linux host easier. The default instance is denoted by an instance with port 0. All additional instances will inherit properties set from the default instance unless they specify different values. For example, if MySQL instance listening on port '3308' is added, the default instance's bind-address, username, and Base64 encoded password will be used to try and monitor the instance listening on 3308. If the instance on 3308 is bound to another address and uses the same MySQL username and password pair only the bind-address is needed, and the other properties will be inherited.

The following table has example instance settings

DESCRIPTION	FILE
Default instance and instance with port 3308.	<pre>0=127.0.0.1, myuser, cnBwdA== 3308=, , AutoUpdate=true</pre>
Default instance and instance with port 3308 and different user name and password.	<pre>0=127.0.0.1, myuser, cnBwdA== 3308=127.0.1.1, myuser2,cGluaGVhZA== AutoUpdate=true</pre>

## MySQL OMI Authentication File Program

Included with the installation of the MySQL OMI provider is a MySQL OMI authentication file program which can be used to edit the MySQL OMI Authentication file. The authentication file program can be found at the following location.

```
/opt/microsoft/mysql-cimprov/bin/mycimprovauth
```

### NOTE

The credentials file must be readable by the omsagent account. Running the mycimprovauth command as omsgent is recommended.

The following table provides details on the syntax for using mycimprovauth.

OPERATION	EXAMPLE	DESCRIPTION
autoupdate <i>false or true</i>	mycimprovauth autoupdate false	Sets whether or not the authentication file will be automatically updated on restart or update.

OPERATION	EXAMPLE	DESCRIPTION
default <i>bind-address username password</i>	mycimprovauth default 127.0.0.1 root pwd	Sets the default instance in the MySQL OMI authentication file. The password field should be entered in plain text - the password in the MySQL OMI authentication file will be Base 64 encoded.
delete <i>default or port_num</i>	mycimprovauth 3308	Deletes the specified instance by either default or by port number.
help	mycimprov help	Prints out a list of commands to use.
print	mycimprov print	Prints out an easy to read MySQL OMI authentication file.
update <i>port_num bind-address username password</i>	mycimprov update 3307 127.0.0.1 root pwd	Updates the specified instance or adds the instance if it does not exist.

The following example commands define a default user account for the MySQL server on localhost. The password field should be entered in plain text - the password in the MySQL OMI authentication file will be Base 64 encoded

```
sudo su omsagent -c '/opt/microsoft/mysql-cimprov/bin/mycimprovauth default 127.0.0.1 <username> <password>'  
sudo /opt/omi/bin/service_control restart
```

### Database Permissions Required for MySQL Performance Counters

The MySQL User requires access to the following queries to collect MySQL Server performance data.

```
SHOW GLOBAL STATUS;  
SHOW GLOBAL VARIABLES;
```

The MySQL user also requires SELECT access to the following default tables.

- information\_schema
- mysql.

These privileges can be granted by running the following grant commands.

```
GRANT SELECT ON information_schema.* TO 'monuser'@'localhost';  
GRANT SELECT ON mysql.* TO 'monuser'@'localhost';
```

#### NOTE

To grant permissions to a MySQL monitoring user the granting user must have the 'GRANT option' privilege as well as the privilege being granted.

### Define performance counters

Once you configure the Log Analytics agent for Linux to send data to Azure Monitor, you must configure the performance counters to collect. Use the procedure in [Windows and Linux performance data sources in Azure Monitor](#) with the counters in the following table.

OBJECT NAME	COUNTER NAME
MySQL Database	Disk Space in Bytes
MySQL Database	Tables
MySQL Server	Aborted Connection Pct
MySQL Server	Connection Use Pct
MySQL Server	Disk Space Use in Bytes
MySQL Server	Full Table Scan Pct
MySQL Server	InnoDB Buffer Pool Hit Pct
MySQL Server	InnoDB Buffer Pool Use Pct
MySQL Server	InnoDB Buffer Pool Use Pct
MySQL Server	Key Cache Hit Pct
MySQL Server	Key Cache Use Pct
MySQL Server	Key Cache Write Pct
MySQL Server	Query Cache Hit Pct
MySQL Server	Query Cache Prunes Pct
MySQL Server	Query Cache Use Pct
MySQL Server	Table Cache Hit Pct
MySQL Server	Table Cache Use Pct
MySQL Server	Table Lock Contention Pct

## Apache HTTP Server

If Apache HTTP Server is detected on the computer when the omsagent bundle is installed, a performance monitoring provider for Apache HTTP Server will be automatically installed. This provider relies on an Apache module that must be loaded into the Apache HTTP Server in order to access performance data. The module can be loaded with the following command:

```
sudo /opt/microsoft/apache-cimprov/bin/apache_config.sh -c
```

To unload the Apache monitoring module, run the following command:

```
sudo /opt/microsoft/apache-cimprov/bin/apache_config.sh -u
```

## Define performance counters

Once you configure the Log Analytics agent for Linux to send data to Azure Monitor, you must configure the performance counters to collect. Use the procedure in [Windows and Linux performance data sources in Azure Monitor](#) with the counters in the following table.

OBJECT NAME	COUNTER NAME
Apache HTTP Server	Busy Workers
Apache HTTP Server	Idle Workers
Apache HTTP Server	Pct Busy Workers
Apache HTTP Server	Total Pct CPU
Apache Virtual Host	Errors per Minute - Client
Apache Virtual Host	Errors per Minute - Server
Apache Virtual Host	KB per Request
Apache Virtual Host	Requests KB per Second
Apache Virtual Host	Requests per Second

## Next steps

- [Collect performance counters](#) from Linux agents.
- Learn about [log queries](#) to analyze the data collected from data sources and solutions.

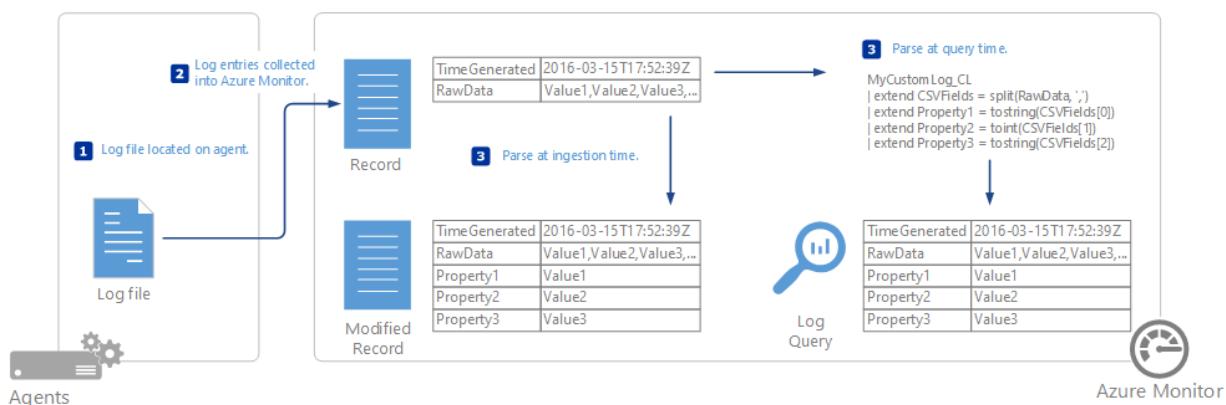

# Collect text logs with the Log Analytics agent in Azure Monitor

9/21/2022 • 8 minutes to read • [Edit Online](#)

The Custom Logs data source for the Log Analytics agent in Azure Monitor allows you to collect events from text files on both Windows and Linux computers. Many applications log information to text files instead of standard logging services, such as Windows Event log or Syslog. After the data is collected, you can either parse it into individual fields in your queries or extract it during collection to individual fields.

## IMPORTANT

The legacy [Log Analytics agent](#) will be deprecated by August 2024. Migrate to [Azure Monitor agent](#) before August 2024 to continue ingesting data.

The log files to be collected must match the following criteria:

- The log must either have a single entry per line or use a timestamp matching one of the following formats at the start of each entry:

YYYY-MM-DD HH:MM:SS  
M/D/YYYY HH:MM:SS AM/PM  
Mon DD, YYYY HH:MM:SS  
yyMMdd HH:mm:ss  
ddMMyy HH:mm:ss  
MMM d hh:mm:ss  
dd/MMM/yyyy:HH:mm:ss zzz  
yyyy-MM-ddTHH:mm:ssK

- The log file must not allow circular logging. This behavior is log rotation where the file is overwritten with new entries or the file is renamed and the same file name is reused for continued logging.
- The log file must use ASCII or UTF-8 encoding. Other formats such as UTF-16 aren't supported.
- For Linux, time zone conversion isn't supported for time stamps in the logs.
- As a best practice, the log file should include the date and time that it was created to prevent log rotation overwriting or renaming.

#### **NOTE**

If there are duplicate entries in the log file, Azure Monitor will collect them. The query results that are generated will be inconsistent. The filter results will show more events than the result count. You must validate the log to determine if the application that creates it is causing this behavior. Address the issue, if possible, before you create the custom log collection definition.

A Log Analytics workspace supports the following limits:

- Only 500 custom logs can be created.
- A table only supports up to 500 columns.
- The maximum number of characters for the column name is 500.

#### **IMPORTANT**

Custom log collection requires that the application writing the log file flushes the log content to the disk periodically. This is because the custom log collection relies on filesystem change notifications for the log file being tracked.

## Define a custom log

Use the following procedure to define a custom log file. Scroll to the end of this article for a walkthrough of a sample of adding a custom log.

### Open the Custom Log wizard

The Custom Log wizard runs in the Azure portal and allows you to define a new custom log to collect.

1. In the Azure portal, select **Log Analytics workspaces** > your workspace > **Settings**.
2. Select **Custom logs**.
3. By default, all configuration changes are automatically pushed to all agents. For Linux agents, a configuration file is sent to the Fluentd data collector.
4. Select **Add** to open the Custom Log wizard.

### Upload and parse a sample log

To start, upload a sample of the custom log. The wizard will parse and display the entries in this file for you to validate. Azure Monitor will use the delimiter that you specify to identify each record.

**New Line** is the default delimiter and is used for log files that have a single entry per line. If the line starts with a date and time in one of the available formats, you can specify a **Timestamp** delimiter, which supports entries that span more than one line.

If a timestamp delimiter is used, the **TimeGenerated** property of each record stored in Azure Monitor will be populated with the date and time specified for that entry in the log file. If a new line delimiter is used, **TimeGenerated** is populated with the date and time when Azure Monitor collected the entry.

1. Select **Browse** and browse to a sample file. This button might be labeled **Choose File** in some browsers.
2. Select **Next**.
3. The Custom Log wizard uploads the file and lists the records that it identifies.
4. Change the delimiter that's used to identify a new record. Select the delimiter that best identifies the records in your log file.
5. Select **Next**.

### Add log collection paths

You must define one or more paths on the agent where it can locate the custom log. You can either provide a

specific path and name for the log file or you can specify a path with a wildcard for the name. This step supports applications that create a new file each day or when one file reaches a certain size. You can also provide multiple paths for a single log file.

For example, an application might create a log file each day with the date included in the name as in `log20100316.txt`. A pattern for such a log might be `/log*.txt`, which would apply to any log file following the application's naming scheme.

The following table provides examples of valid patterns to specify different log files.

DESCRIPTION	PATH
All files in <code>C:\Logs</code> with .txt extension on the Windows agent	<code>C:\Logs\*.txt</code>
All files in <code>C:\Logs</code> with a name starting with <code>log</code> and a .txt extension on the Windows agent	<code>C:\Logs\log*.txt</code>
All files in <code>/var/log/audit</code> with .txt extension on the Linux agent	<code>/var/log/audit/*.txt</code>
All files in <code>/var/log/audit</code> with a name starting with <code>log</code> and a .txt extension on the Linux agent	<code>/var/log/audit/log*.txt</code>

1. Select Windows or Linux to specify which path format you're adding.
2. Enter the path and select the **+** button.
3. Repeat the process for any more paths.

### Provide a name and description for the log

The name that you specify will be used for the log type as described. It will always end with `_CL` to distinguish it as a custom log.

1. Enter a name for the log. The `_CL` suffix is automatically provided.
2. Add an optional **Description**.
3. Select **Next** to save the custom log definition.

### Validate that the custom logs are being collected

It might take up to an hour for the initial data from a new custom log to appear in Azure Monitor. Azure Monitor will start collecting entries from the logs found in the path you specified from the point that you defined the custom log. It won't retain the entries that you uploaded during the custom log creation. It will collect already existing entries in the log files that it locates.

After Azure Monitor starts collecting from the custom log, its records will be available with a log query. Use the name that you gave the custom log as the **Type** in your query.

#### NOTE

If the `RawData` property is missing from the query, you might need to close and reopen your browser.

### Parse the custom log entries

The entire log entry will be stored in a single property called **RawData**. You'll most likely want to separate the different pieces of information in each entry into individual properties for each record. For options on parsing `RawData` into multiple properties, see [Parse text data in Azure Monitor](#).

## Remove a custom log

Use the following process in the Azure portal to remove a custom log that you previously defined.

1. From the **Data** menu in the **Advanced Settings** for your workspace, select **Custom Logs** to list all your custom logs.
2. Select **Remove** next to the custom log to remove the log.

## Data collection

Azure Monitor collects new entries from each custom log approximately every 5 minutes. The agent records its place in each log file that it collects from. If the agent goes offline for a period of time, Azure Monitor collects entries from where it last left off, even if those entries were created while the agent was offline.

The entire contents of the log entry are written to a single property called **RawData**. For methods to parse each imported log entry into multiple properties, see [Parse text data in Azure Monitor](#).

## Custom log record properties

Custom log records have a type with the log name that you provide and the properties in the following table.

PROPERTY	DESCRIPTION
TimeGenerated	Date and time that the record was collected by Azure Monitor. If the log uses a time-based delimiter, this is the time collected from the entry.
SourceSystem	Type of agent the record was collected from. OpsManager – Windows agent, either direct connect or System Center Operations Manager Linux – All Linux agents
RawData	Full text of the collected entry. You'll most likely want to <a href="#">parse this data into individual properties</a> .
ManagementGroupName	Name of the management group for System Center Operations Manager agents. For other agents, this name is AOI-<workspace ID>.

## Sample walkthrough of adding a custom log

The following section walks through an example of creating a custom log. The sample log being collected has a single entry on each line starting with a date and time and then comma-delimited fields for code, status, and message. Several sample entries are shown.

```
2019-08-27 01:34:36 207,Success,Client 05a26a97-272a-4bc9-8f64-269d154b0e39 connected
2019-08-27 01:33:33 208,Warning,Client ec53d95c-1c88-41ae-8174-92104212de5d disconnected
2019-08-27 01:35:44 209,Success,Transaction 10d65890-b003-48f8-9cf8-9c74b51189c8 succeeded
2019-08-27 01:38:22 302,Error,Application could not connect to database
2019-08-27 01:31:34 303,Error,Application lost connection to database
```

### Upload and parse a sample log

We provide one of the log files and can see the events that it will be collecting. In this case, **New line** is a sufficient delimiter. If a single entry in the log could span multiple lines though, a timestamp delimiter would need to be used.

2. Select record delimiter

New line  
 Timestamp

**Record# 1**  
2019-08-27 01:34:36 207,Success,Client 05a26a97-272a-4bc9-8f64-269d154b0e39 connected

**Record# 2**  
2019-08-27 01:33:33 208,Warning,Client ec53d95c-1c88-41ae-8174-92104212de5d disconnected

**Record# 3**  
2019-08-27 01:35:44 209,Success,Transaction 10d65890-b003-48f8-9fcf-9c74b51189c8 succeeded

**Record# 4**  
2019-08-27 01:38:22 302,Error,Application could not connect to database

**Record# 5**  
2019-08-27 01:31:34 303,Error,Application lost connection to database

### Add log collection paths

The log files will be located in *C:\MyApp\Logs*. A new file will be created each day with a name that includes the date in the pattern *appYYYYMMDD.log*. A sufficient pattern for this log would be *C:\MyApp\Logs\\*.log*.

3. Add log collection paths

Windows  Linux

C:\MyApp\Logs\app\*.log +

C:\MyApp\Logs\app\*.log Windows Remove

### Provide a name and description for the log

We use a name of *MyApp\_CL* and type in a Description.

4. Add name and description

Name:

Description

### Validate that the custom logs are being collected

We use a simple query of *MyApp\_CL* to return all records from the collected log.

MyApp\_CL

Completed. Showing results from the last 7 days.

00:00:00.920 17 records Display time (UTC-07:00) ▾

## Alternatives to custom logs

While custom logs are useful if your data fits the criteria listed, there are cases where you need another strategy:

- The data doesn't fit the required structure, such as having the timestamp in a different format.
- The log file doesn't adhere to requirements such as file encoding or an unsupported folder structure.
- The data requires preprocessing or filtering before collection.

In the cases where your data can't be collected with custom logs, consider the following alternate strategies:

- Use a custom script or other method to write data to [Windows Events](#) or [Syslog](#), which are collected by Azure Monitor.
- Send the data directly to Azure Monitor by using [HTTP Data Collector API](#).

## Next steps

- See [Parse text data in Azure Monitor](#) for methods to parse each imported log entry into multiple properties.
- Learn about [log queries](#) to analyze the data collected from data sources and solutions.

# Create custom fields in a Log Analytics workspace in Azure Monitor (Preview)

9/21/2022 • 7 minutes to read • [Edit Online](#)

## NOTE

This article describes how to parse text data in a Log Analytics workspace as it's collected. We recommend parsing text data in a query filter after it's collected following the guidance described in [Parse text data in Azure Monitor](#). It provides several advantages over using custom fields.

## IMPORTANT

Custom fields increases the amount of data collected in the Log Analytics workspace which can increase your cost. See [Azure Monitor Logs pricing details](#) for details.

The **Custom Fields** feature of Azure Monitor allows you to extend existing records in your Log Analytics workspace by adding your own searchable fields. Custom fields are automatically populated from data extracted from other properties in the same record.

For example, the sample record below has useful data buried in the event description. Extracting this data into a separate property makes it available for such actions as sorting and filtering.

TenantId	SourceSystem	TimeGenerated [Local Time]	Source	EventLog	Compute

	Type	Event			
	_ResourceId	<GUID Removed>			

#### NOTE

In the Preview, you are limited to 500 custom fields in your workspace. This limit will be expanded when this feature reaches general availability.

## Creating a custom field

When you create a custom field, Log Analytics must understand which data to use to populate its value. It uses a technology from Microsoft Research called FlashExtract to quickly identify this data. Rather than requiring you to provide explicit instructions, Azure Monitor learns about the data you want to extract from examples that you provide.

The following sections provide the procedure for creating a custom field. At the bottom of this article is a walkthrough of a sample extraction.

#### NOTE

The custom field is populated as records matching the specified criteria are added to the Log Analytics workspace, so it will only appear on records collected after the custom field is created. The custom field will not be added to records that are already in the data store when it's created.

### Step 1 – Identify records that will have the custom field

The first step is to identify the records that will get the custom field. You start with a [standard log query](#) and then select a record to act as the model that Azure Monitor will learn from. When you specify that you are going to extract data into a custom field, the **Field Extraction Wizard** is opened where you validate and refine the criteria.

1. Go to **Logs** and use a [query to retrieve the records](#) that will have the custom field.
2. Select a record that Log Analytics will use to act as a model for extracting data to populate the custom field.  
You will identify the data that you want to extract from this record, and Log Analytics will use this information to determine the logic to populate the custom field for all similar records.

3. Right-click on the record, and select **Extract fields from**.
4. The **Field Extraction Wizard** is opened, and the record you selected is displayed in the **Main Example** column. The custom field will be defined for those records with the same values in the properties that are selected.
5. If the selection is not exactly what you want, select additional fields to narrow the criteria. In order to change the field values for the criteria, you must cancel and select a different record matching the criteria you want.

### **Step 2 - Perform initial extract.**

Once you've identified the records that will have the custom field, you identify the data that you want to extract. Log Analytics will use this information to identify similar patterns in similar records. In the step after this you will be able to validate the results and provide further details for Log Analytics to use in its analysis.

1. Highlight the text in the sample record that you want to populate the custom field. You will then be presented with a dialog box to provide a name and data type for the field and to perform the initial extract. The characters \_CF will automatically be appended.
2. Click **Extract** to perform an analysis of collected records.
3. The **Summary** and **Search Results** sections display the results of the extract so you can inspect its accuracy. **Summary** displays the criteria used to identify records and a count for each of the data values identified. **Search Results** provides a detailed list of records matching the criteria.

### **Step 3 – Verify accuracy of the extract and create custom field**

Once you have performed the initial extract, Log Analytics will display its results based on data that has already been collected. If the results look accurate then you can create the custom field with no further work. If not, then you can refine the results so that Log Analytics can improve its logic.

1. If any values in the initial extract aren't correct, then click the **Edit** icon next to an inaccurate record and select **Modify this highlight** in order to modify the selection.
2. The entry is copied to the **Additional examples** section underneath the **Main Example**. You can adjust the highlight here to help Log Analytics understand the selection it should have made.
3. Click **Extract** to use this new information to evaluate all the existing records. The results may be modified for records other than the one you just modified based on this new intelligence.
4. Continue to add corrections until all records in the extract correctly identify the data to populate the new custom field.
5. Click **Save Extract** when you are satisfied with the results. The custom field is now defined, but it won't be added to any records yet.
6. Wait for new records matching the specified criteria to be collected and then run the log search again. New records should have the custom field.
7. Use the custom field like any other record property. You can use it to aggregate and group data and even use it to produce new insights.

## **Viewing custom fields**

You can view a list of all custom fields in your management group from the **Advanced Settings** menu of your Log Analytics workspace in the Azure portal. Select **Data** and then **Custom fields** for a list of all custom fields in your workspace.

The screenshot shows the 'Advanced settings' interface. On the left, there's a sidebar with 'Connected Sources', 'Data', 'Computer Groups', 'Custom Fields' (which is selected and highlighted in blue), 'Custom Logs', and 'Syslog'. On the right, under 'Manage custom fields (1 fields used)', there's a table with one row:

FIELD NAME	LOG TYPE	FIELD TYPE
Service_CF	Event	Text <a href="#">Go to Remove</a>

## Removing a custom field

There are two ways to remove a custom field. The first is the **Remove** option for each field when viewing the complete list as described above. The other method is to retrieve a record and click the button to the left of the field. The menu will have an option to remove the custom field.

## Sample walkthrough

The following section walks through a complete example of creating a custom field. This example extracts the service name in Windows events that indicate a service changing state. This relies on events created by Service Control Manager during system startup on Windows computers. If you want to follow this example, you must be [collecting Information events for the System log](#).

We enter the following query to return all events from Service Control Manager that have an Event ID of 7036 which is the event that indicates a service starting or stopping.

The screenshot shows the Kibana interface. At the top, there are buttons for 'Run' (highlighted in blue), 'Time range: Last 24 hours', 'Save', 'Copy link', 'Export', 'New alert rule', and 'Pin'. The search bar contains the query:

```
Event
| where Source == "Service Control Manager"
| where EventID == 7036
```

Below the search bar, it says 'Completed. Showing results from the last 24 hours.' and shows '00:00:00.957' and '54 records'. It also shows 'Display time (UTC-07:00)'. The results table has columns: TenantId, SourceSystem, TimeGenerated [Local Time], Source, and EventLog. The data shows three rows of results:

TenantId	SourceSystem	TimeGenerated [Local Time]	Source	EventLog
<GUID Removed>	OpsManager	2019-03-29T10:12:54.803	Service Control Manager	System
<GUID Removed>	OpsManager	2019-03-29T10:16:33.150	Service Control Manager	System
<GUID Removed>	OpsManager	2019-03-29T10:16:36.060	Service Control Manager	System

We then right-click on any record with event ID 7036 and select **Extract fields from 'Event'**.

Completed. Showing results from the last 24 hours.

00:00:00.957 54 records

Display time (UTC-07:00)

TenantId	SourceSystem	TimeGenerated [Local Time]	Source	EventLog
<GUID Removed>	OpsManager	2019-03-29T10:12:54.803	Service Control Manager	System
<GUID Removed>	Manager	2019-03-29T10:16:33.150	Service Control Manager	System
<GUID Removed>	Manager	2019-03-29T10:16:36.060	Service Control Manager	System

The **Field Extraction Wizard** opens with the **EventLog** and **EventID** fields selected in the **Main Example** column. This indicates that the custom field will be defined for events from the System log with an event ID of 7036. This is sufficient so we don't need to select any other fields.

### MAIN EXAMPLE

Event		
<b>FILTER</b>	<b>FIELD NAME</b>	<b>VALUE</b>
<input type="checkbox"/>	SourceSystem	: OpsManager
<input type="checkbox"/>	TimeGenerated	: 2019-03-29T17:40:07.15Z
<input type="checkbox"/>	Source	: Service Control Manager
<input checked="" type="checkbox"/>	EventLog	: System
<input type="checkbox"/>	Computer	: contoso-srv-01.contoso.com
<input type="checkbox"/>	EventLevel	: 4
<input type="checkbox"/>	EventLevelName	: Information
<input type="checkbox"/>	ParameterXml	: <Param>Software Protection</Param><Param>stopped</Param><Param>-</Param><DataItem type="System.XmlData" time="2019-03-29T17:40:07.1493210+00:00" sourceHealthServiceId="0917C52B-0E75-D88B-6452-771406B8EFD2"><EventData xmlns="http://schemas.microsoft.com/oft.com/win/2004/08/events/event"><Data Name="param1">Software Protection</Data><Data Name="param2">stopped</Data><Binary>7300700070007300760063002F0031000000</Binary></EventData></DataItem>
<input type="checkbox"/>	EventData	:
<input checked="" type="checkbox"/>	EventID	: 7036
<input type="checkbox"/>	RenderedDescription	: The Software Protection service entered the stopped state.
<input type="checkbox"/>	AzureDeploymentID	:
<input type="checkbox"/>	Role	:
<input type="checkbox"/>	EventCategory	: 0
<input type="checkbox"/>	UserName	: N/A
<input type="checkbox"/>	Message	:
<input type="checkbox"/>	ManagementGroupName	: <GUID Removed>
<input type="checkbox"/>	DataItem_CF	:

We highlight the name of the service in the **RenderedDescription** property and use **Service** to identify the service name. The custom field will be called **Service\_CF**. The field type in this case is a string, so we can leave that unchanged.

<input checked="" type="checkbox"/> EventID	:	7036
<input type="checkbox"/> RenderedDescription	:	The Software Protection service entered the stopped state.
<input type="checkbox"/> AzureDeploymentID	:	Field value : Software Protection
<input type="checkbox"/> Role	:	Field Title : <input type="text" value="Service_CF"/>
<input type="checkbox"/> EventCategory	:	Field Type : <input type="text" value="Text"/>
<input type="checkbox"/> UserName	:	<input type="button" value="Close"/>
<input type="checkbox"/> Message	:	<input type="button" value="Extract"/>
<input type="checkbox"/> ManagementGroupName	:	<GU>
<input type="checkbox"/> DataItem_CF	:	

We see that the service name is identified properly for some records but not for others. The **Search Results** show that part of the name for the **WMI Performance Adapter** wasn't selected. The **Summary** shows that one record identified **Modules Installer** instead of **Windows Modules Installer**.

SEARCH RESULTS	SUMMARY
<b>Modules Installer</b> The Windows Modules Installer service entered the stopped state.	[ <input type="checkbox"/> hide tips] Condition Event   where EventLog == "System"   where EventID == 7036   limit 100 Service_CF (4 values) <input type="text" value="Modules Installer (1 matches)"/> <input type="text" value="Performance Adapter (39 matches)"/> <input type="text" value="Windows Update (12 matches)"/> <input type="text" value="Software Protection (0 matches)"/>
<b>Performance Adapter</b> The WMI Performance Adapter service entered the running state.	
<b>Performance Adapter</b> The WMI Performance Adapter service entered the stopped state.	
<b>Performance Adapter</b> The WMI Performance Adapter service entered the running state.	
<b>Performance Adapter</b> The WMI Performance Adapter service entered the stopped state.	
<b>Windows Update</b> The Windows Update service entered the stopped state.	

We start with the **WMI Performance Adapter** record. We click its edit icon and then **Modify this highlight**.

<b>Performance Adapter</b> The WMI Performance Adapter service entered the running state.	... <input type="button" value="Modify this highlight..."/>
<b>Performance Adapter</b> The WMI Performance Adapter service entered the stopped state.	<input type="button" value="Ignore results like these."/>  <input type="text" value="Modules Installer (1 matches)"/> <input type="text" value="Performance Adapter (39 matches)"/> <input type="text" value="Windows Update (12 matches)"/> <input type="text" value="Software Protection (0 matches)"/>

We increase the highlight to include the word **WMI** and then rerun the extract.

Additional examples
New - Highlight text to mark a custom field. Click on existing highlights to remove.
<input checked="" type="checkbox"/> RenderedDescription : The WMI Performance Adapter service entered the running state.

We can see that the entries for **WMI Performance Adapter** have been corrected, and Log Analytics also used that information to correct the records for **Windows Module Installer**.

SEARCH RESULTS		SUMMARY
Windows Modules Installer	(1)	[x] hide tips
The Windows Modules Installer service entered the stopped state.		Condition
WMI Performance Adapter	(1)	Event   where EventLog == "System"   where EventID == 7036   limit 100
The WMI Performance Adapter service entered the running state.		Service_CF (4 values)
WMI Performance Adapter	(1)	Windows Modules Installer (1 matches)
The WMI Performance Adapter service entered the stopped state.		WMI Performance Adapter (40 matches)
WMI Performance Adapter	(1)	Windows Update (13 matches)
The WMI Performance Adapter service entered the running state.		Software Protection (5 matches)
WMI Performance Adapter	(1)	
The WMI Performance Adapter service entered the stopped state.		

We can now run a query that verifies Service\_CF is created but is not yet added to any records. That's because the custom field doesn't work against existing records so we need to wait for new records to be collected.

The screenshot shows the Kibana interface with a search results table. The table has two columns: 'Service\_CF' and 'count\_'. There is one row with the value '1,725' under 'count\_'. The table header includes column sorting arrows. At the top, there is a 'Run' button, a time range selector set to 'Last 24 hours', and various action buttons like 'Save', 'Copy link', 'Export', 'New alert rule', and 'Pin'. The status bar at the bottom right shows '00:00:00.770' and '1 records'.

Service_CF	count_
>	1,725

After some time has passed so new events are collected, we can see that the Service\_CF field is now being added to records that match our criteria.

The screenshot shows the Kibana interface with a search results table. The table has two columns: 'Service\_CF' and 'count\_'. There are three rows: one with '1,730' under 'count\_' and two others with '2' under 'count\_'. The table header includes column sorting arrows. At the top, there is a 'Run' button, a time range selector set to 'Last 24 hours', and various action buttons like 'Save', 'Copy link', 'Export', 'New alert rule', and 'Pin'. The status bar at the bottom right shows '00:00:09.985' and '3 records'.

Service_CF	count_
>	1,730
> WMI Performance Adapter	2
> Print Spooler	2

We can now use the custom field like any other record property. To illustrate this, we create a query that groups by the new Service\_CF field to inspect which services are the most active.

TenantId	SourceSystem	TimeGenerated [Local Time]	Source	EventLog	Compute

- Monitor [custom log files](#) that you parse using custom fields.

# Troubleshooting the Log Analytics VM extension in Azure Monitor

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article provides help troubleshooting errors you might experience with the Log Analytics VM extension for Windows and Linux virtual machines running on Microsoft Azure, and suggests possible solutions to resolve them.

To verify the status of the extension, perform the following steps from the Azure portal.

1. Sign into the [Azure portal](#).
2. In the Azure portal, click **All services**. In the list of resources, type **virtual machines**. As you begin typing, the list filters based on your input. Select **Virtual machines**.
3. In your list of virtual machines, find and select it.
4. On the virtual machine, click **Extensions**.
5. From the list, check to see if the Log Analytics extension is enabled or not. For Linux, the agent is listed as **OMSAgentforLinux** and for Windows, the agent is listed as **MicrosoftMonitoringAgent**.

The screenshot shows the Azure portal interface for a virtual machine named "DC01 - Extensions". The left sidebar contains navigation links: Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, SETTINGS, Networking, Disks, Size, and Extensions. The "Extensions" link is highlighted with a blue selection bar. The main content area is titled "+ Add" and shows a table of extensions. The table has columns: NAME, TYPE, VER..., and STATUS. It lists two entries:

NAME	TYPE	VER...	STATUS
IaaS Diagnostics	Microsoft.Azure.Diagnostics.IaaSDi...	1.*	Transitioning
Microsoft Monitoring Agent	Microsoft.EnterpriseCloud.Monitori...	1.*	Provisioning succeeded

6. Click on the extension to view details.

MicrosoftMonitoringAgent	
DC01	
 Uninstall	
TYPE	Microsoft.EnterpriseCloud.Monitoring.MicrosoftMoni...
VERSION	1.0.11081.2
STATUS	Provisioning succeeded
STATUS LEVEL	Info
STATUS MESSAGE	Latest configuration has been applied to the Microsof...
HANDLER STATUS	Ready
HANDLER STATUS LEVEL	Info

## Troubleshooting Azure Windows VM extension

If the *Microsoft Monitoring Agent* VM extension is not installing or reporting, you can perform the following steps to troubleshoot the issue.

1. Check if the Azure VM agent is installed and working correctly by using the steps in [KB 2965986](#).
  - You can also review the VM agent log file `C:\WindowsAzure\logs\WaAppAgent.log`
  - If the log does not exist, the VM agent is not installed.
  - [Install the Azure VM Agent](#)
2. Review the Microsoft Monitoring Agent VM extension log files in  
`C:\Packages\Plugins\Microsoft.EnterpriseCloud.Monitoring.MicrosoftMonitoringAgent`
3. Ensure the virtual machine can run PowerShell scripts
4. Ensure permissions on `C:\Windows\temp` haven't been changed
5. View the status of the Microsoft Monitoring Agent by typing the following in an elevated PowerShell window on the virtual machine  
`(New-Object -ComObject 'AgentConfigManager.MgmtSvcCfg').GetCloudWorkspaces() | Format-List`
6. Review the Microsoft Monitoring Agent setup log files in  
`C:\WindowsAzure\Logs\Plugins\Microsoft.EnterpriseCloud.Monitoring.MicrosoftMonitoringAgent\1.0.18053.0\`.  
 Note that this path will change based on the version number of the agent.

For more information, see [troubleshooting Windows extensions](#).

## Troubleshooting Linux VM extension

### NOTE

As part of the ongoing transition from Microsoft Operations Management Suite to Azure Monitor, the Operations Management Suite Agent for Windows or Linux will be referred to as the Log Analytics agent for Windows and Log Analytics agent for Linux.

If the *Log Analytics agent for Linux* VM extension is not installing or reporting, you can perform the following steps to troubleshoot the issue.

1. If the extension status is *Unknown* check if the Azure VM agent is installed and working correctly by reviewing the VM agent log file `/var/log/waagent.log`
  - If the log does not exist, the VM agent is not installed.
  - [Install the Azure VM Agent on Linux VMs](#)
2. For other unhealthy statuses, review the Log Analytics agent for Linux VM extension logs files in `/var/log/azure/Microsoft.EnterpriseCloud.Monitoring.OmsAgentForLinux/*/extension.log` and `/var/log/azure/Microsoft.EnterpriseCloud.Monitoring.OmsAgentForLinux/*/CommandExecution.log`
3. If the extension status is healthy, but data is not being uploaded review the Log Analytics agent for Linux log files in `/var/opt/microsoft/omsagent/log/omsagent.log`

## Next steps

For additional troubleshooting guidance related to the Log Analytics agent for Linux, see [Troubleshoot Azure Log Analytics Linux Agent](#).

# Troubleshoot issues with the Log Analytics agent for Linux

9/21/2022 • 18 minutes to read • [Edit Online](#)

This article provides help in troubleshooting errors you might experience with the Log Analytics agent for Linux in Azure Monitor and suggests possible solutions to resolve them.

## Log Analytics Troubleshooting Tool

The Log Analytics agent for Linux Troubleshooting Tool is a script designed to help find and diagnose issues with the Log Analytics agent. It's automatically included with the agent upon installation. Running the tool should be the first step in diagnosing an issue.

### Use the Troubleshooting Tool

To run the Troubleshooting Tool, paste the following command into a terminal window on a machine with the Log Analytics agent:

```
sudo /opt/microsoft/omsagent/bin/troubleshooter
```

### Manual installation

The Troubleshooting Tool is automatically included when the Log Analytics agent is installed. If installation fails in any way, you can also install the tool manually:

1. Ensure that the [GNU Project Debugger \(GDB\)](#) is installed on the machine because the troubleshooter relies on it.
2. Copy the troubleshooter bundle onto your machine:

```
wget https://raw.github.com/microsoft/OMS-Agent-for-Linux/master/source/code/troubleshooter/omsagent_tst.tar.gz
```

3. Unpack the bundle: `tar -xvf omsagent_tst.tar.gz`
4. Run the manual installation: `sudo ./install_tst`

### Scenarios covered

The Troubleshooting Tool checks the following scenarios:

- The agent is unhealthy; the heartbeat doesn't work properly.
- The agent doesn't start or can't connect to Log Analytics.
- The agent Syslog isn't working.
- The agent has high CPU or memory usage.
- The agent has installation issues.
- The agent custom logs aren't working.
- Agent logs can't be collected.

For more information, see the [Troubleshooting Tool documentation on GitHub](#).

#### NOTE

Run the Log Collector tool when you experience an issue. Having the logs initially will help our support team troubleshoot your issue faster.

## Purge and reinstall the Linux agent

A clean reinstall of the agent fixes most issues. This task might be the first suggestion from our support team to get the agent into an uncorrupted state. Running the Troubleshooting Tool and Log Collector tool and attempting a clean reinstall helps to solve issues more quickly.

1. Download the purge script:

```
$ wget https://raw.githubusercontent.com/microsoft/OMS-Agent-for-Linux/master/tools/purge_omsagent.sh
```

2. Run the purge script (with sudo permissions):

```
$ sudo sh purge_omsagent.sh
```

## Important log locations and the Log Collector tool

FILE	PATH
Log Analytics agent for Linux log file	/var/opt/microsoft/omsagent/<workspace id>/log/omsagent.log
Log Analytics agent configuration log file	/var/opt/microsoft/omsconfig/omsconfig.log

We recommend that you use the Log Collector tool to retrieve important logs for troubleshooting or before you submit a GitHub issue. For more information about the tool and how to run it, see [OMS Linux Agent Log Collector](#).

## Important configuration files

CATEGORY	FILE LOCATION
Syslog	/etc/syslog-ng/syslog-ng.conf or /etc/rsyslog.conf or /etc/rsyslog.d/95-omsagent.conf
Performance, Nagios, Zabbix, Log Analytics output and general agent	/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf
Extra configurations	/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.d/*.conf

### NOTE

Editing configuration files for performance counters and Syslog is overwritten if the collection is configured from the [agent's configuration](#) in the Azure portal for your workspace. To disable configuration for all agents, disable collection from [Agents configuration](#). For a single agent, run the following script:

```
sudo /opt/microsoft/omsconfig/Scripts/OMS_MetaConfigHelper.py --disable && sudo rm  
/etc/opt/omi/conf/omsconfig/configuration/Current.mof*  
/etc/opt/omi/conf/omsconfig/configuration/Pending.mof*
```

## Installation error codes

ERROR CODE	MEANING

ERROR CODE	MEANING
NOT_DEFINED	Because the necessary dependencies aren't installed, the auoms audited plug-in won't be installed. Installation of auoms failed. Install package audited.
2	Invalid option provided to the shell bundle. Run <code>sudo sh ./omsagent-*.universal*.sh --help</code> for usage.
3	No option provided to the shell bundle. Run <code>sudo sh ./omsagent-*.universal*.sh --help</code> for usage.
4	Invalid package type <i>or</i> invalid proxy settings. The omsagent-rpm.sh packages can only be installed on RPM-based systems. The omsagent-deb.sh packages can only be installed on Debian-based systems. We recommend that you use the universal installer from the <a href="#">latest release</a> . Also review to verify your proxy settings.
5	The shell bundle must be executed as root <i>or</i> there was a 403 error returned during onboarding. Run your command by using <code>sudo</code> .
6	Invalid package architecture <i>or</i> there was a 200 error returned during onboarding. The omsagent-*x64.sh packages can only be installed on 64-bit systems. The omsagent-*x86.sh packages can only be installed on 32-bit systems. Download the correct package for your architecture from the <a href="#">latest release</a> .
17	Installation of OMS package failed. Look through the command output for the root failure.
18	Installation of OMSConfig package failed. Look through the command output for the root failure.
19	Installation of OMI package failed. Look through the command output for the root failure.
20	Installation of SCX package failed. Look through the command output for the root failure.
21	Installation of Provider kits failed. Look through the command output for the root failure.
22	Installation of bundled package failed. Look through the command output for the root failure
23	SCX or OMI package already installed. Use <code>--upgrade</code> instead of <code>--install</code> to install the shell bundle.
30	Internal bundle error. File a <a href="#">GitHub issue</a> with details from the output.
55	Unsupported openssl version <i>or</i> can't connect to Azure Monitor <i>or</i> dpkg is locked <i>or</i> missing curl program.

ERROR CODE	MEANING
61	Missing Python ctypes library. Install the Python ctypes library or package (python-ctypes).
62	Missing tar program. Install tar.
63	Missing sed program. Install sed.
64	Missing curl program. Install curl.
65	Missing gpg program. Install gpg.

## Onboarding error codes

ERROR CODE	MEANING
2	Invalid option provided to the omsadmin script. Run <pre>sudo sh /opt/microsoft/omsagent/bin/omsadmin.sh -h</pre> for usage.
3	Invalid configuration provided to the omsadmin script. Run <pre>sudo sh /opt/microsoft/omsagent/bin/omsadmin.sh -h</pre> for usage.
4	Invalid proxy provided to the omsadmin script. Verify the proxy and see our <a href="#">documentation for using an HTTP proxy</a> .
5	403 HTTP error received from Azure Monitor. See the full output of the omsadmin script for details.
6	Non-200 HTTP error received from Azure Monitor. See the full output of the omsadmin script for details.
7	Unable to connect to Azure Monitor. See the full output of the omsadmin script for details.
8	Error onboarding to Log Analytics workspace. See the full output of the omsadmin script for details.
30	Internal script error. File a <a href="#">GitHub issue</a> with details from the output.
31	Error generating agent ID. File a <a href="#">GitHub issue</a> with details from the output.
32	Error generating certificates. See the full output of the omsadmin script for details.
33	Error generating metaconfiguration for omsconfig. File a <a href="#">GitHub issue</a> with details from the output.

ERROR CODE	MEANING
34	<p>Metaconfiguration generation script not present. Retry onboarding with</p> <pre>sudo sh /opt/microsoft/omsagent/bin/omsadmin.sh -w &lt;Workspace ID&gt; -s &lt;Workspace Key&gt;</pre>

## Enable debug logging

### OMS output plug-in debug

FluentD allows for plug-in-specific logging levels that allow you to specify different log levels for inputs and outputs. To specify a different log level for OMS output, edit the general agent configuration at

```
/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf
```

In the OMS output plug-in, before the end of the configuration file, change the `log_level` property from `info` to `debug`:

```
<match oms.** docker.**>
  type out_oms
  log_level debug
  num_threads 5
  buffer_chunk_limit 5m
  buffer_type file
  buffer_path /var/opt/microsoft/omsagent/<workspace id>/state/out_oms*.buffer
  buffer_queue_limit 10
  flush_interval 20s
  retry_limit 10
  retry_wait 30s
</match>
```

Debug logging allows you to see batched uploads to Azure Monitor separated by type, number of data items, and time taken to send.

Here's an example debug-enabled log:

```
Success sending oms.nagios x 1 in 0.14s
Success sending oms.omi x 4 in 0.52s
Success sending oms.syslog.authpriv.info x 1 in 0.91s
```

### Verbose output

Instead of using the OMS output plug-in, you can output data items directly to `stdout`, which is visible in the Log Analytics agent for Linux log file.

In the Log Analytics general agent configuration file at

```
/etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf
```

comment out the OMS output plug-in by adding a `#` in front of each line:

```
#<match oms.** docker.**>
#  type out_oms
#  log_level info
#  num_threads 5
#  buffer_chunk_limit 5m
#  buffer_type file
#  buffer_path /var/opt/microsoft/omsagent/<workspace id>/state/out_oms*.buffer
#  buffer_queue_limit 10
#  flush_interval 20s
#  retry_limit 10
#  retry_wait 30s
#</match>
```

Below the output plug-in, uncomment the following section by removing the `#` in front of each line:

```
<match **>
  type stdout
</match>
```

## Issue: Unable to connect through proxy to Azure Monitor

### Probable causes

- The proxy specified during onboarding was incorrect.
- The Azure Monitor and Azure Automation service endpoints aren't included in the approved list in your datacenter.

### Resolution

1. Reonboard to Azure Monitor with the Log Analytics agent for Linux by using the following command with the option `-v` enabled. It allows verbose output of the agent connecting through the proxy to Azure Monitor:  
`/opt/microsoft/omsagent/bin/omsadmin.sh -w <Workspace ID> -s <Workspace Key> -p <Proxy Conf> -v`
2. Review the section [Update proxy settings](#) to verify you've properly configured the agent to communicate through a proxy server.
3. Double-check that the endpoints outlined in the Azure Monitor [network firewall requirements](#) list are added to an allow list correctly. If you use Azure Automation, the necessary network configuration steps are also linked above.

## Issue: You receive a 403 error when trying to onboard

### Probable causes

- Date and time are incorrect on the Linux server.
- The workspace ID and workspace key aren't correct.

### Resolution

1. Check the time on your Linux server with the command `date`. If the time is +/- 15 minutes from the current time, onboarding fails. To correct this situation, update the date and/or time zone of your Linux server.
2. Verify that you've installed the latest version of the Log Analytics agent for Linux. The newest version now notifies you if time skew is causing the onboarding failure.
3. Reonboard by using the correct workspace ID and workspace key in the installation instructions earlier in this article.

## Issue: You see a 500 and 404 error in the log file right after onboarding

This is a known issue that occurs on the first upload of Linux data into a Log Analytics workspace. This issue doesn't affect data being sent or service experience.

## Issue: You see omiagent using 100% CPU

### Probable causes

A regression in nss-pem package [v1.0.3-5.el7](#) caused a severe performance issue. We've been seeing this issue come up a lot in Redhat/Centos 7.x distributions. To learn more about this issue, see [1667121 Performance regression in libcurl](#).

Performance-related bugs don't happen all the time, and they're difficult to reproduce. If you experience such an issue with omiagent, use the script `omiHighCPUDiagnostics.sh`, which will collect the stack trace of the omiagent when it exceeds a certain threshold.

1. Download the script:

```
wget https://raw.githubusercontent.com/microsoft/OMS-Agent-for-Linux/master/tools/LogCollector/source/omiHighCPUDiagnostics.sh
```

2. Run diagnostics for 24 hours with 30% CPU threshold:

```
bash omiHighCPUDiagnostics.sh --runtime-in-min 1440 --cpu-threshold 30
```

3. Callstack will be dumped in the `omiagent_trace` file. If you notice many curl and NSS function calls, follow these resolution steps.

### Resolution

1. Upgrade the nss-pem package to [v1.0.3-5.el7\\_6.1](#):

```
sudo yum upgrade nss-pem
```

2. If nss-pem isn't available for upgrade, which mostly happens on Centos, downgrade curl to 7.29.0-46. If you run "yum update" by mistake, curl will be upgraded to 7.29.0-51 and the issue will happen again:

```
sudo yum downgrade curl libcurl
```

3. Restart OMI:

```
sudo scxadmin -restart
```

## Issue: You're not seeing forwarded Syslog messages

### Probable causes

- The configuration applied to the Linux server doesn't allow collection of the sent facilities or log levels.
- Syslog isn't being forwarded correctly to the Linux server.
- The number of messages being forwarded per second is too great for the base configuration of the Log Analytics agent for Linux to handle.

### Resolution

- Verify the configuration in the Log Analytics workspace for Syslog has all the facilities and the correct log levels. Review [configure Syslog collection in the Azure portal](#).
- Verify the native Syslog messaging daemons (`rsyslog`, `syslog-ng`) can receive the forwarded messages.
- Check firewall settings on the Syslog server to ensure that messages aren't being blocked.
- Simulate a Syslog message to Log Analytics by using a `logger` command:  

```
logger -p local0.err "This is my test message"
```

# Issue: You're receiving Errno address already in use in omsagent log file

You see

```
[error]: unexpected error error_class=Errno::EADDRINUSE error=#<Errno::EADDRINUSE: Address already in use - bind(2) for "127.0.0.1" port 25224>
```

in omsagent.log.

## Probable causes

This error indicates that the Linux diagnostic extension (LAD) is installed side by side with the Log Analytics Linux VM extension. It's using the same port for Syslog data collection as omsagent.

## Resolution

1. As root, execute the following commands. Note that 25224 is an example, and it's possible that in your environment you see a different port number used by LAD.

```
/opt/microsoft/omsagent/bin/configure_syslog.sh configure LAD 25229  
sed -i -e 's/25224/25229/' /etc/opt/microsoft/omsagent/LAD/conf/omsagent.d/syslog.conf
```

You then need to edit the correct `rsyslogd` or `syslog_ng` config file and change the LAD-related configuration to write to port 25229.

2. If the VM is running `rsyslogd`, the file to be modified is `/etc/rsyslog.d/95-omsagent.conf` (if it exists, else `/etc/rsyslog`). If the VM is running `syslog_ng`, the file to be modified is `/etc/syslog-ng/syslog-ng.conf`.
3. Restart omsagent `sudo /opt/microsoft/omsagent/bin/service_control restart`.
4. Restart the Syslog service.

# Issue: You're unable to uninstall omsagent using the purge option

## Probable causes

- The Linux diagnostic extension is installed.
- The Linux diagnostic extension was installed and uninstalled, but you still see an error about omsagent being used by mdsd and it can't be removed.

## Resolution

1. Uninstall the Linux diagnostic extension.
2. Remove Linux diagnostic extension files from the machine if they're present in the following location:  
`/var/lib/waagent/Microsoft.Azure.Diagnostics.LinuxDiagnostic-<version>/` and  
`/var/opt/microsoft/omsagent/LAD/`.

# Issue: You can't see any Nagios data

## Probable causes

- The omsagent user doesn't have permissions to read from the Nagios log file.
- The Nagios source and filter haven't been uncommented from the omsagent.conf file.

## Resolution

1. Add the omsagent user to read from the Nagios file by following these [instructions](#).
2. In the Log Analytics agent for Linux general configuration file at  
`/etc/opt/microsoft/omsagent/<workspace_id>/conf/omsagent.conf`, ensure that *both* the Nagios source and

filter are uncommented.

```
<source>
  type tail
  path /var/log/nagios/nagios.log
  format none
  tag oms.nagios
</source>

<filter oms.nagios>
  type filter_nagios_log
</filter>
```

## Issue: You aren't seeing any Linux data

### Probable causes

- Onboarding to Azure Monitor failed.
- Connection to Azure Monitor is blocked.
- Virtual machine was rebooted.
- OMI package was manually upgraded to a newer version compared to what was installed by the Log Analytics agent for Linux package.
- OMI is frozen, blocking the OMS agent.
- DSC resource logs *class not found* error in `omsconfig.log` log file.
- Log Analytics agent for data is backed up.
- DSC logs *Current configuration does not exist. Execute Start-DscConfiguration command with -Path parameter to specify a configuration file and create a current configuration first.* in `omsconfig.log` log file, but no log message exists about `PerformRequiredConfigurationChecks` operations.

### Resolution

1. Install all dependencies like the `auditd` package.
2. Check if onboarding to Azure Monitor was successful by checking if the following file exists:  
`/etc/opt/microsoft/omsagent/<workspace_id>/conf/omsadmin.conf`. If it wasn't, reonboard by using the `omsadmin.sh` command-line [instructions](#).
3. If you're using a proxy, check the preceding proxy troubleshooting steps.
4. In some Azure distribution systems, the `omid` OMI server daemon doesn't start after the virtual machine is rebooted. If this is the case, you won't see Audit, ChangeTracking, or UpdateManagement solution-related data. The workaround is to manually start the OMI server by running  
`sudo /opt/omi/bin/service_control restart`.
5. After the OMI package is manually upgraded to a newer version, it must be manually restarted for the Log Analytics agent to continue functioning. This step is required for some distros where the OMI server doesn't automatically start after it's upgraded. Run `sudo /opt/omi/bin/service_control restart` to restart the OMI.

In some situations, the OMI can become frozen. The OMS agent might enter a blocked state waiting for the OMI, which blocks all data collection. The OMS agent process will be running but there will be no activity, which is evidenced by no new log lines (such as sent heartbeats) present in `omsagent.log`. Restart the OMI with `sudo /opt/omi/bin/service_control restart` to recover the agent.

6. If you see a DSC resource *class not found* error in `omsconfig.log`, run

```
sudo /opt/omi/bin/service_control restart
```

7. In some cases, when the Log Analytics agent for Linux can't talk to Azure Monitor, data on the agent is backed up to the full buffer size of 50 MB. The agent should be restarted by running the following command: `/opt/microsoft/omsagent/bin/service_control restart`.

**NOTE**

This issue is fixed in agent version 1.1.0-28 or later.

- If the `omsconfig.log` log file doesn't indicate that `PerformRequiredConfigurationChecks` operations are running periodically on the system, there might be a problem with the cron job/service. Make sure the cron job exists under `/etc/cron.d/OMSConsistencyInvoker`. If needed, run the following commands to create the cron job:

```
mkdir -p /etc/cron.d/
echo "**/15 * * * * omsagent /opt/omi/bin/OMSConsistencyInvoker >/dev/null 2>&1" | sudo tee
/etc/cron.d/OMSConsistencyInvoker
```

- Also, make sure the cron service is running. You can use `service cron status` with Debian, Ubuntu, and SUSE or `service crond status` with RHEL, CentOS, and Oracle Linux to check the status of this service. If the service doesn't exist, you can install the binaries and start the service by using the following instructions:

**Ubuntu/Debian**

```
# To Install the service binaries
sudo apt-get install -y cron
# To start the service
sudo service cron start
```

**SUSE**

```
# To Install the service binaries
sudo zypper in cron -y
# To start the service
sudo systemctl enable cron
sudo systemctl start cron
```

**RHEL/CentOS**

```
# To Install the service binaries
sudo yum install -y crond
# To start the service
sudo service crond start
```

**Oracle Linux**

```
# To Install the service binaries
sudo yum install -y crondie
# To start the service
sudo service crond start
```

**Issue:** When you configure collection from the portal for Syslog or

# Linux performance counters, the settings aren't applied

## Probable causes

- The Log Analytics agent for Linux hasn't picked up the latest configuration.
- The changed settings in the portal weren't applied.

## Resolution

**Background:** `omsconfig` is the Log Analytics agent for Linux configuration agent that looks for new portal-side configuration every five minutes. This configuration is then applied to the Log Analytics agent for Linux configuration files located at `/etc/opt/microsoft/omsagent/conf/omsagent.conf`.

In some cases, the Log Analytics agent for Linux configuration agent might not be able to communicate with the portal configuration service. This scenario results in the latest configuration not being applied.

1. Check that the `omsconfig` agent is installed by running `dpkg --list omsconfig` or `rpm -qi omsconfig`. If it isn't installed, reinstall the latest version of the Log Analytics agent for Linux.
2. Check that the `omsconfig` agent can communicate with Azure Monitor by running the following command: `sudo su omsagent -c 'python /opt/microsoft/omsconfig/Scripts/GetDscConfiguration.py'`. This command returns the configuration that the agent receives from the service, including Syslog settings, Linux performance counters, and custom logs. If this command fails, run the following command:  
`sudo su omsagent -c 'python /opt/microsoft/omsconfig/Scripts/PerformRequiredConfigurationChecks.py'`.  
This command forces the `omsconfig` agent to talk to Azure Monitor and retrieve the latest configuration.

# Issue: You aren't seeing any custom log data

## Probable causes

- Onboarding to Azure Monitor failed.
- The setting **Apply the following configuration to my Linux Servers** hasn't been selected.
- `omsconfig` hasn't picked up the latest custom log configuration from the service.
- The Log Analytics agent for Linux user `omsagent` is unable to access the custom log due to permissions or not being found. You might see the following errors:
  - [DATETIME] [warn]: file not found. Continuing without tailing it.
  - [DATETIME] [error]: file not accessible by omsagent.
- Known issue with race condition fixed in Log Analytics agent for Linux version 1.1.0-217.

## Resolution

1. Verify onboarding to Azure Monitor was successful by checking if the following file exists:  
`/etc/opt/microsoft/omsagent/<workspace id>/conf/omsadmin.conf`. If not, either:
  - a. Reonboard by using the `omsadmin.sh` command line [instructions](#).
  - b. Under **Advanced Settings** in the Azure portal, ensure that the setting **Apply the following configuration to my Linux Servers** is enabled.
2. Check that the `omsconfig` agent can communicate with Azure Monitor by running the following command: `sudo su omsagent -c 'python /opt/microsoft/omsconfig/Scripts/GetDscConfiguration.py'`. This command returns the configuration that the agent receives from the service, including Syslog settings, Linux performance counters, and custom logs. If this command fails, run the following command:  
`sudo su omsagent -c 'python /opt/microsoft/omsconfig/Scripts/PerformRequiredConfigurationChecks.py'`.  
This command forces the `omsconfig` agent to talk to Azure Monitor and retrieve the latest configuration.

**Background:** Instead of the Log Analytics agent for Linux running as a privileged user - `root`, the agent runs as the `omsagent` user. In most cases, explicit permission must be granted to this user for certain files to be read.

To grant permission to `omsagent` user, run the following commands:

1. Add the `omsagent` user to the specific group: `sudo usermod -a -G <GROUPNAME> <USERNAME>`.
2. Grant universal read access to the required file: `sudo chmod -R ugo+rwx <FILE DIRECTORY>`.

There's a known issue with a race condition with the Log Analytics agent for Linux version earlier than 1.1.0-217.

After you update to the latest agent, run the following command to get the latest version of the output plug-in:

```
sudo cp /etc/opt/microsoft/omsagent/sysconf/omsagent.conf /etc/opt/microsoft/omsagent/<workspace id>/conf/omsagent.conf
```

## Issue: You're trying to reonboard to a new workspace

When you try to reonboard an agent to a new workspace, the Log Analytics agent configuration needs to be cleaned up before reonboarding. To clean up old configuration from the agent, run the shell bundle with

```
--purge :
```

```
sudo sh ./omsagent-*universal.x64.sh --purge
```

Or

```
sudo sh ./onboard_agent.sh --purge
```

You can continue to reonboard after you use the `--purge` option.

## Issue: Log Analytics agent extension in the Azure portal is marked with a failed state: Provisioning failed

### Probable causes

- The Log Analytics agent has been removed from the operating system.
- The Log Analytics agent service is down, disabled, or not configured.

### Resolution

1. Remove the extension from the Azure portal.
2. Install the agent by following the [instructions](#).
3. Restart the agent by running the following command:  
`sudo /opt/microsoft/omsagent/bin/service_control restart`.
4. Wait several minutes until the provisioning state changes to **Provisioning succeeded**.

## Issue: The Log Analytics agent upgrade on-demand

### Probable causes

The Log Analytics agent packages on the host are outdated.

### Resolution

1. Check for the latest release on [this GitHub page](#).
2. Download the installation script (1.4.2-124 is an example version):

```
wget https://github.com/Microsoft/OMS-Agent-for-Linux/releases/download/OMSAgent_GA_v1.4.2-124/omsagent-1.4.2-124.universal.x64.sh
```

3. Upgrade packages by executing `sudo sh ./omsagent-*universal.x64.sh --upgrade`.

**Issue:** Installation is failing and says Python2 can't support ctypes, even though Python3 is being used

#### Probable causes

For this known issue, if the VM's language isn't English, a check will fail when verifying which version of Python is being used. This issue leads to the agent always assuming Python2 is being used and failing if there's no Python2.

#### Resolution

Change the VM's environmental language to English:

```
export LANG=en_US.UTF-8
```

# Overview of VM insights

9/21/2022 • 2 minutes to read • [Edit Online](#)

VM insights monitors the performance and health of your virtual machines and virtual machine scale sets, including their running processes and dependencies on other resources. It can help deliver predictable performance and availability of vital applications by identifying performance bottlenecks and network issues and can also help you understand whether an issue is related to other dependencies.

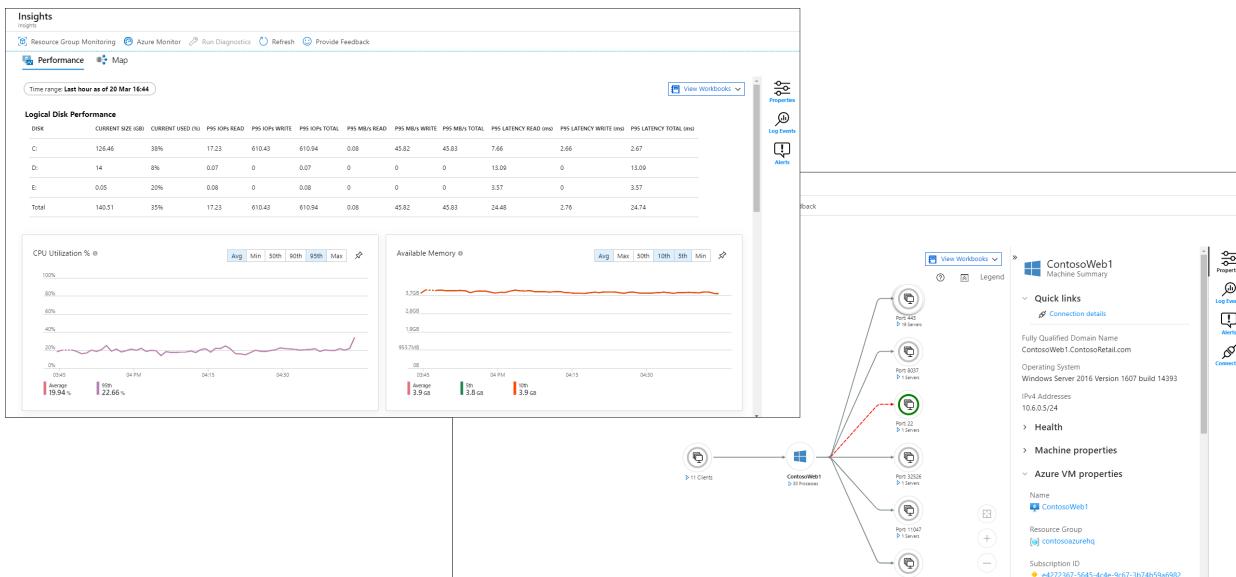

## NOTE

VM insights now supports [Azure Monitor agent](#). See [Enable VM insights overview](#).

VM insights supports Windows and Linux operating systems on the following machines:

- Azure virtual machines
- Azure virtual machine scale sets
- Hybrid virtual machines connected with Azure Arc
- On-premises virtual machines
- Virtual machines hosted in another cloud environment

VM insights stores its data in Azure Monitor Logs, which allows it to deliver powerful aggregation and filtering and to analyze data trends over time. You can view this data in a single VM from the virtual machine directly, or you can use Azure Monitor to deliver an aggregated view of multiple VMs.

## Pricing

There's no direct cost for VM insights, but you're charged for its activity in the Log Analytics workspace. Based on the pricing that's published on the [Azure Monitor pricing page](#), VM insights is billed for:

- Data ingested from agents and stored in the workspace.
- Health state data collected from guest health (preview)
- Alert rules based on log and health data.
- Notifications sent from alert rules.

The log size varies by the string lengths of performance counters, and it can increase with the number of logical disks and network adapters allocated to the VM. If you're already using Service Map, the only change you'll see is the extra performance data that's sent to the Azure Monitor `InsightsMetrics` data type.

## Accessing VM insights

Access VM insights for all your virtual machines and virtual machine scale sets by selecting **Virtual Machines** from the **Monitor** menu in the Azure portal. Access VM insights for a single virtual machine or virtual machine scale set by selecting **Insights** from the machine's menu in the Azure portal.

## Configuring VM insights

The steps to configure VM insights are as follows. Follow each link for detailed guidance on each step:

- [Create Log Analytics workspace](#).
- [Add VMInsights solution to workspace](#). (Log Analytics agent only)
- [Install agents on virtual machine and virtual machine scale set to be monitored](#).

### NOTE

VM Insights does not support sending data to more than one Log Analytics workspace (multi-homing).

## Next steps

- See [Deploy VM insights](#) for requirements and methods that to enable monitoring for your virtual machines.

# Enable VM insights overview

9/21/2022 • 7 minutes to read • [Edit Online](#)

This article provides an overview of the options available to enable VM insights to monitor health and performance of the following:

- Azure virtual machines
- Azure virtual machine scale sets
- Hybrid virtual machines connected with Azure Arc
- On-premises virtual machines
- Virtual machines hosted in another cloud environment.

## Installation options and supported machines

The following table shows the installation methods available for enabling VM insights on supported machines.

METHOD	SCOPE
Azure portal	Enable individual machines with the Azure portal.
Azure Policy	Create policy to automatically enable when a supported machine is created.
Resource Manager templates	Enable multiple machines using any of the supported methods to deploy a Resource Manager template such as CLI and PowerShell.
PowerShell	Use a PowerShell script to enable multiple machines. Log Analytics agent only.
Manual install	Virtual machines or physical computers on-premises other cloud environments. Log Analytics agent only

## Supported Azure Arc machines

VM insights is available for Azure Arc-enabled servers in regions where the Arc extension service is available. You must be running version 0.9 or above of the Arc Agent.

## Supported operating systems

VM insights supports any operating system that supports the Dependency agent and either the Azure Monitor agent (preview) or Log Analytics agent. See [Overview of Azure Monitor agents](#) for a complete list.

### IMPORTANT

If the ethernet device for your virtual machine has more than nine characters, then it won't be recognized by VM insights and data won't be sent to the InsightsMetrics table. The agent will collect data from [other sources](#).

### Linux considerations

See the following list of considerations on Linux support of the Dependency agent that supports VM insights:

- Only default and SMP Linux kernel releases are supported.
- Nonstandard kernel releases, such as Physical Address Extension (PAE) and Xen, aren't supported for any Linux distribution. For example, a system with the release string of *2.6.16.21-0.8-xen* isn't supported.
- Custom kernels, including recompilations of standard kernels, aren't supported.
- For Debian distros other than version 9.4, the map feature isn't supported, and the Performance feature is available only from the Azure Monitor menu. It isn't available directly from the left pane of the Azure VM.
- CentOSPlus kernel is supported.

The Linux kernel must be patched for the Spectre and Meltdown vulnerabilities. Please consult your Linux distribution vendor for more details. Run the following command to check for available if Spectre/Meltdown has been mitigated:

```
$ grep . /sys/devices/system/cpu/vulnerabilities/*
```

Output for this command will look similar to the following and specify whether a machine is vulnerable to either issue. If these files are missing, the machine is unpatched.

```
/sys/devices/system/cpu/vulnerabilities/meltdown:Mitigation: PTI
/sys/devices/system/cpu/vulnerabilities/spectre_v1:Vulnerable
/sys/devices/system/cpu/vulnerabilities/spectre_v2:Vulnerable: Minimal generic ASM retpoline
```

## Log Analytics workspace

VM insights requires a Log Analytics workspace. See [Configure Log Analytics workspace for VM insights](#) for details and requirements of this workspace.

### NOTE

VM Insights does not support sending data to more than one Log Analytics workspace (multi-homing).

## Network requirements

- See [Network requirements](#) for the network requirements for the Log Analytics agent.
- The dependency agent requires a connection from the virtual machine to the address 169.254.169.254. This is the Azure metadata service endpoint. Ensure that firewall settings allow connections to this endpoint.

## Agents

When you enable VM insights for a machine, the following agents are installed. See [Network requirements](#) for the network requirements for these agents.

### IMPORTANT

VM insights support for Azure Monitor agent is currently in public preview. Azure Monitor agent includes several advantages over Log Analytics agent, and is the preferred agent for virtual machines and virtual machine scale sets. See [Migrate to Azure Monitor agent from Log Analytics agent](#) for comparison of the agent and information on migrating.

- [Azure Monitor agent](#) or [Log Analytics agent](#). Collects data from the virtual machine or virtual machine scale set and delivers it to the Log Analytics workspace.
- Dependency agent. Collects discovered data about processes running on the virtual machine and external process dependencies, which are used by the [Map feature in VM insights](#). The Dependency agent relies on

the Azure Monitor agent or Log Analytics agent to deliver its data to Azure Monitor.

## Changes for Azure Monitor agent

There are several changes in the process for enabling VM insights when using the Azure Monitor agent.

**Workspace configuration.** You no longer need to [enable VM insights on the Log Analytics workspace](#) since the VM insights management pack isn't used by Azure Monitor agent.

**Data collection rule.** Azure Monitor agent uses [data collection rules](#) to configure its data collection. VM insights creates a data collection rule that is automatically deployed if you enable your machine using the Azure portal. If you use other methods to onboard your machines, then you may need to install the data collection rule first.

**Agent deployment.** There are minor changes to the process for onboarding virtual machines and virtual machine scale sets to VM insights in the Azure portal. You must now select which agent you want to use, and you must select a data collection rule for Azure Monitor agent. See [Enable VM insights in the Azure portal](#) for details.

## Data collection rule (Azure Monitor agent)

When you enable VM insights on a machine with the Azure Monitor agent you must specify a [data collection rule \(DCR\)](#) to use. The DCR specifies the data to collect and the workspace to use. VM insights creates a default DCR if one doesn't already exist. See [Enable VM insights for Azure Monitor agent](#) for more information on creating and editing the VM insights data collection rule.

### IMPORTANT

It's not recommended to create your own DCR to support VM insights. The DCR created by VM insights includes a special data stream required for its operation. While you can edit this DCR to collect additional data such as Windows and Syslog events, you should create additional DCRs and associate with the machine.

The DCR is defined by the options in the following table.

OPTION	DESCRIPTION
Guest performance	Specifies whether to collect performance data from the guest operating system. This is required for all machines.
Processes and dependencies	Collected details about processes running on the virtual machine and dependencies between machines. This enables the <a href="#">map feature in VM insights</a> . This is optional and enables the <a href="#">VM insights map feature</a> for the machine.
Log Analytics workspace	Workspace to store the data. Only workspaces with VM insights will be listed.

## Management packs (Log Analytics agent)

When a Log Analytics workspace is configured for VM insights, two management packs are forwarded to all the Windows computers connected to that workspace. The management packs are named *Microsoft.IntelligencePacks.ApplicationDependencyMonitor* and *Microsoft.IntelligencePacks.VMInsights* and are written to *%Programfiles%\Microsoft Monitoring Agent\Agent\Health Service State\Management Packs*.

The data source used by the *ApplicationDependencyMonitor* management pack is \*%Program files%\Microsoft

*Monitoring Agent\Agent\Health Service  
State\Resources<AutoGeneratedID>|Microsoft.EnterpriseManagement.Advisor.ApplicationDependencyMonitor  
DataSource.dll. The data source used by the VMInsights management pack is %Program files%\Microsoft  
Monitoring Agent\Agent\Health Service State\Resources<AutoGeneratedID>|  
Microsoft.VirtualMachineMonitoringModule.dll.*

## Migrate from Log Analytics agent

The Azure Monitor agent and the Log Analytics agent can both be installed on the same machine during migration. You should be careful that running both agents may lead to duplication of data and increased cost. If a machine has both agents installed, you'll have a warning in the Azure portal that you may be collecting duplicate data.

### WARNING

Collecting duplicate data from a single machine with both the Azure Monitor agent and Log Analytics agent can result in the following consequences:

- Additional ingestion cost from sending duplicate data to the Log Analytics workspace.
- The map feature of VM insights may be inaccurate since it does not check for duplicate data.

Name	Monitor Coverage	Data collection rule
my-subscription	2 of 20	
srv-01	<span style="color: orange;">!</span> Enabled	MSVMI-mydcr Configure using Azure Monitor Agent
srv-02	Enabled	
my-subscription-01	70 of 87	
my-subscription-02	1 of 1	

You must remove the Log Analytics agent yourself from any machines that are using it. Before you do this, ensure that the machine is not relying any other solutions that require the Log Analytics agent. See [Migrate to Azure Monitor agent from Log Analytics agent](#) for details.

After you verify that no Log Analytics agents are still connected to your Log Analytics workspace, you can [remove the VMInsights solution from the workspace](#) which is no longer needed.

### NOTE

To check if you have any machines with both agents sending data to your Log Analytics workspace, run the following log query in [Log Analytics](#). This will show the last heartbeat for each computer. If a computer has both agents, then it will return two records each with a different category. The Azure Monitor agent will have a category of *Azure Monitor Agent*. The Log Analytics agent will have a category of *Direct Agent*.

```
Heartbeat
| summarize max(TimeGenerated) by Computer, Category
| sort by Computer
```

## Diagnostic and usage data

Microsoft automatically collects usage and performance data through your use of the Azure Monitor service. Microsoft uses this data to improve the quality, security, and integrity of the service.

To provide accurate and efficient troubleshooting capabilities, the Map feature includes data about the configuration of your software. The data provides information such as the operating system and version, IP address, DNS name, and workstation name. Microsoft doesn't collect names, addresses, or other contact information.

For more information about data collection and usage, see the [Microsoft Online Services Privacy Statement](#).

**NOTE**

For information about viewing or deleting personal data, see [Azure Data Subject Requests for the GDPR](#). For more information about GDPR, see the [GDPR section of the Microsoft Trust Center](#) and the [GDPR section of the Service Trust portal](#).

## Next steps

To learn how to use the Performance monitoring feature, see [View VM insights Performance](#). To view discovered application dependencies, see [View VM insights Map](#).

# Enable VM insights in the Azure portal

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article describes how to enable VM insights using the Azure portal for the following :

- Azure virtual machine
- Azure virtual machine scale set
- Hybrid virtual machine connected with Azure Arc

## Prerequisites

- [Create a Log Analytics workspace](#). You can create a new workspace during this process, but you should use an existing workspace if you already have one. See [Log Analytics workspace overview](#) and [Design a Log Analytics workspace architecture](#) for more information.
- See [Supported operating systems](#) to ensure that the operating system of the virtual machine or virtual machine scale set you're enabling is supported.
- See [Manage the Azure Monitor agent](#) for prerequisites related to Azure Monitor agent.

### NOTE

This process describes enabling VM insights from the **Monitor** menu in the Azure portal. You can perform the same process from the **Insights** menu for a particular virtual machine or virtual machine scale set.

## View monitored and unmonitored machines

Open VM insights by selecting **Virtual Machines** from the **Monitor** menu in the Azure portal. The **Overview** page lists all of the virtual machines and virtual machine scale sets in the selected subscriptions. Machines will either be included in the **Monitored** or **Not monitored** tab depending on whether the machine is currently being monitored by VM insights.

A machine may be listed in **Not monitored** even though it has the Azure Monitor or Log Analytics agent installed but has not been enabled for VM insights. If a virtual machine has the Log Analytics agent installed but not the Dependency agent, it will be listed as not monitored. In this case, the Azure Monitor agent will be started without being given the option for the Log Analytics agent.

### NOTE

**Data collection rule** column has replaced the **Workspace** column on the **Overview** page to support the [Azure Monitor agent](#). This either shows the data collection rules used by the Azure Monitor agent for each machine, or it gives the option to configure with the Azure Monitor agent.

## Enable VM insights for Azure Monitor agent

### NOTE

A system-assigned managed identity will be added for a machine as part of the installation process of the Azure Monitor agent if one doesn't already exist.

Use this procedure to enable an unmonitored virtual machine or virtual machine scale set using Azure Monitor agent.

1. Select **Virtual Machines** from the **Monitor** menu in the Azure portal.
2. From the **Overview** page, select **Not Monitored**.
3. Click the **Enable** button next to any machine that you want to enable. If a machine is currently running, then you must start it to enable it.

The screenshot shows the Azure Monitor interface for Virtual Machines. The left sidebar has 'Virtual Machines' selected. The main area shows 'Not monitored (30)' VMs. For 'srv-lx-01', the 'Enable' button is highlighted in blue.

4. Click **Enable** on the introduction page to view the configuration.
5. Select **Azure Monitor agent** from the **Monitoring configuration** page and then select **Azure Monitor agent**.
6. If a **data collection rule (DCR)** hasn't already been created for unmonitored machines, then one will be created with the following details.
  - **Guest performance** enabled.
  - **Processes and dependencies** disabled.
7. If you want this configuration, then click **Configure** to start the agent installation, or select a different data collection rule from the dropdown. Only data collection rules enabled for VM insights will be included.
8. If you want a different configuration or want to use a different Log Analytics workspace, then click **Create new** to create a new data collection rule. This will allow you to select a workspace and specify whether you want to collect processes and dependencies to enable the **map feature in VM insights**.

The screenshot shows the 'Create new rule' dialog. It includes fields for 'Data collection rule name' (set to 'my-dcr'), 'Guest performance' (checkbox checked), 'Processes and dependencies' (checkbox checked), and 'Log Analytics workspaces' (set to 'my-workspace'). At the bottom are 'Configure' and 'Cancel' buttons.

6. Click **Configure** to start the configuration process. It will take several minutes for the agent to be installed and data to start being collected. You'll receive status messages as the configuration is performed.
7. If you use a manual upgrade model for your virtual machine scale set, upgrade the instances to complete the setup. You can start the upgrades from the **Instances** page, in the **Settings** section.

## Enable VM insights for Log Analytics agent

Use this procedure to enable an unmonitored virtual machine or virtual machine scale set using Log Analytics agent.

1. Select **Virtual Machines** from the **Monitor** menu in the Azure portal.
2. From the **Overview** page, select **Not Monitored**.
3. Click the **Enable** button next to any machine that you want to enable. If a machine is currently running, then you must start it to enable it.

Name	Monitor Coverage	Workspace
my-vm	30 of 36	
srv-lx-01	Not enabled	<b>Enable</b>
srv-lx-02	Cannot enable - Virtual machine is not running (Why?)	bren

3. Click **Enable** on the introduction page to view the configuration.
4. Select **Azure Monitor agent** from the **Monitoring configuration** page and then select **Log Analytics agent**.
5. If the virtual machine isn't already connected to a Log Analytics workspace, then you'll be prompted to select one. If you haven't previously [created a workspace](#), then you can select a default for the location where the virtual machine or virtual machine scale set is deployed in the subscription. This workspace will be created and configured if it doesn't already exist. If you select an existing workspace, it will be configured for VM insights if it wasn't already.

### NOTE

If you select a workspace that wasn't previously configured for VM insights, the *VMInsights* management pack will be added to this workspace. This will be applied to any agent already connected to the workspace, whether or not it's enabled for VM insights. Performance data will be collected from these virtual machines and stored in the *InsightsMetrics* table.

6. Click **Configure** to modify the configuration. The only option you can modify is the workspace. You will receive status messages as the configuration is performed.
7. If you use a manual upgrade model for your virtual machine scale set, upgrade the instances to complete the setup. You can start the upgrades from the **Instances** page, in the **Settings** section.

## Enable Azure Monitor agent on monitored machines

Use this procedure to add the Azure Monitor agent to machines that are already enabled with the Log Analytics agent.

1. Select **Virtual Machines** from the **Monitor** menu in the Azure portal.
2. From the **Overview** page, select **Monitored**.
3. Click **Configure using Azure Monitor agent** next to any machine that you want to enable. If a machine is currently running, then you must start it to enable it.

The screenshot shows the Azure portal's 'Monitored' section. At the top, there are filters for Subscription (43 subscriptions), Resource group (All resource groups), Type (All types), and Location (All locations). Below the filters, there are tabs for 'Monitored' (73), 'Not monitored' (45), 'Workspace configuration', and 'Other onboarding options'. The main table lists resources by name, monitor coverage, and data collection rule. A red box highlights the 'Configure using Azure Monitor Agent' button for the 'srv-02' machine under the 'my-resource-group' entry.

4. Follow the process described in [Enable VM insights for Azure Monitor agent](#) to select a data collection rule. The only difference is that the data collection rule hasn't created for monitored machines has **Processes and dependencies** enabled for backward compatibility with the Log Analytics agent.

The screenshot shows the 'Monitoring configuration' dialog. On the left, the Azure portal navigation bar is visible with 'Monitor' selected. The main area shows a list of resources under 'my-subscription' and 'my-workspace'. On the right, the 'Monitoring configuration' dialog is open, showing the 'Data collection rule' dropdown set to 'MSVMI-my-workspace'. The 'Processes and dependencies' checkbox is checked. A note at the bottom states: 'This will also enable System Assigned Managed Identity, in addition to existing User Assigned identities (if any). Note: Unless specified in the request, the machine will default to using System Assigned Identity. Learn More'. Buttons for 'Configure' and 'Cancel' are at the bottom.

5. With both agents installed, a warning will be displayed indicating that you may be collecting duplicate data.

Get Started   Performance   Map

Filter by name...   Subscription : 43 subscriptions   Resource group : All resource groups   Type : All types   Location : All locations

Monitored (73)   Not monitored (45)   Workspace configuration   Other onboarding options

Name	Monitor Coverage	Data collection rule
my-subscription	2 of 20	
srv-01	<span style="color: orange;">⚠ Enabled</span>	MSVMI-mydcr
srv-02	Enabled	Configure using Azure Monitor Agent
my-subscription-01	70 of 87	
my-subscription-02	1 of 1	

The virtual machine is onboarded via Microsoft monitoring agent as well as Azure Monitoring agent resulting in duplication of data and increase cost.

### WARNING

Collecting duplicate data from a single machine with both the Azure Monitor agent and Log Analytics agent can result in the following consequences:

- Additional ingestion cost from sending duplicate data to the Log Analytics workspace.
- The map feature of VM insights may be inaccurate since it does not check for duplicate data.

See [Migrate from Log Analytics agent](#).

6. Once you've verified that the Azure Monitor agent has been enabled, remove the Log Analytics agent from the machine to prevent duplicate data collection.

## Next steps

- See [Use VM insights Map](#) to view discovered application dependencies.
- See [View Azure VM performance](#) to identify bottlenecks, overall utilization, and your VM's performance.

# Enable VM insights by using Azure Policy

9/21/2022 • 7 minutes to read • [Edit Online](#)

This article explains how to enable VM insights for Azure virtual machines or hybrid virtual machine connected with Azure Arc (preview) using Azure Policy. Azure Policy allows you to assign policy definitions that install the required agents for VM insights across your Azure environment and automatically enable monitoring for VMs as each virtual machine is created. VM insights provides a feature that allows you to discover and remediate noncompliant VMs in your environment. Use this feature instead of working directly with Azure Policy.

If you're not familiar with Azure Policy, get a brief introduction at [Deploy Azure Monitor at scale using Azure Policy](#).

## NOTE

This article describes VM insights using the Log Analytics agent. VM insights with the Azure Monitor agent is currently in public preview. See [Enable VM insights overview](#) for details on installing with this agent.

## NOTE

To use Azure Policy with Azure virtual machine scale sets, or to work with Azure Policy directly to enable Azure virtual machines, see [Deploy Azure Monitor at scale using Azure Policy](#).

## VM insights initiatives

VM insights provides builtin policy definitions to install the Log Analytics agent and Dependency agent on Azure virtual machines. The following built-in initiatives install both agents to enable full monitoring. Assign these initiatives to a management group, subscription, or resource group to automatically install the agents on any Windows or Linux Azure virtual machines in that scope.

NAME	DESCRIPTION
Enable VM insights	Installs the Log Analytics agent and Dependency agent on Azure VMs and hybrid VMs connected with Azure Arc.
Enable Azure Monitor for virtual machine scale sets	Installs the Log Analytics agent and Dependency agent on Azure virtual machine scale sets.

## Open Policy Coverage feature

To access **VM insights Policy Coverage**, go the **Virtual machines** in the **Azure Monitor** menu in the Azure portal. Select **Other onboarding options** and then **Enable** under **Enable using policy**.

Monitor | Virtual Machines

Get Started

15 Monitored 114 Not monitored Workspace configuration Other onboarding options

Enable for a single VM

Use the 'Not Monitored' tab to identify and enable insights for Azure VMs. You will need contributor access on the VM, and Log Analytics contributor access on the Resource Group of your chosen Log Analytics workspace.

Optional: List of VM images that have supported Linux OS to add to scope [\(i\)](#)

**Review + create**

Click **Review + Create** to review the details of the assignment before clicking **Create** to create it. Don't create a remediation task at this point since you will most likely need multiple remediation tasks to enable existing virtual machines. See [Remediate compliance results](#) below.

### Review compliance

Once an assignment is created, you can review and manage coverage for the **Enable VM insights** initiative across your management groups and subscriptions. This will show how many virtual machines exist in each of the management groups or subscriptions and their compliance status.

The screenshot shows the Azure Monitor for VMs Policy Coverage initiative page. At the top, there's a search bar labeled "Search by name or ID". Below it, a section titled "Tenant Root Group (details)" shows a single entry: "IT Organization Mgmt Group" with "Owner" role, "16" total VMs, and "100%" assignment coverage, marked as "Complete". To the right, a summary table provides overall compliance statistics: 5 compliant VMs (31%) and 1 non-compliant VM (69%).

The following table provides a description of the information in this view.

FUNCTION	DESCRIPTION
Scope	Management group and subscriptions that you have or inherited access to with ability to drill down through the management group hierarchy.
Role	Your role in the scope, which might be reader, owner, or contributor. This will be blank if you have access to the subscription but not to the management group it belongs to. This role determines what data you can see and actions you can perform in terms of assigning policies or initiatives (owner), editing them, or viewing compliance.
Total VMs	Total number of VMs in that scope regardless of their status. For a management group, this is a sum total of VMs nested under the subscriptions or child management groups.
Assignment Coverage	Percent of VMs that are covered by the initiative.
Assignment Status	<p><b>Success</b> - All VMs in the scope have the Log Analytics and Dependency agents deployed to them.</p> <p><b>Warning</b> - The subscription isn't under a management group.</p> <p><b>Not Started</b> - A new assignment was added.</p> <p><b>Lock</b> - You don't have sufficient privileges to the management group.</p> <p><b>Blank</b> - No VMs exist or a policy isn't assigned.</p>
Compliant VMs	Number of VMs that are compliant, which is the number of VMs that have both Log Analytics agent and Dependency agent installed. This will be blank if there are no assignments, no VMs in the scope, or not proper permissions.
Compliance	The overall compliance number is the sum of distinct resources that are compliant divided by the sum of all distinct resources.
Compliance State	<p><b>Compliant</b> - All VMs in the scope virtual machines have the Log Analytics and Dependency agents deployed to them or any new VMs in the scope subject to the assignment have not yet been evaluated.</p> <p><b>Non-compliant</b> - There are VMs that have been evaluated but are not enabled and may require remediation.</p> <p><b>Not Started</b> - A new assignment was added.</p> <p><b>Lock</b> - You don't have sufficient privileges to the management group.</p> <p><b>Blank</b> - No policy is assigned.</p>

When you assign the initiative, the scope selected in the assignment could be the scope listed or a subset of it. For instance, you might have created an assignment for a subscription (policy scope) and not a management group (coverage scope). In this case, the value of **Assignment Coverage** indicates the VMs in the initiative scope divided by the VMs in coverage scope. In another case, you might have excluded some VMs, resource groups, or a subscription from policy scope. If the value is blank, it indicates that either the policy or initiative doesn't exist or you don't have permission. Information is provided under **Assignment Status**.

## Remediate compliance results

The initiative will be applied to virtual machines as they're created or modified, but it won't be applied to existing VMs. If your assignment doesn't show 100% compliance, create remediation tasks to evaluate and enable existing VMs, select **View Compliance** by selecting the ellipsis (...).

The screenshot shows the 'Azure Monitor for VMs Policy Coverage' page. At the top, there's a search bar and navigation links for Refresh, Configure Workspace, and Provide Feedback. Below that, a message says 'Assess your management groups and subscriptions that do not have the Azure Monitor for VMs agent deployment initiative assigned.' A 'Learn more' link is provided. The main table has columns: Scope, My Role, Total VMs, Assignment Covera..., Assignment Status, Compliant VMs, Compliance, and Compliance State. One row shows 'My Mgmt Group' as the scope, 'Owner' as the role, 5 total VMs, 100% coverage (green), 'Complete' status, 4 compliant VMs, 80% compliance, and 'Non-compliant' state. A context menu is open over this row, listing 'Assign Policy', 'Edit Assignment', 'View Compliance' (which is highlighted with a red box), and 'Learn more'. There's also a '...' option at the end of the menu.

The **Compliance** page lists assignments matching the specified filter and whether they're compliant. Click on an assignment to view its details.

The screenshot shows the 'Policy | Compliance' page. On the left, there's a sidebar with links like Home, Overview, Getting started, Join Preview, Compliance (which is selected and highlighted in grey), Remediation, Authoring, Assignments (which is selected and highlighted in grey), Definitions, Related Services, Blueprints (preview), and Resource Graph. The main area has sections for Overall resource compliance (80%, 4 out of 5), Non-compliant initiatives (1, 1 out of 1), Non-compliant policies (1, 1 out of 10), and Non-compliant resources (1, 1 out of 5). Below these is a table for 'Non-Compliant Resource Details'. The first row shows an assignment named 'Enable Azure Monitor for VMs' with scope 'My Mgmt Group', status 'Non-compliant', and compliance '80% (4 out of 5)'. A context menu is open over this row, with the 'View Compliance' option highlighted with a red box. There are also 'Assign policy', 'Edit assignment', and 'Learn more' options in the menu.

The **Initiative compliance** page lists the policy definitions in the initiative and whether each is in compliance.

Home > Enable Azure Monitor for VMs

Initiative compliance

Compliance state: Non-compliant (80% out of 5)

Overall resource compliance: 80% (4 out of 5)

Audit Dependency agent deployment - VM Image (OS) unlisted	AuditIfNotExists	Compliant	0	0
<b>Deploy Dependency agent for Linux virtual machines</b>	DeployIfNotExists	Non-compliant	1	2
Deploy Dependency agent for Windows virtual machines	DeployIfNotExists	Compliant	0	3
Deploy Log Analytics agent for Linux VMs	DeployIfNotExists	Compliant	0	2
Deploy Log Analytics agent for Windows VMs	DeployIfNotExists	Compliant	0	3

Click on a policy definition to view its details. Scenarios that policy definitions will show as out of compliance include the following:

- Log Analytics agent or Dependency agent isn't deployed. Create a remediation task to mitigate.
- VM image (OS) isn't identified in the policy definition. The criteria of the deployment policy include only VMs that are deployed from well-known Azure VM images. Check the documentation to see whether the VM OS is supported.
- VMs aren't logging to the specified Log Analytics workspace. Some VMs in the initiative scope are connected to a Log Analytics workspace other than the one that's specified in the policy assignment.

7/7/2020, 3:50 PM	In Progress	Deploy Log Analytics agent for Linux VMs	My Mgmt Group	All	0 out of 2

Once the remediation tasks are complete, your VMs should be compliant with agents installed and enabled for VM insights.

## Azure Policy

To use Azure Policy to enable monitoring for virtual machine scale sets, assign the **Enable Azure Monitor for Virtual Machine Scale Sets** initiative to an Azure management group, subscription, or resource group, depending on the scope of your resources to monitor. A **management group** is useful for scoping policy, especially if your organization has multiple subscriptions.

## Next steps

Now that monitoring is enabled for your virtual machines, this information is available for analysis with VM insights.

- To view discovered application dependencies, see [View VM insights Map](#).
- To identify bottlenecks and overall utilization with your VM's performance, see [View Azure VM performance](#).

# Enable VM insights using PowerShell

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article describes how to enable VM insights on Azure virtual machines using PowerShell. This procedure can be used for the following:

- Azure virtual machine
- Azure virtual machine scale set

## NOTE

This article only applies to the Log Analytics agent. To enable VM insights with the Azure monitor agent, use other installation methods described in [Enable VM insights overview](#).

## Prerequisites

- [Create and configure a Log Analytics workspace](#).
- See [Supported operating systems](#) to ensure that the operating system of the virtual machine or virtual machine scale set you're enabling is supported.

## PowerShell script

To enable VM insights for multiple VMs or virtual machine scale sets, use the PowerShell script [Install-VMInsights.ps1](#), which is available from the Azure PowerShell Gallery. This script iterates through:

- Every virtual machine and virtual machine scale set in your subscription.
- The scoped resource group that's specified by *ResourceGroup*.
- A single VM or virtual machine scale set that's specified by *Name*.

For each virtual machine or virtual machine scale set, the script verifies whether the VM extension for the Log Analytics agent and Dependency agent is already installed. If both extensions are installed, the script tries to reinstall it. If both extensions aren't installed, the script installs them.

Verify you are using Azure PowerShell module Az version 1.0.0 or later with `Enable-AzModule` compatibility aliases enabled. Run `Get-Module -ListAvailable Az` to find the version. If you need to upgrade, see [Install Azure PowerShell module](#). If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

To get a list of the script's argument details and example usage, run `Get-Help`.

```
Get-Help .\Install-VMInsights.ps1 -Detailed
```

### SYNOPSIS

This script installs VM extensions for Log Analytics and the Dependency agent as needed for VM Insights.

### SYNTAX

```
.\Install-VMInsights.ps1 [-WorkspaceId] <String> [-WorkspaceKey] <String> [-SubscriptionId] <String> [[-ResourceGroup] <String>] [[-Name] <String>] [[-PolicyAssignmentName] <String>] [-ReInstall] [-TriggerVmssManualVMUpdate] [-Approve] [-WorkspaceRegion] <String> [-WhatIf] [-Confirm] [<CommonParameters>]
```

## DESCRIPTION

This script installs or reconfigures the following on VMs and virtual machine scale sets:

- Log Analytics VM extension configured to supplied Log Analytics workspace
- Dependency agent VM extension

Can be applied to:

- Subscription
- Resource group in a subscription
- Specific VM or virtual machine scale set
- Compliance results of a policy for a VM or VM extension

Script will show you a list of VMs or virtual machine scale sets that will apply to and let you confirm to continue.

Use -Approve switch to run without prompting, if all required parameters are provided.

If the extensions are already installed, they will not install again.

Use -ReInstall switch if you need to, for example, update the workspace.

Use -WhatIf if you want to see what would happen in terms of installs, what workspace configured to, and status of the extension.

## PARAMETERS

-WorkspaceId <String>

Log Analytics WorkspaceID (GUID) for the data to be sent to

-WorkspaceKey <String>

Log Analytics Workspace primary or secondary key

-SubscriptionId <String>

SubscriptionId for the VMs/VM Scale Sets

If using PolicyAssignmentName parameter, subscription that VMs are in

-ResourceGroup <String>

<Optional> Resource Group to which the VMs or VM Scale Sets belong

-Name <String>

<Optional> To install to a single VM/VM Scale Set

-PolicyAssignmentName <String>

<Optional> Take the input VMs to operate on as the Compliance results from this Assignment

If specified will only take from this source.

-ReInstall [<SwitchParameter>]

<Optional> If VM/VM Scale Set is already configured for a different workspace, set this to change to the new workspace

-TriggerVmssManualVMUpdate [<SwitchParameter>]

<Optional> Set this flag to trigger update of VM instances in a scale set whose upgrade policy is set to Manual

-Approve [<SwitchParameter>]

<Optional> Gives the approval for the installation to start with no confirmation prompt for the listed VMs/VM Scale Sets

-WorkspaceRegion <String>

Region the Log Analytics Workspace is in

Supported values: "East US","eastus","Southeast Asia","southeastasia","West Central US","westcentralus","West Europe","westeurope"

For Health supported is: "East US","eastus","West Central US","westcentralus"

-WhatIf [<SwitchParameter>]

<Optional> See what would happen in terms of installs.

If extension is already installed will show what workspace is currently configured, and status of the VM extension

-Confirm [<SwitchParameter>]

<Optional> Confirm every action

```
<CommonParameters>
    This cmdlet supports the common parameters: Verbose, Debug,
    ErrorAction, ErrorVariable, WarningAction, WarningVariable,
    OutBuffer, PipelineVariable, and OutVariable. For more information, see
    about_CommonParameters (https://go.microsoft.com/fwlink/?LinkID=113216).

----- EXAMPLE 1 -----
.\Install-VMInsights.ps1 -WorkspaceRegion eastus -WorkspaceId <WorkspaceId> -WorkspaceKey <WorkspaceKey>
-SubscriptionId <SubscriptionId>
-ResourceGroup <ResourceGroup>

Install for all VMs in a resource group in a subscription

----- EXAMPLE 2 -----
.\Install-VMInsights.ps1 -WorkspaceRegion eastus -WorkspaceId <WorkspaceId> -WorkspaceKey <WorkspaceKey>
-SubscriptionId <SubscriptionId>
-ResourceGroup <ResourceGroup> -ReInstall

Specify to reinstall extensions even if already installed, for example, to update to a different
workspace

----- EXAMPLE 3 -----
.\Install-VMInsights.ps1 -WorkspaceRegion eastus -WorkspaceId <WorkspaceId> -WorkspaceKey <WorkspaceKey>
-SubscriptionId <SubscriptionId>
-PolicyAssignmentName a4f79f8ce891455198c08736 -ReInstall

Specify to use a PolicyAssignmentName for source and to reinstall (move to a new workspace)
```

The following example demonstrates using the PowerShell commands in the folder to enable VM insights and understand the expected output:

```

$WorkspaceId = "<GUID>"
$WorkspaceKey = "<Key>"
$SubscriptionId = "<GUID>"
.\Install-VMInsights.ps1 -WorkspaceId $WorkspaceId -WorkspaceKey $WorkspaceKey -SubscriptionId
$SubscriptionId -WorkspaceRegion eastus

Getting list of VMs or virtual machine scale sets matching criteria specified

VMs or virtual machine scale sets matching criteria:

db-ws-1 VM running
db-ws2012 VM running

This operation will install the Log Analytics and Dependency agent extensions on the previous two VMs or
virtual machine scale sets.
VMs in a non-running state will be skipped.
Extension will not be reinstalled if already installed. Use -ReInstall if desired, for example, to update
workspace.

- See [Use VM insights Map](#) to view discovered application dependencies.
- See [View Azure VM performance](#) to identify bottlenecks, overall utilization, and your VM's performance.

# Enable VM insights for a hybrid virtual machine

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article describes how to enable VM insights for a virtual machine outside of Azure, including on-premises and other cloud environments.

## IMPORTANT

The recommended method of enabling hybrid VMs is first enabling [Azure Arc for servers](#) so that the VMs can be enabled for VM insights using processes similar to Azure VMs. This article describes how to onboard hybrid VMs if you choose not to use Azure Arc.

## NOTE

This article describes VM insights using the Log Analytics agent. VM insights with the Azure Monitor agent is currently in public preview. See [Enable VM insights overview](#) for details on installing with this agent.

## Prerequisites

- [Create and configure a Log Analytics workspace](#).
- See [Supported operating systems](#) to ensure that the operating system of the virtual machine or virtual machine scale set you're enabling is supported.

## Overview

Virtual machines outside of Azure require the same Log Analytics agent and Dependency agent that are used for Azure VMs. Since you can't use VM extensions to install the agents though, you must manually install them in the guest operating system or have them installed through some other method.

See [Connect Windows computers to Azure Monitor](#) or [Connect Linux computers to Azure Monitor](#) for details on deploying the Log Analytics agent. Details for the Dependency agent are provided in this article.

## Firewall requirements

Firewall requirements for the Log Analytics agent are provided in [Log Analytics agent overview](#). The VM insights Map Dependency agent doesn't transmit any data itself, and it doesn't require any changes to firewalls or ports. The Map data is always transmitted by the Log Analytics agent to the Azure Monitor service, either directly or through the [Operations Management Suite gateway](#) if your IT security policies don't allow computers on the network to connect to the internet.

## Dependency agent

### NOTE

The following information described in this section is also applicable to the [Service Map solution](#).

You can download the Dependency agent from these locations:

FILE	OS	VERSION	SHA-256
<a href="#">InstallDependencyAgent-Windows.exe</a>	Windows	9.10.14.20760	D4DB398FAD36E86FEACCC 41D7B8AF46711346A9438 06769B6CE017F0BF1625FF
<a href="#">InstallDependencyAgent-Linux64.bin</a>	Linux	9.10.14.20760	3DE3B485BA79B57E74B3D FB60FD277A30C8A5D1BD 898455AD77FECF20E0E26 10

## Install the Dependency agent on Windows

You can install the Dependency agent manually on Windows computers by running

`InstallDependencyAgent-Windows.exe`. If you run this executable file without any options, it starts a setup wizard that you can follow to install the agent interactively. You require *Administrator* privileges on the guest OS to install or uninstall the agent.

The following table highlights the parameters that are supported by setup for the agent from the command line.

PARAMETER	DESCRIPTION
<code>/?</code>	Returns a list of the command-line options.
<code>/S</code>	Performs a silent installation with no user interaction.

For example, to run the installation program with the `/?` parameter, enter `InstallDependencyAgent-Windows.exe /?`.

Files for the Windows Dependency agent are installed in `C:\Program Files\Microsoft Dependency Agent` by default. If the Dependency agent fails to start after setup is finished, check the logs for detailed error information. The log directory is `%Programfiles%\Microsoft Dependency Agent\logs`.

### PowerShell script

Use the following sample PowerShell script to download and install the agent:

```
Invoke-WebRequest "https://aka.ms/dependencyagentwindows" -OutFile InstallDependencyAgent-Windows.exe
.\InstallDependencyAgent-Windows.exe /S
```

## Install the Dependency agent on Linux

The Dependency agent is installed on Linux servers from `InstallDependencyAgent-Linux64.bin`, a shell script with a self-extracting binary. You can run the file by using `sh` or add execute permissions to the file itself.

### NOTE

Root access is required to install or configure the agent.

PARAMETER	DESCRIPTION
<code>-help</code>	Get a list of the command-line options.

PARAMETER	DESCRIPTION
-s	Perform a silent installation with no user prompts.
--check	Check permissions and the operating system, but don't install the agent.

For example, to run the installation program with the `-help` parameter, enter **InstallDependencyAgent-Linux64.bin -help**. Install the Linux Dependency agent as root by running the command  
`sh InstallDependencyAgent-Linux64.bin`.

If the Dependency agent fails to start, check the logs for detailed error information. On Linux agents, the log directory is `/var/opt/microsoft/dependency-agent/log`.

Files for the Dependency agent are placed in the following directories:

FILES	LOCATION
Core files	<code>/opt/microsoft/dependency-agent</code>
Log files	<code>/var/opt/microsoft/dependency-agent/log</code>
Config files	<code>/etc/opt/microsoft/dependency-agent/config</code>
Service executable files	<code>/opt/microsoft/dependency-agent/bin/microsoft-dependency-agent</code> <code>/opt/microsoft/dependency-agent/bin/microsoft-dependency-agent-manager</code>
Binary storage files	<code>/var/opt/microsoft/dependency-agent/storage</code>

## Shell script

Use the following sample shell script to download and install the agent:

```
wget --content-disposition https://aka.ms/dependencyagentlinux -O InstallDependencyAgent-Linux64.bin
sudo sh InstallDependencyAgent-Linux64.bin -s
```

## Desired State Configuration

To deploy the Dependency agent using Desired State Configuration (DSC), you can use the `xPSDesiredStateConfiguration` module with the following example code:

```

configuration VMInsights {

    Import-DscResource -ModuleName xPSDesiredStateConfiguration

    $DAPackageLocalPath = "C:\InstallDependencyAgent-Windows.exe"

    Node localhost
    {
        # Download and install the Dependency agent
        xRemoteFile DAPackage
        {
            Uri = "https://aka.ms/dependencyagentwindows"
            DestinationPath = $DAPackageLocalPath
        }

        xPackage DA
        {
            Ensure="Present"
            Name = "Dependency Agent"
            Path = $DAPackageLocalPath
            Arguments = '/S'
            ProductId = ""
            InstalledCheckRegKey =
            "HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Microsoft\Windows\CurrentVersion\Uninstall\DependencyAgent"
            InstalledCheckRegValueName = "DisplayName"
            InstalledCheckRegValueData = "Dependency Agent"
            DependsOn = "[xRemoteFile]DAPackage"
        }
    }
}

```

## Troubleshooting

### VM doesn't appear on the map

If your Dependency agent installation succeeded, but you don't see your computer on the map, diagnose the problem by following these steps.

1. Is the Dependency agent installed successfully? You can validate this by checking to see if the service is installed and running.

**Windows:** Look for the service named "Microsoft Dependency agent."

**Linux:** Look for the running process "microsoft-dependency-agent."

2. Are you on the [Free pricing tier of Log Analytics](#)? The Free plan allows for up to five unique computers. Any subsequent computers won't show up on the map, even if the prior five are no longer sending data.
3. Is the computer sending log and perf data to Azure Monitor Logs? Perform the following query for your computer:

```
Usage | where Computer == "computer-name" | summarize sum(Quantity), any(QuantityUnit) by DataType
```

Did it return one or more results? Is the data recent? If so, your Log Analytics agent is operating correctly and communicating with the service. If not, check the agent on your server: [Log Analytics agent for Windows troubleshooting](#) or [Log Analytics agent for Linux troubleshooting](#).

### Computer appears on the map but has no processes

If you see your server on the map, but it has no process or connection data, that indicates that the Dependency agent is installed and running, but the kernel driver didn't load.

Check the C:\Program Files\Microsoft Dependency Agent\logs\wrapper.log file (Windows) or /var/opt/microsoft/dependency-agent/log/service.log file (Linux). The last lines of the file should indicate why the kernel didn't load. For example, the kernel might not be supported on Linux if you updated your kernel.

## Next steps

Now that monitoring is enabled for your virtual machines, this information is available for analysis with VM insights.

- To view discovered application dependencies, see [View VM insights Map](#).
- To identify bottlenecks and overall utilization with your VM's performance, see [View Azure VM performance](#).

# Use the Map feature of VM insights to understand application components

9/21/2022 • 7 minutes to read • [Edit Online](#)

In VM insights, you can view discovered application components on Windows and Linux virtual machines (VMs) that run in Azure or your environment. You can observe the VMs in two ways. View a map directly from a VM or view a map from Azure Monitor to see the components across groups of VMs. This article will help you understand these two viewing methods and how to use the Map feature.

For information about configuring VM insights, see [Enable VM insights](#).

## Prerequisites

To enable the map feature in VM insights, the virtual machine requires one of the following. See [Enable VM insights on unmonitored machine](#) for details on each.

- Azure Monitor agent with **processes and dependencies** enabled.
- Log Analytics agent enabled for VM insights.

### WARNING

Collecting duplicate data from a single machine with both the Azure Monitor agent and Log Analytics agent can result in the map feature of VM insights being inaccurate since it does not check for duplicate data.

See [Migrate from Log Analytics agent](#) for more information.

## Introduction to the Map experience

Before diving into the Map experience, you should understand how it presents and visualizes information. Whether you select the Map feature directly from a VM or from Azure Monitor, the Map feature presents a consistent experience. The only difference is that from Azure Monitor, one map shows all the members of a multiple-tier application or cluster.

The Map feature visualizes the VM dependencies by discovering running processes that have:

- Active network connections between servers.
- Inbound and outbound connection latency.
- Ports across any TCP-connected architecture over a specified time range.

Expand a VM to show process details and only those processes that communicate with the VM. The client group shows the count of front-end clients that connect into the VM. The server-port groups show the count of back-end servers the VM connects to. Expand a server-port group to see the detailed list of servers that connect over that port.

When you select the VM, the **Properties** pane on the right shows the VM's properties. Properties include system information reported by the operating system, properties of the Azure VM, and a doughnut chart that summarizes the discovered connections.

> Azure VM Properties

Properties Log Events Alerts

On the right side of the pane, select **Log Events** to show a list of data that the VM has sent to Azure Monitor. This data is available for querying. Select any record type to open the **Logs** page, where you see the results for that record type. You also see a preconfigured query that's filtered against the VM.

» DC01.Corp.Swanson.Local  
Machine Log Events

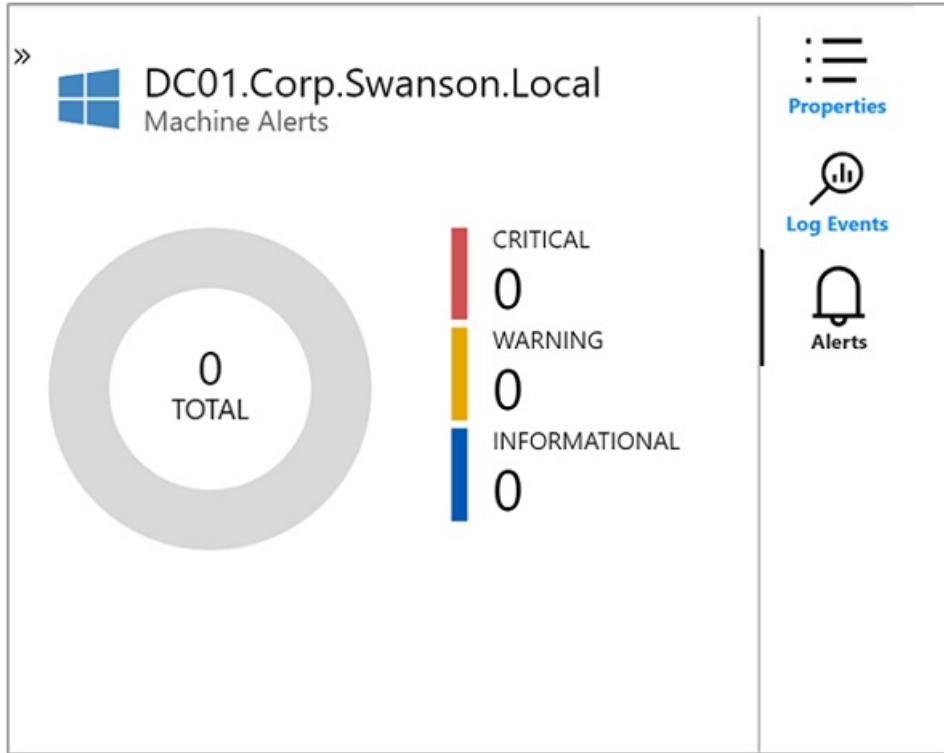

Select an event type to open in Log Analytics

EVENT TYPE	COUNT
Alert	5
Heartbeat	29
Perf	7334
ServiceMapComputer_CL	5
ServiceMapProcess_CL	9
Usage	13
VMConnection	556

Properties Log Events Alerts

Close the **Logs** page and return to the **Properties** pane. There, select **Alerts** to view VM health-criteria alerts. The Map feature integrates with Azure Alerts to show alerts for the selected server in the selected time range.

The server displays an icon for current alerts, and the **Machine Alerts** pane lists the alerts.

To make the Map feature display relevant alerts, create an alert rule that applies to a specific computer:

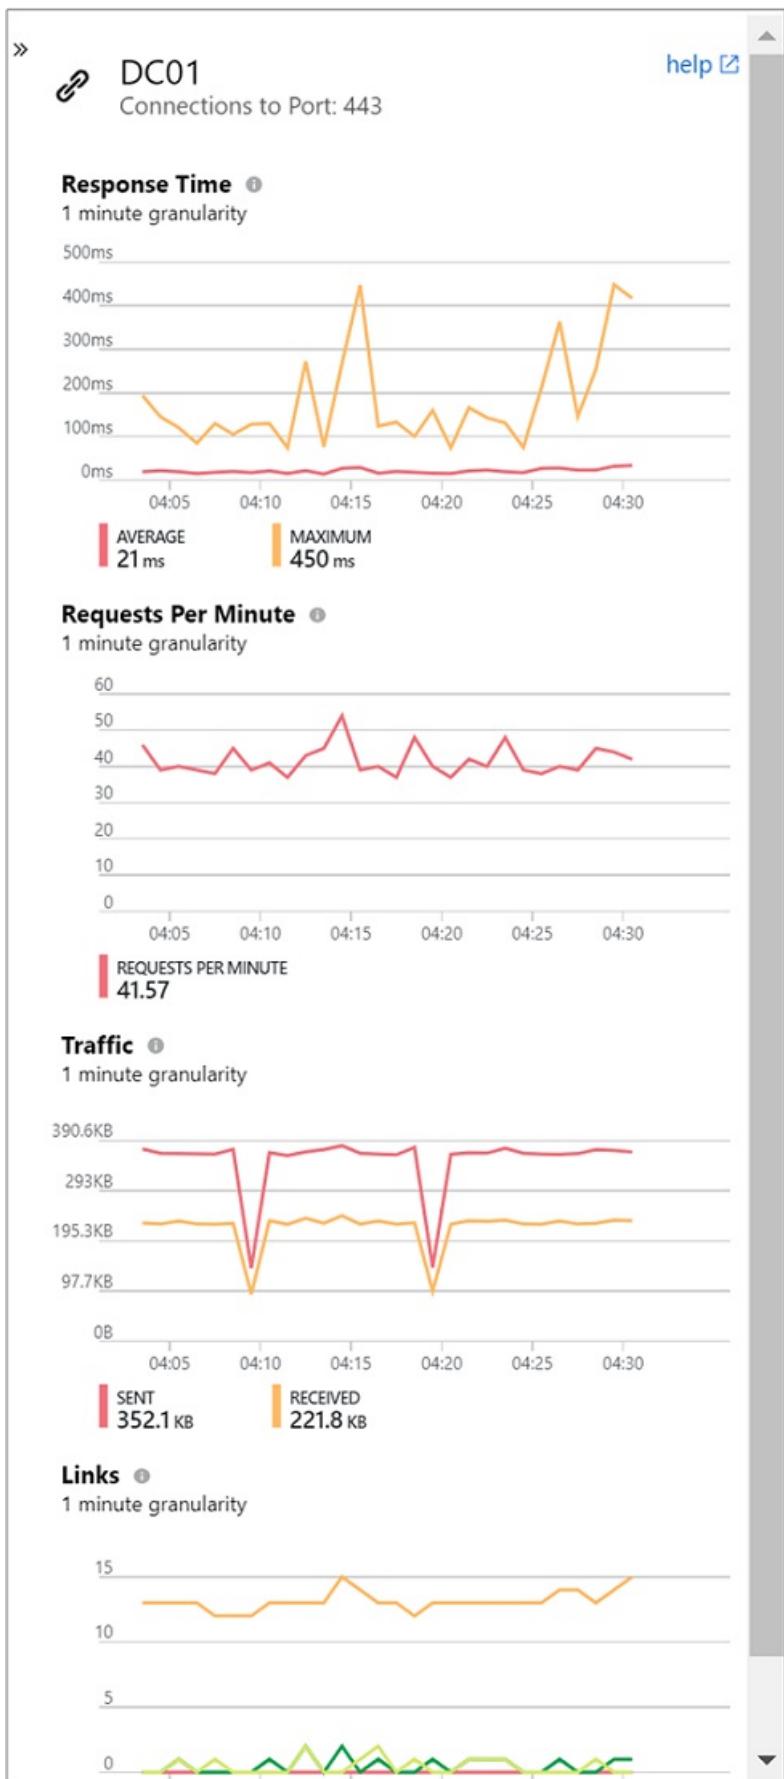

- Include a clause to group alerts by computer (for example, by **Computer interval 1 minute**).
- Base the alert on a metric.

For more information about Azure Alerts and creating alert rules, see [Unified alerts in Azure Monitor](#).

In the upper-right corner, the **Legend** option describes the symbols and roles on the map. For a closer look at your map and to move it around, use the zoom controls in the lower-right corner. You can set the zoom level and fit the map to the size of the page.

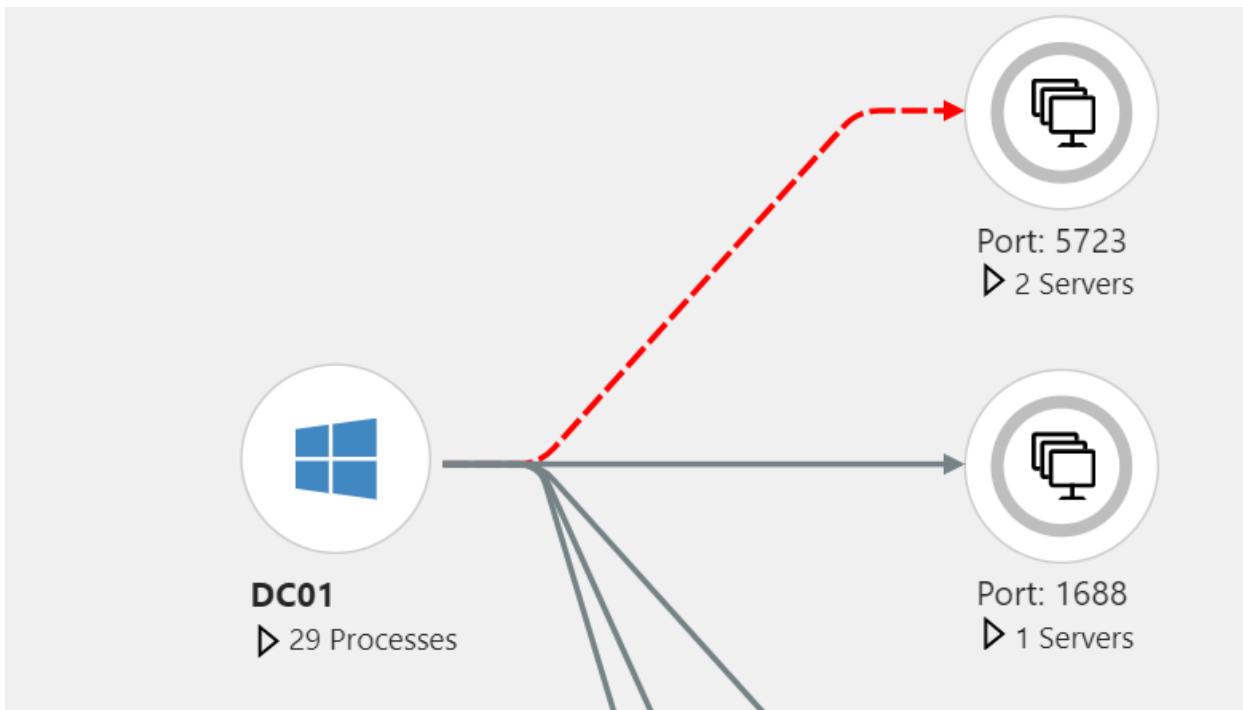

## Connection metrics

The **Connections** pane displays standard metrics for the selected connection from the VM over the TCP port. The metrics include response time, requests per minute, traffic throughput, and links.

## Failed connections

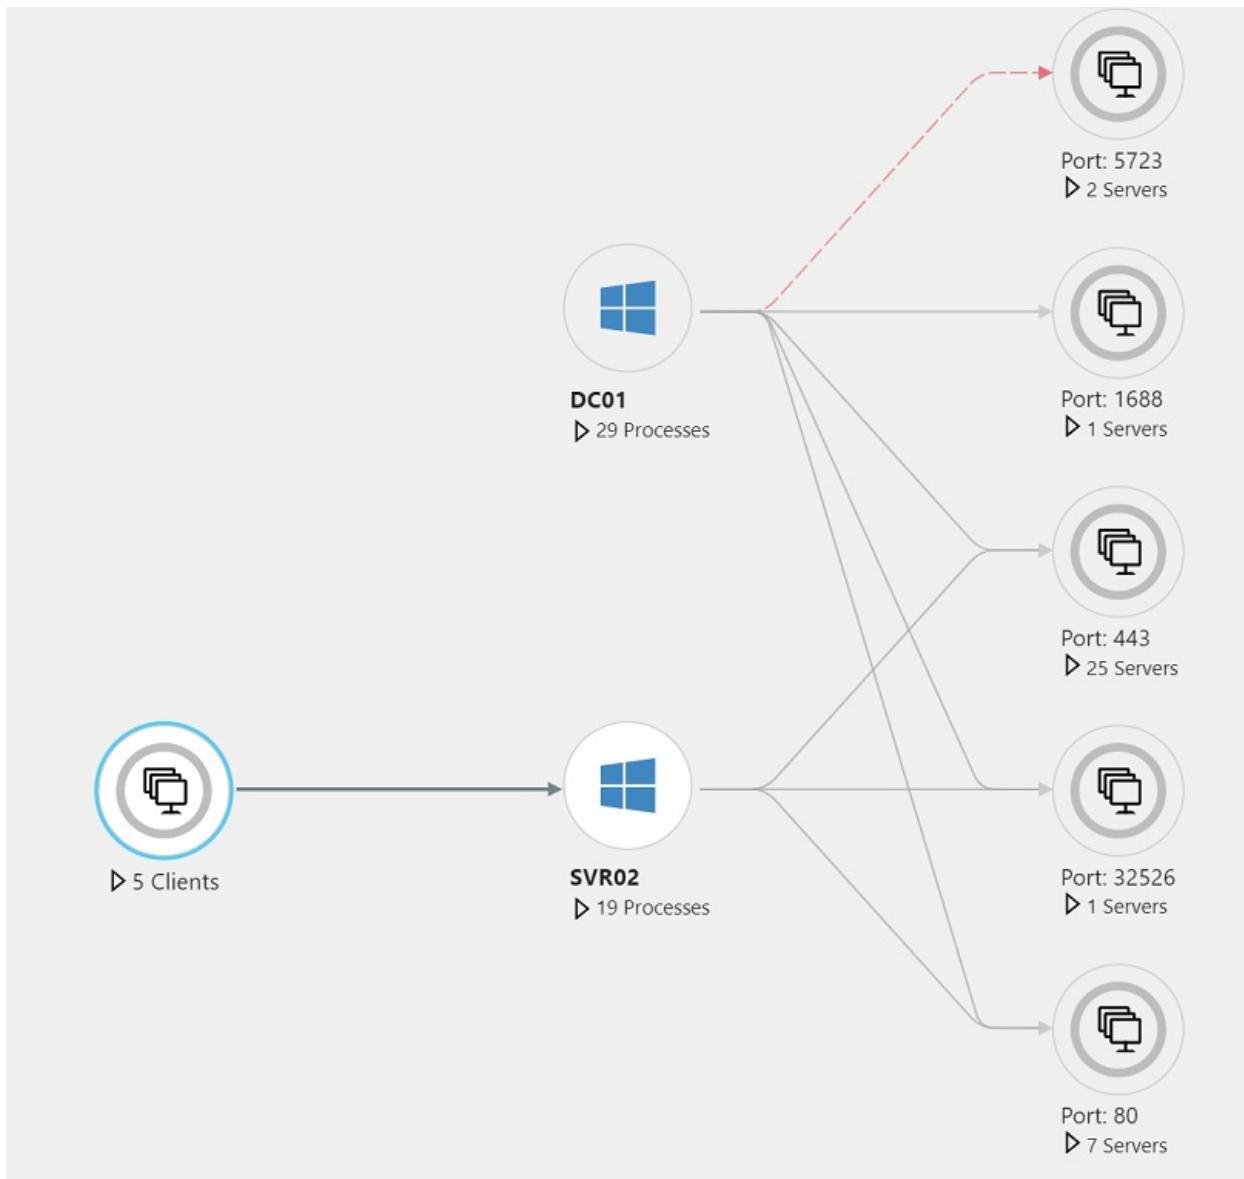

The map shows failed connections for processes and computers. A dashed red line indicates a client system is failing to reach a process or port. For systems that use the Dependency agent, the agent reports on failed connection attempts. The Map feature monitors a process by observing TCP sockets that fail to establish a connection. This failure could result from a firewall, a misconfiguration in the client or server, or an unavailable remote service.

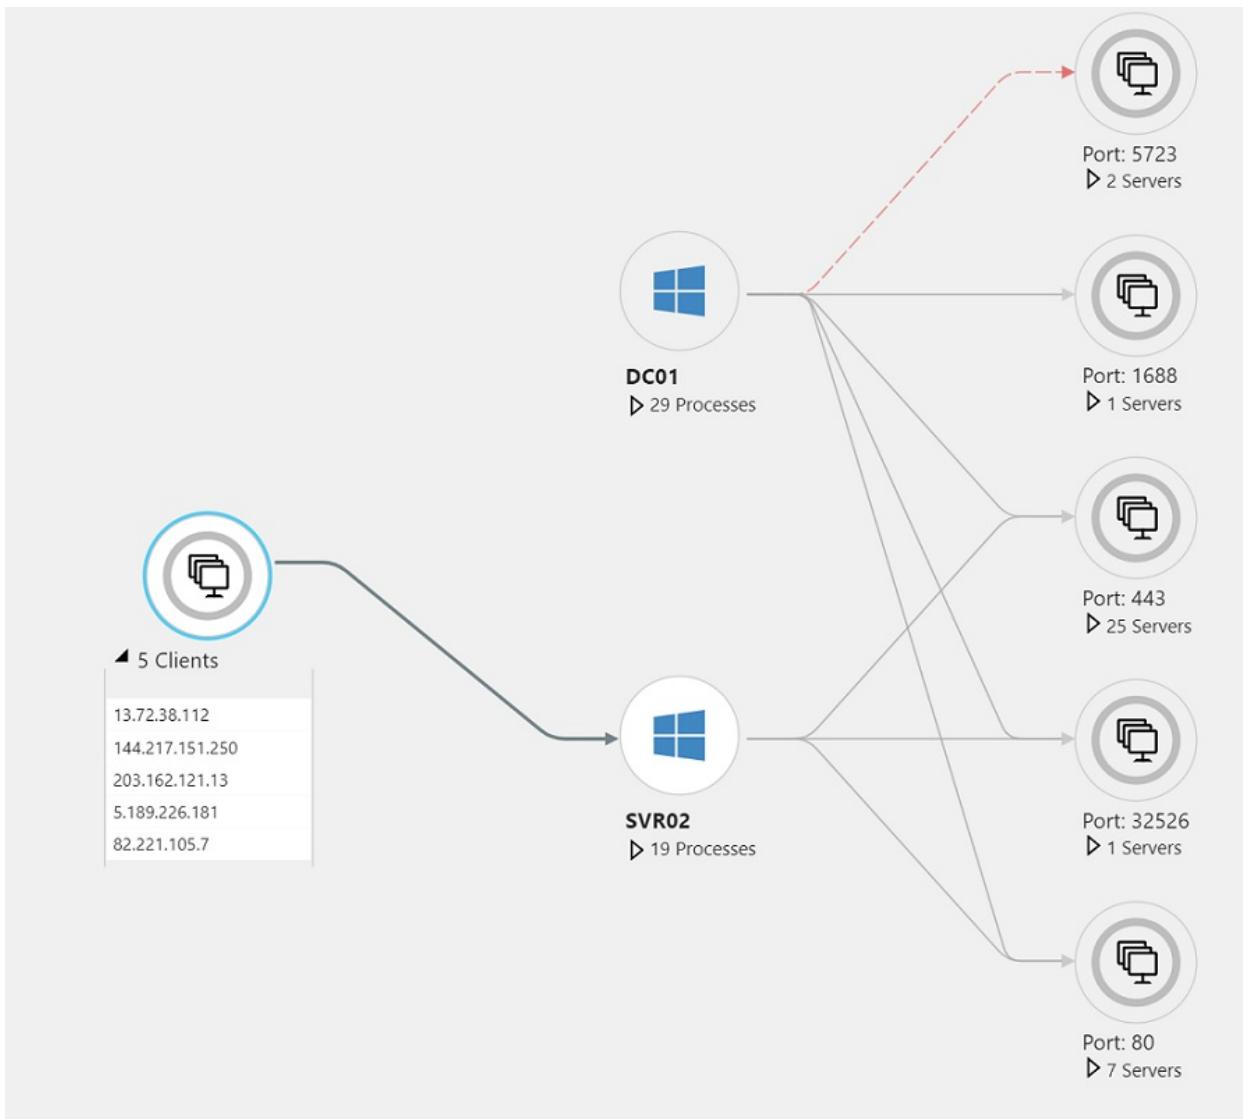

Understanding failed connections can help you troubleshoot, validate migration, analyze security, and understand the overall architecture of the service. Failed connections are sometimes harmless, but they often point to a problem. Connections might fail, for example, when a failover environment suddenly becomes unreachable or when two application tiers can't communicate with each other after a cloud migration.

### **Client groups**

On the map, client groups represent client machines that connect to the mapped machine. A single client group represents the clients for an individual process or machine.

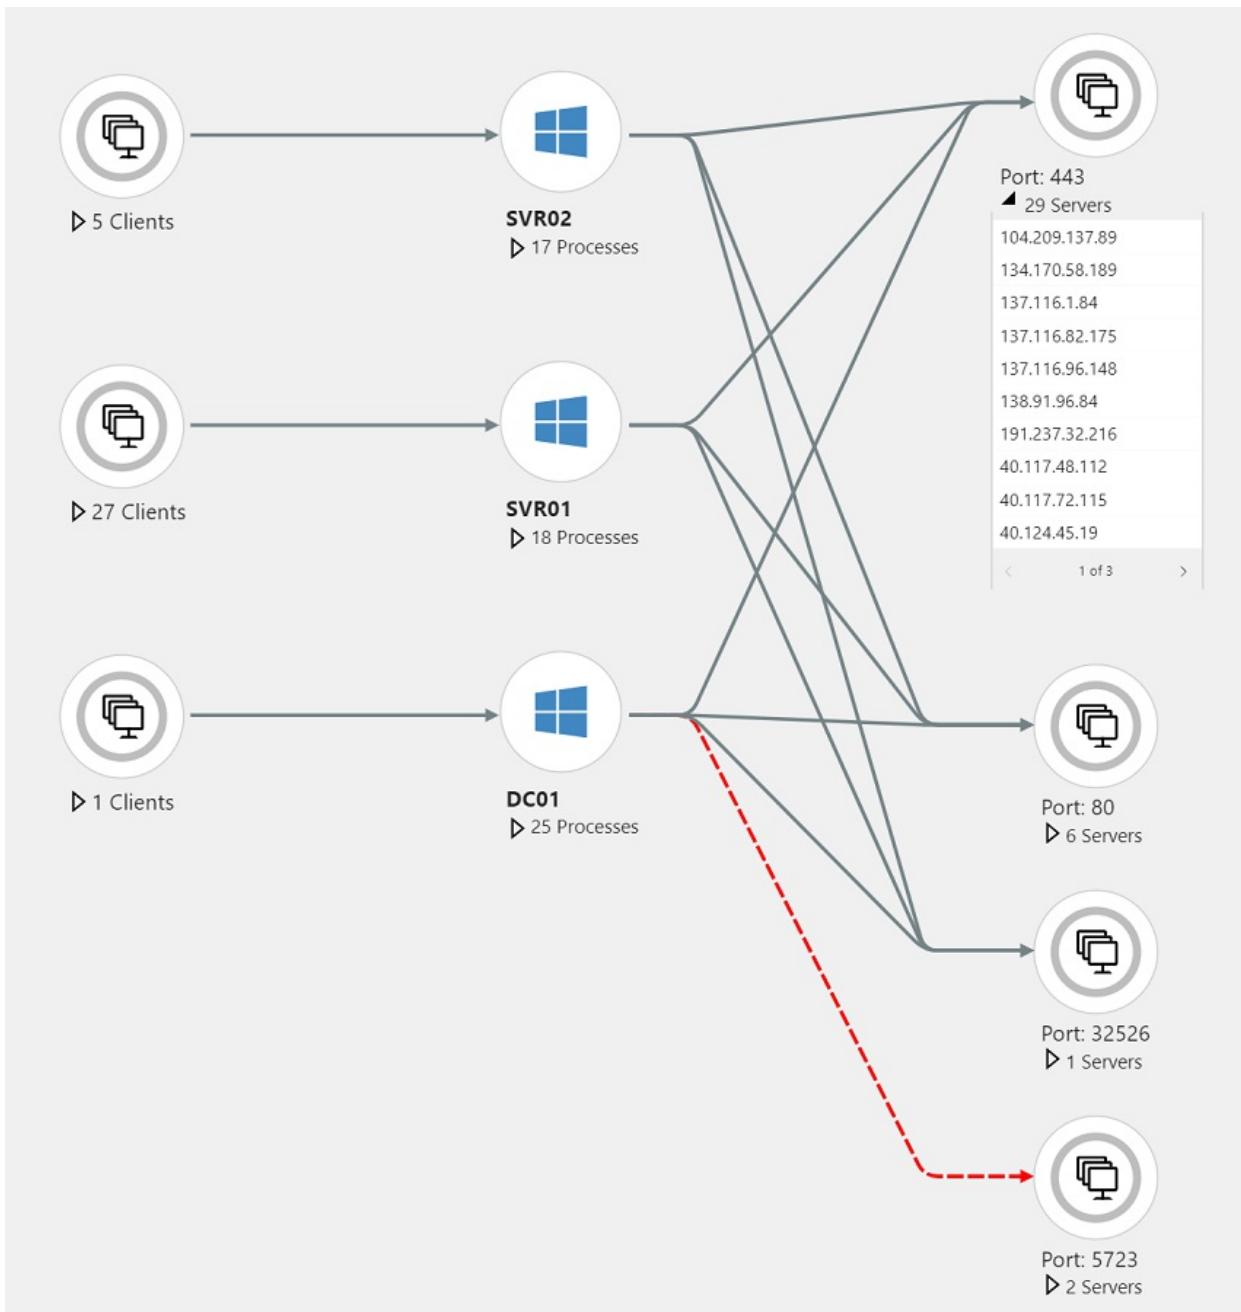

To see the monitored clients and IP addresses of the systems in a client group, select the group. The contents of the group appear below.

If the group includes monitored and unmonitored clients, you can select the appropriate section of the group's doughnut chart to filter the clients.

### Server-port groups

Server-port groups represent ports on servers that have inbound connections from the mapped machine. The group contains the server port and a count of the number of servers that have connections to that port. Select the group to see the individual servers and connections.

If the group includes monitored and unmonitored servers, you can select the appropriate section of the group's doughnut chart to filter the servers.

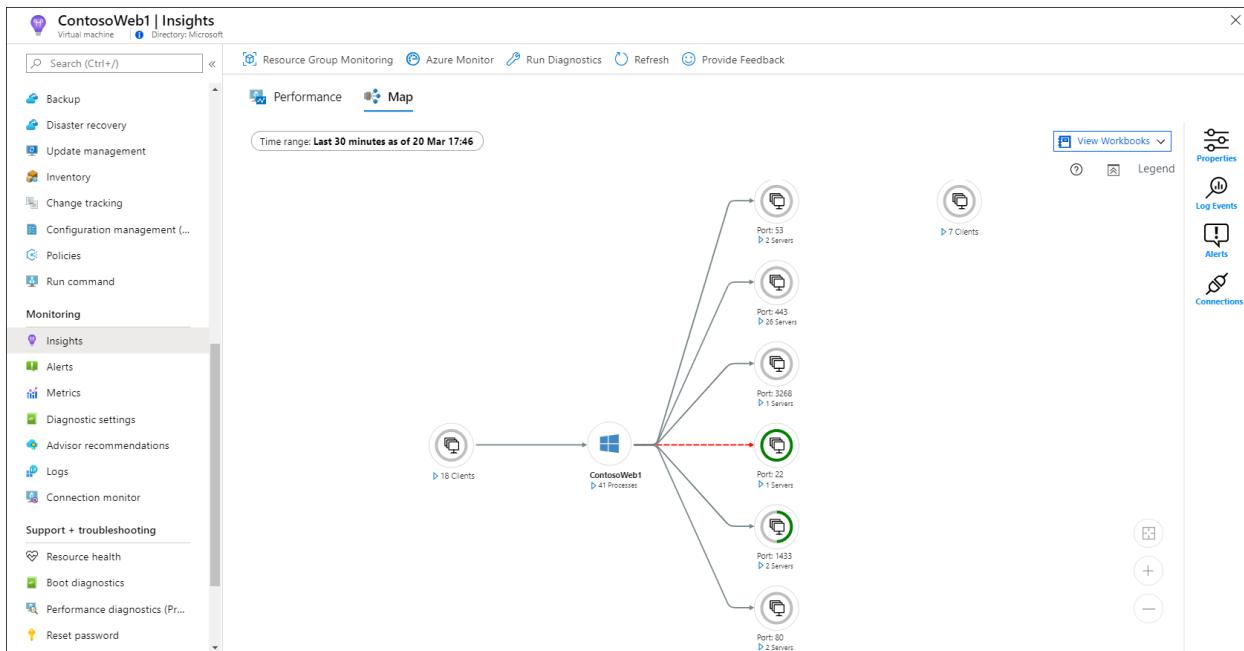

## View a map from a VM

To access VM insights directly from a VM:

1. In the Azure portal, select **Virtual Machines**.
2. From the list, choose a VM. In the **Monitoring** section, choose **Insights**.
3. Select the **Map** tab.

The map visualizes the VM's dependencies by discovering running process groups and processes that have active network connections over a specified time range.

By default, the map shows the last 30 minutes. If you want to see how dependencies looked in the past, you can query for historical time ranges of up to one hour. To run the query, use the **TimeRange** selector in the upper-left corner. You might run a query, for example, during an incident or to see the status before a change.

## View a map from a virtual machine scale set

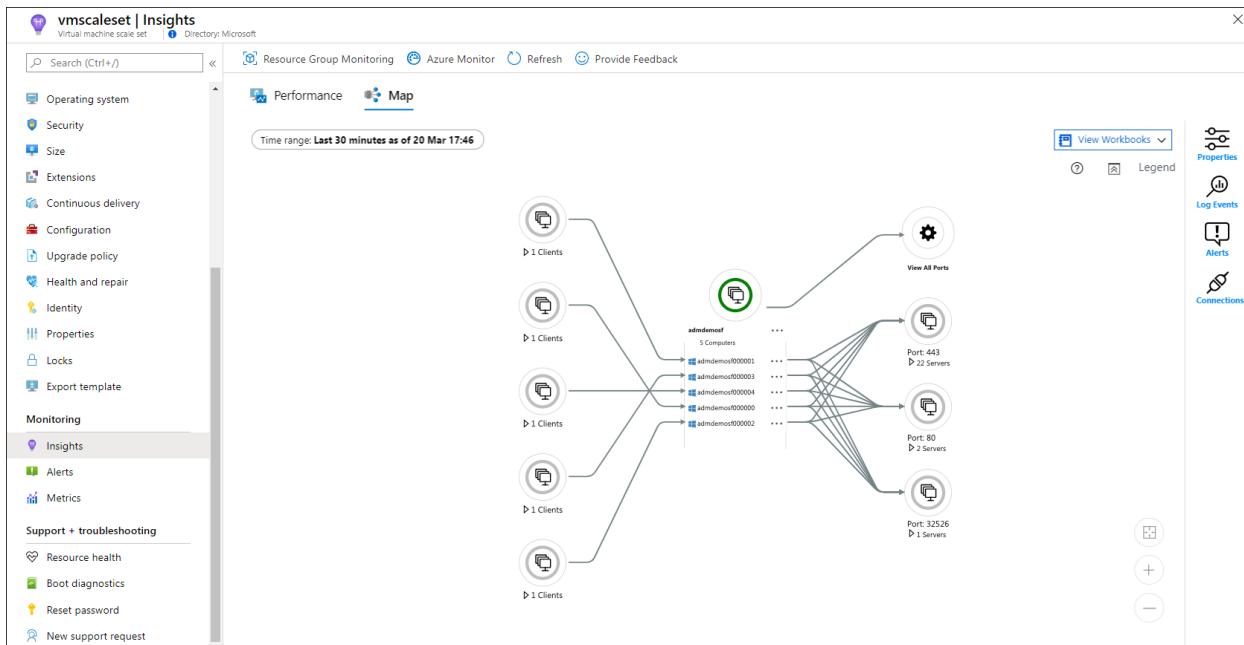

To access VM insights directly from a virtual machine scale set:

1. In the Azure portal, select **Virtual machine scale sets**.
2. From the list, choose a VM. Then in the **Monitoring** section, choose **Insights**.
3. Select the **Map** tab.

The map visualizes all instances in the scale set as a group node along with the group's dependencies. The expanded node lists the instances in the scale set. You can scroll through these instances 10 at a time.

To load a map for a specific instance, first select that instance on the map. Then select the **ellipsis** button (...) to the right and choose **Load Server Map**. In the map that appears, you see process groups and processes that have active network connections over a specified time range.

By default, the map shows the last 30 minutes. If you want to see how dependencies looked in the past, you can query for historical time ranges of up to one hour. To run the query, use the **TimeRange** selector. You might run a query, for example, during an incident or to see the status before a change.

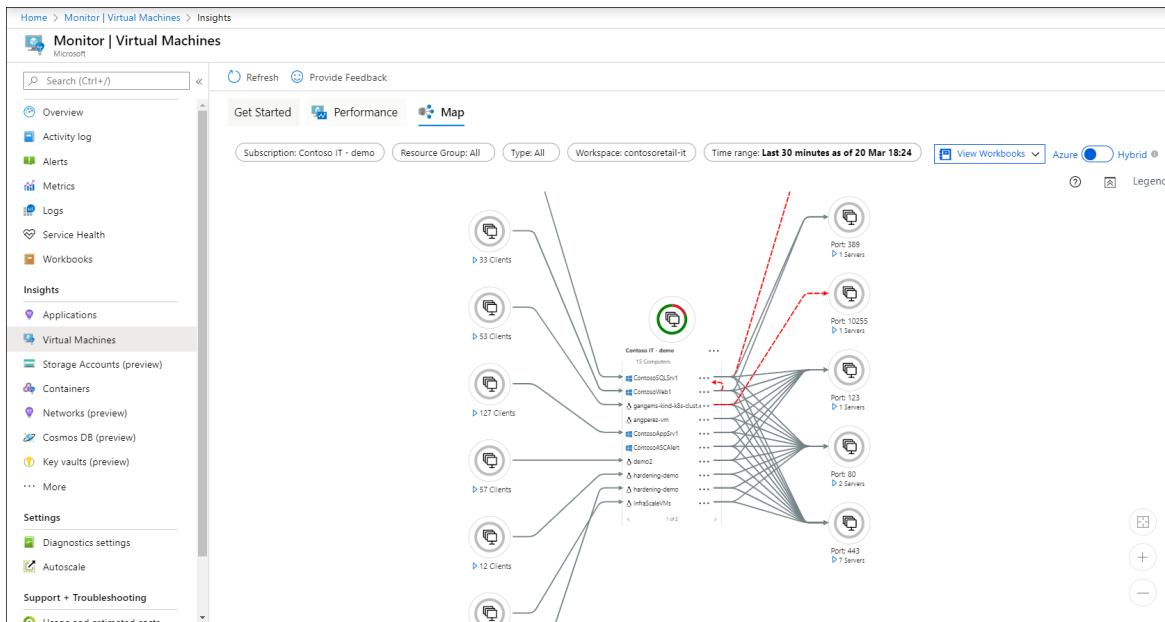

## NOTE

You can also access a map for a specific instance from the **Instances** view for your virtual machine scale set. In the **Settings** section, go to **Instances > Insights**.

## View a map from Azure Monitor

In Azure Monitor, the Map feature provides a global view of your VMs and their dependencies. To access the Map feature in Azure Monitor:

1. In the Azure portal, select **Monitor**.
2. In the **Insights** section, choose **Virtual Machines**.
3. Select the **Map** tab.

Choose a workspace by using the **Workspace** selector at the top of the page. If you have more than one Log Analytics workspace, choose the workspace that's enabled with the solution and that has VMs reporting to it.

The **Group** selector returns subscriptions, resource groups, **computer groups**, and virtual machine scale sets of computers that are related to the selected workspace. Your selection applies only to the Map feature and doesn't carry over to Performance or Health.

By default, the map shows the last 30 minutes. If you want to see how dependencies looked in the past, you can query for historical time ranges of up to one hour. To run the query, use the **TimeRange** selector. You might run a query, for example, during an incident or to see the status before a change.

## Next steps

To identify bottlenecks, check performance, and understand overall utilization of your VMs, see [View performance status for VM insights](#).

# How to chart performance with VM insights

9/21/2022 • 6 minutes to read • [Edit Online](#)

VM insights includes a set of performance charts that target several key performance indicators (KPIs) to help you determine how well a virtual machine is performing. The charts show resource utilization over a period of time so you can identify bottlenecks, anomalies, or switch to a perspective listing each machine to view resource utilization based on the metric selected. While there are numerous elements to consider when dealing with performance, VM insights monitors key operating system performance indicators related to processor, memory, network adapter, and disk utilization. Performance complements the health monitoring feature and helps expose issues that indicate a possible system component failure, support tuning and optimization to achieve efficiency, or support capacity planning.

## Limitations

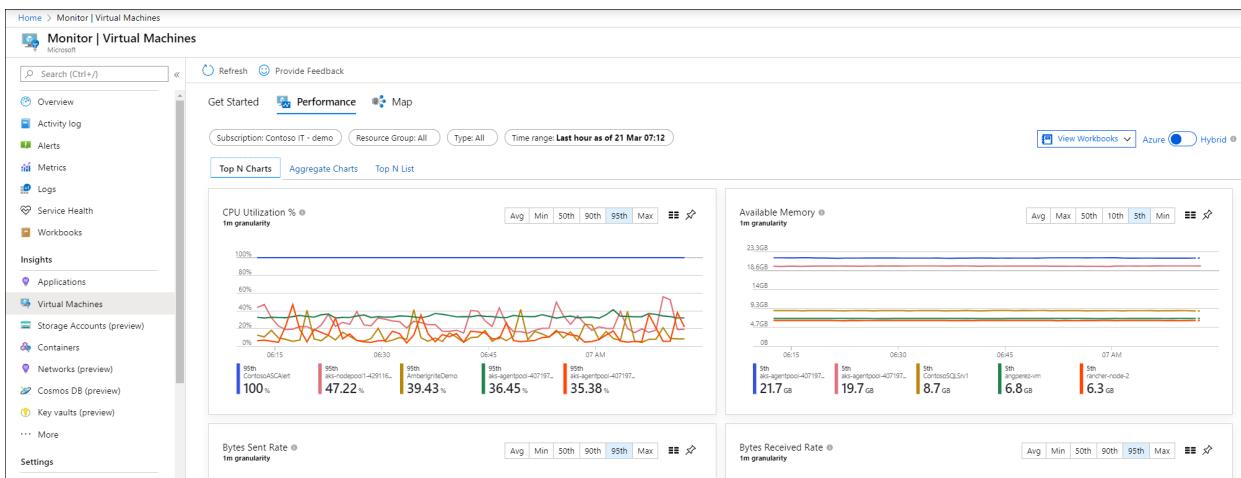

Following are limitations in performance collection with VM insights.

- **Available memory** is not available for virtual machines running Red Hat Linux (RHEL) 6. This metric is calculated from **MemAvailable** which was introduced in [kernel version 3.14](#).
- Metrics are only available for data disks on Linux virtual machines using XFS filesystem or EXT filesystem family (EXT2, EXT3, EXT4).

## Multi-VM perspective from Azure Monitor

From Azure Monitor, the Performance feature provides a view of all monitored VMs deployed across workgroups in your subscriptions or in your environment. To access from Azure Monitor, perform the following steps.

1. In the Azure portal, select **Monitor**.
2. Choose **Virtual Machines** in the **Solutions** section.
3. Select the **Performance** tab.

On the **Top N Charts** tab, if you have more than one Log Analytics workspace, choose the workspace enabled with the solution from the **Workspace** selector at the top of the page. The **Group** selector will return subscriptions, resource groups, [computer groups](#), and virtual machine scale sets of computers related to the selected workspace that you can use to further filter results presented in the charts on this page and across the other pages. Your selection only applies to the Performance feature and does not carry over to Health or Map.

By default, the charts show the last 24 hours. Using the **TimeRange** selector, you can query for historical time ranges of up to 30 days to show how performance looked in the past.

The five capacity utilization charts shown on the page are:

- CPU Utilization % - shows the top five machines with the highest average processor utilization
- Available Memory - shows the top five machines with the lowest average amount of available memory
- Logical Disk Space Used % - shows the top five machines with the highest average disk space used % across all disk volumes
- Bytes Sent Rate - shows the top five machines with highest average of bytes sent
- Bytes Receive Rate - shows the top five machines with highest average of bytes received

Clicking on the pin icon at the upper right-hand corner of any one of the five charts will pin the selected chart to the last Azure dashboard you last viewed. From the dashboard, you can resize and reposition the chart.

Selecting the chart from the dashboard will redirect you to VM insights and load the correct scope and view.

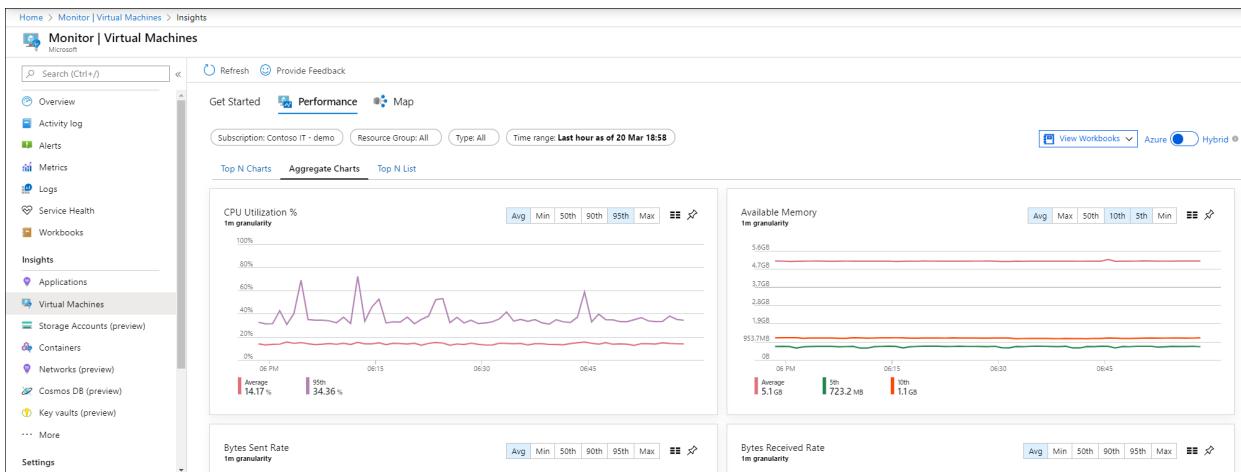

Clicking on the icon located to the left of the pin icon on any one of the five charts opens the **Top N List** view. Here you see the resource utilization for that performance metric by individual VM in a list view and which machine is trending highest.

The screenshot shows the Azure Monitor interface for Virtual Machines. The left sidebar has sections for Overview, Activity log, Alerts, Metrics, Logs, Service Health, Workbooks, and Insights. Under Insights, Virtual Machines is selected. The main area shows a Performance chart with various metrics like CPU Utilization %, Memory Usage, and Disk I/O. Below the chart is a search bar and a dropdown for Metric (set to CPU Utilization %). A table lists the top 10 VMs based on CPU Utilization, showing their names, average utilization, and 5th, 10th, 90th, and 95th percentile utilization. Each row includes a small icon and a bar chart representing the trend. The table shows 32 items in total. The right side of the interface has a Properties pane expanded, showing details for the selected VM.

NAME	AVER...	5TH	10TH	90TH	95TH	TREND 95TH (1 BAR...)	TYPE
ContosoASCAAlert	100%	100%	100%	100%	100%		Virtual machine
aks-nodepool1-42911611-2	29%	16%	17%	47%	53%		Virtual machine
aks-agentpool-40719753-2	33%	31%	31%	35%	35%		Virtual machine
aks-agentpool-40719753-1	14%	6%	6%	28%	33%		Virtual machine
ContosoSQLSrv1	7%	3%	3%	11%	30%		Virtual machine
AmberIgniteDemo	12%	5%	6%	25%	28%		Virtual machine
node-4	14%	9%	9%	25%	27%		Virtual machine
ContosoWeb1	20%	18%	18%	23%	24%		Virtual machine

When you click on the virtual machine, the **Properties** pane is expanded on the right to show the properties of the item selected, such as system information reported by the operating system, properties of the Azure VM, etc. Clicking on one of the options under the **Quick Links** section will redirect you to that feature directly from the selected VM.

Switch to the Aggregated Charts tab to view the performance metrics filtered by average or percentiles measures.

The following capacity utilization charts are provided:

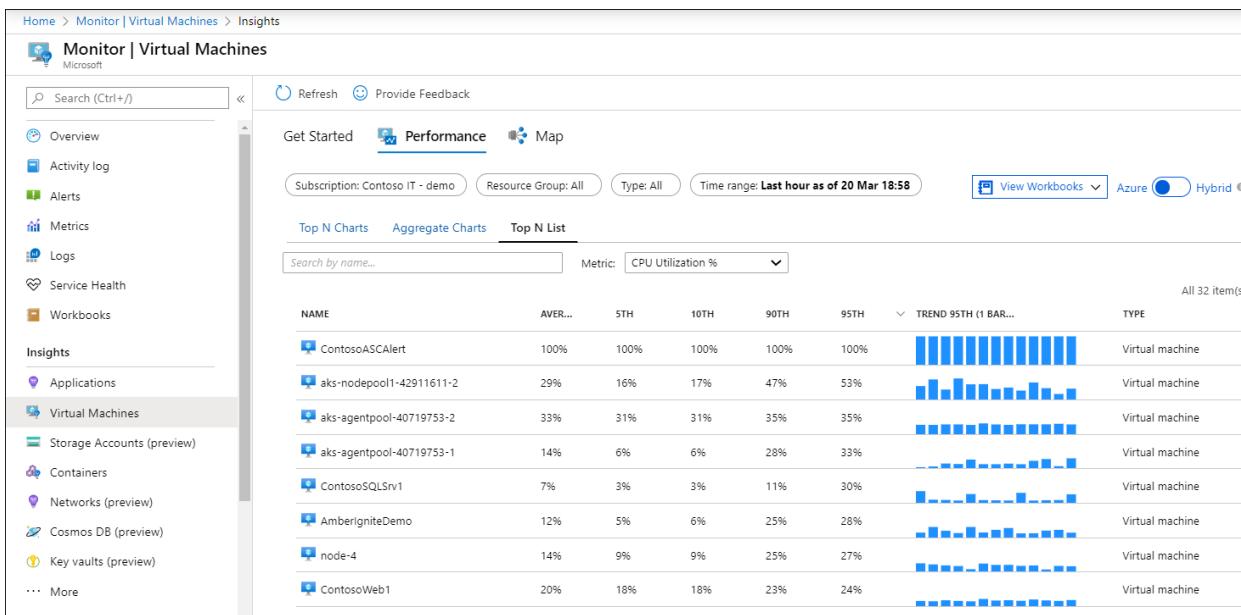

- CPU Utilization % - defaults showing the average and top 95th percentile
- Available Memory - defaults showing the average, top 5th, and 10th percentile
- Logical Disk Space Used % - defaults showing the average and 95th percentile
- Bytes Sent Rate - defaults showing average bytes sent
- Bytes Receive Rate - defaults showing average bytes received

You can also change the granularity of the charts within the time range by selecting **Avg**, **Min**, **Max**, **50th**, **90th**, and **95th** in the percentile selector.

To view the resource utilization by individual VM in a list view and see which machine is trending with highest utilization, select the **Top N List** tab. The **Top N List** page shows the top 20 machines sorted by the most utilized by 95th percentile for the metric *CPU Utilization %*. You can see more machines by selecting **Load More**, and the results expand to show the top 500 machines.

## NOTE

The list cannot show more than 500 machines at a time.

The screenshot shows the Azure Monitor Virtual Machines Insights page. On the left, there's a navigation sidebar with links like Overview, Activity log, Alerts, Metrics, Logs, Service Health, Workbooks, Insights, Applications, Virtual Machines (which is selected), Storage Accounts (preview), Containers, Networks (preview), Cosmos DB (preview), Key vaults (preview), and More. The main area has tabs for Get Started, Performance (which is selected), and Map. It shows a search bar, filter options for Subscription, Resource Group, Type, and Time range (Last hour as of 20 Mar 18:58), and buttons for View Workbooks, Azure, and Hybrid. Below these are three tabs: Top N Charts, Aggregate Charts, and Top N List (which is selected). A search bar under the tabs allows filtering by name. A dropdown menu for Metric shows CPU Utilization % as the current selection. The main content area displays a table of 32 virtual machines with columns for Name, Average, 5th, 10th, 90th, 95th, Trend 95th (1 Bar...), and Type. Each row includes a small icon of the VM and its name. The 'Trend 95th (1 Bar...)' column shows blue bars representing the 95th percentile trend over time. The 'Type' column indicates all listed VMs are Virtual machines.

To filter the results on a specific virtual machine in the list, enter its computer name in the **Search by name** textbox.

If you would rather view utilization from a different performance metric, from the **Metric** drop-down list select **Available Memory**, **Logical Disk Space Used %**, **Network Received Byte/s**, or **Network Sent Byte/s** and the list updates to show utilization scoped to that metric.

Selecting a virtual machine from the list opens the **Properties** panel on the right-side of the page and from here you can select **Performance detail**. The **Virtual Machine Detail** page opens and is scoped to that VM, similar in experience when accessing VM Insights Performance directly from the Azure VM.

## View performance directly from an Azure VM

To access directly from a virtual machine, perform the following steps.

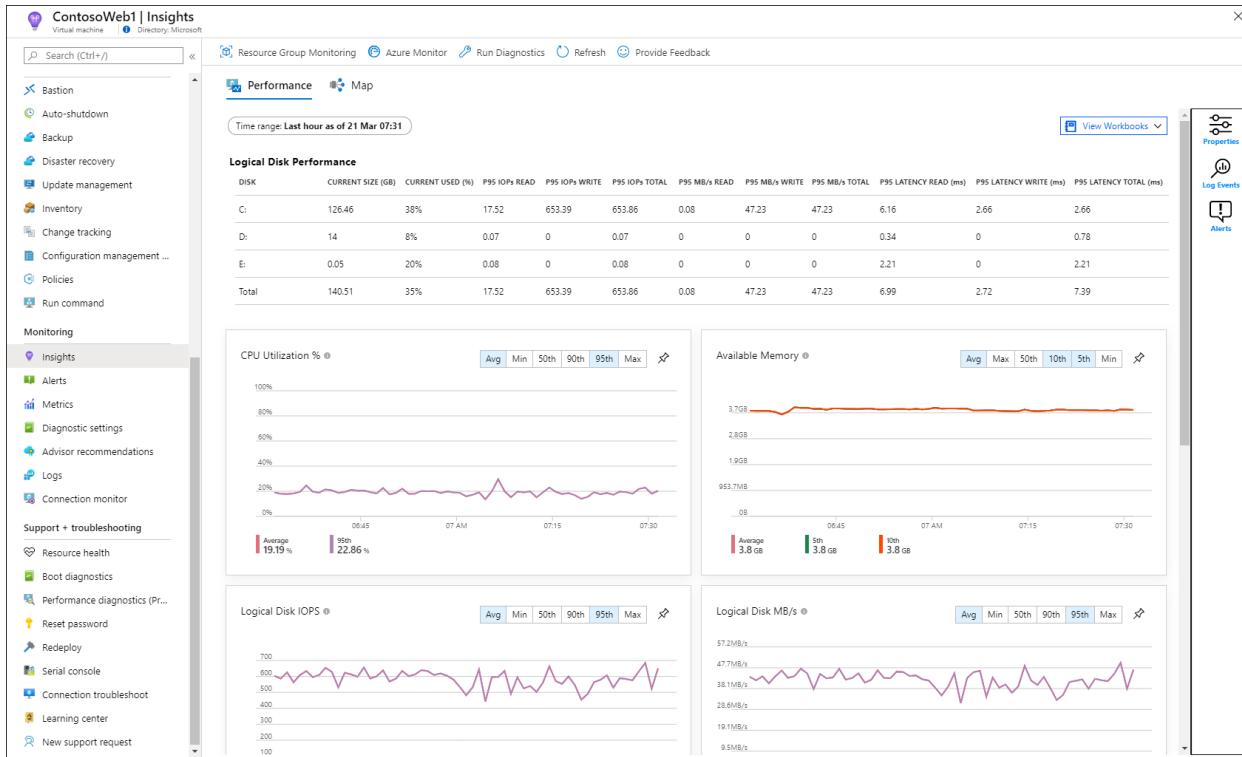

1. In the Azure portal, select **Virtual Machines**.
2. From the list, choose a VM and in the **Monitoring** section choose **Insights**.
3. Select the **Performance** tab.

This page not only includes performance utilization charts, but also a table showing for each logical disk discovered, its capacity, utilization, and total average by each measure.

The following capacity utilization charts are provided:

- CPU Utilization % - defaults showing the average and top 95th percentile
- Available Memory - defaults showing the average, top 5th, and 10th percentile
- Logical Disk Space Used % - defaults showing the average and 95th percentile
- Logical Disk IOPS - defaults showing the average and 95th percentile
- Logical Disk MB/s - defaults showing the average and 95th percentile
- Max Logical Disk Used % - defaults showing the average and 95th percentile
- Bytes Sent Rate - defaults showing average bytes sent
- Bytes Receive Rate - defaults showing average bytes received

Clicking on the pin icon at the upper right-hand corner of any one of the charts pins the selected chart to the last Azure dashboard you viewed. From the dashboard, you can resize and reposition the chart. Selecting the chart from the dashboard redirects you to VM insights and loads the performance detail view for the VM.

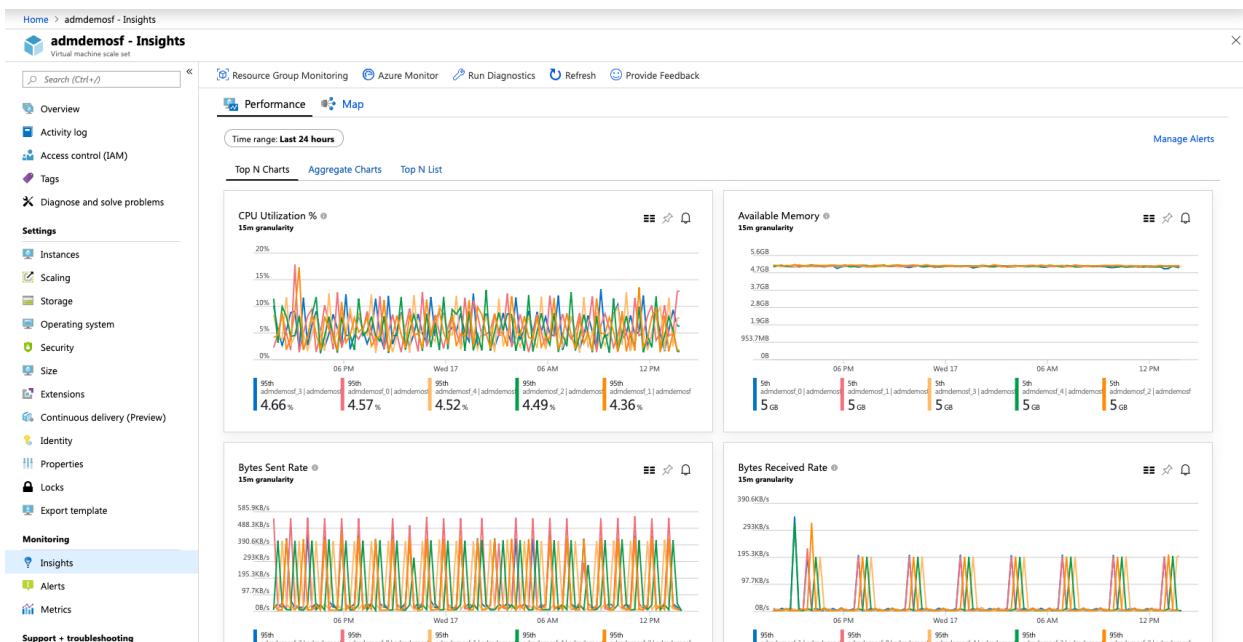

## View performance directly from an Azure virtual machine scale set

To access directly from an Azure virtual machine scale set, perform the following steps.

1. In the Azure portal, select **Virtual machine scale sets**.
2. From the list, choose a VM and in the **Monitoring** section choose **Insights** to view the **Performance** tab.

This page loads the Azure Monitor performance view, scoped to the selected scale set. This enables you to see the Top N Instances in the scale set across the set of monitored metrics, view the aggregate performance across the scale set, and see the trends for selected metrics across the individual instances in the scale set. Selecting an instance from the list view lets you load its map or navigate into a detailed performance view for that instance.

Clicking on the pin icon at the upper right-hand corner of any one of the charts pins the selected chart to the last Azure dashboard you viewed. From the dashboard, you can resize and reposition the chart. Selecting the chart from the dashboard redirects you to VM insights and loads the performance detail view for the VM.

### NOTE

You can also access a detailed performance view for a specific instance from the Instances view for your scale set. Navigate to **Instances** under the **Settings** section, and then choose **Insights**.

## Next steps

- Learn how to use [Workbooks](#) that are included with VM insights to further analyze performance and network metrics.
- To learn about discovered application dependencies, see [View VM insights Map](#).

# How to query logs from VM insights

9/21/2022 • 18 minutes to read • [Edit Online](#)

VM insights collects performance and connection metrics, computer and process inventory data, and health state information and forwards it to the Log Analytics workspace in Azure Monitor. This data is available for [query](#) in Azure Monitor. You can apply this data to scenarios that include migration planning, capacity analysis, discovery, and on-demand performance troubleshooting.

## Map records

One record is generated per hour for each unique computer and process, in addition to the records that are generated when a process or computer starts or is added to VM insights. The fields and values in the ServiceMapComputer\_CL events map to fields of the Machine resource in the ServiceMap Azure Resource Manager API. The fields and values in the ServiceMapProcess\_CL events map to the fields of the Process resource in the ServiceMap Azure Resource Manager API. The ResourceName\_s field matches the name field in the corresponding Resource Manager resource.

There are internally generated properties you can use to identify unique processes and computers:

- Computer: Use *ResourceId* or *ResourceName\_s* to uniquely identify a computer within a Log Analytics workspace.
- Process: Use *ResourceId* to uniquely identify a process within a Log Analytics workspace. *ResourceName\_s* is unique within the context of the machine on which the process is running (*MachineResourceName\_s*)

Because multiple records can exist for a specified process and computer in a specified time range, queries can return more than one record for the same computer or process. To include only the most recent record, add

```
| summarize arg_max(TimeGenerated, *) by ResourceId
```

## Connections and ports

The Connection Metrics feature introduces two new tables in Azure Monitor logs - VMConnection and VMBoundPort. These tables provide information about the connections for a machine (inbound and outbound), as well as the server ports that are open/active on them. ConnectionMetrics are also exposed via APIs that provide the means to obtain a specific metric during a time window. TCP connections resulting from *accepting* on a listening socket are inbound, while those created by *connecting* to a given IP and port are outbound. The direction of a connection is represented by the Direction property, which can be set to either **inbound** or **outbound**.

Records in these tables are generated from data reported by the Dependency Agent. Every record represents an observation over a 1-minute time interval. The TimeGenerated property indicates the start of the time interval. Each record contains information to identify the respective entity, that is, connection or port, as well as metrics associated with that entity. Currently, only network activity that occurs using TCP over IPv4 is reported.

### Common fields and conventions

The following fields and conventions apply to both VMConnection and VMBoundPort:

- Computer: Fully-qualified domain name of reporting machine
- AgentId: The unique identifier for a machine with the Log Analytics agent
- Machine: Name of the Azure Resource Manager resource for the machine exposed by ServiceMap. It is of the form *m-{GUID}*, where *GUID* is the same GUID as AgentId
- Process: Name of the Azure Resource Manager resource for the process exposed by ServiceMap. It is of the form *p-{hex string}*. Process is unique within a machine scope and to generate a unique process ID across

machines, combine Machine and Process fields.

- ProcessName: Executable name of the reporting process.
- All IP addresses are strings in IPv4 canonical format, for example `13.107.3.160`

To manage cost and complexity, connection records do not represent individual physical network connections. Multiple physical network connections are grouped into a logical connection, which is then reflected in the respective table. Meaning, records in `VMConnection` table represent a logical grouping and not the individual physical connections that are being observed. Physical network connection sharing the same value for the following attributes during a given one-minute interval, are aggregated into a single logical record in `VMConnection`.

PROPERTY	DESCRIPTION
Direction	Direction of the connection, value is <i>inbound</i> or <i>outbound</i>
Machine	The computer FQDN
Process	Identity of process or groups of processes, initiating/accepting the connection
Sourcelp	IP address of the source
Destinationlp	IP address of the destination
DestinationPort	Port number of the destination
Protocol	Protocol used for the connection. Values is <i>tcp</i> .

To account for the impact of grouping, information about the number of grouped physical connections is provided in the following properties of the record:

PROPERTY	DESCRIPTION
LinksEstablished	The number of physical network connections that have been established during the reporting time window
LinksTerminated	The number of physical network connections that have been terminated during the reporting time window
LinksFailed	The number of physical network connections that have failed during the reporting time window. This information is currently available only for outbound connections.
LinksLive	The number of physical network connections that were open at the end of the reporting time window

## Metrics

In addition to connection count metrics, information about the volume of data sent and received on a given logical connection or network port are also included in the following properties of the record:

PROPERTY	DESCRIPTION
BytesSent	Total number of bytes that have been sent during the reporting time window

PROPERTY	DESCRIPTION
BytesReceived	Total number of bytes that have been received during the reporting time window
Responses	The number of responses observed during the reporting time window.
ResponseTimeMax	The largest response time (milliseconds) observed during the reporting time window. If no value, the property is blank.
ResponseTimeMin	The smallest response time (milliseconds) observed during the reporting time window. If no value, the property is blank.
ResponseTimeSum	The sum of all response times (milliseconds) observed during the reporting time window. If no value, the property is blank.

The third type of data being reported is response time - how long does a caller spend waiting for a request sent over a connection to be processed and responded to by the remote endpoint. The response time reported is an estimation of the true response time of the underlying application protocol. It is computed using heuristics based on the observation of the flow of data between the source and destination end of a physical network connection. Conceptually, it is the difference between the time the last byte of a request leaves the sender, and the time when the last byte of the response arrives back to it. These two timestamps are used to delineate request and response events on a given physical connection. The difference between them represents the response time of a single request.

In this first release of this feature, our algorithm is an approximation that may work with varying degree of success depending on the actual application protocol used for a given network connection. For example, the current approach works well for request-response based protocols such as HTTP(S), but does not work with one-way or message queue-based protocols.

Here are some important points to consider:

1. If a process accepts connections on the same IP address but over multiple network interfaces, a separate record for each interface will be reported.
2. Records with wildcard IP will contain no activity. They are included to represent the fact that a port on the machine is open to inbound traffic.
3. To reduce verbosity and data volume, records with wildcard IP will be omitted when there is a matching record (for the same process, port, and protocol) with a specific IP address. When a wildcard IP record is omitted, the IsWildcardBind record property with the specific IP address, will be set to "True" to indicate that the port is exposed over every interface of the reporting machine.
4. Ports that are bound only on a specific interface have IsWildcardBind set to *False*.

#### Naming and Classification

For convenience, the IP address of the remote end of a connection is included in the Remotelp property. For inbound connections, Remotelp is the same as Sourcelp, while for outbound connections, it is the same as Destinationlp. The RemoteDnsCanonicalNames property represents the DNS canonical names reported by the machine for Remotelp. The RemoteDnsQuestions property represents the DNS questions reported by the machine for Remotelp. The RemoveClassification property is reserved for future use.

#### Geolocation

*VMConnection* also includes geolocation information for the remote end of each connection record in the following properties of the record:

PROPERTY	DESCRIPTION
RemoteCountry	The name of the country/region hosting Remotelp. For example, <i>United States</i>
RemoteLatitude	The geolocation latitude. For example, <i>47.68</i>
RemoteLongitude	The geolocation longitude. For example, <i>-122.12</i>

#### Malicious IP

Every Remotelp property in *VMConnection* table is checked against a set of IPs with known malicious activity. If the Remotelp is identified as malicious the following properties will be populated (they are empty, when the IP is not considered malicious) in the following properties of the record:

PROPERTY	DESCRIPTION
MaliciousIp	The Remotelp address
IndicatorThreadType	Threat indicator detected is one of the following values, <i>Botnet, C2, CryptoMining, Darknet, DDos, MaliciousUrl, Malware, Phishing, Proxy, PUA, Watchlist</i> .
Description	Description of the observed threat.
TLPLevel	Traffic Light Protocol (TLP) Level is one of the defined values, <i>White, Green, Amber, Red</i> .
Confidence	Values are <i>0 – 100</i> .
Severity	Values are <i>0 – 5</i> , where <i>5</i> is the most severe and <i>0</i> is not severe at all. Default value is <i>3</i> .
FirstReportedDateTime	The first time the provider reported the indicator.
LastReportedDateTime	The last time the indicator was seen by Interflow.
IsActive	Indicates indicators are deactivated with <i>True</i> or <i>False</i> value.
ReportReferenceLink	Links to reports related to a given observable.
AdditionalInformation	Provides additional information, if applicable, about the observed threat.

#### Ports

Ports on a machine that actively accept incoming traffic or could potentially accept traffic, but are idle during the reporting time window, are written to the *VMBoundPort* table.

Every record in *VMBoundPort* is identified by the following fields:

PROPERTY	DESCRIPTION
Process	Identity of process (or groups of processes) with which the port is associated with.

PROPERTY	DESCRIPTION
Ip	Port IP address (can be wildcard IP, <i>0.0.0.0</i> )
Port	The Port number
Protocol	The protocol. Example, <i>tcp</i> or <i>udp</i> (only <i>tcp</i> is currently supported).

The identity a port is derived from the above five fields and is stored in the *PortId* property. This property can be used to quickly find records for a specific port across time.

#### Metrics

Port records include metrics representing the connections associated with them. Currently, the following metrics are reported (the details for each metric are described in the previous section):

- BytesSent and BytesReceived
- LinksEstablished, LinksTerminated, LinksLive
- ResponseTime, ResponseTimeMin, ResponseTimeMax, ResponseTimeSum

Here are some important points to consider:

- If a process accepts connections on the same IP address but over multiple network interfaces, a separate record for each interface will be reported.
- Records with wildcard IP will contain no activity. They are included to represent the fact that a port on the machine is open to inbound traffic.
- To reduce verbosity and data volume, records with wildcard IP will be omitted when there is a matching record (for the same process, port, and protocol) with a specific IP address. When a wildcard IP record is omitted, the *IsWildcardBind* property for the record with the specific IP address, will be set to *True*. This indicates the port is exposed over every interface of the reporting machine.
- Ports that are bound only on a specific interface have *IsWildcardBind* set to *False*.

#### VMComputer records

Records with a type of *VMComputer* have inventory data for servers with the Dependency agent. These records have the properties in the following table:

PROPERTY	DESCRIPTION
TenantId	The unique identifier for the workspace
SourceSystem	<i>Insights</i>
TimeGenerated	Timestamp of the record (UTC)
Computer	The computer FQDN
AgentId	The unique ID of the Log Analytics agent
Machine	Name of the Azure Resource Manager resource for the machine exposed by ServiceMap. It is of the form <i>m-{GUID}</i> , where <i>GUID</i> is the same GUID as AgentId.
DisplayName	Display name

PROPERTY	DESCRIPTION
FullDisplayName	Full display name
HostName	The name of machine without domain name
BootTime	The machine boot time (UTC)
TimeZone	The normalized time zone
VirtualizationState	<i>virtual, hypervisor, physical</i>
Ipv4Addresses	Array of IPv4 addresses
Ipv4SubnetMasks	Array of IPv4 subnet masks (in the same order as Ipv4Addresses).
Ipv4DefaultGateways	Array of IPv4 gateways
Ipv6Addresses	Array of IPv6 addresses
MacAddresses	Array of MAC addresses
DnsNames	Array of DNS names associated with the machine.
DependencyAgentVersion	The version of the Dependency agent running on the machine.
OperatingSystemFamily	<i>Linux, Windows</i>
OperatingSystemFullName	The full name of the operating system
PhysicalMemoryMB	The physical memory in megabytes
Cpus	The number of processors
CpuSpeed	The CPU speed in MHz
VirtualMachineType	<i>hyperv, vmware, xen</i>
VirtualMachineNativeId	The VM ID as assigned by its hypervisor
VirtualMachineNativeName	The name of the VM
VirtualMachineHypervisorId	The unique identifier of the hypervisor hosting the VM
HypervisorType	<i>hyperv</i>
HypervisorId	The unique ID of the hypervisor
HostingProvider	<i>azure</i>

PROPERTY	DESCRIPTION
_ResourceId	The unique identifier for an Azure resource
AzureSubscriptionId	A globally unique identifier that identifies your subscription
AzureResourceGroup	The name of the Azure resource group the machine is a member of.
AzureResourceName	The name of the Azure resource
AzureLocation	The location of the Azure resource
AzureUpdateDomain	The name of the Azure update domain
AzureFaultDomain	The name of the Azure fault domain
AzureVmId	The unique identifier of the Azure virtual machine
AzureSize	The size of the Azure VM
AzureImagePublisher	The name of the Azure VM publisher
AzureImageOffering	The name of the Azure VM offer type
AzureImageSku	The SKU of the Azure VM image
AzureImageVersion	The version of the Azure VM image
AzureCloudServiceName	The name of the Azure cloud service
AzureCloudServiceDeployment	Deployment ID for the Cloud Service
AzureCloudServiceRoleName	Cloud Service role name
AzureCloudServiceRoleType	Cloud Service role type: <i>worker</i> or <i>web</i>
AzureCloudServiceInstanceId	Cloud Service role instance ID
AzureVmScaleSetName	The name of the virtual machine scale set
AzureVmScaleSetDeployment	Virtual machine scale set deployment ID
AzureVmScaleSetResourceId	The unique identifier of the virtual machine scale set resource.
AzureVmScaleSetInstanceId	The unique identifier of the virtual machine scale set
AzureServiceFabricClusterId	The unique identifier of the Azure Service Fabric cluster
AzureServiceFabricClusterName	The name of the Azure Service Fabric cluster

## VM Process records

Records with a type of *VMProcess* have inventory data for TCP-connected processes on servers with the Dependency agent. These records have the properties in the following table:

PROPERTY	DESCRIPTION
TenantId	The unique identifier for the workspace
SourceSystem	<i>Insights</i>
TimeGenerated	Timestamp of the record (UTC)
Computer	The computer FQDN
AgentId	The unique ID of the Log Analytics agent
Machine	Name of the Azure Resource Manager resource for the machine exposed by ServiceMap. It is of the form <i>m-{GUID}</i> , where <i>GUID</i> is the same GUID as AgentId.
Process	The unique identifier of the Service Map process. It is in the form of <i>p-{GUID}</i> .
ExecutableName	The name of the process executable
DisplayName	Process display name
Role	Process role: <i>webserver, appServer, databaseServer, ldapServer, smbServer</i>
Group	Process group name. Processes in the same group are logically related, e.g., part of the same product or system component.
StartTime	The process pool start time
FirstPid	The first PID in the process pool
Description	The process description
CompanyName	The name of the company
InternalName	The internal name
ProductName	The name of the product
ProductVersion	The version of the product
FileVersion	The version of the file
ExecutablePath	The path of the executable
CommandLine	The command line
WorkingDirectory	The working directory

PROPERTY	DESCRIPTION
Services	An array of services under which the process is executing
UserName	The account under which the process is executing
UserDomain	The domain under which the process is executing
_ResourceId	The unique identifier for a process within the workspace

## Sample map queries

### List all known machines

```
VMComputer | summarize arg_max(TimeGenerated, *) by _ResourceId
```

### When was the VM last rebooted

```
let Today = now(); VMComputer | extend DaysSinceBoot = Today - BootTime | summarize by Computer, DaysSinceBoot, BootTime | sort by BootTime asc
```

### Summary of Azure VMs by image, location, and SKU

```
VMComputer | where AzureLocation != "" | summarize by Computer, AzureImageOffering, AzureLocation, AzureImageSku
```

### List the physical memory capacity of all managed computers

```
VMComputer | summarize arg_max(TimeGenerated, *) by _ResourceId | project PhysicalMemoryMB, Computer
```

### List computer name, DNS, IP, and OS

```
VMComputer | summarize arg_max(TimeGenerated, *) by _ResourceId | project Computer, OperatingSystemFullName, DnsNames, Ipv4Addresses
```

### Find all processes with "sql" in the command line

```
VMProcess | where CommandLine contains_cs "sql" | summarize arg_max(TimeGenerated, *) by _ResourceId
```

### Find a machine (most recent record) by resource name

```
search in (VMComputer) "m-4b9c93f9-bc37-46df-b43c-899ba829e07b" | summarize arg_max(TimeGenerated, *) by _ResourceId
```

### Find a machine (most recent record) by IP address

```
search in (VMComputer) "10.229.243.232" | summarize arg_max(TimeGenerated, *) by _ResourceId
```

### List all known processes on a specified machine

```
VMProcess | where Machine == "m-559dbcd8-3130-454d-8d1d-f624e57961bc" | summarize arg_max(TimeGenerated, *) by _ResourceId
```

## List all computers running SQL Server

```
VMComputer | where AzureResourceName in ((search in (VMProcess) "*sql*" | distinct Machine)) | distinct Computer
```

## List all unique product versions of curl in my datacenter

```
VMProcess | where ExecutableName == "curl" | distinct ProductVersion
```

## Create a computer group of all computers running CentOS

```
VMComputer | where OperatingSystemFullName contains_cs "CentOS" | distinct Computer
```

## Bytes sent and received trends

```
VMConnection | summarize sum(BytesSent), sum(BytesReceived) by bin(TimeGenerated,1hr), Computer | order by Computer desc | render timechart
```

## Which Azure VMs are transmitting the most bytes

```
VMConnection | join kind=fullouter(VMComputer) on $left.Computer == $right.Computer | summarize count(BytesSent) by Computer, AzureVMSize | sort by count(BytesSent) desc
```

## Link status trends

```
VMConnection | where TimeGenerated >= ago(24hr) | where Computer == "acme-demo" | summarize dcount(LinksEstablished), dcount(LinksLive), dcount(LinksFailed), dcount(LinksTerminated) by bin(TimeGenerated, 1h) | render timechart
```

## Connection failures trend

```
VMConnection | where Computer == "acme-demo" | extend bythehour = datetime_part("hour", TimeGenerated) | project bythehour, LinksFailed | summarize failCount = count() by bythehour | sort by bythehour asc | render timechart
```

## Bound Ports

```
VMBoundPort  
| where TimeGenerated >= ago(24hr)  
| where Computer == 'admdemo-appsvr'  
| distinct Port, ProcessName
```

## Number of open ports across machines

```
VMBoundPort  
| where Ip != "127.0.0.1"  
| summarize by Computer, Machine, Port, Protocol  
| summarize OpenPorts=count() by Computer, Machine  
| order by OpenPorts desc
```

## Score processes in your workspace by the number of ports they have open

```
VMBoundPort
| where Ip != "127.0.0.1"
| summarize by ProcessName, Port, Protocol
| summarize OpenPorts=count() by ProcessName
| order by OpenPorts desc
```

## Aggregate behavior for each port

This query can then be used to score ports by activity, e.g., ports with most inbound/outbound traffic, ports with most connections

```
//
VMBoundPort
| where Ip != "127.0.0.1"
| summarize BytesSent=sum(BytesSent), BytesReceived=sum(BytesReceived),
LinksEstablished=sum(LinksEstablished), LinksTerminated=sum(LinksTerminated), arg_max(TimeGenerated,
LinksLive) by Machine, Computer, ProcessName, Ip, Port, IsWildcardBind
| project-away TimeGenerated
| order by Machine, Computer, Port, Ip, ProcessName
```

## Summarize the outbound connections from a group of machines

```

// the machines of interest
let machines = datatable(m: string) ["m-82412a7a-6a32-45a9-a8d6-538354224a25"];
// map of ip to monitored machine in the environment
let ips=materialize(VMComputer
| summarize ips=makeset(todynamic(Ipv4Addresses)) by MonitoredMachine=AzureResourceName
| mvexpand ips to typeof(string));
// all connections to/from the machines of interest
let out=materialize(VMConnection
| where Machine in (machines)
| summarize arg_max(TimeGenerated, *) by ConnectionId;
// connections to localhost augmented with RemoteMachine
let local=out
| where RemoteIp startswith "127."
| project ConnectionId, Direction, Machine, Process, ProcessName, SourceIp, DestinationIp, DestinationPort,
Protocol, RemoteIp, RemoteMachine=Machine;
// connections not to localhost augmented with RemoteMachine
let remote=materialize(out
| where RemoteIp !startswith "127."
| join kind=leftouter (ips) on $left.RemoteIp == $right.ips
| summarize by ConnectionId, Direction, Machine, Process, ProcessName, SourceIp, DestinationIp,
DestinationPort, Protocol, RemoteIp, RemoteMachine=MonitoredMachine);
// the remote machines to/from which we have connections
let remoteMachines = remote | summarize by RemoteMachine;
// all augmented connections
(local)
| union (remote)
//Take all outbound records but only inbound records that come from either //unmonitored machines or
monitored machines not in the set for which we are computing dependencies.
| where Direction == 'outbound' or (Direction == 'inbound' and RemoteMachine !in (machines))
| summarize by ConnectionId, Direction, Machine, Process, ProcessName, SourceIp, DestinationIp,
DestinationPort, Protocol, RemoteIp, RemoteMachine
// identify the remote port
| extend RemotePort=iff(Direction == 'outbound', DestinationPort, 0)
// construct the join key we'll use to find a matching port
| extend JoinKey=strcat_delim(':', RemoteMachine, RemoteIp, RemotePort, Protocol)
// find a matching port
| join kind=leftouter (VMBoundPort
| where Machine in (remoteMachines)
| summarize arg_max(TimeGenerated, *) by PortId
| extend JoinKey=strcat_delim(':', Machine, Ip, Port, Protocol)) on JoinKey
// aggregate the remote information
| summarize Remote=makeset(ifempty(RemoteMachine), todynamic('{}'), pack('Machine', RemoteMachine,
'Process', Process1, 'ProcessName', ProcessName1))) by ConnectionId, Direction, Machine, Process,
ProcessName, SourceIp, DestinationIp, DestinationPort, Protocol

```

## Performance records

Records with a type of *InsightsMetrics* have performance data from the guest operating system of the virtual machine. These records have the properties in the following table:

PROPERTY	DESCRIPTION
TenantId	Unique identifier for the workspace
SourceSystem	<i>Insights</i>
TimeGenerated	Time the value was collected (UTC)
Computer	The computer FQDN
Origin	<i>vm.azm.ms</i>

PROPERTY	DESCRIPTION
Namespace	Category of the performance counter
Name	Name of the performance counter
Val	Collected value
Tags	Related details about the record. See the table below for tags used with different record types.
AgentId	Unique identifier for each computer's agent
Type	<i>InsightsMetrics</i>
ResourceId	Resource ID of the virtual machine

The performance counters currently collected into the *InsightsMetrics* table are listed in the following table:

NAMESPACE	NAME	DESCRIPTION	UNIT	TAGS
Computer	Heartbeat	Computer Heartbeat		
Memory	AvailableMB	Memory Available Bytes	Megabytes	memorySizeMB - Total memory size
Network	WriteBytesPerSecond	Network Write Bytes Per Second	BytesPerSecond	NetworkDeviceId - Id of the device bytes - Total sent bytes
Network	ReadBytesPerSecond	Network Read Bytes Per Second	BytesPerSecond	networkDeviceId - Id of the device bytes - Total received bytes
Processor	UtilizationPercentage	Processor Utilization Percentage	Percent	totalCpus - Total CPUs
LogicalDisk	WritesPerSecond	Logical Disk Writes Per Second	CountPerSecond	mountId - Mount ID of the device
LogicalDisk	WriteLatencyMs	Logical Disk Write Latency Millisecond	Milliseconds	mountId - Mount ID of the device
LogicalDisk	WriteBytesPerSecond	Logical Disk Write Bytes Per Second	BytesPerSecond	mountId - Mount ID of the device
LogicalDisk	TransfersPerSecond	Logical Disk Transfers Per Second	CountPerSecond	mountId - Mount ID of the device
LogicalDisk	TransferLatencyMs	Logical Disk Transfer Latency Millisecond	Milliseconds	mountId - Mount ID of the device

NAMESPACE	NAME	DESCRIPTION	UNIT	TAGS
LogicalDisk	ReadsPerSecond	Logical Disk Reads Per Second	CountPerSecond	mountId - Mount ID of the device
LogicalDisk	ReadLatencyMs	Logical Disk Read Latency Millisecond	MilliSeconds	mountId - Mount ID of the device
LogicalDisk	ReadBytesPerSecond	Logical Disk Read Bytes Per Second	BytesPerSecond	mountId - Mount ID of the device
LogicalDisk	FreeSpacePercentage	Logical Disk Free Space Percentage	Percent	mountId - Mount ID of the device
LogicalDisk	FreeSpaceMB	Logical Disk Free Space Bytes	Megabytes	mountId - Mount ID of the device diskSizeMB - Total disk size
LogicalDisk	BytesPerSecond	Logical Disk Bytes Per Second	BytesPerSecond	mountId - Mount ID of the device

## Next steps

- If you are new to writing log queries in Azure Monitor, review [how to use Log Analytics](#) in the Azure portal to write log queries.
- Learn about [writing search queries](#).

# Create interactive reports VM insights with workbooks

9/21/2022 • 12 minutes to read • [Edit Online](#)

Workbooks combine text, log queries, metrics, and parameters into rich interactive reports. Workbooks are editable by any other team members who have access to the same Azure resources.

Workbooks are helpful for scenarios such as:

- Exploring the usage of your virtual machine when you don't know the metrics of interest in advance: CPU utilization, disk space, memory, network dependencies, etc. Unlike other usage analytics tools, workbooks let you combine multiple kinds of visualizations and analyses, making them great for this kind of free-form exploration.
- Explaining to your team how a recently provisioned VM is performing, by showing metrics for key counters and other log events.
- Sharing the results of a resizing experiment of your VM with other members of your team. You can explain the goals for the experiment with text, then show each usage metric and analytics queries used to evaluate the experiment, along with clear call-outs for whether each metric was above- or below-target.
- Reporting the impact of an outage on the usage of your VM, combining data, text explanation, and a discussion of next steps to prevent outages in the future.

## VM insights workbooks

VM insights includes the following workbooks. You can use these workbooks or use them as a start to create custom workbooks to address your particular requirements.

### Single virtual machine

WORKBOOK	DESCRIPTION
Performance	Provides a customizable version of the Performance view that leverages all of the Log Analytics performance counters that you have enabled.
Connections	Connections provides an in-depth view of the inbound and outbound connections from your VM.

### Multiple virtual machines

WORKBOOK	DESCRIPTION
Performance	Provides a customizable version of the Top N List and Charts view in a single workbook that leverages all of the Log Analytics performance counters that you have enabled.
Performance counters	A Top N chart view across a wide set of performance counters.
Connections	Connections provides an in-depth view of the inbound and outbound connections from your monitored VMs.

WORKBOOK	DESCRIPTION
Active Ports	Provides a list of the processes that have bound to the ports on the monitored VMs and their activity in the chosen timeframe.
Open Ports	Provides the number of ports open on your monitored VMs and the details on those open ports.
Failed Connections	Display the count of failed connections on your monitored VMs, the failure trend, and if the percentage of failures is increasing over time.
Security and Audit	An analysis of your TCP/IP traffic that reports on overall connections, malicious connections, where the IP endpoints reside globally. To enable all features, you will need to enable Security Detection.
TCP Traffic	A ranked report for your monitored VMs and their sent, received, and total network traffic in a grid and displayed as a trend line.
Traffic Comparison	This workbook lets you compare network traffic trends for a single machine or a group of machines.

## Creating a new workbook

A workbook is made up of sections consisting of independently editable charts, tables, text, and input controls. To better understand workbooks, let's start by opening a template and walk through creating a custom workbook.

1. Go to the **Monitor** menu in the Azure portal.
2. Select a virtual machine.
3. On the VM insights page, select **Performance** or **Maps** tab and then select **View Workbooks** from the link on the page. From the drop-down list, select **Go to Gallery**.

The screenshot shows the Azure VM Insights interface for a virtual machine named 'ContosoWeb1'. The 'Performance' tab is selected. In the center, there are three charts: 'Logical Disk Performance' (showing disk usage for C:, D:, E:, and Total), 'CPU Utilization %' (a line chart showing CPU usage over time), and 'Available Memory' (a line chart showing memory usage over time). On the right side, there is a sidebar with various monitoring links like 'Resource Group Monitoring', 'Azure Monitor', 'Run Diagnostics', and 'Properties'. The 'Workbooks' section is expanded, showing 'View Workbooks' (dropdown), 'Performance Analysis', 'Network Dependencies', and 'Workbooks Gallery'. A red box highlights the 'Workbooks Gallery' link. At the bottom of the sidebar, there are links for 'Log Events' and 'Alerts'.

This launches the workbook gallery with a number of prebuilt workbooks to help you get started.

#### 4. Create a new workbook by selecting New.

The screenshot shows the Azure Monitor Gallery interface. At the top, there are navigation links for Home, Monitor, and a search bar. Below that, a header bar includes 'New', 'Refresh', 'Feedback', 'Help', 'Community Git repo', 'Browse across galleries', and filter options for 'Subscription: AzureMonitor\_Docs' and 'Resource Group: All'. A 'Reset filters' button is also present. The main content area is organized into sections: 'Quick start' (Empty), 'Recently modified workbooks (3)' (VM Insights Report 3, VM Insights Report 2, VM Insights Report 1), 'Network Dependencies (7)' (Connections Overview, Open Ports, Active Ports, Failed Connections, Security and Audit, Traffic Comparison, TCP Traffic), and 'Performance Analysis (2)' (Performance, Perf Counters). Each item has a thumbnail icon and a brief description.

## Editing workbook sections

Workbooks have two modes: **editing mode**, and **reading mode**. When a new workbook is first launched, it opens in **editing mode**. It shows all the content of the workbook, including any steps and parameters that are otherwise hidden. **Reading mode** presents a simplified report style view. Reading mode allows you to abstract away the complexity that went into creating a report while still having the underlying mechanics only a few clicks away when needed for modification.

The screenshot shows a 'New workbook' page in the Azure Monitor. The top navigation bar includes 'Home > Monitor - Virtual Machines > Workbook 1', 'Workbook 1', 'InfraLabDefaultWorkspace', and standard browser controls. Below the toolbar, a section titled 'New workbook' contains a welcome message and a basic analytics query: `union withsource=TableName * | summarize Count=count() by TableName | render barchart`. The 'Edit' button is visible in the top right of this section. At the bottom of the section, there is a note about a failed operation: 'Can not perform requested operation on nested resource. Parent resource 'InfraLabDefaultWorkspace' not found. Click to Retry.' Below this note are four numbered buttons (1, 2, 3, 4) and a row of action buttons: 'Done Editing', 'Add text', 'Add query', 'Add metric', 'Add parameters', and icons for copy/paste and refresh. A footer at the bottom of the page provides links to 'Add text', 'Add query', 'Add metric', and 'Add parameters'.

1. When you're done editing a section, click **Done Editing** in the bottom-left corner of the section.
2. To create a duplicate of a section, click the **Clone this section** icon. Creating duplicate sections is a great way to iterate on a query without losing previous iterations.
3. To move up a section in a workbook, click the **Move up** or **Move down** icon.
4. To remove a section permanently, click the **Remove** icon.

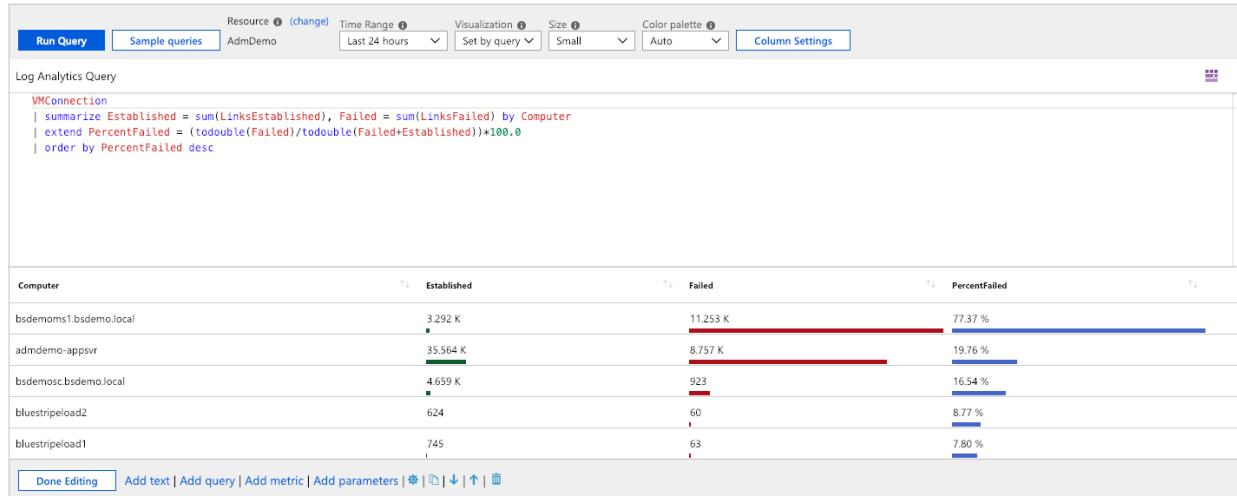

## Adding text and Markdown sections

Adding headings, explanations, and commentary to your workbooks helps turn a set of tables and charts into a

narrative. Text sections in workbooks support the [Markdown syntax](#) for text formatting, like headings, bold, italics, and bulleted lists.

To add a text section to your workbook, use the **Add text** button at the bottom of the workbook, or at the bottom of any section.

## Adding query sections

To add query section to your workbook, use the **Add query** button at the bottom of the workbook, or at the bottom of any section.

Query sections are highly flexible and can be used to answer questions like:

- How was my CPU utilization during the same time period as an increase in network traffic?
- What was the trend in available disk space over the last month?
- How many network connection failures did my VM experience over the last two weeks?

You also aren't only limited to querying from the context of the virtual machine you launched the workbook from. You can query across multiple virtual machines, as well as Log Analytics workspaces, as long as you have access permission to those resources.

To include data from other Log Analytics workspaces or from a specific Application Insights app using the **workspace** identifier. To learn more about cross-resource queries, refer to the [official guidance](#).

### Advanced analytic query settings

Each section has its own advanced settings, which are accessible via the settings icon located to the right of the **Add parameters** button.

The screenshot shows the 'Advanced Settings' dialog for a query section. It contains the following options:

- Make this item a custom width [i](#)
- Make this item conditionally visible [i](#)
- When an item is selected, export a parameter [i](#)
- Show query when not editing
- Show open in analytics button when not editing

Below these is a 'Chart title' field with the placeholder 'Enter a title, or leave blank for no title'.

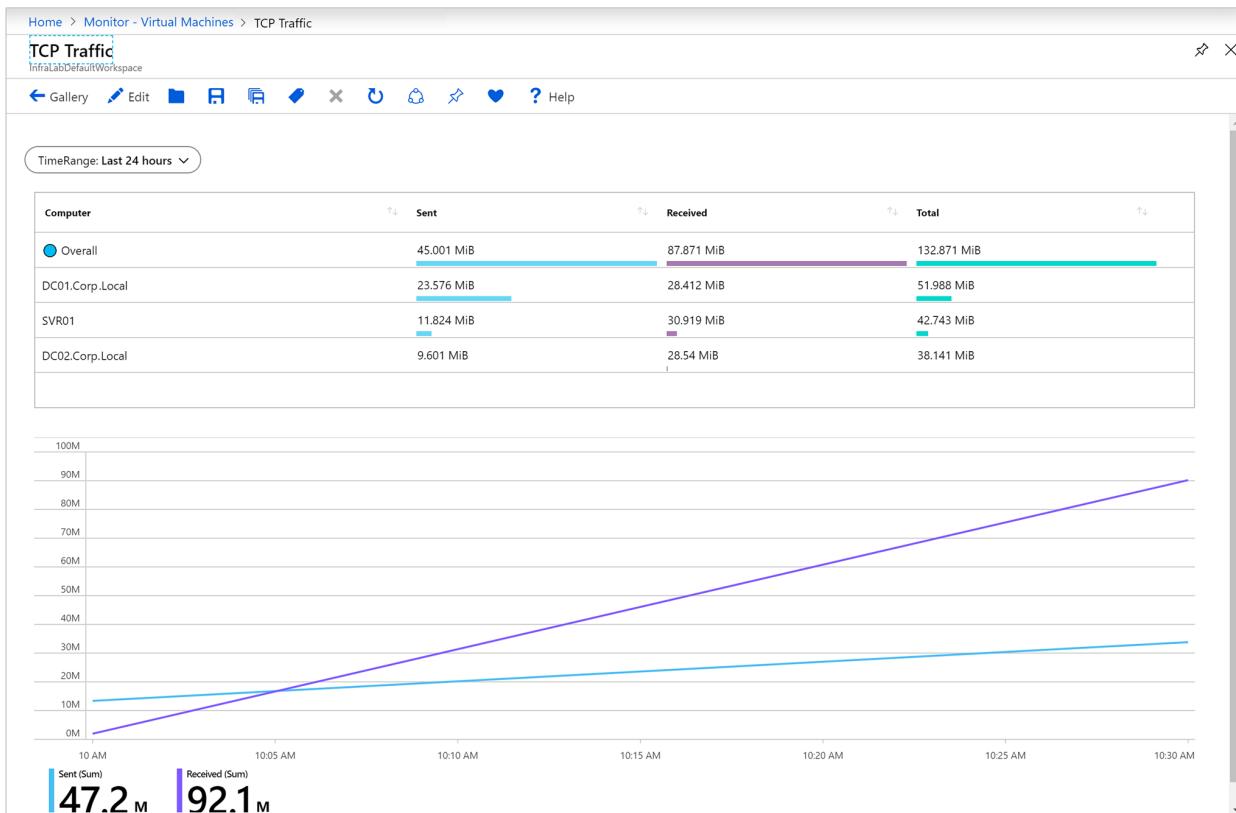

At the bottom are buttons for 'Done Editing', 'Add text', 'Add query', 'Add metric', 'Add parameters', and icons for copy, paste, up, down, and delete.

SETTING	DESCRIPTION
Custom width	Makes an item an arbitrary size, so you can fit many items on a single line allowing you to better organize your charts and tables into rich interactive reports.
Conditionally visible	Specify to hide steps based on a parameter when in reading mode.
Export a parameter	Allow a selected row in the grid or chart to cause later steps to change values or become visible.
Show query when not editing	Displays the query above the chart or table even when in reading mode.
Show open in analytics button when not editing	Adds the blue Analytics icon to the right-hand corner of the chart to allow one-click access.

Most of these settings are fairly intuitive, but to understand **Export a parameter** it is better to examine a workbook that makes use of this functionality.

One of the prebuilt workbooks - **TCP Traffic**, provides information on connection metrics from a VM.

The first section of the workbook is based on log query data. The second section is also based on log query data, but selecting a row in the first table will interactively update the contents of the charts:

The behavior is possible through use of the **When an item is selected, export a parameter** advanced settings, which are enabled in the table's log query.

## Advanced Settings

- Make this item a custom width [i](#)
- Make this item conditionally visible [i](#)
- When an item is selected, export a parameter [i](#)

Field to export [i](#)

Values

Parameter name

Filter

The second log query then utilizes the exported values when a row is selected to create a set of values that are then used by the section heading and charts. If no row is selected, it hides the section heading and charts.

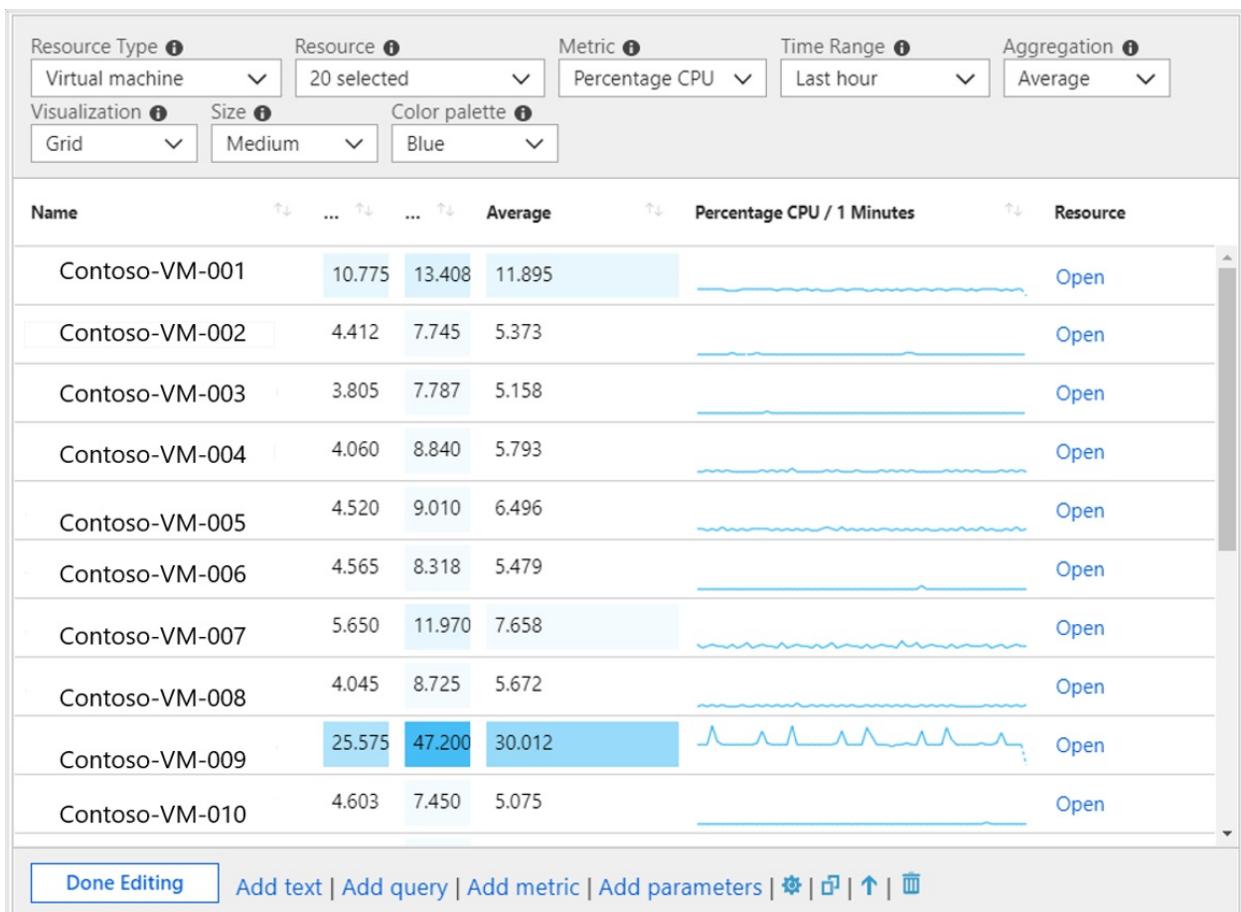

For example, the hidden parameter in the second section uses the following reference from the row selected in the grid:

```
VMConnection
| where TimeGenerated {TimeRange}
| where Computer in ("{ComputerName}") or '*' in ("{ComputerName}")
| summarize Sent = sum(BytesSent), Received = sum(BytesReceived) by bin(TimeGenerated, {TimeRange:grain})
```

## Adding metrics sections

Metrics sections give you full access to incorporate Azure Monitor metrics data into your interactive reports. In VM insights, the prebuilt workbooks will typically contain analytic query data rather than metric data. You may choose to create workbooks with metric data, allowing you to take full advantage of the best of both features all in one place. You also have the ability to pull in metric data from resources in any of the subscriptions you have access to.

Here is an example of virtual machine data being pulled into a workbook to provide a grid visualization of CPU performance:

## Adding parameter sections

Workbook parameters allow you to change values in the workbook without having to manually edit the query or text sections. This removes the requirement of needing to understand the underlying analytics query language and greatly expands the potential audience of workbook-based reporting.

The values of parameters are replaced in query, text or other parameter sections by putting the name of the parameter in braces, like `{parameterName}`. Parameter names are limited to similar rules as JavaScript identifiers, alphabetic characters or underscores, followed by alphanumeric characters or underscores. For example, `a1` is allowed, but `1a` is not allowed.

Parameters are linear, starting from the top of a workbook and flowing down to later steps. Parameters declared later in a workbook can override parameters that were declared earlier. This also lets parameters that use queries to access the values from parameters defined earlier. Within a parameter's step itself, parameters are also linear, left to right, where parameters to the right can depend on a parameter declared earlier in that same step.

There are four different types of parameters, which are currently supported:

PARAMETER	DESCRIPTION
Text	Allows the user to edit a text box, and you can optionally supply a query to fill in the default value.
Drop down	Allows the user to choose from a set of values.
Time range picker	Allows the user to choose from a predefined set of time range values, or pick from a custom time range.

PARAMETER	DESCRIPTION
Resource picker	Allows the user to choose from the resources selected for the workbook.

## Using a text parameter

The value a user types in the text box is replaced directly in the query, with no escaping or quoting. If the value you need is a string, the query should have quotes around the parameter (like '{parameter}').

The text parameter allows the value in a text box to be used anywhere. It can be a table name, column name, function name, operator, etc. The text parameter type has a setting **Get default value from analytics query**, which allows the workbook author to use a query to populate the default value for that text box.

When using the default value from a log query, only the first value of the first row (row 0, column 0) is used as the default value. Therefore it is recommended to limit your query to return just one row and one column. Any other data returned by the query is ignored.

Whatever value the query returns will be replaced directly with no escaping or quoting. If the query returns no rows, the result of the parameter is either an empty string (if the parameter is not required) or undefined (if the parameter is required).

## Using a drop-down

The dropdown parameter type lets you create a drop-down control, allowing the selection of one or many values.

The dropdown is populated by a log query or JSON. If the query returns one column, the values in that column are both the value and the label in the drop-down control. If the query returns two columns, the first column is the value, and the second column is the label shown in the drop-down. If the query returns three columns, the third column is used to indicate the default selection in that drop-down. This column can be any type, but the simplest is to use bool or numeric types, where 0 is false, and 1 is true.

If the column is a string type, null/empty string is considered false, and any other value is considered true. For single selection drop-downs, the first value with a true value is used as the default selection. For multiple selection drop-downs, all values with a true value are used as the default selected set. The items in the drop-down are shown in whatever order the query returned rows.

Let's look at the parameters present in the Connections Overview report. Click the edit symbol next to **Direction**.

This will launch the **Edit Parameter** menu item.

**Edit Parameter**

JSON Input ⓘ

Update

```
[{"value": "inbound", "label": "Inbound"}, {"value": "outbound", "label": "Outbound"}]
```

The JSON lets you generate an arbitrary table populated with content. For example, the following JSON generates two values in the drop-down:

```
[{"value": "inbound", "label": "Inbound"}, {"value": "outbound", "label": "Outbound"}]
```

A more applicable example is using a drop-down to pick from a set of performance counters by name:

```
Perf
| summarize by CounterName, ObjectName
| order by ObjectName asc, CounterName asc
| project Counter = pack('counter', CounterName, 'object', ObjectName), CounterName, group = ObjectName
```

The query will display results as follows:

## Edit Parameter

```
// {Workspaces:label}
Perf
| where TimeGenerated < TimeRange
| where ObjectName != 'Network' and ObjectName != 'Network Interface'
| summarize by CounterName, ObjectName, CounterText = CounterName
| order by ObjectName asc, CounterText asc
| project Counter = pack('counter', CounterName, 'object', ObjectName)
, CounterText, group = ObjectName
```

Counter	CounterText	group
("counter": "% Used Inodes", "object": "Logical Disk")	% Used Inodes	Log
("counter": "% Used Space", "object": "Logical Disk")	% Used Space	Log
("counter": "Disk Read Bytes/sec", "object": "Logical Disk")	Disk Read Bytes/sec	Log
("counter": "Disk Reads/sec", "object": "Logical Disk")	Disk Reads/sec	Log

Drop-downs are incredibly powerful tools for customizing and creating interactive reports.

### Time range parameters

While you can make your own custom time range parameter via the dropdown parameter type, you can also use the out-of-box time range parameter type if you don't need the same degree of flexibility.

Time range parameter types have 15 default ranges that go from five minutes to the last 90 days. There is also an option to allow custom time range selection, which allows the operator of the report to choose explicit start and stop values for the time range.

### Resource picker

The resource picker parameter type gives you the ability to scope your report to certain types of resources. An example of a prebuilt workbook that leverages the resource picker type is the **Performance** workbook.

## Saving and sharing workbooks with your team

Workbooks are saved within a Log Analytics Workspace or a virtual machine resource, depending on how you access the workbooks gallery. The workbook can be saved to the **My Reports** section that's private to you or in the **Shared Reports** section that's accessible to everyone with access to the resource. To view all the

workbooks in the resource, click the **Open** button in the action bar.

To share a workbook that's currently in **My Reports**:

1. Click **Open** in the action bar
2. Click the "..." button beside the workbook you want to share
3. Click **Move to Shared Reports**.

To share a workbook with a link or via email, click **Share** in the action bar. Keep in mind that recipients of the link need access to this resource in the Azure portal to view the workbook. To make edits, recipients need at least Contributor permissions for the resource.

To pin a link to a workbook to an Azure Dashboard:

1. Click **Open** in the action bar
2. Click the "..." button beside the workbook you want to pin
3. Click **Pin to dashboard**.

# Monitor virtual machines with Azure Monitor: Alerts

9/21/2022 • 10 minutes to read • [Edit Online](#)

This article is part of the scenario [Monitor virtual machines and their workloads in Azure Monitor](#). It provides guidance on creating alert rules for your virtual machines and their guest operating systems. [Alerts in Azure Monitor](#) proactively notify you of interesting data and patterns in your monitoring data. There are no preconfigured alert rules for virtual machines, but you can create your own based on data collected by VM insights.

## NOTE

This scenario describes how to implement complete monitoring of your Azure and hybrid virtual machine environment. To get started monitoring your first Azure virtual machine, see [Monitor Azure virtual machines](#), [Tutorial: Create a metric alert for an Azure resource](#), or [Tutorial: Create alert when Azure virtual machine is unavailable](#).

## IMPORTANT

Most alert rules have a cost that's dependent on the type of rule, how many dimensions it includes, and how frequently it's run. Before you create any alert rules, refer to [Alert rules in Azure Monitor pricing](#).

## Choose the alert type

The most common types of alert rules in Azure Monitor are [metric alerts](#) and [log query alerts](#). The type of alert rule that you create for a particular scenario depends on where the data is located that you're alerting on. You might have cases where data for a particular alerting scenario is available in both Metrics and Logs, and you'll need to determine which rule type to use. You might also have flexibility in how you collect certain data and let your decision of alert rule type drive your decision for data collection method.

Typically, the best strategy is to use metric alerts instead of log alerts when possible because they're more responsive and stateful. To use metric alerts, the data you're alerting on must be available in Metrics. VM insights currently sends all of its data to Logs, so you must install the Azure Monitor agent to use metric alerts with data from the guest operating system. Use Log query alerts with metric data when it's unavailable in Metrics or if you require logic beyond the relatively simple logic for a metric alert rule.

### Metric alerts

[Metric alert rules](#) are useful for alerting when a particular metric exceeds a threshold. An example is when the CPU of a machine is running high. The target of a metric alert rule can be a specific machine, a resource group, or a subscription. In this instance, you can create a single rule that applies to a group of machines.

Metric rules for virtual machines can use the following data:

- Host metrics for Azure virtual machines, which are collected automatically.
- Metrics that are collected by the Azure Monitor agent from the guest operating system.

## NOTE

When VM insights supports the Azure Monitor agent, which is currently in public preview, it sends performance data from the guest operating system to Metrics so that you can use metric alerts.

## Log alerts

Log alerts can measure two different things which can be used to monitor virtual machines in different scenarios:

- **Result count:** Counts the number of rows returned by the query, and can be used to work with events such as Windows event logs, syslog, application exceptions.
- **Calculation of a value:** Makes a calculation based on a numeric column, and can be used to include any number of resources. For example, CPU percentage.

## Targeting resources and dimensions

You can monitor multiple instances' values with one rule using dimensions. You would use dimensions if, for example, you want to monitor CPU usage on multiple instances running your web site or app for CPU usage over 80%.

To create resource-centric alerts at scale for a subscription or resource group, you can **Split by dimensions**. When you want to monitor the same condition on multiple Azure resources, splitting by dimensions splits the alerts into separate alerts by grouping unique combinations using numerical or string columns. Splitting on Azure resource ID column makes the specified resource into the alert target.

You may also decide not to split when you want a condition on multiple resources in the scope, for example, if you want to alert if at least five machines in the resource group scope have CPU usage over 80%.

The screenshot shows the 'Create an alert rule' interface in the Microsoft Azure (Preview) portal. The 'Condition' tab is active. In the 'Split by dimensions' section, a dimension named '\_ResourceId' is selected. The 'Alert logic' section includes an operator 'Less than', a threshold value of '20', and a frequency of evaluation of '10 minutes'. The top right of the interface includes a search bar and a 'Report a bug' button.

You might want to see a list of the alerts with the affected computers. You can use a custom workbook that uses a custom [Resource Graph](#) to provide this view. Use the following query to display alerts, and use the data source

Azure Resource Graph in the workbook.

```
alertsmanagementresources
| extend dimension = properties.context.context.condition.allOf
| mv-expand dimension
| extend dimension = dimension.dimensions
| mv-expand dimension
| extend Computer = dimension.value
| extend AlertStatus = properties.essentials.alertState
| summarize count() by Alert=name, tostring(AlertStatus), tostring(Computer)
| project Alert, AlertStatus, Computer
```

## Common alert rules

The following section lists common alert rules for virtual machines in Azure Monitor. Details for metric alerts and log metric measurement alerts are provided for each. For guidance on which type of alert to use, see [Choose the alert type](#).

If you're unfamiliar with the process for creating alert rules in Azure Monitor, see the [instructions to create a new alert rule](#).

### Machine unavailable

The most basic requirement is to send an alert when a machine is unavailable. It could be stopped, the guest operating system could be unresponsive, or the agent could be unresponsive. There are various ways to configure this alerting, but the most common is to use the heartbeat sent from the Log Analytics agent.

#### Log query alert rules

Log query alerts use the [Heartbeat table](#), which should have a heartbeat record every minute from each machine.

Use a rule with the following query.

```
Heartbeat
| summarize TimeGenerated=max(TimeGenerated) by Computer, _ResourceId
| extend Duration = datetime_diff('minute',now(),TimeGenerated)
| summarize AggregatedValue = min(Duration) by Computer, bin(TimeGenerated,5m), _ResourceId
```

#### Metric alert rules

A metric called *Heartbeat* is included in each Log Analytics workspace. Each virtual machine connected to that workspace sends a heartbeat metric value each minute. Because the computer is a dimension on the metric, you can fire an alert when any computer fails to send a heartbeat. Set the **Aggregation type** to **Count** and the **Threshold** value to match the **Evaluation granularity**.

### CPU alerts

#### Metric alert rules

TARGET	METRIC
Host	Percentage CPU
Windows guest	\Processor Information(_Total)% Processor Time
Linux guest	cpu/usage_active

#### Log alert rules

### CPU utilization

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Processor" and Name == "UtilizationPercentage"
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId

```

## Memory alerts

### Metric alert rules

TARGET	METRIC
Windows guest	\Memory% Committed Bytes in Use \Memory\Available Bytes
Linux guest	mem/available mem/available_percent

### Log alert rules

#### Available memory in MB

```

InsightsMetrics

```

## Logical disk data rate

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "LogicalDisk" and Name == "BytesPerSecond"
| extend Disk=tostring(todynamic(Tags)["vm.azm.ms/mountId"])
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId, Disk

```

# Network alerts

## Metric alert rules

TARGET	METRIC
Windows guest	\Network Interface\Bytes Sent/sec \Logical Disk(_Total)\Free Megabytes
Linux guest	disk/free disk/free_percent

## Log query alert rules

### Network interfaces bytes received - all interfaces

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Network" and Name == "ReadBytesPerSecond"
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId

```

### Network interfaces bytes received - individual interfaces

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Network" and Name == "ReadBytesPerSecond"
| extend NetworkInterface=tostring(todynamic(Tags)["vm.azm.ms/networkDeviceId"])
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId, NetworkInterface

```

### Network interfaces bytes sent - all interfaces

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Network" and Name == "WriteBytesPerSecond"
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId

```

## Network interfaces bytes sent - individual interfaces

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Network" and Name == "WriteBytesPerSecond"
| extend NetworkInterface=tostring(todynamic(Tags)["vm.azm.ms/networkDeviceId"])
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId, NetworkInterface

```

## Example log query alert

Here's a walk-through of creating a log alert for when the CPU of a virtual machine exceeds 80 percent. The data you need is in the [InsightsMetrics table](#). The following query returns the records that need to be evaluated for the alert. Each type of alert rule uses a variant of this query.

### Create the log alert rule

1. In the portal, select the relevant resource. We recommend scaling resources by using subscriptions or resource groups.
2. In the Resource menu, select **Logs**.
3. Use this query to monitor for virtual machines CPU usage:

```

InsightsMetrics
| where Origin == "vm.azm.ms"
| where Namespace == "Processor" and Name == "UtilizationPercentage"
| summarize AggregatedValue = avg(Val) by bin(TimeGenerated, 15m), Computer, _ResourceId

```

4. Run the query to make sure you get the results you were expecting.
5. From the top command bar, Select **+ New alert rule** to create a rule using the current query.
6. The **Create an alert rule** page opens with your query. We try to detect summarized data from the query results automatically. If detected, the appropriate values are automatically selected.

The screenshot shows the 'Create an alert rule' interface. On the left, there's a sidebar with icons for Scope, Condition, Actions, Details, Tags, and Review + create. The 'Scope' tab is currently selected. The main area has tabs for Scope, Condition, Actions, Details, Tags, and Review + create. Under 'Condition', there's a star icon and a note: 'Configure when the alert rule should trigger by selecting a signal and defining its logic.' Below that is a 'Log query' section with a note: 'Define the logic for triggering an alert. Use the chart to view trends in the data. Learn more'. It shows the query: 'The query to run on this resource's logs. The results returned by this query are used to populate the alert definition below.' A 'Search query' input field contains the InsightsMetrics query. At the bottom of the 'Log query' section is a link: 'View result and edit query in Logs'.

7. In the **Measurement** section, select the values for these fields if they are not already automatically selected.

FIELD	DESCRIPTION	VALUE FOR THIS SCENARIO
-------	-------------	-------------------------

FIELD	DESCRIPTION	VALUE FOR THIS SCENARIO
Measure	The number of table rows or a numeric column to aggregate	AggregatedValue
Aggregation type	The type of aggregation to apply to the data points in aggregation granularity	Average
Aggregation granularity	The interval over which data points are grouped by the aggregation type	15 minutes

Measurement

Select how to summarize the results. We try to detect summarized data from the query results automatically.

Measure: AggregatedValue

Aggregation type: Average

Aggregation granularity: 15 minutes

8. In the **Split by dimensions** section, select the values for these fields if they are not already automatically selected.

FIELD	DESCRIPTION	VALUE FOR THIS SCENARIO
Resource ID column	An Azure Resource ID column that will split the alerts and set the fired alert target scope.	_ResourceId
Dimension name	Dimensions monitor specific time series and provide context to the fired alert. Dimensions can be either number or string columns. If you select more than one dimension value, each time series that results from the combination will trigger its own alert and will be charged separately. The displayed dimension values are based on data from the last 48 hours. Custom dimension values can be added by clicking 'Add custom value'.	Computer
Operator	The operator to compare the dimension value	=
Dimension value	The list of dimension column values	All current and future values

Split by dimensions

Resource ID column: \_ResourceId

Dimension name	Operator	Dimension values
Computer	=	All current and future values

Add custom value

9. In the **Alert Logic** section, select the values for these fields if they are not already automatically selected.

FIELD	DESCRIPTION	VALUE FOR THIS SCENARIO
Operator	The operator to compare the metric value against the threshold	Greater than
Threshold value	The value that the result is measured against.	80
Frequency of evaluation	How often the alert rule should run. A frequency smaller than the aggregation granularity results in a sliding window evaluation.	15 minutes

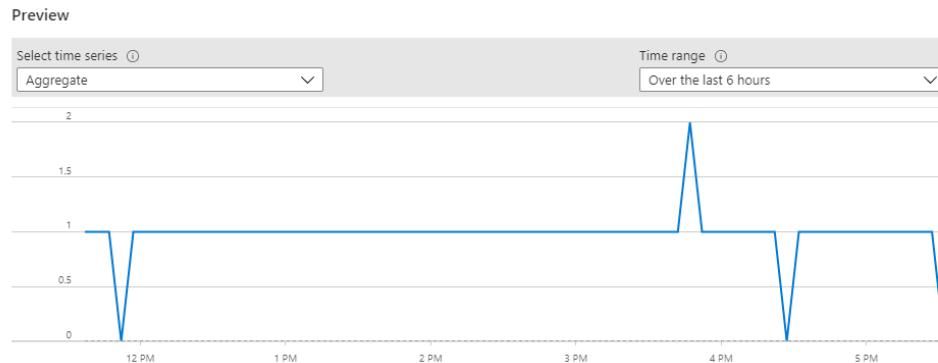

10. (Optional) In the **Advanced options** section, set the **Number of violations to trigger alert**.

Advanced options

Number of violations to trigger the alert:

Number of violations	<input type="text" value="1"/>
Evaluation period	<input type="text" value="5 minutes"/> (1 aggregated points)
Override query time range ⓘ	<input type="text" value="None (5 minutes)"/>

11. The **Preview** chart shows query evaluations results over time. You can change the chart period or select different time series that resulted from unique alert splitting by dimensions.

12. From this point on, you can select the **Review + create** button at any time.

13. In the **Actions** tab, select or create the required **action groups**.

Scope Condition Actions Details Tags Review + create

An action group is a set of actions that can be applied to an alert rule. [Learn more](#)

requirements.

16. In the **Tags** tab, set any required tags on the alert rule resource.

The screenshot shows the 'Tags' tab of an alert rule configuration. At the top, there are tabs for Scope, Condition, Actions, Details, Tags (which is underlined), and Review + create. Below the tabs, a note states: 'Tags are name and value pairs that enable you to categorize resources and view consolidated billing by applying the same tag to multiple resources and resource groups. [Learn more about using tags](#)'.

Note that if you later change resource settings on other tabs, your tags will be automatically updated.

Below this, there is a table with two columns: 'Name' and 'Value'. A single row is shown with a placeholder 'Name : Value'. At the bottom of the screen, there are three buttons: 'Review + create' (highlighted in blue), 'Previous', and 'Next: Review + create >'.

17. In the **Review + create** tab, a validation will run and inform you of any issues.

18. When validation passes and you have reviewed the settings, click the **Create** button.

The screenshot shows the 'Review + create' tab of the alert rule configuration. It includes sections for Product Details, Scope, Condition, Alert logic, and Advanced options. The 'Product Details' section shows Log alerts, 1 Condition (highlighted in red), Terms of use | Privacy statement, Total Total pricing (\$), and Pricing. The 'Scope' section shows Resource: ACME-Portal, ACME Telco, and MyResourceGro... The 'Condition' section has a collapsed 'Search query' section. The 'Alert logic' section shows Operator: GreaterThan, Threshold value: 5, and Frequency of evaluation: 5 minutes. The 'Advanced options' section is collapsed. At the bottom, there are 'Create' and 'Previous' buttons.

## Next steps

- [Monitor workloads running on virtual machines.](#)
- [Analyze monitoring data collected for virtual machines.](#)

# Dependency Agent

9/21/2022 • 3 minutes to read • [Edit Online](#)

The Dependency Agent collects data about processes running on the virtual machine and external process dependencies. Dependency Agent updates include bug fixes or support of new features or functionality. This article describes Dependency Agent requirements and how to upgrade Dependency Agent manually or through automation.

## Dependency Agent requirements

- The Dependency Agent requires the Log Analytics Agent to be installed on the same machine.
- On both the Windows and Linux versions, the Dependency Agent collects data using a user-space service and a kernel driver.
  - Dependency Agent supports the same [Windows versions Log Analytics Agent supports](#), except Windows Server 2008 SP2 and Azure Stack HCI.
  - For Linux, see [Dependency Agent Linux support](#).

## Upgrade Dependency Agent

You can upgrade the Dependency agent for Windows and Linux manually or automatically, depending on the deployment scenario and environment the machine is running in, using these methods:

ENVIRONMENT	INSTALLATION METHOD	UPGRADE METHOD
Azure VM	Dependency agent VM extension for <a href="#">Windows</a> and <a href="#">Linux</a>	Agent is automatically upgraded by default unless you configured your Azure Resource Manager template to opt out by setting the property <code>autoUpgradeMinorVersion</code> to <code>false</code> . The upgrade for minor version where auto upgrade is disabled, and a major version upgrade follow the same method - uninstall and reinstall the extension.
Custom Azure VM images	Manual install of Dependency agent for Windows/Linux	Updating VMs to the newest version of the agent needs to be performed from the command line running the Windows installer package or Linux self-extracting and installable shell script bundle.
Non-Azure VMs	Manual install of Dependency agent for Windows/Linux	Updating VMs to the newest version of the agent needs to be performed from the command line running the Windows installer package or Linux self-extracting and installable shell script bundle.

### Upgrade Windows agent

Update the agent on a Windows VM from the command prompt, with a script or other automation solution, or by using the `InstallDependencyAgent-Windows.exe` Setup Wizard.

Download the latest version of the Windows agent.

#### Using the Setup Wizard

1. Sign on to the computer with an account that has administrative rights.
2. Execute `InstallDependencyAgent-Windows.exe` to start the Setup Wizard.
3. Follow the **Dependency Agent Setup** wizard to uninstall the previous version of the dependency agent and then install the latest version.

#### From the command line

1. Sign on to the computer with an account that has administrative rights.
2. Run the following command.

```
InstallDependencyAgent-Windows.exe /S /RebootMode=manual
```

The `/RebootMode=manual` parameter prevents the upgrade from automatically rebooting the machine if some processes are using files from the previous version and have a lock on them.

3. To confirm the upgrade was successful, check the `install.log` for detailed setup information. The log directory is `%Programfiles%\Microsoft Dependency Agent\logs`.

#### Upgrade Linux agent

Upgrade from prior versions of the Dependency agent on Linux is supported and performed following the same command as a new installation.

You can download the latest version of the Linux agent from [here](#).

1. Sign on to the computer with an account that has administrative rights.
2. Run the following command as root.

```
InstallDependencyAgent-Linux64.bin -s
```

If the Dependency agent fails to start, check the logs for detailed error information. On Linux agents, the log directory is `/var/opt/microsoft/dependency-agent/log`.

## Dependency Agent Linux support

Since the Dependency agent works at the kernel level, support is also dependent on the kernel version. As of Dependency agent version 9.10.\* the agent supports \* kernels. The following table lists the major and minor Linux OS release and supported kernel versions for the Dependency agent.

#### NOTE

Dependency agent is not supported for Azure Virtual Machines with Ampere Altra ARM-based processors.

DISTRIBUTION	OS VERSION	KERNEL VERSION

## Next steps

If you want to stop monitoring your VMs for a while or remove VM insights entirely, see [Disable monitoring of your VMs in VM insights](#).

# Disable monitoring of your VMs in VM insights

9/21/2022 • 3 minutes to read • [Edit Online](#)

After you enable monitoring of your virtual machines (VMs), you can later choose to disable monitoring in VM insights. This article shows how to disable monitoring for one or more VMs.

Currently, VM insights doesn't support selective disabling of VM monitoring. Your Log Analytics workspace might support VM insights and other solutions. It might also collect other monitoring data. If your Log Analytics workspace provides these services, you need to understand the effect and methods of disabling monitoring before you start.

VM insights relies on the following components to deliver its experience:

- A Log Analytics workspace, which stores monitoring data from VMs and other sources.
- A collection of performance counters configured in the workspace. The collection updates the monitoring configuration on all VMs connected to the workspace.
- `VMInsights`, which is a monitoring solution configured in the workspace. This solution updates the monitoring configuration on all VMs connected to the workspace.
- `MicrosoftMonitoringAgent` (for Windows) or `OmsAgentForLinux` (for Linux), and `DependencyAgent`, which are Azure VM extensions. These extensions collect and send data to the workspace.

As you prepare to disable monitoring of your VMs, keep these considerations in mind:

- If you evaluated with a single VM and used the preselected default Log Analytics workspace, you can disable monitoring by uninstalling the Dependency agent from the VM and disconnecting the Log Analytics agent from this workspace. This approach is appropriate if you intend to use the VM for other purposes and decide later to reconnect it to a different workspace.
- If you selected a preexisting Log Analytics workspace that supports other monitoring solutions and data collection from other sources, you can remove solution components from the workspace without interrupting or affecting your workspace.

## NOTE

After removing the solution components from your workspace, you might continue to see performance and map data for your Azure VMs. Data will eventually stop appearing in the **Performance** and **Map** views. The **Enable** option will be available from the selected Azure VM so you can re-enable monitoring in the future.

## Remove VM insights completely

If you still need the Log Analytics workspace, follow these steps to completely remove VM insights. You'll remove the `VMInsights` solution from the workspace.

1. Sign in to the [Azure portal](#).
2. In the Azure portal, select **All services**. In the list of resources, type **Log Analytics**. As you begin typing, the list filters suggestions based on your input. Select **Log Analytics**.
3. In your list of Log Analytics workspaces, select the workspace you chose when you enabled VM insights.
4. On the left, select **Solutions**.
5. In the list of solutions, select **VMInsights(workspace name)**. On the **Overview** page for the solution, select **Delete**. When prompted to confirm, select **Yes**.

## Disable monitoring and keep the workspace

If your Log Analytics workspace still needs to support monitoring from other sources, following these steps to disable monitoring on the VM that you used to evaluate VM insights. For Azure VMs, you'll remove the dependency agent VM extension and the Log Analytics agent VM extension for Windows or Linux directly from the VM.

### NOTE

Don't remove the Log Analytics agent if:

- Azure Automation manages the VM to orchestrate processes or to manage configuration or updates.
- Microsoft Defender for Cloud manages the VM for security and threat detection.

If you do remove the Log Analytics agent, you will prevent those services and solutions from proactively managing your VM.

1. Sign in to the [Azure portal](#).
2. In the Azure portal, select **Virtual Machines**.
3. From the list, select a VM.
4. On the left, select **Extensions**. On the **Extensions** page, select **DependencyAgent**.
5. On the extension properties page, select **Uninstall**.
6. On the **Extensions** page, select **MicrosoftMonitoringAgent**. On the extension properties page, select **Uninstall**.

# Understanding Azure virtual machine usage

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

By analyzing your Azure usage data, powerful consumption insights can be gained – insights that can enable better cost management and allocation throughout your organization. This document provides a deep dive into your Azure Compute consumption details. For more details on general Azure usage, navigate to [Understanding your bill](#).

## Download your usage details

To begin, [download your usage details](#). The table below provides the definition and example values of usage for Virtual Machines deployed via the Azure Resource Manager. This document does not contain detailed information for VMs deployed via our classic model.

FIELD	MEANING	EXAMPLE VALUES
Usage Date	The date when the resource was used	11/23/2017
Meter ID	Identifies the top-level service for which this usage belongs to	Virtual Machines
Meter Sub-Category	<p>The billed meter identifier.</p> <p>For Compute Hour usage, there is a meter for each VM Size + OS (Windows, Non-Windows) + Region.</p> <p>For Premium software usage, there is a meter for each software type. Most premium software images have different meters for each core size. For more information, visit the <a href="#">Compute Pricing Page</a></p>	2005544f-659d-49c9-9094-8e0aea1be3a5
Meter Name	This is specific for each service in Azure. For compute, it is always "Compute Hours".	Compute Hours
Meter Region	Identifies the location of the datacenter for certain services that are priced based on datacenter location.	JA East
Unit	Identifies the unit that the service is charged in. Compute resources are billed per hour.	Hours
Consumed	The amount of the resource that has been consumed for that day. For Compute, we bill for each minute the VM ran for a given hour (up to 6 decimals of accuracy).	1, 0.5
Resource Location	Identifies the datacenter where the resource is running.	JA East
Consumed Service	The Azure platform service that you used.	Microsoft.Compute
Resource Group	The resource group in which the deployed resource is running in. For more information, see <a href="#">Azure Resource Manager overview</a> .	MyRG

FIELD	MEANING	EXAMPLE VALUES
Instance ID	The identifier for the resource. The identifier contains the name you specify for the resource when it was created. For VMs, the Instance ID will contain the SubscriptionId, ResourceGroupName, and VMName (or scale set name for scale set usage).	/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/MyRG/providers/Microsoft.Compute/virtualMachines/ or /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/MyRG/providers/Microsoft.Compute/virtualMachines/
Tags	Tag you assign to the resource. Use tags to group billing records. Learn how to tag your Virtual Machines using the <a href="#">CLI</a> or <a href="#">PowerShell</a> . This is available for Resource Manager VMs only.	{"myDepartment": "RD", "myUser": "myName"}
Additional Info	<p>Service-specific metadata. For VMs, we populate the following data in the additional info field:</p> <p>Image Type- specific image that you ran. Find the full list of supported strings below under Image Types.</p> <p>Service Type: the size that you deployed.</p> <p>VMName: name of your VM. This field is only populated for scale set VMs. If you need your VM Name for scale set VMs, you can find that in the Instance ID string above.</p> <p>UsageType: This specifies the type of usage this represents.</p> <p>ComputeHR is the Compute Hour usage for the underlying VM, like Standard_D1_v2.</p> <p>ComputeHR_SW is the premium software charge if the VM is using premium software.</p>	<p>Virtual Machines</p> <pre>{"ImageType": "Canonical", "ServiceType": "Standard_DS1_v2", "VMName": "UsageType": "ComputeHR"}</pre> <p>Virtual Machine Scale Sets</p> <pre>{"ImageType": "Canonical", "ServiceType": "Standard_DS1_v2", "VMName": "UsageType": "ComputeHR"}</pre> <p>Premium Software</p> <pre>{"ImageType": "", "ServiceType": "Standard_DS1_v2", "VMName": "", "UsageType": "ComputeHR_SW"}</pre>

## Image Type

For some images in the Azure gallery, the image type is populated in the Additional Info field. This enables users to understand and track what they have deployed on their Virtual Machine. The following values that are populated in this field based on the image you have deployed:

- BitRock
- Canonical FreeBSD
- Open Logic
- Oracle
- SLES for SAP
- SQL Server 14 Preview on Windows Server 2012 R2 Preview
- SUSE
- SUSE Premium
- StorSimple Cloud Appliance
- Red Hat
- Red Hat for SAP Business Applications
- Red Hat for SAP HANA
- Windows Client BYOL
- Windows Server BYOL
- Windows Server Preview

## Service Type

The service type field in the Additional Info field corresponds to the exact VM size you deployed. Premium storage VMs (SSD-based) and non-premium storage VMs (HDD-based) are priced the same. If you deploy an SSD-based size, like Standard\_DS2\_v2, you see the non-SSD size (`Standard_D2_v2 VM`) in the Meter Sub-Category column and the SSD-size (`Standard_DS2_v2`) in the Additional Info field.

## Region Names

The region name populated in the Resource Location field in the usage details varies from the region name used in the Azure Resource Manager. Here is a mapping between the region values:

RESOURCE MANAGER REGION NAME	RESOURCE LOCATION IN USAGE DETAILS
australiaeast	AU East
australiasoutheast	AU Southeast
brazilsouth	BR South
CanadaCentral	CA Central
CanadaEast	CA East
CentralIndia	IN Central
centralus	Central US
chinaeast	China East
chinanorth	China North
eastasia	East Asia
eastus	East US
eastus2	East US 2
GermanyCentral	DE Central
GermanyNortheast	DE Northeast
japaneast	JA East
japanwest	JA West
KoreaCentral	KR Central
KoreaSouth	KR South
northcentralus	North Central US
northeurope	North Europe
southcentralus	South Central US
southeastasia	Southeast Asia
SouthIndia	IN South
UKNorth	US North
uksouth	UK South
UKSouth2	UK South 2
ukwest	UK West
USDoDCentral	US DoD Central
USDoDEast	US DoD East
USGovArizona	USGov Arizona
usgoviowa	USGov Iowa

RESOURCE MANAGER REGION NAME	RESOURCE LOCATION IN USAGE DETAILS
USGovTexas	USGov Texas
usgovvirginia	USGov Virginia
westcentralus	US West Central
westeurope	West Europe
WestIndia	IN West
westus	West US
westus2	US West 2

## Virtual machine usage FAQ

### What resources are charged when deploying a VM?

VMs acquire costs for the VM itself, any premium software running on the VM, the storage account\managed disk associated with the VM, and the networking bandwidth transfers from the VM.

### How can I tell if a VM is using Azure Hybrid Benefit in the Usage CSV?

If you deploy using the [Azure Hybrid Benefit](#), you are charged the Non-Windows VM rate since you are bringing your own license to the cloud. In your bill, you can distinguish which Resource Manager VMs are running Azure Hybrid Benefit because they have either "Windows\_Server BYOL" or "Windows\_Client BYOL" in the ImageType column.

### How are Basic vs. Standard VM Types differentiated in the Usage CSV?

Both Basic and Standard A-Series VMs are offered. If you deploy a Basic VM, in the Meter Sub Category, it has the string "Basic." If you deploy a Standard A-Series VM, then the VM size appears as "A1 VM" since Standard is the default. To learn more about the differences between Basic and Standard, see the [Pricing Page](#).

### What are ExtraSmall, Small, Medium, Large, and ExtraLarge sizes?

ExtraSmall - ExtraLarge are the legacy names for Standard\_A0 – Standard\_A4. In classic VM usage records, you might see this convention used if you have deployed these sizes.

### What is the difference between Meter Region and Resource Location?

The Meter Region is associated with the meter. For some Azure services who use one price for all regions, the Meter Region field could be blank. However, since VMs have dedicated prices per region for Virtual Machines, this field is populated. Similarly, the Resource Location for Virtual Machines is the location where the VM is deployed. The Azure regions in both fields are the same, although they might have a different string convention for the region name.

### Why is the ImageType value blank in the Additional Info field?

The ImageType field is only populated for a subset of images. If you did not deploy one of the images above, the ImageType is blank.

### Why is the VMName blank in the Additional Info?

The VMName is only populated in the Additional Info field for VMs in a scale set. The InstanceID field contains the VM name for non-scale set VMs.

### What does ComputeHR mean in the UsageType field in the Additional Info?

ComputeHR stands for Compute Hour which represents the usage event for the underlying infrastructure cost. If the UsageType is ComputeHR\_SW, the usage event represents the premium software charge for the VM.

### How do I know if I am charged for premium software?

When exploring which VM Image best fits your needs, be sure to check out [Azure Marketplace](#). The image has the software plan rate. If you see "Free" for the rate, there is no additional cost for the software.

### What is the difference between Microsoft.ClassicCompute and Microsoft.Compute in the Consumed service?

Microsoft.ClassicCompute represents classic resources deployed via the Azure Service Manager. If you deploy via the Resource Manager, then Microsoft.Compute is populated in the consumed service. Learn more about the [Azure Deployment models](#).

### Why is the InstanceID field blank for my Virtual Machine usage?

If you deploy via the classic deployment model, the InstanceID string is not available.

### Why are the tags for my VMs not flowing to the usage details?

Tags flow to the Usage CSV for Resource Manager VMs only. Classic resource tags are not available in the usage details.

**How can the consumed quantity be more than 24 hours one day?**

In the Classic model, billing for resources is aggregated at the Cloud Service level. If you have more than one VM in a Cloud Service that uses the same billing meter, your usage is aggregated together. VMs deployed via Resource Manager are billed at the VM level, so this aggregation will not apply.

**Why is pricing not available for DS/FS/GS/LS sizes on the pricing page?**

Premium storage capable VMs are billed at the same rate as non-premium storage capable VMs. Only your storage costs differ. Visit the [storage pricing page](#) for more information.

## Next steps

To learn more about your usage details, see [Understand your bill for Microsoft Azure](#).

# How to tag a VM using the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes how to tag a VM using the Azure CLI. Tags are user-defined key/value pairs which can be placed directly on a resource or a resource group. Azure currently supports up to 50 tags per resource and resource group. Tags may be placed on a resource at the time of creation or added to an existing resource. You can also tag a virtual machine using Azure [PowerShell](#).

You can view all properties for a given VM, including the tags, using `az vm show`.

```
az vm show --resource-group myResourceGroup --name myVM --query tags
```

To add a new VM tag through the Azure CLI, you can use the `azure vm update` command along with the tag parameter `--set`:

```
az vm update \
--resource-group myResourceGroup \
--name myVM \
--set tags.myNewTagName1=myNewTagValue1 tags.myNewTagName2=myNewTagValue2
```

To remove tags, you can use the `--remove` parameter in the `azure vm update` command.

```
az vm update \
--resource-group myResourceGroup \
--name myVM \
--remove tags.myNewTagName1
```

Now that we have applied tags to our resources Azure CLI and the Portal, let's take a look at the usage details to see the tags in the billing portal.

## Next steps

- To learn more about tagging your Azure resources, see [Azure Resource Manager Overview](#) and [Using Tags to organize your Azure Resources](#).
- To see how tags can help you manage your use of Azure resources, see [Understanding your Azure Bill](#).

# Tagging a VM using the portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes how to add tags to a VM using the portal. Tags are user-defined key/value pairs which can be placed directly on a resource or a resource group. Azure currently supports up to 50 tags per resource and resource group. Tags may be placed on a resource at the time of creation or added to an existing resource.

1. Navigate to your VM in the portal.
2. In Essentials, select [Click here to add tags](#).

^ Essentials

Resource group ([change](#)) : myResourceGroup

Status : Running

Location : East US 2

Subscription ([change](#)) : myAzureSubscription

Subscription ID : 1010acb-1010-a1b2-c3d4-1010abcd1010

Tags ([change](#)) : [Click here to add tags](#)

3. Add a value for **Name** and **Value**, and then select **Save**.

## Edit tags

X

Tags are name/value pairs that enable you to categorize resources and view consolidated billing by applying the same tag to multiple resources and resource groups. Tag names are case insensitive, but tag values are case sensitive. [Learn more about tags](#) ↗

# How to tag a virtual machine in Azure using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes how to tag a VM in Azure using PowerShell. Tags are user-defined key/value pairs which can be placed directly on a resource or a resource group. Azure currently supports up to 50 tags per resource and resource group. Tags may be placed on a resource at the time of creation or added to an existing resource. If you want to tag a virtual machine using the Azure CLI, see [How to tag a virtual machine in Azure using the Azure CLI](#).

Use the `Get-AzVM` cmdlet to view the current list of tags for your VM.

```
Get-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM" | Format-List -Property Tags
```

If your Virtual Machine already contains tags, you will then see all the tags in list format.

To add tags, use the `Set-AzResource` command. When updating tags through PowerShell, tags are updated as a whole. If you are adding one tag to a resource that already has tags, you will need to include all the tags that you want to be placed on the resource. Below is an example of how to add additional tags to a resource through PowerShell Cmdlets.

Assign all of the current tags for the VM to the `$tags` variable, using the `Get-AzResource` and `Tags` property.

```
$tags = (Get-AzResource -ResourceGroupName myResourceGroup -Name myVM).Tags
```

To see the current tags, type the variable.

```
$tags
```

Here is what the output might look like:

Key	Value
Department	MyDepartment
Application	MyApp1
Created By	MyName
Environment	Production

In the following example, we add a tag called `Location` with the value `myLocation`. Use `+=` to append the new key/value pair to the `$tags` list.

```
$tags += @{Location="myLocation"}
```

Use `Set-AzResource` to set all of the tags defined in the `$tags` variable on the VM.

```
Set-AzResource -ResourceGroupName myResourceGroup -Name myVM -ResourceType "Microsoft.Compute/VirtualMachines" -Tag $tags
```

Use `Get-AzResource` to display all of the tags on the resource.

```
(Get-AzResource -ResourceGroupName myResourceGroup -Name myVM).Tags
```

The output should look something like the following, which now includes the new tag:

Key	Value
----	-----
Department	MyDepartment
Application	MyApp1
Created By	MyName
Environment	Production
Location	MyLocation

## Next steps

- To learn more about tagging your Azure resources, see [Azure Resource Manager Overview](#) and [Using Tags to organize your Azure Resources](#).
- To see how tags can help you manage your use of Azure resources, see [Understanding your Azure Bill](#).

# Tagging a VM using a template

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article describes how to tag a VM in Azure using a Resource Manager template. Tags are user-defined key/value pairs which can be placed directly on a resource or a resource group. Azure currently supports up to 50 tags per resource and resource group. Tags may be placed on a resource at the time of creation or added to an existing resource.

This template places tags on the following resources: Compute (Virtual Machine), Storage (Storage Account), and Network (Public IP Address, Virtual Network, and Network Interface). This template is for a Windows VM but can be adapted for Linux VMs.

Click the **Deploy to Azure** button from the [template link](#). This will navigate to the [Azure portal](#) where you can deploy this template.

## Simple deployment of a VM with Tags

 Deploy to Azure

 Visualize

This template includes the following tags: *Department*, *Application*, and *Created By*. You can add/edit these tags directly in the template if you would like different tag names.

```
"apiVersion": "2015-05-01-preview",
"type": "Microsoft.Compute/virtualMachines",
"name": "[variables('vmName')]",
"location": "[variables('location')]",
"tags": {
    "Department": "[parameters('departmentName')]",
    "Application": "[parameters('applicationName')]",
    "Created By": "[parameters('createdBy')]"
},
```

As you can see, the tags are defined as key/value pairs, separated by a colon (:). The tags must be defined in this format:

```
"tags": {
    "Key1" : "Value1",
    "Key2" : "Value2"
}
```

Save the template file after you finish editing it with the tags of your choice.

Next, in the **Edit Parameters** section, you can fill out the values for your tags.

DEPARTMENTNAME (string) ⓘ
MyDepartment
APPLICATIONNAME (string) ⓘ
MyApp
CREATEDBY (string) ⓘ
MyName

Click **Create** to deploy this template with your tag values.

### Next steps

- To learn more about tagging your Azure resources, see [Azure Resource Manager Overview](#) and [Using Tags to organize your Azure Resources](#).
- To see how tags can help you manage your use of Azure resources, see [Understanding your Azure Bill](#).

# Azure Instance Metadata Service (Linux)

9/21/2022 • 36 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The Azure Instance Metadata Service (IMDS) provides information about currently running virtual machine instances. You can use it to manage and configure your virtual machines. This information includes the SKU, storage, network configurations, and upcoming maintenance events. For a complete list of the data available, see the [Endpoint Categories Summary](#).

IMDS is available for running instances of virtual machines (VMs) and virtual machine scale set instances. All endpoints support VMs created and managed by using [Azure Resource Manager](#). Only the Attested category and Network portion of the Instance category support VMs created by using the classic deployment model. The Attested endpoint does so only to a limited extent.

IMDS is a REST API that's available at a well-known, non-routable IP address (`169.254.169.254`). You can only access it from within the VM. Communication between the VM and IMDS never leaves the host. Have your HTTP clients bypass web proxies within the VM when querying IMDS, and treat `169.254.169.254` the same as `168.63.129.16`.

## Usage

### Access Azure Instance Metadata Service

To access IMDS, create a VM from [Azure Resource Manager](#) or the [Azure portal](#), and use the following samples. For more examples, see [Azure Instance Metadata Samples](#).

Here's sample code to retrieve all metadata for an instance. To access a specific data source, see [Endpoint Categories](#) for an overview of all available features.

### Request

#### IMPORTANT

This example bypasses proxies. You **must** bypass proxies when querying IMDS. See [Proxies](#) for additional information.

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance?api-version=2021-02-01" | ConvertTo-Json -Depth 64
```

`-NoProxy` requires PowerShell V6 or greater. See our [samples repository](#) for examples with older PowerShell versions.

### Response

#### NOTE

The response is a JSON string. The following example response is pretty-printed for readability.

```

## Security and authentication

The Instance Metadata Service is only accessible from within a running virtual machine instance on a non-routable IP address. VMs are limited to interacting with metadata/functionality that pertains to themselves. The API is HTTP only and never leaves the host.

In order to ensure that requests are directly intended for IMDS and prevent unintended or unwanted redirection of requests, requests:

- Must contain the header `Metadata: true`
- Must **not** contain an `X-Forwarded-For` header

Any request that does not meet **both** of these requirements will be rejected by the service.

### IMPORTANT

IMDS is **not** a channel for sensitive data. The API is unauthenticated and open to all processes on the VM. Information exposed through this service should be considered as shared information to all applications running inside the VM.

If it is not necessary for every process on the VM to access IMDS endpoint, you can set local firewall rules to limit the access. For example, if only a known system service needs to access instance metadata service, you can set a firewall rule on IMDS endpoint, only allowing the specific process(es) to access, or denying access for the rest of the processes.

## Proxies

IMDS is **not** intended to be used behind a proxy and doing so is unsupported. Most HTTP clients provide an

option for you to disable proxies on your requests, and this functionality must be utilized when communicating with IMDS. Consult your client's documentation for details.

#### IMPORTANT

Even if you don't know of any proxy configuration in your environment, **you still must override any default client proxy settings**. Proxy configurations can be automatically discovered, and failing to bypass such configurations exposes you to outage risks should the machine's configuration be changed in the future.

## Rate limiting

In general, requests to IMDS are limited to 5 requests per second (on a per VM basis). Requests exceeding this threshold will be rejected with 429 responses. Requests to the [Managed Identity](#) category are limited to 20 requests per second and 5 concurrent requests.

## HTTP verbs

The following HTTP verbs are currently supported:

VERB	DESCRIPTION
GET	Retrieve the requested resource

## Parameters

Endpoints may support required and/or optional parameters. See [Schema](#) and the documentation for the specific endpoint in question for details.

### Query parameters

IMDS endpoints support HTTP query string parameters. For example:

```
http://169.254.169.254/metadata/instance/compute?api-version=2021-01-01&format=json
```

Specifies the parameters:

NAME	VALUE
api-version	2021-01-01
format	json

Requests with duplicate query parameter names will be rejected.

### Route parameters

For some endpoints that return larger json blobs, we support appending route parameters to the request endpoint to filter down to a subset of the response:

```
http://169.254.169.254/metadata/<endpoint>/[<filter parameter>/...]?<query parameters>
```

The parameters correspond to the indexes/keys that would be used to walk down the json object were you interacting with a parsed representation.

For example, `/metatadata/instance` returns the json object:

```
{  
    "compute": { ... },  
    "network": {  
        "interface": [  
            {  
                "ipv4": {  
                    "ipAddress": [{  
                        "privateIpAddress": "10.144.133.132",  
                        "publicIpAddress": ""  
                    }],  
                    "subnet": [{  
                        "address": "10.144.133.128",  
                        "prefix": "26"  
                    }]  
                },  
                "ipv6": {  
                    "ipAddress": [  
                        ...  
                    ]  
                },  
                "macAddress": "0011AAFFBB22"  
            },  
            ...  
        ]  
    }  
}
```

If we want to filter the response down to just the compute property, we would send the request:

```
http://169.254.169.254/metadata/instance/compute?api-version=<version>
```

Similarly, if we want to filter to a nested property or specific array element we keep appending keys:

```
http://169.254.169.254/metadata/instance/network/interface/0?api-version=<version>
```

would filter to the first element from the `Network.interface` property and return:

```
{  
    "ipv4": {  
        "ipAddress": [{  
            "privateIpAddress": "10.144.133.132",  
            "publicIpAddress": ""  
        }],  
        "subnet": [{  
            "address": "10.144.133.128",  
            "prefix": "26"  
        }]  
    },  
    "ipv6": {  
        "ipAddress": [  
            ...  
        ]  
    },  
    "macAddress": "0011AAFFBB22"  
}
```

#### NOTE

When filtering to a leaf node, `format=json` doesn't work. For these queries `format=text` needs to be explicitly specified since the default format is json.

## Schema

### Data format

By default, IMDS returns data in JSON format (`Content-Type: application/json`). However, endpoints that support response filtering (see [Route Parameters](#)) also support the format `text`.

To access a non-default response format, specify the requested format as a query string parameter in the request. For example:

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance?api-version=2017-08-01&format=text"
```

In json responses, all primitives will be of type `string`, and missing or inapplicable values are always included but will be set to an empty string.

### Versioning

IMDS is versioned and specifying the API version in the HTTP request is mandatory. The only exception to this requirement is the [versions](#) endpoint, which can be used to dynamically retrieve the available API versions.

As newer versions are added, older versions can still be accessed for compatibility if your scripts have dependencies on specific data formats.

When you don't specify a version, you get an error with a list of the newest supported versions:

```
{
    "error": "Bad request. api-version was not specified in the request. For more information refer to aka.ms/azureimds",
    "newest-versions": [
        "2020-10-01",
        "2020-09-01",
        "2020-07-15"
    ]
}
```

### Supported API versions

- 2017-03-01
- 2017-04-02
- 2017-08-01
- 2017-10-01
- 2017-12-01

## Swagger

A full Swagger definition for IMDS is available at: <https://github.com/Azure/azure-rest-api-specs/blob/main/specification/imds/data-plane/readme.md>

## Regional availability

The service is **generally available** in all Azure Clouds.

## Root endpoint

The root endpoint is `http://169.254.169.254/metadata`.

## Endpoint categories

The IMDS API contains multiple endpoint categories representing different data sources, each of which contains one or more endpoints. See each category for details.

CATEGORY ROOT	DESCRIPTION	VERSION INTRODUCED
<code>/metadata/attested</code>	See <a href="#">Attested Data</a>	2018-10-01
<code>/metadata/identity</code>	See <a href="#">Managed Identity via IMDS</a>	2018-02-01
<code>/metadata/instance</code>	See <a href="#">Instance Metadata</a>	2017-04-02
<code>/metadata/loadbalancer</code>	See <a href="#">Retrieve Load Balancer metadata via IMDS</a>	2020-10-01
<code>/metadata/scheduledevents</code>	See <a href="#">Scheduled Events via IMDS</a>	2017-08-01
<code>/metadata/versions</code>	See <a href="#">Versions</a>	N/A

# Versions

## NOTE

This feature was released alongside version 2020-10-01, which is currently being rolled out and may not yet be available in every region.

## List API versions

Returns the set of supported API versions.

```
GET /metadata/versions
```

### Parameters

None (this endpoint is unversioned).

### Response

```
{
  "apiVersions": [
    "2017-03-01",
    "2017-04-02",
    ...
  ]
}
```

# Instance metadata

## Get VM metadata

Exposes the important metadata for the VM instance, including compute, network, and storage.

```
GET /metadata/instance
```

### Parameters

NAME	REQUIRED/OPTIONAL	DESCRIPTION
<code>api-version</code>	Required	The version used to service the request.
<code>format</code>	Optional*	The format ( <code>json</code> or <code>text</code> ) of the response. *Note: May be required when using request parameters

This endpoint supports response filtering via [route parameters](#).

Schema breakdown:

## Compute

DATA	DESCRIPTION	VERSION INTRODUCED
<code>azEnvironment</code>	Azure Environment where the VM is running in	2018-10-01
<code>additionalCapabilities.hibernationEnabled</code>	Identifies if hibernation is enabled on the VM	2021-11-01+
<code>customData</code>	This feature is deprecated and disabled <a href="#">in IMDS</a> . It has been superseded by <code>userData</code>	2019-02-01
<code>evictionPolicy</code>	Sets how a <a href="#">Spot VM</a> will be evicted.	2020-12-01
<code>extendedLocation.type</code>	Type of the extended location of the VM.	2021-03-01
<code>extendedLocation.name</code>	Name of the extended location of the VM	2021-03-01
<code>host.id</code>	Name of the host of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15+
<code>hostGroup.id</code>	Name of the hostGroup of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15+
<code>isHostCompatibilityLayerVm</code>	Identifies if the VM runs on the Host Compatibility Layer	2020-06-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>licenseType</code>	Type of license for <a href="#">Azure Hybrid Benefit</a> . This is only present for AHB-enabled VMs	2020-09-01
<code>location</code>	Azure Region the VM is running in	2017-04-02
<code>name</code>	Name of the VM	2017-04-02
<code>offer</code>	Offer information for the VM image and is only present for images deployed from Azure image gallery	2017-04-02
<code>osProfile.adminUsername</code>	Specifies the name of the admin account	2020-07-15
<code>osProfile.computerName</code>	Specifies the name of the computer	2020-07-15
<code>osProfile.disablePasswordAuthentication</code>	Specifies if password authentication is disabled. This is only present for Linux VMs	2020-10-01
<code>osType</code>	Linux or Windows	2017-04-02
<code>placementGroupId</code>	<a href="#">Placement Group</a> of your virtual machine scale set	2017-08-01
<code>plan</code>	<a href="#">Plan</a> containing name, product, and publisher for a VM if it is an Azure Marketplace Image	2018-04-02
<code>platformUpdateDomain</code>	<a href="#">Update domain</a> the VM is running in	2017-04-02
<code>platformFaultDomain</code>	<a href="#">Fault domain</a> the VM is running in	2017-04-02
<code>platformSubFaultDomain</code>	Sub fault domain the VM is running in, if applicable.	2021-10-01
<code>priority</code>	Priority of the VM. Refer to <a href="#">Spot VMs</a> for more information	2020-12-01
<code>provider</code>	Provider of the VM	2018-10-01
<code>publicKeys</code>	<a href="#">Collection of Public Keys</a> assigned to the VM and paths	2018-04-02
<code>publisher</code>	Publisher of the VM image	2017-04-02
<code>resourceGroupName</code>	<a href="#">Resource group</a> for your Virtual Machine	2017-08-01
<code>resourceId</code>	The <a href="#">fully qualified</a> ID of the resource	2019-03-11

DATA	DESCRIPTION	VERSION INTRODUCED
<code>sku</code>	Specific SKU for the VM image	2017-04-02
<code>securityProfile.secureBootEnabled</code>	Identifies if UEFI secure boot is enabled on the VM	2020-06-01
<code>securityProfile.virtualTpmEnabled</code>	Identifies if the virtual Trusted Platform Module (TPM) is enabled on the VM	2020-06-01
<code>securityProfile.encryptionAtHost</code>	Identifies if <a href="#">Encryption at Host</a> is enabled on the VM	2021-11-01†
<code>securityProfile.securityType</code>	Identifies if the VM is a <a href="#">Trusted VM</a> or a <a href="#">Confidential VM</a>	2021-12-13†
<code>storageProfile</code>	See Storage Profile below	2019-06-01
<code>subscriptionId</code>	Azure subscription for the Virtual Machine	2017-08-01
<code>tags</code>	<a href="#">Tags</a> for your Virtual Machine	2017-08-01
<code>tagsList</code>	Tags formatted as a JSON array for easier programmatic parsing	2019-06-04
<code>userData</code>	The set of data specified when the VM was created for use during or after provisioning (Base64 encoded)	2021-01-01
<code>version</code>	Version of the VM image	2017-04-02
<code>virtualMachineScaleSet.id</code>	ID of the <a href="#">Virtual Machine Scale Set created with flexible orchestration</a> the Virtual Machine is part of. This field is not available for Virtual Machine Scale Sets created with uniform orchestration.	2021-03-01
<code>vmId</code>	<a href="#">Unique identifier</a> for the VM. The blog referenced only suits for VMs that have SMBIOS < 2.6. For VMs that have SMBIOS >= 2.6, the UUID from DMI is displayed in little-endian format, thus, there is no requirement to switch bytes.	2017-04-02
<code>vmScaleSetName</code>	<a href="#">Virtual machine scale set Name</a> of your virtual machine scale set	2017-12-01
<code>vmSize</code>	<a href="#">VM size</a>	2017-04-02
<code>zone</code>	<a href="#">Availability Zone</a> of your virtual machine	2017-12-01

† This version is not fully available yet and may not be supported in all regions.

## Storage profile

The storage profile of a VM is divided into three categories: image reference, OS disk, and data disks, plus an additional object for the local temporary disk.

The image reference object contains the following information about the OS image:

DATA	DESCRIPTION
<code>id</code>	Resource ID
<code>offer</code>	Offer of the platform or marketplace image
<code>publisher</code>	Image publisher
<code>sku</code>	Image sku
<code>version</code>	Version of the platform or marketplace image

The OS disk object contains the following information about the OS disk used by the VM:

DATA	DESCRIPTION
<code>caching</code>	Caching requirements
<code>createOption</code>	Information about how the VM was created
<code>diffDiskSettings</code>	Ephemeral disk settings
<code>diskSizeGB</code>	Size of the disk in GB
<code>image</code>	Source user image virtual hard disk
<code>managedDisk</code>	Managed disk parameters
<code>name</code>	Disk name
<code>vhd</code>	Virtual hard disk
<code>writeAcceleratorEnabled</code>	Whether or not writeAccelerator is enabled on the disk

The data disks array contains a list of data disks attached to the VM. Each data disk object contains the following information:

DATA	DESCRIPTION	VERSION INTRODUCED
<code>bytesPerSecondThrottle</code> *	Disk read/write quota in bytes	2021-05-01
<code>caching</code>	Caching requirements	2019-06-01
<code>createOption</code>	Information about how the VM was created	2019-06-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>diffDiskSettings</code>	Ephemeral disk settings	2019-06-01
<code>diskCapacityBytes</code> *	Size of disk in bytes	2021-05-01
<code>diskSizeGB</code>	Size of the disk in GB	2019-06-01
<code>encryptionSettings</code>	Encryption settings for the disk	2019-06-01
<code>image</code>	Source user image virtual hard disk	2019-06-01
<code>isSharedDisk</code> *	Identifies if the disk is shared between resources	2021-05-01
<code>isUltraDisk</code>	Identifies if the data disk is an Ultra Disk	2021-05-01
<code>lun</code>	Logical unit number of the disk	2019-06-01
<code>managedDisk</code>	Managed disk parameters	2019-06-01
<code>name</code>	Disk name	2019-06-01
<code>opsPerSecondThrottle</code> *	Disk read/write quota in IOPS	2021-05-01
<code>osType</code>	Type of OS included in the disk	2019-06-01
<code>vhd</code>	Virtual hard disk	2019-06-01
<code>writeAcceleratorEnabled</code>	Whether or not writeAccelerator is enabled on the disk	2019-06-01

\* These fields are only populated for Ultra Disks; they will be empty strings from non-Ultra Disks.

The encryption settings blob contains data about how the disk is encrypted (if it is encrypted):

DATA	DESCRIPTION	VERSION INTRODUCED
<code>diskEncryptionKey.sourceVault.id</code>	The location of the disk encryption key	2021-11-01†
<code>diskEncryptionKey.secretUrl</code>	The location of the secret	2021-11-01†
<code>keyEncryptionKey.sourceVault.id</code>	The location of the key encryption key	2021-11-01†
<code>keyEncryptionKey.keyUrl</code>	The location of the key	2021-11-01†

\† This version is not fully available yet and may not be supported in all regions.

The resource disk object contains the size of the [Local Temp Disk](#) attached to the VM, if it has one, in kilobytes. If there is [no local temp disk for the VM](#), this value is 0.

DATA	DESCRIPTION	VERSION INTRODUCED
<code>resourceDisk.size</code>	Size of the local temp disk for the VM (in kB)	2021-02-01

## Network

DATA	DESCRIPTION	VERSION INTRODUCED
<code>ipv4.privateIpAddress</code>	Local IPv4 address of the VM	2017-04-02
<code>ipv4.publicIpAddress</code>	Public IPv4 address of the VM	2017-04-02
<code>subnet.address</code>	Subnet address of the VM	2017-04-02
<code>subnet.prefix</code>	Subnet prefix, example 24	2017-04-02
<code>ipv6.ipAddress</code>	Local IPv6 address of the VM	2017-04-02
<code>macAddress</code>	VM mac address	2017-04-02

### NOTE

The nics returned by the network call are not guaranteed to be in order.

## Get user data

When creating a new VM, you can specify a set of data to be used during or after the VM provision, and retrieve it through IMDS. Check the end to end user data experience [here](#).

To set up user data, utilize the quickstart template [here](#). The sample below shows how to retrieve this data through IMDS. This feature is released with version `2021-01-01` and above.

### NOTE

Security notice: IMDS is open to all applications on the VM, sensitive data should not be placed in the user data.

- [Windows](#)
- [Linux](#)

```
$userData = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/compute/userData?api-version=2021-01-01&format=text" [System.Text.Encoding]::UTF8.GetString([Convert]::FromBase64String($userData))
```

### Sample 1: Tracking VM running on Azure

As a service provider, you may require to track the number of VMs running your software or have agents that need to track uniqueness of the VM. To be able to get a unique ID for a VM, use the `vmId` field from Instance Metadata Service.

## Request

- [Windows](#)

- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/vmId?api-version=2017-08-01&format=text"
```

## Response

```
5c08b38e-4d57-4c23-ac45-aca61037f084
```

### Sample 2: Placement of different data replicas

For certain scenarios, placement of different data replicas is of prime importance. For example, [HDFS replica placement](#) or container placement via an [orchestrator](#) might require you to know the `platformFaultDomain` and `platformUpdateDomain` the VM is running on. You can also use [Availability Zones](#) for the instances to make these decisions. You can query this data directly via IMDS.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/platformFaultDomain?api-version=2017-08-01&format=text"
```

## Response

```
0
```

### Sample 3: Get VM tags

VM tags are included the instance API under `instance/compute/tags` endpoint. Tags may have been applied to your Azure VM to logically organize them into a taxonomy. The tags assigned to a VM can be retrieved by using the request below.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/tags?api-version=2017-08-01&format=text"
```

## Response

```
Department:IT;ReferenceNumber:123456;TestStatus:Pending
```

The `tags` field is a string with the tags delimited by semicolons. This output can be a problem if semicolons are used in the tags themselves. If a parser is written to programmatically extract the tags, you should rely on the `tagsList` field. The `tagsList` field is a JSON array with no delimiters, and consequently, easier to parse. The `tagsList` assigned to a VM can be retrieved by using the request below.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/compute/tagsList?api-version=2019-06-04" | ConvertTo-Json -Depth 64
```

## Response

- [Windows](#)
- [Linux](#)

```
{
  "value": [
    {
      "name": "Department",
      "value": "IT"
    },
    {
      "name": "ReferenceNumber",
      "value": "123456"
    },
    {
      "name": "TestStatus",
      "value": "Pending"
    }
  ],
  "Count": 3
}
```

## Sample 4: Get more information about the VM during support case

As a service provider, you may get a support call where you would like to know more information about the VM. Asking the customer to share the compute metadata can provide basic information for the support professional to know about the kind of VM on Azure.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/compute?api-version=2020-09-01" | ConvertTo-Json -Depth 64
```

## Response

### NOTE

The response is a JSON string. The following example response is pretty-printed for readability.

- [Windows](#)
- [Linux](#)

```
{

    }  
}
```

#### Sample 5: Get the Azure Environment where the VM is running

Azure has various sovereign clouds like [Azure Government](#). Sometimes you need the Azure Environment to make some runtime decisions. The following sample shows you how you can achieve this behavior.

##### Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/azEnvironment?api-version=2018-10-01&format=text"
```

##### Response

```
AzurePublicCloud
```

The cloud and the values of the Azure environment are listed here.

CLOUD	AZURE ENVIRONMENT
All generally available global Azure regions	AzurePublicCloud
Azure Government	AzureUSGovernmentCloud
Azure China 21Vianet	AzureChinaCloud
Azure Germany	AzureGermanCloud

#### Sample 6: Retrieve network information

##### Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/network?api-version=2017-08-01" | ConvertTo-Json -Depth 64
```

##### Response

```
{
  "interface": [
    {
      "ipv4": {
        "ipAddress": [
          {
            "privateIpAddress": "10.1.0.4",
            "publicIpAddress": "X.X.X.X"
          }
        ],
        "subnet": [
          {
            "address": "10.1.0.0",
            "prefix": "24"
          }
        ]
      },
      "ipv6": {
        "ipAddress": []
      },
      "macAddress": "000D3AF806EC"
    }
  ]
}
```

#### Sample 7: Retrieve public IP address

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/network/interface/0/ipv4/ipAddress/0/publicIpAddress?api-
version=2017-08-01&format=text"
```

#### NOTE

- If you are looking to retrieve IMDS information for **Standard** SKU Public IP address, review [Load Balancer Metadata API](#) for more information.

## Attested data

### Get Attested data

IMDS helps to provide guarantees that the data provided is coming from Azure. Microsoft signs part of this information, so you can confirm that an image in Azure Marketplace is the one you are running on Azure.

```
GET /metadata/attested/document
```

#### Parameters

NAME	REQUIRED/OPTIONAL	DESCRIPTION
<code>api-version</code>	Required	The version used to service the request.

Name	Required/Optional	Description
nonce	Optional	A 10-digit string that serves as a cryptographic nonce. If no value is provided, IMDS uses the current UTC timestamp.

## Response

```
{
  "encoding": "pkcs7",

```

The signature blob is a [pkcs7](#)-signed version of document. It contains the certificate used for signing along with certain VM-specific details.

For VMs created by using Azure Resource Manager, the document includes `vmId`, `sku`, `nonce`, `subscriptionId`, `timeStamp` for creation and expiry of the document, and the plan information about the image. The plan information is only populated for Azure Marketplace images.

For VMs created by using the classic deployment model, only the `vmId` and `subscriptionId` are guaranteed to be populated. You can extract the certificate from the response, and use it to confirm that the response is valid and is coming from Azure.

The decoded document contains the following fields:

Data	Description	Version Introduced
<code>licenseType</code>	Type of license for <a href="#">Azure Hybrid Benefit</a> . This is only present for AHB-enabled VMs.	2020-09-01
<code>nonce</code>	A string that can be optionally provided with the request. If no <code>nonce</code> was supplied, the current Coordinated Universal Time timestamp is used.	2018-10-01
<code>plan</code>	The <a href="#">Azure Marketplace Image plan</a> . Contains the plan ID (name), product image or offer (product), and publisher ID (publisher).	2018-10-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>timestamp.createdOn</code>	The UTC timestamp for when the signed document was created	2018-20-01
<code>timestamp.expiresOn</code>	The UTC timestamp for when the signed document expires	2018-10-01
<code>vmId</code>	Unique identifier for the VM	2018-10-01
<code>subscriptionId</code>	Azure subscription for the Virtual Machine	2019-04-30
<code>sku</code>	Specific SKU for the VM image (correlates to <code>compute/sku</code> property from the Instance Metadata endpoint [ <code>/metadata/instance</code> ])	2019-11-01

#### NOTE

For Classic (non-Azure Resource Manager) VMs, only the `vmId` is guaranteed to be populated.

Example document:

```
{
  "nonce": "20201130-211924",
  "plan": {
    "name": "planName",
    "product": "planProduct",
    "publisher": "planPublisher"
  },
  "sku": "Windows-Server-2012-R2-Datacenter",
  "subscriptionId": "8d10da13-8125-4ba9-a717-bf7490507b3d",
  "timeStamp": {
    "createdOn": "11/30/20 21:19:19 -0000",
    "expiresOn": "11/30/20 21:19:24 -0000"
  },
  "vmId": "02aab8a4-74ef-476e-8182-f6d2ba4166a6"
}
```

#### Sample 1: Validate that the VM is running in Azure

Vendors in Azure Marketplace want to ensure that their software is licensed to run only in Azure. If someone copies the VHD to an on-premises environment, the vendor needs to be able to detect that. Through IMDS, these vendors can get signed data that guarantees response only from Azure.

#### NOTE

This sample requires the jq utility to be installed.

## Validation

- [Windows](#)
- [Linux](#)

```

# Get the signature
$attestedDoc = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
http://169.254.169.254/metadata/attested/document?api-version=2020-09-01
# Decode the signature
$signature = [System.Convert]::FromBase64String($attestedDoc.signature)

```

Verify that the signature is from Microsoft Azure and check the certificate chain for errors.

```

# Get certificate chain
$cert = [System.Security.Cryptography.X509Certificates.X509Certificate2]($signature)
$chain = New-Object -TypeName System.Security.Cryptography.X509Certificates.X509Chain
$chain.Build($cert)
# Print the Subject of each certificate in the chain
foreach($element in $chain.ChainElements)
{
    Write-Host $element.Certificate.Subject
}

# Get the content of the signed document
Add-Type -AssemblyName System.Security
$signedCms = New-Object -TypeName System.Security.Cryptography.Pkcs.SignedCms
$signedCms.Decode($signature);
$content = [System.Text.Encoding]::UTF8.GetString($signedCms.ContentInfo.Content)
Write-Host "Attested data: " $content
$json = $content | ConvertFrom-Json
# Do additional validation here

```

#### NOTE

Due to IMDS's caching mechanism, a previously cached `nonce` value might be returned.

The `nonce` in the signed document can be compared if you provided a `nonce` parameter in the initial request.

#### NOTE

The certificate for the public cloud and each sovereign cloud will be different.

CLOUD	CERTIFICATE
All generally available global Azure regions	*.metadata.azure.com
Azure Government	*.metadata.azure.us
Azure China 21Vianet	*.metadata.azure.cn
Azure Germany	*.metadata.microsoftazure.de

#### NOTE

The certificates might not have an exact match of `metadata.azure.com` for the public cloud. For this reason, the certification validation should allow a common name from any `.metadata.azure.com` subdomain.

In cases where the intermediate certificate can't be downloaded due to network constraints during validation, you can pin the intermediate certificate. Azure rolls over the certificates, which is standard PKI practice. You must

update the pinned certificates when rollover happens. Whenever a change to update the intermediate certificate is planned, the Azure blog is updated, and Azure customers are notified.

You can find the intermediate certificates on [this page](#). The intermediate certificates for each of the regions can be different.

#### NOTE

The intermediate certificate for Azure China 21Vianet will be from DigiCert Global Root CA, instead of Baltimore. If you pinned the intermediate certificates for Azure China as part of a root chain authority change, the intermediate certificates must be updated.

#### NOTE

Starting February 2022, our Attested Data certificates will be impacted by a TLS change. Due to this, the root CA will change from Baltimore CyberTrust to DigiCert Global G2 only for Public and US Government clouds. If you have the Baltimore CyberTrust cert or other intermediate certificates listed in [this post](#) pinned, please follow the instructions listed there **immediately** to prevent any disruptions from using the Attested Data endpoint.

## Managed identity

A managed identity, assigned by the system, can be enabled on the VM. You can also assign one or more user-assigned managed identities to the VM. You can then request tokens for managed identities from IMDS. Use these tokens to authenticate with other Azure services, such as Azure Key Vault.

For detailed steps to enable this feature, see [Acquire an access token](#).

## Load Balancer Metadata

When you place virtual machine or virtual machine set instances behind an Azure Standard Load Balancer, you can use IMDS to retrieve metadata related to the load balancer and the instances. For more information, see [Retrieve load balancer information](#).

## Scheduled events

You can obtain the status of the scheduled events by using IMDS. Then the user can specify a set of actions to run upon these events. For more information, see [Scheduled events for Linux](#) or [Scheduled events for Windows](#).

## Sample code in different languages

The following table lists samples of calling IMDS by using different languages inside the VM:

LANGUAGE	EXAMPLE
Bash	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.sh">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.sh</a>
C#	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.cs">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.cs</a>
Go	<a href="https://github.com/Microsoft/azureimds/blob/master/imdssample.go">https://github.com/Microsoft/azureimds/blob/master/imdssample.go</a>

LANGUAGE	EXAMPLE
Java	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.java">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.java</a>
NodeJS	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.js">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.js</a>
Perl	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.pl">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.pl</a>
PowerShell	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.ps1">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.ps1</a>
Puppet	<a href="https://github.com/keirans/azurometadata">https://github.com/keirans/azurometadata</a>
Python	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.py">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.py</a>
Ruby	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.rb">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.rb</a>

## Errors and debugging

If there is a data element not found or a malformed request, the Instance Metadata Service returns standard HTTP errors. For example:

HTTP STATUS CODE	REASON
200 OK	The request was successful.
400 Bad Request	Missing <code>Metadata: true</code> header or missing parameter <code>format=json</code> when querying a leaf node
404 Not Found	The requested element doesn't exist
405 Method Not Allowed	The HTTP method (verb) is not supported on the endpoint.
410 Gone	Retry after some time for a max of 70 seconds
429 Too Many Requests	API <a href="#">Rate Limits</a> have been exceeded
500 Service Error	Retry after some time

## Frequently asked questions

- I am getting the error `400 Bad Request, Required metadata header not specified`. What does this mean?
  - IMDS requires the header `Metadata: true` to be passed in the request. Passing this header in the REST call allows access to IMDS.
- Why am I not getting compute information for my VM?
  - Currently, IMDS only supports instances created with Azure Resource Manager.

- I created my VM through Azure Resource Manager some time ago. Why am I not seeing compute metadata information?
  - If you created your VM after September 2016, add a [tag](#) to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions or data disks to the VM instance to refresh metadata.
- Is user data the same as custom data?
  - User data offers the similar functionality to custom data, allowing you to pass your own metadata to the VM instance. The difference is, user data is retrieved through IMDS, and is persistent throughout the lifetime of the VM instance. Existing custom data feature will continue to work as described in [this article](#). However you can only get custom data through local system folder, not through IMDS.
- Why am I not seeing all data populated for a new version?
  - If you created your VM after September 2016, add a [tag](#) to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions or data disks to the VM instance to refresh metadata.
- Why am I getting the error `500 Internal Server Error` or `410 Resource Gone ?`
  - Retry your request. For more information, see [Transient fault handling](#). If the problem persists, create a support issue in the Azure portal for the VM.
- Would this work for virtual machine scale set instances?
  - Yes, IMDS is available for virtual machine scale set instances.
- I updated my tags in virtual machine scale sets, but they don't appear in the instances (unlike single instance VMs). Am I doing something wrong?
  - Currently tags for virtual machine scale sets only show to the VM on a reboot, reimagine, or disk change to the instance.
- Why am I am not seeing the SKU information for my VM in `instance/compute` details?
  - For custom images created from Azure Marketplace, Azure platform doesn't retain the SKU information for the custom image and the details for any VMs created from the custom image. This is by design and hence not surfaced in the VM `instance/compute` details.
- Why is my request timed out for my call to the service?
  - Metadata calls must be made from the primary IP address assigned to the primary network card of the VM. Additionally, if you've changed your routes, there must be a route for the 169.254.169.254/32 address in your VM's local routing table.
    - [Windows](#)
    - [Linux](#)

1. Dump your local routing table and look for the IMDS entry. For example:

```

> route print
IPv4 Route Table
=====
Active Routes:
Network Destination      Netmask        Gateway       Interface Metric
          0.0.0.0        0.0.0.0    172.16.69.1   172.16.69.7    10
         127.0.0.0    255.0.0.0     On-link        127.0.0.1    331
         127.0.0.1  255.255.255.255     On-link        127.0.0.1    331
  127.255.255.255  255.255.255.255     On-link        127.0.0.1    331
  168.63.129.16  255.255.255.255    172.16.69.1   172.16.69.7    11
 169.254.169.254  255.255.255.255    172.16.69.1   172.16.69.7    11
... (continues) ...

```

2. Verify that a route exists for `169.254.169.254`, and note the corresponding network interface (for example, `172.16.69.7`).
3. Dump the interface configuration and find the interface that corresponds to the one referenced in the routing table, noting the MAC (physical) address.

```

> ipconfig /all
... (continues) ...
Ethernet adapter Ethernet:

Connection-specific DNS Suffix . : xic3mnxjiefupcwr1mcs1rjqiqa.cx.internal.cloudapp.net
Description . . . . . : Microsoft Hyper-V Network Adapter
Physical Address. . . . . : 00-0D-3A-E5-1C-C0
DHCP Enabled. . . . . : Yes
Autoconfiguration Enabled . . . . : Yes
Link-local IPv6 Address . . . . : fe80::3166:ce5a:2bd5:a6d1%3(Preferred)
IPv4 Address. . . . . : 172.16.69.7(Preferred)
Subnet Mask . . . . . : 255.255.255.0
... (continues) ...

```

4. Confirm that the interface corresponds to the VM's primary NIC and primary IP. You can find the primary NIC and IP by looking at the network configuration in the Azure portal, or by looking it up with the Azure CLI. Note the private IPs (and the MAC address if you're using the CLI). Here's a PowerShell CLI example:

```

$ResourceGroup = '<Resource_Group>'
$VmName = '<VM_Name>'
$NicNames = az vm nic list --resource-group $ResourceGroup --vm-name $VmName |
ConvertFrom-Json | Foreach-Object { $_.id.Split('/')[-1] }
foreach($NicName in $NicNames)
{
    $Nic = az vm nic show --resource-group $ResourceGroup --vm-name $VmName --nic
    $NicName | ConvertFrom-Json
    Write-Host $NicName, $Nic.primary, $Nic.macAddress
}
# Output: wintest767 True 00-0D-3A-E5-1C-C0

```

5. If they don't match, update the routing table so that the primary NIC and IP are targeted.

- Failover clustering in Windows Server
  - When you're querying IMDS with failover clustering, it's sometimes necessary to add a route to the routing table. Here's how:
    1. Open a command prompt with administrator privileges.
    2. Run the following command, and note the address of the Interface for Network Destination (`0.0.0.0`) in the IPv4 Route Table.

```
route print
```

#### NOTE

The following example output is from a Windows Server VM with failover cluster enabled. For simplicity, the output contains only the IPv4 Route Table.

#### IPv4 Route Table

Active Routes:					
Network Destination	Netmask	Gateway	Interface	Metric	
0.0.0.0	0.0.0.0	10.0.1.1	10.0.1.10	266	
10.0.1.0	255.255.255.192	On-link	10.0.1.10	266	
10.0.1.10	255.255.255.255	On-link	10.0.1.10	266	
10.0.1.15	255.255.255.255	On-link	10.0.1.10	266	
10.0.1.63	255.255.255.255	On-link	10.0.1.10	266	
127.0.0.0	255.0.0.0	On-link	127.0.0.1	331	
127.0.0.1	255.255.255.255	On-link	127.0.0.1	331	
127.255.255.255	255.255.255.255	On-link	127.0.0.1	331	
169.254.0.0	255.255.0.0	On-link	169.254.1.156	271	
169.254.1.156	255.255.255.255	On-link	169.254.1.156	271	
169.254.255.255	255.255.255.255	On-link	169.254.1.156	271	
224.0.0.0	240.0.0.0	On-link	127.0.0.1	331	
224.0.0.0	240.0.0.0	On-link	169.254.1.156	271	
255.255.255.255	255.255.255.255	On-link	127.0.0.1	331	
255.255.255.255	255.255.255.255	On-link	169.254.1.156	271	
255.255.255.255	255.255.255.255	On-link	10.0.1.10	266	

Run the following command and use the address of the Interface for Network Destination ( `0.0.0.0` ), which is ( `10.0.1.10` ) in this example.

```
route add 169.254.169.254/32 10.0.1.10 metric 1 -p
```

## Support

If you aren't able to get a metadata response after multiple attempts, you can create a support issue in the Azure portal.

## Product feedback

You can provide product feedback and ideas to our user feedback channel under Virtual Machines > Instance Metadata Service [here](#)

## Next steps

- [Scheduled events for Windows](#)

# Azure Instance Metadata Service (Windows)

9/21/2022 • 36 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The Azure Instance Metadata Service (IMDS) provides information about currently running virtual machine instances. You can use it to manage and configure your virtual machines. This information includes the SKU, storage, network configurations, and upcoming maintenance events. For a complete list of the data available, see the [Endpoint Categories Summary](#).

IMDS is available for running instances of virtual machines (VMs) and virtual machine scale set instances. All endpoints support VMs created and managed by using [Azure Resource Manager](#). Only the Attested category and Network portion of the Instance category support VMs created by using the classic deployment model. The Attested endpoint does so only to a limited extent.

IMDS is a REST API that's available at a well-known, non-routable IP address (`169.254.169.254`). You can only access it from within the VM. Communication between the VM and IMDS never leaves the host. Have your HTTP clients bypass web proxies within the VM when querying IMDS, and treat `169.254.169.254` the same as `168.63.129.16`.

## Usage

### Access Azure Instance Metadata Service

To access IMDS, create a VM from [Azure Resource Manager](#) or the [Azure portal](#), and use the following samples. For more examples, see [Azure Instance Metadata Samples](#).

Here's sample code to retrieve all metadata for an instance. To access a specific data source, see [Endpoint Categories](#) for an overview of all available features.

### Request

#### IMPORTANT

This example bypasses proxies. You **must** bypass proxies when querying IMDS. See [Proxies](#) for additional information.

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance?api-version=2021-02-01" | ConvertTo-Json -Depth 64
```

`-NoProxy` requires PowerShell V6 or greater. See our [samples repository](#) for examples with older PowerShell versions.

### Response

#### NOTE

The response is a JSON string. The following example response is pretty-printed for readability.

```

## Security and authentication

The Instance Metadata Service is only accessible from within a running virtual machine instance on a non-routable IP address. VMs are limited to interacting with metadata/functionality that pertains to themselves. The API is HTTP only and never leaves the host.

In order to ensure that requests are directly intended for IMDS and prevent unintended or unwanted redirection of requests, requests:

- Must contain the header `Metadata: true`
- Must not contain an `X-Forwarded-For` header

Any request that does not meet **both** of these requirements will be rejected by the service.

### IMPORTANT

IMDS is **not** a channel for sensitive data. The API is unauthenticated and open to all processes on the VM. Information exposed through this service should be considered as shared information to all applications running inside the VM.

If it is not necessary for every process on the VM to access IMDS endpoint, you can set local firewall rules to limit the access. For example, if only a known system service needs to access instance metadata service, you can set a firewall rule on IMDS endpoint, only allowing the specific process(es) to access, or denying access for the rest of the processes.

## Proxies

IMDS is **not** intended to be used behind a proxy and doing so is unsupported. Most HTTP clients provide an

option for you to disable proxies on your requests, and this functionality must be utilized when communicating with IMDS. Consult your client's documentation for details.

#### IMPORTANT

Even if you don't know of any proxy configuration in your environment, **you still must override any default client proxy settings**. Proxy configurations can be automatically discovered, and failing to bypass such configurations exposes you to outage risks should the machine's configuration be changed in the future.

## Rate limiting

In general, requests to IMDS are limited to 5 requests per second (on a per VM basis). Requests exceeding this threshold will be rejected with 429 responses. Requests to the [Managed Identity](#) category are limited to 20 requests per second and 5 concurrent requests.

## HTTP verbs

The following HTTP verbs are currently supported:

VERB	DESCRIPTION
GET	Retrieve the requested resource

## Parameters

Endpoints may support required and/or optional parameters. See [Schema](#) and the documentation for the specific endpoint in question for details.

### Query parameters

IMDS endpoints support HTTP query string parameters. For example:

```
http://169.254.169.254/metadata/instance/compute?api-version=2021-01-01&format=json
```

Specifies the parameters:

NAME	VALUE
api-version	2021-01-01
format	json

Requests with duplicate query parameter names will be rejected.

### Route parameters

For some endpoints that return larger json blobs, we support appending route parameters to the request endpoint to filter down to a subset of the response:

```
http://169.254.169.254/metadata/<endpoint>/[<filter parameter>/...]?<query parameters>
```

The parameters correspond to the indexes/keys that would be used to walk down the json object were you interacting with a parsed representation.

For example, `/metatadata/instance` returns the json object:

```
{  
    "compute": { ... },  
    "network": {  
        "interface": [  
            {  
                "ipv4": {  
                    "ipAddress": [{  
                        "privateIpAddress": "10.144.133.132",  
                        "publicIpAddress": ""  
                    }],  
                    "subnet": [{  
                        "address": "10.144.133.128",  
                        "prefix": "26"  
                    }]  
                },  
                "ipv6": {  
                    "ipAddress": [  
                        ...  
                    ]  
                },  
                "macAddress": "0011AAFFBB22"  
            },  
            ...  
        ]  
    }  
}
```

If we want to filter the response down to just the compute property, we would send the request:

```
http://169.254.169.254/metadata/instance/compute?api-version=<version>
```

Similarly, if we want to filter to a nested property or specific array element we keep appending keys:

```
http://169.254.169.254/metadata/instance/network/interface/0?api-version=<version>
```

would filter to the first element from the `Network.interface` property and return:

```
{  
    "ipv4": {  
        "ipAddress": [{  
            "privateIpAddress": "10.144.133.132",  
            "publicIpAddress": ""  
        }],  
        "subnet": [{  
            "address": "10.144.133.128",  
            "prefix": "26"  
        }]  
    },  
    "ipv6": {  
        "ipAddress": [  
            ...  
        ]  
    },  
    "macAddress": "0011AAFFBB22"  
}
```

#### NOTE

When filtering to a leaf node, `format=json` doesn't work. For these queries `format=text` needs to be explicitly specified since the default format is json.

## Schema

### Data format

By default, IMDS returns data in JSON format (`Content-Type: application/json`). However, endpoints that support response filtering (see [Route Parameters](#)) also support the format `text`.

To access a non-default response format, specify the requested format as a query string parameter in the request. For example:

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance?api-version=2017-08-01&format=text"
```

In json responses, all primitives will be of type `string`, and missing or inapplicable values are always included but will be set to an empty string.

### Versioning

IMDS is versioned and specifying the API version in the HTTP request is mandatory. The only exception to this requirement is the [versions](#) endpoint, which can be used to dynamically retrieve the available API versions.

As newer versions are added, older versions can still be accessed for compatibility if your scripts have dependencies on specific data formats.

When you don't specify a version, you get an error with a list of the newest supported versions:

```
{
    "error": "Bad request. api-version was not specified in the request. For more information refer to aka.ms/azureimds",
    "newest-versions": [
        "2020-10-01",
        "2020-09-01",
        "2020-07-15"
    ]
}
```

### Supported API versions

- 2017-03-01
- 2017-04-02
- 2017-08-01
- 2017-10-01
- 2017-12-01

## Swagger

A full Swagger definition for IMDS is available at: <https://github.com/Azure/azure-rest-api-specs/blob/main/specification/imds/data-plane/readme.md>

## Regional availability

The service is **generally available** in all Azure Clouds.

## Root endpoint

The root endpoint is `http://169.254.169.254/metadata`.

## Endpoint categories

The IMDS API contains multiple endpoint categories representing different data sources, each of which contains one or more endpoints. See each category for details.

CATEGORY ROOT	DESCRIPTION	VERSION INTRODUCED
<code>/metadata/attested</code>	See <a href="#">Attested Data</a>	2018-10-01
<code>/metadata/identity</code>	See <a href="#">Managed Identity via IMDS</a>	2018-02-01
<code>/metadata/instance</code>	See <a href="#">Instance Metadata</a>	2017-04-02
<code>/metadata/loadbalancer</code>	See <a href="#">Retrieve Load Balancer metadata via IMDS</a>	2020-10-01
<code>/metadata/scheduledevents</code>	See <a href="#">Scheduled Events via IMDS</a>	2017-08-01
<code>/metadata/versions</code>	See <a href="#">Versions</a>	N/A

# Versions

## NOTE

This feature was released alongside version 2020-10-01, which is currently being rolled out and may not yet be available in every region.

## List API versions

Returns the set of supported API versions.

```
GET /metadata/versions
```

### Parameters

None (this endpoint is unversioned).

### Response

```
{
  "apiVersions": [
    "2017-03-01",
    "2017-04-02",
    ...
  ]
}
```

# Instance metadata

## Get VM metadata

Exposes the important metadata for the VM instance, including compute, network, and storage.

```
GET /metadata/instance
```

### Parameters

NAME	REQUIRED/OPTIONAL	DESCRIPTION
<code>api-version</code>	Required	The version used to service the request.
<code>format</code>	Optional*	The format ( <code>json</code> or <code>text</code> ) of the response. *Note: May be required when using request parameters

This endpoint supports response filtering via [route parameters](#).

<code>host.id</code>	Name of the host of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15+
<code>hostGroup.id</code>	Name of the hostGroup of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15+
<code>isHostCompatibilityLayerVm</code>	Identifies if the VM runs on the Host Compatibility Layer	2020-06-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>licenseType</code>	Type of license for <a href="#">Azure Hybrid Benefit</a> . This is only present for AHB-enabled VMs	2020-09-01
<code>location</code>	Azure Region the VM is running in	2017-04-02
<code>name</code>	Name of the VM	2017-04-02
<code>offer</code>	Offer information for the VM image and is only present for images deployed from Azure image gallery	2017-04-02
<code>osProfile.adminUsername</code>	Specifies the name of the admin account	2020-07-15
<code>osProfile.computerName</code>	Specifies the name of the computer	2020-07-15
<code>osProfile.disablePasswordAuthentication</code>	Specifies if password authentication is disabled. This is only present for Linux VMs	2020-10-01
<code>osType</code>	Linux or Windows	2017-04-02
<code>placementGroupId</code>	<a href="#">Placement Group</a> of your virtual machine scale set	2017-08-01
<code>plan</code>	<a href="#">Plan</a> containing name, product, and publisher for a VM if it is an Azure Marketplace Image	2018-04-02
<code>platformUpdateDomain</code>	<a href="#">Update domain</a> the VM is running in	2017-04-02
<code>platformFaultDomain</code>	<a href="#">Fault domain</a> the VM is running in	2017-04-02
<code>platformSubFaultDomain</code>	Sub fault domain the VM is running in, if applicable.	2021-10-01
<code>priority</code>	Priority of the VM. Refer to <a href="#">Spot VMs</a> for more information	2020-12-01
<code>provider</code>	Provider of the VM	2018-10-01
<code>publicKeys</code>	<a href="#">Collection of Public Keys</a> assigned to the VM and paths	2018-04-02
<code>publisher</code>	Publisher of the VM image	2017-04-02
<code>resourceGroupName</code>	<a href="#">Resource group</a> for your Virtual Machine	2017-08-01
<code>resourceId</code>	The <a href="#">fully qualified</a> ID of the resource	2019-03-11

DATA	DESCRIPTION	VERSION INTRODUCED
<code>sku</code>	Specific SKU for the VM image	2017-04-02
<code>securityProfile.secureBootEnabled</code>	Identifies if UEFI secure boot is enabled on the VM	2020-06-01
<code>securityProfile.virtualTpmEnabled</code>	Identifies if the virtual Trusted Platform Module (TPM) is enabled on the VM	2020-06-01
<code>securityProfile.encryptionAtHost</code>	Identifies if <a href="#">Encryption at Host</a> is enabled on the VM	2021-11-01†
<code>securityProfile.securityType</code>	Identifies if the VM is a <a href="#">Trusted VM</a> or a <a href="#">Confidential VM</a>	2021-12-13†
<code>storageProfile</code>	See Storage Profile below	2019-06-01
<code>subscriptionId</code>	Azure subscription for the Virtual Machine	2017-08-01
<code>tags</code>	<a href="#">Tags</a> for your Virtual Machine	2017-08-01
<code>tagsList</code>	Tags formatted as a JSON array for easier programmatic parsing	2019-06-04
<code>userData</code>	The set of data specified when the VM was created for use during or after provisioning (Base64 encoded)	2021-01-01
<code>version</code>	Version of the VM image	2017-04-02
<code>virtualMachineScaleSet.id</code>	ID of the <a href="#">Virtual Machine Scale Set created with flexible orchestration</a> the Virtual Machine is part of. This field is not available for Virtual Machine Scale Sets created with uniform orchestration.	2021-03-01
<code>vmId</code>	<a href="#">Unique identifier</a> for the VM. The blog referenced only suits for VMs that have SMBIOS < 2.6. For VMs that have SMBIOS >= 2.6, the UUID from DMI is displayed in little-endian format, thus, there is no requirement to switch bytes.	2017-04-02
<code>vmScaleSetName</code>	<a href="#">Virtual machine scale set Name</a> of your virtual machine scale set	2017-12-01
<code>vmSize</code>	<a href="#">VM size</a>	2017-04-02
<code>zone</code>	<a href="#">Availability Zone</a> of your virtual machine	2017-12-01

† This version is not fully available yet and may not be supported in all regions.

## Storage profile

The storage profile of a VM is divided into three categories: image reference, OS disk, and data disks, plus an additional object for the local temporary disk.

The image reference object contains the following information about the OS image:

DATA	DESCRIPTION
<code>id</code>	Resource ID
<code>offer</code>	Offer of the platform or marketplace image
<code>publisher</code>	Image publisher
<code>sku</code>	Image sku
<code>version</code>	Version of the platform or marketplace image

The OS disk object contains the following information about the OS disk used by the VM:

DATA	DESCRIPTION
<code>caching</code>	Caching requirements
<code>createOption</code>	Information about how the VM was created
<code>diffDiskSettings</code>	Ephemeral disk settings
<code>diskSizeGB</code>	Size of the disk in GB
<code>image</code>	Source user image virtual hard disk
<code>managedDisk</code>	Managed disk parameters
<code>name</code>	Disk name
<code>vhd</code>	Virtual hard disk
<code>writeAcceleratorEnabled</code>	Whether or not writeAccelerator is enabled on the disk

The data disks array contains a list of data disks attached to the VM. Each data disk object contains the following information:

DATA	DESCRIPTION	VERSION INTRODUCED
<code>bytesPerSecondThrottle</code> *	Disk read/write quota in bytes	2021-05-01
<code>caching</code>	Caching requirements	2019-06-01
<code>createOption</code>	Information about how the VM was created	2019-06-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>diffDiskSettings</code>	Ephemeral disk settings	2019-06-01
<code>diskCapacityBytes</code> *	Size of disk in bytes	2021-05-01
<code>diskSizeGB</code>	Size of the disk in GB	2019-06-01
<code>encryptionSettings</code>	Encryption settings for the disk	2019-06-01
<code>image</code>	Source user image virtual hard disk	2019-06-01
<code>isSharedDisk</code> *	Identifies if the disk is shared between resources	2021-05-01
<code>isUltraDisk</code>	Identifies if the data disk is an Ultra Disk	2021-05-01
<code>lun</code>	Logical unit number of the disk	2019-06-01
<code>managedDisk</code>	Managed disk parameters	2019-06-01
<code>name</code>	Disk name	2019-06-01
<code>opsPerSecondThrottle</code> *	Disk read/write quota in IOPS	2021-05-01
<code>osType</code>	Type of OS included in the disk	2019-06-01
<code>vhd</code>	Virtual hard disk	2019-06-01
<code>writeAcceleratorEnabled</code>	Whether or not writeAccelerator is enabled on the disk	2019-06-01

\* These fields are only populated for Ultra Disks; they will be empty strings from non-Ultra Disks.

The encryption settings blob contains data about how the disk is encrypted (if it is encrypted):

DATA	DESCRIPTION	VERSION INTRODUCED
<code>diskEncryptionKey.sourceVault.id</code>	The location of the disk encryption key	2021-11-01†
<code>diskEncryptionKey.secretUrl</code>	The location of the secret	2021-11-01†
<code>keyEncryptionKey.sourceVault.id</code>	The location of the key encryption key	2021-11-01†
<code>keyEncryptionKey.keyUrl</code>	The location of the key	2021-11-01†

\† This version is not fully available yet and may not be supported in all regions.

The resource disk object contains the size of the [Local Temp Disk](#) attached to the VM, if it has one, in kilobytes. If there is [no local temp disk for the VM](#), this value is 0.

DATA	DESCRIPTION	VERSION INTRODUCED
<code>resourceDisk.size</code>	Size of the local temp disk for the VM (in kB)	2021-02-01

## Network

DATA	DESCRIPTION	VERSION INTRODUCED
<code>ipv4.privateIpAddress</code>	Local IPv4 address of the VM	2017-04-02
<code>ipv4.publicIpAddress</code>	Public IPv4 address of the VM	2017-04-02
<code>subnet.address</code>	Subnet address of the VM	2017-04-02
<code>subnet.prefix</code>	Subnet prefix, example 24	2017-04-02
<code>ipv6.ipAddress</code>	Local IPv6 address of the VM	2017-04-02
<code>macAddress</code>	VM mac address	2017-04-02

### NOTE

The nics returned by the network call are not guaranteed to be in order.

## Get user data

When creating a new VM, you can specify a set of data to be used during or after the VM provision, and retrieve it through IMDS. Check the end to end user data experience [here](#).

To set up user data, utilize the quickstart template [here](#). The sample below shows how to retrieve this data through IMDS. This feature is released with version `2021-01-01` and above.

### NOTE

Security notice: IMDS is open to all applications on the VM, sensitive data should not be placed in the user data.

- [Windows](#)
- [Linux](#)

```
$userData = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/compute/userData?api-version=2021-01-01&format=text" [System.Text.Encoding]::UTF8.GetString([Convert]::FromBase64String($userData))
```

### Sample 1: Tracking VM running on Azure

As a service provider, you may require to track the number of VMs running your software or have agents that need to track uniqueness of the VM. To be able to get a unique ID for a VM, use the `vmId` field from Instance Metadata Service.

## Request

- [Windows](#)

- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/vmId?api-version=2017-08-01&format=text"
```

## Response

```
5c08b38e-4d57-4c23-ac45-aca61037f084
```

### Sample 2: Placement of different data replicas

For certain scenarios, placement of different data replicas is of prime importance. For example, [HDFS replica placement](#) or container placement via an [orchestrator](#) might require you to know the `platformFaultDomain` and `platformUpdateDomain` the VM is running on. You can also use [Availability Zones](#) for the instances to make these decisions. You can query this data directly via IMDS.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/platformFaultDomain?api-version=2017-08-01&format=text"
```

## Response

```
0
```

### Sample 3: Get VM tags

VM tags are included the instance API under `instance/compute/tags` endpoint. Tags may have been applied to your Azure VM to logically organize them into a taxonomy. The tags assigned to a VM can be retrieved by using the request below.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/tags?api-version=2017-08-01&format=text"
```

## Response

```
Department:IT;ReferenceNumber:123456;TestStatus:Pending
```

The `tags` field is a string with the tags delimited by semicolons. This output can be a problem if semicolons are used in the tags themselves. If a parser is written to programmatically extract the tags, you should rely on the `tagsList` field. The `tagsList` field is a JSON array with no delimiters, and consequently, easier to parse. The `tagsList` assigned to a VM can be retrieved by using the request below.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute/tagsList?api-version=2019-06-04" | ConvertTo-Json -Depth
64
```

## Response

- [Windows](#)
- [Linux](#)

```
{
  "value": [
    {
      "name": "Department",
      "value": "IT"
    },
    {
      "name": "ReferenceNumber",
      "value": "123456"
    },
    {
      "name": "TestStatus",
      "value": "Pending"
    }
  ],
  "Count": 3
}
```

## Sample 4: Get more information about the VM during support case

As a service provider, you may get a support call where you would like to know more information about the VM. Asking the customer to share the compute metadata can provide basic information for the support professional to know about the kind of VM on Azure.

## Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute?api-version=2020-09-01" | ConvertTo-Json -Depth 64
```

## Response

### NOTE

The response is a JSON string. The following example response is pretty-printed for readability.

- [Windows](#)
- [Linux](#)

```

    }  
}
```

#### Sample 5: Get the Azure Environment where the VM is running

Azure has various sovereign clouds like [Azure Government](#). Sometimes you need the Azure Environment to make some runtime decisions. The following sample shows you how you can achieve this behavior.

##### Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/compute/azEnvironment?api-version=2018-10-01&format=text"
```

##### Response

```
AzurePublicCloud
```

The cloud and the values of the Azure environment are listed here.

CLOUD	AZURE ENVIRONMENT
All generally available global Azure regions	AzurePublicCloud
Azure Government	AzureUSGovernmentCloud
Azure China 21Vianet	AzureChinaCloud
Azure Germany	AzureGermanCloud

#### Sample 6: Retrieve network information

##### Request

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri  
"http://169.254.169.254/metadata/instance/network?api-version=2017-08-01" | ConvertTo-Json -Depth 64
```

##### Response

```
{
  "interface": [
    {
      "ipv4": {
        "ipAddress": [
          {
            "privateIpAddress": "10.1.0.4",
            "publicIpAddress": "X.X.X.X"
          }
        ],
        "subnet": [
          {
            "address": "10.1.0.0",
            "prefix": "24"
          }
        ]
      },
      "ipv6": {
        "ipAddress": []
      },
      "macAddress": "000D3AF806EC"
    }
  ]
}
```

#### Sample 7: Retrieve public IP address

- [Windows](#)
- [Linux](#)

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/network/interface/0/ipv4/ipAddress/0/publicIpAddress?api-
version=2017-08-01&format=text"
```

#### NOTE

- If you are looking to retrieve IMDS information for **Standard** SKU Public IP address, review [Load Balancer Metadata API](#) for more infomration.

## Attested data

### Get Attested data

IMDS helps to provide guarantees that the data provided is coming from Azure. Microsoft signs part of this information, so you can confirm that an image in Azure Marketplace is the one you are running on Azure.

```
GET /metadata/attested/document
```

#### Parameters

NAME	REQUIRED/OPTIONAL	DESCRIPTION
<code>api-version</code>	Required	The version used to service the request.

Name	Required/Optional	Description
nonce	Optional	A 10-digit string that serves as a cryptographic nonce. If no value is provided, IMDS uses the current UTC timestamp.

## Response

```
{

nprQ="
}
```

The signature blob is a [pkcs7](#)-signed version of document. It contains the certificate used for signing along with certain VM-specific details.

For VMs created by using Azure Resource Manager, the document includes `vmId`, `sku`, `nonce`, `subscriptionId`, `timeStamp` for creation and expiry of the document, and the plan information about the image. The plan information is only populated for Azure Marketplace images.

For VMs created by using the classic deployment model, only the `vmId` and `subscriptionId` are guaranteed to be populated. You can extract the certificate from the response, and use it to confirm that the response is valid and is coming from Azure.

The decoded document contains the following fields:

Data	Description	Version Introduced
<code>licenseType</code>	Type of license for <a href="#">Azure Hybrid Benefit</a> . This is only present for AHB-enabled VMs.	2020-09-01
<code>nonce</code>	A string that can be optionally provided with the request. If no <code>nonce</code> was supplied, the current Coordinated Universal Time timestamp is used.	2018-10-01
<code>plan</code>	The <a href="#">Azure Marketplace Image plan</a> . Contains the plan ID (name), product image or offer (product), and publisher ID (publisher).	2018-10-01

DATA	DESCRIPTION	VERSION INTRODUCED
<code>timestamp.createdOn</code>	The UTC timestamp for when the signed document was created	2018-20-01
<code>timestamp.expiresOn</code>	The UTC timestamp for when the signed document expires	2018-10-01
<code>vmId</code>	Unique identifier for the VM	2018-10-01
<code>subscriptionId</code>	Azure subscription for the Virtual Machine	2019-04-30
<code>sku</code>	Specific SKU for the VM image (correlates to <code>compute/sku</code> property from the Instance Metadata endpoint [ <code>/metadata/instance</code> ])	2019-11-01

#### NOTE

For Classic (non-Azure Resource Manager) VMs, only the `vmId` is guaranteed to be populated.

Example document:

```
{
  "nonce": "20201130-211924",
  "plan": {
    "name": "planName",
    "product": "planProduct",
    "publisher": "planPublisher"
  },
  "sku": "Windows-Server-2012-R2-Datacenter",
  "subscriptionId": "8d10da13-8125-4ba9-a717-bf7490507b3d",
  "timeStamp": {
    "createdOn": "11/30/20 21:19:19 -0000",
    "expiresOn": "11/30/20 21:19:24 -0000"
  },
  "vmId": "02aab8a4-74ef-476e-8182-f6d2ba4166a6"
}
```

#### Sample 1: Validate that the VM is running in Azure

Vendors in Azure Marketplace want to ensure that their software is licensed to run only in Azure. If someone copies the VHD to an on-premises environment, the vendor needs to be able to detect that. Through IMDS, these vendors can get signed data that guarantees response only from Azure.

#### NOTE

This sample requires the jq utility to be installed.

## Validation

- [Windows](#)
- [Linux](#)

```

# Get the signature
$attestedDoc = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
http://169.254.169.254/metadata/attested/document?api-version=2020-09-01
# Decode the signature
$signature = [System.Convert]::FromBase64String($attestedDoc.signature)

```

Verify that the signature is from Microsoft Azure and check the certificate chain for errors.

```

# Get certificate chain
$cert = [System.Security.Cryptography.X509Certificates.X509Certificate2]($signature)
$chain = New-Object -TypeName System.Security.Cryptography.X509Certificates.X509Chain
$chain.Build($cert)
# Print the Subject of each certificate in the chain
foreach($element in $chain.ChainElements)
{
    Write-Host $element.Certificate.Subject
}

# Get the content of the signed document
Add-Type -AssemblyName System.Security
$signedCms = New-Object -TypeName System.Security.Cryptography.Pkcs.SignedCms
$signedCms.Decode($signature);
$content = [System.Text.Encoding]::UTF8.GetString($signedCms.ContentInfo.Content)
Write-Host "Attested data: " $content
$json = $content | ConvertFrom-Json
# Do additional validation here

```

#### NOTE

Due to IMDS's caching mechanism, a previously cached `nonce` value might be returned.

The `nonce` in the signed document can be compared if you provided a `nonce` parameter in the initial request.

#### NOTE

The certificate for the public cloud and each sovereign cloud will be different.

CLOUD	CERTIFICATE
All generally available global Azure regions	*.metadata.azure.com
Azure Government	*.metadata.azure.us
Azure China 21Vianet	*.metadata.azure.cn
Azure Germany	*.metadata.microsoftazure.de

#### NOTE

The certificates might not have an exact match of `metadata.azure.com` for the public cloud. For this reason, the certification validation should allow a common name from any `.metadata.azure.com` subdomain.

In cases where the intermediate certificate can't be downloaded due to network constraints during validation, you can pin the intermediate certificate. Azure rolls over the certificates, which is standard PKI practice. You must

update the pinned certificates when rollover happens. Whenever a change to update the intermediate certificate is planned, the Azure blog is updated, and Azure customers are notified.

You can find the intermediate certificates on [this page](#). The intermediate certificates for each of the regions can be different.

#### NOTE

The intermediate certificate for Azure China 21Vianet will be from DigiCert Global Root CA, instead of Baltimore. If you pinned the intermediate certificates for Azure China as part of a root chain authority change, the intermediate certificates must be updated.

#### NOTE

Starting February 2022, our Attested Data certificates will be impacted by a TLS change. Due to this, the root CA will change from Baltimore CyberTrust to DigiCert Global G2 only for Public and US Government clouds. If you have the Baltimore CyberTrust cert or other intermediate certificates listed in [this post](#) pinned, please follow the instructions listed there **immediately** to prevent any disruptions from using the Attested Data endpoint.

## Managed identity

A managed identity, assigned by the system, can be enabled on the VM. You can also assign one or more user-assigned managed identities to the VM. You can then request tokens for managed identities from IMDS. Use these tokens to authenticate with other Azure services, such as Azure Key Vault.

For detailed steps to enable this feature, see [Acquire an access token](#).

## Load Balancer Metadata

When you place virtual machine or virtual machine set instances behind an Azure Standard Load Balancer, you can use IMDS to retrieve metadata related to the load balancer and the instances. For more information, see [Retrieve load balancer information](#).

## Scheduled events

You can obtain the status of the scheduled events by using IMDS. Then the user can specify a set of actions to run upon these events. For more information, see [Scheduled events for Linux](#) or [Scheduled events for Windows](#).

## Sample code in different languages

The following table lists samples of calling IMDS by using different languages inside the VM:

LANGUAGE	EXAMPLE
Bash	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.sh">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.sh</a>
C#	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.cs">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.cs</a>
Go	<a href="https://github.com/Microsoft/azureimds/blob/master/imdssample.go">https://github.com/Microsoft/azureimds/blob/master/imdssample.go</a>

LANGUAGE	EXAMPLE
Java	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.java">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.java</a>
NodeJS	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.js">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.js</a>
Perl	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.pl">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.pl</a>
PowerShell	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.ps1">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.ps1</a>
Puppet	<a href="https://github.com/keirans/azurometadata">https://github.com/keirans/azurometadata</a>
Python	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.py">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.py</a>
Ruby	<a href="https://github.com/Microsoft/azureimds/blob/master/IMDSSample.rb">https://github.com/Microsoft/azureimds/blob/master/IMDSSample.rb</a>

## Errors and debugging

If there is a data element not found or a malformed request, the Instance Metadata Service returns standard HTTP errors. For example:

HTTP STATUS CODE	REASON
200 OK	The request was successful.
400 Bad Request	Missing <code>Metadata: true</code> header or missing parameter <code>format=json</code> when querying a leaf node
404 Not Found	The requested element doesn't exist
405 Method Not Allowed	The HTTP method (verb) is not supported on the endpoint.
410 Gone	Retry after some time for a max of 70 seconds
429 Too Many Requests	API <a href="#">Rate Limits</a> have been exceeded
500 Service Error	Retry after some time

## Frequently asked questions

- I am getting the error `400 Bad Request, Required metadata header not specified`. What does this mean?
  - IMDS requires the header `Metadata: true` to be passed in the request. Passing this header in the REST call allows access to IMDS.
- Why am I not getting compute information for my VM?
  - Currently, IMDS only supports instances created with Azure Resource Manager.

- I created my VM through Azure Resource Manager some time ago. Why am I not seeing compute metadata information?
  - If you created your VM after September 2016, add a [tag](#) to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions or data disks to the VM instance to refresh metadata.
- Is user data the same as custom data?
  - User data offers the similar functionality to custom data, allowing you to pass your own metadata to the VM instance. The difference is, user data is retrieved through IMDS, and is persistent throughout the lifetime of the VM instance. Existing custom data feature will continue to work as described in [this article](#). However you can only get custom data through local system folder, not through IMDS.
- Why am I not seeing all data populated for a new version?
  - If you created your VM after September 2016, add a [tag](#) to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions or data disks to the VM instance to refresh metadata.
- Why am I getting the error `500 Internal Server Error` or `410 Resource Gone ?`?
  - Retry your request. For more information, see [Transient fault handling](#). If the problem persists, create a support issue in the Azure portal for the VM.
- Would this work for virtual machine scale set instances?
  - Yes, IMDS is available for virtual machine scale set instances.
- I updated my tags in virtual machine scale sets, but they don't appear in the instances (unlike single instance VMs). Am I doing something wrong?
  - Currently tags for virtual machine scale sets only show to the VM on a reboot, reimagine, or disk change to the instance.
- Why am I am not seeing the SKU information for my VM in `instance/compute` details?
  - For custom images created from Azure Marketplace, Azure platform doesn't retain the SKU information for the custom image and the details for any VMs created from the custom image. This is by design and hence not surfaced in the VM `instance/compute` details.
- Why is my request timed out for my call to the service?
  - Metadata calls must be made from the primary IP address assigned to the primary network card of the VM. Additionally, if you've changed your routes, there must be a route for the `169.254.169.254/32` address in your VM's local routing table.
    - [Windows](#)
    - [Linux](#)

1. Dump your local routing table and look for the IMDS entry. For example:

```

> route print
IPv4 Route Table
=====
Active Routes:
Network Destination      Netmask        Gateway       Interface Metric
          0.0.0.0        0.0.0.0    172.16.69.1   172.16.69.7    10
         127.0.0.0    255.0.0.0     On-link        127.0.0.1    331
         127.0.0.1  255.255.255.255     On-link        127.0.0.1    331
  127.255.255.255  255.255.255.255     On-link        127.0.0.1    331
  168.63.129.16  255.255.255.255    172.16.69.1   172.16.69.7    11
 169.254.169.254  255.255.255.255    172.16.69.1   172.16.69.7    11
... (continues) ...

```

2. Verify that a route exists for `169.254.169.254`, and note the corresponding network interface (for example, `172.16.69.7`).
3. Dump the interface configuration and find the interface that corresponds to the one referenced in the routing table, noting the MAC (physical) address.

```

> ipconfig /all
... (continues) ...
Ethernet adapter Ethernet:

Connection-specific DNS Suffix . : xic3mnxjiefupcwr1mcs1rjqiqa.cx.internal.cloudapp.net
Description . . . . . : Microsoft Hyper-V Network Adapter
Physical Address. . . . . : 00-0D-3A-E5-1C-C0
DHCP Enabled. . . . . : Yes
Autoconfiguration Enabled . . . . : Yes
Link-local IPv6 Address . . . . : fe80::3166:ce5a:2bd5:a6d1%3(Preferred)
IPv4 Address. . . . . : 172.16.69.7(Preferred)
Subnet Mask . . . . . : 255.255.255.0
... (continues) ...

```

4. Confirm that the interface corresponds to the VM's primary NIC and primary IP. You can find the primary NIC and IP by looking at the network configuration in the Azure portal, or by looking it up with the Azure CLI. Note the private IPs (and the MAC address if you're using the CLI). Here's a PowerShell CLI example:

```

$ResourceGroup = '<Resource_Group>'
$VmName = '<VM_Name>'
$NicNames = az vm nic list --resource-group $ResourceGroup --vm-name $VmName |
ConvertFrom-Json | Foreach-Object { $_.id.Split('/')[-1] }
foreach($NicName in $NicNames)
{
    $Nic = az vm nic show --resource-group $ResourceGroup --vm-name $VmName --nic
    $NicName | ConvertFrom-Json
    Write-Host $NicName, $Nic.primary, $Nic.macAddress
}
# Output: wintest767 True 00-0D-3A-E5-1C-C0

```

5. If they don't match, update the routing table so that the primary NIC and IP are targeted.

- Failover clustering in Windows Server
  - When you're querying IMDS with failover clustering, it's sometimes necessary to add a route to the routing table. Here's how:
    1. Open a command prompt with administrator privileges.
    2. Run the following command, and note the address of the Interface for Network Destination (`0.0.0.0`) in the IPv4 Route Table.

```
route print
```

#### NOTE

The following example output is from a Windows Server VM with failover cluster enabled. For simplicity, the output contains only the IPv4 Route Table.

#### IPv4 Route Table

Active Routes:					
Network Destination	Netmask	Gateway	Interface	Metric	
0.0.0.0	0.0.0.0	10.0.1.1	10.0.1.10	266	
10.0.1.0	255.255.255.192	On-link	10.0.1.10	266	
10.0.1.10	255.255.255.255	On-link	10.0.1.10	266	
10.0.1.15	255.255.255.255	On-link	10.0.1.10	266	
10.0.1.63	255.255.255.255	On-link	10.0.1.10	266	
127.0.0.0	255.0.0.0	On-link	127.0.0.1	331	
127.0.0.1	255.255.255.255	On-link	127.0.0.1	331	
127.255.255.255	255.255.255.255	On-link	127.0.0.1	331	
169.254.0.0	255.255.0.0	On-link	169.254.1.156	271	
169.254.1.156	255.255.255.255	On-link	169.254.1.156	271	
169.254.255.255	255.255.255.255	On-link	169.254.1.156	271	
224.0.0.0	240.0.0.0	On-link	127.0.0.1	331	
224.0.0.0	240.0.0.0	On-link	169.254.1.156	271	
255.255.255.255	255.255.255.255	On-link	127.0.0.1	331	
255.255.255.255	255.255.255.255	On-link	169.254.1.156	271	
255.255.255.255	255.255.255.255	On-link	10.0.1.10	266	

Run the following command and use the address of the Interface for Network Destination ( `0.0.0.0` ), which is ( `10.0.1.10` ) in this example.

```
route add 169.254.169.254/32 10.0.1.10 metric 1 -p
```

## Support

If you aren't able to get a metadata response after multiple attempts, you can create a support issue in the Azure portal.

## Product feedback

You can provide product feedback and ideas to our user feedback channel under Virtual Machines > Instance Metadata Service [here](#)

## Next steps

- [Acquire an access token for the VM](#)
- [Scheduled events for Linux](#)
- [Scheduled events for Windows](#)

# Get Virtual Machine usage metrics using the REST API

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This example shows how to retrieve the CPU usage for a Linux Virtual Machine using the [Azure REST API](#).

Complete reference documentation and additional samples for the REST API are available in the [Azure Monitor REST reference](#).

## Build the request

Use the following GET request to collect the [Percentage CPU metric](#) from a Virtual Machine

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmname}/providers/microsoft.insights/metrics?api-version=2018-01-01&metricnames=Percentage%20CPU&timespan=2018-06-05T03:00:00Z/2018-06-07T03:00:00Z
```

### Request headers

The following headers are required:

REQUEST HEADER	DESCRIPTION
<i>Content-Type</i> :	Required. Set to <code>application/json</code> .
<i>Authorization</i> :	Required. Set to a valid <code>Bearer</code> access token.

### URI parameters

NAME	DESCRIPTION
subscriptionId	The subscription ID that identifies an Azure subscription. If you have multiple subscriptions, see <a href="#">Working with multiple subscriptions</a> .
resourceGroupName	The name of the Azure resource group associated with the resource. You can get this value from the Azure Resource Manager API, CLI, or the portal.
vmname	The name of the Azure Virtual Machine.
metricnames	Comma-separated list of valid <a href="#">Load Balancer metrics</a> .
api-version	The API version to use for the request.  This document covers api-version <code>2018-01-01</code> , included in the above URL.

NAME	DESCRIPTION
timespan	String with the following format <code>startDateTime_ISO/endDateTime_ISO</code> that defines the time range of the returned metrics. This optional parameter is set to return a day's worth of data in the example.

## Request body

No request body is needed for this operation.

## Handle the response

Status code 200 is returned when the list of metric values is returned successfully. A full list of error codes is available in the [reference documentation](#).

## Example response

```
{
  "cost": 0,
  "timespan": "2018-06-08T23:48:10Z/2018-06-09T00:48:10Z",
  "interval": "PT1M",
  "value": [
    {
      "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmname}/providers/microsoft.insights/metrics?api-version=2018-01-01&metricnames=Percentage%20CPU",
      "type": "Microsoft.Insights/metrics",
      "name": {
        "value": "Percentage CPU",
        "localizedValue": "Percentage CPU"
      },
      "unit": "Percent",
      "timeseries": [
        {
          "metadatavalues": [],
          "data": [
            {
              "timeStamp": "2018-06-08T23:48:00Z",
              "average": 0.44
            },
            {

    }
  ]
}
```

# Azure boot diagnostics

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Boot diagnostics is a debugging feature for Azure virtual machines (VM) that allows diagnosis of VM boot failures. Boot diagnostics enables a user to observe the state of their VM as it is booting up by collecting serial log information and screenshots.

## Boot diagnostics storage account

When you create a VM in Azure portal, boot diagnostics is enabled by default. The recommended boot diagnostics experience is to use a managed storage account, as it yields significant performance improvements in the time to create an Azure VM. This is because an Azure managed storage account will be used, removing the time it takes to create a new user storage account to store the boot diagnostics data.

### IMPORTANT

The boot diagnostics data blobs (which comprise of logs and snapshot images) are stored in a managed storage account. Customers will be charged only on used GiBs by the blobs, not on the disk's provisioned size. The snapshot meters will be used for billing of the managed storage account. Because the managed accounts are created on either Standard LRS or Standard ZRS, customers will be charged at \$0.05/GB per month for the size of their diagnostic data blobs only. For more information on this pricing, see [Managed disks pricing](#). Customers will see this charge tied to their VM resource URI.

An alternative boot diagnostic experience is to use a custom storage account. A user can either create a new storage account or use an existing one. When the storage firewall is enabled on the custom storage account (**Enabled from all networks** option isn't selected), you must:

- Make sure that access through the storage firewall is allowed for the Azure platform to publish the screenshot and serial log. To do this, go to the custom boot diagnostics storage account in the Azure portal and then select **Networking** from the **Security + networking** section. Check if the **Allow Azure services on the trusted services list to access this storage account** checkbox is selected.
- Allow storage firewall for users to view the boot screenshots or serial logs. To do this, add your network or the client/browser's Internet IPs as firewall exclusions. For more information, see [Configure Azure Storage firewalls and virtual networks](#).

To configure the storage firewall for Azure Serial Console, see [Use Serial Console with custom boot diagnostics storage account firewall enabled](#).

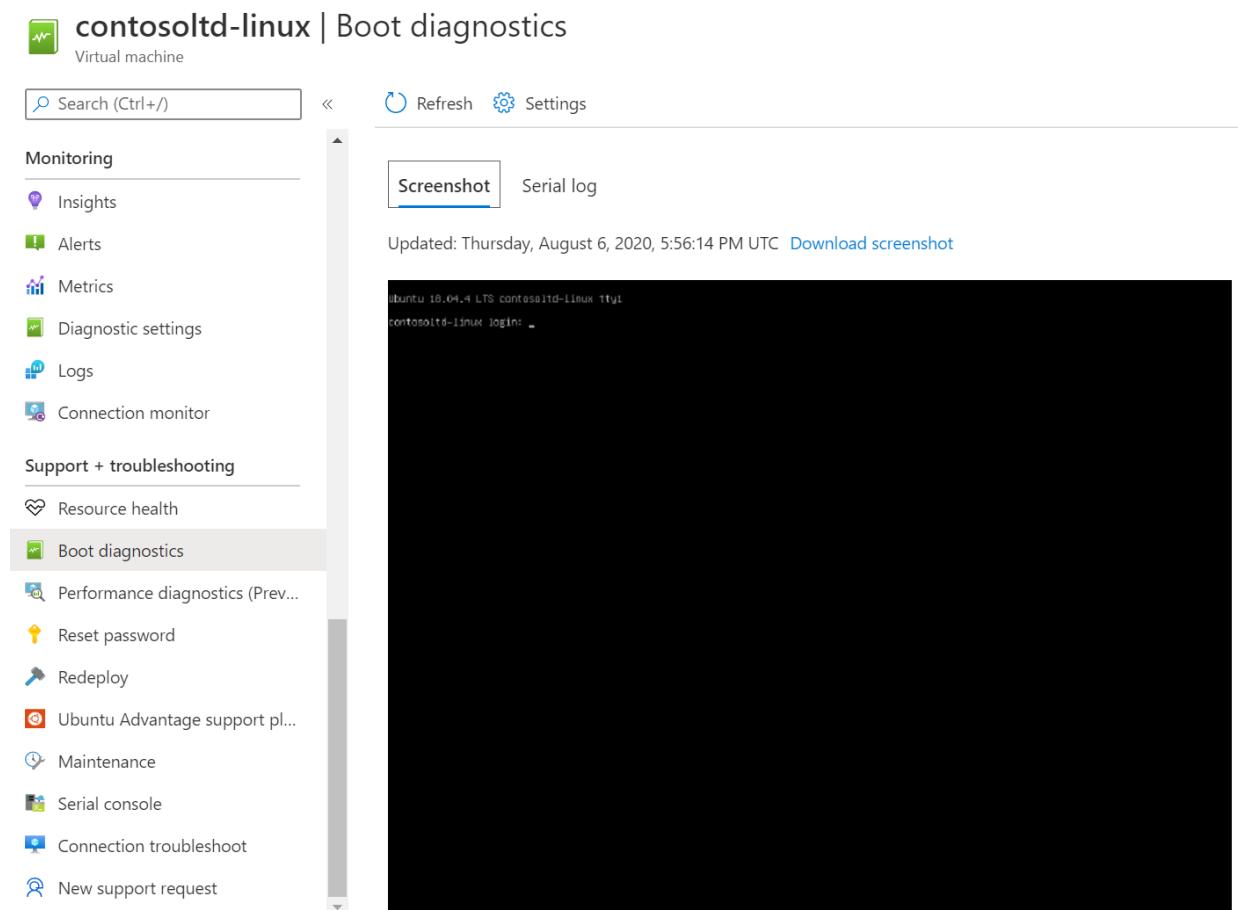

### NOTE

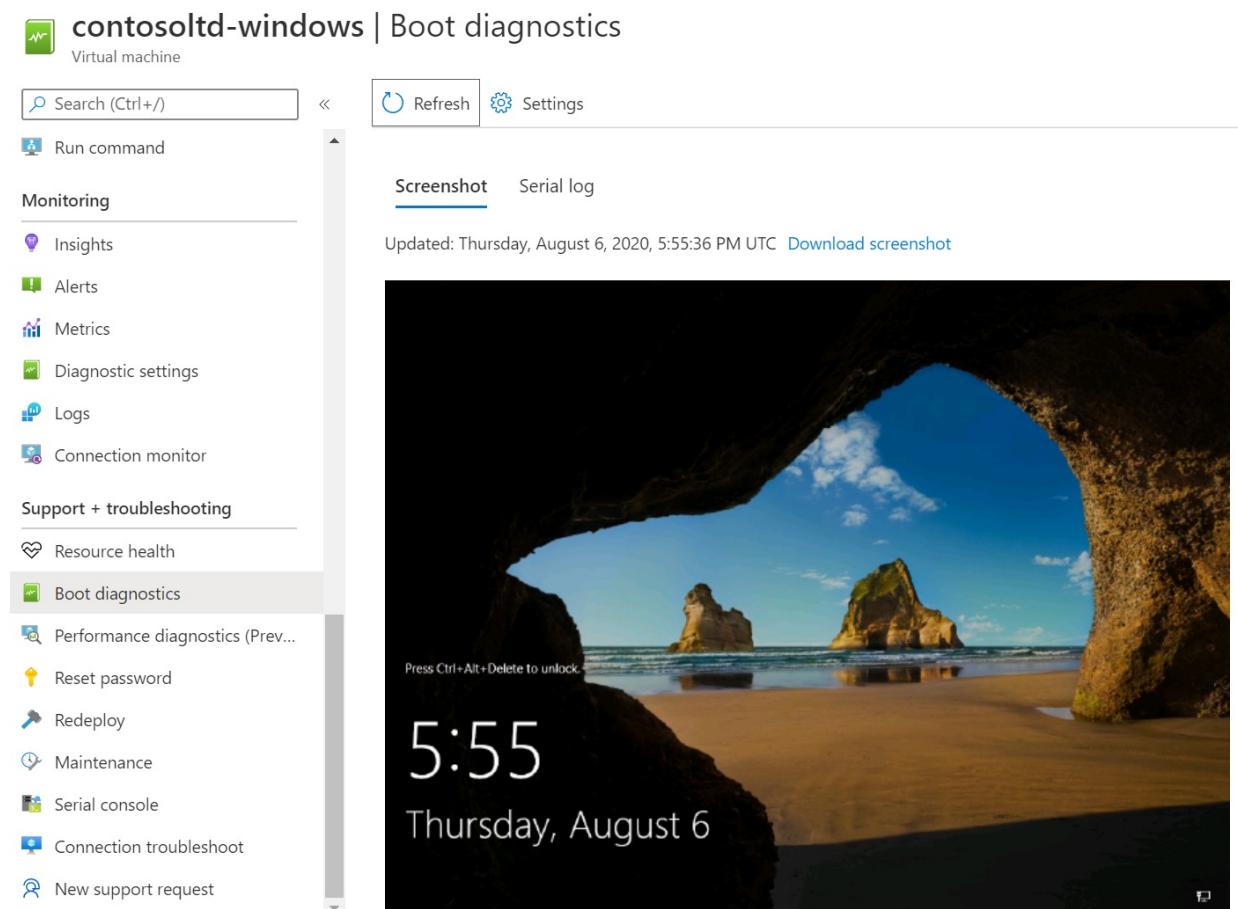

The custom storage account associated with boot diagnostics requires the storage account and the associated virtual machines reside in the same region and subscription.

## Boot diagnostics view

Go to the virtual machine blade in the Azure portal, the boot diagnostics option is under the *Support and Troubleshooting* section in the Azure portal. Selecting boot diagnostics will display a screenshot and serial log information. The serial log contains kernel messaging and the screenshot is a snapshot of your VMs current

state. Based on if the VM is running Windows or Linux determines what the expected screenshot would look like. For Windows, users will see a desktop background and for Linux, users will see a login prompt.

## Enable managed boot diagnostics

Managed boot diagnostics can be enabled through the Azure portal, CLI and ARM Templates.

### Enable managed boot diagnostics using the Azure portal

When you create a VM in the Azure portal, the default setting is to have boot diagnostics enabled using a managed storage account. To view this, navigate to the *Management* tab during the VM creation.

## Create a virtual machine

Basics Disks Networking **Management** Advanced Tags Review + create

Configure monitoring and management options for your VM.

**Azure Security Center**

Azure Security Center provides unified security management and advanced threat protection across hybrid cloud workloads. [Learn more](#)

Your subscription is protected by Azure Security Center basic plan.

**Monitoring**

Enable detailed monitoring  On  Off

Boot diagnostics  Enable with managed storage account (recommended)  Enable with custom storage account  Disable

OS guest diagnostics  On  Off

### Enable managed boot diagnostics using CLI

Boot diagnostics with a managed storage account is supported in Azure CLI 2.12.0 and later. If you don't input a name or URI for a storage account, a managed account will be used. For more information and code samples, see the [CLI documentation for boot diagnostics](#).

### Enable managed boot diagnostics using PowerShell

Boot diagnostics with a managed storage account is supported in Azure PowerShell 6.6.0 and later. If you don't input a name or URI for a storage account, a managed account will be used. For more information and code samples, see the [PowerShell documentation for boot diagnostics](#).

### Enable managed boot diagnostics using Azure Resource Manager (ARM) templates

Everything after API version 2020-06-01 supports managed boot diagnostics. For more information, see [boot diagnostics instance view](#).

                }
            }
        }
    }
],

```

## Limitations

- Managed boot diagnostics is only available for Azure Resource Manager VMs.
- Managed boot diagnostics doesn't support VMs using unmanaged OS disks.
- Boot diagnostics doesn't support premium storage accounts or zone redundant storage accounts. If either of these are used for boot diagnostics users will receive an `StorageAccountTypeNotSupported` error when starting the VM.
- Managed storage accounts are supported in Resource Manager API version "2020-06-01" and later.
- Portal only supports the use of boot diagnostics with a managed storage account for single instance VMs.
- Users cannot configure a retention period for Managed Boot Diagnostics. The logs will be overwritten when the total size crosses 1 GB.

# Backup and restore options for virtual machines in Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

You can protect your data by taking backups at regular intervals. There are several backup options available for virtual machines (VMs), depending on your use-case.

## Azure Backup

You'll use Azure Backup for most use-cases involving backup operations on Azure VMs running production workloads. Azure Backup supports application-consistent backups for both Windows and Linux VMs. Azure Backup creates recovery points that are stored in geo-redundant recovery vaults. When you restore from a recovery point, you can restore entire VM or specific files.

For a simple, hands-on introduction to Azure Backup for Azure VMs, see the [Azure Backup quickstart](#).

For more information on how Azure Backup works, see [Plan your VM backup infrastructure in Azure](#)

## Azure Site Recovery

Azure Site Recovery protects your VMs from a major disaster scenario. These scenarios may include widespread service interruptions or regional outages caused by natural disasters. You can configure Azure Site Recovery for your VMs so that your applications are recoverable in matter of minutes with a single click. You can replicate to an Azure region of your choice, since recovery isn't restricted to paired regions.

You can run disaster-recovery drills with on-demand test failovers, without affecting your production workloads or ongoing replication. Create recovery plans to orchestrate failover and fallback of the entire application running on multiple VMs. The recovery plan feature is integrated with Azure automation runbooks.

You can get started by [replicating your virtual machines](#).

## Managed snapshots

In development and test environments, snapshots provide a quick and simple option for backing up VMs that use managed disks. A managed snapshot is a full, read-only copy of a managed disk. Snapshots exist independently of their source disks.

Snapshots can be used to create new managed disks when a VM is rebuilt. They're billed based on the used portion of the disk. For example, if you create a snapshot of a managed disk with provisioned capacity of 64 GB and actual used data size of 10 GB, snapshot will be billed only for the used data size of 10 GB.

For more information on creating snapshots, see:

- [Create copy of VHD stored as a Managed Disk](#)

## Virtual machine restore points

At this time, you can use Azure REST APIs to back up and restore your VMs. This approach is most often used by independent software vendor (ISVs) or organizations with a relatively small number of VMs to manage.

You can use the API to create a VM restore point collection. The restore point collection itself contains individual restore points for specific VMs. Each restore point stores a VM's configuration and a snapshot for each attached managed disk. To save space and costs, you can exclude any disk from your VM restore points.

Once created, VM restore points can then be used to restore individual disks. To restore a VM, restore all relevant disks and attach them to a new VM.

Learn more about [working with VM restore points](#) and the [restore point collections API](#).

## Next steps

You can try out Azure Backup by following the [Azure Backup quickstart](#).

# What if an Azure service disruption impacts Azure VMs

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

At Microsoft, we work hard to make sure that our services are always available to you when you need them. Forces beyond our control sometimes impact us in ways that cause unplanned service disruptions.

Microsoft provides a Service Level Agreement (SLA) for its services as a commitment for uptime and connectivity. The SLA for individual Azure services can be found at [Azure Service Level Agreements](#).

Azure already has many built-in platform features that support highly available applications. For more about these services, read [Disaster recovery and high availability for Azure applications](#).

This article covers a true disaster recovery scenario, when a whole region experiences an outage due to major natural disaster or widespread service interruption. These are rare occurrences, but you must prepare for the possibility that there is an outage of an entire region. If an entire region experiences a service disruption, the locally redundant copies of your data would temporarily be unavailable. If you have enabled geo-replication, three additional copies of your Azure Storage blobs and tables are stored in a different region. In the event of a complete regional outage or a disaster in which the primary region is not recoverable, Azure remaps all of the DNS entries to the geo-replicated region.

To help you handle these rare occurrences, we provide the following guidance for Azure virtual machines in the case of a service disruption of the entire region where your Azure virtual machine application is deployed.

## Option 1: Initiate a failover by using Azure Site Recovery

You can configure Azure Site Recovery for your VMs so that you can recover your application with a single click in matter of minutes. You can replicate to Azure region of your choice and not restricted to paired regions. You can get started by [replicating your virtual machines](#). You can [create a recovery plan](#) so that you can automate the entire failover process for your application. You can [test your failovers](#) beforehand without impacting production application or the ongoing replication. In the event of a primary region disruption, you just [initiate a failover](#) and bring your application in target region.

## Option 2: Wait for recovery

In this case, no action on your part is required. Know that we are working diligently to restore service availability. You can see the current service status on our [Azure Service Health Dashboard](#).

This is the best option if you have not set up Azure Site Recovery, read-access geo-redundant storage, or geo-redundant storage prior to the disruption. If you have set up geo-redundant storage or read-access geo-redundant storage for the storage account where your VM virtual hard drives (VHDs) are stored, you can look to recover the base image VHD and try to provision a new VM from it. This is not a preferred option because there are no guarantees of synchronization of data. Consequently, this option is not guaranteed to work.

**NOTE**

Be aware that you do not have any control over this process, and it will only occur for region-wide service disruptions. Because of this, you must also rely on other application-specific backup strategies to achieve the highest level of availability. For more information, see the section on [Data strategies for disaster recovery](#).

## Next steps

- Start [protecting your applications running on Azure virtual machines](#) using Azure Site Recovery
- To learn more about how to implement a disaster recovery and high availability strategy, see [Disaster recovery and high availability for Azure applications](#).
- To develop a detailed technical understanding of a cloud platform's capabilities, see [Azure resiliency technical guidance](#).
- If the instructions are not clear, or if you would like Microsoft to do the operations on your behalf, contact [Customer Support](#).

# An overview of Azure VM backup

9/21/2022 • 12 minutes to read • [Edit Online](#)

This article describes how the [Azure Backup service](#) backs up Azure virtual machines (VMs).

Azure Backup provides independent and isolated backups to guard against unintended destruction of the data on your VMs. Backups are stored in a Recovery Services vault with built-in management of recovery points. Configuration and scaling are simple, backups are optimized, and you can easily restore as needed.

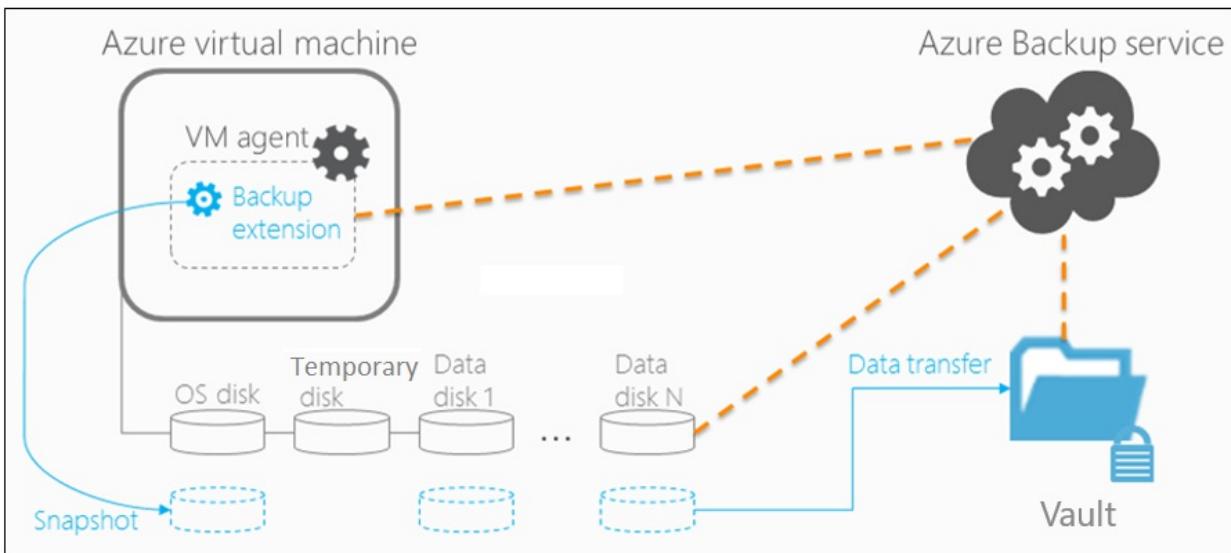

As part of the backup process, a [snapshot is taken](#), and the data is transferred to the Recovery Services vault with no impact on production workloads. The snapshot provides different levels of consistency, as described [here](#).

Azure Backup also has specialized offerings for database workloads like [SQL Server](#) and [SAP HANA](#) that are workload-aware, offer 15 minute RPO (recovery point objective), and allow backup and restore of individual databases.

## Backup process

Here's how Azure Backup completes a backup for Azure VMs:

1. For Azure VMs that are selected for backup, Azure Backup starts a backup job according to the backup schedule you specify.
2. During the first backup, a backup extension is installed on the VM if the VM is running.
  - For Windows VMs, the [VMSnapshot extension](#) is installed.
  - For Linux VMs, the [VMSnapshotLinux extension](#) is installed.
3. For Windows VMs that are running, Backup coordinates with Windows Volume Shadow Copy Service (VSS) to take an app-consistent snapshot of the VM.
  - By default, Backup takes full VSS backups.
  - If Backup can't take an app-consistent snapshot, then it takes a file-consistent snapshot of the underlying storage (because no application writes occur while the VM is stopped).
4. For Linux VMs, Backup takes a file-consistent backup. For app-consistent snapshots, you need to manually customize pre/post scripts.
5. After Backup takes the snapshot, it transfers the data to the vault.
  - The backup is optimized by backing up each VM disk in parallel.
  - For each disk that's being backed up, Azure Backup reads the blocks on the disk and identifies and transfers only the data blocks that changed (the delta) since the previous backup.
  - Snapshot data might not be immediately copied to the vault. It might take some hours at peak times. Total backup time for a VM will be less than 24 hours for daily backup policies.
6. Changes made to a Windows VM after Azure Backup is enabled on it are:
  - Microsoft Visual C++ 2013 Redistributable(x64) - 12.0.40660 is installed in the VM
  - Startup type of Volume Shadow Copy service (VSS) changed to automatic from manual
  - IaaSVmProvider Windows service is added
7. When the data transfer is complete, the snapshot is removed, and a recovery point is created.

## Encryption of Azure VM backups

When you back up Azure VMs with Azure Backup, VMs are encrypted at rest with Storage Service Encryption (SSE). Azure Backup can also back up Azure VMs that are encrypted by using Azure Disk Encryption.

ENCRYPTION	DETAILS	SUPPORT
SSE	<p>With SSE, Azure Storage provides encryption at rest by automatically encrypting data before storing it. Azure Storage also decrypts data before retrieving it. Azure Backup supports backups of VMs with two types of Storage Service Encryption:</p> <ul style="list-style-type: none"> <li><b>SSE with platform-managed keys:</b> This encryption is by default for all disks in your VMs. See more <a href="#">here</a>.</li> <li><b>SSE with customer-managed keys.</b> With CMK, you manage the keys used to encrypt the disks. See more <a href="#">here</a>.</li> </ul>	Azure Backup uses SSE for at-rest encryption of Azure VMs.
Azure Disk Encryption	<p>Azure Disk Encryption encrypts both OS and data disks for Azure VMs.</p> <p>Azure Disk Encryption integrates with BitLocker encryption keys (BEKs), which are safeguarded in a key vault as secrets. Azure Disk Encryption also integrates with Azure Key Vault key encryption keys (KEKs).</p>	<p>Azure Backup supports backup of managed and unmanaged Azure VMs encrypted with BEKs only, or with BEKs together with KEKs.</p> <p>Both BEKs and KEKs are backed up and encrypted.</p> <p>Because KEKs and BEKs are backed up, users with the necessary permissions can restore keys and secrets back to the key vault if needed. These users can also recover the encrypted VM.</p> <p>Encrypted keys and secrets can't be read by unauthorized users or by Azure.</p>

For managed and unmanaged Azure VMs, Backup supports both VMs encrypted with BEKs only or VMs encrypted with BEKs together with KEKs.

The backed-up BEKs (secrets) and KEKs (keys) are encrypted. They can be read and used only when they're

restored back to the key vault by authorized users. Neither unauthorized users, or Azure, can read or use backed-up keys or secrets.

BEKs are also backed up. So, if the BEKs are lost, authorized users can restore the BEKs to the key vault and recover the encrypted VMs. Only users with the necessary level of permissions can back up and restore encrypted VMs or keys and secrets.

## Snapshot creation

Azure Backup takes snapshots according to the backup schedule.

- **Windows VMs:** For Windows VMs, the Backup service coordinates with VSS to take an app-consistent snapshot of the VM disks. By default, Azure Backup takes a full VSS backup (it truncates the logs of application such as SQL Server at the time of backup to get application level consistent backup). If you're using a SQL Server database on Azure VM backup, then you can modify the setting to take a VSS Copy backup (to preserve logs). For more information, see [this article](#).
- **Linux VMs:** To take app-consistent snapshots of Linux VMs, use the Linux pre-script and post-script framework to write your own custom scripts to ensure consistency.
  - Azure Backup invokes only the pre/post scripts written by you.
  - If the pre-scripts and post-scripts execute successfully, Azure Backup marks the recovery point as application-consistent. However, when you're using custom scripts, you're ultimately responsible for the application consistency.
  - [Learn more](#) about how to configure scripts.

## Snapshot consistency

The following table explains the different types of snapshot consistency:

SNAPSHOT	DETAILS	RECOVERY	CONSIDERATION
Application-consistent	App-consistent backups capture memory content and pending I/O operations. App-consistent snapshots use a VSS writer (or pre/post scripts for Linux) to ensure the consistency of the app data before a backup occurs.	When you're recovering a VM with an app-consistent snapshot, the VM boots up. There's no data corruption or loss. The apps start in a consistent state.	Windows: All VSS writers succeeded  Linux: Pre/post scripts are configured and succeeded
File-system consistent	File-system consistent backups provide consistency by taking a snapshot of all files at the same time.	When you're recovering a VM with a file-system consistent snapshot, the VM boots up. There's no data corruption or loss. Apps need to implement their own "fix-up" mechanism to make sure that restored data is consistent.	Windows: Some VSS writers failed  Linux: Default (if pre/post scripts aren't configured or failed)

Snapshot	Details	Recovery	Consideration
Crash-consistent	Crash-consistent snapshots typically occur if an Azure VM shuts down at the time of backup. Only the data that already exists on the disk at the time of backup is captured and backed up.	Starts with the VM boot process followed by a disk check to fix corruption errors. Any in-memory data or write operations that weren't transferred to disk before the crash are lost. Apps implement their own data verification. For example, a database app can use its transaction log for verification. If the transaction log has entries that aren't in the database, the database software rolls transactions back until the data is consistent.	VM is in shutdown (stopped/ deallocated) state.

#### NOTE

If the provisioning state is **succeeded**, Azure Backup takes file-system consistent backups. If the provisioning state is **unavailable** or **failed**, crash-consistent backups are taken. If the provisioning state is **creating** or **deleting**, that means Azure Backup is retrying the operations.

## Backup and restore considerations

Consideration	Details
Disk	Backup of VM disks is parallel. For example, if a VM has four disks, the Backup service attempts to back up all four disks in parallel. Backup is incremental (only changed data).
Scheduling	To reduce backup traffic, back up different VMs at different times of the day and make sure the times don't overlap. Backing up VMs at the same time causes traffic jams.
Preparing backups	Keep in mind the time needed to prepare the backup. The preparation time includes installing or updating the backup extension and triggering a snapshot according to the backup schedule.

CONSIDERATION	DETAILS
Data transfer	<p>Consider the time needed for Azure Backup to identify the incremental changes from the previous backup.</p> <p>In an incremental backup, Azure Backup determines the changes by calculating the checksum of the block. If a block is changed, it's marked for transfer to the vault. The service analyzes the identified blocks to attempt to further minimize the amount of data to transfer. After evaluating all the changed blocks, Azure Backup transfers the changes to the vault.</p> <p>There might be a lag between taking the snapshot and copying it to vault. At peak times, it can take up to eight hours for the snapshots to be transferred to the vault. The backup time for a VM will be less than 24 hours for the daily backup.</p>
Initial backup	Although the total backup time for incremental backups is less than 24 hours, that might not be the case for the first backup. The time needed for the initial backup will depend on the size of the data and when the backup is processed.
Restore queue	Azure Backup processes restore jobs from multiple storage accounts at the same time, and it puts restore requests in a queue.
Restore copy	<p>During the restore process, data is copied from the vault to the storage account.</p> <p>The total restore time depends on the I/O operations per second (IOPS) and the throughput of the storage account.</p> <p>To reduce the copy time, select a storage account that isn't loaded with other application writes and reads.</p>

## Backup performance

These common scenarios can affect the total backup time:

- **Adding a new disk to a protected Azure VM:** If a VM is undergoing incremental backup and a new disk is added, the backup time will increase. The total backup time might last more than 24 hours because of initial replication of the new disk, along with delta replication of existing disks.
- **Fragmented disks:** Backup operations are faster when disk changes are contiguous. If changes are spread out and fragmented across a disk, backup will be slower.
- **Disk churn:** If protected disks that are undergoing incremental backup have a daily churn of more than 200 GB, backup can take a long time (more than eight hours) to complete.
- **Backup versions:** The latest version of Backup (known as the Instant Restore version) uses a more optimized process than checksum comparison for identifying changes. But if you're using Instant Restore and have deleted a backup snapshot, the backup switches to checksum comparison. In this case, the backup operation will exceed 24 hours (or fail).

## Restore performance

These common scenarios can affect the total restore time:

- The total restore time depends on the Input/output operations per second (IOPS) and the throughput of the storage account.
- The total restore time can be affected if the target storage account is loaded with other application read and

write operations. To improve restore operation, select a storage account that isn't loaded with other application data.

## Best practices

When you're configuring VM backups, we suggest following these practices:

- Modify the default schedule times that are set in a policy. For example, if the default time in the policy is 12:00 AM, increment the timing by several minutes so that resources are optimally used.
- If you're restoring VMs from a single vault, we highly recommend that you use different [general-purpose v2 storage accounts](#) to ensure that the target storage account doesn't get throttled. For example, each VM must have a different storage account. For example, if 10 VMs are restored, use 10 different storage accounts.
- For backup of VMs that are using premium storage with Instant Restore, we recommend allocating 50% free space of the total allocated storage space, which is required **only** for the first backup. The 50% free space isn't a requirement for backups after the first backup is complete
- The limit on the number of disks per storage account is relative to how heavily the disks are being accessed by applications that are running on an infrastructure as a service (IaaS) VM. As a general practice, if 5 to 10 disks or more are present on a single storage account, balance the load by moving some disks to separate storage accounts.
- To restore VMs with managed disks using PowerShell, provide the additional parameter **TargetResourceGroupName** to specify the resource group to which managed disks will be restored, [Learn more here](#).

## Backup costs

Azure VMs backed up with Azure Backup are subject to [Azure Backup pricing](#).

Billing doesn't start until the first successful backup finishes. At this point, the billing for both storage and protected VMs begins. Billing continues as long as any backup data for the VM is stored in a vault. If you stop protection for a VM, but backup data for the VM exists in a vault, billing continues.

Billing for a specified VM stops only if the protection is stopped and all backup data is deleted. When protection stops and there are no active backup jobs, the size of the last successful VM backup becomes the protected instance size used for the monthly bill.

The protected-instance size calculation is based on the *actual* size of the VM. The VM's size is the sum of all the data in the VM, excluding the temporary storage. Pricing is based on the actual data that's stored on the data disks, not on the maximum supported size for each data disk that's attached to the VM.

Similarly, the backup storage bill is based on the amount of data that's stored in Azure Backup, which is the sum of the actual data in each recovery point.

For example, take an A2-Standard-sized VM that has two additional data disks with a maximum size of 32 TB each. The following table shows the actual data stored on each of these disks:

DISK	MAX SIZE	ACTUAL DATA PRESENT
OS disk	32 TB	17 GB
Local/temporary disk	135 GB	5 GB (not included for backup)
Data disk 1	32 TB	30 GB
Data disk 2	32 TB	0 GB

The actual size of the VM in this case is 17 GB + 30 GB + 0 GB = 47 GB. This protected-instance size (47 GB) becomes the basis for the monthly bill. As the amount of data in the VM grows, the protected-instance size used for billing changes to match.

## Next steps

- [Prepare for Azure VM backup.](#)

# Back up a virtual machine in Azure with the Azure CLI

9/21/2022 • 6 minutes to read • [Edit Online](#)

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. You can protect your data by taking backups at regular intervals. Azure Backup creates recovery points that can be stored in geo-redundant recovery vaults. This article details how to back up a virtual machine (VM) in Azure with the Azure CLI. You can also perform these steps with [Azure PowerShell](#) or in the [Azure portal](#).

This quickstart enables backup on an existing Azure VM. If you need to create a VM, you can [create a VM with the Azure CLI](#).

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This quickstart requires version 2.0.18 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a Recovery Services vault

A Recovery Services vault is a logical container that stores the backup data for each protected resource, such as Azure VMs. When the backup job for a protected resource runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

Create a Recovery Services vault with `az backup vault create`. Specify the same resource group and location as the VM you wish to protect. If you used the [VM quickstart](#), then you created:

- a resource group named *myResourceGroup*,
- a VM named *myVM*,
- resources in the *eastus* location.

```
az backup vault create --resource-group myResourceGroup \
--name myRecoveryServicesVault \
--location eastus
```

By default, the Recovery Services vault is set for Geo-Redundant storage. Geo-Redundant storage ensures your backup data is replicated to a secondary Azure region that's hundreds of miles away from the primary region. If the storage redundancy setting needs to be modified, use [az backup vault backup-properties set cmdlet](#).

```
az backup vault backup-properties set \
--name myRecoveryServicesVault \
--resource-group myResourceGroup \
--backup-storage-redundancy "LocallyRedundant/GeoRedundant"
```

## Enable backup for an Azure VM

Create a protection policy to define: when a backup job runs, and how long the recovery points are stored. The default protection policy runs a backup job each day and retains recovery points for 30 days. You can use these default policy values to quickly protect your VM. To enable backup protection for a VM, use [az backup protection enable-for-vm](#). Specify the resource group and VM to protect, then the policy to use:

```
az backup protection enable-for-vm \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--vm myVM \
--policy-name DefaultPolicy
```

### NOTE

If the VM isn't in the same resource group as that of the vault, then myResourceGroup refers to the resource group where vault was created. Instead of VM name, provide the VM ID as indicated below.

```
az backup protection enable-for-vm \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--vm $(az vm show -g VMResourceGroup -n MyVm --query id | tr -d '') \
--policy-name DefaultPolicy
```

### IMPORTANT

While using CLI to enable backup for multiple VMs at once, ensure that a single policy doesn't have more than 100 VMs associated with it. This is a [recommended best practice](#). Currently, the PowerShell client doesn't explicitly block if there are more than 100 VMs, but the check is planned to be added in the future.

## Prerequisites to backup encrypted VMs

To enable protection on encrypted VMs (encrypted using BEK and KEK), you must provide the Azure Backup service permission to read keys and secrets from the key vault. To do so, set a *keyvault* access policy with the required permissions, as demonstrated below:

```

# Enter the name of the resource group where the key vault is located on this variable
AZ_KEYVAULT_RGROUP=TestKeyVaultRG

# Enter the name of the key vault on this variable
AZ_KEYVAULT_NAME=TestKeyVault

# Get the object id for the Backup Management Service on your subscription
AZ_ABM_OBJECT_ID=$( az ad sp list --display-name "Backup Management Service" --query '[].objectId' -o tsv --only-show-errors )

# This command will grant the permissions required by the Backup Management Service to access the key vault
az keyvault set-policy --key-permissions get list backup --secret-permissions get list backup \
--resource-group $AZ_KEYVAULT_RGROUP --name $AZ_KEYVAULT_NAME --object-id $AZ_ABM_OBJECT_ID

```

## Start a backup job

To start a backup now rather than wait for the default policy to run the job at the scheduled time, use [az backup protection backup-now](#). This first backup job creates a full recovery point. Each backup job after this initial backup creates incremental recovery points. Incremental recovery points are storage and time-efficient, as they only transfer changes made since the last backup.

The following parameters are used to back up the VM:

- `--container-name` is the name of your VM
- `--item-name` is the name of your VM
- `--retain-until` value should be set to the last available date, in UTC time format (**dd-mm-yyyy**), that you wish the recovery point to be available

The following example backs up the VM named *myVM* and sets the expiration of the recovery point to October 18, 2017:

```

az backup protection backup-now \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--container-name myVM \
--item-name myVM \
--backup-management-type AzureIaaSVM
--retain-until 18-10-2017

```

## Monitor the backup job

To monitor the status of backup jobs, use [az backup job list](#):

```

az backup job list \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--output table

```

The output is similar to the following example, which shows the backup job is *InProgress*.

Name	Operation	Status	Item Name	Start Time UTC	Duration
a0a8e5e6	Backup	InProgress	myvm	2017-09-19T03:09:21	0:00:48.718366
fe5d0414	ConfigureBackup	Completed	myvm	2017-09-19T03:03:57	0:00:31.191807

When the *Status* of the backup job reports *Completed*, your VM is protected with Recovery Services and has a

full recovery point stored.

## Clean up deployment

When no longer needed, you can disable protection on the VM, remove the restore points and Recovery Services vault, then delete the resource group and associated VM resources. If you used an existing VM, you can skip the final `az group delete` command to leave the resource group and VM in place.

If you want to try a Backup tutorial that explains how to restore data for your VM, go to [Next steps](#).

```
az backup protection disable \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --container-name myVM \
    --item-name myVM \
    --backup-management-type AzureIaaSVM
    --delete-backup-data true
az backup vault delete \
    --resource-group myResourceGroup \
    --name myRecoveryServicesVault \
az group delete --name myResourceGroup
```

## Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point. To learn more about Azure Backup and Recovery Services, continue to the tutorials.

[Back up multiple Azure VMs](#)

# Back up a virtual machine in Azure with PowerShell

9/21/2022 • 4 minutes to read • [Edit Online](#)

The [Azure PowerShell AZ](#) module is used to create and manage Azure resources from the command line or in scripts.

[Azure Backup](#) backs up on-premises machines and apps, and Azure VMs. This article shows you how to back up an Azure VM with the AZ module. Alternatively, you can back up a VM using the [Azure CLI](#), or in the [Azure portal](#).

This quickstart enables backup on an existing Azure VM. If you need to create a VM, you can [create a VM with Azure PowerShell](#).

This quickstart requires the Azure PowerShell AZ module version 1.0.0 or later. Run

```
Get-Module -ListAvailable Az
```

to find the version. If you need to install or upgrade, see [Install Azure PowerShell module](#).

## NOTE

To interact with Azure, the Azure Az PowerShell module is recommended. See [Install Azure PowerShell](#) to get started. To learn how to migrate to the Az PowerShell module, see [Migrate Azure PowerShell from AzureRM to Az](#).

## Sign in and register

1. Sign in to your Azure subscription with the `Connect-AzAccount` command and follow the on-screen directions.

```
Connect-AzAccount
```

2. The first time you use Azure Backup, you must register the Azure Recovery Service provider in your subscription with [Register-AzResourceProvider](#), as follows:

```
Register-AzResourceProvider -ProviderNamespace "Microsoft.RecoveryServices"
```

## Create a Recovery Services vault

A [Recovery Services vault](#) is a logical container that stores backup data for protected resources, such as Azure VMs. When a backup job runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

When you create the vault:

- For the resource group and location, specify the resource group and location of the VM you want to back up.
- If you used this [sample script](#) to create the VM, the resource group is `myResourceGroup`, the VM is `*myVM`, and the resources are in the `WestEurope` region.
- Azure Backup automatically handles storage for backed up data. By default the vault uses [Geo-Redundant Storage \(GRS\)](#). Geo-redundancy ensures that backed up data is replicated to a secondary Azure region, hundreds of miles away from the primary region.

Now create a vault:

1. Use the [New-AzRecoveryServicesVault](#) to create the vault:

```
New-AzRecoveryServicesVault  
-ResourceGroupName "myResourceGroup"  
-Name "myRecoveryServicesVault"  
-Location "WestEurope"
```

2. Set the vault context with [Set-AzRecoveryServicesVaultContext](#), as follows:

```
Get-AzRecoveryServicesVault  
-Name "myRecoveryServicesVault" | Set-AzRecoveryServicesVaultContext
```

3. Change the storage redundancy configuration (LRS/GRS) of the vault with [Set-AzRecoveryServicesBackupProperty](#), as follows:

```
Get-AzRecoveryServicesVault  
-Name "myRecoveryServicesVault" | Set-AzRecoveryServicesBackupProperty -BackupStorageRedundancy  
LocallyRedundant/GeoRedundant
```

**NOTE**

Storage Redundancy can be modified only if there are no backup items protected to the vault.

## Enable backup for an Azure VM

You enable backup for an Azure VM, and specify a backup policy.

- The policy defines when backups run, and how long recovery points created by the backups should be retained.
- The default protection policy runs a backup once a day for the VM, and retains the created recovery points for 30 days. You can use this default policy to quickly protect your VM.

Enable backup as follows:

1. First, set the default policy with [Get-AzRecoveryServicesBackupProtectionPolicy](#):

```
$policy = Get-AzRecoveryServicesBackupProtectionPolicy -Name "DefaultPolicy"
```

2. Enable VM backup with [Enable-AzRecoveryServicesBackupProtection](#). Specify the policy, the resource group, and the VM name.

```
Enable-AzRecoveryServicesBackupProtection  
-ResourceGroupName "myResourceGroup"  
-Name "myVM"  
-Policy $policy
```

## Start a backup job

Backups run according to the schedule specified in the backup policy. You can also run an on-demand backup:

- The first initial backup job creates a full recovery point.

- After the initial backup, each backup job creates incremental recovery points.
- Incremental recovery points are storage and time-efficient, as they only transfer changes made since the last backup.

To run an on-demand backup, you use the [Backup-AzRecoveryServicesBackupItem](#).

- You specify a container in the vault that holds your backup data with [Get-AzRecoveryServicesBackupContainer](#).
- Each VM to back up is treated as an item. To start a backup job, you obtain information about the VM with [Get-AzRecoveryServicesBackupItem](#).

Run an on-demand backup job as follows:

1. Specify the container, obtain VM information, and run the backup.

```
$backupcontainer = Get-AzRecoveryServicesBackupContainer ` 
    -ContainerType "AzureVM" ` 
    -FriendlyName "myVM"

$item = Get-AzRecoveryServicesBackupItem ` 
    -Container $backupcontainer ` 
    -WorkloadType "AzureVM"

Backup-AzRecoveryServicesBackupItem -Item $item
```

2. You might need to wait up to 20 minutes, since the first backup job creates a full recovery point. Monitor the job as described in the next procedure.

## Monitor the backup job

1. Run [Get-AzRecoveryServicesBackupJob](#) to monitor the job status.

```
Get-AzRecoveryServicesBackupJob
```

Output is similar to the following example, which shows the job as **InProgress**:

WorkloadName	Operation	Status	StartTime	EndTime	JobID
myvm	Backup	InProgress	9/18/2017 9:38:02 PM		9f9e8f14
myvm	ConfigureBackup	Completed	9/18/2017 9:33:18 PM	9/18/2017 9:33:51 PM	fe79c739

2. When the job status is **Completed**, the VM is protected and has a full recovery point stored.

## Manage VM backups

If you want to perform more actions such as change policy, edit policy etc.. refer to the [manage VM backups section](#).

## Clean up the deployment

If you no longer need to back up the VM, you can clean it up.

- If you want to try out restoring the VM, skip the clean-up.
- If you used an existing VM, you can skip the final [Remove-AzResourceGroup](#) cmdlet to leave the resource group and VM in place.

Disable protection, remove the restore points and vault. Then delete the resource group and associated VM resources, as follows:

```
Disable-AzRecoveryServicesBackupProtection -Item $item -RemoveRecoveryPoints  
$vault = Get-AzRecoveryServicesVault -Name "myRecoveryServicesVault"  
Remove-AzRecoveryServicesVault -Vault $vault  
Remove-AzResourceGroup -Name "myResourceGroup"
```

## Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point.

- [Learn how](#) to back up VMs in the Azure portal.
- [Learn how](#) to quickly restore a VM

# Back up a virtual machine in Azure

9/21/2022 • 10 minutes to read • [Edit Online](#)

Azure backups can be created through the Azure portal. This method provides a browser-based user interface to create and configure Azure backups and all related resources. You can protect your data by taking backups at regular intervals. Azure Backup creates recovery points that can be stored in geo-redundant recovery vaults. This article details how to back up a virtual machine (VM) with the Azure portal.

This quickstart enables backup on an existing Azure VM. If you need to create a VM, you can [create a VM with the Azure portal](#).

## Sign in to Azure

Sign in to the [Azure portal](#).

### NOTE

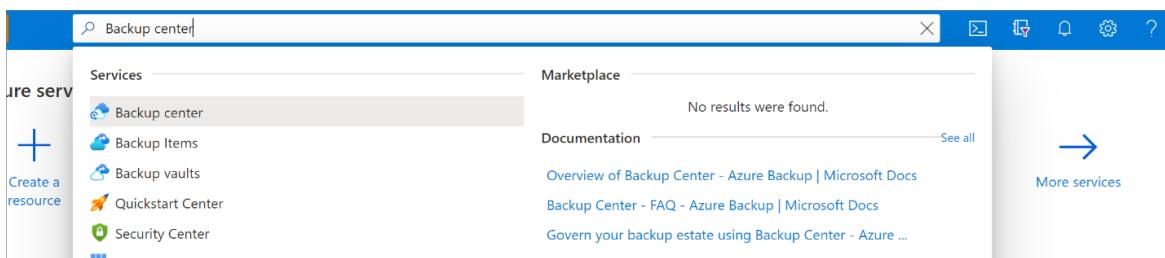

The functionality described in the following sections can also be accessed via [Backup center](#). Backup center is a single unified management experience in Azure. It enables enterprises to govern, monitor, operate, and analyze backups at scale. With this solution, you can perform most of the key backup management operations without being limited to the scope of an individual vault.

## Create a Recovery Services vault

A Recovery Services vault is a management entity that stores recovery points created over time and provides an interface to perform backup-related operations. These operations include taking on-demand backups, performing restores, and creating backup policies.

To create a Recovery Services vault:

1. Sign in to your subscription in the [Azure portal](#).
2. Search for **Backup center** in the Azure portal, and go to the **Backup Center** dashboard.

3. Select **+Vault** from the **Overview** tab.

**Backup center** Microsoft

Search (Ctrl+ /) <> + Backup ⌂ Restore + Policy + Vault ⌂ Refresh

Datasource subscription == **66 selected** Datasource resource group == All Datasource location == All Datasource type == Azure Virtual machines

**Datasource type: Azure Virtual machines**

Overview of Jobs and Backup instances

Jobs (last 24 Hours)				<a href="#">View all</a>
Operation	Failed	In progress	Completed	
Scheduled backup	64	8	246	
On-demand backup	0	0	12	
Restore	1	0	57	

Backup instances			
Azure Virtual machines			
<b>359</b>	Protection configured	<b>338</b>	
	Protection stopped	<b>16</b>	
	Soft deleted	<b>5</b>	
<b>86</b> out of 359	Backup instances with the underlying datasource not found		

#### 4. Select Recovery Services vault > Continue.

Home > Backup center > Start: Create Vault ...

A vault is an entity that stores the backups and restore points created over time. The vault also contains the backup policies that are associated with the protected virtual machines. Proceed to vault creation by selecting vault type.

Vault Type

Recovery Services vault

Supported datasources

- ✓ Azure Virtual machines
- ✓ SQL in Azure VM
- ✓ Azure Files (Azure Storage)
- ✓ SAP HANA in Azure VM
- ✓ Azure Backup Server
- ✓ Azure Backup Agent
- ✓ DPM

Backup vault

Supported datasources

- ✓ Azure Database for PostgreSQL servers (Preview)
- ✓ Azure Blobs (Azure Storage)
- ✓ Azure Disks

Learn more about Backup vault. [Click here](#) ↗

Learn more about Recovery Services vault. [Click here](#) ↗

[Continue](#) [Cancel](#)

#### 5. The Recovery Services vault dialog opens. Provide the following values:

- Subscription:** Choose the subscription to use. If you're a member of only one subscription, you'll see that name. If you're not sure which subscription to use, use the default (suggested) subscription. There are multiple choices only if your work or school account is associated with more than one Azure subscription.
- Resource group:** Use an existing resource group or create a new one. To see the list of available resource groups in your subscription, select **Use existing**, and then select a resource from the dropdown list. To create a new resource group, select **Create new** and enter the name. For more information about resource groups, see [Azure Resource Manager overview](#).
- Vault name:** Enter a friendly name to identify the vault. The name must be unique to the Azure

subscription. Specify a name that has at least 2 but not more than 50 characters. The name must start with a letter and consist only of letters, numbers, and hyphens.

- **Region:** Select the geographic region for the vault. For you to create a vault to help protect any data source, the vault *must* be in the same region as the data source.

#### IMPORTANT

If you're not sure of the location of your data source, close the dialog. Go to the list of your resources in the portal. If you have data sources in multiple regions, create a Recovery Services vault for each region. Create the vault in the first location before you create the vault for another location. There's no need to specify storage accounts to store the backup data. The Recovery Services vault and Azure Backup handle that automatically.

The screenshot shows the 'Create Recovery Services vault' wizard in the 'Basics' step. It includes fields for 'Subscription' (dropdown), 'Resource group' (dropdown with 'Create new' option), 'Vault name' (text input placeholder 'Enter the name for your vault.'), and 'Region' (dropdown set to 'East US'). Navigation buttons at the bottom are 'Review + create' (highlighted in red) and 'Next: Tags'.

6. After you provide the values, select **Review + create**.

The screenshot shows the 'Review + create' step with the 'Create' button highlighted in red. Other buttons include 'Review + create' (highlighted in blue) and 'Next: Tags'.

7. When you're ready to create the Recovery Services vault, select **Create**.

The screenshot shows the final step with the 'Create' button highlighted in red. Other buttons include 'Previous: Tags' and 'Download a template for automation'.

8. It can take a while to create the Recovery Services vault. Monitor the status notifications in the **Notifications** area at the upper-right corner of the portal. After your vault is created, it's visible in the list of Recovery Services vaults. If you don't see your vault, select **Refresh**.

The screenshot shows the 'Recovery Services vaults' list page. The 'Refresh' button in the toolbar is highlighted in red. Other buttons include '+ Add', 'Edit columns', 'Try preview', and 'Assign tags'.

# Apply a backup policy

To apply a backup policy to your Azure VMs, follow these steps:

1. Go to **Backup center** and click **+ Backup** from the **Overview** tab.

The screenshot shows the Azure Backup center interface. The left sidebar includes links for Overview, Getting started, Community, Manage (Backup instances, Backup policies, Vaults), Monitoring + reporting (Backup jobs, Backup reports), Policy and compliance (Backup compliance, Azure policies for backup, Protectable datasources), and Support + troubleshooting (New support request). The main area displays 'Jobs (last 24 Hours)' with a table showing counts for Failed, In progress, and Completed operations (Scheduled backup: 64 Failed, 8 In progress, 246 Completed; On-demand backup: 0 Failed, 0 In progress, 12 Completed; Restore: 1 Failed, 0 In progress, 57 Completed). Below this is a 'Backup instances' section for 'Azure Virtual machines', showing a total of 359 instances: 338 with protection configured, 16 stopped, and 5 soft deleted. A note indicates 86 instances have underlying datasources not found. A red box highlights the '+ Backup' button in the top navigation bar.

2. Select **Azure Virtual machines** as the **Datasource type** and select the vault you have created. Then click **Continue**.

The screenshot shows the 'Initiate: Configure Backup' step. It has three dropdown fields: 'Datasource type' set to 'Azure Virtual machines', 'Vault type' set to 'Recovery Services Vault', and 'Vault \*' with a placeholder 'Select a Vault' and a 'Select' button. A blue info box at the bottom left states: 'Selected vault is maintained in Recovery Services Vault, you will be redirected to Recovery Services Vault for configuring backup. Learn more.' The URL in the browser header is 'Home > Backup Center > Initiate: Configure Backup'.

3. Assign a Backup policy.

- The default policy backs up the VM once a day. The daily backups are retained for *30 days*. Instant recovery snapshots are retained for two days.

Home > Backup center > Start: Configure Backup >

## Configure Backup

VaultWithTag

Backup policy \* ⓘ DefaultPolicy  Create a new policy

**Policy Details**

Full Backup      **Backup Frequency**  
Daily at 6:00 PM UTC

Instant Restore  
Retain instant recovery snapshot(s) for 2 day(s)

Retention of daily backup point  
Retain backup taken every day at 6:00 PM for 30 Day(s)

**Virtual machines**

Name	Resource Group	OS Disk Only
No Virtual machines selected.		

Add

**OS Disk only backup** option allows you to backup Azure Virtual Machine with only OS disk and exclude all the data disks. You can use Selective Disk Backup feature through Powershell or CLI to include or exclude specific data disks. Know more about Selective Disk Backup feature, its limitation and pricing- [Learn more](#).

- If you don't want to use the default policy, select **Create New**, and create a custom policy as described in the next procedure.

## Select a VM to back up

Create a simple scheduled daily backup to a Recovery Services vault.

1. Under **Virtual Machines**, select Add.

**Virtual Machines**

Virtual machine name	Resource Group
No Virtual Machines Selected	

Add

2. The **Select virtual machines** pane will open. Select the VMs you want to back up using the policy. Then select **OK**.

- The selected VMs are validated.
- You can only select VMs in the same region as the vault.
- VMs can only be backed up in a single vault.

## Select virtual machines

X

Filter items ...

Virtual machine name	Resource Group
<input checked="" type="checkbox"/> myVM	myResourceGroup
<input checked="" type="checkbox"/> myVMH1	myResourceGroup
<input checked="" type="checkbox"/> myVMR1	myResourceGroup

**OK**

### NOTE

All the VMs in the same region and subscription as that of the vault are available to configure backup. When configuring backup, you can browse to the virtual machine name and its resource group, even though you don't have the required permission on those VMs. If your VM is in soft deleted state, then it won't be visible in this list. If you need to re-protect the VM, then you need to wait for the soft delete period to expire or undelete the VM from the soft deleted list. For more information, see [the soft delete for VMs article](#).

## Enable backup on a VM

A Recovery Services vault is a logical container that stores the backup data for each protected resource, such as Azure VMs. When the backup job for a protected resource runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

To enable VM backup, in **Backup**, select **Enable backup**. This deploys the policy to the vault and to the VMs, and installs the backup extension on the VM agent running on the Azure VM.

After enabling backup:

- The Backup service installs the backup extension whether or not the VM is running.
- An initial backup will run in accordance with your backup schedule.
- When backups run, note that:
  - A VM that's running has the greatest chance for capturing an application-consistent recovery point.
  - However, even if the VM is turned off, it's backed up. Such a VM is known as an offline VM. In this case, the recovery point will be crash-consistent.
- Explicit outbound connectivity isn't required to allow backup of Azure VMs.

### Create a custom policy

If you selected to create a new backup policy, fill in the policy settings.

1. In **Policy name**, specify a meaningful name.
2. In **Backup schedule**, specify when backups should be taken. You can take daily or weekly backups for Azure VMs.

3. In **Instant Restore**, specify how long you want to retain snapshots locally for instant restore.
  - When you restore, backed up VM disks are copied from storage, across the network to the recovery storage location. With instant restore, you can leverage locally stored snapshots taken during a backup job, without waiting for backup data to be transferred to the vault.
  - You can retain snapshots for instant restore for between one to five days. The default value is two days.
4. In **Retention range**, specify how long you want to keep your daily or weekly backup points.
5. In **Retention of monthly backup point** and **Retention of yearly backup point**, specify whether you want to keep a monthly or yearly backup of your daily or weekly backups.
6. Select **OK** to save the policy.

**NOTE**

To store the restore point collection (RPC), the Backup service creates a separate resource group (RG). This RG is different than RG of the VM. [Learn more](#).

Azure Backup service creates a separate resource group to store the instant recovery points of managed virtual machines. The default naming format of resource group created by Azure Backup service is AzureBackupRG\_{Geo}\_{n}. It is optional to customize the name as per your requirement. [Learn More](#)

Azure Backup Resource Group (Optional) ⓘ

Enter the name

n

Suffix (Optional)

OK

### NOTE

Azure Backup doesn't support automatic clock adjustment for daylight-saving changes for Azure VM backups. As time changes occur, modify backup policies manually as required.

Start a backup job

The initial backup will run in accordance with the schedule, but you can run it immediately as follows:

1. Go to **Backup center** and select the **Backup Instances** menu item.
2. Select **Azure Virtual machines** as the **Datasource type**. Then search for the VM that you have configured for backup.
3. Right-click the relevant row or select the more icon (...), and then click **Backup Now**.
4. In **Backup Now**, use the calendar control to select the last day that the recovery point should be retained. Then select **OK**.
5. Monitor the portal notifications. To monitor the job progress, go to **Backup center > Backup Jobs** and filter the list for **In progress** jobs. Depending on the size of your VM, creating the initial backup may take a while.

## Monitor the backup job

The Backup job details for each VM backup consist of two phases, the **Snapshot** phase followed by the **Transfer data to vault** phase.

The snapshot phase guarantees the availability of a recovery point stored along with the disks for **Instant Restores** and are available for a maximum of five days depending on the snapshot retention configured by the user. Transfer data to vault creates a recovery point in the vault for long-term retention. Transfer data to vault only starts after the snapshot phase is completed.

Backup instance	Datasource subs...	Datasource reso...	Datasource locat...	Operation	Status	Vault	Start time	Duration	...
CH1-JBOXVM00	Contoso Hotels Tena...	CH1-OpsRG-Pri	East US	Scheduled Backup	Completed	CH1-RV-Pri	3/8/2021, 7:24:04 AM	02:21:14	...

CH1-AppBEVM00	Contoso Hotels Tena...	CH1-RetailRG-Pri	East US	Scheduled Backup	Completed	CH1-RV-Pri	3/8/2021, 7:17:36 AM	02:26:17	...
CH1-SQLVM00	Contoso Hotels Tena...	CH1-RetailRG-Pri	East US	Scheduled Backup	Completed	CH1-RV-Pri	3/8/2021, 7:15:45 AM	02:51:18	...
CH1-DCVM00	Contoso Hotels Tena...	CH1-InfraRG-Pri	East US	Scheduled Backup	Completed	CH1-RV-Pri	3/8/2021, 7:15:23 AM	02:51:14	...
CH1-JBOXVM10	Contoso Hotels Tena...	CH1-OpsRG-Sec	West US 2	Scheduled Backup	Completed	CH1-RV-Sec	3/8/2021, 7:07:28 AM	02:21:12	...
CH1-SQLVM12	Contoso Hotels Tena...	CH1-RetailRG-Sec	West US 2	Scheduled Backup	Completed	CH1-RV-Sec	3/8/2021, 7:07:00 AM	02:31:17	...
CH1-DCVM11	Contoso Hotels Tena...	CH1-InfraRG-Sec	West US 2	Scheduled Backup	Completed	CH1-RV-Sec	3/8/2021, 7:04:54 AM	02:21:13	...
CH1-DCVM10	Contoso Hotels Tena...	CH1-InfraRG-Sec	West US 2	Scheduled Backup	Completed	CH1-RV-Sec	3/8/2021, 7:01:17 AM	02:21:14	...

There are two **Sub Tasks** running at the backend, one for front-end backup job that can be checked from the **Backup Job** details pane as given below:

Name	Status
Take Snapshot	Completed
Transfer data to vault	Completed

The **Transfer data to vault** phase can take multiple days to complete depending on the size of the disks, churn

per disk and several other factors.

Job status can vary depending on the following scenarios:

SNAPSHOT	TRANSFER DATA TO VAULT	JOB STATUS
Completed	In progress	In progress
Completed	Skipped	Completed
Completed	Completed	Completed
Completed	Failed	Completed with warning
Failed	Failed	Failed

Now with this capability, for the same VM, two backups can run in parallel, but in either phase (snapshot, transfer data to vault) only one sub task can be running. So in scenarios where a backup job in progress resulted in the next day's backup to fail, it will be avoided with this decoupling functionality. Subsequent days' backups can have the snapshot completed, while **Transfer data to vault** is skipped if an earlier day's backup job is in progress state. The incremental recovery point created in the vault will capture all the churn from the most recent recovery point created in the vault. There's no cost impact on the user.

## Optional steps

### Install the VM agent

Azure Backup backs up Azure VMs by installing an extension to the Azure VM agent running on the machine. If your VM was created from an Azure Marketplace image, the agent is installed and running. If you create a custom VM, or you migrate an on-premises machine, you might need to install the agent manually, as summarized in the table.

VM	DETAILS
Windows	<ol style="list-style-type: none"><li>1. <a href="#">Download and install</a> the agent MSI file.</li><li>2. Install with admin permissions on the machine.</li><li>3. Verify the installation. In <i>C:\WindowsAzure\Packages</i> on the VM, right-click <b>WaAppAgent.exe</b> &gt; <b>Properties</b>. On the <b>Details</b> tab, <b>Product Version</b> should be 2.6.1198.718 or higher.</li></ol> <p>If you're updating the agent, make sure that no backup operations are running, and <a href="#">reinstall the agent</a>.</p>
Linux	<p>Install by using an RPM or a DEB package from your distribution's package repository. This is the preferred method for installing and upgrading the Azure Linux agent. All the <a href="#">endorsed distribution providers</a> integrate the Azure Linux agent package into their images and repositories. The agent is available on <a href="#">GitHub</a>, but we don't recommend installing from there.</p> <p>If you're updating the agent, make sure no backup operations are running, and update the binaries.</p>

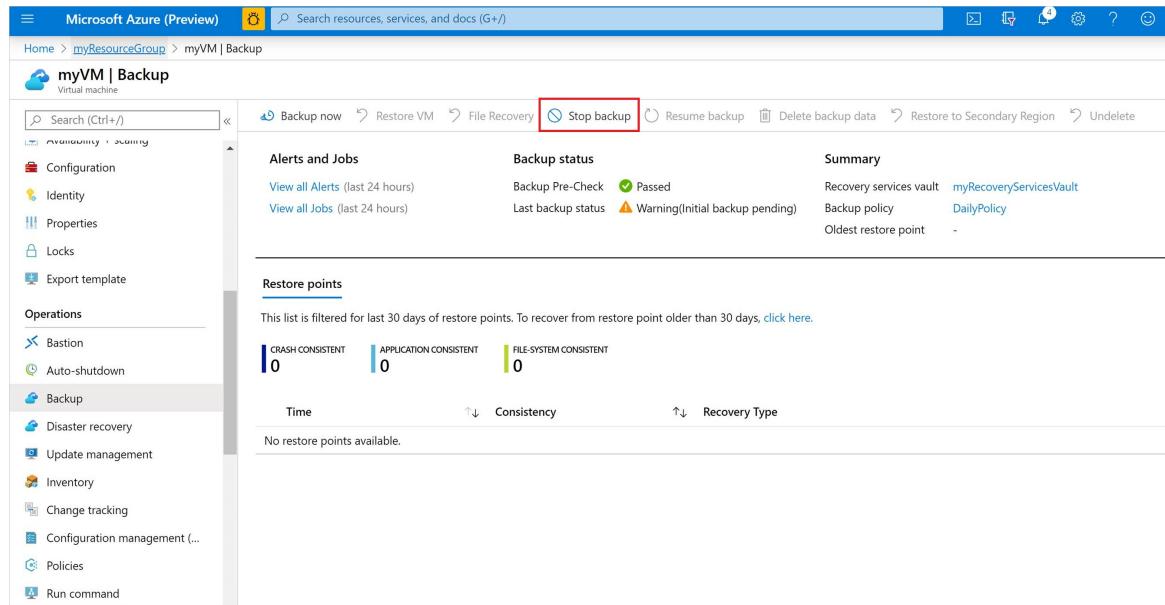

# Clean up deployment

When no longer needed, you can disable protection on the VM, remove the restore points and Recovery Services vault, then delete the resource group and associated VM resources

If you're going to continue on to a Backup tutorial that explains how to restore data for your VM, skip the steps in this section and go to [Next steps](#).

1. Select the **Backup** option for your VM.

2. Choose **Stop backup**.

The screenshot shows the Azure portal interface for a virtual machine named 'myVM'. On the left, there's a navigation menu with options like Configuration, Identity, Properties, Locks, Export template, Operations, Bastion, Auto-shutdown, Backup (which is selected), Disaster recovery, Update management, Inventory, Change tracking, Configuration management, Policies, and Run command. The main content area is titled 'myVM | Backup'. It has sections for 'Alerts and Jobs', 'Backup status' (showing a green 'Passed' status), 'Summary' (Recovery services vault: myRecoveryServicesVault, Backup policy: DailyPolicy), and 'Restore points' (which is currently empty). At the top right, there are several buttons: 'Backup now', 'Restore VM', 'File Recovery', 'Stop backup' (highlighted with a red box), 'Resume backup', 'Delete backup data', 'Restore to Secondary Region', and 'Undelete'.

3. Select **Delete Backup Data** from the drop-down menu.

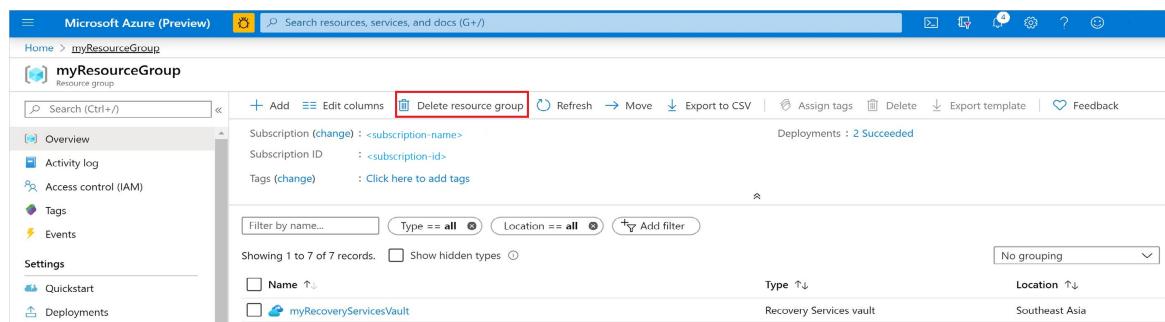

4. In the **Type the name of the Backup item** dialog, enter your VM name, such as *myVM*. Select **Stop Backup**.

Once the VM backup has been stopped and recovery points removed, you can delete the resource group. If you used an existing VM, you may wish to leave the resource group and VM in place.

5. In the menu on the left, select **Resource groups**.

6. From the list, choose your resource group. If you used the sample VM quickstart commands, the resource group is named *myResourceGroup*.

7. Select **Delete resource group**. To confirm, enter the resource group name, then select **Delete**.

The screenshot shows the Azure portal interface for a resource group named 'myResourceGroup'. On the left, there's a navigation menu with options like Overview, Activity log, Access control (IAM), Tags, Events, Settings, Quickstart, and Deployments. The main content area shows details for the resource group, including Subscription (change), Subscription ID, and Tags (change). It also lists deployments (2 Succeeded). Below this is a table showing resource group details: Name (myResourceGroup), Type (Recovery Services vault), Location (Southeast Asia). At the top right, there are buttons for '+ Add', 'Edit columns', 'Delete resource group' (highlighted with a red box), Refresh, Move, Export to CSV, Assign tags, Delete, Export template, and Feedback.

## Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point. To learn more about Azure Backup and Recovery Services, continue to the tutorials.

[Back up multiple Azure VMs](#)

# Back up a virtual machine in Azure with an ARM template

9/21/2022 • 5 minutes to read • [Edit Online](#)

Azure Backup backs up on-premises machines and apps, and Azure VMs. This article shows you how to back up an Azure VM with an Azure Resource Manager template (ARM template) and Azure PowerShell. This quickstart focuses on the process of deploying an ARM template to create a Recovery Services vault. For more information on developing ARM templates, see the [Azure Resource Manager documentation](#) and the [template reference](#).

An [ARM template](#) is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

A [Recovery Services vault](#) is a logical container that stores backup data for protected resources, such as Azure VMs. When a backup job runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time. Alternatively, you can back up a VM using [Azure PowerShell](#), the [Azure CLI](#), or in the [Azure portal](#).

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

## Review the template

The template used in this quickstart is from [Azure quickstart Templates](#). This template allows you to deploy simple Windows VM and Recovery Services vault configured with the *DefaultPolicy* for *Protection*.

```

The resources defined in the template are:

- [Microsoft.Storage/storageAccounts](#)
- [Microsoft.Network/publicIPAddresses](#)
- [Microsoft.Network/networkSecurityGroups](#)
- [Microsoft.Network/virtualNetworks](#)
- [Microsoft.Network/networkInterfaces](#)
- [Microsoft.Compute/virtualMachines](#)
- [Microsoft.RecoveryServices/vaults](#)
- [Microsoft.RecoveryServices/vaults/backupFabrics/protectionContainers/protectedItems](#)

## Deploy the template

To deploy the template, select **Try it** to open the Azure Cloud Shell, and then paste the following PowerShell script into the shell window. To paste the code, right-click the shell window and then select **Paste**.

```

$ projectName = Read-Host -Prompt "Enter a project name (limited to eight characters) that is used to generate Azure resource names"
$ location = Read-Host -Prompt "Enter the location (for example, centralus)"
$ adminUsername = Read-Host -Prompt "Enter the administrator username for the virtual machine"
$ adminPassword = Read-Host -Prompt "Enter the administrator password for the virtual machine" -AsSecureString
$ dnsPrefix = Read-Host -Prompt "Enter the unique DNS Name for the Public IP used to access the virtual machine"

$ resourceGroupName = "${projectName}rg"
$ templateUri = "https://raw.githubusercontent.com/Azure/azure-quickstart-templates/master/quickstarts/microsoft.recoveryservices/recovery-services-create-vm-and-configure-backup/azuredeploy.json"

New-AzResourceGroup -Name $resourceGroupName -Location $location
New-AzResourceGroupDeployment -ResourceGroupName $resourceGroupName -TemplateUri $templateUri - projectName $projectName -adminUsername $adminUsername -adminPassword $adminPassword -dnsLabelPrefix $dnsPrefix

```

Azure PowerShell is used to deploy the ARM template in this quickstart. The [Azure portal](#), [Azure CLI](#), and [REST API](#) can also be used to deploy templates.

## Validate the deployment

### Start a backup job

The template creates a VM and enables backup on the VM. After you deploy the template, you need to start a backup job. For more information, see [Start a backup job](#).

### Monitor the backup job

To monitor the backup job, see [Monitor the backup job](#).

## Clean up resources

If you no longer need to back up the VM, you can clean it up.

- If you want to try out restoring the VM, skip the cleanup.
- If you used an existing VM, you can skip the final `Remove-AzResourceGroup` cmdlet to leave the resource group and VM in place.

Disable protection, remove the restore points and vault. Then delete the resource group and associated VM resources, as follows:

```

Disable-AzRecoveryServicesBackupProtection -Item $item -RemoveRecoveryPoints
$vault = Get-AzRecoveryServicesVault -Name "myRecoveryServicesVault"
Remove-AzRecoveryServicesVault -Vault $vault
Remove-AzResourceGroup -Name "myResourceGroup"

```

## Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point.

- [Learn how](#) to back up VMs in the Azure portal.
- [Learn how](#) to quickly restore a VM
- [Learn how](#) to create ARM templates.

# Use Azure portal to back up multiple virtual machines

9/21/2022 • 7 minutes to read • [Edit Online](#)

When you back up data in Azure, you store that data in an Azure resource called a Recovery Services vault. The Recovery Services vault resource is available from the Settings menu of most Azure services. The benefit of having the Recovery Services vault integrated into the Settings menu of most Azure services is the ease of backing up data. However, working individually with each database or virtual machine in your business is tedious. What if you want to back up the data for all virtual machines in one department, or in one location? It's easy to back up multiple virtual machines by creating a backup policy and applying that policy to the desired virtual machines. This tutorial explains how to:

- Create a Recovery Services vault
- Define a backup policy
- Apply the backup policy to protect multiple virtual machines
- Trigger an on-demand backup job for the protected virtual machines

## Sign in to the Azure portal

Sign in to the [Azure portal](#).

### NOTE

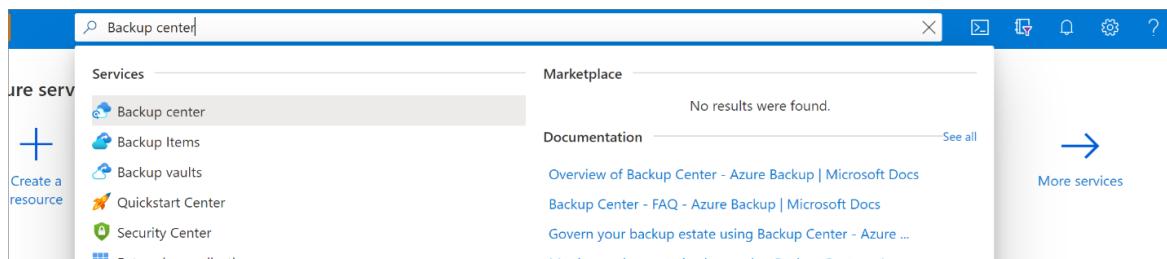

The functionality described in the following sections can also be accessed via [Backup center](#). Backup center is a single unified management experience in Azure. It enables enterprises to govern, monitor, operate, and analyze backups at scale. With this solution, you can perform most of the key backup management operations without being limited to the scope of an individual vault.

## Create a Recovery Services vault

A Recovery Services vault is a management entity that stores recovery points created over time and provides an interface to perform backup-related operations. These operations include taking on-demand backups, performing restores, and creating backup policies.

To create a Recovery Services vault:

1. Sign in to your subscription in the [Azure portal](#).
2. Search for **Backup center** in the Azure portal, and go to the **Backup Center** dashboard.

3. Select **+Vault** from the **Overview** tab.

**Backup center** Microsoft

Search (Ctrl+ /) <> + Backup ⌂ Restore + Policy + Vault ⌂ Refresh

Datasource subscription == **66 selected** Datasource resource group == All Datasource location == All Datasource type == Azure Virtual machines

**Datasource type: Azure Virtual machines**

Overview of Jobs and Backup instances

Jobs (last 24 Hours)				<a href="#">View all</a>
Operation	Failed	In progress	Completed	
Scheduled backup	64	8	246	
On-demand backup	0	0	12	
Restore	1	0	57	

Backup instances			
Azure Virtual machines			
<b>359</b>	Protection configured	<b>338</b>	
	Protection stopped	<b>16</b>	
	Soft deleted	<b>5</b>	
<b>86</b> out of 359	Backup instances with the underlying datasource not found		

#### 4. Select Recovery Services vault > Continue.

Home > Backup center > Start: Create Vault ...

A vault is an entity that stores the backups and restore points created over time. The vault also contains the backup policies that are associated with the protected virtual machines. Proceed to vault creation by selecting vault type.

Vault Type

Recovery Services vault

Supported datasources

- ✓ Azure Virtual machines
- ✓ SQL in Azure VM
- ✓ Azure Files (Azure Storage)
- ✓ SAP HANA in Azure VM
- ✓ Azure Backup Server
- ✓ Azure Backup Agent
- ✓ DPM

Backup vault

Supported datasources

- ✓ Azure Database for PostgreSQL servers (Preview)
- ✓ Azure Blobs (Azure Storage)
- ✓ Azure Disks

Learn more about Backup vault. [Click here](#).

Learn more about Recovery Services vault. [Click here](#).

[Continue](#) [Cancel](#)

#### 5. The Recovery Services vault dialog opens. Provide the following values:

- Subscription:** Choose the subscription to use. If you're a member of only one subscription, you'll see that name. If you're not sure which subscription to use, use the default (suggested) subscription. There are multiple choices only if your work or school account is associated with more than one Azure subscription.
- Resource group:** Use an existing resource group or create a new one. To see the list of available resource groups in your subscription, select **Use existing**, and then select a resource from the dropdown list. To create a new resource group, select **Create new** and enter the name. For more information about resource groups, see [Azure Resource Manager overview](#).
- Vault name:** Enter a friendly name to identify the vault. The name must be unique to the Azure

subscription. Specify a name that has at least 2 but not more than 50 characters. The name must start with a letter and consist only of letters, numbers, and hyphens.

- **Region:** Select the geographic region for the vault. For you to create a vault to help protect any data source, the vault *must* be in the same region as the data source.

#### IMPORTANT

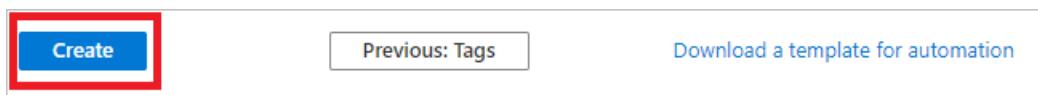

If you're not sure of the location of your data source, close the dialog. Go to the list of your resources in the portal. If you have data sources in multiple regions, create a Recovery Services vault for each region. Create the vault in the first location before you create the vault for another location. There's no need to specify storage accounts to store the backup data. The Recovery Services vault and Azure Backup handle that automatically.

The screenshot shows the 'Create Recovery Services vault' wizard in the 'Basics' step. It includes fields for 'Subscription' (dropdown), 'Resource group' (dropdown with 'Create new' option), 'Vault name' (text input placeholder 'Enter the name for your vault.'), and 'Region' (dropdown set to 'East US'). Navigation buttons at the bottom are 'Review + create' (highlighted in red) and 'Next: Tags'.

6. After you provide the values, select **Review + create**.

7. When you're ready to create the Recovery Services vault, select **Create**.

8. It can take a while to create the Recovery Services vault. Monitor the status notifications in the **Notifications** area at the upper-right corner of the portal. After your vault is created, it's visible in the list of Recovery Services vaults. If you don't see your vault, select **Refresh**.

The screenshot shows the 'Recovery Services vaults' list page. At the top right, there is a 'Refresh' button highlighted with a red box. Other buttons include '+ Add', 'Edit columns', 'Try preview', and 'Assign tags'. The Microsoft logo is also visible.

When you create a Recovery Services vault, by default the vault has geo-redundant storage. To provide data resiliency, geo-redundant storage replicates the data multiple times across two Azure regions.

## Set backup policy to protect VMs

After creating the Recovery Services vault, the next step is to configure the vault for the type of data, and to set the backup policy. Backup policy is the schedule for how often and when recovery points are taken. Policy also includes the retention range for the recovery points. For this tutorial, let's assume your business is a sports complex with a hotel, stadium, and restaurants and concessions, and you're protecting the data on the virtual machines. The following steps create a backup policy for the financial data.

To set a backup policy to your Azure VMs, follow these steps:

1. Go to **Backup center** and click **+ Backup** from the **Overview** tab.

The screenshot shows the Azure Backup center interface. The left sidebar contains navigation links like Overview, Getting started, Community, Manage (Backup instances, Backup policies, Vaults), Monitoring + reporting (Backup jobs, Backup reports), Policy and compliance (Backup compliance, Azure policies for backup, Protectable datasources), and Support + troubleshooting (New support request). The main area is titled 'Datasource type: Azure Virtual machines' and shows 'Overview of Jobs and Backup instances'. It includes a table for 'Jobs (last 24 Hours)' with columns for Operation (Scheduled backup, On-demand backup, Restore), Failed, In progress, and Completed counts. Below this is a 'Backup instances' section for 'Azure Virtual machines' with counts for Protection configured (359), Protection stopped (16), Soft deleted (5), and a note about 86 instances not found. A red box highlights the '+ Backup' button in the top navigation bar.

2. Select **Azure Virtual machines** as the **Datasource type** and select the vault you have created. Then click **Continue**.

The screenshot shows the 'Initiate: Configure Backup' step. It has three dropdown fields: 'Datasource type' set to 'Azure Virtual machines', 'Vault type' set to 'Recovery Services Vault', and 'Vault \*' with a placeholder 'Select a Vault' and a 'Select' button. A blue info box at the bottom states: 'Selected vault is maintained in **Recovery Services Vault**, you will be redirected to Recovery Services Vault for configuring backup. [Learn more](#)'.

3. Assign a Backup policy.

- The default policy backs up the VM once a day. The daily backups are retained for 30 days. Instant recovery snapshots are retained for two days.

Home > Backup center > Start: Configure Backup >

## Configure Backup

VaultWithTag

Backup policy \* ⓘ DefaultPolicy  Create a new policy

**Policy Details**

Full Backup      **Backup Frequency**  
Daily at 6:00 PM UTC

Instant Restore  
Retain instant recovery snapshot(s) for 2 day(s)

Retention of daily backup point  
Retain backup taken every day at 6:00 PM for 30 Day(s)

**Virtual machines**

Name	Resource Group	OS Disk Only
No Virtual machines selected.		

Add

**OS Disk only backup** option allows you to backup Azure Virtual Machine with only OS disk and exclude all the data disks. You can use Selective Disk Backup feature through Powershell or CLI to include or exclude specific data disks. Know more about Selective Disk Backup feature, its limitation and pricing- [Learn more](#).

- If you don't want to use the default policy, select **Create New**, and create a custom policy as described in the next procedure.

4. Under **Virtual Machines**, select Add.

### Virtual Machines

Virtual machine name	Resource Group
No Virtual Machines Selected	

Add

5. The **Select virtual machines** pane will open. Select the VMs you want to back up using the policy. Then select **OK**.

- The selected VMs are validated.
- You can only select VMs in the same region as the vault.
- VMs can only be backed up in a single vault.

## Select virtual machines

X

Virtual machine name	Resource Group
myVM	myResourceGroup
myVMH1	myResourceGroup
myVMR1	myResourceGroup

OK

### NOTE

All the VMs in the same region and subscription as that of the vault are available to configure backup. When configuring backup, you can browse to the virtual machine name and its resource group, even though you don't have the required permission on those VMs. If your VM is in soft deleted state, then it won't be visible in this list. If you need to re-protect the VM, then you need to wait for the soft delete period to expire or undelete the VM from the soft deleted list. For more information, see [the soft delete for VMs article](#).

6. In **Backup**, select **Enable backup**. This deploys the policy to the vault and to the VMs, and installs the backup extension on the VM agent running on the Azure VM.

After enabling backup:

- The Backup service installs the backup extension whether or not the VM is running.
- An initial backup will run in accordance with your backup schedule.
- When backups run, note that:
  - A VM that's running has the greatest chance for capturing an application-consistent recovery point.
  - However, even if the VM is turned off, it's backed up. Such a VM is known as an offline VM. In this case, the recovery point will be crash-consistent.
- Explicit outbound connectivity isn't required to allow backup of Azure VMs.

## Initial backup

You've enabled backup for the Recovery Services vaults, but an initial backup hasn't been created. It's a disaster recovery best practice to trigger the first backup, so that your data is protected.

The initial backup will run in accordance with the schedule, but you can run it immediately as follows:

1. Go to **Backup center** and select the **Backup Instances** menu item.
2. Select **Azure Virtual machines** as the **Datasource type**. Then search for the VM that you have configured for backup.
3. Right-click the relevant row or select the more icon (...), and then click **Backup Now**.
4. In **Backup Now**, use the calendar control to select the last day that the recovery point should be retained. Then select **OK**.

5. Monitor the portal notifications. To monitor the job progress, go to **Backup center > Backup Jobs** and filter the list for **In progress** jobs. Depending on the size of your VM, creating the initial backup may take a while.

## Clean up resources

If you plan to continue on to work with subsequent tutorials, don't clean up the resources created in this tutorial. If you don't plan to continue, use the following steps to delete all resources created by this tutorial in the Azure portal.

1. On the **myRecoveryServicesVault** dashboard, select **3** under **Backup Items** to open the **Backup Items** menu.

The screenshot shows the Microsoft Azure portal interface for the 'myRecoveryServicesVault' Recovery Services vault. The left sidebar contains navigation links for 'All resources', 'Overview', 'Activity log', 'Access control (IAM)', 'Tags', 'Diagnose and solve problems', 'Settings' (Identity, Private endpoint connections, Properties, Locks, Export template), 'Getting started' (Backup, Site Recovery), 'Protected items' (Backup items, Replicated items), 'Manage' (Backup policies, Backup Infrastructure, Site Recovery infrastructure), and 'Usage'. The main content area displays the vault's details: Resource group (myResourceGroup), Location (East US), Subscription (subscription-name, subscription-id). It includes tabs for 'Overview', 'Backup' (selected), and 'Site Recovery'. The 'Monitoring' section shows 'Backup Alerts (last 24 hours)' for Critical (0) and Warning (0) levels. The 'Usage' section shows 'Backup items' (3 highlighted with a red box) and 'Backup Storage' (Cloud - LRS: 0 B, Cloud - GRS: 0 B). A 'Backup Pre-Check Status (Azure VMs)' chart indicates 0 Critical and 0 Warning errors.

2. On the **Backup Items** menu, select **Azure Virtual Machine** to open the list of virtual machines associated with the vault.

The screenshot shows the 'myRecoveryServicesVault | Backup items' page. The left sidebar is identical to the previous dashboard. The main content area lists 'BACKUP MANAGEMENT TYPE' categories: 'Azure Virtual Machine' (selected and highlighted with a red box), 'SAP HANA in Azure VM', 'SQL in Azure VM', 'Azure Storage (Azure Files)', 'DPM', 'Azure Backup Server', and 'Azure Backup Agent'. To the right, a 'BACKUP ITEM COUNT' column shows values: 3 for Azure Virtual Machine, 0 for SAP HANA in Azure VM, 0 for SQL in Azure VM, 0 for Azure Storage (Azure Files), 0 for DPM, 0 for Azure Backup Server, and 0 for Azure Backup Agent.

The **Backup Items** list opens.

3. In the **Backup Items** menu, select the ellipsis to open the Context menu.

All services > myRecoveryServicesVault | Backup items >

## Backup Items (Azure Virtual Machine)

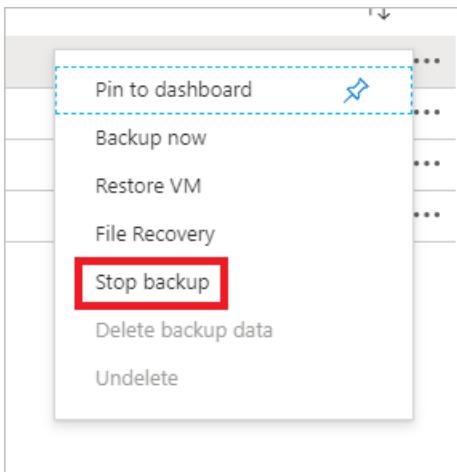

myRecoveryServicesVault

Refresh Add Filter

Fetching data from service completed.

Name	Resource Group	Backup Pre-Check	Last Backup Status	Latest restore point	...
myVM	myResourceGroup	Passed	Success	7/26/2020, 4:23:25 PM	

4. On the context menu, select **Stop backup** to open Stop Backup menu.

5. In the **Stop Backup** menu, select the upper drop-down menu and choose **Delete Backup Data**.
6. In the **Type the name of the Backup item** dialog, type *myVM*.
7. Once the backup item is verified (a check mark appears), **Stop backup** button is enabled. Select **Stop Backup** to stop the policy and delete the restore points.

### Stop Backup

myVM

Delete Backup Data

This option will stop all scheduled backup jobs and delete backup data. Learn more <https://aka.ms/SoftDeleteCloudWorkloads>

Type the name of Backup Item \*

Reason

Comments

Stop backup

## NOTE

Deleted items are retained in the soft delete state for 14 days. Only after that period can the vault be deleted. For more information, see [Delete an Azure Backup Recovery Services vault](#).

- When there are no more items in the vault, select **Delete**.

The screenshot shows the Azure Recovery Services vault overview page. On the left, a navigation menu includes options like Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, Properties, Locks, Automation script, Backup, Site Recovery, Backup Jobs, and Site Recovery Jobs. The main area displays monitoring and usage statistics. Under Monitoring, it shows 'Backup Alerts (last 24 hours)' with 0 Critical and 0 Warning alerts. Under Usage, it shows 'Backup items' (0) and 'Backup Storage' (Cloud - LRS: 0 B, Cloud - GRS: 0 B). A large circular gauge chart indicates 'Backup Pre-Check Status (Azure VMs)' with 0 Critical and 0 Warning issues.

Once the vault is deleted, you'll return to the list of Recovery Services vaults.

## Next steps

In this tutorial, you used the Azure portal to:

- Create a Recovery Services vault
- Set the vault to protect virtual machines
- Create a custom backup and retention policy
- Assign the policy to protect multiple virtual machines
- Trigger an on-demand back up for virtual machines

Continue to the next tutorial to restore an Azure virtual machine from disk.

[Restore VMs using CLI](#)

# How to restore Azure VM data in Azure portal

9/21/2022 • 21 minutes to read • [Edit Online](#)

This article describes how to restore Azure VM data from the recovery points stored in [Azure Backup Recovery Services vaults](#).

## Restore options

Azure Backup provides several ways to restore a VM.

RESTORE OPTION	DETAILS
<b>Create a new VM</b>	<p>Quickly creates and gets a basic VM up and running from a restore point.</p> <p>You can specify a name for the VM, select the resource group and virtual network (VNet) in which it will be placed, and specify a storage account for the restored VM. The new VM must be created in the same region as the source VM.</p> <p>If a VM restore fails because an Azure VM SKU wasn't available in the specified region of Azure, or because of any other issues, Azure Backup still restores the disks in the specified resource group.</p>
<b>Restore disk</b>	<p>Restores a VM disk, which can then be used to create a new VM.</p> <p>Azure Backup provides a template to help you customize and create a VM.</p> <p>The restore job generates a template that you can download and use to specify custom VM settings, and create a VM.</p> <p>The disks are copied to the Resource Group you specify.</p> <p>Alternatively, you can attach the disk to an existing VM, or create a new VM using PowerShell.</p> <p>This option is useful if you want to customize the VM, add configuration settings that weren't there at the time of backup, or add settings that must be configured using the template or PowerShell.</p>

RESTORE OPTION	DETAILS
<b>Replace existing</b>	<p>You can restore a disk, and use it to replace a disk on the existing VM.</p> <p>The current VM must exist. If it's been deleted, this option can't be used.</p> <p>Azure Backup takes a snapshot of the existing VM before replacing the disk, and stores it in the staging location you specify. Existing disks connected to the VM are replaced with the selected restore point.</p> <p>The snapshot is copied to the vault, and retained in accordance with the retention policy.</p> <p>After the replace disk operation, the original disk is retained in the resource group. You can choose to manually delete the original disks if they aren't needed.</p> <p>Replace existing is supported for unencrypted managed VMs, including VMs <a href="#">created using custom images</a>. It's unsupported for classic VMs, unmanaged VMs, and <a href="#">generalized VMs</a>.</p> <p>If the restore point has more or less disks than the current VM, then the number of disks in the restore point will only reflect the VM configuration.</p> <p>Replace existing is also supported for VMs with linked resources, like <a href="#">user-assigned managed-identity</a> or <a href="#">Key Vault</a>.</p>
<b>Cross Region (secondary region)</b>	<p>Cross Region restore can be used to restore Azure VMs in the secondary region, which is an <a href="#">Azure paired region</a>.</p> <p>You can restore all the Azure VMs for the selected recovery point if the backup is done in the secondary region.</p> <p>During the backup, snapshots aren't replicated to the secondary region. Only the data stored in the vault is replicated. So secondary region restores are only <a href="#">vault tier</a> restores. The restore time for the secondary region will be almost the same as the vault tier restore time for the primary region.</p> <p>This feature is available for the options below:</p> <ul style="list-style-type: none"> <li>- <a href="#">Create a VM</a></li> <li>- <a href="#">Restore Disks</a></li> </ul> <p>We don't currently support the <a href="#">Replace existing disks</a> option.</p> <p><b>Permissions</b> The restore operation on secondary region can be performed by Backup Admins and App admins.</p>

RESTORE OPTION	DETAILS
Cross Subscription Restore	<p>Allows you to restore Azure Virtual Machines or disks to any subscription (as per the Azure RBAC capabilities) from restore points.</p> <p>You can trigger Cross Subscription Restore for managed virtual machines only.</p> <p>Cross Subscription Restore is supported for <a href="#">Restore with Managed System Identities (MSI)</a>.</p> <p>It's unsupported from <a href="#">snapshots</a> and <a href="#">secondary region</a> restores.</p> <p>It's unsupported for <a href="#">Encrypted Azure VMs</a> and <a href="#">Trusted Launch VMs</a>.</p>

#### TIP

To receive alerts/notifications when a restore operation fails, use [Azure Monitor alerts for Azure Backup](#). This helps you to monitor such failures and take necessary actions to remediate the issues.

#### NOTE

You can also recover specific files and folders on an Azure VM. [Learn more](#).

## Storage accounts

Some details about storage accounts:

- **Create VM:** When you create a new VM, the VM will be placed in the storage account you specify.
- **Restore disk:** When you restore a disk, the disk is copied to the storage account you specify. The restore job generates a template that you can download and use to specify custom VM settings. This template is placed in the specified storage account.
- **Replace disk:** When you replace a disk in an existing VM, Azure Backup takes a snapshot of the existing VM before replacing the disk. The snapshot is also copied to the Recovery Services vault through data transfer, as a background process. However, once the snapshot phase is completed, the replace disks operation is triggered. After the replace disk operation, the disks of the source Azure VM are left in the specified Resource group for your operation and the VHDs are stored in the specified storage account. You can choose to delete or retain these VHDs and disks.
- **Storage account location:** The storage account must be in the same region as the vault. Only these accounts are displayed. If there are no storage accounts in the location, you need to create one.
- **Storage type:** Blob storage isn't supported.
- **Storage redundancy:** Zone redundant storage (ZRS) isn't supported. The replication and redundancy information for the account is shown in parentheses after the account name.
- **Premium storage:**
  - When you restore non-premium VMs, premium storage accounts aren't supported.
  - When you restore managed VMs, premium storage accounts configured with network rules aren't supported.

## Before you start

To restore a VM (create a new VM), make sure you have the correct Azure role-based access control (Azure RBAC) permissions for the Restore VM operation.

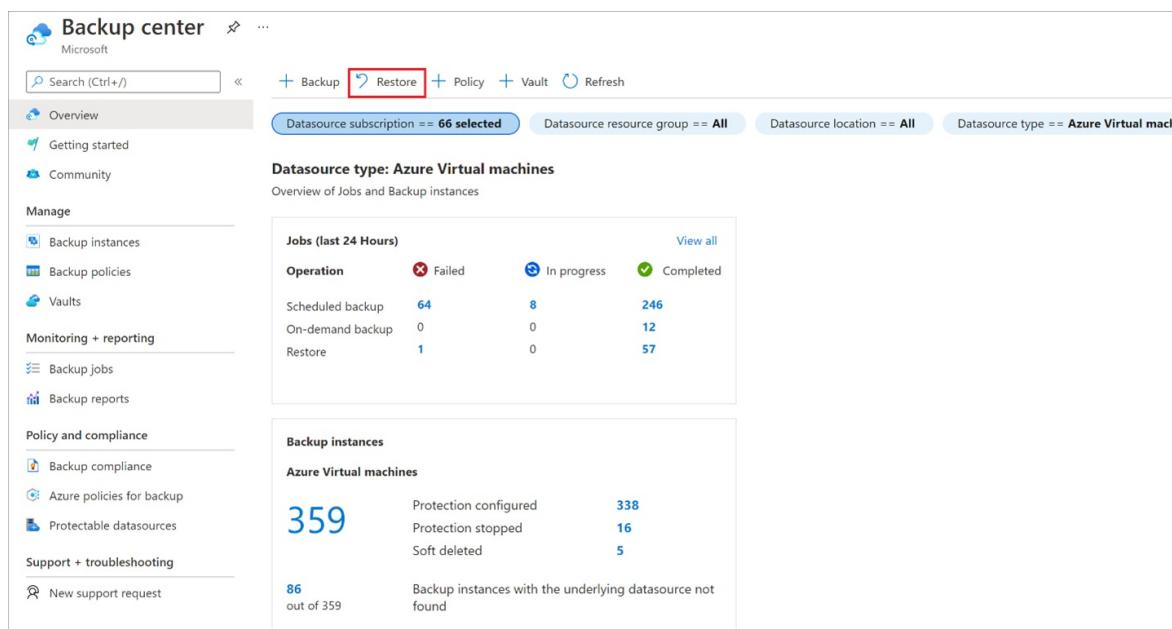

If you don't have permissions, you can [restore a disk](#), and then after the disk is restored, you can [use the template](#) that was generated as part of the restore operation to create a new VM.

#### NOTE

The functionality described in the following sections can also be accessed via [Backup center](#). Backup center is a single unified management experience in Azure. It enables enterprises to govern, monitor, operate, and analyze backups at scale. With this solution, you can perform most of the key backup management operations without being limited to the scope of an individual vault.

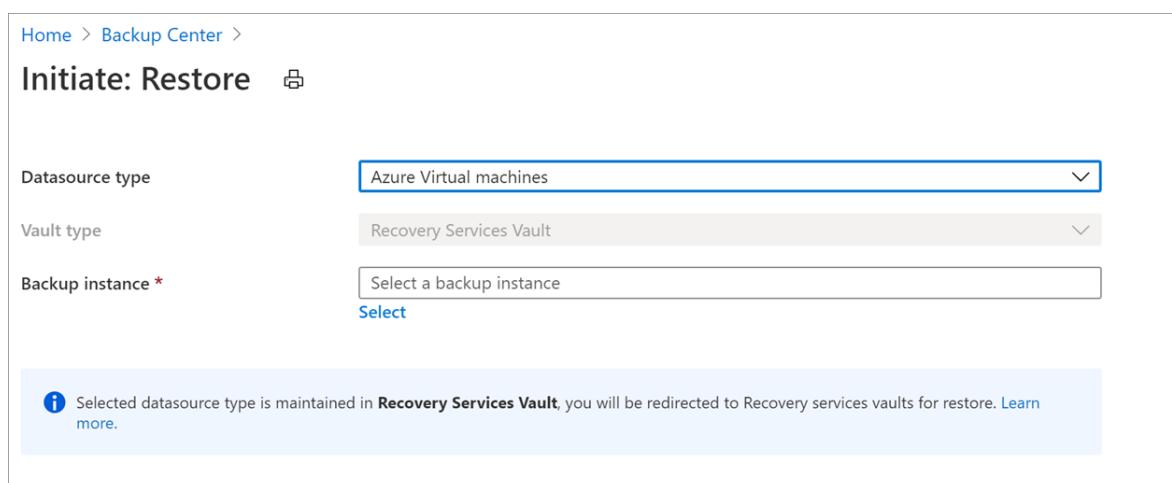

## Select a restore point

1. Navigate to **Backup center** in the Azure portal and click **Restore** from the **Overview** tab.

The screenshot shows the Azure Backup center interface. The left sidebar includes links for Overview, Getting started, Community, Manage (Backup instances, Backup policies, Vaults, Monitoring + reporting, Backup jobs, Backup reports), Policy and compliance (Backup compliance, Azure policies for backup, Protectable datasources), Support + troubleshooting, and New support request. The main area displays 'Jobs (last 24 Hours)' with a table showing Failed (64), In progress (8), and Completed (246) scheduled backups, and one restore job. Below this is a 'Backup instances' section for Azure Virtual machines, showing 359 total instances with 338 protected, 16 stopped, and 5 soft deleted. A note indicates 86 instances are not found. The top navigation bar has tabs for Backup, Restore (highlighted with a red box), Policy, Vault, and Refresh, along with filters for Datasource subscription (66 selected), Datasource resource group (All), Datasource location (All), and Datasource type (Azure Virtual machines).

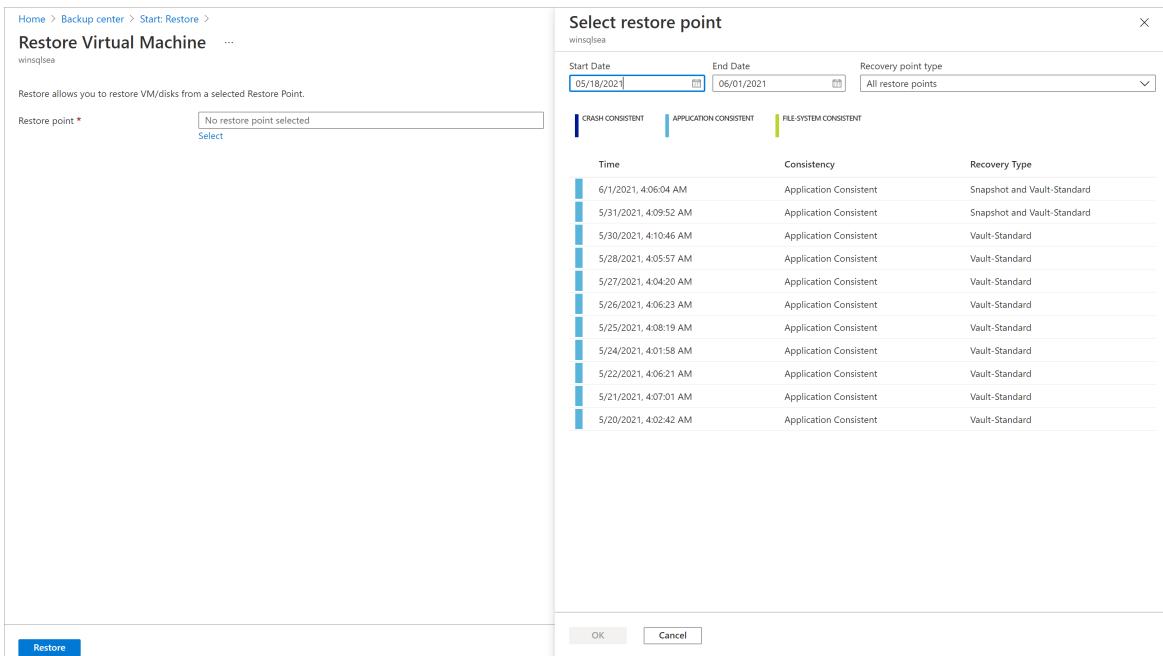

2. Select **Azure Virtual machines** as the **Datasource type**, and then select a **Backup instance**.

The screenshot shows the 'Initiate: Restore' step. It has fields for 'Datasource type' (set to 'Azure Virtual machines'), 'Vault type' (set to 'Recovery Services Vault'), and 'Backup instance \*' (with a dropdown menu open). A note at the bottom says: 'Selected datasource type is maintained in Recovery Services Vault, you will be redirected to Recovery services vaults for restore. [Learn more.](#)'

3. Select a VM and click **Continue**.

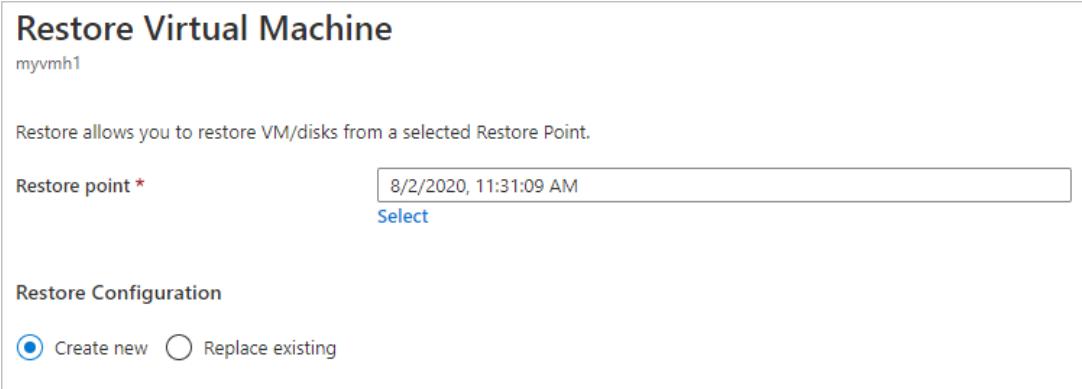

4. In the next screen that appears, select a restore point to use for the recovery.

## Choose a VM restore configuration

1. In **Restore Virtual Machine**, select a restore option:

- **Create new:** Use this option if you want to create a new VM. You can create a VM with simple settings, or restore a disk and create a customized VM.
- **Replace existing:** Use this option if you want to replace disks on an existing VM.

2. Specify settings for your selected restore option.

## Create a VM

As one of the [restore options](#), you can create a VM quickly with basic settings from a restore point.

1. In **Restore Virtual Machine > Create new > Restore Type**, select **Create new virtual machine**.
2. In **Virtual machine name**, specify a VM that doesn't exist in the subscription.
3. In **Resource group**, select an existing resource group for the new VM, or create a new one with a globally unique name. If you assign a name that already exists, Azure assigns the group the same name as the VM.
4. In **Virtual network**, select the VNet in which the VM will be placed. All VNets associated with the subscription in the same location as the vault, which is active and not attached with any affinity group, are displayed. Select the subnet.

The first subnet is selected by default.

5. In **Staging Location**, specify the storage account for the VM. [Learn more](#).

The screenshot shows the 'Restore Virtual Machine' page in the Azure portal. The URL is: Home > myRecoveryServicesVault | Backup items > Backup Items (Azure Virtual Machine) > myVMH1 > Restore Virtual Machine.

Section: myvmh1

Description: Restore allows you to restore VM/disks from a selected Restore Point.

Restore point \*: 8/2/2020, 11:31:09 AM (Select)

Restore Configuration:

Create new  Replace existing

**Info:** To create an alternate configuration when restoring your VM (from the following menus), use PowerShell cmdlets.

Restore Type \*: Create new virtual machine

Virtual machine name \*: vm1Restore

Resource group \*: myResourceGroup

Virtual network \*: Test-Resource-Group-vnet (myResourceGroup)

Subnet \*: default

Staging Location \*: testresourcegroupdiag856 (StandardLRS)

[Can't find your storage account ?](#)

**Restore**

6. Choose the required subscription from the **Subscription** drop-down list to restore an Azure VM to a different subscription.

Azure Backup now supports Cross Subscription Restore (CSR), you can now restore an Azure VM using a recovery point from default subscription to another. Default subscription is the subscription where recovery point is available.

The following screenshot lists all subscriptions under the tenant where you've permissions, which enable you to restore the Azure VM to another subscription.

# Restore Virtual Machine

demorestoredvm1

Restore allows you to restore VM/disks from a backup.

**Restore point \***

Identities ⓘ

Disabled

**Restore**

4. Choose the required subscription from the **Subscription** drop-down list to restore the VM disks to a different subscription.

Azure Backup now supports Cross Subscription Restore (CSR). Like Azure VM, you can now restore Azure VM disks using a recovery point from default subscription to another. Default subscription is the subscription where recovery point is available.

5. Select **Restore** to trigger the restore operation.

When your virtual machine uses managed disks and you select the **Create virtual machine** option, Azure Backup doesn't use the specified storage account. In the case of **Restore disks** and **Instant Restore**, the storage account is used only for storing the template. Managed disks are created in the specified resource group. When your virtual machine uses unmanaged disks, they're restored as blobs to the storage account.

While you restore disks for a Managed VM from a Vault-Standard recovery point, it restores the Managed disk and Azure Resource Manager (ARM) templates, along with the VHD files of the disks in staging location. If you restore disks from an Instant recovery point, it restores the Managed disks and ARM templates only.

#### NOTE

- For restoring disk from a Vault-Standard recovery point that is/was greater than 4 TB, Azure Backup doesn't restore the VHD files.
- For information on managed/premium disk performance after restored via Azure Backup, see the [Latency](#) section.

## Use templates to customize a restored VM

After the disk is restored, use the template that was generated as part of the restore operation to customize and create a new VM:

1. In **Backup Jobs**, select the relevant restore job.
2. In **Restore**, select **Deploy Template** to initiate template deployment.

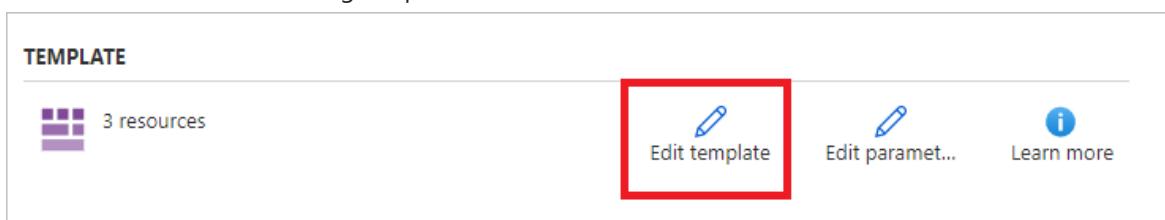

The screenshot shows the 'Restore' blade for a job named 'myvmh1'. The 'Deploy Template' button is highlighted with a red box. Below it, the 'Job Details' table lists various parameters such as Job Type (Recover disks), Target Storage Account Name (testresourcegroupdiag856), Recovery point time (8/2/2020 8:31:09 AM), and Config Blob Uri (https://testresourcegroupdiag856.blob.core.windows.net/myvhm1-ec54d603d8154087a6112a4d26273024/config-myvhm1-044cc161-656d-4618-b741-38fb712d2ec0.json).

#### NOTE

For a shared access signature (SAS) that has **Allow storage account key access** set to disabled, the template won't deploy when you select **Deploy Template**.

3. To customize the VM setting provided in the template, select **Edit template**. If you want to add more customizations, select **Edit parameters**.
  - [Learn more](#) about deploying resources from a custom template.
  - [Learn more](#) about authoring templates.

The screenshot shows the 'TEMPLATE' blade with a '3 resources' count and three buttons: 'Edit template' (highlighted with a red box), 'Edit paramet...', and 'Learn more'.

4. Enter the custom values for the VM, accept the **Terms and Conditions** and select **Purchase**.

## Cross Region Restore

As one of the [restore options](#), Cross Region Restore (CRR) allows you to restore Azure VMs in a secondary region, which is an Azure paired region.

To begin using the feature, read the [Before You Begin](#) section.

To see if CRR is enabled, follow the instructions in [Configure Cross Region Restore](#).

### View backup items in secondary region

If CRR is enabled, you can view the backup items in the secondary region.

1. From the portal, go to **Recovery Services vault > Backup items**.
2. Select **Secondary Region** to view the items in the secondary region.

#### NOTE

Only Backup Management Types supporting the CRR feature will be shown in the list. Currently, only support for restoring secondary region data to a secondary region is allowed.

CRR for Azure VMs is supported for Azure Managed VMs (including encrypted Azure VMs). See the [management types that support Cross Region Restore](#).

**CRRIgniteDemoVault - Backup items**

## Restore in secondary region

The secondary region restore user experience will be similar to the primary region restore user experience. When configuring details in the Restore Configuration pane to configure your restore, you'll be prompted to provide only secondary region parameters.

Currently, secondary region **RPO** is *36 hours*. This is because the RPO in the primary region is *24 hours* and can take up to *12 hours* to replicate the backup data from the primary to the secondary region.

Home > Backup center >

<b>Restore</b>													

- To restore and create a VM, refer to [Create a VM](#).
- To restore as a disk, refer to [Restore disks](#).

**NOTE**

- You can cancel the restore job till the data transfer phase. Once it enters VM creation phase, you can't cancel the restore job.
- The Cross Region Restore feature restores CMK (customer-managed keys) enabled Azure VMs, which aren't backed-up in a CMK enabled Recovery Services vault, as non-CMK enabled VMs in the secondary region.
- The Azure roles needed to restore in the secondary region are the same as those in the primary region.
- While restoring an Azure VM, Azure Backup configures the virtual network settings in the secondary region automatically. If you are [restoring disks](#) while deploying the template, ensure to provide the virtual network settings, corresponding to the secondary region.
- If VNet/Subnet is not available in the primary region or is not configured in the secondary region, Azure portal doesn't auto-populate any default values during restore operation.
- For Cross Region Restores, the **Staging Location** (that is the storage account location) must be in the region that the Recovery Services vault treats as the *secondary* region. For example, a Recovery Services vault is located in East US 2 region (with Geo-Redundancy and Cross Region Restore enabled). This means that the *secondary* region would be *Central US*. Therefore, you need to create a storage account in *Central US* to perform a Cross Region Restore of the VM.

Learn more about [Azure cross-region replication pairings for all geographies](#).

Azure zone pinned VMs can be restored in any availability zones of the same region.

In the restore process, you'll see the option **Availability Zone**. You'll see your default zone first. To choose a different zone, choose the number of the zone of your choice. If the pinned zone is unavailable, you won't be able to restore the data to another zone because the backed-up data isn't zonally replicated. The restore in

availability zones is possible from recovery points in vault tier only.

In summary, the **Availability Zone** will only appear when

- The source VM is zone pinned and is NOT encrypted
- The recovery point is present in vault tier only (Snapshots only or snapshot and vault tier are not supported)
- The recovery option is to either create a new VM or to restore disks (replace disks option replaces source data and hence the availability zone option is not applicable)
- Creating VM/disks in the same region when vault's storage redundancy is ZRS (Doesn't work when vault's storage redundancy is GRS even though the source VM is zone pinned)
- Creating VM/disks in the paired region when vault's storage redundancy is enabled for Cross-Region-Restore AND if the paired region supports zones

## Restoring unmanaged VMs and disks as managed

You're provided with an option to restore **unmanaged disks** as **managed disks** during restore. By default, the unmanaged VMs / disks are restored as unmanaged VMs / disks. However, if you choose to restore as managed VMs / disks, it's now possible to do so. These restore operations aren't triggered from the snapshot phase but only from the vault phase. This feature isn't available for unmanaged encrypted VMs.

### Restore Virtual Machine

## Restore VMs with special configurations

There are many common scenarios in which you might need to restore VMs.

SCENARIO	GUIDANCE
<b>Restore VMs using Hybrid Use Benefit</b>	If a Windows VM uses <a href="#">Hybrid Use Benefit (HUB) licensing</a> , restore the disks, and create a new VM using the provided template (with <b>License Type</b> set to <b>Windows_Server</b> ), or PowerShell. This setting can also be applied after creating the VM.
<b>Restore VMs during an Azure datacenter disaster</b>	<p>If the vault uses GRS and the primary datacenter for the VM goes down, Azure Backup supports restoring backed-up VMs to the paired datacenter. You select a storage account in the paired datacenter, and restore as normal. Azure Backup uses the compute service in the paired region to create the restored VM. <a href="#">Learn more</a> about datacenter resiliency.</p> <p>If the vault uses GRS, you can choose the new feature, <a href="#">Cross Region Restore</a>. This lets you restore to a second region in either full or partial outage scenarios, or even if there's no outage at all.</p>
<b>Bare-metal restore</b>	The major difference between Azure VMs and on-premises hypervisors is that there's no VM console available in Azure. A console is required for certain scenarios, such as recovering by using a bare-metal recovery (BMR)-type backup. However, VM restore from the vault is a full replacement for BMR.
<b>Restore VMs with special network configurations</b>	Special network configurations include VMs using internal or external load balancing, using multiple NICs, or multiple reserved IP addresses. You restore these VMs by using the <a href="#">restore disk option</a> . This option makes a copy of the VHDs into the specified storage account, and you can then create a VM with an <a href="#">internal</a> or <a href="#">external</a> load balancer, <a href="#">multiple NICs</a> , or <a href="#">multiple reserved IP addresses</a> , in accordance with your configuration.
<b>Network Security Group (NSG) on NIC/Subnet</b>	Azure VM backup supports Backup and Restore of NSG information at vnet, subnet, and NIC level.
<b>Zone Pinned VMs</b>	If you back up an Azure VM that's pinned to a zone (with Azure Backup), then you can restore it in the same zone where it was pinned. <a href="#">Learn more</a>
<b>Restore VM in any availability set</b>	When you restore a VM from the portal, there's no option to choose an availability set. A restored VM doesn't have an availability set. If you use the restore disk option, then you can <a href="#">specify an availability set</a> when you create a VM from the disk using the provided template or PowerShell.
<b>Restore special VMs such as SQL VMs</b>	If you're backing up a SQL VM using Azure VM backup and then use the restore VM option or create a VM after restoring disks, then the newly created VM must be registered with the SQL provider as mentioned <a href="#">here</a> . This will convert the restored VM into a SQL VM.

## Restore domain controller VMs

SCENARIO	GUIDANCE
Restore a single domain controller VM in a single domain	<p>Restore the VM like any other VM. Note that:</p> <p>From an Active Directory perspective, the Azure VM is like any other VM.</p> <p>Directory Services Restore Mode (DSRM) is also available, so all Active Directory recovery scenarios are viable. <a href="#">Learn more</a> about backup and restore considerations for virtualized domain controllers.</p>
Restore multiple domain controller VMs in a single domain	If other domain controllers in the same domain can be reached over the network, the domain controller can be restored like any VM. If it's the last remaining domain controller in the domain, or a recovery in an isolated network is performed, use a <a href="#">forest recovery</a> .
Restore a single domain controller VM in a multiple domain configuration	Restore the disks and create a VM by <a href="#">using PowerShell</a>
Restore multiple domains in one forest	We recommend a <a href="#">forest recovery</a> .

For more information, see [Back up and restore Active Directory domain controllers](#).

## Restore VMs with managed identities

Managed identities eliminate the need for the user to maintain the credentials. Managed identities provide an identity for applications to use when connecting to resources that support Azure Active Directory (Azure AD) authentication.

Azure Backup offers the flexibility to restore the managed Azure VM with [managed identities](#). You can choose to select [system-managed identities](#) or user-managed identities as shown in the figure below. This is introduced as one of the input parameters in the [Restore configuration blade](#) of Azure VM. Managed identities used as one of the input parameters is only used for accessing the storage accounts, which are used as staging location during restore and not for any other Azure resource controlling. These managed identities have to be associated to the vault.

## Restore Virtual Machine

Can't find your storage account?

The identities listed here are based on the MSI configurations in the corresponding Recovery services vault. Learn more.

Identities

**Restore**

If you choose to select system-assigned or user-assigned managed identities, check for the below actions for managed identity on the target staging Storage Account.

```
"permissions": [
    {
        "actions": [
            "Microsoft.Authorization/*/read",
            "Microsoft.Storage/storageAccounts/blobServices/containers/delete",
            "Microsoft.Storage/storageAccounts/blobServices/containers/read",
            "Microsoft.Storage/storageAccounts/blobServices/containers/write"
        ],
        "notActions": [],
        "dataActions": [
            "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/delete",
            "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/read",
            "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/write",
            "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/add/action"
        ],
        "notDataActions": []
    }
]
```

Or, add the role assignment on the staging location (Storage Account) to have [Storage account Backup Contributor](#) and [Storage Blob data Contributor](#) for the successful restore operation.

**Restore**

## NOTE

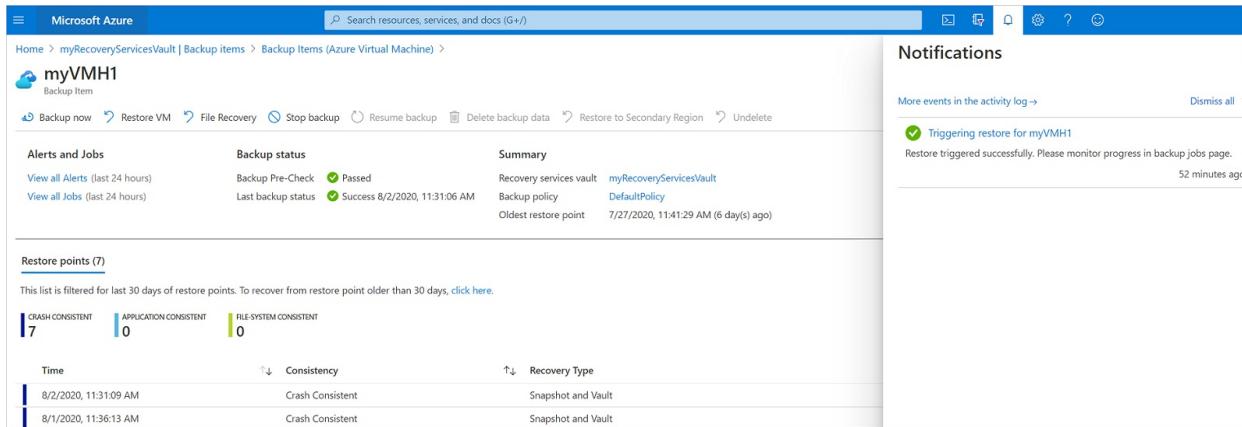

The support is available for only managed VMs, and not supported for classic VMs and unmanaged VMs. For the [storage accounts that are restricted with firewalls](#), system MSI is only supported.

Cross Region Restore isn't supported with managed identities.

Currently, this is available in all Azure public and national cloud regions.

# Track the restore operation

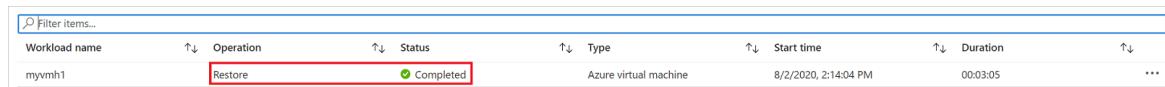

After you trigger the restore operation, the backup service creates a job for tracking. Azure Backup displays notifications about the job in the portal. If they aren't visible, select the **Notifications** symbol, and then select **More events in the activity log** to see the Restore Process Status.

The screenshot shows the Azure portal interface for a backup item named 'myVMH1'. In the top navigation bar, there's a search bar and several icons. Below the navigation, the breadcrumb path is 'Home > myRecoveryServicesVault | Backup items > Backup Items (Azure Virtual Machine) > myVMH1'. Under the 'myVMH1' heading, there are links for 'Backup now', 'Restore VM', 'File Recovery', 'Stop backup', 'Resume backup', 'Delete backup data', 'Restore to Secondary Region', and 'Undelete'. A 'Backup status' section shows 'Backup Pre-Check' as 'Passed' and 'Last backup status' as 'Success 8/2/2020, 11:31:06 AM'. A 'Summary' section indicates the 'Backup policy' is 'DefaultPolicy' and the 'Oldest restore point' is '7/27/2020, 11:41:29 AM (6 day(s) ago)'. Below this, a 'Restore points (7)' section lists two entries: '8/2/2020, 11:31:09 AM' (Crash Consistent, Snapshot and Vault) and '8/1/2020, 11:36:13 AM' (Crash Consistent, Snapshot and Vault). On the right side, the 'Notifications' pane is open, showing a single event: 'Triggering restore for myVMH1' with the message 'Restore triggered successfully. Please monitor progress in backup jobs page.' and a timestamp of '52 minutes ago'. There's also a 'Dismiss all' button.

Track restore as follows:

1. To view operations for the job, select the notifications hyperlink. Alternatively, in the vault, select **Backup jobs**, and then select the relevant VM.

The screenshot shows a table of backup jobs for the 'myvmh1' workload. The columns are: Workload name, Operation, Status, Type, Start time, Duration, and an ellipsis button. One row is highlighted with a red border, showing 'myvmh1' as the workload, 'Restore' as the operation, 'Completed' as the status, 'Azure virtual machine' as the type, '8/2/2020, 2:14:04 PM' as the start time, and '00:03:05' as the duration. The 'Status' column for this row contains a green checkmark icon.

2. To monitor restore progress, select any restore job with a status of **In-progress**. This displays the progress bar, which displays information about the restore progress:

- **Estimated time of restore:** Initially provides the time taken to complete the restore operation. As the operation progresses, the time taken reduces and reaches zero when the restore operation finishes.
- **Percentage of restore:** Shows the percentage of restore operation that's done.
- **Number of bytes transferred:** If you're restoring by creating a new VM, it shows the bytes that were transferred against the total number of bytes to be transferred.

## Post-restore steps

There are a few things to note after restoring a VM:

- Extensions present during the backup configuration are installed, but not enabled. If you see an issue, reinstall the extensions.
- If the backed-up VM had a static IP address, the restored VM will have a dynamic IP address to avoid conflict. You can [add a static IP address to the restored VM](#).
- A restored VM doesn't have an availability set. If you use the restore disk option, then you can [specify an availability set](#) when you create a VM from the disk using the provided template or PowerShell.
- If you use a cloud-init-based Linux distribution, such as Ubuntu, for security reasons the password is blocked after the restore. Use the VMAccess extension on the restored VM to [reset the password](#). We recommend using SSH keys on these distributions, so you don't need to reset the password after the restore.
- If you're unable to access a VM once restored because the VM has a broken relationship with the domain controller, then follow the steps below to bring up the VM:

- Attach OS disk as a data disk to a recovered VM.
- Manually install VM agent if Azure Agent is found to be unresponsive by following this [link](#).
- Enable Serial Console access on VM to allow command-line access to VM

```

bcdedit /store <drive letter>:\boot\bcd /enum
bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set {bootmgr} displaybootmenu yes
bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set {bootmgr} timeout 5
bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set {bootmgr} bootems yes
bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /ems {<<BOOT LOADER IDENTIFIER>>}
ON
bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /emssettings EMSPORT:1
EMSBAUDRATE:115200

```

- When the VM is rebuilt use Azure portal to reset local administrator account and password
- Use Serial console access and CMD to disjoin VM from domain

```

cmd /c "netdom remove <> /domain:<> /userD:<> /passwordD:<> /reboot:10 /Force"

```

- Once the VM is disjoined and restarted, you'll be able to successfully RDP to the VM with local admin credentials and rejoin VM back to domain successfully.

## Backing up restored VMs

- If you restored a VM to the same resource group with the same name as the originally backed-up VM, backup continues on the VM after restore.
- If you restored the VM to a different resource group or you specified a different name for the restored VM, you need to set up backup for the restored VM.

## Next steps

- If you experience difficulties during the restore process, [review](#) common issues and errors.
- After the VM is restored, learn about [managing virtual machines](#)

# Support matrix for Azure VM backup

9/21/2022 • 18 minutes to read • [Edit Online](#)

You can use the [Azure Backup service](#) to back up on-premises machines and workloads, and Azure virtual machines (VMs). This article summarizes support settings and limitations when you back up Azure VMs with Azure Backup.

Other support matrices:

- [General support matrix](#) for Azure Backup
- [Support matrix](#) for Azure Backup server / System Center Data Protection Manager (DPM) backup
- [Support matrix](#) for backup with the Microsoft Azure Recovery Services (MARS) agent

## Supported scenarios

Here's how you can back up and restore Azure VMs with the Azure Backup service.

SCENARIO	BACKUP	AGENT	RESTORE
Direct backup of Azure VMs	Back up the entire VM.	No additional agent is needed on the Azure VM. Azure Backup installs and uses an extension to the <a href="#">Azure VM agent</a> that's running on the VM.	<p>Restore as follows:</p> <ul style="list-style-type: none"><li>- <b>Create a basic VM.</b> This is useful if the VM has no special configuration such as multiple IP addresses.</li><li>- <b>Restore the VM disk.</b> Restore the disk. Then attach it to an existing VM, or create a new VM from the disk by using PowerShell.</li><li>- <b>Replace VM disk.</b> If a VM exists and it uses managed disks (unencrypted), you can restore a disk and use it to replace an existing disk on the VM.</li><li>- <b>Restore specific files/folders.</b> You can restore files/folders from a VM instead of from the entire VM.</li></ul>
Direct backup of Azure VMs (Windows only)	Back up specific files/folders/volume.	Install the <a href="#">Azure Recovery Services agent</a> .  You can run the MARS agent alongside the backup extension for the Azure VM agent to back up the VM at file/folder level.	Restore specific folders/files.

SCENARIO	BACKUP	AGENT	RESTORE
Back up Azure VM to the backup server	Back up files/folders/volumes; system state/bare metal files; app data to System Center DPM or to Microsoft Azure Backup Server (MABS).  DPM/MABS then backs up to the backup vault.	Install the DPM/MABS protection agent on the VM. The MARS agent is installed on DPM/MABS.	Restore files/folders/volumes; system state/bare metal files; app data.

Learn more about backup [using a backup server](#) and about [support requirements](#).

## Supported backup actions

ACTION	SUPPORT
Back up a VM that's shutdown/offline VM	Supported.  Snapshot is crash-consistent only, not app-consistent.
Back up disks after migrating to managed disks	Supported.  Backup will continue to work. No action is required.
Back up managed disks after enabling resource group lock	Not supported.  Azure Backup can't delete the older restore points, and backups will start to fail when the maximum limit of restore points is reached.
Modify backup policy for a VM	Supported.  The VM will be backed up by using the schedule and retention settings in new policy. If retention settings are extended, existing recovery points are marked and kept. If they're reduced, existing recovery points will be pruned in the next cleanup job and eventually deleted.
Cancel a backup job	Supported during snapshot process.  Not supported when the snapshot is being transferred to the vault.
Back up the VM to a different region or subscription	Not supported.  To successfully back up, virtual machines must be in the same subscription as the vault for backup.
Backups per day (via the Azure VM extension)	Four backups per day - one scheduled backup as per the Backup policy, and three on-demand backups.  However, to allow user retries in case of failed attempts, hard limit for on-demand backups is set to nine attempts.
Backups per day (via the MARS agent)	Three scheduled backups per day.

ACTION	SUPPORT
Backups per day (via DPM/MABS)	Two scheduled backups per day.
Monthly/yearly backup	<p>Not supported when backing up with Azure VM extension. Only daily and weekly is supported.</p> <p>You can set up the policy to retain daily/weekly backups for monthly/yearly retention period.</p>
Automatic clock adjustment	<p>Not supported.</p> <p>Azure Backup doesn't automatically adjust for daylight saving time changes when backing up a VM.</p> <p>Modify the policy manually as needed.</p>
<a href="#">Security features for hybrid backup</a>	Disabling security features isn't supported.
Back up the VM whose machine time is changed	<p>Not supported.</p> <p>If the machine time is changed to a future date-time after enabling backup for that VM, however even if the time change is reverted, successful backup isn't guaranteed.</p>
Multiple Backups Per Day	<p>Supported (in preview), using <i>Enhanced policy</i> (in preview).</p> <p>For hourly backup, the minimum RPO is 4 hours and the maximum is 24 hours. You can set the backup schedule to 4, 6, 8, 12, and 24 hours respectively. Learn about how to <a href="#">back up an Azure VM using Enhanced policy</a>.</p>
Back up a VM with deprecated plan when publisher has removed it from Azure Marketplace	<p>Not supported.</p> <p>Backup is possible. However, restore will fail.</p> <p>If you've already configured backup for VM with deprecated virtual machine offer and encounter restore error, see <a href="#">Troubleshoot backup errors with Azure VMs</a>.</p>

## Operating system support (Windows)

The following table summarizes the supported operating systems when backing up Azure VMs running Windows.

SCENARIO	OS SUPPORT

SCENARIO	OS SUPPORT
Back up with Azure VM agent extension	<ul style="list-style-type: none"> <li>- Windows 10 Client (64 bit only)</li> <li>- Windows Server 2022 (Datacenter/Datacenter Core/Standard)</li> <li>- Windows Server 2019 (Datacenter/Datacenter Core/Standard)</li> <li>- Windows Server 2016 (Datacenter/Datacenter Core/Standard)</li> <li>- Windows Server 2012 R2 (Datacenter/Standard)</li> <li>- Windows Server 2012 (Datacenter/Standard)</li> <li>- Windows Server 2008 R2 (RTM and SP1 Standard)</li> <li>- Windows Server 2008 (64 bit only)</li> </ul>
Back up with MARS agent	<a href="#">Supported</a> operating systems.
Back up with DPM/MABS	Supported operating systems for backup with <a href="#">MABS</a> and <a href="#">DPM</a> .

Azure Backup doesn't support 32-bit operating systems.

## Support for Linux backup

Here's what's supported if you want to back up Linux machines.

ACTION	SUPPORT
Back up Linux Azure VMs with the Linux Azure VM agent	<p>File consistent backup.</p> <p>App-consistent backup using <a href="#">custom scripts</a>.</p> <p>During restore, you can create a new VM, restore a disk and use it to create a VM, or restore a disk, and use it to replace a disk on an existing VM. You can also restore individual files and folders.</p>
Back up Linux Azure VMs with MARS agent	<p>Not supported.</p> <p>The MARS agent can only be installed on Windows machines.</p>
Back up Linux Azure VMs with DPM/MABS	Not supported.
Back up Linux Azure VMs with docker mount points	Currently, Azure Backup doesn't support exclusion of docker mount points as these are mounted at different paths every time.

## Operating system support (Linux)

For Azure VM Linux backups, Azure Backup supports the list of Linux [distributions endorsed by Azure](#). Note the following:

- Azure Backup doesn't support Core OS Linux.
- Azure Backup doesn't support 32-bit operating systems.
- Other bring-your-own Linux distributions might work as long as the [Azure VM agent for Linux](#) is available on the VM, and as long as Python is supported.
- Azure Backup doesn't support a proxy-configured Linux VM if it doesn't have Python version 2.7 or higher installed.
- Azure Backup doesn't support backing up NFS files that are mounted from storage, or from any other NFS server, to Linux or Windows machines. It only backs up disks that are locally attached to the VM.

## Support matrix for managed pre-post scripts for Linux databases

Azure Backup provides support for customers to author their own pre-post scripts

SUPPORTED DATABASE	OS VERSION	DATABASE VERSION
Oracle in Azure VMs	Oracle Linux	Oracle 12.x or greater

## Backup frequency and retention

SETTING	LIMITS
Maximum recovery points per protected instance (machine/workload)	9999.
Maximum expiry time for a recovery point	No limit (99 years).
Maximum backup-frequency to vault (Azure VM extension)	Once a day.
Maximum backup-frequency to vault (MARS agent)	Three backups per day.
Maximum backup-frequency to DPM/MABS	Every 15 minutes for SQL Server. Once an hour for other workloads.
Recovery point retention	Daily, weekly, monthly, and yearly.
Maximum retention period	Depends on backup frequency.
Recovery points on DPM/MABS disk	64 for file servers, and 448 for app servers. Tape recovery points are unlimited for on-premises DPM.

## Supported restore methods

RESTORE OPTION	DETAILS
Create a new VM	Quickly creates and gets a basic VM up and running from a restore point.  You can specify a name for the VM, select the resource group and virtual network (VNet) in which it will be placed, and specify a storage account for the restored VM. The new VM must be created in the same region as the source VM.

RESTORE OPTION	DETAILS
<b>Restore disk</b>	<p>Restores a VM disk, which can then be used to create a new VM.</p> <p>Azure Backup provides a template to help you customize and create a VM.</p> <p>The restore job generates a template that you can download and use to specify custom VM settings, and create a VM.</p> <p>The disks are copied to the Resource Group you specify.</p> <p>Alternatively, you can attach the disk to an existing VM, or create a new VM using PowerShell.</p> <p>This option is useful if you want to customize the VM, add configuration settings that weren't there at the time of backup, or add settings that must be configured using the template or PowerShell.</p>
<b>Replace existing</b>	<p>You can restore a disk, and use it to replace a disk on the existing VM.</p> <p>The current VM must exist. If it's been deleted, this option can't be used.</p> <p>Azure Backup takes a snapshot of the existing VM before replacing the disk, and stores it in the staging location you specify. Existing disks connected to the VM are replaced with the selected restore point.</p> <p>The snapshot is copied to the vault, and retained in accordance with the retention policy.</p> <p>After the replace disk operation, the original disk is retained in the resource group. You can choose to manually delete the original disks if they aren't needed.</p> <p>Replace existing is supported for unencrypted managed VMs and for VMs <a href="#">created using custom images</a>. It's not supported for unmanaged disks and VMs, classic VMs, and <a href="#">generalized VMs</a>.</p> <p>If the restore point has more or less disks than the current VM, then the number of disks in the restore point will only reflect the VM configuration.</p> <p>Replace existing is also supported for VMs with linked resources, like <a href="#">user-assigned managed-identity</a> and <a href="#">Key Vault</a>.</p>

RESTORE OPTION	DETAILS
Cross Region (secondary region)	<p>Cross Region restore can be used to restore Azure VMs in the secondary region, which is an <a href="#">Azure paired region</a>.</p> <p>You can restore all the Azure VMs for the selected recovery point if the backup is done in the secondary region.</p> <p>This feature is available for the options below:</p> <ul style="list-style-type: none"> <li>• <a href="#">Create a VM</a></li> <li>• <a href="#">Restore Disks</a></li> </ul> <p>We don't currently support the <a href="#">Replace existing disks</a> option.</p> <p>Permissions The restore operation on secondary region can be performed by Backup Admins and App admins.</p>

## Support for file-level restore

RESTORE	SUPPORTED
Restoring files across operating systems	You can restore files on any machine that has the same (or compatible) OS as the backed-up VM. See the <a href="#">Compatible OS table</a> .
Restoring files from encrypted VMs	Not supported.
Restoring files from network-restricted storage accounts	Not supported.
Restoring files on VMs using Windows Storage Spaces	Restore not supported on same VM.  Instead, restore the files on a compatible VM.
Restore files on Linux VM using LVM/raid arrays	Restore not supported on same VM.  Restore on a compatible VM.
Restore files with special network settings	Restore not supported on same VM.  Restore on a compatible VM.
Restore files from Shared disk, Temp drive, Deduplicated Disk, Ultra disk and disk with write Accelerator enabled	Restore not supported, see <a href="#">Azure VM storage support</a> .

## Support for VM management

The following table summarizes support for backup during VM management tasks, such as adding or replacing VM disks.

RESTORE	SUPPORTED
Restore across subscription	<a href="#">Cross Subscription Restore</a> is now supported in Azure VMs.
<a href="#">Restore across region</a>	Supported.

RESTORE	SUPPORTED
Restore across zone	Unsupported.
Restore to an existing VM	Use replace disk option.
Restore disk with storage account enabled for Azure Storage Service Encryption (SSE)	Not supported.  Restore to an account that doesn't have SSE enabled.
Restore to mixed storage accounts	Not supported.  Based on the storage account type, all restored disks will be either premium or standard, and not mixed.
Restore VM directly to an availability set	For managed disks, you can restore the disk and use the availability set option in the template.  Not supported for unmanaged disks. For unmanaged disks, restore the disk, and then create a VM in the availability set.
Restore backup of unmanaged VMs after upgrading to managed VM	Supported.  You can restore disks, and then create a managed VM.
Restore VM to restore point before the VM was migrated to managed disks	Supported.  You restore to unmanaged disks (default), convert the restored disks to managed disk, and create a VM with the managed disks.
Restore a VM that's been deleted.	Supported.  You can restore the VM from a recovery point.
Restore a domain controller VM	Supported. For details, see <a href="#">Restore domain controller VMs</a> .
Restore VM in different virtual network	Supported.  The virtual network must be in the same subscription and region.

## VM compute support

COMPUTE	SUPPORT
VM size	Any Azure VM size with at least 2 CPU cores and 1-GB RAM.  <a href="#">Learn more</a> .
Back up VMs in <a href="#">availability sets</a>	Supported.  You can't restore a VM in an available set by using the option to quickly create a VM. Instead, when you restore the VM, restore the disk and use it to deploy a VM, or restore a disk and use it to replace an existing disk.

COMPUTE	SUPPORT
Back up VMs that are deployed with <a href="#">Hybrid Use Benefit (HUB)</a>	Supported.
Back up VMs that are deployed from <a href="#">Azure Marketplace</a> (Published by Microsoft, third party)	Supported.  The VM must be running a supported operating system.  When recovering files on the VM, you can restore only to a compatible OS (not an earlier or later OS). We don't restore Azure Marketplace VMs backed as VMs, as these need purchase information. They're only restored as disks.
Back up VMs that are deployed from a custom image (third-party)	Supported.  The VM must be running a supported operating system.  When recovering files on the VM, you can restore only to a compatible OS (not an earlier or later OS).
Back up VMs that are migrated to Azure	Supported.  To back up the VM, the VM agent must be installed on the migrated machine.
Back up Multi-VM consistency	Azure Backup doesn't provide data and application consistency across multiple VMs.
Backup with <a href="#">Diagnostic Settings</a>	Unsupported.  If the restore of the Azure VM with diagnostic settings is triggered using the <a href="#">Create New</a> option, then the restore fails.
Restore of Zone-pinned VMs	Supported (for a VM that's backed-up after Jan 2019 and where <a href="#">availability zones</a> are available).  We currently support restoring to the same zone that's pinned in VMs. However, if the zone is unavailable due to an outage, the restore will fail.
Gen2 VMs	Supported Azure Backup supports backup and restore of <a href="#">Gen2 VMs</a> . When these VMs are restored from Recovery point, they're restored as <a href="#">Gen2 VMs</a> .
Backup of Azure VMs with locks	Unsupported for unmanaged VMs.  Supported for managed VMs.
Spot VMs	Unsupported. Azure Backup restores Spot VMs as regular Azure VMs.

COMPUTE	SUPPORT
Azure Dedicated Host	<p>Supported</p> <p>While restoring an Azure VM through the <a href="#">Create New</a> option, though the restore gets successful, Azure VM can't be restored in the dedicated host. To achieve this, we recommend you to restore as disks. While <a href="#">restoring as disks</a> with the template, create a VM in dedicated host, and then attach the disks.</p> <p>This is not applicable in secondary region, while performing <a href="#">Cross Region Restore</a>.</p>
Windows Storage Spaces configuration of standalone Azure VMs	Supported
Azure Virtual Machine Scale Sets	Supported for flexible orchestration model to back up and restore Single Azure VM.
Restore with Managed identities	<p>Yes, supported for managed Azure VMs, and not supported for classic and unmanaged Azure VMs.</p> <p>Cross Region Restore isn't supported with managed identities.</p> <p>Currently, this is available in all Azure public and national cloud regions.</p> <p><a href="#">Learn more</a>.</p>
Trusted Launch VM	<p>Backup supported.</p> <p>Backup of Trusted Launch VM is supported through <a href="#">Enhanced policy</a>. You can enable backup through <a href="#">Recovery Services vault</a>, <a href="#">VM Manage blade</a>, and <a href="#">Create VM blade</a>.</p> <p><b>Feature details</b></p> <ul style="list-style-type: none"> <li>• Backup is supported in all regions where Trusted Launch VM is available.</li> <li>• Configurations of Backup, Alerts, and Monitoring for Trusted Launch VM are currently not supported through Backup center.</li> <li>• Migration of an existing <a href="#">Generation 2</a> VM (protected with Azure Backup) to Trusted Launch VM is currently not supported. Learn about how to <a href="#">create a Trusted Launch VM</a>.</li> </ul>

## VM storage support

COMPONENT	SUPPORT
Azure VM data disks	<p>Support for backup of Azure VMs with up to 32 disks.</p> <p>Support for backup of Azure VMs with unmanaged disks or classic VMs is up to 16 disks only.</p>

Component	Support
Data disk size	Individual disk size can be up to 32 TB and a maximum of 256 TB combined for all disks in a VM.
Storage type	Standard HDD, Standard SSD, Premium SSD.  Backup and restore of <a href="#">ZRS disks</a> is supported.
Managed disks	Supported.
Encrypted disks	Supported.  Azure VMs enabled with Azure Disk Encryption can be backed up (with or without the Azure AD app).  Encrypted VMs can't be recovered at the file/folder level. You must recover the entire VM.  You can enable encryption on VMs that are already protected by Azure Backup.
Disks with Write Accelerator enabled	Azure VM with WA disk backup is available in all Azure public regions starting from May 18, 2020. If WA disk backup is not required as part of VM backup, you can choose to remove with <a href="#">Selective disk feature</a> .  <b>Important</b> Virtual machines with WA disks need internet connectivity for a successful backup (even though those disks are excluded from the backup).
Disks enabled for access with private EndPoint	Unsupported.
Back up & Restore deduplicated VMs/disks	Azure Backup doesn't support deduplication. For more information, see this <a href="#">article</a> <ul style="list-style-type: none"> <li>- Azure Backup doesn't deduplicate across VMs in the Recovery Services vault</li> <li>- If there are VMs in deduplication state during restore, the files can't be restored because the vault doesn't understand the format. However, you can successfully perform the full VM restore.</li> </ul>
Add disk to protected VM	Supported.
Resize disk on protected VM	Supported.
Shared storage	Backing up VMs using Cluster Shared Volume (CSV) or Scale-Out File Server isn't supported. CSV writers are likely to fail during backup. On restore, disks containing CSV volumes might not come-up.
Shared disks	Not supported.
Ultra SSD disks	Not supported. For more information, see these <a href="#">limitations</a> .

Component	Support
Temporary disks	Temporary disks aren't backed up by Azure Backup.
NVMe/ephemeral disks	Not supported.
ReFS restore	Supported. VSS supports app-consistent backups on ReFS also like NFS.
Dynamic disk with spanned/stripped volumes	<p>Supported</p> <p>If you enable selective disk feature on an Azure VM, then this won't be supported.</p>

## VM network support

Component	Support
Number of network interfaces (NICs)	<p>Up to maximum number of NICs supported for a specific Azure VM size.</p> <p>NICs are created when the VM is created during the restore process.</p> <p>The number of NICs on the restored VM mirrors the number of NICs on the VM when you enabled protection. Removing NICs after you enable protection doesn't affect the count.</p>
External/internal load balancer	<p>Supported.</p> <p><a href="#">Learn more</a> about restoring VMs with special network settings.</p>
Multiple reserved IP addresses	<p>Supported.</p> <p><a href="#">Learn more</a> about restoring VMs with special network settings.</p>
VMs with multiple network adapters	<p>Supported.</p> <p><a href="#">Learn more</a> about restoring VMs with special network settings.</p>
VMs with public IP addresses	<p>Supported.</p> <p>Associate an existing public IP address with the NIC, or create an address and associate it with the NIC after restore is done.</p>
Network security group (NSG) on NIC/subnet.	Supported.

COMPONENT	SUPPORT
Static IP address	<p>Not supported.</p> <p>A new VM that's created from a restore point is assigned a dynamic IP address.</p> <p>For classic VMs, you can't back up a VM with a reserved IP address and no defined endpoint.</p>
Dynamic IP address	<p>Supported.</p> <p>If the NIC on the source VM uses dynamic IP addressing, by default the NIC on the restored VM will use it too.</p>
Azure Traffic Manager	<p>Supported.</p> <p>If the backed-up VM is in Traffic Manager, manually add the restored VM to the same Traffic Manager instance.</p>
Azure DNS	Supported.
Custom DNS	Supported.
Outbound connectivity via HTTP proxy	<p>Supported.</p> <p>An authenticated proxy isn't supported.</p>
Virtual network service endpoints	<p>Supported.</p> <p>Firewall and virtual network storage account settings should allow access from all networks.</p>

## VM security and encryption support

Azure Backup supports encryption for in-transit and at-rest data:

Network traffic to Azure:

- Backup-traffic from servers to the Recovery Services vault is encrypted by using Advanced Encryption Standard 256.
- Backup data is sent over a secure HTTPS link.
- The backup data is stored in the Recovery Services vault in encrypted form.
- Only you have the encryption key to unlock this data. Microsoft can't decrypt the backup data at any point.

### WARNING

After you set up the vault, only you have access to the encryption key. Microsoft never maintains a copy and doesn't have access to the key. If the key is misplaced, Microsoft can't recover the backup data.

Data security:

- When backing up Azure VMs, you need to set up encryption *within* the virtual machine.

- Azure Backup supports Azure Disk Encryption, which uses BitLocker on virtual machines running Windows and uses **dm-crypt** on Linux virtual machines.
- On the back end, Azure Backup uses [Azure Storage Service encryption](#), which protects data at rest.

MACHINE	IN TRANSIT	AT REST
On-premises Windows machines without DPM/MABS		
Azure VMs		
On-premises/Azure VMs with DPM		
On-premises/Azure VMs with MABS		

## VM compression support

Backup supports the compression of backup traffic, as summarized in the following table. Note the following:

- For Azure VMs, the VM extension reads the data directly from the Azure storage account over the storage network. It isn't necessary to compress this traffic.
- If you're using DPM or MABS, you can save bandwidth by compressing the data before it's backed up to DPM/MABS.

MACHINE	COMPRESS TO MABS/DPM (TCP)	COMPRESS TO VAULT (HTTPS)
On-premises Windows machines without DPM/MABS	NA	
Azure VMs	NA	NA
On-premises/Azure VMs with DPM		
On-premises/Azure VMs with MABS		

## Next steps

- [Back up Azure VMs](#).
- [Back up Windows machines directly](#), without a backup server.
- [Set up MABS](#) for backup to Azure, and then back up workloads to MABS.
- [Set up DPM](#) for backup to Azure, and then back up workloads to DPM.

# Azure Backup pricing

9/21/2022 • 8 minutes to read • [Edit Online](#)

To learn about Azure Backup pricing, visit the [Azure Backup pricing page](#).

## Download detailed estimates for Azure Backup pricing

If you're looking to estimate your costs for budgeting or cost comparison purposes, download the detailed [Azure Backup pricing estimator](#).

### What does the estimator contain?

The Azure Backup cost estimator sheet has an option for you to estimate all possible workloads you're looking to back up using Azure Backup. These workloads include:

- Azure VMs
- On-premises servers
- SQL in Azure VMs
- SAP HANA in Azure VMs
- Azure files shares

## Estimate costs for backing up Azure VMs or on-premises servers

To estimate the costs of backing up Azure VMs or on-premises servers using Azure Backup, you'll need the following parameters:

- Size of the VMs or on-premises servers that you're trying to back up
  - Enter the "used size" of disks or servers required to be backed up
- Number of servers with that size
- What is the expected amount of data churn on these servers?

Churn refers to the amount of change in data. For example, if you had a VM with 200 GB of data to be backed up and 10 GB of it changes every day, the daily churn is 5%.

  - Higher churn will mean that you back up more data
  - Pick **Low** or **Moderate** for file servers and **High** if you're running databases
  - If you know your **churn%**, you can use the **Enter your own%** option
- Choose the backup policy
  - How long do you expect to retain "Daily" backups? (in days)
  - How long do you expect to retain "Weekly" backups? (in weeks)
  - How long do you expect to retain "Monthly" backups? (in months)
  - How long do you expect to retain "Yearly" backups? (in years)
  - How long do you expect to retain "Instant restore snapshots"? (1-5 days)
  - This option lets you restore from as far back as seven days in a quick manner using snapshots stored on disks.

- **Optional** – Selective Disk backup
  - If you're using the **Selective Disk Backup** option while backing up Azure VMs, choose the **Exclude Disk** option and enter the percentage of disks excluded from backup in terms of size. For example, if you have a VM connected to three disks with 200 GB used in each disk and if you want to exclude two of them from backing up, enter 66.7%.
- **Optional** – Backup Storage Redundancy
  - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if you're backing up development or test environments that don't need an enterprise-level backup. Select the **RAGRS** option in the sheet if you want to understand costs when **Cross-Region Restore** is enabled for your backups.
- **Optional** – Modify regional pricing or apply discounted rates
  - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

## Estimate costs for backing up SQL servers in Azure VMs

To estimate the costs of backing up SQL servers running in Azure VMs using Azure Backup, you'll need the following parameters:

- Size of the SQL servers that you're trying to back up
- Number of SQL servers with the above size
- What is the expected compression for your SQL servers' backup data?
  - Most Azure Backup customers see that the backup data has 80% compression compared to the SQL server size when the SQL compression is **enabled**.
  - If you expect to see a different compression, enter the number in this field
- What is the expected size of log backups?
  - The % indicates daily log size as a % of the SQL server size
- What is the expected amount of daily data churn on these servers?
  - Typically, databases have "High" churn
  - If you know your **churn%**, you can use the **Enter your own%** option
- Choose the backup policy
  - Backup Type
    - The most effective policy you can choose is **Daily differentials** with weekly/monthly/yearly full backups. Azure Backup can restore from differentials through single-click as well.
    - You can also choose to have a policy with daily/weekly/monthly/yearly full backups. This option will consume slightly more storage than the first option.
    - How long do you expect to retain "log" backups? (in days) [7-35]
    - How long do you expect to retain "Daily" backups? (in days)

- How long do you expect to retain "Weekly" backups? (in weeks)
- How long do you expect to retain "Monthly" backups? (in months)
- How long do you expect to retain "Yearly" backups? (in years)
- **Optional – Backup Storage Redundancy**
  - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if you're backing up development or test environments that don't need an enterprise-level backup.
- **Optional – Modify regional pricing or apply discounted rates**
  - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

## Estimate costs for backing up SAP HANA servers in Azure VMs

To estimate the costs of backing up SAP HANA servers running in Azure VMs using Azure Backup, you'll need the following parameters:

- Total size of the SAP HANA databases that you're trying to back up. This should be the sum of full backup size of each of the databases, as reported by SAP HANA.
- Number of SAP HANA servers with the above size
- What is the expected size of log backups?
  - The % indicates average daily log size as a % of the total size of SAP HANA databases that you're backing up on the SAP HANA server
- What is the expected amount of daily data churn on these servers?
  - The % indicates average daily churn size as a % of the total size of SAP HANA databases that you're backing up on the SAP HANA server
  - Typically, databases have "High" churn
  - If you know your **churn%**, you can use the **Enter your own%** option
- Choose the backup policy
  - Backup Type
    - The most effective policy you can choose is **Daily differentials** with **weekly/monthly/yearly** full backups. Azure Backup can restore from differentials through single-click as well.
    - You can also choose to have a policy with **daily/weekly/monthly/yearly** full backups. This option will consume slightly more storage than the first option.
  - How long do you expect to retain "log" backups? (in days) [7-35]
  - How long do you expect to retain "Daily" backups? (in days)
  - How long do you expect to retain "Weekly" backups? (in weeks)
  - How long do you expect to retain "Monthly" backups? (in months)
  - How long do you expect to retain "Yearly" backups? (in years)
- **Optional – Backup Storage Redundancy**
  - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if

you're backing up development or test environments that don't need an enterprise-level backup.

- **Optional** – Modify regional pricing or apply discounted rates
  - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

## Estimate costs for backing up Azure file shares

To estimate the costs of backing up Azure file shares using the [snapshot-based backup solution](#) offered by Azure Backup, you'll need the following parameters:

- Size (in GB) of the file shares that you want to back up.
- If you want to back up file shares spread across multiple storage accounts, specify the number of storage accounts hosting the file shares with the above size.
- Expected amount of data churn on the file shares that you want to back up.

Churn refers to the amount of change in data and it directly impacts the snapshot storage size. For example, if you have a file share with 200 GB of data to be backed up, and 10 GB of it changes every day, the daily churn is 5%.

  - Higher churn means the amount of data change in the file share contents every day is high, and so incremental snapshot (capturing only the data changes) size would also be more.
  - Select Low (1%), Moderate (3%), or High (5%) based on your file share characteristics and usage.
  - If you know the exact **churn%** for your file share, you can select the **Enter your own%** option from the drop-down. Specify the values (in %) for daily, weekly, monthly, and yearly churn.
- Type of storage account (standard or premium) and the storage redundancy setting of the storage account hosting the backed-up file share.

In the current backup solution for Azure file shares, snapshots are stored in the same storage account as the backed-up file share. So the storage cost associated with snapshots is billed as part of your Azure files bill, based on the snapshot pricing for the account type and redundancy setting of the storage account hosting the backed-up file share and snapshots.
- Retention for different backups
  - How long do you expect to retain "Daily" backups? (in days)
  - How long do you expect to retain "Weekly" backups? (in weeks)
  - How long do you expect to retain "Monthly" backups? (in months)
  - How long do you expect to retain "Yearly" backups? (in years)

Refer to [the Azure File share support matrix](#) for the maximum supported retention values in each category.
- **Optional** – Modify regional pricing or apply discounted rates.
  - The default values set for snapshot storage cost per GB and protected instance cost in the estimator are for the East US region. If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option, and enter the rates with which you want to run the estimates.

[What is the Azure Backup service?](#)

# About Site Recovery

9/21/2022 • 3 minutes to read • [Edit Online](#)

Welcome to the Azure Site Recovery service! This article provides a quick service overview.

As an organization, you need to adopt a business continuity and disaster recovery (BCDR) strategy that keeps your data safe, and your apps and workloads online, when planned and unplanned outages occur.

Azure Recovery Services contributes to your BCDR strategy:

- **Site Recovery service:** Site Recovery helps ensure business continuity by keeping business apps and workloads running during outages. Site Recovery [replicates](#) workloads running on physical and virtual machines (VMs) from a primary site to a secondary location. When an outage occurs at your primary site, you fail over to a secondary location, and access apps from there. After the primary location is running again, you can fail back to it.
- **Backup service:** The [Azure Backup](#) service keeps your data safe and recoverable.

Site Recovery can manage replication for:

- Azure VMs replicating between Azure regions.
- On-premises VMs, Azure Stack VMs, and physical servers.

## What does Site Recovery provide?

FEATURE	DETAILS
Simple BCDR solution	Using Site Recovery, you can set up and manage replication, failover, and fallback from a single location in the Azure portal.
Azure VM replication	You can set up disaster recovery of Azure VMs from a primary region to a secondary region.
VMware VM replication	You can replicate VMware VMs to Azure using the improved Azure Site Recovery replication appliance that offers better security and resilience than the configuration server. For more information, see <a href="#">Disaster recovery of VMware VMs</a> .
On-premises VM replication	You can replicate on-premises VMs and physical servers to Azure, or to a secondary on-premises datacenter. Replication to Azure eliminates the cost and complexity of maintaining a secondary datacenter.
Workload replication	Replicate any workload running on supported Azure VMs, on-premises Hyper-V and VMware VMs, and Windows/Linux physical servers.
Data resilience	Site Recovery orchestrates replication without intercepting application data. When you replicate to Azure, data is stored in Azure storage, with the resilience that provides. When failover occurs, Azure VMs are created based on the replicated data.

FEATURE	DETAILS
RTO and RPO targets	Keep recovery time objectives (RTO) and recovery point objectives (RPO) within organizational limits. Site Recovery provides continuous replication for Azure VMs and VMware VMs, and replication frequency as low as 30 seconds for Hyper-V. You can reduce RTO further by integrating with <a href="#">Azure Traffic Manager</a> .
Keep apps consistent over failover	You can replicate using recovery points with application-consistent snapshots. These snapshots capture disk data, all data in memory, and all transactions in process.
Testing without disruption	You can easily run disaster recovery drills, without affecting ongoing replication.
Flexible failovers	You can run planned failovers for expected outages with zero-data loss. Or, unplanned failovers with minimal data loss, depending on replication frequency, for unexpected disasters. You can easily fail back to your primary site when it's available again.
Customized recovery plans	Using recovery plans, you can customize and sequence the failover and recovery of multi-tier applications running on multiple VMs. You group machines together in a recovery plan, and optionally add scripts and manual actions. Recovery plans can be integrated with Azure automation runbooks.
BCDR integration	Site Recovery integrates with other BCDR technologies. For example, you can use Site Recovery to protect the SQL Server backend of corporate workloads, with native support for SQL Server Always On, to manage the failover of availability groups.
Azure automation integration	A rich Azure Automation library provides production-ready, application-specific scripts that can be downloaded and integrated with Site Recovery.
Network integration	Site Recovery integrates with Azure for application network management. For example, to reserve IP addresses, configure load-balancers, and use Azure Traffic Manager for efficient network switchovers.

## What can I replicate?

SUPPORTED	DETAILS
Replication scenarios	<ul style="list-style-type: none"> <li>Replicate Azure VMs from one Azure region to another.</li> <li>Replicate on-premises VMware VMs, Hyper-V VMs, physical servers (Windows and Linux), Azure Stack VMs to Azure.</li> <li>Replicate AWS Windows instances to Azure.</li> <li>Replicate on-premises VMware VMs, Hyper-V VMs managed by System Center VMM, and physical servers to a secondary site.</li> </ul>

SUPPORTED	DETAILS
<b>Regions</b>	Review <a href="#">supported regions</a> for Site Recovery.
<b>Replicated machines</b>	Review the replication requirements for <a href="#">Azure VM replication</a> , <a href="#">on-premises VMware VMs</a> and physical servers, and <a href="#">on-premises Hyper-V VMs</a> .
<b>Workloads</b>	You can replicate any workload running on a machine that's supported for replication. And, the Site Recovery team did app-specific tests for a <a href="#">number of apps</a> .

# Tutorial: Set up disaster recovery for Linux virtual machines

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This tutorial shows you how to set up disaster recovery for Azure VMs running Linux. In this article, learn how to:

- Enable disaster recovery for a Linux VM
- Run a disaster recovery drill to check it works as expected
- Stop replicating the VM after the drill

When you enable replication for a VM, the Site Recovery Mobility service extension installs on the VM, and registers it with [Azure Site Recovery](#). During replication, VM disk writes are sent to a cache storage account in the source VM region. Data is sent from there to the target region, and recovery points are generated from the data. When you fail a VM over to another region during disaster recovery, a recovery point is used to create a VM in the target region.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Prerequisites

1. Check that your Azure subscription allows you to create a VM in the target region. If you just created your free Azure account, you're the administrator of the subscription, and you have the permissions you need.
2. If you're not the subscription administrator, work with the administrator to assign you:
  - Either the Virtual Machine Contributor built-in role, or specific permissions to:
    - Create a VM in the selected virtual network.
    - Write to an Azure storage account.
    - Write to an Azure managed disk.
  - The Site Recovery Contributor built-in role, to manage Site Recovery operations in the vault.
3. Check that the Linux VM is running a [supported operating system](#).
4. If VM outbound connections use a URL-based proxy, make sure it can access these URLs. Using an authenticated proxy isn't supported.

Name	Public Cloud	Government Cloud	Details
Storage	*.blob.core.windows.net	*.blob.core.usgovcloudapi.net	Write data from the VM to the cache storage account in the source region.
Azure AD	login.microsoftonline.com	login.microsoftonline.us	Authorize and authenticate to Site Recovery service URLs.
Replication	*.hypervrecoverymanager.wi	*.hypervrecoverymanager.wi	Establish communication with the Site Recovery service.

Name	Public Cloud	Government Cloud	Details
Service Bus	*.servicebus.windows.net	*.servicebus.usgovcloudapi.net	Writes to Site Recovery for monitoring and diagnostic data.

5. If you're using network security groups (NSGs) to limit network traffic for VMs, create NSG rules that allow outbound connectivity (HTTPS 443) for the VM using these service tags (groups of IP addresses). Try out the rules on a test NSG first.

Tag	Allow
Storage tag	Allows data to be written from the VM to the cache storage account.
Azure AD tag	Allows access to all IP addresses that correspond to Azure AD.
EventsHub tag	Allows access to Site Recovery monitoring.
AzureSiteRecovery tag	Allows access to the Site Recovery service in any region.
GuestAndHybridManagement	Use if you want to automatically upgrade the Site Recovery Mobility agent that's running on VMs enabled for replication.

6. Make sure VMs have the latest root certificates. On Linux VMs, follow the guidance provided by your Linux distributor, to get the latest trusted root certificates and certificate revocation list on the VM.

## Create a VM and enable disaster recovery

You can optionally enable disaster recovery when you create a VM.

1. [Create a Linux VM](#).
2. On the **Management** tab, under **Site Recovery** select **Enable disaster recovery**.
3. In **Secondary region**, select the target region to which you want to replicate the VM for disaster recovery.
4. In **Secondary subscription**, select the target subscription in which the target VM will be created. The target VM is created when you fail over the source VM from the source region to the target region.
5. In **Recovery Services vault**, select the vault you want to use for the replication. If you don't have a vault, select **Create new**. Select a resource group in which to place the vault, and a vault name.
6. In **Site Recovery policy**, leave the default policy, or select **Create new** to set custom values.
  - Recovery points are created from snapshots of VM disks taken at a specific point in time. When you fail over a VM, you use a recovery point to restore the VM in the target region.
  - A crash-consistent recovery point is created every five minutes. This setting can't be modified. A crash-consistent snapshot captures data that was on the disk when the snapshot was taken. It doesn't include anything in memory.
  - By default Site Recovery keeps crash-consistent recovery points for 24 hours. You can set a custom value between 0 and 72 hours.
  - An app-consistent snapshot is taken every 4 hours.

- By default Site Recovery stores recovery points for 24 hours.
7. In **Availability options**, specify whether the VM is deployed as standalone, in an availability zone, or in an availability set.

The screenshot shows the 'Create a virtual machine' wizard in the Azure portal. The 'Site Recovery' section is highlighted, showing the following configuration:

- Enable Disaster Recovery:** Checked (indicated by a blue checkmark).
- Secondary region:** (Asia Pacific) South India
- Secondary subscription:** <subscription-name>
- Recovery Services vault:** ResourceMove-southeastasia-southindia-153c3e-0  
A red box highlights the 'Create new' button next to the vault name.
- Site Recovery policy:** RmsReplicationPolicy  
A red box highlights the 'Create new' button next to the policy name.
- Availability options:** No infrastructure redundancy required

A tooltip at the bottom left of the wizard window states: "By default, Azure Site Recovery will use the source machine's configuration for replication. After the virtual machine is created, you can edit these settings in 'Disaster recovery'. Click to learn more."

8. Finish creating the VM.

## Enable disaster recovery for an existing VM

If you want to enable disaster recovery on an existing VM, use this procedure.

1. In the Azure portal, open the VM properties page.
2. In **Operations**, select **Disaster recovery**.

Home > Virtual machines >

**azurevm2** Virtual machine

Search (Ctrl+ /) Connect Start Restart Stop Capture Delete Refresh

Diagnose and solve problems

Previous

Next : Advanced settings

5. Select **Next: Advanced settings**.

6. In **Advanced settings**, you can review settings, and modify values to custom settings. By default, Site Recovery mirrors the source settings to create target resources.

- **Target subscription.** The subscription in which the target VM is created after failover.
- **Target VM resource group.** The resource group in which the target VM is created after failover.
- **Target virtual network.** The Azure virtual network in which the target VM is located when it's created after failover.
- **Target availability.** When the target VM is created as a single instance, in an availability set, or availability zone.
- **Proximity placement.** If applicable, select the proximity placement group in which the target VM is located after failover.
- **Storage settings-Cache storage account.** Recovery uses a storage account in the source region as a temporary data store. Source VM changes are cached in this account, before being replicated to the target location.
  - By default one cache storage account is created per vault and reused.
  - You can select a different storage account if you want to customize the cache account for the VM.
- **Storage settings-Replica managed disk.** By default, Site Recovery creates replica managed disks

in the target region.

- By default the target managed disk mirror the source VM managed disks, using the same storage type (standard HDD/SSD, or premium SSD).
- You can customize the storage type as needed.
- **Replication settings.** Shows the vault in which the VM is located, and the replication policy used for the VM. By default, recovery points created by Site Recovery for the VM are kept for 24 hours.
- **Extension settings.** Indicates that Site Recovery manages updates to the Site Recovery Mobility Service extension that's installed on VMs you replicate.
  - The indicated Azure automation account manages the update process.
  - You can customize the automation account.

7. Select **Review + Start replication**.

8. Select **Start replication**. Deployment starts, and Site Recovery starts creating target resources. You can monitor replication progress in the notifications.

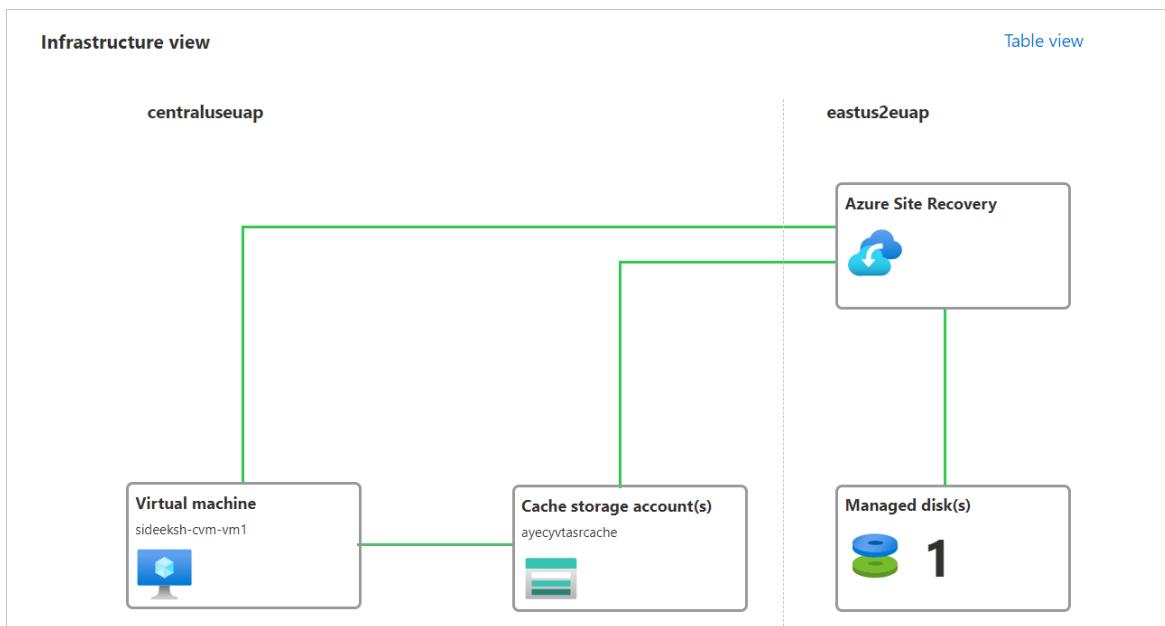

## Check VM status

After the replication job finishes, you can check the VM replication status.

1. Open the VM properties page.
2. In **Operations**, select **Disaster recovery**.
3. Expand the **Essentials** section to review defaults about the vault, replication policy, and target settings.
4. In **Health and status**, get information about replication state for the VM, the agent version, failover readiness, and the latest recovery points.

This screenshot shows the 'Health and status' section of the Azure portal. It includes tabs for Failover, Test Failover, Cleanup test failover, Commit, Resynchronize, Change recovery point, Re-protect, Disable Replication, Error Details, and Refresh. The 'Health and status' panel displays 'Replication Health' (Healthy, Protected, 1 min [As on 9/30/2020, 1:40:12 PM]), 'Failover readiness' (Last successful Test Failover, Configuration issues, Agent version, Agent status), and 'Latest recovery points' (Never performed successfully, No issues, 9.38.5739.1, Healthy). The 'Errors(0)' and 'Events - Last 72 hours(4)' sections show no errors or events.

5. In **Infrastructure view**, get a visual overview of source and target VMs, managed disks, and the cache storage account.

## Run a drill

Run a drill to make sure disaster recovery works as expected. When you run a test failover, it creates a copy of the VM, with no impact on ongoing replication, or on your production environment.

1. In the VM disaster recovery page, select **Test failover**.
2. In **Test failover**, leave the default **Latest processed (low RPO)** setting for the recovery point.

This option provides the lowest recovery point objective (RPO), and generally spins up the VM most quickly in the target region. It first processes all the data that has been sent to Site Recovery service, to create a recovery point for each VM, before failing over to it. This recovery point has all the data replicated to Site Recovery when the failover was triggered.

3. Select the virtual network in which the VM will be located after failover.

The screenshot shows the 'Test failover' configuration page for a VM named 'RayneTestVM-1'. The 'Failover direction' section shows 'From' set to 'East US 2' and 'To' set to 'West US'. Under 'Recovery Point', a dropdown menu is open, showing 'Latest processed (low RTO) (1 out of 1 disks) (10/1/2020, 10:53:40 AM)'. The 'Azure virtual network \*' section has a dropdown menu with 'Select' as the current choice. The URL at the top is 'Home > RayneTestVM-1 > RayneTestVM-1 > Test failover'.

4. The test failover process begins. You can monitor the progress in notifications.

The screenshot shows the 'Notifications' page with one active notification: 'Starting the test failover of 'RayneTestVM-1'...'. The status is 'Running' and the message says 'The operation is in progress.' with a timestamp 'a few seconds ago'. There is also a link 'More events in the activity log →' and a 'Dismiss all' button.

After the test failover completes, the VM is in the *Cleanup test failover pending* state on the Essentials

page.

## Clean up resources

The VM is automatically cleaned up by Site Recovery after the drill.

1. To begin automatic cleanup, select **Cleanup test failover**.

The screenshot shows the Site Recovery interface with the 'Cleanup test failover' button highlighted with a red box. The interface includes sections for Health and status, Failover readiness, and Latest recovery points. It also displays error and event logs.

2. In **Test failover cleanup**, type in any notes you want to record for the failover, and then select **Testing is complete. Delete test failover virtual machine**. Then select **OK**.

The dialog box shows the path Home > RayneTestVM-1 > Test failover cleanup. It contains a notes section with the text "Successful test failover. First try." and a checkbox labeled "Testing is complete. Delete test failover virtual machine(s.)".

3. The delete process begins. You can monitor progress in notifications.

## Stop replicating the VM

After completing a disaster recovery drill, we suggest you continue to try out a full failover. If you don't want to do a full failover, you can disable replication. This does the following:

- Removes the VM from the Site Recovery list of replicated machines.
- Stops Site Recovery billing for the VM.
- Automatically cleans up source replication settings.

Stop replication as follows:

1. In the VM disaster recovery page, select **Disable Replication**.
2. In **Disable Replication**, select the reasons that you want to disable replication. Then select **OK**.

Home > RayneTestVM-1 >

### Disable Replication

RayneTestVM-1

This will remove the replicated item from Azure Site Recovery. Replication configuration on source will not be cleaned up. Site Recovery billing for the machine will stop. Click to learn more.

Please select the reason(s) for disabling protection for this virtual machine. Your feedback is important to improve our product to meet your requirements.

I don't want to provide feedback.

I completed migrating my application.

I am doing a proof of concept (POC) or trial with Azure Site Recovery.

Are you likely to use Azure Site Recovery in the future? \*

Yes

Please share feedback on what went well while using Azure Site Recovery and what did not?

I faced issues with Azure Site Recovery.

Other reasons

The Site Recovery extension installed on the VM during replication isn't removed automatically. If you disable replication for the VM, and you don't want to replicate it again at a later time, you can remove the Site Recovery extension manually, as follows:

1. Go to the VM > **Settings** > **Extensions**.
2. In the **Extensions** page, select each *Microsoft.Azure.RecoveryServices* entry for Linux.

3. In the properties page for the extension, select **Uninstall**.

## Next steps

In this tutorial, you configured disaster recovery for an Azure VM, and ran a disaster recovery drill. Now, you can perform a full failover for the VM.

[Fail over a VM to another region](#)

# Tutorial: Enable disaster recovery for Windows VMs

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

This tutorial shows you how to set up disaster recovery for Azure VMs running Windows. In this article, learn how to:

- Enable disaster recovery for a Windows VM
- Run a disaster recovery drill to check it works as expected
- Stop replicating the VM after the drill

When you enable replication for a VM, the Site Recovery Mobility service extension installs on the VM, and registers it with [Azure Site Recovery](#). During replication, VM disk writes are sent to a cache storage account in the source region. Data is sent from there to the target region, and recovery points are generated from the data. When you fail over a VM during disaster recovery, a recovery point is used to create a VM in the target region.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Prerequisites

1. Check that your Azure subscription allows you to create a VM in the target region. If you just created your free Azure account, you're the administrator of the subscription, and you have the permissions you need.
2. If you're not the subscription administrator, work with the administrator to assign you:
  - Either the Virtual Machine Contributor built-in role, or specific permissions to:
    - Create a VM in the selected virtual network.
    - Write to an Azure storage account.
    - Write to an Azure-managed disk.
  - The Site Recovery Contributor built-in role, to manage Site Recovery operations in the vault.
3. We recommend you use a Windows VM running Windows Server 2012 or later. The VM disk shouldn't be encrypted for the purpose of this tutorial.
4. If VM outbound connections use a URL-based proxy, make sure it can access these URLs. Using an authenticated proxy isn't supported.

NAME	PUBLIC CLOUD	GOVERNMENT CLOUD	DETAILS
Storage	*.blob.core.windows.net	*.blob.core.usgovcloudapi.net	Write data from the VM to the cache storage account in the source region.
Azure AD	login.microsoftonline.com	login.microsoftonline.us	Authorize and authenticate to Site Recovery service URLs.
Replication	*.hypervrecoverymanager.wi	*.hypervrecoverymanager.wi	VM communication with the Site Recovery service.

Name	Public Cloud	Government Cloud	Details
Service Bus	*.servicebus.windows.net	*.servicebus.usgovcloudapi. <sup>VM</sup>	writes to Site Recovery monitoring and diagnostic data.

5. If you're using network security groups (NSGs) to limit network traffic for VMs, create NSG rules that allow outbound connectivity (HTTPS 443) for the VM using these service tags (groups of IP addresses). Try out the rules on a test NSG first.

Tag	Allow
Storage tag	Allows data to be written from the VM to the cache storage account.
Azure AD tag	Allows access to all IP addresses that correspond to Azure AD.
EventsHub tag	Allows access to Site Recovery monitoring.
AzureSiteRecovery tag	Allows access to the Site Recovery service in any region.
GuestAndHybridManagement	Use if you want to automatically upgrade the Site Recovery Mobility agent that's running on VMs enabled for replication.

6. On Windows VMs, install the latest Windows updates, to make sure that VMs have the latest root certificates.

## Create a VM and enable disaster recovery

You can optionally enable disaster recovery when you create a VM.

1. [Create a VM](#).
2. On the **Management** tab, select **Enable disaster recovery**.
3. In **Secondary region**, select the target region to which you want to replicate a VM for disaster recovery.
4. In **Secondary subscription**, select the target subscription in which the target VM will be created. The target VM is created when you fail over the source VM from the source region to the target region.
5. In **Recovery Services vault**, select the vault you want to use for the replication. If you don't have a vault, select **Create new**. Select a resource group in which to place the vault, and a vault name.
6. In **Site Recovery policy**, leave the default policy, or select **Create new** to set custom values.
  - Recovery points are created from snapshots of VM disks taken at a specific point in time. When you fail over a VM, you use a recovery point to restore the VM in the target region.
  - A crash-consistent recovery point is created every five minutes. This setting can't be modified. A crash-consistent snapshot captures data that was on the disk when the snapshot was taken. It doesn't include anything in memory.
  - By default Site Recovery keeps crash-consistent recovery points for 24 hours. You can set a custom value between 0 and 72 hours.
  - An app-consistent snapshot is taken every 4 hours. An app-consistent snapshot
  - By default Site Recovery stores recovery points for 24 hours.

7. In **Availability options**, specify whether the VM is deployed as standalone, in an availability zone, or in an availability set.

The screenshot shows the 'Create a virtual machine' wizard in the Azure portal. The 'Site Recovery' section is highlighted, indicating it's the current step. Under 'Site Recovery', the 'Enable Disaster Recovery' checkbox is checked. Below it, the 'Secondary region' dropdown is set to '(Asia Pacific) South India'. The 'Secondary subscription' dropdown shows '<subscription-name>' and the 'Recovery Services vault' dropdown shows 'ResourceMove-southeastasia-southindia-153c3e-0'. Both the 'Site Recovery policy' and 'Availability options' dropdowns show 'Create new' and 'No infrastructure redundancy required' respectively. A note at the bottom states: 'By default, Azure Site Recovery will use the source machine's configuration for replication. After the virtual machine is created, you can edit these settings in "Disaster recovery". Click to learn more.'

8. Finish creating the VM.

#### NOTE

When you enable replication while creating a Windows VM, only the OS disk gets replicated. Data disks need to be initialized by you, after which Azure Site Recovery automatically replicates them.

## Enable disaster recovery for an existing VM

If you want to enable disaster recovery on an existing VM instead of for a new VM, use this procedure.

1. In the Azure portal, open the VM properties page.
2. In **Operations**, select **Disaster recovery**.

Home > Virtual machines >

**azurevm2** Virtual machine

Search (Ctrl+ /) Connect Start Restart Stop Capture Delete Refresh

7. Select **Review + Start replication**.

8. Select **Start replication**. Deployment starts, and Site Recovery starts creating target resources. You can monitor replication progress in the notifications.

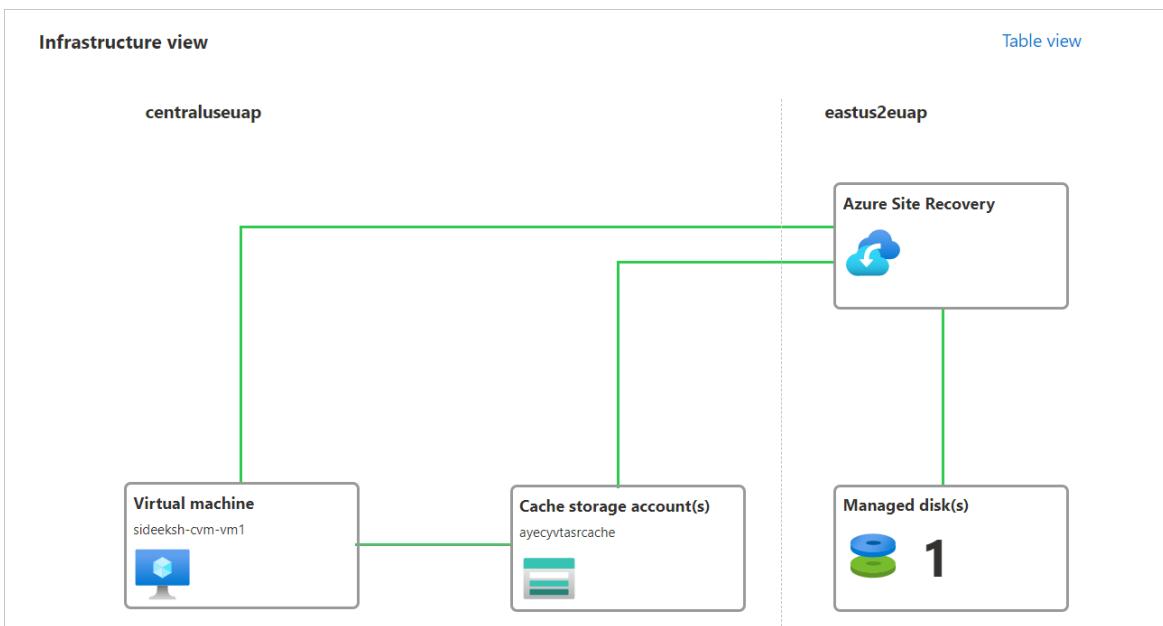

## Check VM status

After the replication job finishes, you can check the VM replication status.

1. Open the VM properties page.
2. In **Operations**, select **Disaster recovery**.
3. Expand the **Essentials** section to review defaults about the vault, replication policy, and target settings.
4. In **Health and status**, get information about replication state for the VM, the agent version, failover readiness, and the latest recovery points.

This screenshot shows the 'Health and status' blade for disaster recovery. It includes tabs for Failover, Test Failover, Cleanup test failover, Commit, Resynchronize, Change recovery point, Re-protect, Disable Replication, Error Details, and Refresh. The main area has sections for 'Health and status' (Replication Health: Healthy, Status: Protected, RPO: 1 min [As on 9/30/2020, 1:40:12 PM]), 'Failover readiness' (Last successful Test Failover: Never performed successfully, Configuration issues: No issues, Agent version: 9.38.5739.1, Agent status: Healthy), and 'Latest recovery points' (Click above to see the latest recovery points). At the bottom, there are sections for Errors (0) and Events - Last 72 hours (4).

5. In **Infrastructure view**, get a visual overview of source and target VMs, managed disks, and the cache storage account.

## Run a drill

Run a drill to make sure disaster recovery works as expected. When you run a test failover, it creates a copy of the VM, with no impact on ongoing replication, or on your production environment.

1. In the VM disaster recovery page, select **Test failover**.
2. In **Test failover**, leave the default **Latest processed (low RPO)** setting for the recovery point.

This option provides the lowest recovery point objective (RPO), and generally the quickest spin up of the target VM. It first processes all the data that has been sent to Site Recovery service, to create a recovery point for each VM, before failing over to it. This recovery point has all the data replicated to Site Recovery when the failover was triggered.

3. Select the virtual network in which the VM will be located after failover.

The screenshot shows the 'Test failover' configuration page for a VM named 'RayneTestVM-1'. The 'Failover direction' section shows 'From' set to 'East US 2' and 'To' set to 'West US'. Under 'Recovery Point', a dropdown menu is open, showing 'Latest processed (low RTO) (1 out of 1 disks) (10/1/2020, 10:53:40 AM)'. The 'Azure virtual network \*' section has a dropdown menu labeled 'Select'.

4. The test failover process begins. You can monitor the progress in notifications.

The screenshot shows the 'Notifications' window. It displays a single notification: 'Starting the test failover of 'RayneTestVM-1'...' with a status of 'Running'. Below the notification, it says 'The operation is in progress.' and 'a few seconds ago'. There is also a link to 'More events in the activity log' and a 'Dismiss all' button.

After the test failover completes, the VM is in the *Cleanup test failover pending* state on the **Essentials**

page.

## Clean up resources

The VM is automatically cleaned up by Site Recovery after the drill.

1. To begin automatic cleanup, select **Cleanup test failover**.

The screenshot shows the Site Recovery interface with the 'Cleanup test failover' button highlighted with a red box. The interface includes sections for Health and status, Failover readiness, and Latest recovery points. It also displays error and event logs.

2. In **Test failover cleanup**, type in any notes you want to record for the failover, and then select **Testing is complete. Delete test failover virtual machine**. Then select **OK**.

The dialog box shows the path Home > RayneTestVM-1 > Test failover cleanup. It contains a notes section with the text "Successful test failover. First try." and a checkbox labeled "Testing is complete. Delete test failover virtual machine(s.)".

3. The delete process begins. You can monitor progress in notifications.

# Notifications

## Stop replicating the VM

After completing a disaster recovery drill, we suggest you continue to try out a full failover. If you don't want to do a full failover, you can disable replication. This does the following:

- Removes the VM from the Site Recovery list of replicated machines.
- Stops Site Recovery billing for the VM.
- Automatically cleans up source replication settings.

Stop replication as follows:

1. In the VM disaster recovery page, select **Disable Replication**.
2. In **Disable Replication**, select the reasons that you want to disable replication. Then select **OK**.

Home > RayneTestVM-1 >

### Disable Replication

RayneTestVM-1

This will remove the replicated item from Azure Site Recovery. Replication configuration on source will not be cleaned up. Site Recovery billing for the machine will stop. Click to learn more.

Please select the reason(s) for disabling protection for this virtual machine. Your feedback is important to improve our product to meet your requirements.

I don't want to provide feedback.

I completed migrating my application.

I am doing a proof of concept (POC) or trial with Azure Site Recovery.

Are you likely to use Azure Site Recovery in the future? \*

Yes

Please share feedback on what went well while using Azure Site Recovery and what did not?

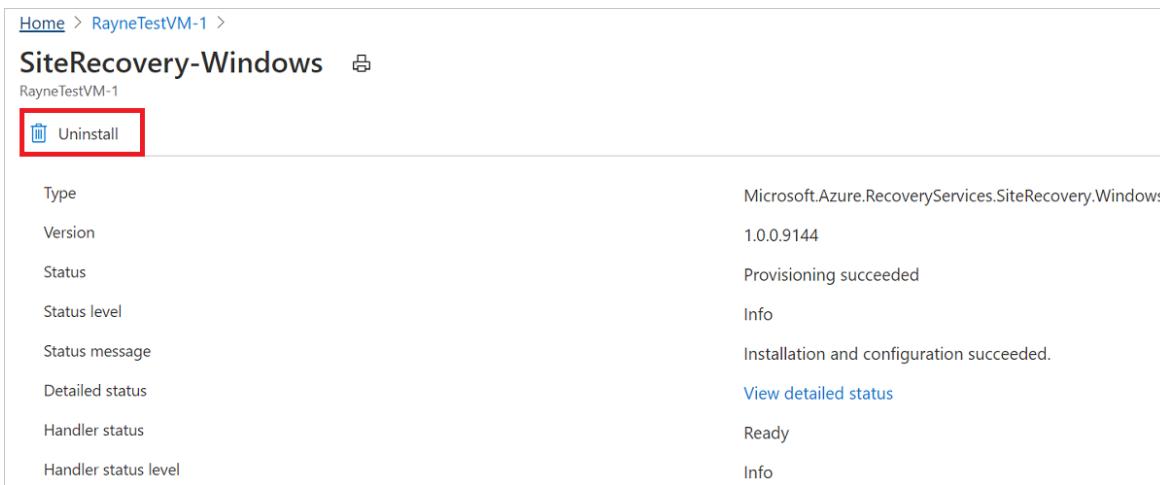

I faced issues with Azure Site Recovery.

Other reasons

The Site Recovery extension installed on the VM during replication isn't removed automatically. If you disable replication for the VM, and you don't want to replicate it again at a later time, you can remove the Site Recovery extension manually, as follows:

1. Go to the VM > **Settings** > **Extensions**.
2. In the **Extensions** page, select each *Microsoft.Azure.RecoveryServices* entry for Linux.

3. In the properties page for the extension, select **Uninstall**.

The screenshot shows the Azure portal interface for managing extensions. At the top, there's a breadcrumb navigation: Home > RayneTestVM-1 >. Below it, the title is SiteRecovery-Windows. Underneath the title, it says RayneTestVM-1. A prominent red box highlights the "Uninstall" button, which has a trash can icon. To the right of the button is a table with the following data:

Type	Microsoft.Azure.RecoveryServices.SiteRecovery.Windows
Version	1.0.0.9144
Status	Provisioning succeeded
Status level	Info
Status message	Installation and configuration succeeded.
Detailed status	<a href="#">View detailed status</a>
Handler status	Ready
Handler status level	Info

## Next steps

In this tutorial, you configured disaster recovery for an Azure VM, and ran a disaster recovery drill. Now, you can perform a full failover for the VM.

[Fail over a VM to another region](#)

# Tutorial: Fail over Azure VMs to a secondary region

9/21/2022 • 3 minutes to read • [Edit Online](#)

Learn how to fail over Azure VMs that are enabled for disaster recovery with [Azure Site Recovery](#), to a secondary Azure region. After failover, you reprotect VMs in the target region so that they replicate back to the primary region. In this article, you learn how to:

- Check prerequisites
- Verify VM settings
- Run a failover to the secondary region
- Start replicating the VM back to the primary region.

## NOTE

This tutorial shows you how to fail over VMs with minimal steps. If you want to run a failover with full settings, learn about Azure VM [networking](#), [automation](#), and [troubleshooting](#).

## Prerequisites

Before you start this tutorial, you should have:

1. Set up replication for one or more Azure VMs. If you haven't, [complete the first tutorial](#) in this series to do that.
2. We recommend you [run a disaster recovery drill](#) for replicated VMs. Running a drill before you run a full failover helps ensure everything works as expected, without impacting your production environment.

## Verify the VM settings

1. In the vault > **Replicated items**, select the VM.

Name	Replication Health	Status	Active location
RayneTest-VM-EastUS	Healthy	Protected	East US

2. On the **VM Overview** page, check that the VM is protected and healthy, before you run a failover.

3. Before you fail over, check that:

- The VM is running a supported [Windows](#) or [Linux](#) operating system.
- The VM complies with [compute](#), [storage](#), and [networking](#) requirements.

# Run a failover

1. On the VM Overview page, select Failover.

The screenshot shows the Azure VM Overview page for 'AdminVM1'. The 'Failover' tab is selected in the top navigation bar. In the main content area, there's a 'Health and status' summary table and a 'Failover readiness' table. The 'Failover readiness' table includes columns for 'Last successful Test Failover' (Never performed successfully), 'Configuration issues' (No issues), 'Agent version' (9.45.6096.1), and 'Agent status' (Healthy).

Health and status		Failover readiness	
Replication Health	Healthy	Last successful Test Failover	Never performed successfully
Status	Protected	Configuration issues	No issues
RPO	2 mins [As on 10/1/2021, 5:56:33 PM]	Agent version	9.45.6096.1
		Agent status	Healthy

2. In Failover, choose a recovery point. The Azure VM in the target region is created using data from this recovery point.

- **Latest processed:** Uses the latest recovery point processed by Site Recovery. The time stamp is shown. No time is spent processing data, so it provides a low recovery time objective (RTO).
- **Latest:** Processes all the data sent to Site Recovery, to create a recovery point for each VM before failing over to it. Provides the lowest recovery point objective (RPO), because all data is replicated to Site Recovery when the failover is triggered.
- **Latest app-consistent:** This option fails over VMs to the latest app-consistent recovery point. The time stamp is shown.
- **Custom:** Fail over to particular recovery point. Custom is only available when you fail over a single VM, and don't use a recovery plan.

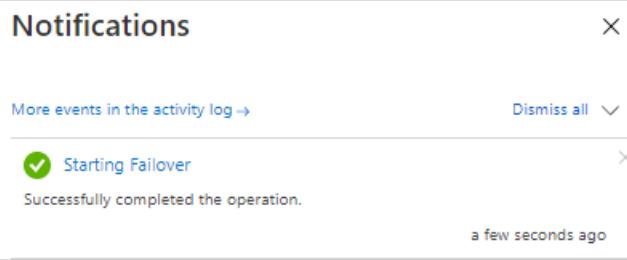

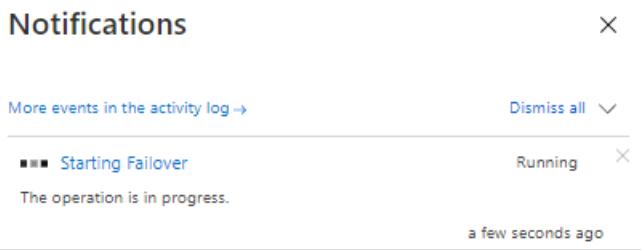

## NOTE

If you added a disk to a VM after you enabled replication, replication points shows disks available for recovery. For example, a replication point created before you added a second disk will show as "1 of 2 disks".

3. Select **Shut down machine before beginning failover** if you want Site Recovery to try to shut down the source VMs before starting failover. Shutdown helps to ensure no data loss. Failover continues even if shutdown fails.

The screenshot shows the 'Failover' configuration dialog for 'RayneTest-VMEastUS'. It includes fields for 'Failover direction' (From: East US(Zone null), To: East US 2(Zone null)), 'Recovery Point' (Choose a recovery point: Latest processed (low RTO) (1 out of 1 ...)), and a checked checkbox for 'Shut down machine before beginning failover.'

4. To start the failover, select OK.
5. Monitor the failover in notifications.

6. After the failover, the Azure VM created in the target region appears in **Virtual Machines**. Make sure that the VM is running, and sized appropriately. If you want to use a different recovery point for the VM, select **Change recovery point**, on the **Essentials** page.
7. When you're satisfied with the failed over VM, select **Commit** on the overview page, to finish the failover.

The screenshot shows the 'Site Recovery' blade in the Azure portal. At the top, there are several buttons: 'Failover', 'Test Failover', 'Cleanup test failover', 'Commit' (which is highlighted with a red box), 'Resynchronize', 'Change recovery point', 'Re-protect', and 'Disable Replication'. Below this, there's a section titled 'Essentials' with two main sections: 'Health and status' and 'Failover readiness'. Under 'Health and status', it shows 'Replication Health' as '-' and 'Status' as 'Failover completed'. Under 'Failover readiness', it shows 'Last successful Test Failover', 'Configuration issues', 'Agent version', and 'Agent status'.

8. In **Commit**, select **OK** to confirm. Commit deletes all the available recovery points for the VM in Site Recovery, and you won't be able to change the recovery point.
9. Monitor the commit progress in notifications.

The first screenshot shows a 'NOTIFICATIONS' window with a single entry: 'Committing Failover' status 'Running'. The message says 'The operation is in progress.' and was 'a few seconds ago'. The second screenshot shows a 'Notifications' window with a single entry: 'Committing Failover' status 'Successfully completed the operation.' and was 'a few seconds ago'.

## Reprotect the VM

After failover, you reprotect the VM in the secondary region, so that it replicates back to the primary region.

1. Make sure that **VM Status** is *Failover committed* before you start.

2. Check that you can access the primary region is available, and that you have permissions to create VMs in it.

3. On the VM Overview page, select Re-Protect.

The screenshot shows the 'RayneTest-VMEastUS' VM Overview page in the Azure portal. The 'Re-protect' button is highlighted with a red box. Other buttons visible include Failover, Test Failover, Cleanup test failover, Commit, Resynchronize, Change recovery point, Disable Replication, Error Details, and Refresh.

4. In Re-protect, verify the replication direction (secondary to primary region), and review the target settings for the primary region. Resources marked as new are created by Site Recovery as part of the reprotect operation.

The screenshot shows the 'Re-protect' configuration dialog. It displays the replication direction as 'eastus to eastus2'. A warning message states: '⚠ If you are choosing General Purpose v2 storage accounts, ensure that operations and data transfer prices are understood clearly before you proceed. [Learn more](#)'. Below this, there are sections for 'Resource group, Network, Storage and Availability' (Customize) and 'Target resource group' (RayneTest-EastUSRG). The 'Cache storage accounts' section lists 'qikc7eraynetestvasrcache'. The 'Target virtual network' is set to 'RayneTest-EastUSRG-vnet'. Under 'Replica managed disks', it shows '(new) 1 premium disk(s), 0 standard disk(s)'. The 'Target availability sets' section indicates 'Not Applicable'.

5. Select OK to start the reprotect process. The process sends initial data to the target location, and then replicates delta information for the VMs to the target.

6. Monitor reprotect progress in the notifications.

The first screenshot shows a 'Notifications' pane with one event: 'Reprotecting virtual machine' (Running, 'The operation is in progress.' a few seconds ago). The second screenshot shows the same pane after completion, with the event status changed to 'Succeeded' (Successfully completed the operation. 8 minutes ago).

## Next steps

In this tutorial, you failed over from the primary region to the secondary, and started replicating VMs back to the primary region. Now you can fail back from the secondary region to the primary.

[Fail back to the primary region](#)

# Tutorial: Fail back Azure VM to the primary region

9/21/2022 • 3 minutes to read • [Edit Online](#)

After failing over an Azure VM to a secondary Azure region, follow this tutorial to fail the VM to the primary Azure region, using [Azure Site Recovery](#). In this article, you learn how to:

- Review the prerequisites.
- Fail back the VM in the secondary region.
- Reprotect primary VMs back to the secondary region.

## NOTE

This tutorial shows you how to fail back with minimal steps. If you want to run a failover with full settings, learn about Azure VM [networking](#), [automation](#), and [troubleshooting](#).

## Prerequisites

Before you start this tutorial, you should have:

1. [Set up replication](#) for at least one Azure VM, and tried out a [disaster recovery drill](#) for it.
2. [Failed over the VM](#) from the primary region to a secondary region, and reprotected it so that it replicates from the secondary region to the primary.
3. Check that the primary region is available, and that you're able to create and access new resources in it.

## Fail back to the primary region

After VMs are reprotected, you can fail back to the primary region as needed.

1. In the vault > **Replicated items**, select the VM.
2. On the VM overview page, check that the VM is healthy, and that synchronization is complete, before you run a failover. The VM should be in a *Protected* state.

The screenshot shows the Azure portal interface for a replicated item named "AdminVM1". The "Overview" tab is active. Key details shown include:

- Health and status:** Replication Health is "Healthy", Status is "Protected", RPO is "1 min [As on 10/1/2021, 7:35:56 PM]".
- Failover readiness:** Last successful Test Failover is "Never performed successfully". Configuration issues, Agent version (9.45.6096.1), and Agent status are all marked as "No issues".
- Action bar:** Includes buttons for Failover, Test Failover, Cleanup test failover, Commit, Resynchronize, Change recovery point, Re-protect, and a refresh icon.

3. On the overview page, select **Failover**. Since we're not doing a test failover this time, we're prompted to verify.

[Page showing we agree to run failover without a test failover](#)

4. In **Failover**, note the direction from secondary to primary, and select a recovery point. The Azure VM in the target (primary region) is created using data from this point.
  - **Latest processed:** Uses the latest recovery point processed by Site Recovery. The time stamp is

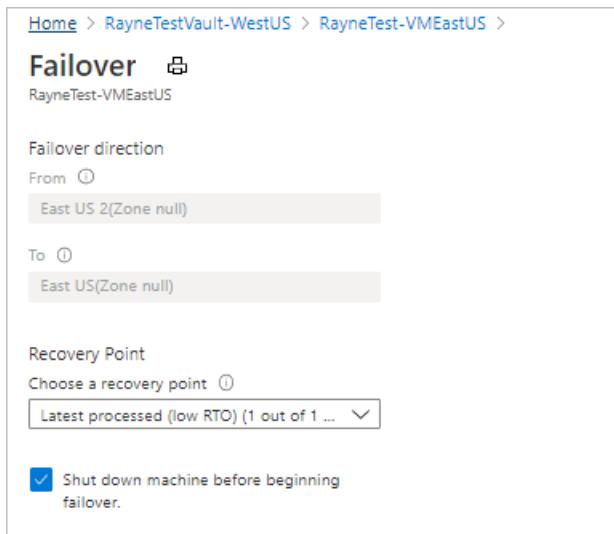

shown. No time is spent processing data, so it provides a low recovery time objective (RTO).

- **Latest**: Processes all the data sent to Site Recovery, to create a recovery point for each VM before failing over to it. Provides the lowest recovery point objective (RPO), because all data is replicated to Site Recovery when the failover is triggered.
- **Latest app-consistent**: This option fails over VMs to the latest app-consistent recovery point. The time stamp is shown.
- **Custom**: Fail over to particular recovery point. Custom is only available when you fail over a single VM, and don't use a recovery plan.

#### NOTE

If you fail over a VM to which you added a disk after you enabled replication for the VM, replication points will show the disks available for recovery. For example, a replication point that was created before you added a second disk will show as "1 of 2 disks".

5. Select **Shut down machine before beginning failover** if you want Site Recovery to attempt to shut down the source VMs before starting failover. Shutdown helps to ensure no data loss. Failover continues even if shutdown fails.

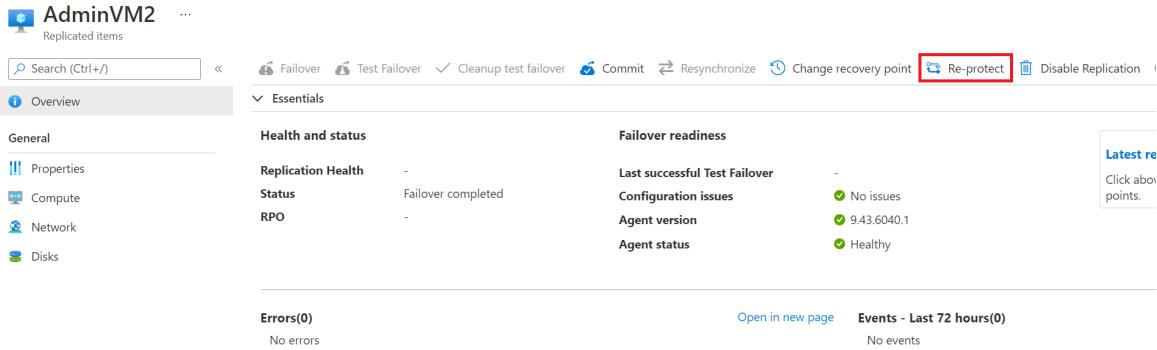

6. To start the failover, select OK.
7. Monitor the failover in notifications.

The first screenshot shows a 'Notifications' dialog box with one item: 'Starting Failover' (Running, 'The operation is in progress.' a few seconds ago). The second screenshot shows the same dialog box with the same item, but with a checkmark icon and the message 'Successfully completed the operation.'

# Reprotect VMs

After failing back VMs to the primary region, you need to reprotect them, so that they start replicating to the secondary region again.

1. In the **Overview** page for the VM, select **Re-protect**.

The screenshot shows the 'Overview' page for a replicated item named 'AdminVM2'. The top navigation bar includes buttons for Failover, Test Failover, Cleanup test failover, Commit, Resynchronize, Change recovery point, Re-protect (which is highlighted with a red box), and Disable Replication. The main content area is divided into sections: General, Health and status, Failover readiness, Errors(0), and Events - Last 72 hours(0). The 'Health and status' section shows Replication Health as 'Completed', Status as 'Failover completed', and RPO as '-'. The 'Failover readiness' section shows 'Last successful Test Failover' as '-' and 'Configuration issues' as 'No issues'. The 'Errors(0)' section indicates 'No errors' with a link to 'Open in new page'. The 'Events - Last 72 hours(0)' section indicates 'No events'.

2. Review the target settings for the primary region. Resources marked as new are created by Site Recovery as part of the reprotect operation.
3. Select **OK** to start the reprotect process. The process sends initial data to the target location, and then replicates delta information for the VMs to the target.

## Re-protect

eastus to eastus2

**!** If you are choosing General Purpose v2 storage accounts, ensure that operations and data transfer prices are understood clearly before you proceed. [Learn more](#)

Resource group, Network, Storage and Availability [Customize](#)

By default, Site Recovery will pick the original source resource group, virtual network, storage accounts and availability sets as below. Click 'Customize' above to change the configuration. The resources created are appended with "asr" suffix.

**Target resource group** ⓘ

RayneTest-EastUSRG-asr-1

**Target virtual network** ⓘ

RayneTest-EastUSRG-vnet-asr

**Cache storage accounts** ⓘ

qikc7eraynetestvasrcache

**Replica managed disks** ⓘ

(new) 1 premium disk(s), 0 standard disk(s)

**Target availability sets** ⓘ

Not Applicable

**OK**

4. Monitor reprotect progress in notifications.

## Clean up resources

For VMs with managed disks, after failback is complete and VMs are reprotected for replication from primary to secondary, Site Recovery automatically cleans up machines in the secondary disaster recovery region. You don't need to manually delete VMs and NICs in the secondary region. VMs with unmanaged disks aren't cleaned up.

If you completely disable replication after failing back, Site Recovery cleans up machines protected by it. In this case, it also cleans up disks for VMs that don't use managed disks.

## Next steps

In this tutorial, you failed VMs back from the secondary region to the primary. This is the last step in the process that includes enabling replication for a VM, trying out a disaster recovery drill, failing over from the primary region to the secondary, and finally failing back.

Now, try out disaster recovery to Azure for an [on-premises VM](#)

# Overview of VM restore points

9/21/2022 • 3 minutes to read • [Edit Online](#)

Business continuity and disaster recovery (BCDR) solutions are primarily designed to address site-wide data loss. Solutions that operate at this scale will often manage and execute automated failovers and failbacks across multiple regions. Azure VM restore points can be used to implement granular backup and retention policies.

You can protect your data and guard against extended downtime by creating virtual machine (VM) restore points at regular intervals. There are several backup options available for virtual machines (VMs), depending on your use-case. For more information, see [Backup and restore options for virtual machines in Azure](#).

## About VM restore points

An individual VM restore point is a resource that stores VM configuration and point-in-time application consistent snapshots of all the managed disks attached to the VM. You can use VM restore points to easily capture multi-disk consistent backups. VM restore points contain a disk restore point for each of the attached disks and a disk restore point consists of a snapshot of an individual managed disk.

VM restore points support application consistency for VMs running Windows operating systems and support file system consistency for VMs running Linux operating system. Application consistent restore points use VSS writers (or pre/post scripts for Linux) to ensure the consistency of the application data before a restore point is created. To get an application consistent restore point, the application running in the VM needs to provide a VSS writer (for Windows), or pre and post scripts (for Linux) to achieve application consistency.

VM restore points are organized into restore point collections. A restore point collection is an Azure Resource Management resource that contains the restore points for a specific VM. If you want to utilize ARM templates for creating restore points and restore point collections, visit the public [Virtual-Machine-Restore-Points](#) repository on GitHub.

The following image illustrates the relationship between restore point collections, VM restore points, and disk restore points.

VM restore points are incremental. The first restore point stores a full copy of all disks attached to the VM. For each successive restore point for a VM, only the incremental changes to your disks are backed up. To reduce your costs, you can optionally exclude any disk when creating a restore point for your VM.

## Restore points for VMs inside Virtual Machine Scale Set and Availability Set (AvSet)

Currently, restore points can only be created in one VM at a time, that is, you cannot create a single restore point across multiple VMs. Due to this limitation, we currently support creating restore points for individual VMs with

a Virtual Machine Scale Set and Availability Set. If you want to back up your entire Virtual Machine Scale Set instance or your Availability Set instance, you must individually create restore points for all the VMs that are part of the instance.

**NOTE**

Virtual Machine Scale Set with Unified orchestration is not supported by restore points. You cannot create restore points of VMs inside a Virtual Machine Scale Set with Unified orchestration.

## Limitations

- Restore points are supported only for managed disks.
- Ultra-disks, Ephemeral OS disks, and Shared disks are not supported.
- Restore points APIs require an API of version 2021-03-01 or later.
- A maximum of 500 VM restore points can be retained at any time for a VM, irrespective of the number of restore point collections.
- Concurrent creation of restore points for a VM is not supported.
- Movement of Virtual Machines (VM) between Resource Groups (RG), or Subscriptions is not supported when the VM has restore points. Moving the VM between Resource Groups or Subscriptions will not update the source VM reference in the restore point and will cause a mismatch of ARM IDs between the actual VM and the restore points.

**NOTE**

Public preview of cross-region creation and copying of VM restore points is available, with the following limitations:

- Private links are not supported when copying restore points across regions or creating restore points in a region other than the source VM.
- Customer-managed key encrypted restore points, when copied to a target region or created directly in the target region are created as platform-managed key encrypted restore points.

## Troubleshoot VM restore points

Most common restore points failures are attributed to the communication with the VM agent and extension, and can be resolved by following the troubleshooting steps listed in the [troubleshooting](#) article.

## Next steps

- [Create a VM restore point](#).
- [Learn more](#) about Backup and restore options for virtual machines in Azure.

# Quickstart: Create VM restore points using APIs

9/21/2022 • 2 minutes to read • [Edit Online](#)

You can protect your data by taking backups at regular intervals. Azure VM restore point APIs are a lightweight option you can use to implement granular backup and retention policies. VM restore points support application consistency for VMs running Windows operating systems and support file system consistency for VMs running Linux operating system.

You can use the APIs to create restore points for your source VM in either the same region, or in other regions. You can also copy existing VM restore points between regions.

## Prerequisites

- [Learn more](#) about the requirements for a VM restore point.
- Consider the [limitations](#) before creating a restore point.

## Create VM restore points

The following sections outline the steps you need to take to create VM restore points with the Azure Compute REST APIs.

You can find more information in the [Restore Points](#), [PowerShell](#), and [Restore Point Collections API](#) documentation.

### Step 1: Create a VM restore point collection

Before you create VM restore points, you must create a restore point collection. A restore point collection holds all the restore points for a specific VM. Depending on your needs, you can create VM restore points in the same region as the VM, or in a different region. To create a restore point collection, call the restore point collection's Create or Update API.

- If you're creating restore point collection in the same region as the VM, then specify the VM's region in the location property of the request body.
- If you're creating the restore point collection in a different region than the VM, specify the target region for the collection in the location property, but also specify the source restore point collection ARM resource ID in the request body.

To create a restore point collection, call the restore point collection's [Create or Update](#) API.

### Step 2: Create a VM restore point

After you create the restore point collection, the next step is to create a VM restore point within the restore point collection. For more information about restore point creation, see the [Restore Points - Create API](#) documentation.

#### TIP

To save space and costs, you can exclude any disk from either local region or cross-region VM restore points. To exclude a disk, add its identifier to the `excludeDisks` property in the request body.

### Step 3: Track the status of the VM restore point creation

Restore point creation in your local region will be completed within a few seconds. Scenarios, which involve the

creation of cross-region restore points will take considerably longer. To track the status of the creation operation, follow the guidance in [Get restore point copy or replication status](#). This is only applicable for scenarios where the restore points are created in a different region than the source VM.

## Get restore point copy or replication status

Creation of a cross-region VM restore point is a long running operation. The VM restore point can be used to restore a VM only after the operation is completed for all disk restore points. To track the operation's status, call the [Restore Point - Get](#) API on the target VM restore point and include the `instanceView` parameter. The return will include the percentage of data that has been copied at the time of the request.

During restore point creation, the `ProvisioningState` will appear as `Creating` in the response. If creation fails, `ProvisioningState` is set to `Failed`.

## Next steps

- [Learn more](#) about managing restore points.
- Create restore points using the [Azure portal](#), [CLI](#), or [PowerShell](#).
- [Learn more](#) about Backup and restore options for virtual machines in Azure.

# Manage VM restore points

9/21/2022 • 3 minutes to read • [Edit Online](#)

This article explains how to copy and restore a VM from a VM restore point and track the progress of the copy operation. This article also explains how to create a disk from a disk restore point and to create a shared access signature for a disk.

## Copy a VM restore point between regions

The VM restore point APIs can be used to restore a VM in a different region than the source VM. Use the following steps:

### Step 1: Create a destination VM restore point collection

To copy an existing VM restore point from one region to another, your first step is to create a restore point collection in the target or destination region. To do this, reference the restore point collection from the source region as detailed in [Create a VM restore point collection](#).

### Step 2: Create the destination VM restore point

After the restore point collection is created, trigger the creation of a restore point in the target restore point collection. Ensure that you've referenced the restore point in the source region that you want to copy and specified the source restore point's identifier in the request body. The source VM's location is inferred from the target restore point collection in which the restore point is being created. See the [Restore Points - Create API](#) documentation to create a `RestorePoint`.

### Step 3: Track copy status

To track the status of the copy operation, follow the guidance in the [Get restore point copy or replication status](#) section below. This is only applicable for scenarios where the restore points are copied to a different region than the source VM.

## Get restore point copy or replication status

Creation of a cross-region VM restore point is a long running operation. The VM restore point can be used to restore a VM only after the operation is completed for all disk restore points. To track the operation's status, call the [Restore Point - Get](#) API on the target VM restore point and include the `instanceView` parameter. The return will include the percentage of data that has been copied at the time of the request.

During restore point creation, the `ProvisioningState` will appear as `Creating` in the response. If creation fails, `ProvisioningState` is set to `Failed`.

## Create a disk using disk restore points

You can use the VM restore points APIs to restore a VM disk, which can then be used to create a new VM. Use the following steps:

### Step 1: Retrieve disk restore point identifiers

Call the [Restore Point Collections - Get](#) API on the restore point collection to get access to associated restore points and their IDs. Each VM restore point will in turn contain individual disk restore point identifiers.

### Step 2: Create a disk

After you have the list of disk restore point IDs, you can use the [Disks - Create Or Update](#) API to create a disk

from the disk restore points.

## Restore a VM with a restore point

To restore a full VM from a VM restore point, you must restore individual disks from each disk restore point. This process is described in the [Create a disk](#) section. After you restore all the disks, create a new VM and attach the restored disks to the new VM. You can also use the [ARM template](#) to restore a full VM along with all the disks.

## Get a shared access signature for a disk

To create a Shared Access Signature (SAS) for a disk within a VM restore point, pass the ID of the disk restore points via the `BeginGetAccess` API. If no active SAS exists on the restore point snapshot, a new SAS is created. The new SAS URL is returned in the response. If an active SAS already exists, the SAS duration is extended, and the pre-existing SAS URL is returned in the response.

For more information about granting access to snapshots, see the [Grant Access](#) API documentation.

## Next steps

[Learn more](#) about Backup and restore options for virtual machines in Azure.

# Create virtual machine restore points using Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

You can protect your data and guard against extended downtime by creating [VM restore points](#) at regular intervals. You can create VM restore points, and [exclude disks](#) while creating the restore point, using Azure CLI. Azure CLI is used to create and manage Azure resources using command line or scripts. Alternatively, you can create VM restore points using the [Azure portal](#) or using [PowerShell](#).

The [az restore-point](#) module is used to create and manage restore points from the command line or in scripts.

In this tutorial, you learn how to:

- [Create a VM restore point collection](#)
- [Create a VM restore point](#)
- [Track the progress of Copy operation](#)
- [Restore a VM](#)

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the [az login](#) command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run [az version](#) to find the version and dependent libraries that are installed. To upgrade to the latest version, run [az upgrade](#).
- Learn more about the [support requirements](#) and [limitations](#) before creating a restore point.

## Step 1: Create a VM restore point collection

Use the [az restore-point collection create](#) command to create a VM restore point collection, as shown below:

```
az restore-point collection create --location "norwayeast" --source-id "/subscriptions/{subscription-id}/resourceGroups/ExampleRg/providers/Microsoft.Compute/virtualMachines/ExampleVM" --tags myTag1="tagValue1" --resource-group "ExampleRg" --collection-name "ExampleRpc"
```

## Step 2: Create a VM restore point

Create a VM restore point with the [az restore-point create](#) command as follows:

```
az restore-point create --resource-group "ExampleRg" --collection-name "ExampleRpc" --name "ExampleRp"
```

### Exclude disks when creating a restore point

Exclude the disks that you do not want to be a part of the restore point with the `--exclude-disks` parameter, as follows:

```
az restore-point create --exclude-disks "/subscriptions/{subscription-id}/resourceGroups/ExampleRg/providers/Microsoft.Compute/disks/ExampleDisk1" --resource-group "ExampleRg" --collection-name "ExampleRpc" --name "ExampleRp"
```

## Step 3: Track the status of the VM restore point creation

Use the [az restore-point show](#) command to track the progress of the VM restore point creation.

```
az restore-point show --resource-group "ExampleRg" --collection-name "ExampleRpc" --name "ExampleRp"
```

## Restore a VM from VM restore point

To restore a VM from a VM restore point, first restore individual disks from each disk restore point. You can also use the [ARM template](#) to restore a full VM along with all the disks.

```
# Create Disks from disk restore points
$osDiskRestorePoint = az restore-point show --resource-group "ExampleRg" --collection-name "ExampleRpc" --name "ExampleRp" --query "sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"
$dataDisk1RestorePoint = az restore-point show --resource-group "ExampleRg" --collection-name "ExampleRpcTarget" --name "ExampleRpTarget" --query "sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"
$dataDisk2RestorePoint = az restore-point show --resource-group "ExampleRg" --collection-name "ExampleRpcTarget" --name "ExampleRpTarget" --query "sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"

az disk create --resource-group "ExampleRg" --name "ExampleOSDisk" --sku Premium_LRS --size-gb 128 --source $osDiskRestorePoint

az disk create --resource-group "ExampleRg" --name "ExampleDataDisk1" --sku Premium_LRS --size-gb 128 --source $dataDisk1RestorePoint

az disk create --resource-group "ExampleRg" --name "ExampleDataDisk1" --sku Premium_LRS --size-gb 128 --source $dataDisk2RestorePoint
```

Once you have created the disks, [create a new VM](#) and [attach these restored disks](#) to the newly created VM.

## Next steps

[Learn more](#) about Backup and restore options for virtual machines in Azure.

# Create virtual machine restore points using PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

## NOTE

To interact with Azure, the Azure Az PowerShell module is recommended. See [Install Azure PowerShell](#) to get started. To learn how to migrate to the Az PowerShell module, see [Migrate Azure PowerShell from AzureRM to Az](#).

You can create Virtual Machine restore points using PowerShell scripts. The [Azure PowerShell Az](#) module is used to create and manage Azure resources from the command line or in scripts.

You can protect your data and guard against extended downtime by creating [VM restore points](#) at regular intervals. This article shows you how to create VM restore points, and [exclude disks](#) from the restore point, using the [Az.Compute](#) module. Alternatively, you can create VM restore points using the [Azure CLI](#) or in the [Azure portal](#).

In this tutorial, you learn how to:

- [Create a VM restore point collection](#)
- [Create a VM restore point](#)
- [Track the progress of Copy operation](#)
- [Restore a VM](#)

## Prerequisites

- Learn more about the [support requirements](#) and [limitations](#) before creating a restore point.

## Step 1: Create a VM restore point collection

Use the [New-AzRestorePointCollection](#) cmdlet to create a VM restore point collection.

```
New-AzRestorePointCollection -ResourceGroupName ExampleRG -Name ExampleRPC -VmId  
"/subscriptions/{SubscriptionId}/resourcegroups/  
ExampleRG/providers/microsoft.compute/virtualmachines/Example-vm-1" -Location "WestEurope"
```

## Step 2: Create a VM restore point

Create a VM restore point with the [New-AzRestorePoint](#) cmdlet as shown below:

```
New-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName ExampleRPC -Name ExampleRP
```

### Exclude disks from the restore point

Exclude certain disks that you do not want to be a part of the restore point with the `-DisksToExclude` parameter, as follows:

```
New-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName ExampleRPC -Name ExampleRP -  
DisksToExclude "/subscriptions/{SubscriptionId}/resourcegroups/  
ExampleRG/providers/Microsoft.Compute/disks/example-vm-1-data_disk_1"
```

## Step 3: Track the status of the VM restore point creation

You can track the progress of the VM restore point creation using the [Get-AzRestorePoint](#) cmdlet, as follows:

```
Get-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName ExampleRPC -Name ExampleRP
```

## Restore a VM from VM restore point

To restore a VM from a VM restore point, first restore individual disks from each disk restore point. You can also use the [ARM template](#) to restore a full VM along with all the disks.

```
# Create Disks from disk restore points  
$restorePoint = Get-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName ExampleRPC -Name ExampleRP  
  
$osDiskRestorePoint = $restorePoint.SourceMetadata.StorageProfile.OsDisk.DiskRestorePoint.Id  
$dataDisk1RestorePoint = $restorePoint.sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id  
$dataDisk2RestorePoint = $restorePoint.sourceMetadata.storageProfile.dataDisks[1].diskRestorePoint.id  
  
New-AzDisk -DiskName "ExampleOSDisk" (New-AzDiskConfig -Location eastus -CreateOption Restore -  
SourceResourceId $osDiskRestorePoint) -ResourceGroupName ExampleRg  
  
New-AzDisk -DiskName "ExampleDataDisk1" (New-AzDiskConfig -Location eastus -CreateOption Restore -  
SourceResourceId $dataDisk1RestorePoint) -ResourceGroupName ExampleRg  
  
New-AzDisk -DiskName "ExampleDataDisk2" (New-AzDiskConfig -Location eastus -CreateOption Restore -  
SourceResourceId $dataDisk2RestorePoint) -ResourceGroupName ExampleRg
```

After you create the disks, [create a new VM](#) and [attach these restored disks](#) to the newly created VM.

## Next steps

[Learn more](#) about Backup and restore options for virtual machines in Azure.

# Create virtual machine restore points using Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

You can create virtual machine restore points through the Azure portal. You can protect your data and guard against extended downtime by creating [VM restore points](#) at regular intervals. This article shows you how to create VM restore points using the Azure portal. Alternatively, you can create VM restore points using the [Azure CLI](#) or using [PowerShell](#).

In this tutorial, you learn how to:

- [Create a VM restore point collection](#)
- [Create a VM restore point](#)
- [Track the progress of Copy operation](#)
- [Restore a VM](#)

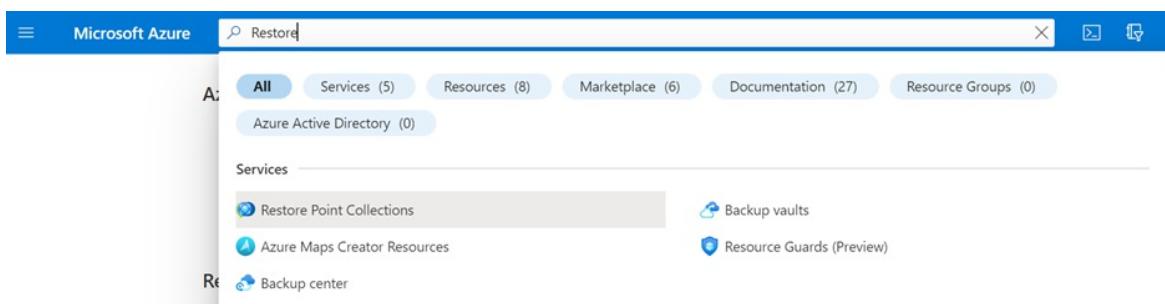

## Prerequisites

- Learn more about the [support requirements](#) and [limitations](#) before creating a restore point.

## Step 1: Create a VM restore point collection

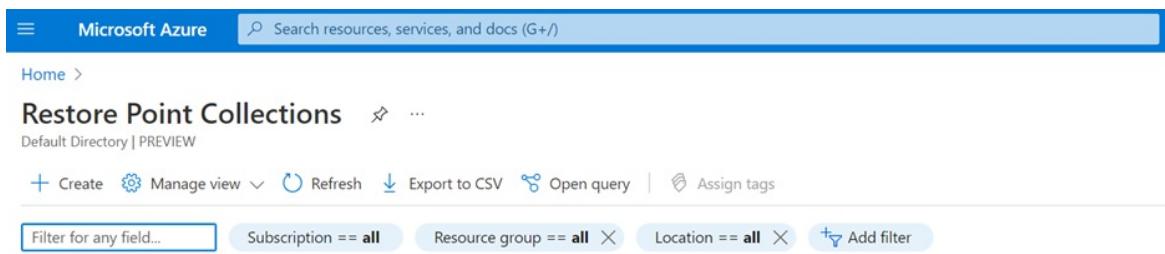

Use the following steps to create a VM restore points collection:

1. Sign in to the [Azure portal](#).
2. In the Search box, enter **Restore Point Collections**.

The screenshot shows the Microsoft Azure portal interface. At the top, there's a search bar with the word 'Restore'. Below the search bar, a navigation menu includes 'All', 'Services (5)', 'Resources (8)', 'Marketplace (6)', 'Documentation (27)', and 'Resource Groups (0)'. Under the 'Services' heading, there are several items: 'Restore Point Collections' (which is highlighted with a gray background), 'Backup vaults', 'Azure Maps Creator Resources', and 'Resource Guards (Preview)'. At the bottom of the list, there's a 'Backup center' item.

3. Select **+ Create** to create a new Restore Point Collection.

The screenshot shows the 'Restore Point Collections' blade in the Azure portal. At the top, there's a header with 'Home > Restore Point Collections' and a 'PREVIEW' note. Below the header, there are buttons for '+ Create', 'Manage view', 'Refresh', 'Export to CSV', 'Open query', and 'Assign tags'. There are also filters for 'Subscription', 'Resource group', and 'Location'. The main area displays a table of existing restore point collections, each with a name like 'Windows VM Backup' and a status like 'Success'.

4. Enter the details and select the VM for which you want to create a restore point collection.

## Create a restore point collection

Basics    Restore point    Tags    Review + create

A virtual machine restore point collection contains restore points specific to a virtual machine and each restore point contains disk restore points for each included disk. (if the VM is shutdown) or application consistent snapshot for all managed disks attached to a virtual machine.

## Step 2: Create a VM restore point

Use the following steps to create a VM restore point:

1. Navigate to the restore point collection where you want to create restore points and select + **Create a restore point** to create new restore point for the VM.

The screenshot shows the Azure portal interface for a 'Restore Point Collection' named 'Test-RPC-1'. The left sidebar has sections for Overview, Activity log, Access control (IAM), Tags, Settings, Restore Points, Properties, Locks, Automation, Tasks (preview), Export template, Support + troubleshooting, and New Support Request. The 'Overview' tab is selected. The main content area shows 'Essentials' details: Resource group (move) : eastus2euap, Location (move) : eastus2euap, Subscription (move) : Visual Studio Enterprise Subscription, Subscription ID : (redacted), and Status : Succeeded. Below this, there's a 'Tags (edit)' section with a link to 'Click here to add tags'. A 'Get started' button is followed by a 'Restore points' button, which is underlined, indicating it's the active section. A search bar shows 'Showing 1 of 1 restore points'. Under the search bar are 'Delete' and 'Restore points' buttons. A single restore point is listed with a checkbox next to it and the name 'Test-RPC-1-rp-2022-06-22-13-30-08'.

2. Enter a name for the restore point and other required details and select **Next: Disks >**.

## Create a restore point ...

# Support matrix for VM restore points

9/21/2022 • 3 minutes to read • [Edit Online](#)

This article summarizes the support matrix and limitations of using [VM restore points](#).

## VM restore points support matrix

The following table summarizes the support matrix for VM restore points.

SCENARIOS	SUPPORTED BY VM RESTORE POINTS
VMs using Managed disks	Yes
VMs using unmanaged disks	No
VMs using Ultra Disks	No. Exclude these disks and create a VM restore point.
VMs using Ephemeral OS Disks	No. Exclude these disks and create a VM restore point.
VMs using shared disks	No. Exclude these disks and create a VM restore point.
VMs with extensions	Yes
VMs with trusted launch	Yes
Confidential VMs	Yes
Generation 2 VMs (UEFI boot)	Yes
VMs with NVMe disks (Storage optimized - Lsv2-series)	Yes
VMs in Proximity placement groups	Yes
VMs in an availability set	Yes. You can create VM restore points for individual VMs within an availability set. You need to create restore points for all the VMs within an availability set to protect an entire availability set instance.
VMs inside VMSS with uniform orchestration	No
VMs inside VMSS with flexible orchestration	Yes. You can create VM restore points for individual VMs within the virtual machine scale set flex. However, you need to create restore points for all the VMs within the virtual machine scale set flex to protect an entire virtual machine scale set flex instance.
Spot VMs (Low priority VMs)	Yes
VMs with dedicated hosts	Yes

SCENARIOS	SUPPORTED BY VM RESTORE POINTS
VMs with Host caching enabled	Yes
VMs created from marketplace images	Yes
VMs created from custom images	Yes
VM with HUB (Hybrid Use Benefit) license	Yes
VMs migrated from on-prem using Azure Migrate	Yes
VMs with RBAC policies	Yes
Temporary disk in VMs	Yes. You can create VM restore point for VMs with temporary disks. However, the restore points created don't contain the data from the temporary disks.
VMs with standard HDDs	Yes
VMs with standard SSDs	Yes
VMs with premium SSDs	Yes
VMs with ZRS disks	Yes
VMs with server-side encryption using service-managed keys	Yes
VMs with server-side encryption using customer-managed keys	Yes
VMs with double encryption at rest	Yes
VMs with Host based encryption enabled with PMK/CMK/Double encryption	Yes
VMs with ADE (Azure Disk Encryption)	Yes
VMs using Accelerated Networking	Yes
Frequency supported	Three hours for app consistent restore points. One hour for <a href="#">crash consistent restore points (preview)</a>

## Operating system support

### Windows

The following Windows operating systems are supported when creating restore points for Azure VMs running on Windows.

- Windows 10 Client (64 bit only)
- Windows Server 2022 (Datacenter/Datacenter Core/Standard)
- Windows Server 2019 (Datacenter/Datacenter Core/Standard)

- Windows Server 2016 (Datacenter/Datacenter Core/Standard)
- Windows Server 2012 R2 (Datacenter/Standard)
- Windows Server 2012 (Datacenter/Standard)
- Windows Server 2008 R2 (RTM and SP1 Standard)
- Windows Server 2008 (64 bit only)

Restore points don't support 32-bit operating systems.

## Linux

For Azure VM Linux VMs, restore points support the list of Linux [distributions endorsed by Azure](#). Note the following:

- Restore points don't support Core OS Linux.
- Restore points don't support 32-bit operating systems.
- Other bring-your-own Linux distributions might work as long as the [Azure VM agent for Linux](#) is available on the VM, and as long as Python is supported.
- Restore points don't support a proxy-configured Linux VM if it doesn't have Python version 2.7 or higher installed.
- Restore points don't back up NFS files that are mounted from storage, or from any other NFS server, to Linux or Windows machines. It only backs up disks that are locally attached to the VM.

## Other limitations

- Restore points are supported only for managed disks.
- Ultra-disks, Ephemeral OS disks, and Shared disks aren't supported.
- Restore points APIs require an API of version 2021-03-01 or later.
- A maximum of 500 VM restore points can be retained at any time for a VM, irrespective of the number of restore point collections.
- Concurrent creation of restore points for a VM isn't supported.
- Movement of Virtual Machines (VM) between Resource Groups (RG), or Subscriptions isn't supported when the VM has restore points. Moving the VM between Resource Groups or Subscriptions won't update the source VM reference in the restore point and will cause a mismatch of ARM processor IDs between the actual VM and the restore points.

### NOTE

Public preview of cross-region creation and copying of VM restore points is available, with the following limitations:

- Private links aren't supported when copying restore points across regions or creating restore points in a region other than the source VM.
- Customer-managed key encrypted restore points, when copied to a target region or created directly in the target region are created as platform-managed key encrypted restore points.
- No portal support for cross region copy and cross region creation of restore points

## Next steps

- Learn how to create VM restore points using [CLI](#), [Azure portal](#), and [PowerShell](#).

# Troubleshoot restore point failures: Issues with the agent or extension

9/21/2022 • 19 minutes to read • [Edit Online](#)

This article provides troubleshooting steps that can help you resolve restore point errors related to communication with the VM agent and extension.

If your Azure issue is not addressed in this article, visit the Azure forums on [Microsoft Q & A and Stack Overflow](#). You can post your issue in these forums, or post to [@AzureSupport on Twitter](#). You also can submit an Azure support request. To submit a support request, on the [Azure support](#) page, select **Get support**.

## Step-by-step guide to troubleshoot restore point failures

Most common restore point failures can be resolved by following the troubleshooting steps listed below:

### Step 1: Check the health of Azure VM

- Ensure Azure VM provisioning state is 'Running': If the [VM provisioning state](#) is in the **Stopped/Deallocated/Updating** state, it interferes with the restore point operation. In the Azure portal, go to **Virtual Machines > Overview** and ensure the VM status is **Running** and retry the restore point operation.
- Review pending OS updates or reboots: Ensure there are no pending OS updates or pending reboots on the VM.

### Step 2: Check the health of Azure VM Guest Agent service

Ensure Azure VM Guest Agent service is started and up-to-date:

- On a Windows VM:
  - Navigate to **services.msc** and ensure **Windows Azure VM Guest Agent service** is up and running. Also, ensure the [latest version](#) is installed. [Learn more](#).
  - The Azure VM Agent is installed by default on any Windows VM deployed from an Azure Marketplace image from the portal, PowerShell, Command Line Interface, or an Azure Resource Manager template. A [manual installation of the Agent](#) may be necessary when you create a custom VM image that's deployed to Azure.
  - Review the support matrix to check if VM runs on the [supported Windows operating system](#).
- On Linux VM,
  - Ensure the Azure VM Guest Agent service is running by executing the command `ps -e`. Also, ensure the [latest version](#) is installed. [Learn more](#).
  - Ensure the [Linux VM agent dependencies on system packages](#) have the supported configuration. For example: Supported Python version is 2.6 and above.
  - Review the support matrix to check if VM runs on the [supported Linux operating system](#).

### Step 3: Check the health of Azure VM Extension

- Ensure all Azure VM Extensions are in 'provisioning succeeded' state: If any extension is in a failed state, then it can interfere with the restore point operation.
  - In the Azure portal, go to **Virtual machines > Settings > Extensions > Extensions status** and check if all the extensions are in **provisioning succeeded** state.
  - Ensure all [extension issues](#) are resolved and retry the restore point operation.
- Ensure COM+ System Application is up and running. Also, the **Distributed Transaction Coordinator**

service should be running as **Network Service account**.

Follow the troubleshooting steps in [troubleshoot COM+ and MSDTC issues](#) in case of issues.

#### Step 4: Check the health of Azure VM Snapshot Extension

Restore points use the VM Snapshot Extension to take an application consistent snapshot of the Azure virtual machine. Restore points install the extension as part of the first restore point creation operation.

- **Ensure VMSnapshot extension isn't in a failed state:** Follow the steps in [Troubleshooting](#) to verify and ensure the Azure VM snapshot extension is healthy.
- **Check if antivirus is blocking the extension:** Certain antivirus software can prevent extensions from executing.

At the time of the restore point failure, verify if there are log entries in **Event Viewer Application logs** with *faulting application name: IaaSBcdrExtension.exe*. If you see entries, the antivirus configured in the VM could be restricting the execution of the VMSnapshot extension. Test by excluding the following directories in the antivirus configuration and retry the restore point operation.

- C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot
- C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot

- **Check if network access is required:** Extension packages are downloaded from the Azure Storage extension repository and extension status uploads are posted to Azure Storage. [Learn more](#).
  - If you're on a non-supported version of the agent, you need to allow outbound access to Azure storage in that region from the VM.
  - If you've blocked access to 168.63.129.16 using the guest firewall or with a proxy, extensions will fail regardless of the above. Ports 80, 443, and 32526 are required. [Learn more](#).
- **Ensure DHCP is enabled inside the guest VM:** This is required to get the host or fabric address from DHCP for the restore point to work. If you need a static private IP, you should configure it through the [Azure portal](#), or [PowerShell](#) and make sure the DHCP option inside the VM is enabled. [Learn more](#).
- **Ensure the VSS writer service is up and running:** Follow these steps to [troubleshoot VSS writer issues](#).

## Common issues

### DiskRestorePointUsedByCustomer - There is an active shared access signature outstanding for disk restore point

**Error code:** DiskRestorePointUsedByCustomer

**Error message:** There is an active shared access signature outstanding for disk restore point. Call EndGetAccess before deleting the restore point.

You can't delete a restore point if there are active Shared Access Signatures (SAS) on any of the underlying disk restore points. End the shared access on the disk restore points and retry the operation.

### OperationNotAllowed - Changes were made to the Virtual Machine while the operation 'Create Restore Point' was in progress.

**Error code:** OperationNotAllowed

**Error message:** Changes were made to the Virtual Machine while the operation 'Create Restore Point' was in progress. Operation Create Restore Point cannot be completed at this time. Please try again later.

Restore point creation fails if there are changes being made in parallel to the VM model, for example, a new disk being attached or an existing disk being detached. This is to ensure data integrity of the restore point that is created. Retry creating the restore point once the VM model has been updated.

## **OperationNotAllowed - Operation 'Create Restore Point' is not allowed as disk(s) have not been allocated successfully.**

**Error code:** OperationNotAllowed

**Error message:** Operation 'Create Restore Point' is not allowed as disk(s) have not been allocated successfully. Please exclude these disk(s) using excludeDisks property and retry.

If any one of the disks attached to the VM isn't allocated properly, the restore point fails. You must exclude these disks before triggering creation of restore points for the VM. If you're using ARM processor API to create a restore point, to exclude a disk, add its identifier to the excludeDisks property in the request body. If you're using [CLI](#), [PowerShell](#), or [Portal](#), set the respective parameters.

## **OperationNotAllowed - Creation of Restore Point of a Virtual Machine with Shared disks is not supported.**

**Error code:** VMRestorePointClientError

**Error message:** Creation of Restore Point of a Virtual Machine with Shared disks is not supported. You may exclude this disk from the restore point via excludeDisks property.

Restore points are currently not supported for shared disks. You need to exclude these disks before triggering creation of restore point for the VM. If you are using ARM processor API to create restore point, to exclude a disk, add its identifier to the excludeDisks property in the request body. If you are using [CLI](#), [PowerShell](#), or [Portal](#), follow the respective steps.

## **VMAgentStatusCommunicationError - VM agent unable to communicate with compute service**

**Error code:** VMAgentStatusCommunicationError

**Error message:** VM has not reported status for VM agent or extensions.

The Azure VM agent might be stopped, outdated, in an inconsistent state, or not installed. These states prevent the creation of restore points.

- In the Azure portal, go to **Virtual Machines > Settings > Properties** and ensure that the **VM Status** is **Running** and **Agent status** is **Ready**. If the VM agent is stopped or is in an inconsistent state, restart the agent.
  - [Restart](#) the Guest Agent for Windows VMs.
  - [Restart](#) the Guest Agent for Linux VMs.
- In the Azure portal, go to **Virtual Machines > Settings > Extensions** and ensure all extensions are in **provisioning succeeded** state. If not, follow these [steps](#) to resolve the issue.

## **VMRestorePointInternalError - Restore Point creation failed due to an internal execution error while creating VM snapshot. Please retry the operation after some time.Internal**

**Error code:** VMRestorePointInternalError

**Error message:** Restore Point creation failed due to an internal execution error while creating VM snapshot. Please retry the operation after some time.

After you trigger a restore point operation, the compute service starts the job by communicating with the VM backup extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, restore point creation will fail. Complete the following troubleshooting steps in the order listed, and then retry your operation:

**Cause 1:** [The agent is installed in the VM, but it's unresponsive \(for Windows VMs\)](#)

**Cause 2:** [The agent installed in the VM is out of date \(for Linux VMs\)](#)

**Cause 3:** [The snapshot status can't be retrieved, or a snapshot can't be taken](#)

**Cause 4:** [VM-Agent configuration options aren't set \(for Linux VMs\)](#)

## Cause 5: Application control solution is blocking IaaSBcdrExtension.exe

This error could also occur when one of the extension failures puts the VM into provisioning failed state. If the above steps didn't resolve your issue, then do the following:

In the Azure portal, go to **Virtual Machines > Settings > Extensions** and ensure all extensions are in **provisioning succeeded** state. [Learn more](#) about Provisioning states.

- If any extension is in a failed state, it can interfere with the restore point operation. Ensure the extension issues are resolved and retry the restore point operation.
- If the VM provisioning state is in an updating state, it can interfere with the restore point operation. Ensure that it's healthy and retry the restore point operation.

## VMRestorePointClientError - Restore Point creation failed due to COM+ error.

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to COM+ error. Please restart windows service "COM+ System Application" (COMSysApp). If the issue persists, restart the VM.

Restore point operations fail if the COM+ service is not running or if there are any errors with this service. Restart the COM+ System Application, and restart the VM and retry the restore point operation.

## VMRestorePointClientError - Restore Point creation failed due to insufficient memory available in COM+ memory quota.

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to insufficient memory available in COM+ memory quota. Please restart windows service "COM+ System Application" (COMSysApp). If the issue persists, restart the VM.

Restore point operations fail if there's insufficient memory in the COM+ service. Restarting the COM+ System Application service and the VM usually frees up the memory. Once restarted, retry the restore point operation.

## VMRestorePointClientError - Restore Point creation failed due to VSS Writers in bad state.

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to VSS Writers in bad state. Restart VSS Writer services and reboot VM.

Restore point creation invokes VSS writers to flush in-memory IOs to the disk before taking snapshots to achieve application consistency. If the VSS writers are in bad state, it affects the restore point creation operation. Restart the VSS writer service and restart the VM before retrying the operation.

## VMRestorePointClientError - Restore Point creation failed due to failure in installation of Visual C++ Redistributable for Visual Studio 2012.

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to failure in installation of Visual C++ Redistributable for Visual Studio 2012. Please install Visual C++ Redistributable for Visual Studio 2012. If you are observing issues with installation or if it is already installed and you are observing this error, please restart the VM to clean installation issues.

Restore point operations require Visual C++ Redistributable for Visual Studio 2021. Download Visual C++ Redistributable for Visual Studio 2012 and restart the VM before retrying the restore point operation.

## VMRestorePointClientError - Restore Point creation failed as the maximum allowed snapshot limit of one or more disk blobs has been reached. Please delete some existing restore points of this VM and then retry.

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed as the maximum allowed snapshot limit of one or more disk blobs

has been reached. Please delete some existing restore points of this VM and then retry.

The number of restore points across the restore point collections and resource groups for a VM can't exceed 500. To create a new restore point, delete the existing restore points.

### **VMRestorePointClientError - Restore Point creation failed with the error "COM+ was unable to talk to the Microsoft Distributed Transaction Coordinator".**

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed with the error "COM+ was unable to talk to the Microsoft Distributed Transaction Coordinator".

Follow these steps to resolve this error:

- Open services.msc from an elevated command prompt
- Make sure that **Log On As** value for **Distributed Transaction Coordinator** service is set to **Network Service** and the service is running.
- If this service fails to start, reinstall this service.

### **VMRestorePointClientError - Restore Point creation failed due to inadequate VM resources.**

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to inadequate VM resources. Increase VM resources by changing the VM size and retry the operation. To resize the virtual machine, refer <https://azure.microsoft.com/blog/resize-virtual-machines/>.

Creating a restore point requires enough compute resource to be available. If you get the above error when creating a restore point, you need resize the VM and choose a higher VM size. Follow the steps in [how to resize your VM](#). Once the VM is resized, retry the restore point operation.

### **VMRestorePointClientError - Restore point creation failed due to no network connectivity on the virtual machine.**

**Error code:** VMRestorePointClientError

**Error message:** Restore Point creation failed due to no network connectivity on the virtual machine. Ensure that VM has network access. Either allowlist the Azure datacenter IP ranges or set up a proxy server for network access. For more information, see <https://go.microsoft.com/fwlink/?LinkId=800034>. If you are already using proxy server, make sure that proxy server settings are configured correctly.

After you trigger creation of restore point, the compute service starts communicating with the VM snapshot extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, a restore point failure might occur. Complete the following troubleshooting step, and then retry your operation:

[The snapshot status can't be retrieved, or a snapshot can't be taken].(#the-snapshot-status-can't-be-retrieved-or-a-snapshot-can't-be-taken)

### **VMRestorePointClientError - RestorePoint creation failed since a concurrent 'Create RestorePoint' operation was triggered on the VM.**

**Error code:** VMRestorePointClientError

**Error message:** RestorePoint creation failed since a concurrent 'Create RestorePoint' operation was triggered on the VM.

Your recent restore point creation failed because there's already an existing restore point being created. You can't create a new restore point until the current restore point is fully created. Ensure the restore point creation operation currently in progress is completed before triggering another restore point creation operation.

To check the restore points in progress, do the following steps:

1. Sign in to the Azure portal, select **All services**. Enter **Recovery Services** and select **Restore point collection**. The list of Restore point collections appears.
2. From the list of Restore point collections, select a Restore point collection in which the restore point is being created.
3. Select **Settings > Restore points** to view all the restore points. If a restore point is in progress, wait for it to complete.
4. Retry creating a new restore point.

**DiskRestorePointClientError - Keyvault associated with DiskEncryptionSet is not found.**

**Error code:** DiskRestorePointClientError

**Error message:** Keyvault associated with DiskEncryptionSet not found. The resource may have been deleted due to which Restore Point creation failed. Please retry the operation after re-creating the missing resource with the same name.

If you are creating restore points for a VM that has encrypted disks, you must ensure the keyvault where the keys are stored, is available. We use the same keys to create encrypted restore points.

**BadRequest - This request can be made with api-version '2021-03-01' or newer**

**Error code:** BadRequest

**Error message:** This request can be made with api-version '2022-03-01' or newer.

Restore points are supported only with API version 2022-03-01 or later. If you are using REST APIs to create and manage restore points, use the specified API version when calling the restore point API.

**InternalError / InternalExecutionError / InternalOperationError - An internal execution error occurred. Please retry later.**

**Error code:** InternalError / InternalExecutionError / InternalOperationError

**Error message:** An internal execution error occurred. Please retry later.

After you trigger creation of restore point, the compute service starts communicating with the VM snapshot extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, a restore point failure might occur. Complete the following troubleshooting steps in the order listed, and then retry your operation:

- Cause 1: [The agent is installed in the VM, but it's unresponsive \(for Windows VMs\)](#).
- Cause 2: [The agent installed in the VM is out of date \(for Linux VMs\)](#).
- Cause 3: [The snapshot status can't be retrieved, or a snapshot can't be taken](#).
- Cause 4: [Compute service does not have permission to delete the old restore points because of a resource group lock](#).
- Cause 5: There's an extension version/bits mismatch with the Windows version you're running, or the following module is corrupt:

C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot\<extension version>\iaasvmprovider.dll

To resolve this issue, check if the module is compatible with x86 (32-bit)/x64 (64-bit) version of *regsvr32.exe*, and then follow these steps:

1. In the affected VM, go to Control panel > Program and features.
2. Uninstall Visual C++ Redistributable x64 for Visual Studio 2013.
3. Reinstall Visual C++ Redistributable for Visual Studio 2013 in the VM. To install, follow these

steps:

- a. Go to the folder: C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot\<LatestVersion>.
- b. Search and run the vcredist2013\_x64 file to install.
4. Retry the restore point operation.

#### **OSProvisioningClientError - Restore points operation failed due to an error. For details, see restore point provisioning error Message details**

**Error code:** OSProvisioningClientError

**Error message:** OS Provisioning did not finish in the allotted time. This error occurred too many times consecutively from image. Make sure the image has been properly prepared (generalized).

This error is reported from the IaaS VM. Take necessary actions as described in the error message and retry the operation.

#### **AllocationFailed - Restore points operation failed due to an error. For details, see restore point provisioning error Message details**

**Error code:** AllocationFailed

**Error message:** Allocation failed. If you are trying to add a new VM to an Availability Set or update/resize an existing VM in an Availability Set, please note that such Availability Set allocation is scoped to a single cluster, and it is possible that the cluster is out of capacity. [Learn more](#) about improving likelihood of allocation success.

This error is reported from the IaaS VM. Take necessary actions as described in the error message and retry the operation.

## Causes and solutions

### **The agent is installed in the VM, but it's unresponsive (for Windows VMs)**

#### **Solution**

The VM agent might have been corrupted, or the service might have been stopped. Reinstalling the VM agent helps get the latest version. It also helps restart communication with the service.

1. Determine whether the Microsoft Azure Guest Agent service is running in the VM services (services.msc). Try to restart the Microsoft Azure Guest Agent service and initiate the restore point operation.
2. If the Microsoft Azure Guest Agent service isn't visible in services, in Control Panel, go to **Programs and Features** to determine whether the Microsoft Azure Guest Agent service is installed.
3. If the Microsoft Azure Guest Agent appears in **Programs and Features**, uninstall the Microsoft Azure Guest Agent.
4. Download and install the [latest version of the agent MSI](#). You must have Administrator rights to complete the installation.
5. Verify that the Microsoft Azure Guest Agent services appear in services.
6. Retry the restore point operation.

Also, verify that [Microsoft .NET 4.5 is installed](#) in the VM. .NET 4.5 is required for the VM agent to communicate with the service.

### **The agent installed in the VM is out of date (for Linux VMs)**

#### **Solution**

Most agent-related or extension-related failures for Linux VMs are caused by issues that affect an outdated VM agent. To troubleshoot this issue, follow these general guidelines:

1. Follow the instructions for [updating the Linux VM agent](#).

#### NOTE

We *strongly recommend* that you update the agent only through a distribution repository. We don't recommend downloading the agent code directly from GitHub and updating it. If the latest agent for your distribution is not available, contact distribution support for instructions on how to install it. To check for the most recent agent, go to the [Windows Azure Linux agent](#) page in the GitHub repository.

2. Ensure that the Azure agent is running on the VM by running the following command: `ps -e`

If the process isn't running, restart it by using the following commands:

- For Ubuntu: `service walinuxagent start`
- For other distributions: `service waagent start`

3. [Configure the auto restart agent](#).

4. Retry the restore point operation. If the failure persists, collect the following logs from the VM:

- `/var/lib/waagent/*.xml`
- `/var/log/waagent.log`
- `/var/log/azure/*`

If you require verbose logging for waagent, follow these steps:

1. In the `/etc/waagent.conf` file, locate the following line: **Enable verbose logging (y|n)**.
2. Change the **Logs.Verbose** value from *n* to *y*.
3. Save the change, and then restart waagent by completing the steps described earlier in this section.

#### VM-Agent configuration options are not set (for Linux VMs)

A configuration file (`/etc/waagent.conf`) controls the actions of waagent. Configuration File Options **Extensions.Enable** should be set to *y* and **Provisioning.Agent** should be set to **auto** for restore points to work. For the full list of VM-Agent Configuration File Options, see <https://github.com/Azure/WALinuxAgent#configuration-file-options>.

#### Application control solution is blocking IaaSBcdrExtension.exe

If you're running [AppLocker](#) (or another application control solution), and the rules are publisher or path based, they may block the **IaaSBcdrExtension.exe** executable from running.

#### Solution

Exclude the `/var/lib` path or the **IaaSBcdrExtension.exe** executable from AppLocker (or other application control software.)

#### The snapshot status can't be retrieved, or a snapshot can't be taken

Restore points rely on issuing a snapshot command to the underlying storage account. Restore point can fail either because it has no access to the storage account, or because the execution of the snapshot task is delayed.

#### Solution

The following conditions might cause the snapshot task to fail:

CAUSE	SOLUTION
The VM status is reported incorrectly because the VM is shut down in Remote Desktop Protocol (RDP).	If you shut down the VM in RDP, check the portal to determine whether the VM status is correct. If it's not correct, shut down the VM in the portal by using the <b>Shutdown</b> option on the VM dashboard.

CAUSE	SOLUTION
The VM can't get the host or fabric address from DHCP.	DHCP must be enabled inside the guest for restore point to work. If the VM can't get the host or fabric address from DHCP response 245, it can't download or run any extensions. If you need a static private IP, you should configure it through the <a href="#">Azure portal</a> , or <a href="#">PowerShell</a> and make sure the DHCP option inside the VM is enabled. <a href="#">Learn more</a> about setting up a static IP address with PowerShell.

## Remove lock from the recovery point resource group

1. Sign in to the [Azure portal](#).
2. Go to **All Resources**, select the restore point collection resource group.
3. In the **Settings** section, select **Locks** to display the locks.
4. To remove the lock, select **Delete**.

Lock name	Lock type	Scope	Notes
TestLock	Read-only	[Scope Icon]	

[Edit](#)  [Delete](#)

# Move a VM to another subscription or resource group

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article walks you through how to move a virtual machine (VM) between resource groups or subscriptions. Moving a VM between subscriptions can be handy if you created a VM in a personal subscription and now want to move it to your company's subscription.

## IMPORTANT

New resource IDs are created as part of the move. After the VM has been moved, you will need to update your tools and scripts to use the new resource IDs.

## Use the Azure CLI to move a VM

Before you can move your VM by using the Azure CLI, you need to make sure the source and destination subscriptions exist within the same tenant. To check that both subscriptions have the same tenant ID, use [az account show](#).

```
az account show --subscription mySourceSubscription --query tenantId
az account show --subscription myDestinationSubscription --query tenantId
```

If the tenant IDs for the source and destination subscriptions are not the same, you must contact [support](#) to move the resources to a new tenant.

To successfully move a VM, you need to move the VM and all its supporting resources. Use the [az resource list](#) command to list all the resources in a resource group and their IDs. It helps to pipe the output of this command to a file so you can copy and paste the IDs into later commands.

```
az resource list --resource-group "mySourceResourceGroup" --query "[].{Id:id}" --output table
```

The `table` output isn't available if you use `--interactive`. Change the output to another option like `json`.

To move a VM and its resources to another resource group, use [az resource move](#). The following example shows how to move a VM and the most common resources it requires. Use the `-ids` parameter and pass in a comma-separated list (without spaces) of IDs for the resources to move.

```

vm=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM
nic=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Network/networkInterfaces/myNIC
nsg=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Network/networkSecurityGroups/myNSG
pip=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Network/publicIPAddresses/myPublicIPAddress
vnet=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Network/virtualNetworks/myVNet
diag=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Storage/storageAccounts/mydiagnosticstorageaccount
storage=/subscriptions/mySourceSubscriptionID/resourceGroups/mySourceResourceGroup/providers/Microsoft.Storage/storageAccounts/mystorageaccountname

az resource move \
    --ids $vm $nic $nsg $pip $vnet $storage $diag \
    --destination-group "myDestinationResourceGroup"

```

If you want to move the VM and its resources to a different subscription, add the **--destination-subscriptionId** parameter to specify the destination subscription.

When you are asked to confirm that you want to move the specified resources, enter Y to confirm.

## Use the Azure portal to move a VM to a different subscription

You can move a VM and its associated resources to a different subscription by using the Azure portal.

1. Go to the [Azure portal](#) to manage the resource group containing the VM to move. Search for and select **Resource groups**.
2. Choose the resource group containing the VM that you would like to move.
3. At the top of the page for the resource group, select **Move** and then select **Move to another subscription**. The **Move resources** page opens.
4. Select each of the resources to move. In most cases, you should move all of the related resources that are listed.
5. Select the **Subscription** where you want the VM to be moved.
6. Select an existing **Resource group**, or enter a name to have a new resource group created.
7. When you are done, select that you understand that new resource IDs will be created and that the new IDs will need to be used with the VM after it is moved, and then select **OK**.

## Use the Azure portal to move a VM to another resource group

You can move a VM and its associated resources to another resource group by using the Azure portal.

1. Go to the [Azure portal](#) to manage the resource group containing the VM to move. Search for and select **Resource groups**.
2. Choose the resource group containing the VM that you would like to move.
3. At the top of the page for the resource group, select **Move** and then select **Move to another resource group**. The **Move resources** page opens.
4. Select each of the resources to move. In most cases, you should move all of the related resources that are listed.
5. Select an existing **Resource group**, or enter a name to have a new resource group created.
6. When you are done, select that you understand that new resource IDs will be created and that the new IDs will need to be used with the VM after it is moved, and then select **OK**.

## Next steps

You can move many different types of resources between resource groups and subscriptions. For more information, see [Move resources to a new resource group or subscription](#).

# Move a Windows VM to another Azure subscription or resource group

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article walks you through how to move a Windows virtual machine (VM) between resource groups or subscriptions. Moving between subscriptions can be handy if you originally created a VM in a personal subscription and now want to move it to your company's subscription to continue your work. You do not need to stop the VM in order to move it and it should continue to run during the move.

## IMPORTANT

New resource IDs are created as part of the move. After the VM has been moved, you will need to update your tools and scripts to use the new resource IDs.

## Use the Azure portal to move a VM to a different subscription

You can move a VM and its associated resources to a different subscription by using the Azure portal.

1. Go to the [Azure portal](#) to manage the resource group containing the VM to move. Search for and select **Resource groups**.
2. Choose the resource group containing the VM that you would like to move.
3. At the top of the page for the resource group, select **Move** and then select **Move to another subscription**. The **Move resources** page opens.
4. Select each of the resources to move. In most cases, you should move all of the related resources that are listed.
5. Select the **Subscription** where you want the VM to be moved.
6. Select an existing **Resource group**, or enter a name to have a new resource group created.
7. When you are done, select that you understand that new resource IDs will be created and that the new IDs will need to be used with the VM after it is moved, and then select **OK**.

## Use the Azure portal to move a VM to another resource group

You can move a VM and its associated resources to another resource group by using the Azure portal.

1. Go to the [Azure portal](#) to manage the resource group containing the VM to move. Search for and select **Resource groups**.
2. Choose the resource group containing the VM that you would like to move.
3. At the top of the page for the resource group, select **Move** and then select **Move to another resource group**. The **Move resources** page opens.
4. Select each of the resources to move. In most cases, you should move all of the related resources that are listed.
5. Select an existing **Resource group**, or enter a name to have a new resource group created.
6. When you are done, select that you understand that new resource IDs will be created and that the new IDs will need to be used with the VM after it is moved, and then select **OK**.

## Use PowerShell to move a VM

To move a virtual machine to another resource group, you need to make sure that you also move all of the dependent resources. To get a list with the resource ID of each of these resources, use the [Get-AzResource](#) cmdlet.

```
Get-AzResource -ResourceGroupName myResourceGroup | Format-table -wrap -Property ResourceId
```

You can use the output of the previous command to create a comma-separated list of resource IDs to [Move-AzResource](#) to move each resource to the destination.

```
Move-AzResource -DestinationResourceGroupName "myDestinationResourceGroup" `  
-ResourceId <myResourceId,myResourceId,myResourceId>
```

To move the resources to different subscription, include the **-DestinationSubscriptionId** parameter.

```
Move-AzResource -DestinationSubscriptionId "<myDestinationSubscriptionID>" `  
-DestinationResourceGroupName "<myDestinationResourceGroup>" `  
-ResourceId <myResourceId,myResourceId,myResourceId>
```

When you are asked to confirm that you want to move the specified resources, enter Y to confirm.

## Next steps

You can move many different types of resources between resource groups and subscriptions. For more information, see [Move resources to a new resource group or subscription](#).

# Move a Marketplace Azure Virtual Machine to another subscription

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

To move a Marketplace virtual machine to a different subscription, you must move the OS disk to that subscription and then recreate the virtual machine.

You don't need this procedure to move a data disk to a new subscription. Instead, create a new virtual machine in the new subscription from the Marketplace, then move and attach the data disk.

This script demonstrates three operations:

- Create a snapshot of an OS disk.
- Move the snapshot to a different subscription.
- Create a virtual machine based on that snapshot.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.

## Sample script

To move a Marketplace virtual machine to a different subscription, you must create a new virtual machine for the same Marketplace offer from the moved OS disk.

### NOTE

If the virtual machine plan is no longer available in the Marketplace, you can't use this procedure.

```
#!/bin/bash
# Set variable values before proceeding.
```

```

# Variables
sourceResourceGroup= Resource group for the current virtual machine
sourceSubscription= Subscription for the current virtual machine
vmName= Name of the current virtual machine

destinationResourceGroup= Resource group for the new virtual machine, create if necessary
destinationSubscription= Subscription for the new virtual machine

# Set your current subscription for the source virtual machine
az account set --subscription $sourceSubscription

# Load variables about your virtual machine
# osType = windows or linux
osType=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--name $vmName --subscription $sourceSubscription \
--query 'storageProfile.osDisk.osType' --output tsv)

# offer = Your offer in Marketplace
offer=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--name $vmName --query 'storageProfile.imageReference.offer' --output tsv)

# plan = Your plan in Marketplace
plan=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--name $vmName --query 'plan' --output tsv)

# publisher = Your publisher in Marketplace
publisher=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--name $vmName --query 'storageProfile.imageReference.publisher' --output tsv)

# Get information to create new virtual machine
planName=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--subscription $sourceSubscription --query 'plan.name' --name $vmName)
planProduct=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--subscription $sourceSubscription --query 'plan.product' --name $vmName)
planPublisher=$(az vm get-instance-view --resource-group $sourceResourceGroup \
--subscription $sourceSubscription --query 'plan.publisher' --name $vmName)

# Get the name of the OS disk
osDiskName=$(az vm show --resource-group $sourceResourceGroup --name $vmName \
--query 'storageProfile.osDisk.name' --output tsv)

# Verify the terms for your market virtual machine
az vm image terms show --offer $offer --plan '$plan' --publisher $publisher \
--subscription $sourceSubscription

# Deallocate the virtual machine
az vm deallocate --resource-group $sourceResourceGroup --name $vmName

# Create a snapshot of the OS disk
az snapshot create --resource-group $sourceResourceGroup --name MigrationSnapshot \
--source
"/subscriptions/$sourceSubscription/resourceGroups/$sourceResourceGroup/providers/Microsoft.Compute/disks/$o
sDiskName"

# Move the snapshot to your destination resource group
az resource move --destination-group $destinationResourceGroup \
--destination-subscription-id $destinationSubscription \
--ids
"/subscriptions/$sourceSubscription/resourceGroups/$sourceResourceGroup/providers/Microsoft.Compute/snapshot
s/MigrationSnapshot"

# Set your subscription to the destination value
az account set --subscription $destinationSubscription

# Accept the terms from the Marketplace
az vm image terms accept --offer $offer --plan '$plan' --publisher $publisher \
--subscription $destinationSubscription

# Create disk from the snapshot

```

```
az disk create --resource-group $destinationResourceGroup --name DestinationDisk \
    --source
"/subscriptions/$destinationSubscription/resourceGroups/$destinationResourceGroup/providers/Microsoft.Compute/snapshots/MigrationSnapshot" \
    --os-type $osType

# Create virtual machine from disk
az vm create --resource-group $destinationResourceGroup --name $vmName \
    --plan-name $planName --plan-product $planProduct --plan-publisher $planPublisher \
    --attach-os-disk
"/subscriptions/$destinationSubscription/resourceGroups/$destinationResourceGroup/providers/Microsoft.Compute/disks/DestinationDisk" \
    --os-type $osType
```

## Clean up resources

After the sample has been run, use the following commands to remove the resource groups and all associated resources:

```
az group delete --name $sourceResourceGroup --subscription $sourceSubscription
az group delete --name $destinationResourceGroup --subscription $destinationSubscription
```

## Azure CLI references used in this article

## Next steps

- [Move VMs to another Azure region](#)
- [Move a VM to another subscription or resource group](#)

# Move VMs to another Azure region

9/21/2022 • 7 minutes to read • [Edit Online](#)

There are scenarios in which you'd want to move your existing Azure IaaS virtual machines (VMs) from one region to another. For example, you want to improve reliability and availability of your existing VMs, to improve manageability, or to move for governance reasons. For more information, see the [Azure VM move overview](#).

You can use [Azure Site Recovery](#) service to move Azure VMs to a secondary region.

In this tutorial, you learn how to:

- Verify prerequisites for the move
- Prepare the source VMs and the target region
- Copy the data and enable replication
- Test the configuration and perform the move
- Delete the resources in the source region

## IMPORTANT

To move Azure VMs to another region, we now recommend using [Azure Resource Mover](#). Resource Mover is in public preview and provides:

- A single hub for moving resources across regions.
- Reduced move time and complexity. Everything you need is in a single location.
- A simple and consistent experience for moving different types of Azure resources.
- An easy way to identify dependencies across resources you want to move. This helps you to move related resources together, so that everything works as expected in the target region, after the move.
- Automatic cleanup of resources in the source region, if you want to delete them after the move.
- Testing. You can try out a move, and then discard it if you don't want to do a full move.

## NOTE

This tutorial shows you how to move Azure VMs from one region to another as is. If you need to improve availability by moving VMs in an availability set to zone pinned VMs in a different region, see the [Move Azure VMs into Availability Zones tutorial](#).

## Prerequisites

- Make sure that the Azure VMs are in the Azure region from which you want to move.
- Verify that your choice of [source region - target region combination is supported](#), and make an informed decision about the target region.
- Make sure that you understand the [scenario architecture and components](#).
- Review the [support limitations and requirements](#).
- Verify account permissions. If you created your free Azure account, you're the administrator of your subscription. If you're not the subscription administrator, work with the administrator to assign the permissions that you need. To enable replication for a VM and essentially copy data by using Azure Site Recovery, you must have:

- Permissions to create a VM in Azure resources. The Virtual Machine Contributor built-in role has these permissions, which include:
  - Permission to create a VM in the selected resource group
  - Permission to create a VM in the selected virtual network
  - Permission to write to the selected storage account
- Permissions to manage Azure Site Recovery operations. The Site Recovery Contributor role has all the permissions that are required to manage Site Recovery operations in a Recovery Services vault.
- Make sure that all the latest root certificates are on the Azure VMs that you want to move. If the latest root certificates aren't on the VM, security constraints will prevent the data copy to the target region.
- For Windows VMs, install all the latest Windows updates on the VM, so that all the trusted root certificates are on the machine. In a disconnected environment, follow the standard Windows Update and certificate update processes for your organization.
- For Linux VMs, follow the guidance provided by your Linux distributor to get the latest trusted root certificates and certificate revocation list on the VM.
- Make sure that you're not using an authentication proxy to control network connectivity for VMs that you want to move.
- If the VM that you're trying to move doesn't have access to the internet, or it's using a firewall proxy to control outbound access, [check the requirements](#).
- Identify the source networking layout and all the resources that you're currently using. This includes but isn't limited to load balancers, network security groups (NSGs), and public IPs.
- Verify that your Azure subscription allows you to create VMs in the target region that's used for disaster recovery. Contact support to enable the required quota.
- Make sure that your subscription has enough resources to support VMs with sizes that match your source VMs. If you're using Site Recovery to copy data to the target, Site Recovery chooses the same size or the closest possible size for the target VM.
- Make sure that you create a target resource for every component that's identified in the source networking layout. This step is important to ensure that your VMs have all the functionality and features in the target region that you had in the source region.

**NOTE**

Azure Site Recovery automatically discovers and creates a virtual network when you enable replication for the source VM. You can also pre-create a network and assign it to the VM in the user flow for enable replication. As mentioned later, you need to manually create any other resources in the target region.

To create the most commonly used network resources that are relevant for you based on the source VM configuration, see the following documentation:

- [Network security groups](#)
- [Load balancers](#)
- [Public IP](#)
- For any other networking components, see the [networking documentation](#).

## Prepare

The following steps shows how to prepare the virtual machine for the move using Azure Site Recovery as a solution.

### Create the vault in any region, except the source region

1. Sign in to the [Azure portal](#)
2. In search, type Recovery Services > click Recovery Services vaults
3. In Recovery Services vaults menu, click +Add.
4. In **Name**, specify the friendly name **ContosoVMVault**. If you have more than one subscription, select the appropriate one.
5. Create the resource group **ContosoRG**.
6. Specify an Azure region. To check supported regions, see geographic availability in [Azure Site Recovery pricing details](#).
7. In **Recovery Services vaults**, select **ContosoVMVault** > **Replicated items** > +Replicate.
8. In the dropdown, select **Azure Virtual Machines**.
9. In **Source location**, select the source Azure region where your VMs are currently running.
10. Select the Resource Manager deployment model. Then select the **Source subscription** and **Source resource group**.
11. Select **OK** to save the settings.

### Enable replication for Azure VMs and start copying the data

Site Recovery retrieves a list of the VMs that are associated with the subscription and resource group.

1. In the next step, select the VM that you want to move, then select **OK**.
2. In **Settings**, select **Disaster recovery**.
3. In **Configure disaster recovery** > **Target region**, select the target region to which you'll replicate.
4. For this tutorial, accept the other default settings.
5. Select **Enable replication**. This step starts a job to enable replication for the VM.

## Move

The following steps shows how to perform the move to the target region.

1. Go to the vault. In **Settings** > **Replicated items**, select the VM, and then select **Failover**.
2. In **Failover**, select **Latest**.
3. Select **Shut down machine before beginning failover**. Site Recovery attempts to shut down the source VM before triggering the failover. Failover continues even if shutdown fails. You can follow the failover progress on the **Jobs** page.
4. After the job is finished, check that the VM appears in the target Azure region as expected.

## Discard

In case you checked the moved VM and need to make changes to point of failover or want to go back to a previous point, in the **Replicated items**, right-select the VM > **Change recovery point**. This step provides you the option to specify a different recovery point and failover to that one.

## Commit

Once you have checked the moved VM and are ready to commit the change, in the **Replicated items**, right-select the VM > **Commit**. This step finishes the move process to the target region. Wait until the commit job finishes.

## Clean up

The following steps will guide you through how to clean up the source region as well as related resources that were used for the move.

For all resources that were used for the move:

- Go to the VM. Select **Disable Replication**. This step stops the process from copying the data for the VM.

### IMPORTANT

It's important to perform this step to avoid being charged for Azure Site Recovery replication.

If you have no plans to reuse any of the source resources, complete these additional steps:

1. Delete all the relevant network resources in the source region that you identified in [prerequisites](#).
2. Delete the corresponding storage account in the source region.

## Next steps

In this tutorial, you moved an Azure VM to a different Azure region. Now you can configure disaster recovery for the VM that you moved.

[Set up disaster recovery after migration](#)

# Move Azure VMs into Availability Zones

9/21/2022 • 8 minutes to read • [Edit Online](#)

This article describes how to move Azure VMs to an availability zone in a different region. If you want to move to a different zone in the same region, [review this article](#).

Availability Zones in Azure help protect your applications and data from datacenter failures. Each Availability Zone is made up of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there's a minimum of three separate zones in all enabled regions. The physical separation of Availability Zones within a region helps protect applications and data from datacenter failures. With Availability Zones, Azure offers a service-level agreement (SLA) of 99.99% for uptime of virtual machines (VMs). Availability Zones are supported in select regions, as mentioned in [Regions that support Availability Zones](#).

In a scenario where your VMs are deployed as *single instance* into a specific region, and you want to improve your availability by moving these VMs into an Availability Zone, you can do so by using Azure Site Recovery. This action can further be categorized into:

- Move single-instance VMs into Availability Zones in a target region
- Move VMs in an availability set into Availability Zones in a target region

## IMPORTANT

To move Azure VMs to an availability zone in a different region, we now recommend using [Azure Resource Mover](#). Resource Mover is in public preview and provides:

- A single hub for moving resources across regions.
- Reduced move time and complexity. Everything you need is in a single location.
- A simple and consistent experience for moving different types of Azure resources.
- An easy way to identify dependencies across resources you want to move. This helps you to move related resources together, so that everything works as expected in the target region, after the move.
- Automatic cleanup of resources in the source region, if you want to delete them after the move.
- Testing. You can try out a move, and then discard it if you don't want to do a full move.

## Check prerequisites

- Check whether the target region has [support for Availability Zones](#). Check that your choice of [source region/target region combination is supported](#). Make an informed decision on the target region.
- Make sure that you understand the [scenario architecture and components](#).
- Review the [support limitations and requirements](#).
- Check account permissions. If you just created your free Azure account, you're the admin of your subscription. If you aren't the subscription admin, work with the admin to assign the permissions you need. To enable replication for a VM and eventually copy data to the target by using Azure Site Recovery, you must have:
  1. Permission to create a VM in Azure resources. The *Virtual Machine Contributor* built-in role has these permissions, which include:
    - Permission to create a VM in the selected resource group
    - Permission to create a VM in the selected virtual network

- Permission to write to the selected storage account
2. Permission to manage Azure Site Recovery tasks. The *Site Recovery Contributor* role has all permissions required to manage Site Recovery actions in a Recovery Services vault.

## Prepare the source VMs

1. Your VMs should use managed disks if you want to move them to an Availability Zone by using Site Recovery. You can convert existing Windows VMs that use unmanaged disks to use managed disks. Follow the steps at [Convert a Windows virtual machine from unmanaged disks to managed disks](#). Ensure that the availability set is configured as *managed*.
2. Check that all the latest root certificates are present on the Azure VMs you want to move. If the latest root certificates aren't present, the data copy to the target region can't be enabled because of security constraints.
3. For Windows VMs, install all the latest Windows updates on the VM, so that all the trusted root certificates are on the machine. In a disconnected environment, follow the standard Windows update and certificate update processes for your organization.
4. For Linux VMs, follow the guidance provided by your Linux distributor to get the latest trusted root certificates and certificate revocation list on the VM.
5. Make sure you don't use an authentication proxy to control network connectivity for VMs that you want to move.
6. Verify [outbound connectivity requirements for VMs](#).
7. Identify the source networking layout and the resources you currently use for verification, including load balancers, NSGs, and public IP.

## Prepare the target region

1. Check that your Azure subscription lets you create VMs in the target region used for disaster recovery. If necessary, contact support to enable the required quota.
2. Make sure your subscription has enough resources to support VMs with sizes that match your source VMs. If you use Site Recovery to copy data to the target, it picks the same size or the closest possible size for the target VM.
3. Create a target resource for every component identified in the source networking layout. This action ensures that after you cut over to the target region, your VMs have all the functionality and features that you had in the source.

### NOTE

Azure Site Recovery automatically discovers and creates a virtual network and storage account when you enable replication for the source VM. You can also pre-create these resources and assign to the VM as part of the enable replication step. But for any other resources, as mentioned later, you need to manually create them in the target region.

The following documents tell how to create the most commonly used network resources that are relevant to you, based on the source VM configuration.

- [Network security groups](#)
- [Load balancers](#)
- [Public IP](#)

For any other networking components, refer to the networking [documentation](#).

**IMPORTANT**

Ensure that you use a zone-redundant load balancer in the target. You can read more at [Standard Load Balancer and Availability Zones](#).

4. Manually [create a non-production network](#) in the target region if you want to test the configuration before you cut over to the target region. We recommend this approach because it causes minimal interference with the production environment.

## Enable replication

The following steps will guide you when using Azure Site Recovery to enable replication of data to the target region, before you eventually move them into Availability Zones.

**NOTE**

These steps are for a single VM. You can extend the same to multiple VMs. Go to the Recovery Services vault, select + **Replicate**, and select the relevant VMs together.

1. In the Azure portal, select **Virtual machines**, and select the VM you want to move into Availability Zones.
2. In **Operations**, select **Disaster recovery**.
3. In **Configure disaster recovery > Target region**, select the target region to which you'll replicate. Ensure this region [supports](#) Availability Zones.
4. Select **Next: Advanced settings**.
5. Choose the appropriate values for the target subscription, target VM resource group, and virtual network.
6. In the **Availability** section, choose the Availability Zone into which you want to move the VM.

**NOTE**

If you don't see the option for availability set or Availability Zone, ensure that the [prerequisites](#) are met and the [preparation](#) of source VMs is complete.

7. Select **Enable Replication**. This action starts a job to enable replication for the VM.

## Check settings

After the replication job has finished, you can check the replication status, modify replication settings, and test the deployment.

1. In the VM menu, select **Disaster recovery**.
2. You can check replication health, the recovery points that have been created and the source, and target regions on the map.

## Test the configuration

1. In the virtual machine menu, select **Disaster recovery**.

2. Select the **Test Failover** icon.
3. In **Test Failover**, select a recovery point to use for the failover:
  - **Latest processed**: Fails the VM over to the latest recovery point that was processed by the Site Recovery service. The time stamp is shown. With this option, no time is spent processing data, so it provides a low recovery time objective (RTO).
  - **Latest app-consistent**: This option fails over all VMs to the latest app-consistent recovery point. The time stamp is shown.
  - **Custom**: Select any recovery point.
4. Select the test target Azure virtual network to which you want to move the Azure VMs to test the configuration.

**IMPORTANT**

We recommend that you use a separate Azure VM network for the test failure, and not the production network in the target region into which you want to move your VMs.

5. To start testing the move, select **OK**. To track progress, select the VM to open its properties. Or, you can select the **Test Failover** job in the vault name > **Settings** > **Jobs** > **Site Recovery jobs**.
6. After the failover finishes, the replica Azure VM appears in the Azure portal > **Virtual Machines**. Make sure that the VM is running, sized appropriately, and connected to the appropriate network.
7. If you want to delete the VM created as part of testing the move, select **Cleanup test failover** on the replicated item. In **Notes**, record and save any observations associated with the test.

## Move to the target region and confirm

1. In the virtual machine menu, select **Disaster recovery**.
2. Select the **Failover** icon.
3. In **Failover**, select **Latest**.
4. Select **Shut down machine before beginning failover**. Site Recovery attempts to shut down the source VM before triggering the failover. Failover continues even if shutdown fails. You can follow the failover progress on the **Jobs** page.
5. After the job is finished, check that the VM appears in the target Azure region as expected.
6. In **Replicated items**, right-click the VM > **Commit**. This finishes the move process to the target region. Wait until the commit job is finished.

## Discard the resource in the source region

Go to the VM. Select **Disable Replication**. This action stops the process of copying the data for the VM.

**IMPORTANT**

Do the preceding step to avoid getting charged for Site Recovery replication after the move. The source replication settings are cleaned up automatically. Note that the Site Recovery extension that is installed as part of the replication isn't removed and needs to be removed manually.

## Next steps

In this tutorial, you increased the availability of an Azure VM by moving into an availability set or Availability Zone. Now you can set disaster recovery for the moved VM.

Set up disaster recovery after migration

# Move a Maintenance Control configuration to another region

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Follow this article to move a Maintenance Control configuration to a different Azure region. You might want to move a configuration for a number of reasons. For example, to take advantage of a new region, to deploy features or services available in a specific region, to meet internal policy and governance requirements, or in response to capacity planning.

[Maintenance control](#), with customized maintenance configurations, allows you to control how platform updates are applied to VMs, and to Azure Dedicated Hosts. There are a couple of scenarios for moving maintenance control across regions:

- To move your maintenance control configuration, but not the resources associated with the configuration, follow the instructions in this article.
- To move the resources associated with a maintenance configuration, but not the configuration itself, follow [these instructions](#).
- To move both the maintenance configuration and the resources associated with it, first follow the instructions in this article. Then, follow [these instructions](#).

## Prerequisites

Before you begin moving a maintenance control configuration:

- Maintenance configurations are associated with Azure VMs or Azure Dedicated Hosts. Make sure that VM/host resources exist in the new region before you begin.
- Identify:
  - Existing maintenance control configurations.
  - The resource groups in which existing configurations currently reside.
  - The resource groups to which the configurations will be added after moving to the new region.
  - The resources associated with the maintenance configuration you want to move.
  - Check that the resources in the new region are the same as those associated with the current maintenance configurations. The configurations can have the same names in the new region as they did in the old, but this isn't required.

## Prepare and move

1. Retrieve all of the maintenance configurations in each subscription. Run the CLI [az maintenance configuration list](#) command to do this, replacing \$subId with your subscription ID.

```
az maintenance configuration list --subscription $subId --query "[*].{Name:name, Location:location, ResGroup:resourceGroup}" --output table
```

2. Review the returned table list of configuration records within the subscription. Here's an example. Your list will contain values for your specific environment.

NAME	LOCATION	RESOURCE GROUP
Skip Maintenance	eastus2	configuration-resource-group
IgniteDemoConfig	eastus2	configuration-resource-group
defaultMaintenanceConfiguration-eastus	eastus	test-configuration

3. Save your list for reference. As you move the configurations, it helps you to verify that everything's been moved.
4. As a reference, map each configuration/resource group to the new resource group in the new region.
5. Create new maintenance configurations in the new region using [PowerShell](#), or [CLI](#).
6. Associate the configurations with the resources in the new region, using [PowerShell](#), or [CLI](#).

## Verify the move

After moving the configurations, compare configurations and resources in the new region with the table list you prepared.

## Clean up source resources

After the move, consider deleting the moved maintenance configurations in the source region, [PowerShell](#), or [CLI](#).

## Next steps

Follow [these instructions](#) if you need to move resources associated with maintenance configurations.

# Move resources in a Maintenance Control configuration to another region

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Follow this article to move resources associated with a Maintenance Control configuration to a different Azure region. You might want to move a configuration for a number of reasons. For example, to take advantage of a new region, to deploy features or services available in a specific region, to meet internal policy and governance requirements, or in response to capacity planning.

[Maintenance control](#), with customized maintenance configurations, allows you to control how platform updates are applied to VMs, and to Azure Dedicated Hosts. There are a couple of scenarios for moving maintenance control across regions:

- To move the resources associated with a maintenance configuration, but not the configuration itself, follow this article.
- To move your maintenance control configuration, but not the resources associated with the configuration, follow [these instructions](#).
- To move both the maintenance configuration and the resources associated with it, first follow [these instructions](#). Then, follow the instructions in this article.

## Prerequisites

Before you begin moving the resources associated with a Maintenance Control configuration:

- Make sure that the resources you're moving exist in the new region before you begin.
- Verify the Maintenance Control configurations associated with the Azure VMs and Azure Dedicated Hosts that you want to move. Check each resource individually. There's currently no way to retrieve configurations for multiple resources.
- When retrieving configurations for a resource:
  - Make sure you use the subscription ID for the account, not an Azure Dedicated Host ID.
  - CLI: The --output table parameter is used for readability only, and can be deleted or changed.
  - PowerShell: The Format-Table Name parameter is used for readability only, and can be deleted or changed.
  - If you use PowerShell, you get an error if you try to list configurations for a resource that doesn't have any associated configurations. The error will be similar to: "Operation failed with status: 'Not Found'. Details: 404 Client Error: Not Found for url".

## Prepare to move

1. Before you start, define these variables. We've provided an example for each.

VARIABLE	DETAILS	EXAMPLE
\$subId	ID for subscription containing the maintenance configurations	"our-subscription-ID"
\$srcGroupName	Resource group name (Azure VM)	"VMResourceGroup"

VARIABLE	DETAILS	EXAMPLE
\$vmName	VM resource name	"myVM"
\$adhRsrcGroupName	Resource group (Dedicated hosts)	"HostResourceGroup"
\$adh	Dedicated host name	"myHost"
\$adhParentName	Parent resource name	"HostGroup"

2. To retrieve the maintenance configurations using the PowerShell [Get-AZConfigurationAssignment](#) command:

- For Azure Dedicated Hosts, run:

```
Get-AzConfigurationAssignment -ResourceGroupName $adhRsrcGroupName -ResourceName $adh -  
ResourceType hosts -ProviderName Microsoft.Compute -ResourceParentName $adhParentName -  
ResourceParentType hostGroups | Format-Table Name
```

- For Azure VMs, run:

```
Get-AzConfigurationAssignment -ResourceGroupName $rgName -ResourceName $vmName -ProviderName  
Microsoft.Compute -ResourceType virtualMachines | Format-Table Name
```

3. To retrieve the maintenance configurations using the CLI [az maintenance assignment](#) command:

- For Azure Dedicated Hosts:

```
az maintenance assignment list --subscription $subId --resource-group $adhRsrcGroupName --  
resource-name $adh --resource-type hosts --provider-name Microsoft.Compute --resource-parent-  
name $adhParentName --resource-parent-type hostGroups --query "[].  
{HostResourceGroup:resourceGroup,ConfigName:name}" --output table
```

- For Azure VMs:

```
az maintenance assignment list --subscription $subId --provider-name Microsoft.Compute --  
resource-group $rsrcGroupName --resource-name $vmName --resource-type virtualMachines --query  
"[].{HostResourceGroup:resourceGroup, ConfigName:name}" --output table
```

## Move

1. [Follow these instructions](#) to move the Azure VMs to the new region.
2. After the resources are moved, reapply maintenance configurations to the resources in the new region as appropriate, depending on whether you moved the maintenance configurations. You can apply a maintenance configuration to a resource using [PowerShell](#) or [CLI](#).

## Verify the move

Verify resources in the new region, and verify associated configurations for the resources in the new region.

## Clean up source resources

After the move, consider deleting the moved resources in the source region.

## Next steps

Follow [these instructions](#) if you need to move maintenance configurations.

# Migrate from Amazon Web Services (AWS) and other platforms to managed disks in Azure

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

You can upload VHD files from AWS or on-premises virtualization solutions to Azure to create virtual machines (VMs) that use managed disks. Azure managed disks removes the need to manage storage accounts for Azure IaaS VMs. You just specify the type of disk, and the size of that disk that you need, and Azure creates and manages the disk for you.

You can upload either generalized and specialized VHDs.

- **Generalized VHD** - has had all of your personal account information removed using Sysprep.
- **Specialized VHD** - maintains the user accounts, applications, and other state data from your original VM.

## IMPORTANT

Before uploading any VHD to Azure, you should follow [Prepare a Windows VHD or VHDX to upload to Azure](#)

SCENARIO	DOCUMENTATION
You have existing AWS EC2 instances that you would like to migrate to Azure VMs using managed disks	<a href="#">Move a VM from Amazon Web Services (AWS) to Azure</a>
You have a VM from another virtualization platform that you would like to use as an image to create multiple Azure VMs.	<a href="#">Upload a generalized VHD and use it to create a new VM in Azure</a>
You have a uniquely customized VM that you would like to recreate in Azure.	<a href="#">Upload a specialized VHD to Azure and create a new VM</a>

## Overview of managed disks

Azure managed disks simplifies VM management by removing the need to manage storage accounts. Managed disks also benefit from better reliability of VMs in an Availability Set. It ensures that the disks of different VMs in an Availability Set are sufficiently isolated from each other to avoid a single point of failure. It automatically places disks of different VMs in an Availability Set in different Storage scale units (stamps) which limits the impact of single Storage scale unit failures caused due to hardware and software failures. Based on your needs, you can choose from four types of storage options. To learn about the available disk types, see our article [Select a disk type](#).

## Plan for the migration to managed disks

This section helps you to make the best decision on VM and disk types.

If you are planning on migrating from unmanaged disks to managed disks, you should be aware that users with the [Virtual Machine Contributor](#) role will not be able to change the VM size (as they could pre-conversion). This is because VMs with managed disks require the user to have the Microsoft.Compute/disks/write permission on the OS disks.

## Location

Pick a location where Azure managed disks are available. If you are migrating to premium SSDs, also ensure that premium storage is available in the region where you are planning to migrate to. See [Azure Services by Region](#) for up-to-date information on available locations.

## VM sizes

If you are migrating to premium SSDs, you have to update the size of the VM to premium storage capable size available in the region where VM is located. Review the VM sizes that are premium storage capable. The Azure VM size specifications are listed in [Sizes for virtual machines](#). Review the performance characteristics of virtual machines that work with premium storage and choose the most appropriate VM size that best suits your workload. Make sure that there is sufficient bandwidth available on your VM to drive the disk traffic.

## Disk sizes

For information on available disk types and sizes, see [What disk types are available in Azure?](#).

## Disk caching policy

### Premium Managed Disks

By default, disk caching policy is *Read-Only* for all the Premium data disks, and *Read-Write* for the Premium operating system disk attached to the VM. This configuration setting is recommended to achieve the optimal performance for your application's IOs. For write-heavy or write-only data disks (such as SQL Server log files), disable disk caching so that you can achieve better application performance.

## Pricing

Review the [pricing for managed disks](#).

## Next Steps

- Before uploading any VHD to Azure, you should follow [Prepare a Windows VHD or VHDX to upload to Azure](#)

# Move a Windows VM from Amazon Web Services (AWS) to an Azure virtual machine

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

If you are evaluating Azure virtual machines for hosting your workloads, you can export an existing Amazon Web Services (AWS) EC2 Windows VM instance then upload the virtual hard disk (VHD) to Azure. Once the VHD is uploaded, you can create a new VM in Azure from the VHD.

This article covers moving a single VM from AWS to Azure. If you want to move VMs from AWS to Azure at scale, see [Migrate virtual machines in Amazon Web Services \(AWS\) to Azure with Azure Site Recovery](#).

## Prepare the VM

You can upload both generalized and specialized VHDs to Azure. Each type requires that you prepare the VM before exporting from AWS.

- **Generalized VHD** - a generalized VHD has had all of your personal account information removed using Sysprep. If you intend to use the VHD as an image to create new VMs from, you should:
  - [Prepare a Windows VM](#).
  - Generalize the virtual machine using Sysprep.
- **Specialized VHD** - a specialized VHD maintains the user accounts, applications and other state data from your original VM. If you intend to use the VHD as-is to create a new VM, ensure the following steps are completed.
  - [Prepare a Windows VHD to upload to Azure](#). **Do not** generalize the VM using Sysprep.
  - Remove any guest virtualization tools and agents that are installed on the VM (i.e. VMware tools).
  - Ensure the VM is configured to pull its IP address and DNS settings via DHCP. This ensures that the server obtains an IP address within the VNet when it starts up.

## Export and download the VHD

Export the EC2 instance to a VHD in an Amazon S3 bucket. Follow the steps in the Amazon documentation article [Exporting an Instance as a VM Using VM Import/Export](#) and run the `create-instance-export-task` command to export the EC2 instance to a VHD file.

The exported VHD file is saved in the Amazon S3 bucket you specify. The basic syntax for exporting the VHD is below, just replace the placeholder text in <brackets> with your information.

```
aws ec2 create-instance-export-task --instance-id <instanceID> --target-environment Microsoft \
--export-to-s3-task DiskImageFormat=VHD,ContainerFormat=ova,S3Bucket=<bucket>,S3Prefix=<prefix>
```

Once the VHD has been exported, follow the instructions in [How Do I Download an Object from an S3 Bucket?](#) to download the VHD file from the S3 bucket.

**IMPORTANT**

AWS charges data transfer fees for downloading the VHD. See [Amazon S3 Pricing](#) for more information.

## Next steps

Now you can upload the VHD to Azure and create a new VM.

- If you ran Sysprep on your source to **generalize** it before exporting, see [Upload a generalized VHD and use it to create a new VMs in Azure](#)
- If you did not run Sysprep before exporting, the VHD is considered **specialized**, see [Upload a specialized VHD to Azure and create a new VM](#)
- Secure the VM using the Defender for Servers plan, which is part of [Microsoft Defender for Cloud](#).

# Create a Linux VM from a custom disk with the Azure CLI

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This article shows you how to upload a customized virtual hard disk (VHD), and how to copy an existing VHD in Azure. The newly created VHD is then used to create new Linux virtual machines (VMs). You can install and configure a Linux distro to your requirements and then use that VHD to create a new Azure virtual machine.

To create multiple VMs from your customized disk, first create an image from your VM or VHD. For more information, see [Create a custom image of an Azure VM by using the CLI](#).

You have two options to create a custom disk:

- Upload a VHD
- Copy an existing Azure VM

## Requirements

To complete the following steps, you'll need:

- A Linux virtual machine that has been prepared for use in Azure. The [Prepare the VM](#) section of this article covers how to find distro-specific information on installing the Azure Linux Agent (waagent), which is needed for you to connect to a VM with SSH.
- The VHD file from an existing [Azure-endorsed Linux distribution](#) (or see [information for non-endorsed distributions](#)) to a virtual disk in the VHD format. Multiple tools exist to create a VM and VHD:
  - Install and configure [QEMU](#) or [KVM](#), taking care to use VHD as your image format. If needed, you can [convert an image](#) with `qemu-img convert`.
  - You can also use Hyper-V [on Windows 10](#) or [on Windows Server 2012/2012 R2](#).

### NOTE

The newer VHDX format is not supported in Azure. When you create a VM, specify VHD as the format. If needed, you can convert VHDX disks to VHD with `qemu-img convert` or the [Convert-VHD](#) PowerShell cmdlet. Azure does not support uploading dynamic VHDs, so you'll need to convert such disks to static VHDs before uploading. You can use tools such as [Azure VHD Utilities for GO](#) to convert dynamic disks during the process of uploading them to Azure.

- Make sure that you have the latest [Azure CLI](#) installed and you are signed in to an Azure account with `az login`.

In the following examples, replace example parameter names with your own values, such as `myResourceGroup`, `mystorageaccount`, and `mydisks`.

## Prepare the VM

Azure supports various Linux distributions (see [Endorsed Distributions](#)). The following articles describe how to prepare the various Linux distributions that are supported on Azure:

- [CentOS-based Distributions](#)

- [Debian Linux](#)
- [Oracle Linux](#)
- [Red Hat Enterprise Linux](#)
- [SLES & openSUSE](#)
- [Ubuntu](#)
- [Others: Non-Endorsed Distributions](#)

Also see the [Linux Installation Notes](#) for more general tips on preparing Linux images for Azure.

#### **NOTE**

The [Azure platform SLA](#) applies to VMs running Linux only when one of the endorsed distributions is used with the configuration details as specified under "Supported Versions" in [Linux on Azure-Endorsed Distributions](#).

## Option 1: Upload a VHD

You can now upload VHD straight into a managed disk. For instructions, see [Upload a VHD to Azure using Azure CLI](#).

## Option 2: Copy an existing VM

You can also create a customized VM in Azure and then copy the OS disk and attach it to a new VM to create another copy. This is fine for testing, but if you want to use an existing Azure VM as the model for multiple new VMs, create an *image* instead. For more information about creating an image from an existing Azure VM, see [Create a custom image of an Azure VM by using the CLI](#).

If you want to copy an existing VM to another region, you might want to use azcopy to [create a copy of a disk in another region](#).

Otherwise, you should take a snapshot of the VM and then create a new OS VHD from the snapshot.

### Create a snapshot

This example creates a snapshot of a VM named *myVM* in resource group *myResourceGroup* and creates a snapshot named *osDiskSnapshot*.

```
osDiskId=$(az vm show -g myResourceGroup -n myVM --query "storageProfile.osDisk.managedDisk.id" -o tsv)
az snapshot create \
    -g myResourceGroup \
    --source "$osDiskId" \
    --name osDiskSnapshot
```

### Create the managed disk

Create a new managed disk from the snapshot.

Get the ID of the snapshot. In this example, the snapshot is named *osDiskSnapshot* and it is in the *myResourceGroup* resource group.

```
snapshotId=$(az snapshot show --name osDiskSnapshot --resource-group myResourceGroup --query [id] -o tsv)
```

Create the managed disk. In this example, we will create a managed disk named *myManagedDisk* from our snapshot, where the disk is in standard storage and sized at 128 GB.

```
az disk create \
    --resource-group myResourceGroup \
    --name myManagedDisk \
    --sku Standard_LRS \
    --size-gb 128 \
    --source $snapshotId
```

## Create the VM

Create your VM with [az vm create](#) and attach (--attach-os-disk) the managed disk as the OS disk. The following example creates a VM named *myNewVM* using the managed disk you created from your uploaded VHD:

```
az vm create \
    --resource-group myResourceGroup \
    --location eastus \
    --name myNewVM \
    --os-type linux \
    --attach-os-disk myManagedDisk
```

You should be able to SSH into the VM with the credentials from the source VM.

## Next steps

After you have prepared and uploaded your custom virtual disk, you can read more about [using Resource Manager and templates](#). You may also want to [add a data disk](#) to your new VMs. If you have applications running on your VMs that you need to access, be sure to [open ports and endpoints](#).

# Migrating to Azure

9/21/2022 • 2 minutes to read • [Edit Online](#)

For migration, we recommend that you use the Azure Migrate service to migrate VMs and servers to Azure, rather than the Azure Site Recovery service. [Learn more](#) about Azure Migrate.

## Why use Azure Migrate?

Using Azure Migrate for migration provides a number of advantages:

- Azure Migrate provides a centralized hub for discovery, assessment, and migration to Azure.
- Using Azure Migrate provides interoperability and future extensibility with Azure Migrate tools, other Azure services, and third-party tools.
- The Azure Migrate:Server Migration tool is purpose-built for server migration to Azure. It's optimized for migration. You don't need to learn about concepts and scenarios that aren't directly relevant to migration.
- There are no tool usage charges for migration for 180 days, from the time replication is started for a VM. This gives you time to complete migration. You only pay for the storage and network resources used in replication, and for compute charges consumed during test migrations.
- Azure Migrate supports all migration scenarios supported by Site Recovery. In addition, for VMware VMs, Azure Migrate provides an agentless migration option.
- We're prioritizing new migration features for the Azure Migrate:Server Migration tool only. These features aren't targeted for Site Recovery.

## When to use Site Recovery?

Site Recovery should be used:

- For disaster recovery of on-premises machines to Azure.
- For disaster recovery of Azure VMs, between Azure regions.

Although we recommend using Azure Migrate to migrate on-premises servers to Azure, if you've already started your migration journey with Site Recovery, you can continue using it to complete your migration.

## Next steps

[Review common questions](#) about Azure Migrate.

# Use infrastructure automation tools with virtual machines in Azure

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

To create and manage Azure virtual machines (VMs) in a consistent manner at scale, some form of automation is typically desired. There are many tools and solutions that allow you to automate the complete Azure infrastructure deployment and management lifecycle. This article introduces some of the infrastructure automation tools that you can use in Azure. These tools commonly fit in to one of the following approaches:

- Automate the configuration of VMs
  - Tools include [Ansible](#), [Chef](#), [Puppet](#), and [Azure Resource Manager template](#).
  - Tools specific to VM customization include [cloud-init](#) for Linux VMs, [PowerShell Desired State Configuration \(DSC\)](#), and the [Azure Custom Script Extension](#) for all Azure VMs.
- Automate infrastructure management
  - Tools include [Packer](#) to automate custom VM image builds, and [Terraform](#) to automate the infrastructure build process.
  - [Azure Automation](#) can perform actions across your Azure and on-premises infrastructure.
- Automate application deployment and delivery
  - Examples include [Azure DevOps Services](#) and [Jenkins](#).

## Ansible

[Ansible](#) is an automation engine for configuration management, VM creation, or application deployment. Ansible uses an agent-less model, typically with SSH keys, to authenticate and manage target machines. Configuration tasks are defined in playbooks, with a number of Ansible modules available to carry out specific tasks. For more information, see [How Ansible works](#).

Learn how to:

- [Install and configure Ansible on Linux for use with Azure](#).
- [Create a Linux virtual machine](#).
- [Manage a Linux virtual machine](#).

## Chef

[Chef](#) is an automation platform that helps define how your infrastructure is configured, deployed, and managed. Additional components included Chef Habitat for application lifecycle automation rather than the infrastructure, and Chef InSpec that helps automate compliance with security and policy requirements. Chef Clients are installed on target machines, with one or more central Chef Servers that store and manage the configurations. For more information, see [An Overview of Chef](#).

Learn how to:

- [Deploy Chef Automate from the Azure Marketplace](#).
- [Install Chef on Windows and create Azure VMs](#).

## Puppet

Puppet is an enterprise-ready automation platform that handles the application delivery and deployment process. Agents are installed on target machines to allow Puppet Master to run manifests that define the desired configuration of the Azure infrastructure and VMs. Puppet can integrate with other solutions such as Jenkins and GitHub for an improved devops workflow. For more information, see [How Puppet works](#).

Learn how to:

- [Deploy Puppet](#).

## Cloud-init

Cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. Because cloud-init is called during the initial boot process, there are no additional steps or required agents to apply your configuration. For more information on how to properly format your `#cloud-config` files, see the [cloud-init documentation site](#).

`#cloud-config` files are text files encoded in base64.

Cloud-init also works across distributions. For example, you don't use `apt-get install` or `yum install` to install a package. Instead you can define a list of packages to install. Cloud-init automatically uses the native package management tool for the distro you select.

We are actively working with our endorsed Linux distro partners in order to have cloud-init enabled images available in the Azure Marketplace. These images make your cloud-init deployments and configurations work seamlessly with VMs and virtual machine scale sets. Learn more details about cloud-init on Azure:

- [Cloud-init support for Linux virtual machines in Azure](#)
- [Try a tutorial on automated VM configuration using cloud-init](#).

## PowerShell DSC

PowerShell Desired State Configuration (DSC) is a management platform to define the configuration of target machines. DSC can also be used on Linux through the [Open Management Infrastructure \(OMI\) server](#).

DSC configurations define what to install on a machine and how to configure the host. A Local Configuration Manager (LCM) engine runs on each target node that processes requested actions based on pushed configurations. A pull server is a web service that runs on a central host to store the DSC configurations and associated resources. The pull server communicates with the LCM engine on each target host to provide the required configurations and report on compliance.

Learn how to:

- [Create a basic DSC configuration](#).
- [Configure a DSC pull server](#).
- [Use DSC for Linux](#).

## Azure Custom Script Extension

The Azure Custom Script Extension for [Linux](#) or [Windows](#) downloads and executes scripts on Azure VMs. You can use the extension when you create a VM, or any time after the VM is in use.

Scripts can be downloaded from Azure storage or any public location such as a GitHub repository. With the Custom Script Extension, you can write scripts in any language that runs on the source VM. These scripts can be used to install applications or configure the VM as desired. To secure credentials, sensitive information such as passwords can be stored in a protected configuration. These credentials are only decrypted inside the VM.

Learn how to:

- [Create a Linux VM with the Azure CLI and use the Custom Script Extension.](#)
- [Create a Windows VM with Azure PowerShell and use the Custom Script Extension.](#)

## Packer

[Packer](#) automates the build process when you create a custom VM image in Azure. You use Packer to define the OS and run post-configuration scripts that customize the VM for your specific needs. Once configured, the VM is then captured as a Managed Disk image. Packer automates the process to create the source VM, network and storage resources, run configuration scripts, and then create the VM image.

Learn how to:

- [Use Packer to create a Linux VM image in Azure.](#)
- [Use Packer to create a Windows VM image in Azure.](#)

## Terraform

[Terraform](#) is an automation tool that allows you to define and create an entire Azure infrastructure with a single template format language - the HashiCorp Configuration Language (HCL). With Terraform, you define templates that automate the process to create network, storage, and VM resources for a given application solution. You can use your existing Terraform templates for other platforms with Azure to ensure consistency and simplify the infrastructure deployment without needing to convert to an Azure Resource Manager template.

Learn how to:

- [Install and configure Terraform with Azure.](#)
- [Create an Azure infrastructure with Terraform.](#)

## Azure Automation

[Azure Automation](#) uses runbooks to process a set of tasks on the VMs you target. Azure Automation is used to manage existing VMs rather than to create an infrastructure. Azure Automation can run across both Linux and Windows VMs, as well as on-premises virtual or physical machines with a hybrid runbook worker. Runbooks can be stored in a source control repository, such as GitHub. These runbooks can then run manually or on a defined schedule.

Azure Automation also provides a Desired State Configuration (DSC) service that allows you to create definitions for how a given set of VMs should be configured. DSC then ensures that the required configuration is applied and the VM stays consistent. Azure Automation DSC runs on both Windows and Linux machines.

Learn how to:

- [Create a PowerShell runbook.](#)
- [Use Hybrid Runbook Worker to manage on-premises resources.](#)
- [Use Azure Automation DSC.](#)

## Azure DevOps Services

[Azure DevOps Services](#) is a suite of tools that help you share and track code, use automated builds, and create a complete continuous integration and development (CI/CD) pipeline. Azure DevOps Services integrates with Visual Studio and other editors to simplify usage. Azure DevOps Services can also create and configure Azure VMs and then deploy code to them.

Learn more about:

- [Azure DevOps Services](#).

## Jenkins

[Jenkins](#) is a continuous integration server that helps deploy and test applications, and create automated pipelines for code delivery. There are hundreds of plugins to extend the core Jenkins platform, and you can also integrate with many other products and solutions through webhooks. You can manually install Jenkins on an Azure VM, run Jenkins from within a Docker container, or use a pre-built Azure Marketplace image.

Learn how to:

- [Create a development infrastructure on a Linux VM in Azure with Jenkins, GitHub, and Docker](#).

## Azure Resource Manager template

[Azure Resource Manager](#) is the deployment and management service for Azure. It provides a management layer that enables you to create, update, and delete resources in your Azure subscription. You use management features, like access control, locks, and tags, to secure and organize your resources after deployment.

Learn how to:

- [Deploy Spot VMs using a Resource Manager template](#).
- [Create a Windows virtual machine from a Resource Manager template](#).
- [Download the template for a VM](#).
- [Create an Azure Image Builder template](#).

## Next steps

There are many different options to use infrastructure automation tools in Azure. You have the freedom to use the solution that best fits your needs and environment. To get started and try some of the tools built-in to Azure, see how to automate the customization of a [Linux](#) or [Windows](#) VM.

# User Data for Azure Virtual Machine

9/21/2022 • 3 minutes to read • [Edit Online](#)

User data allows you to pass your own scripts or metadata to your virtual machine.

## What is "user data"

User data is a set of scripts or other metadata, that will be inserted to an Azure virtual machine at provision time. Any application on the virtual machine can access the user data from the Azure Instance Metadata Service (IMDS) after provision.

User data is a new version of [custom data](#) and it offers added benefits:

- User data can be retrieved from Azure Instance Metadata Service(IMDS) after provision.
- User data is persistent. It will be available during the lifetime of the VM.
- User data can be updated from outside the VM, without stopping or rebooting the VM.
- User data can be queried via GET VM/VMSS API with \$expand option.

In addition, if user data is not added at provision time, you can still add it after provision.

### Security warning

#### WARNING

User data will not be encrypted, and any process on the VM can query this data. You should not store confidential information in user data.

Make sure you get the latest Azure Resource Manager API to use the new user data features. The contents should be base64 encoded before passed to the API. The size cannot exceed 64 KB.

## Create user data for Azure VM/VMSS

### Adding user data when creating new VM

Use [this Azure Resource Manager template](#) to create a new VM with user data. If you are using rest API, for single VMs, add 'UserData' to the "properties" section with the PUT request to create the VM.

```
{
  "name": "testVM",
  "location": "West US",
  "properties": {
    "hardwareProfile": {
      "vmSize": "Standard_A1"
    },
    "storageProfile": {
      "osDisk": {
        "osType": "Windows",
        "name": "osDisk",
        "createOption": "Attach",
        "vhd": {
          "uri": "http://myaccount.blob.core.windows.net/container/directory/blob.vhd"
        }
      }
    },
    "userData": "c2FtcGxlIHVzZXJEYXRh",
    "networkProfile": { "networkInterfaces" : [ { "name" : "nic1" } ] },
  }
}
```

## Adding user data when you create new virtual machine scale set

Using rest API, add 'UserData' to the "virtualMachineProfile" section with the PUT request when creating the virtual machine scale set.

```
{
  "location": "West US",
  "sku": {
    "name": "Standard_A1",
    "capacity": 1
  },
  "properties": {
    "upgradePolicy": {
      "mode": "Automatic"
    },
    "virtualMachineProfile": {
      "userData": "VXNlckRhdGE=",
      "osProfile": {
        "computerNamePrefix": "TestVM",
        "adminUsername": "TestUserName",
        "windowsConfiguration": {
          "provisionVMAgent": true,
          "timeZone": "Dateline Standard Time"
        }
      },
      "storageProfile": {
        "osDisk": {
          "createOption": "FromImage",
          "caching": "ReadOnly"
        },
        "imageReference": {
          "publisher": "publisher",
          "offer": "offer",
          "sku": "sku",
          "version": "1.2.3"
        }
      },
      "networkProfile": {"networkInterfaceConfigurations": [{"name": "nicconfig1", "properties": {"ipConfigurations": [{"name": "ip1", "properties": {"subnet": {"id": "vmssSubnet0"}}}]}]}},
      "diagnosticsProfile": {
        "bootDiagnostics": {
          "enabled": true,
          "storageUri": "https://crputest.blob.core.windows.net"
        }
      }
    },
    "provisioningState": 0,
    "overprovision": false,
    "uniqueId": "00000000-0000-0000-0000-000000000000"
  }
}
```

## Retrieving user data

Applications running inside the VM can retrieve user data from IMDS endpoint. For details, see [IMDS sample code here](#).

Customers can retrieve existing value of user data via rest API using \$expand=userData endpoint (request body can be left empty).

Single VMs:

```
GET "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachines/{VMName}?
$expand=userData"
```

Virtual machine scale set:

```
GET "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSSName}?
$expand=userData"
```

Virtual machine scale set VM:

```
GET  
"/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSSName}/virtualmachines/  
instance id}?$expand=userData"
```

## Updating user data

With REST API, you can use a normal PUT or PATCH request to update the user data. The user data will be updated without the need to stop or reboot the VM.

```
PUT "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/ virtualMachines/{VMName}
```

```
PATCH "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/ virtualMachines/{VMName}
```

The VM.Properties in these requests should contain your desired UserData field, like this:

```
"properties": {  
    "hardwareProfile": {  
        "vmSize": "Standard_D1_v2"  
    },  
    "storageProfile": {  
        "imageReference": {  
            "sku": "2016-Datacenter",  
            "publisher": "MicrosoftWindowsServer",  
            "version": "latest",  
            "offer": "WindowsServer"  
        },  
        "osDisk": {  
            "caching": "ReadWrite",  
            "managedDisk": {  
                "storageAccountType": "StandardSSD_LRS"  
            },  
            "name": "vmOsdisk",  
            "createOption": "FromImage"  
        }  
    },  
    "networkProfile": {  
        "networkInterfaces": [  
            {  
                "id": "/subscriptions/{subscription-  
id}/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkInterfaces/{existing-nic-name}",  
                "properties": {  
                    "primary": true  
                }  
            }  
        ]  
    },  
    "osProfile": {  
        "adminUsername": "{your-username}",  
        "computerName": "{vm-name}",  
        "adminPassword": "{your-password}"  
    },  
    "diagnosticsProfile": {  
        "bootDiagnostics": {  
            "storageUri": "http://{existing-storage-account-name}.blob.core.windows.net",  
            "enabled": true  
        }  
    },  
    "userData": "U29tZSBDDxN0b20gRGF0YQ=="  
}
```

### NOTE

If you pass in an empty string for "userData" in this case, the user data will be deleted.

## User data and custom data

Custom data will continue to work the same way as today. Note you cannot retrieve custom data from IMDS.

## Adding user data to an existing VM

If you have an existing VM/VMSS without user data, you can still add user data to this VM by using the updating commands, as described in the "[Updating the User data](#)" section. Make sure you upgrade to the latest version of Azure Resource Manager API.

## Next steps

Try out [Azure Instance Metadata Service](#), learn how to get the VM instance metadata and user data from its endpoint.

# Custom data and cloud-init on Azure Virtual Machines

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

You might need to inject a script or other metadata into a Microsoft Azure virtual machine (VM) at provisioning time. In other clouds, this concept is often called *user data*. Microsoft Azure has a similar feature called *custom data*.

Custom data is made available to the VM during first startup or setup, which is called *provisioning*. Provisioning is the process where VM creation parameters (for example, host name, username, password, certificates, custom data, and keys) are made available to the VM. A provisioning agent, such as the [Linux Agent](#) or [cloud-init](#), processes those parameters.

## Pass custom data to the VM

To use custom data, you must Base64-encode the contents before passing the data to the API--unless you're using a CLI tool that does the conversion for you, such as the Azure CLI. The size can't exceed 64 KB.

In the CLI, you can pass your custom data as a file, as the following example shows. The file will be converted to Base64.

```
az vm create \
--resource-group myResourceGroup \
--name centos74 \
--image OpenLogic:CentOS-CI:7-CI:latest \
--custom-data cloud-init.txt \
--generate-ssh-keys
```

In Azure Resource Manager, there's a [base64 function](#):

```
"name": "[parameters('virtualMachineName')]",
"type": "Microsoft.Compute/virtualMachines",
"apiVersion": "2019-07-01",
"location": "[parameters('location')]",
"dependsOn": [
...],
"variables": {
    "customDataBase64": "[base64(parameters('stringData'))]"
},
"properties": {
...
    "osProfile": {
        "computerName": "[parameters('virtualMachineName')]",
        "adminUsername": "[parameters('adminUsername')]",
        "adminPassword": "[parameters('adminPassword')]",
        "customData": "[variables('customDataBase64')]"
    },
}
```

## Process custom data

The provisioning agents installed on the VMs handle communication with the platform and placing data on the

file system.

## Windows

Custom data is placed in `%SYSTEMDRIVE%\AzureData\CustomData.bin` as a binary file, but it isn't processed. If you want to process this file, you'll need to build a custom image and write code to process `CustomData.bin`.

## Linux

On Linux operating systems, custom data is passed to the VM via the `ovf-env.xml` file. That file is copied to the `/var/lib/waagent` directory during provisioning. Newer versions of the Linux Agent will also copy the Base64-encoded data to `/var/lib/waagent/CustomData` for convenience.

Azure currently supports two provisioning agents:

- **Linux Agent.** By default, the agent won't process custom data. You need to build a custom image with the data enabled. The [relevant settings](#) are:

- `Provisioning.DecodeCustomData`
- `Provisioning.ExecuteCustomData`

When you enable custom data and run a script, it will delay the VM reporting that it's ready or that provisioning has succeeded until the script has finished. If the script exceeds the total VM provisioning time allowance of 40 minutes, VM creation will fail.

If the script fails to run, or errors happen during execution, that's not a fatal provisioning failure. You'll need to create a notification path to alert you for the completion state of the script.

To troubleshoot custom data execution, review `/var/log/waagent.log`.

- **cloud-init.** By default, this agent will process custom data. It accepts [multiple formats](#) of custom data, such as cloud-init configuration and scripts.

Similar to the Linux Agent, if errors happen during execution of the configuration processing or scripts when cloud-init is processing the custom data, that's not a fatal provisioning failure. You'll need to create a notification path to alert you for the completion state of the script.

However, unlike the Linux Agent, cloud-init doesn't wait for custom data configurations from the user to finish before reporting to the platform that the VM is ready. For more information on cloud-init on Azure, including troubleshooting, see [cloud-init support for virtual machines in Azure](#).

## FAQ

### Can I update custom data after the VM has been created?

For single VMs, you can't update custom data in the VM model. But for virtual machine scale sets, you can update custom data via the [REST API](#), the [Azure CLI](#), or [Azure PowerShell](#). When you update custom data in the model for a virtual machine scale set:

- Existing instances in the scale set won't get the updated custom data until they're reimaged.
- Existing instances in the scale set that are upgraded won't get the updated custom data.
- New instances will receive the new custom data.

### Can I place sensitive values in custom data?

We advise *not* to store sensitive data in custom data. For more information, see [Azure data security and encryption best practices](#).

### Is custom data made available in IMDS?

Custom data is not available in Azure Instance Metadata Service (IMDS). We suggest using user data in IMDS instead. For more information, see [User data through Azure Instance Metadata Service](#).

# Configure the blue-green deployment strategy for Azure Linux virtual machines

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

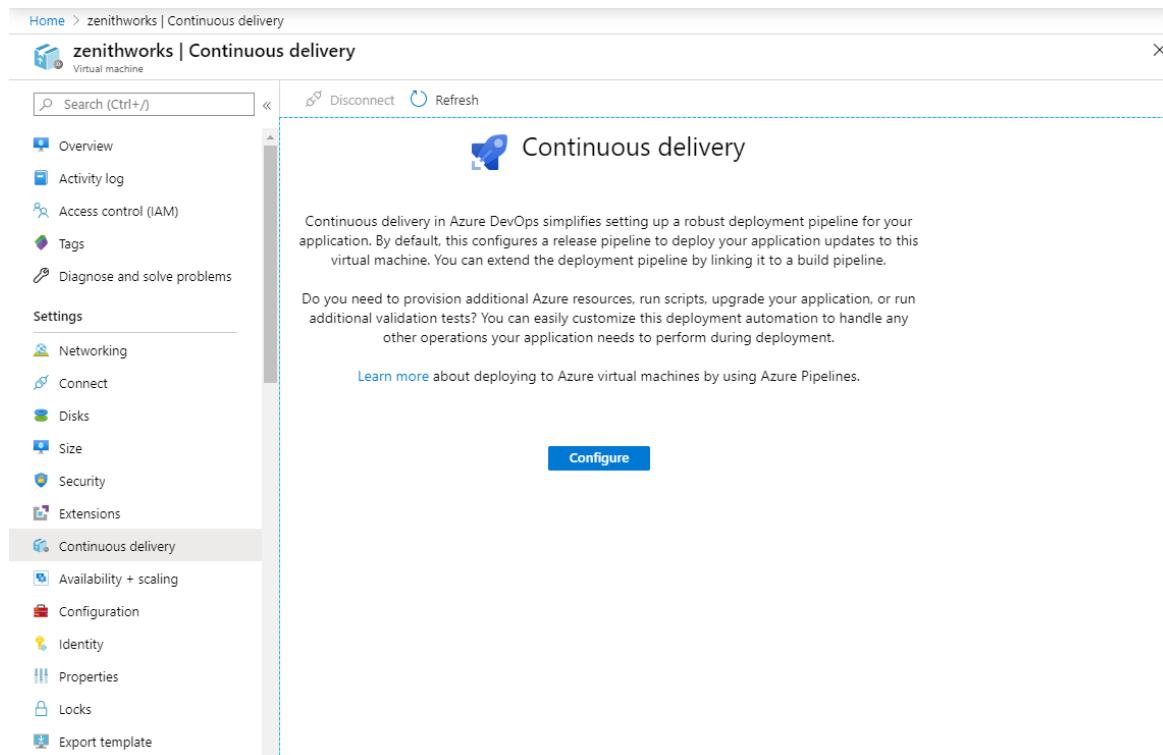

Azure Pipelines provides a fully featured set of CI/CD automation tools for deployments to virtual machines. This article will show you how to set up a classic release pipeline that uses the blue-green strategy to deploy to Linux virtual machines. Azure also supports other strategies like [rolling](#) and [canary](#) deployments.

## Blue-green deployments

A blue-green deployment is a deployment strategy where you create two separate and identical environments but only one is live at any time. This strategy is used to increase availability and reduce downtime by switching between the blue/green environments. The blue environment is usually set to run the current version of the application while the green environment is set to host the updated version. When all updates are completed, traffic is directed to the green environment and blue environment is set to idle.

Using the [Continuous-delivery](#) feature, you can use the blue-green deployment strategy to deploy to your virtual machines from Azure portal.

1. Sign in to [Azure portal](#) and navigate to a virtual machine.
2. Select [Continuous delivery](#), and then select [Configure](#).

3. In the configuration panel, select **Use existing** and select your organization/project or select **Create** and create new ones.
4. Select your **Deployment group name** from the dropdown menu or create a new one.
5. Select your **Build pipeline** from the dropdown menu.

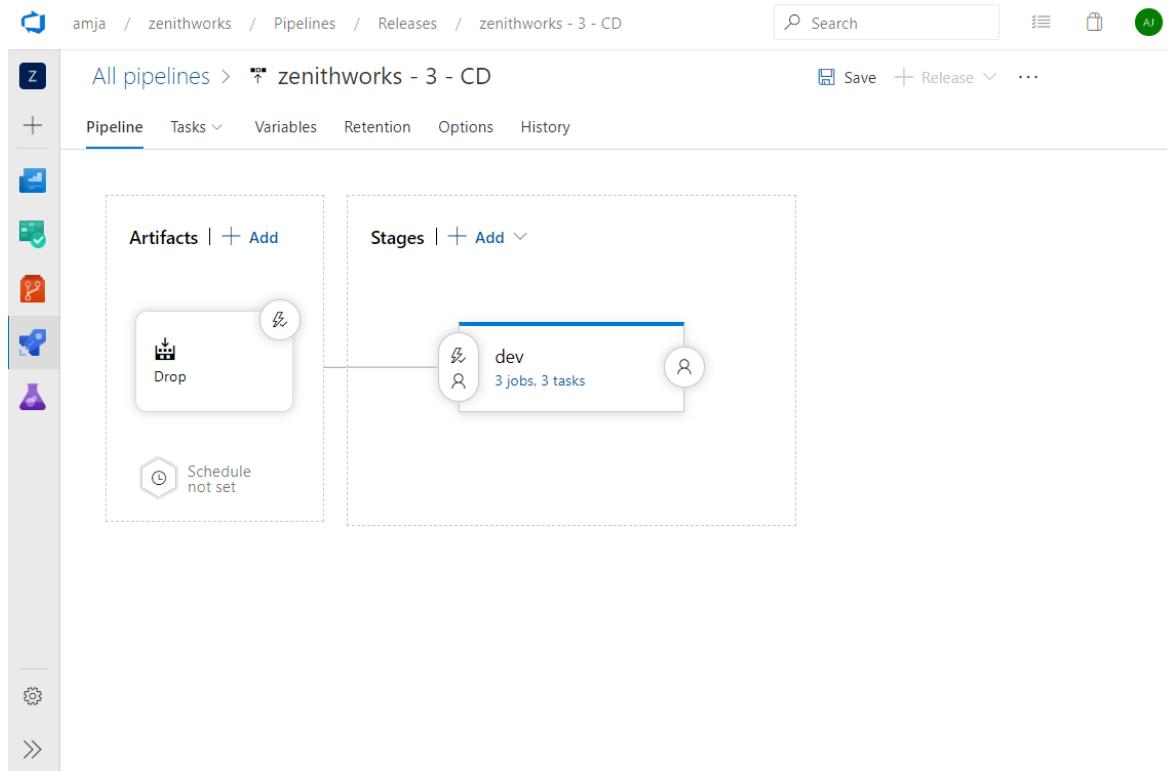

6. Select the Deployment strategy dropdown menu, and then select **Blue-Green**.

The screenshot shows the Azure portal interface for configuring continuous delivery. On the left, there's a sidebar with various settings like Overview, Activity log, and Tags. The main area is titled 'Continuous delivery' and contains instructions about setting up a release pipeline. A prominent 'Configure' button is at the bottom. To the right, a detailed configuration dialog is open. It asks for the Azure DevOps Organization (set to 'amja') and the Project ('zenithworks'). It also defines a 'Deployment group' and 'Deployment group name' ('production-dg'), and specifies a 'Build pipeline' ('zw-core-CI'). The 'Deployment strategy' dropdown is open, showing 'Rolling' and 'Blue-Green' as options, with 'Blue-Green' highlighted. At the bottom right of the dialog is a large blue 'OK' button.

7. Add a "blue" or "green" tag to VMs that are used for blue-green deployments. If a VM is for a standby role, tag it as "green". Otherwise, tag it as "blue".

This screenshot is similar to the previous one but includes a 'Tags' section at the bottom of the configuration dialog. This section contains a single tag labeled 'green'. The rest of the dialog is identical to the first screenshot, showing the organization 'amja', project 'zenithworks', deployment group 'production-dg', build pipeline 'zw-core-CI', and the 'Deployment strategy' set to 'Blue-Green'.

8. Select **OK** to configure the classic release pipeline to deploy to your virtual machine.

9. Navigate to your release pipeline and then select **Edit** to view the pipeline configuration. In this example, the *dev* stage is composed of three jobs:
  - a. Deploy Green: the app is deployed to a standby VM tagged "green".
  - b. Wait for manual resumption: the pipeline pauses and waits for manual intervention.
  - c. Swap Blue-Green: this job swaps the "blue" and "green" tags in the VMs. This ensures that VMs with older application versions are now tagged as "green". During the next pipeline run, applications will be deployed to these VMs.

The screenshot shows the Azure DevOps Pipeline configuration for the release pipeline 'zenithworks - 3 - CD'. The pipeline has two stages: 'Drop' and 'dev'. The 'dev' stage is currently selected. The 'dev' stage contains three tasks: 'Deploy Green', 'Execute Deploy Script', and 'Wait for Manual resumption'. The 'Deploy Green' task is selected. The configuration pane on the right shows the deployment group 'production-dg' selected, and the 'Required tags' field contains 'green'. Other settings include 'Targets to deploy in parallel' set to 'Multiple' and 'Maximum number of targets in parallel' set to 100%.

# Common Azure CLI commands for managing Azure resources

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

The Azure CLI allows you to create and manage your Azure resources on macOS, Linux, and Windows. This article details some of the most common commands to create and manage virtual machines (VMs).

This article requires the Azure CLI version 2.0.4 or later. Run `az --version` to find the version. If you need to upgrade, see [Install Azure CLI](#). You can also use [Cloud Shell](#) from your browser.

## Basic Azure Resource Manager commands in Azure CLI

For more detailed help with specific command line switches and options, you can use the online command help and options by typing `az <command> <subcommand> --help`.

### Create VMs

TASK	AZURE CLI COMMANDS
Create a resource group	<code>az group create --name myResourceGroup --location eastus</code>
Create a Linux VM	<code>az vm create --resource-group myResourceGroup --name myVM --image ubuntults</code>
Create a Windows VM	<code>az vm create --resource-group myResourceGroup --name myVM --image win2016datacenter</code>

### Manage VM state

TASK	AZURE CLI COMMANDS
Start a VM	<code>az vm start --resource-group myResourceGroup --name myVM</code>
Stop a VM	<code>az vm stop --resource-group myResourceGroup --name myVM</code>
Deallocate a VM	<code>az vm deallocate --resource-group myResourceGroup --name myVM</code>
Restart a VM	<code>az vm restart --resource-group myResourceGroup --name myVM</code>
Redeploy a VM	<code>az vm redeploy --resource-group myResourceGroup --name myVM</code>
Delete a VM	<code>az vm delete --resource-group myResourceGroup --name myVM</code>

### Get VM info

TASK	AZURE CLI COMMANDS
List VMs	<code>az vm list</code>
Get information about a VM	<code>az vm show --resource-group myResourceGroup --name myVM</code>
Get usage of VM resources	<code>az vm list-usage --location eastus</code>
Get all available VM sizes	<code>az vm list-sizes --location eastus</code>

## Disk and images

TASK	AZURE CLI COMMANDS
Add a data disk to a VM	<code>az vm disk attach --resource-group myResourceGroup --vm-name myVM --disk myDataDisk --size-gb 128 --new</code>
Remove a data disk from a VM	<code>az vm disk detach --resource-group myResourceGroup --vm-name myVM --disk myDataDisk</code>
Resize a disk	<code>az disk update --resource-group myResourceGroup --name myDataDisk --size-gb 256</code>
Snapshot a disk	<code>az snapshot create --resource-group myResourceGroup --name mySnapshot --source myDataDisk</code>
Create image of a VM	<code>az image create --resource-group myResourceGroup --source myVM --name myImage</code>
Create VM from image	<code>az vm create --resource-group myResourceGroup --name myNewVM --image myImage</code>

## Next steps

For additional examples of the CLI commands, see the [Create and Manage Linux VMs with the Azure CLI](#) tutorial.

# Common PowerShell commands for creating and managing Azure Virtual Machines

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article covers some of the Azure PowerShell commands that you can use to create and manage virtual machines in your Azure subscription. For more detailed help with specific command-line switches and options, you can use the [Get-Help command](#).

These variables might be useful for you if running more than one of the commands in this article:

- \$location - The location of the virtual machine. You can use [Get-AzLocation](#) to find a geographical region that works for you.
- \$myResourceGroup - The name of the resource group that contains the virtual machine.
- \$myVM - The name of the virtual machine.

## Create a VM - simplified

TASK	COMMAND
Create a simple VM	<code>New-AzVM -Name \$myVM</code>  New-AzVM has a set of <i>simplified</i> parameters, where all that is required is a single name. The value for -Name will be used as the name for all of the resources required for creating a new VM. You can specify more, but this is all that is required.
Create a VM from a custom image	<code>New-AzVm -ResourceGroupName \$myResourceGroup -Name \$myVM ImageName "myImage" -Location \$location</code>  You need to have already created your own <a href="#">managed image</a> . You can use an image to make multiple, identical VMs.

## Create a VM configuration

TASK	COMMAND
Create a VM configuration	<code>\$vm = New-AzVMConfig -VMName \$myVM -VMSize "Standard_D1_v1"</code>  The VM configuration is used to define or update settings for the VM. The configuration is initialized with the name of the VM and its <a href="#">size</a> .

TASK	COMMAND
Add configuration settings	\$vm = <a href="#">Set-AzVMOperatingSystem</a> -VM \$vm -Windows -ComputerName \$myVM -Credential \$cred -ProvisionVMAgent -EnableAutoUpdate
	<p>Operating system settings including <a href="#">credentials</a> are added to the configuration object that you previously created using <a href="#">New-AzVMConfig</a>.</p>
Add a network interface	\$vm = <a href="#">Add-AzVMNetworkInterface</a> -VM \$vm -Id \$nic.Id
	<p>A VM must have a <a href="#">network interface</a> to communicate in a virtual network. You can also use <a href="#">Get-AzNetworkInterface</a> to retrieve an existing network interface object.</p>
Specify a platform image	\$vm = <a href="#">Set-AzVMSourceImage</a> -VM \$vm -PublisherName "publisher_name" -Offer "publisher_offer" -Skus "product_sku" -Version "latest"
	<p><a href="#">Image information</a> is added to the configuration object that you previously created using <a href="#">New-AzVMConfig</a>. The object returned from this command is only used when you set the OS disk to use a platform image.</p>
Create a VM	<a href="#">New-AzVM</a> -ResourceGroupName \$myResourceGroup -Location \$location -VM \$vm
	<p>All resources are created in a <a href="#">resource group</a>. Before you run this command, run <a href="#">New-AzVMConfig</a>, <a href="#">Set-AzVMOperatingSystem</a>, <a href="#">Set-AzVMSourceImage</a>, <a href="#">Add-AzVMNetworkInterface</a>, and <a href="#">Set-AzVMOSDisk</a>.</p>
Update a VM	<a href="#">Update-AzVM</a> -ResourceGroupName \$myResourceGroup -VM \$vm
	<p>Get the current VM configuration using <a href="#">Get-AzVM</a>, change configuration settings on the VM object, and then run this command.</p>

## Get information about VMs

TASK	COMMAND
List VMs in a subscription	<a href="#">Get-AzVM</a>

TASK	COMMAND
List VMs in a resource group	<code>Get-AzVM -ResourceGroupName \$myResourceGroup</code>
	To get a list of resource groups in your subscription, use <a href="#">Get-AzResourceGroup</a> .
Get information about a VM	<code>Get-AzVM -ResourceGroupName \$myResourceGroup -Name \$myVM</code>

## Manage VMs

TASK	COMMAND
Start a VM	<code>Start-AzVM -ResourceGroupName \$myResourceGroup -Name \$myVM</code>
Stop a VM	<code>Stop-AzVM -ResourceGroupName \$myResourceGroup -Name \$myVM</code>
Restart a running VM	<code>Restart-AzVM -ResourceGroupName \$myResourceGroup -Name \$myVM</code>
Delete a VM	<code>Remove-AzVM -ResourceGroupName \$myResourceGroup -Name \$myVM</code>

## Next steps

# Common PowerShell commands for Azure Virtual Networks

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

If you want to create a virtual machine, you need to create a [virtual network](#) or know about an existing virtual network in which the VM can be added. Typically, when you create a VM, you also need to consider creating the resources described in this article.

See [How to install and configure Azure PowerShell](#) for information about installing the latest version of Azure PowerShell, selecting your subscription, and signing in to your account.

Some variables might be useful for you if running more than one of the commands in this article:

- \$location - The location of the network resources. You can use [Get-AzLocation](#) to find a [geographical region](#) that works for you.
- \$myResourceGroup - The name of the resource group where the network resources are located.

## Create network resources

TASK	COMMAND
Create subnet configurations	\$subnet1 = <a href="#">New-AzVirtualNetworkSubnetConfig</a> -Name "mySubnet1" -AddressPrefix XX.X.X.X/XX \$subnet2 = <a href="#">New-AzVirtualNetworkSubnetConfig</a> -Name "mySubnet2" -AddressPrefix XX.X.X.X/XX  A typical network might have a subnet for an <a href="#">internet facing load balancer</a> and a separate subnet for an <a href="#">internal load balancer</a> .
Create a virtual network	\$vnet = <a href="#">New-AzVirtualNetwork</a> -Name "myVNet" -ResourceGroupName \$myResourceGroup -Location \$location -AddressPrefix XX.X.X.X/XX -Subnet \$subnet1, \$subnet2
Test for a unique domain name	<a href="#">Test-AzDnsAvailability</a> -DomainNameLabel "myDNS" -Location \$location  You can specify a DNS domain name for a <a href="#">public IP resource</a> , which creates a mapping for domainname.location.cloudapp.azure.com to the public IP address in the Azure-managed DNS servers. The name can contain only letters, numbers, and hyphens. The first and last character must be a letter or number and the domain name must be unique within its Azure location. If <b>True</b> is returned, your proposed name is globally unique.

TASK	COMMAND
Create a public IP address	<pre>\$pip = <a href="#">New-AzPublicIpAddress</a> -Name "myPublicIp" -ResourceGroupName \$myResourceGroup -DomainNameLabel "myDNS" -Location \$location -AllocationMethod Dynamic</pre> <p>The public IP address uses the domain name that you previously tested and is used by the frontend configuration of the load balancer.</p>
Create a frontend IP configuration	<pre>\$frontendIP = <a href="#">New-AzLoadBalancerFrontendIpConfig</a> -Name "myFrontendIP" -PublicIpAddress \$pip</pre> <p>The frontend configuration includes the public IP address that you previously created for incoming network traffic.</p>
Create a backend address pool	<pre>\$beAddressPool = <a href="#">New-AzLoadBalancerBackendAddressPoolConfig</a> -Name "myBackendAddressPool"</pre> <p>Provides internal addresses for the backend of the load balancer that are accessed through a network interface.</p>
Create a probe	<pre>\$healthProbe = <a href="#">New-AzLoadBalancerProbeConfig</a> -Name "myProbe" -RequestPath 'HealthProbe.aspx' -Protocol http -Port 80 -IntervalInSeconds 15 -ProbeCount 2</pre> <p>Contains health probes used to check availability of virtual machines instances in the backend address pool.</p>
Create a load balancing rule	<pre>\$lbRule = <a href="#">New-AzLoadBalancerRuleConfig</a> -Name HTTP -FrontendIpConfiguration \$frontendIP -BackendAddressPool \$beAddressPool -Probe \$healthProbe -Protocol Tcp -FrontendPort 80 -BackendPort 80</pre> <p>Contains rules that assign a public port on the load balancer to a port in the backend address pool.</p>
Create an inbound NAT rule	<pre>\$inboundNATRule = <a href="#">New-AzLoadBalancerInboundNatRuleConfig</a> -Name "myInboundRule1" -FrontendIpConfiguration \$frontendIP -Protocol TCP -FrontendPort 3441 -BackendPort 3389</pre> <p>Contains rules mapping a public port on the load balancer to a port for a specific virtual machine in the backend address pool.</p>
Create a load balancer	<pre>\$loadBalancer = <a href="#">New-AzLoadBalancer</a> -ResourceGroupName \$myResourceGroup -Name "myLoadBalancer" -Location \$location -FrontendIpConfiguration \$frontendIP -InboundNatRule \$inboundNATRule -LoadBalancingRule \$lbRule -BackendAddressPool \$beAddressPool -Probe \$healthProbe</pre>

TASK	COMMAND
Create a network interface	<pre>\$nic1 = New-AzNetworkInterface -ResourceGroupName \$myResourceGroup -Name "myNIC" -Location \$location - PrivateIpAddress XX.X.X.X -Subnet \$subnet2 - LoadBalancerBackendAddressPool \$loadBalancer.BackendAddressPools[0] - LoadBalancerInboundNatRule \$loadBalancer.InboundNatRules[0]</pre> <p>Create a network interface using the public IP address and virtual network subnet that you previously created.</p>

## Get information about network resources

TASK	COMMAND
List virtual networks	<pre>Get-AzVirtualNetwork -ResourceGroupName \$myResourceGroup</pre> <p>Lists all the virtual networks in the resource group.</p>
Get information about a virtual network	<pre>Get-AzVirtualNetwork -Name "myVNet" - ResourceGroupName \$myResourceGroup</pre>
List subnets in a virtual network	<pre>Get-AzVirtualNetwork -Name "myVNet" - ResourceGroupName \$myResourceGroup   Select Subnets</pre>
Get information about a subnet	<pre>Get-AzVirtualNetworkSubnetConfig -Name "mySubnet1" - VirtualNetwork \$vnet</pre> <p>Gets information about the subnet in the specified virtual network. The \$vnet value represents the object returned by Get-AzVirtualNetwork.</p>
List IP addresses	<pre>Get-AzPublicIpAddress -ResourceGroupName \$myResourceGroup</pre> <p>Lists the public IP addresses in the resource group.</p>
List load balancers	<pre>Get-AzLoadBalancer -ResourceGroupName \$myResourceGroup</pre> <p>Lists all the load balancers in the resource group.</p>
List network interfaces	<pre>Get-AzNetworkInterface -ResourceGroupName \$myResourceGroup</pre> <p>Lists all the network interfaces in the resource group.</p>
Get information about a network interface	<pre>Get-AzNetworkInterface -Name "myNIC" - ResourceGroupName \$myResourceGroup</pre> <p>Gets information about a specific network interface.</p>

TASK	COMMAND
Get the IP configuration of a network interface	<p><code>Get-AzNetworkInterfaceIPConfig -Name "myNICIP" -NetworkInterface \$nic</code></p> <p>Gets information about the IP configuration of the specified network interface. The \$nic value represents the object returned by <code>Get-AzNetworkInterface</code>.</p>

## Manage network resources

TASK	COMMAND
Add a subnet to a virtual network	<p><code>Add-AzVirtualNetworkSubnetConfig -AddressPrefix XX.X.X.X/XX -Name "mySubnet1" -VirtualNetwork \$vnet</code></p> <p>Adds a subnet to an existing virtual network. The \$vnet value represents the object returned by <code>Get-AzVirtualNetwork</code>.</p>
Delete a virtual network	<p><code>Remove-AzVirtualNetwork -Name "myVNet" -ResourceGroupName \$myResourceGroup</code></p> <p>Removes the specified virtual network from the resource group.</p>
Delete a network interface	<p><code>Remove-AzNetworkInterface -Name "myNIC" -ResourceGroupName \$myResourceGroup</code></p> <p>Removes the specified network interface from the resource group.</p>
Delete a load balancer	<p><code>Remove-AzLoadBalancer -Name "myLoadBalancer" -ResourceGroupName \$myResourceGroup</code></p> <p>Removes the specified load balancer from the resource group.</p>
Delete a public IP address	<p><code>Remove-AzPublicIpAddress -Name "myIPAddress" -ResourceGroupName \$myResourceGroup</code></p> <p>Removes the specified public IP address from the resource group.</p>

## Next Steps

Use the network interface that you just created when you [create a VM](#).

# Virtual machines in an Azure Resource Manager template

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article describes aspects of an Azure Resource Manager template that apply to virtual machines. This article doesn't describe a complete template for creating a virtual machine; for that you need resource definitions for storage accounts, network interfaces, public IP addresses, and virtual networks. For more information about how these resources can be defined together, see the [Resource Manager template walkthrough](#).

There are many [templates in the gallery](#) that include the VM resource. Not all elements that can be included in a template are described here.

This example shows a typical resource section of a template for creating a specified number of VMs:

```
"resources": [
  {
    "apiVersion": "2016-04-30-preview",
    "type": "Microsoft.Compute/virtualMachines",
    "name": "[concat('myVM', copyindex())]",
    "location": "[resourceGroup().location]",
    "copy": {
      "name": "virtualMachineLoop",
      "count": "[parameters('numberOfInstances')]"
    },
    "dependsOn": [
      "[concat('Microsoft.Network/networkInterfaces/myNIC', copyindex())]"
    ],
    "properties": {
      "hardwareProfile": {
        "vmSize": "Standard_DS1"
      },
      "osProfile": {
        "computerName": "[concat('myVM', copyindex())]",
        "adminUsername": "[parameters('adminUsername')]",
        "adminPassword": "[parameters('adminPassword')]"
      },
      "storageProfile": {
        "imageReference": {
          "publisher": "MicrosoftWindowsServer",
          "offer": "WindowsServer",
          "sku": "2012-R2-Datacenter",
          "version": "latest"
        },
        "osDisk": {
          "name": "[concat('myOSDisk', copyindex())]",
          "caching": "ReadWrite",
          "createOption": "FromImage"
        },
        "dataDisks": [
          {
            "name": "[concat('myDataDisk', copyindex())]",
            "diskSizeGB": "100",
            "lun": 0,
            "createOption": "Empty"
          }
        ]
      }
    }
  }
]
```

```

"networkProfile": {
    "networkInterfaces": [
        {
            "id": "[resourceId('Microsoft.Network/networkInterfaces',
                concat('myNIC', copyindex()))]"
        }
    ]
},
"diagnosticsProfile": {
    "bootDiagnostics": {
        "enabled": "true",
        "storageUri": "[concat('https://', variables('storageName'), '.blob.core.windows.net')]"
    }
}
},
"resources": [
{
    "name": "Microsoft.Insights.VMDiagnosticsSettings",
    "type": "extensions",
    "location": "[resourceGroup().location]",
    "apiVersion": "2016-03-30",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
    ],
    "properties": {
        "publisher": "Microsoft.Azure.Diagnostics",
        "type": "IaaS.Diagnostics",
        "typeHandlerVersion": "1.5",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "xmlCfg": "[base64(concat(variables('wadcfgxstart'),
                variables('wadmetricsresourceid'),
                concat('myVM', copyindex()),
                variables('wadcfgxend'))))",
            "storageAccount": "[variables('storageName')]"
        },
        "protectedSettings": {
            "storageAccountName": "[variables('storageName')]",
            "storageAccountKey": "[listkeys(variables('accountid'),
                '2015-06-15').key1]",
            "storageAccountEndPoint": "https://core.windows.net"
        }
    }
},
{
    "name": "MyCustomScriptExtension",
    "type": "extensions",
    "apiVersion": "2016-03-30",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
    ],
    "properties": {
        "publisher": "Microsoft.Compute",
        "type": "CustomScriptExtension",
        "typeHandlerVersion": "1.7",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "fileUris": [
                "[concat('https://', variables('storageName'),
                    '.blob.core.windows.net/customscripts/start.ps1')]"
            ],
            "commandToExecute": "powershell.exe -ExecutionPolicy Unrestricted -File start.ps1"
        }
    }
}
]
}
]
```

## NOTE

This example relies on a storage account that was previously created. You could create the storage account by deploying it from the template. The example also relies on a network interface and its dependent resources that would be defined in the template. These resources are not shown in the example.

## API Version

When you deploy resources using a template, you have to specify a version of the API to use. The example shows the virtual machine resource using this `apiVersion` element:

```
"apiVersion": "2016-04-30-preview",
```

The version of the API you specify in your template affects which properties you can define in the template. In general, you should select the most recent API version when creating templates. For existing templates, you can decide whether you want to continue using an earlier API version, or update your template for the latest version to take advantage of new features.

Use these opportunities for getting the latest API versions:

- REST API - [List all resource providers](#)
- PowerShell - [Get-AzResourceProvider](#)
- Azure CLI - [az provider show](#)

## Parameters and variables

**Parameters** make it easy for you to specify values for the template when you run it. This parameters section is used in the example:

```
"parameters": {  
    "adminUsername": { "type": "string" },  
    "adminPassword": { "type": "securestring" },  
    "numberOfInstances": { "type": "int" }  
},
```

When you deploy the example template, you enter values for the name and password of the administrator account on each VM and the number of VMs to create. You have the option of specifying parameter values in a separate file that's managed with the template, or providing values when prompted.

**Variables** make it easy for you to set up values in the template that are used repeatedly throughout it or that can change over time. This variables section is used in the example:

```

"variables": {
    "storageName": "mystore1",
    "accountid": "[concat('/subscriptions/', subscription().subscriptionId,
        '/resourceGroups/', resourceGroup().name,
        '/providers/', 'Microsoft.Storage/storageAccounts/', variables('storageName'))]",
    "wadlogs": "<WadCfg>
        <DiagnosticMonitorConfiguration overallQuotaInMB=\"4096\" xmlns=\"http://schemas.microsoft.com/ServiceHosting/2010/10/DiagnosticsConfiguration\">
            <DiagnosticInfrastructureLogs scheduledTransferLogLevelFilter=\"Error\"/>
            <WindowsEventLog scheduledTransferPeriod=\"PT1M\" >
                <DataSource name=\"Application!*[System[(Level = 1 or Level = 2)]]\" />
                <DataSource name=\"Security!*[System[(Level = 1 or Level = 2)]]\" />
                <DataSource name=\"System!*[System[(Level = 1 or Level = 2)]]\" />
            </WindowsEventLog>",
        <wadperfcounters": "<PerformanceCounters scheduledTransferPeriod=\"PT1M\">
            <PerformanceCounterConfiguration counterSpecifier=\"\\Process(_Total)\\Thread Count\" sampleRate=\"PT15S\" unit=\"Count\">
                <annotation displayName=\"Threads\" locale=\"en-us\"/>
            </PerformanceCounterConfiguration>
        </PerformanceCounters>",
        "wadcfgxstart": "[concat(variables('wadlogs'), variables('wadperfcounters'),
            '<Metrics resourceId=\"\"\'])",
        "wadmetricsresourceid": "[concat('/subscriptions/', subscription().subscriptionId,
            '/resourceGroups/', resourceGroup().name ,
            '/providers/', 'Microsoft.Compute/virtualMachines/')]",
        "wadcfgxend": "\"><MetricAggregation scheduledTransferPeriod=\"PT1H\"/>
            <MetricAggregation scheduledTransferPeriod=\"PT1M\"/>
        </Metrics></DiagnosticMonitorConfiguration>
    </WadCfg>"}
},

```

When you deploy the example template, variable values are used for the name and identifier of the previously created storage account. Variables are also used to provide the settings for the diagnostic extension. Use the [best practices for creating Azure Resource Manager templates](#) to help you decide how you want to structure the parameters and variables in your template.

## Resource loops

When you need more than one virtual machine for your application, you can use a copy element in a template. This optional element loops through creating the number of VMs that you specified as a parameter:

```

"copy": {
    "name": "virtualMachineLoop",
    "count": "[parameters('numberOfInstances')]"
},

```

Also, notice in the example that the loop index is used when specifying some of the values for the resource. For example, if you entered an instance count of three, the names of the operating system disks are myOSDisk1, myOSDisk2, and myOSDisk3:

```

"osDisk": {
    "name": "[concat('myOSDisk', copyindex())]",
    "caching": "ReadWrite",
    "createOption": "FromImage"
}

```

#### NOTE

This example uses managed disks for the virtual machines.

Keep in mind that creating a loop for one resource in the template may require you to use the loop when creating or accessing other resources. For example, multiple VMs can't use the same network interface, so if your template loops through creating three VMs it must also loop through creating three network interfaces. When assigning a network interface to a VM, the loop index is used to identify it:

```
"networkInterfaces": [ {  
    "id": "[resourceId('Microsoft.Network/networkInterfaces',  
        concat('myNIC', copyindex()))]"  
} ]
```

## Dependencies

Most resources depend on other resources to work correctly. Virtual machines must be associated with a virtual network and to do that it needs a network interface. The `dependsOn` element is used to make sure that the network interface is ready to be used before the VMs are created:

```
"dependsOn": [  
    "[concat('Microsoft.Network/networkInterfaces/', 'myNIC', copyindex())]"  
,
```

Resource Manager deploys in parallel any resources that aren't dependent on another resource being deployed. Be careful when setting dependencies because you can inadvertently slow your deployment by specifying unnecessary dependencies. Dependencies can chain through multiple resources. For example, the network interface depends on the public IP address and virtual network resources.

How do you know if a dependency is required? Look at the values you set in the template. If an element in the virtual machine resource definition points to another resource that is deployed in the same template, you need a dependency. For example, your example virtual machine defines a network profile:

```
"networkProfile": {  
    "networkInterfaces": [ {  
        "id": "[resourceId('Microsoft.Network/networkInterfaces',  
            concat('myNIC', copyindex()))]"  
    } ]  
},
```

To set this property, the network interface must exist. Therefore, you need a dependency. You also need to set a dependency when one resource (a child) is defined within another resource (a parent). For example, the diagnostic settings and custom script extensions are both defined as child resources of the virtual machine. They can't be created until the virtual machine exists. Therefore, both resources are marked as dependent on the virtual machine.

## Profiles

Several profile elements are used when defining a virtual machine resource. Some are required and some are optional. For example, the `hardwareProfile`, `osProfile`, `storageProfile`, and `networkProfile` elements are required, but the `diagnosticsProfile` is optional. These profiles define settings such as:

- `size`

- [name](#) and credentials
- disk and [operating system settings](#)
- [network interface](#)
- boot diagnostics

## Disks and images

In Azure, vhd files can represent [disks or images](#). When the operating system in a vhd file is specialized to be a specific VM, it's referred to as a disk. When the operating system in a vhd file is generalized to be used to create many VMs, it's referred to as an image.

### Create new virtual machines and new disks from a platform image

When you create a VM, you must decide what operating system to use. The `imageReference` element is used to define the operating system of a new VM. The example shows a definition for a Windows Server operating system:

```
"imageReference": {
  "publisher": "MicrosoftWindowsServer",
  "offer": "WindowsServer",
  "sku": "2012-R2-Datacenter",
  "version": "latest"
},
```

If you want to create a Linux operating system, you might use this definition:

```
"imageReference": {
  "publisher": "Canonical",
  "offer": "UbuntuServer",
  "sku": "14.04.2-LTS",
  "version": "latest"
},
```

Configuration settings for the operating system disk are assigned with the `osDisk` element. The example defines a new managed disk with the caching mode set to **ReadWrite** and that the disk is being created from a [platform image](#):

```
"osDisk": {
  "name": "[concat('myOSDisk', copyindex())]",
  "caching": "ReadWrite",
  "createOption": "FromImage"
},
```

### Create new virtual machines from existing managed disks

If you want to create virtual machines from existing disks, remove the `imageReference` and the `osProfile` elements and define these disk settings:

```
"osDisk": {
  "osType": "Windows",
  "managedDisk": {
    "id": "[resourceId('Microsoft.Compute/disks', [concat('myOSDisk', copyindex())])]"
  },
  "caching": "ReadWrite",
  "createOption": "Attach"
},
```

## Create new virtual machines from a managed image

If you want to create a virtual machine from a managed image, change the `imageReference` element and define these disk settings:

```
"storageProfile": {
  "imageReference": {
    "id": "[resourceId('Microsoft.Compute/images', 'myImage')]"
  },
  "osDisk": {
    "name": "[concat('myOSDisk', copyindex())]",
    "osType": "Windows",
    "caching": "ReadWrite",
    "createOption": "FromImage"
  }
},
```

## Attach data disks

You can optionally add data disks to the VMs. The [number of disks](#) depends on the size of operating system disk that you use. With the size of the VMs set to Standard\_DS1\_v2, the maximum number of data disks that could be added to them is two. In the example, one managed data disk is being added to each VM:

```
"dataDisks": [
  {
    "name": "[concat('myDataDisk', copyindex())]",
    "diskSizeGB": "100",
    "lun": 0,
    "caching": "ReadWrite",
    "createOption": "Empty"
  }
],
```

## Extensions

Although [extensions](#) are a separate resource, they're closely tied to VMs. Extensions can be added as a child resource of the VM or as a separate resource. The example shows the [Diagnostics Extension](#) being added to the VMs:

```
{
  "name": "Microsoft.Insights.VMDiagnosticsSettings",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2016-03-30",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Diagnostics",
    "type": "IaaSDiagnostics",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "xmlCfg": "[base64(concat(variables('wadcfgxstart'),
variables('wadmetricsresourceid'),
concat('myVM', copyindex()),
variables('wadcfgxend')))]",
      "storageAccount": "[variables('storageName')]"
    },
    "protectedSettings": {
      "storageAccountName": "[variables('storageName')]",
      "storageAccountKey": "[listkeys(variables('accountid'),
'2015-06-15').key1]",
      "storageAccountEndPoint": "https://core.windows.net"
    }
  }
},
}
```

This extension resource uses the storageName variable and the diagnostic variables to provide values. If you want to change the data that is collected by this extension, you can add more performance counters to the wadperfcounters variable. You could also choose to put the diagnostics data into a different storage account than where the VM disks are stored.

There are many extensions that you can install on a VM, but the most useful is probably the [Custom Script Extension](#). In the example, a PowerShell script named start.ps1 runs on each VM when it first starts:

```
{
  "name": "MyCustomScriptExtension",
  "type": "extensions",
  "apiVersion": "2016-03-30",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
  ],
  "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.7",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "[concat('https://', variables('storageName'),
'.blob.core.windows.net/customscripts/start.ps1')]"
      ],
      "commandToExecute": "powershell.exe -ExecutionPolicy Unrestricted -File start.ps1"
    }
  }
}
```

The start.ps1 script can accomplish many configuration tasks. For example, the data disks that are added to the VMs in the example aren't initialized; you can use a custom script to initialize them. If you have multiple startup tasks to do, you can use the start.ps1 file to call other PowerShell scripts in Azure storage. The example uses

PowerShell, but you can use any scripting method that is available on the operating system that you're using.

You can see the status of the installed extensions from the Extensions settings in the portal:

NAME	TYPE	V...	STATUS
Microsoft.Insights.VMDiagnosticsSettings	Microsoft.Azur...	1.*	Provisioning succ...
MyCustomScriptExtension	Microsoft.Com...	1.*	Provisioning succ...

You can also get extension information by using the **Get-AzVMExtension** PowerShell command, the **vm extension get** Azure CLI command, or the **Get extension information** REST API.

## Deployments

When you deploy a template, Azure tracks the resources that you deployed as a group and automatically assigns a name to this deployed group. The name of the deployment is the same as the name of the template.

If you're curious about the status of resources in the deployment, view the resource group in the Azure portal:

Essentials ^

Subscription name [REDACTED]

Last deployment **7/25/2016 (Succeeded)**

Subscription ID [REDACTED]

Location Central US

It's not a problem to use the same template to create resources or to update existing resources. When you use commands to deploy templates, you have the opportunity to say which **mode** you want to use. The mode can be set to either **Complete** or **Incremental**. The default is to do incremental updates. Be careful when using the **Complete** mode because you may accidentally delete resources. When you set the mode to **Complete**, Resource Manager deletes any resources in the resource group that aren't in the template.

## Next Steps

- Create your own template using [Authoring Azure Resource Manager templates](#).
- Deploy the template that you created using [Create a Windows virtual machine with a Resource Manager template](#).
- Learn how to manage the VMs that you created by reviewing [Create and manage Windows VMs with the Azure PowerShell module](#).
- For the JSON syntax and properties of resource types in templates, see [Azure Resource Manager template reference](#).

# Support and troubleshooting for Azure VMs

9/21/2022 • 2 minutes to read • [Edit Online](#)

Here are suggestions for where you can get help when developing your Azure Virtual Machines solutions.

## Self help troubleshooting

Various articles explain how to determine, diagnose, and fix issues that you might encounter when using Azure Virtual Machines. Use these articles to troubleshoot deployment failures, unexpected restarts, connection issues and more.

For a full list of self help troubleshooting content, see [Azure Virtual Machine troubleshooting documentation](#)

## Post a question on Microsoft Q&A

For quick and reliable answers on your technical product questions from Microsoft Engineers, Azure Most Valuable Professionals (MVPs), or our expert community, engage with us on [Microsoft Q&A](#), Azure's preferred destination for community support.

If you can't find an answer to your problem using search, submit a new question to Microsoft Q&A. Use one of the following tags when asking your question:

AREA	TAG
Azure Virtual Machines	<a href="#">azure-virtual-machines</a>
Azure SQL Virtual Machines	<a href="#">azure-sql-virtual-machines</a>
Azure Virtual Machine backup	<a href="#">azure-virtual-machine-backup</a>
Azure Virtual Machine extension	<a href="#">azure-virtual-machine-extension</a>
Azure Virtual Machine Images	<a href="#">azure-virtual-machine-images</a>
Azure Virtual Machine migration	<a href="#">azure-virtual-machine-migration</a>
Azure Virtual Machine monitoring	<a href="#">azure-virtual-machine-monitoring</a>
Azure Virtual Machine networking	<a href="#">azure-virtual-machine-networking</a>
Azure Virtual Machine storage	<a href="#">azure-virtual-machine-storage</a>

## Create an Azure support request

Explore the range of [Azure support options and choose the plan](#) that best fits, whether you're a developer just starting your cloud journey or a large organization deploying business-critical, strategic applications. Azure customers can create and manage support requests in the Azure portal.

- If you already have an Azure Support Plan, [open a support request here](#).
- To sign up for a new Azure Support Plan, [compare support plans](#) and select the plan that works for you.

## Create a GitHub issue

If you need help with the language and tools used to develop and manage Azure Virtual Machines, open an issue in its repository on GitHub.
