[Dependency management](#)

Global and local tools

[Manage tools](#)

Troubleshoot tools

Create tools for the CLI

- 1 - Create a tool
- 2 - Use a global tool
- 3 - Use a local tool

Additional tools

Overview

- .NET uninstall tool
- .NET install tool for extension authors
- Generate self-signed certificates
- WCF web service reference provider
- WCF service utility
- WCF service XML serializer
- XML serializer generator

Diagnostics and instrumentation

Overview

Managed debuggers

Diagnostic port

Dumps

Overview

Linux dumps

SOS debugger extension

Logging and tracing

Overview

Well-known event providers

Event Source

Overview

Getting started

Get started with .NET

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article teaches you how to create and run a "Hello World!" app with [.NET](#).

Create an application

First, download and install the [.NET SDK](#) on your computer.

Next, open a terminal such as **PowerShell**, **Command Prompt**, or **bash**.

Type the following commands:

```
dotnet new console -o sample1  
cd sample1  
dotnet run
```

You should see the following output:

```
Hello World!
```

Congratulations! You've created a simple .NET application.

Next steps

Get started on developing .NET applications by following a [step-by-step tutorial](#) or by watching [.NET 101 videos](#) on YouTube.

Tutorials for getting started with .NET

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following step-by-step tutorials run on Windows, Linux, or macOS, except as noted.

Tutorials for creating apps

- Create a console app
 - [using Visual Studio Code](#)
 - [using Visual Studio \(Windows\)](#)
 - [using Visual Studio for Mac \(macOS\)](#)
- Create a web app
 - [with server-side web UI](#)
 - [with client-side web UI](#)
- [Create a web API](#)
- [Create a remote procedure call web app](#)
- [Create a real-time web app](#)
- [Create a serverless function in the cloud](#)
- [Create a mobile app for Android and iOS \(Windows\)](#)
- Create a Windows desktop app
 - [WPF](#)
 - [Windows Forms](#)
 - [Universal Windows Platform \(UWP\)](#)
- [Create a game using Unity](#)
- [Create a Windows service](#)

Tutorials for creating class libraries

- Create a class library
 - [using Visual Studio Code](#)
 - [using Visual Studio \(Windows\)](#)
 - [using Visual Studio for Mac \(macOS\)](#)

Resources for learning .NET languages

- [Get started with C#](#)
- [Get started with F#](#)
- [Get started with Visual Basic](#)

Other get-started resources

The following resources are for getting started with developing .NET apps but aren't step-by-step tutorials:

- [Internet of Things \(IoT\)](#)
- [Machine learning](#)

Next steps

To learn more about .NET, see [Introduction to .NET](#).

Install .NET on Windows

9/20/2022 • 11 minutes to read • [Edit Online](#)

In this article, you'll learn how to install .NET on Windows. .NET is made up of the runtime and the SDK. The runtime is used to run a .NET app and may or may not be included with the app. The SDK is used to create .NET apps and libraries. The .NET runtime is always installed with the SDK.

The latest version of .NET is 6.

[DOWNLOAD
.NET](#)

Install with Windows Package Manager (winget)

You can install and manage .NET through the Windows Package Manager service, using the `winget` tool. For more information about how to install and use `winget`, see [Use the winget tool](#).

If you're installing .NET system-wide, install with administrative privileges.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtimes. To install the .NET SDK, run the following command:

```
winget install Microsoft.DotNet.SDK.6
```

Install the runtime

For Windows, there are three .NET runtimes you can install. You should install both the .NET Desktop Runtime and the ASP.NET Core Runtime to ensure that you're compatible with all types of .NET apps.

- .NET Desktop Runtime

This runtime includes the base .NET runtime, and supports Windows Presentation Foundation (WPF) and Windows Forms apps that are built with .NET. This isn't the same as .NET Framework, which comes with Windows.

```
winget install Microsoft.DotNet/DesktopRuntime.6
```

- ASP.NET Core Runtime

This runtime includes the base .NET runtime, and runs web server apps. The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
winget install Microsoft.DotNet/AspNetCore.6
```

- .NET Runtime

This is the base runtime, and contains just the components needed to run a console app. Typically, you'd install the other runtimes.

```
winget install Microsoft.DotNet.Runtime.6
```

You can install preview versions of the runtimes by substituting the version number, such as `6`, with the word `Preview`. The following example installs the preview release of the .NET Desktop Runtime:

```
winget install Microsoft.DotNet.DesktopRuntime.Preview
```

Install alongside Visual Studio Code

Visual Studio Code is a powerful and lightweight source code editor that runs on your desktop. Visual Studio Code is available for Windows, macOS, and Linux.

While Visual Studio Code doesn't come with an automated .NET Core installer like Visual Studio does, adding .NET Core support is simple.

1. [Download and install Visual Studio Code](#).
2. [Download and install the .NET SDK](#).
3. [Install the C# extension from the Visual Studio Code marketplace](#).

Install with Windows Installer

The [download page](#) for .NET provides Windows Installer executables.

When you use the Windows installers to install .NET, you can customize the installation path by setting the `DOTNETHOME_X64` and `DOTNETHOME_X86` parameters:

```
dotnet-sdk-3.1.301-win-x64.exe DOTNETHOME_X64="F:\dotnet\x64" DOTNETHOME_X86="F:\dotnet\x86"
```

If you want to install .NET silently, such as in a production environment or to support continuous integration, use the following switches:

- `/install`
Installs .NET.
- `/quiet`
Prevents any UI and prompts from displaying.
- `/norestart`
Suppresses any attempts to restart.

```
dotnet-sdk-3.1.301-win-x64.exe /install /quiet /norestart
```

For more information, see [Standard Installer Command-Line Options](#).

TIP

The installer returns an exit code of 0 for success and an exit code of 3010 to indicate that a restart is required. Any other value is generally an error code.

Install with PowerShell automation

The [dotnet-install scripts](#) are used for CI automation and non-admin installs of the runtime. You can download the script from the [dotnet-install script reference page](#).

The script defaults to installing the latest [long term support \(LTS\)](#) version, which is .NET 6. You can choose a specific release by specifying the `-Channel` switch. Include the `-Runtime` switch to install a runtime. Otherwise, the script installs the SDK.

```
dotnet-install.ps1 -Channel 6.0 -Runtime aspnetcore
```

Install the SDK by omitting the `-Runtime` switch. The `-Channel` switch is set in this example to `Current`, which installs the latest supported version.

```
dotnet-install.ps1 -Channel Current
```

Install with Visual Studio

If you're using Visual Studio to develop .NET apps, the following table describes the minimum required version of Visual Studio based on the target .NET SDK version.

.NET SDK VERSION	VISUAL STUDIO VERSION
6.0	Visual Studio 2022 version 17.0 or higher.
5.0	Visual Studio 2019 version 16.8 or higher.
3.1	Visual Studio 2019 version 16.4 or higher.
3.0	Visual Studio 2019 version 16.3 or higher.
2.2	Visual Studio 2017 version 15.9 or higher.
2.1	Visual Studio 2017 version 15.7 or higher.

If you already have Visual Studio installed, you can check your version with the following steps.

1. Open Visual Studio.
2. Select **Help > About Microsoft Visual Studio**.
3. Read the version number from the **About** dialog.

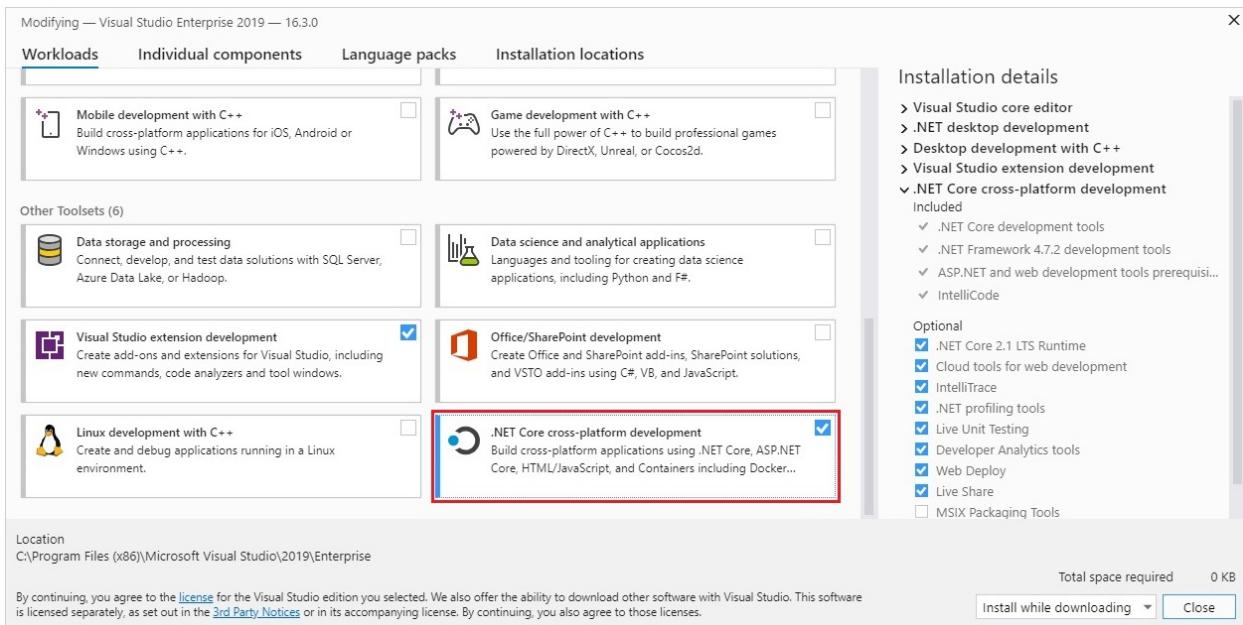

Visual Studio can install the latest .NET SDK and runtime.

Select a workload

When installing or modifying Visual Studio, select one or more of the following workloads, depending on the kind of application you're building:

- The **.NET Core cross-platform development** workload in the **Other Toolsets** section.
- The **ASP.NET and web development** workload in the **Web & Cloud** section.
- The **Azure development** workload in the **Web & Cloud** section.
- The **.NET desktop development** workload in the **Desktop & Mobile** section.

Supported releases

The following table is a list of currently supported .NET releases and the versions of Windows they're supported on. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of [Windows reaches end-of-life](#).

Windows 10 versions end-of-service dates are segmented by edition. Only **Home**, **Pro**, **Pro Education**, and **Pro for Workstations** editions are considered in the following table. Check the [Windows lifecycle fact sheet](#) for specific details.

TIP

A symbol represents the minimum version.

OPERATING SYSTEM	.NET CORE 3.1	.NET 6
Windows 11	✓	✓
Windows Server 2022	✓	✓
Windows 10 Version 21H1	✓	✓
Windows 10 / Windows Server, Version 20H2	✓	✓
Windows 10 / Windows Server, Version 2004	✓	✓
Windows 10 / Windows Server, Version 1909	✓	✓
Windows 10 / Windows Server, Version 1903	✓	✓
Windows 10, Version 1809	✓	✓

OPERATING SYSTEM	.NET CORE 3.1	.NET 6
Windows 10, Version 1803	✓	✓
Windows 10, Version 1709	✓	✓
Windows 10, Version 1607	✓	✓
Windows 8.1	✓	✓
Windows 7 SP1 ESU	✓	✓
Windows Server 2019 Windows Server 2016 Windows Server 2012 R2 Windows Server 2012	✓	✓
Windows Server Core 2012 R2	✓	✓
Windows Server Core 2012	✓	✓
Nano Server, Version 1809+	✓	✓
Nano Server, Version 1803	✓	✗

For more information about .NET 6 supported operating systems, distributions, and lifecycle policy, see [.NET 6 Supported OS Versions](#).

Unsupported releases

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Runtime information

The runtime is used to run apps created with .NET. When an app author publishes an app, they can include the runtime with their app. If they don't include the runtime, it's up to the user to install the runtime.

There are three different runtimes you can install on Windows:

- *ASP.NET Core runtime*
Runs ASP.NET Core apps. Includes the .NET runtime.
- *Desktop runtime*
Runs .NET WPF and Windows Forms desktop apps for Windows. Includes the .NET runtime.
- *.NET runtime*
This runtime is the simplest runtime and doesn't include any other runtime. It's highly recommended that you install both *ASP.NET Core runtime* and *Desktop runtime* for the best compatibility with .NET apps.

[DOWNLOAD .NET](#)
[RUNTIME](#)

SDK information

The SDK is used to build and publish .NET apps and libraries. Installing the SDK includes all three [runtimes](#): ASP.NET Core, Desktop, and .NET.

[DOWNLOAD .NET](#)
[SDK](#)

Arm-based Windows PCs

The following sections describe things you should consider when installing .NET on an Arm-based Windows PC.

What's supported

The following table describes which versions of .NET are supported on an Arm-based Windows PC:

.NET VERSION	ARCHITECTURE	SDK	RUNTIME	PATH CONFLICT
6.0	Arm64	Yes	Yes	No
6.0	x64	Yes	Yes	No
5.0	Arm64	Yes	Yes	Yes
5.0	x64	No	Yes	Yes
3.1	Arm64	No	No	N/A
3.1	x64	No	Yes	Yes

The x64 and Arm64 versions of the .NET 6 SDK exist independently from each other. If a new version is released, each install needs to be upgraded.

Path differences

On an Arm-based Windows PC, all Arm64 versions of .NET are installed to the normal *C:\Program Files\dotnet* folder. However, when you install the x64 version of .NET 6 SDK, it's installed to the *C:\Program Files\dotnet\x64* folder.

Path conflicts

The x64 .NET 6 SDK installs to its own directory, as described in the previous section. This allows the Arm64 and x64 versions of the .NET 6 SDK to exist on the same machine. However, any x64 SDK prior to 6.0 isn't supported and installs to the same location as the Arm64 version, the *C:\Program Files\dotnet* folder. If you want to install an unsupported x64 SDK, you'll need to first uninstall the Arm64 version. The opposite is also true, you'll need to uninstall the unsupported x64 SDK to install the Arm64 version.

Path variables

Environment variables that add .NET to system path, such as the `PATH` variable, may need to be changed if you have both the x64 and Arm64 versions of the .NET 6 SDK installed. Additionally, some tools rely on the `DOTNET_ROOT` environment variable, which would also need to be updated to point to the appropriate .NET 6 SDK installation folder.

Dependencies

- [.NET 6](#)
- [.NET Core 3.1](#)

The following Windows versions are supported with .NET 6:

NOTE

A  symbol represents the minimum version.

OS	VERSION	ARCHITECTURES
Windows 11	21H2	x64, Arm64
Windows 10 Client	1607+	x64, x86, Arm64
Windows Client	7 SP1+, 8.1	x64, x86
Windows Server	2012+	x64, x86
Windows Server Core	2012+	x64, x86
Nano Server	1809+	x64

For more information about .NET 6 supported operating systems, distributions, and lifecycle policy, see [.NET 6 Supported OS Versions](#).

Windows 7 / Vista / 8.1 / Server 2008 R2 / Server 2012 R2

More dependencies are required if you're installing the .NET SDK or runtime on the following Windows versions:

OPERATING SYSTEM	PREREQUISITES
Windows 7 SP1 ESU	<ul style="list-style-type: none">- Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit- KB3063858 64-bit / 32-bit- Microsoft Root Certificate Authority 2011 (.NET Core 2.1 offline installer only)
Windows Vista SP 2	Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit
Windows 8.1	Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit
Windows Server 2008 R2	Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit
Windows Server 2012	Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit
Windows Server 2012 R2	Microsoft Visual C++ 2015-2019 Redistributable 64-bit / 32-bit

The previous requirements are also required if you receive an error related to either of the following dlls:

- *api-ms-win-crt-runtime-l1-1-0.dll*
- *api-ms-win-cor-timezone-l1-1-0.dll*
- *hostfxr.dll*

Docker

Containers provide a lightweight way to isolate your application from the rest of the host system. Containers on the same machine share just the kernel and use resources given to your application.

.NET can run in a Docker container. Official .NET Docker images are published to the Microsoft Container Registry (MCR) and are discoverable at the [Microsoft .NET Docker Hub repository](#). Each repository contains images for different combinations of the .NET (SDK or Runtime) and OS that you can use.

Microsoft provides images that are tailored for specific scenarios. For example, the [ASP.NET Core repository](#) provides images that are built for running ASP.NET Core apps in production.

For more information about using .NET in a Docker container, see [Introduction to .NET and Docker](#) and [Samples](#).

Troubleshooting

After installing the .NET SDK, you may run into problems trying to run .NET CLI commands. This section collects those common problems and provides solutions.

- [It was not possible to find any installed .NET Core SDKs](#)

It was not possible to find any installed .NET Core SDKs

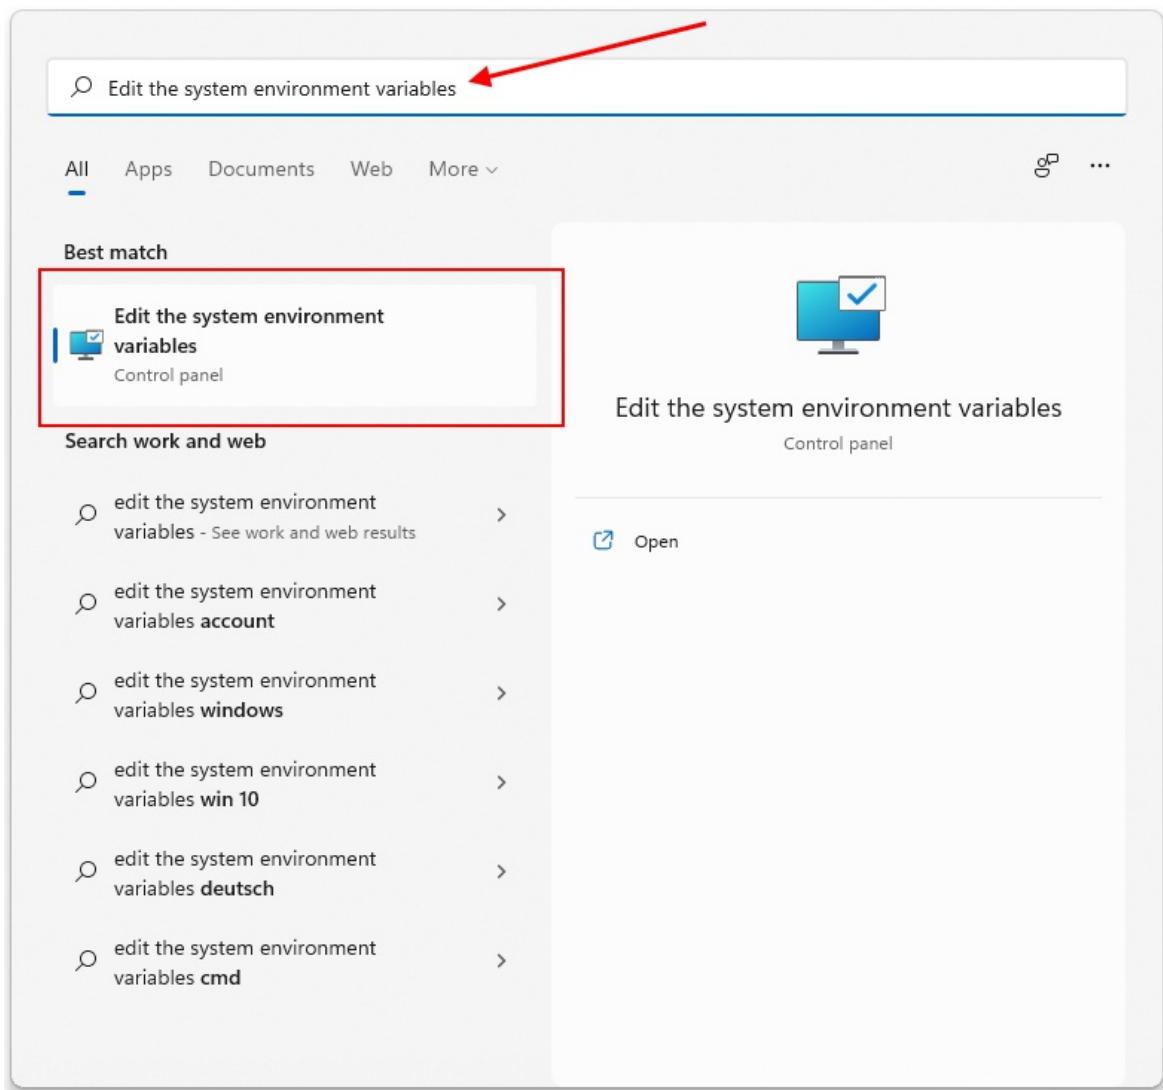

Most likely you've installed both the x86 (32-bit) and x64 (64-bit) versions of the .NET SDK. This is causing a conflict because when you run the `dotnet` command it's resolving to the x86 version when it should resolve to the x64 version. This is usually fixed by adjusting the `%PATH%` variable to resolve the x64 version first.

1. Verify that you have both versions installed by running the `where.exe dotnet` command. If you do, you should see an entry for both the *Program Files* and *Program Files (x86)* folders. If the *Program Files (x86)* folder is first as indicated by the following example, it's incorrect and you should continue on to the next step.

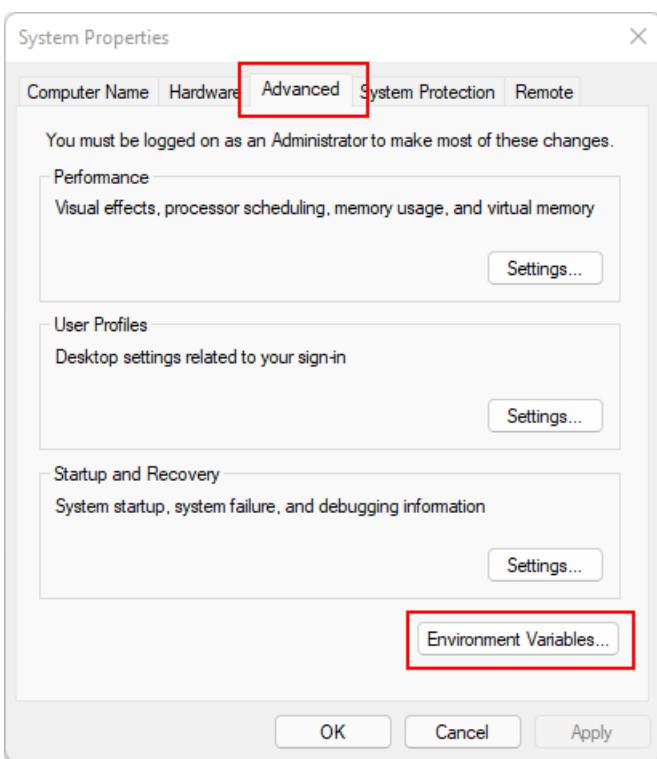

```
> where.exe dotnet
C:\Program Files (x86)\dotnet\dotnet.exe
C:\Program Files\dotnet\dotnet.exe
```

If it's correct and the *Program Files* is first, you don't have the problem this section is discussing and you should create a [.NET help request issue on GitHub](#)

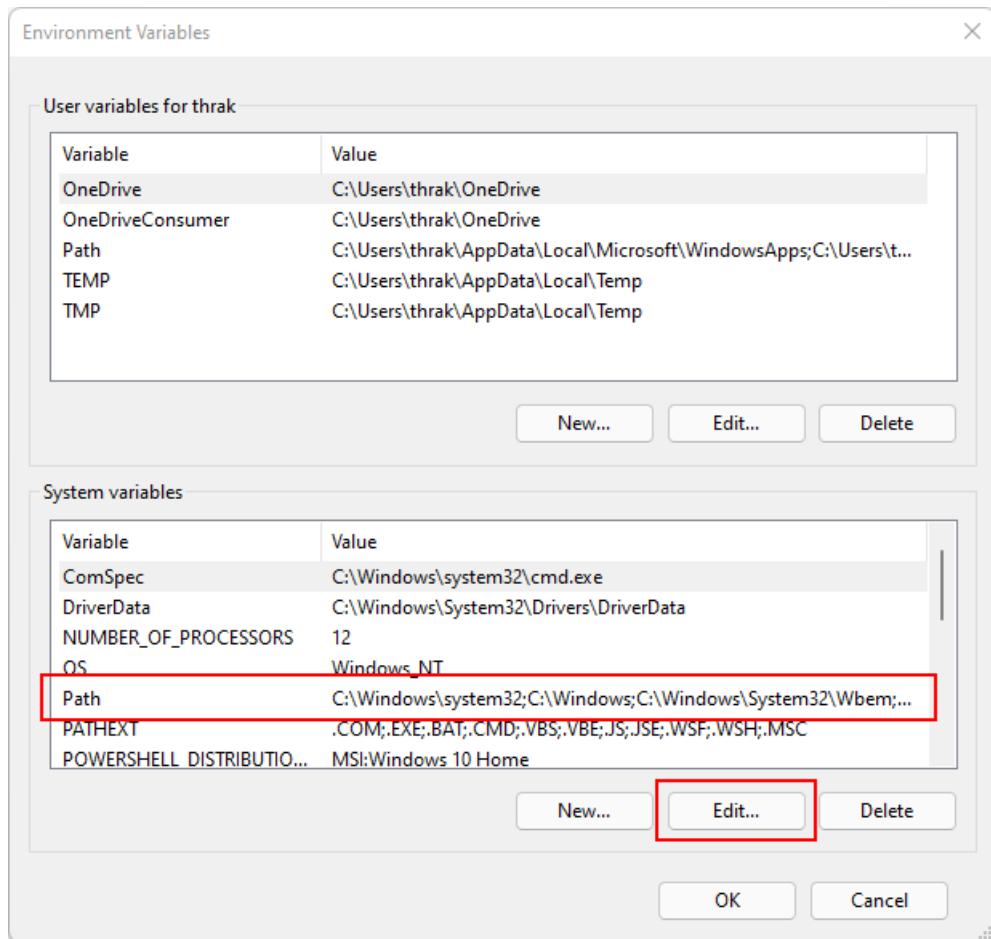

2. Press the Windows button and type "Edit the system environment variables" into search. Select **Edit the system environment variables**.

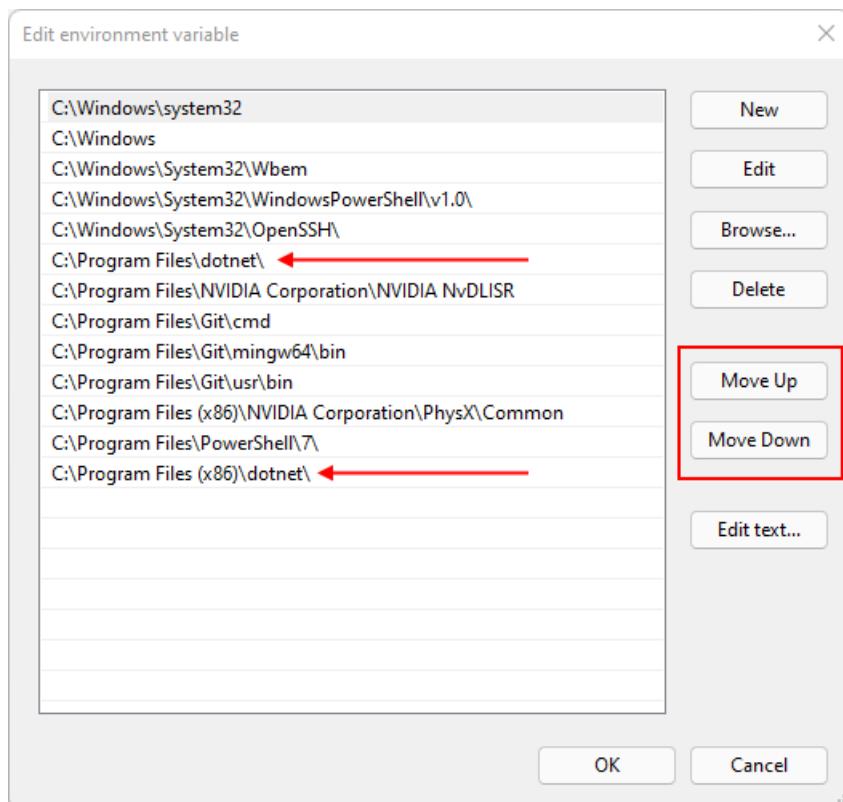

3. The System Properties window opens up to the Advanced Tab. Select Environment Variables.

4. On the Environment Variables window, under the System variables group, select the *Path** row and then select the Edit button.

5. Use the Move Up and Move Down buttons to move the C:\Program Files\dotnet\ entry above C:\Program Files (x86)\dotnet\.

Install .NET on macOS

9/20/2022 • 7 minutes to read • [Edit Online](#)

In this article, you'll learn how to install .NET on macOS. .NET is made up of the runtime and the SDK. The runtime is used to run a .NET app and may or may not be included with the app. The SDK is used to create .NET apps and libraries. The .NET runtime is always installed with the SDK.

The latest version of .NET is 6.0.

[DOWNLOAD .NET
CORE](#)

Supported releases

The following table is a list of currently supported .NET releases and the versions of macOS they're supported on. These versions remain supported until the version of .NET reaches [end-of-support](#).

- A ✓ indicates that the version of .NET is still supported.
- A ✗ indicates that the version of .NET isn't supported.

OPERATING SYSTEM	.NET CORE 3.1	.NET 6
macOS 12.0 "Monterey"	✓ 3.1	✓ 6.0
macOS 11.0 "Big Sur"	✓ 3.1	✓ 6.0
macOS 10.15 "Catalina"	✓ 3.1	✓ 6.0

For more information about the life cycle of .NET releases, see [.NET and .NET Core Support Policy](#).

Unsupported releases

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Runtime information

The runtime is used to run apps created with .NET. When an app author publishes an app, they can include the runtime with their app. If they don't include the runtime, it's up to the user to install the runtime.

There are two different runtimes you can install on macOS:

- *ASP.NET Core runtime*
Runs ASP.NET Core apps. Includes the .NET runtime.
- *.NET runtime*
This runtime is the simplest runtime and doesn't include any other runtime. It's highly recommended that

you install *ASP.NET Core runtime* for the best compatibility with .NET apps.

[DOWNLOAD .NET](#)

[RUNTIME](#)

SDK information

The SDK is used to build and publish .NET apps and libraries. Installing the SDK includes both [runtimes](#): ASP.NET Core and .NET.

Notarization

Beginning with macOS Catalina (version 10.15), all software built after June 1, 2019 that is distributed with Developer ID, must be notarized. This requirement applies to the .NET runtime, .NET SDK, and software created with .NET.

The runtime and SDK installers for .NET have been notarized since February 18, 2020. Prior released versions aren't notarized. If you run a non-notarized app, you'll see an error similar to the following image:

For more information about how enforced-notarization affects .NET (and your .NET apps), see [Working with macOS Catalina Notarization](#).

libgdiplus

.NET applications that use the *System.Drawing.Common* assembly require libgdiplus to be installed.

An easy way to obtain libgdiplus is by using the [Homebrew \("brew"\)](#) package manager for macOS. After installing *brew*, install libgdiplus by executing the following commands at a Terminal (command) prompt:

```
brew update  
brew install mono-libgdiplus
```

Install with an installer

macOS has standalone installers that can be used to install the .NET 6 SDK:

- [x64 and Arm64 CPUs](#)

Download and manually install

As an alternative to the macOS installers for .NET, you can download and manually install the SDK and runtime. Manual installation is usually performed as part of continuous integration testing. For a developer or user, it's generally better to use an [installer](#).

First, download a **binary** release for either the SDK or the runtime from one of the following sites. If you install the .NET SDK, you will not need to install the corresponding runtime:

- ✓ [.NET 6 downloads](#)
- ✓ [.NET Core 3.1 downloads](#)
- [All .NET downloads](#)

Next, extract the downloaded file and use the `export` command to set `DOTNET_ROOT` to the extracted folder's location and then ensure .NET is in PATH. This should make the .NET CLI commands available at the terminal.

Alternatively, after downloading the .NET binary, the following commands may be run from the directory where the file is saved to extract the runtime. This will also make the .NET CLI commands available at the terminal and set the required environment variables. **Remember to change the `DOTNET_FILE` value to the name of the downloaded binary:**

```
DOTNET_FILE=dotnet-sdk-6.0.100-osx-x64.tar.gz
export DOTNET_ROOT=$(pwd)/dotnet

mkdir -p "$DOTNET_ROOT" && tar zxf "$DOTNET_FILE" -C "$DOTNET_ROOT"

export PATH=$PATH:$DOTNET_ROOT
```

TIP

The preceding `export` commands only make the .NET CLI commands available for the terminal session in which it was run.

You can edit your shell profile to permanently add the commands. There are a number of different shells available for Linux and each has a different profile. For example:

- **Bash Shell:** `~/.bash_profile`, `~/.bashrc`
- **Korn Shell:** `~/.kshrc` or `.profile`
- **Z Shell:** `~/.zshrc` or `.zprofile`

Edit the appropriate source file for your shell and add `:$HOME/dotnet` to the end of the existing `PATH` statement. If no `PATH` statement is included, add a new line with `export PATH=$PATH:$HOME/dotnet`.

Also, add `export DOTNET_ROOT=$HOME/dotnet` to the end of the file.

This approach lets you install different versions into separate locations and choose explicitly which one to use by which application.

Arm-based Macs

The following sections describe things you should consider when installing .NET on an Arm-based Mac.

What's supported

The following table describes which versions of .NET are supported on an Arm-based Mac:

.NET VERSION	ARCHITECTURE	SDK	RUNTIME	PATH CONFLICT
6.0	Arm64	Yes	Yes	No
6.0	x64	Yes	Yes	No
3.1	Arm64	No	No	N/A
3.1	x64	No	Yes	Yes

The x64 and Arm64 versions of the .NET 6 SDK exist independently from each other. If a new version is released, each install needs to be upgraded.

Path differences

On an Arm-based Mac, all Arm64 versions of .NET are installed to the normal `/usr/local/share/dotnet`/folder. However, when you install the **x64** version of .NET 6 SDK, it's installed to the `/usr/local/share/dotnet/x64/dotnet`/folder.

Path conflicts

The **x64** .NET 6 SDK installs to its own directory, as described in the previous section. This allows the Arm64 and x64 versions of the .NET 6 SDK to exist on the same machine. However, any **x64** SDK prior to 6.0 isn't supported and installs to the same location as the Arm64 version, the `/usr/local/share/dotnet`/folder. If you want to install an unsupported x64 SDK, you'll need to first uninstall the Arm64 version. The opposite is also true, you'll need to uninstall the unsupported x64 SDK to install the Arm64 version.

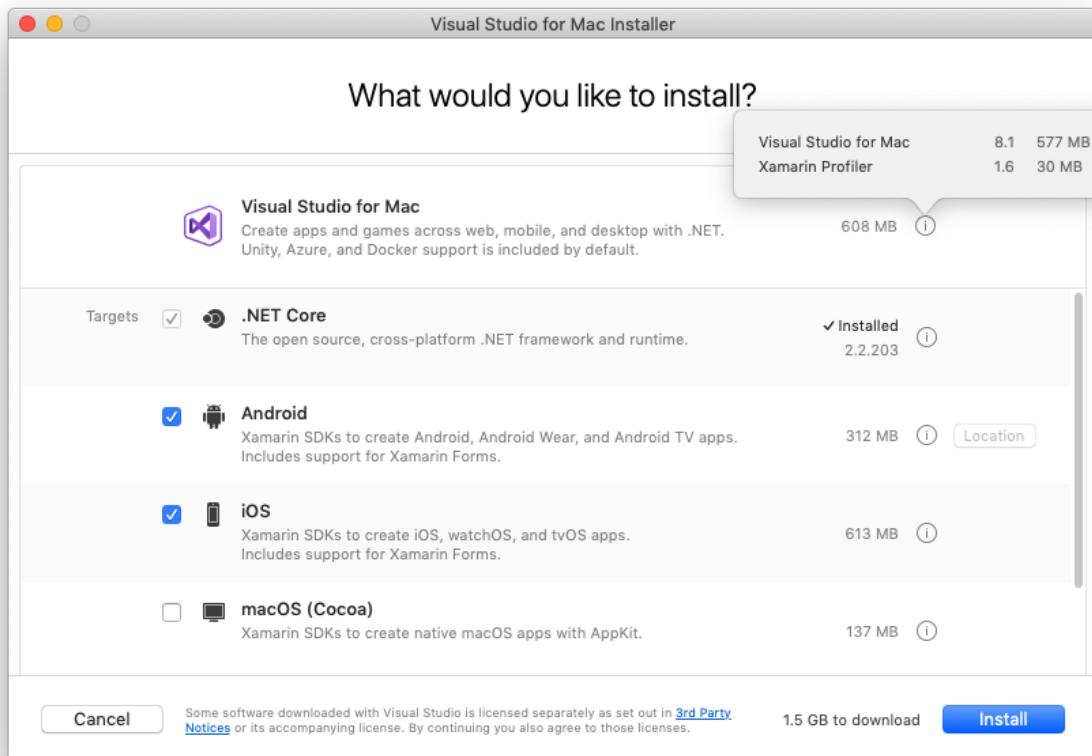

Path variables

Environment variables that add .NET to system path, such as the `PATH` variable, may need to be changed if you have both the x64 and Arm64 versions of the .NET 6 SDK installed. Additionally, some tools rely on the `DOTNET_ROOT` environment variable, which would also need to be updated to point to the appropriate .NET 6 SDK installation folder.

Install with Visual Studio for Mac

Visual Studio for Mac installs the .NET SDK when the **.NET** workload is selected. To get started with .NET development on macOS, see [Install Visual Studio 2019 for Mac](#).

.NET SDK VERSION	VISUAL STUDIO VERSION
6.0	Visual Studio 2022 for Mac Preview 3 17.0 or higher.
3.1	Visual Studio 2019 for Mac version 8.4 or higher.

Install alongside Visual Studio Code

Visual Studio Code is a powerful and lightweight source code editor that runs on your desktop. Visual Studio Code is available for Windows, macOS, and Linux.

While Visual Studio Code doesn't come with an automated .NET installer like Visual Studio does, adding .NET support is simple.

1. [Download and install Visual Studio Code.](#)
2. [Download and install the .NET SDK.](#)
3. [Install the C# extension from the Visual Studio Code marketplace.](#)

Install with bash automation

The [dotnet-install scripts](#) are used for automation and non-admin installs of the runtime. You can download the script from the [dotnet-install script reference page](#).

The script defaults to installing the latest [long term support \(LTS\)](#) version, which is .NET 6.0. You can choose a specific release by specifying the `current` switch. Include the `runtime` switch to install a runtime. Otherwise, the script installs the [SDK](#).

```
./dotnet-install.sh --channel 6.0 --runtime aspnetcore
```

NOTE

The previous command installs the ASP.NET Core runtime for maximum compatibility. The ASP.NET Core runtime also includes the standard .NET runtime.

Docker

Containers provide a lightweight way to isolate your application from the rest of the host system. Containers on the same machine share just the kernel and use resources given to your application.

.NET can run in a Docker container. Official .NET Docker images are published to the Microsoft Container Registry (MCR) and are discoverable at the [Microsoft .NET Docker Hub repository](#). Each repository contains images for different combinations of the .NET (SDK or Runtime) and OS that you can use.

Microsoft provides images that are tailored for specific scenarios. For example, the [ASP.NET Core repository](#) provides images that are built for running ASP.NET Core apps in production.

For more information about using .NET in a Docker container, see [Introduction to .NET and Docker](#) and [Samples](#).

- [Tutorial: Create a new app with Visual Studio Code](#).
- [Tutorial: Containerize a .NET app](#).

Install .NET on Linux

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article details how to install .NET on various Linux distributions, manually and via a package manager. Typically, stable .NET versions are available in a package manager, and Preview versions are not.

Manual installation

You can install .NET manually in the following ways:

- [Download tarballs](#)
- [Scripted install](#)
- [Manual binary extraction](#)

You may need to install [.NET dependencies](#) if you install .NET manually.

Official package archives

.NET is available in the [official package archives](#) for various Linux distributions, including the following ones:

- [Alpine Linux](#)
- [Arch Linux](#)
- [Arch Linux User Repository](#)
- [Fedora](#)
- [Red Hat Enterprise Linux](#)
- [Ubuntu](#)

Microsoft collaborates with partners to ensure .NET works well on their Linux distributions. Support is provided by those distributions. You can still [open issues at dotnet/core](#) if you run into problems.

Microsoft packages

.NET is also available via [packages.microsoft.com](#).

- [CentOS](#)
- [Debian](#)
- [Fedora](#)
- [openSUSE](#)
- [SLES](#)
- [Ubuntu](#)

These packages are [supported by Microsoft](#).

You're encouraged to install .NET from the official archive for your distribution if it's available there, even if it's also available at [packages.microsoft.com](#).

Other distributions

Installation information is also provided for other distributions.

- [Alpine](#)

- [Containers](#)
- [Snap](#)

Next steps

- [How to check if .NET is already installed.](#)
- [Tutorial: Create a new app with Visual Studio Code.](#)
- [Tutorial: Containerize a .NET app.](#)

Install the .NET SDK or the .NET Runtime on Ubuntu

9/20/2022 • 11 minutes to read • [Edit Online](#)

.NET is supported on Ubuntu. This article describes how to install .NET on Ubuntu. When an [Ubuntu version](#) falls out of support, .NET is no longer supported with that version.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the [ASP.NET Core Runtime](#) as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap.](#)
- [Alternatively install .NET with `install-dotnet` script.](#)
- [Manually install .NET](#)

Supported distributions

The following table is a list of currently supported .NET releases and the versions of Ubuntu they're supported on.

UBUNTU	.NET
22.04 (LTS)	6+
20.04 (LTS)	3.1, 6
18.04 (LTS)	3.1, 6
16.04 (LTS)	3.1, 6

The following versions of .NET are **X** no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

22.04

WARNING

If you've previously installed .NET 6 from packages.microsoft.com, see the [Advisory on installing .NET 6 on Ubuntu 22.04](#).

.NET 6 is included in the Ubuntu 22.04 package manager feeds.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y dotnet
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

22.04 (Microsoft package feed)

NOTE

Warning: .NET 6 is included in Ubuntu 22.04. See the [Advisory on installing .NET 6 on Ubuntu 22.04](#) if you want to use .NET packages from packages.microsoft.com.

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/ubuntu/22.04/packages-microsoft-prod.deb -O packages-microsoft-prod.deb  
sudo dpkg -i packages-microsoft-prod.deb  
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

NOTE

Ubuntu 22.04 includes OpenSSL 3 as the baseline version. .NET 6 supports OpenSSL 3 while earlier .NET versions don't. Microsoft doesn't test or support using OpenSSL 1.x on Ubuntu 22.04. For more information, see [.NET 6 Security Improvements](#).

20.04

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/ubuntu/20.04/packages-microsoft-prod.deb -O packages-microsoft-prod.deb  
sudo dpkg -i packages-microsoft-prod.deb  
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

18.04

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/ubuntu/18.04/packages-microsoft-prod.deb -O packages-microsoft-prod.deb  
sudo dpkg -i packages-microsoft-prod.deb  
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

16.04

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/ubuntu/16.04/packages-microsoft-prod.deb -O packages-microsoft-prod.deb  
sudo dpkg -i packages-microsoft-prod.deb  
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version} .
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Use APT to update .NET

When a new patch release is available for .NET, you can simply upgrade it through APT with the following commands:

```
sudo apt-get update  
sudo apt-get upgrade
```

If you've upgraded your Linux distribution since installing .NET, you may need to reconfigure the Microsoft package repository. Run the installation instructions for your current distribution version to upgrade to the appropriate package repository for .NET updates.

APT troubleshooting

This section provides information on common errors you may get while using APT to install .NET.

Unable to find package

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap](#).
- [Alternatively install .NET with `install-dotnet` script](#).

- Manually install .NET

Unable to locate \ Some packages could not be installed

NOTE

This information only applies when .NET is installed from the Microsoft package feed.

If you receive an error message similar to **Unable to locate package {dotnet-package}** or **Some packages could not be installed**, run the following commands.

There are two placeholders in the following set of commands.

- `{dotnet-package}`

This represents the .NET package you're installing, such as `aspnetcore-runtime-3.1`. This is used in the following `sudo apt-get install` command.

- `{os-version}`

This represents the distribution version you're on. This is used in the `wget` command below. The distribution version is the numerical value, such as `20.04` on Ubuntu or `10` on Debian.

First, try purging the package list:

```
sudo dpkg --purge packages-microsoft-prod && sudo dpkg -i packages-microsoft-prod.deb  
sudo apt-get update
```

Then, try to install .NET again. If that doesn't work, you can run a manual install with the following commands:

```
sudo apt-get install -y gpg  
wget -O - https://packages.microsoft.com/keys/microsoft.asc | gpg --dearmor -o microsoft.asc.gpg  
sudo mv microsoft.asc.gpg /etc/apt/trusted.gpg.d/  
wget https://packages.microsoft.com/config/ubuntu/{os-version}/prod.list  
sudo mv prod.list /etc/apt/sources.list.d/microsoft-prod.list  
sudo chown root:root /etc/apt/trusted.gpg.d/microsoft.asc.gpg  
sudo chown root:root /etc/apt/sources.list.d/microsoft-prod.list  
sudo apt-get update && \  
sudo apt-get install -y {dotnet-package}
```

Failed to fetch

While installing the .NET package, you may see an error similar to

`Failed to fetch ... File has unexpected size ... Mirror sync in progress?`. This error could mean that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed shouldn't be unavailable for more than 30 minutes. If you continually receive this error for more than 30 minutes, please file an issue at <https://github.com/dotnet/core/issues>.

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET or you publish a self-contained app, you'll need to make sure these libraries are installed:

- libc6
- libgcc1
- libgssapi-krb5-2
- libicu52 (for 14.x)
- libicu55 (for 16.x)

- libicu60 (for 18.x)
- libicu66 (for 20.x)
- libssl1.0.0 (for 14.x, 16.x)
- libssl1.1 (for 18.x, 20.x)
- libstdc++6
- zlib1g

For .NET apps that use the *System.Drawing.Common* assembly, you also need the following dependency:

- libgdiplus (version 6.0.1 or later)

WARNING

You can install a recent version of *libgdiplus* by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

Install the .NET SDK or the .NET Runtime on Alpine

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes how to install .NET on Alpine. When an Alpine version falls out of support, .NET is no longer supported with that version. However, these instructions may help you to get .NET running on those versions, even though it isn't supported.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

Install

Installers aren't available for Alpine Linux. You must install .NET in one of the following ways:

- Scripted install with [*install-dotnet.sh*](#)
- Manual binary extraction

Supported distributions

The following table is a list of currently supported .NET releases and the versions of Alpine they're supported on. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of [Alpine reaches end-of-life](#).

- A ✓ indicates that the version of Alpine or .NET is still supported.
- A ✗ indicates that the version of Alpine or .NET isn't supported on that Alpine release.
- When both a version of Alpine and a version of .NET have ✓, that OS and .NET combination is supported.

ALPINE	.NET CORE 3.1	.NET 6
✓ 3.15	✓ 3.1	✓ 6.0
✓ 3.14	✓ 3.1	✓ 6.0
✓ 3.13	✓ 3.1	✓ 6.0
✓ 3.12	✓ 3.1	✓ 6.0
✗ 3.11	✓ 3.1	✗ 6.0
✗ 3.10	✓ 3.1	✗ 6.0
✗ 3.9	✓ 3.1	✗ 6.0
✗ 3.8	✓ 3.1	✗ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Dependencies

.NET on Alpine Linux requires the following dependencies installed:

- icu-libs
- krb5-libs
- libgcc
- libgdiplus (if the .NET app requires the *System.Drawing.Common* assembly)
- libintl
- libssl1.1 (Alpine v3.9 or greater)
- libssl1.0 (Alpine v3.8 or lower)
- libstdc++
- zlib

To install the needed requirements, run the following command:

```
apk add bash icu-libs krb5-libs libgcc libintl libssl1.1 libstdc++ zlib
```

To install **libgdiplus**, you may need to specify a repository:

```
apk add libgdiplus --repository https://dl-3.alpinelinux.org/alpine/edge/testing/
```

Next steps

- [How to enable TAB completion for the .NET CLI](#)
- [Tutorial: Create a console application with .NET SDK using Visual Studio Code](#)

Install the .NET SDK or the .NET Runtime on CentOS

9/20/2022 • 7 minutes to read • [Edit Online](#)

.NET is supported on CentOS. This article describes how to install .NET on CentOS. If you need to install .NET On CentOS Stream, see [Install the .NET SDK or the .NET Runtime on RHEL and CentOS Stream](#).

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap](#).
- [Alternatively install .NET with `install-dotnet` script](#).
- [Manually install .NET](#)

Supported distributions

The following table is a list of currently supported .NET releases on both CentOS 7 and CentOS 8. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of CentOS is no longer supported.

- A ✓ indicates that the version of CentOS or .NET is still supported.
- A ✗ indicates that the version of CentOS or .NET isn't supported on that CentOS release.
- When both a version of CentOS and a version of .NET have ✓, that OS and .NET combination is supported.

CENTOS	.NET CORE 3.1	.NET 6
✓ 7	✓ 3.1	✓ 6.0
✗ 8*	✓ 3.1	✗ 6.0

WARNING

*CentOS 8 reached an early End Of Life (EOL) on December 31st, 2021. For more information, see the official [CentOS Linux EOL page](#). Because of this, .NET 6 won't be supported on CentOS Linux 8.

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap.](#)
- [Alternatively install .NET with `install-dotnet` script.](#)
- [Manually install .NET](#)

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with `install-dotnet.sh`](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

CentOS 7 ✓

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

```
sudo rpm -Uvh https://packages.microsoft.com/config/centos/7/packages-microsoft-prod.rpm
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo yum install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command installs the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo yum install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo yum install dotnet-runtime-6.0
```

CentOS 8 ✓

WARNING

*CentOS 8 will reach an early End Of Life (EOL) on December 31st, 2021. For more information, see the official [CentOS Linux EOL page](#). Because of this, .NET 6 won't be supported on CentOS Linux 8.

.NET 5 is available in the default package repositories for CentOS 8.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-5.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-5.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-5.0` in the previous command with `dotnet-runtime-5.0`:

```
sudo dnf install dotnet-runtime-5.0
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version} .
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET.

Unable to find package

IMPORTANT

Package manager installs are only supported on the `x64` architecture. Other architectures, such as `Arm`, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET without a package manager, see one of the following articles:

- [Alternatively install .NET with Snap](#).
- [Alternatively install .NET with `install-dotnet` script](#).
- [Manually install .NET](#)

Failed to fetch

While installing the .NET package, you may see an error similar to

`signature verification failed for file 'repomd.xml' from repository 'packages-microsoft-com-prod'`. Generally speaking, this error means that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed should not be unavailable for more than 2 hours. If you continually receive this error for more than 2 hours, please file an issue at <https://github.com/dotnet/core/issues>.

Errors related to missing `fxr`, `libhostfxr.so`, or `FrameworkList.xml`

For more information about solving these problems, see [Troubleshoot `fxr`](#), [libhostfxr.so](#), and [FrameworkList.xml errors](#).

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET Core or you publish a self-contained app, you'll need to make sure these libraries are installed:

- krb5-libs
- libicu
- openssl-libs
- zlib

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET Core apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- `libgdiplus` (version 6.0.1 or later)

WARNING

You can install a recent version of `libgdiplus` by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

- [How to enable TAB completion for the .NET CLI](#)
- [Tutorial: Create a console application with .NET SDK using Visual Studio Code](#)

Install the .NET SDK or the .NET Runtime on RHEL and CentOS Stream

9/20/2022 • 8 minutes to read • [Edit Online](#)

.NET is supported on Red Hat Enterprise Linux (RHEL). This article describes how to install .NET on RHEL and CentOS Stream.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

Register your Red Hat subscription

To install .NET from Red Hat on RHEL, you first need to register using the Red Hat Subscription Manager. If this hasn't been done on your system, or if you're unsure, see the [Red Hat Product Documentation for .NET](#).

IMPORTANT

This doesn't apply to CentOS Stream.

Supported distributions

The following table is a list of currently supported .NET releases on both RHEL and CentOS Stream. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the Linux distribution is no longer supported.

- A ✓ indicates that the version of RHEL or .NET is still supported.
- A ✗ indicates that the version of RHEL or .NET isn't supported on that RHEL release.
- When both a version of Linux distribution and a version of .NET have ✓, that OS and .NET combination is supported.

DISTRIBUTION	.NET CORE 3.1	.NET 6
✓ RHEL 8	✓ 3.1	✓ 6.0
✓ RHEL 7	✓ 3.1	✓ 6.0
✓ CentOS Stream 9	✗ 3.1	✓ 6.0
✓ CentOS Stream 8	✓ 3.1	✓ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0

- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

RHEL 8 ✓

.NET is included in the AppStream repositories for RHEL 8.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

RHEL 7 ✓ .NET 6.0

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the

corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet60 -y  
scl enable rh-dotnet60 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet60` because it may affect other programs. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet60
```

Install the runtime

The .NET Runtime allows you to run apps that were made with .NET that didn't include the runtime. The commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet60-aspnetcore-runtime-6.0 -y  
scl enable rh-dotnet60 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet60` because it may affect other programs. If you want to enable `rh-dotnet60` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet60
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet60-aspnetcore-runtime-6.0` in the preceding command with `rh-dotnet60-dotnet-runtime-6.0`.

RHEL 7 ✓ .NET 5.0

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet50 -y  
scl enable rh-dotnet50 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet50` because it may affect other programs. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet50
```

Install the runtime

The .NET Runtime allows you to run apps that were made with .NET that didn't include the runtime. The

commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet50-aspnetcore-runtime-5.0 -y
scl enable rh-dotnet50 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet50` because it may affect other programs. If you want to enable `rh-dotnet50` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet50
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet50-aspnetcore-runtime-5.0` in the commands above with `rh-dotnet50-dotnet-runtime-5.0`.

RHEL 7 ✓ .NET Core 3.1

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

.NET SDK allows you to develop apps with .NET Core. If you install .NET SDK, you don't need to install the corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet31 -y
scl enable rh-dotnet31 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet31` because it may affect other programs. For example, `rh-dotnet31` includes a version of `libcurl` that differs from the base RHEL version. This may lead to issues in programs that do not expect a different version of `libcurl`. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet31
```

Install the runtime

The .NET Core Runtime allows you to run apps that were made with .NET Core that didn't include the runtime. The commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet31-aspnetcore-runtime-3.1 -y
scl enable rh-dotnet31 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet31` because it may affect other programs. For example, `rh-dotnet31` includes a version of `libcurl` that differs from the base RHEL version. This may lead to

issues in programs that do not expect a different version of `libcurl`. If you want to enable `rh-dotnet31` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet31
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Core Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet31-aspnetcore-runtime-3.1` in the commands above with `rh-dotnet31-dotnet-runtime-3.1`.

CentOS Stream 9 ✓

.NET is included in the AppStream repositories for CentOS Stream 9. However, .NET Core 3.1 and .NET 5 have been removed from CentOS Stream 9 and you should use .NET 6. For more information, see the blog post [Using .NET with OpenSSL in CentOS Stream 9 | Omair Majid](#).

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

CentOS Stream 8 ✓

.NET is included in the AppStream repositories for CentOS Stream 8.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET Core or you publish a self-contained app, you'll need to make sure these libraries are installed:

- `krb5-libs`
- `libicu`
- `openssl-libs`
- `zlib`

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET Core apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- [libgdiplus \(version 6.0.1 or later\)](#)

WARNING

You can install a recent version of `libgdiplus` by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

How to install other versions

Consult the [Red Hat documentation for .NET](#) on the steps required to install other releases of .NET.

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET or .NET Core.

Errors related to missing `fxr`, `libhostfxr.so`, or `FrameworkList.xml`

For more information about solving these problems, see [Troubleshoot `fxr`, `libhostfxr.so`, and `FrameworkList.xml` errors](#).

Install the .NET SDK or the .NET Runtime on Debian

9/20/2022 • 10 minutes to read • [Edit Online](#)

This article describes how to install .NET on Debian. When a Debian version falls out of support, .NET is no longer supported with that version. However, these instructions may help you to get .NET running on those versions, even though it isn't supported.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap.](#)
- [Alternatively install .NET with `install-dotnet` script.](#)
- [Manually install .NET](#)

Supported distributions

The following table is a list of currently supported .NET releases and the versions of Debian they're supported on. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of [Debian reaches end-of-life](#).

- A ✓ indicates that the version of Debian or .NET is still supported.
- A ✗ indicates that the version of Debian or .NET isn't supported on that Debian release.
- When both a version of Debian and a version of .NET have ✓, that OS and .NET combination is supported.

DEBIAN	.NET CORE 3.1	.NET 6
✓ 11	✓ 3.1	✓ 6.0
✓ 10	✓ 3.1	✓ 6.0
✓ 9	✓ 3.1	✓ 6.0
✗ 8	✗ 3.1	✗ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5

- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

Debian 11 ✓

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/debian/11/packages-microsoft-prod.deb -O packages-microsoft-prod.deb
sudo dpkg -i packages-microsoft-prod.deb
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

Debian 10 ✓

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget https://packages.microsoft.com/config/debian/10/packages-microsoft-prod.deb -O packages-microsoft-
prod.deb
sudo dpkg -i packages-microsoft-prod.deb
rm packages-microsoft-prod.deb
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

Debian 9 ✓

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget -O - https://packages.microsoft.com/keys/microsoft.asc | gpg --dearmor > microsoft.asc.gpg  
sudo mv microsoft.asc.gpg /etc/apt/trusted.gpg.d/  
wget https://packages.microsoft.com/config/debian/9/prod.list  
sudo mv prod.list /etc/apt/sources.list.d/microsoft-prod.list  
sudo chown root:root /etc/apt/trusted.gpg.d/microsoft.asc.gpg  
sudo chown root:root /etc/apt/sources.list.d/microsoft-prod.list
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y dotnet-sdk-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-6.0**, see the [APT troubleshooting](#) section.

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following commands:

```
sudo apt-get update && \  
sudo apt-get install -y aspnetcore-runtime-6.0
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-6.0**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo apt-get install -y dotnet-runtime-6.0
```

Debian 8 X

X Please note that this version of Debian is no longer supported.

Installing with APT can be done with a few commands. Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the package repository.

Open a terminal and run the following commands:

```
wget -O - https://packages.microsoft.com/keys/microsoft.asc | gpg --dearmor > microsoft.asc.gpg
sudo mv microsoft.asc.gpg /etc/apt/trusted.gpg.d/
wget https://packages.microsoft.com/config/debian/8/prod.list
sudo mv prod.list /etc/apt/sources.list.d/microsoft-prod.list
sudo chown root:root /etc/apt/trusted.gpg.d/microsoft.asc.gpg
sudo chown root:root /etc/apt/sources.list.d/microsoft-prod.list
```

Install the SDK

The .NET Core SDK allows you to develop apps with .NET Core. If you install the .NET Core SDK, you don't need to install the corresponding runtime. To install the .NET Core SDK, run the following commands:

```
sudo apt-get update && \
sudo apt-get install -y dotnet-sdk-2.1
```

IMPORTANT

If you receive an error message similar to **Unable to locate package dotnet-sdk-2.1**, see the [APT troubleshooting](#) section.

Install the runtime

The .NET Core Runtime allows you to run apps that were made with .NET Core that didn't include the runtime. The following commands install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
sudo apt-get update && \
sudo apt-get install -y aspnetcore-runtime-2.1
```

IMPORTANT

If you receive an error message similar to **Unable to locate package aspnetcore-runtime-2.1**, see the [APT troubleshooting](#) section.

As an alternative to the ASP.NET Core Runtime, you can install the .NET Core Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-2.1` in the previous command with `dotnet-runtime-2.1`.

```
sudo apt-get install -y dotnet-runtime-2.1
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version}.
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Use APT to update .NET

When a new patch release is available for .NET, you can simply upgrade it through APT with the following commands:

```
sudo apt-get update  
sudo apt-get upgrade
```

If you've upgraded your Linux distribution since installing .NET, you may need to reconfigure the Microsoft package repository. Run the installation instructions for your current distribution version to upgrade to the appropriate package repository for .NET updates.

APT troubleshooting

This section provides information on common errors you may get while using APT to install .NET.

Unable to find package

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap.](#)
- [Alternatively install .NET with `install-dotnet` script.](#)
- [Manually install .NET](#)

Unable to locate \ Some packages could not be installed

If you receive an error message similar to **Unable to locate package {dotnet-package}** or **Some packages could not be installed**, run the following commands.

There are two placeholders in the following set of commands.

- `{dotnet-package}`
This represents the .NET package you're installing, such as `aspnetcore-runtime-3.1`. This is used in the following `sudo apt-get install` command.
- `{os-version}`
This represents the distribution version you're on. This is used in the `wget` command below. The distribution version is the numerical value, such as `20.04` on Ubuntu or `10` on Debian.

First, try purging the package list:

```
sudo dpkg --purge packages-microsoft-prod && sudo dpkg -i packages-microsoft-prod.deb  
sudo apt-get update
```

Then, try to install .NET again. If that doesn't work, you can run a manual install with the following commands:

```
sudo apt-get install -y gpg  
wget -O - https://packages.microsoft.com/keys/microsoft.asc | gpg --dearmor -o microsoft.asc.gpg  
sudo mv microsoft.asc.gpg /etc/apt/trusted.gpg.d/  
wget https://packages.microsoft.com/config/debian/{os-version}/prod.list  
sudo mv prod.list /etc/apt/sources.list.d/microsoft-prod.list  
sudo chown root:root /etc/apt/trusted.gpg.d/microsoft.asc.gpg  
sudo chown root:root /etc/apt/sources.list.d/microsoft-prod.list  
sudo apt-get update && \  
sudo apt-get install -y {dotnet-package}
```

Failed to fetch

While installing the .NET package, you may see an error similar to

`Failed to fetch ... File has unexpected size ... Mirror sync in progress?`. This error could mean that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed shouldn't be unavailable for more than 30 minutes. If you continually receive this error for more than 30 minutes, please file an issue at <https://github.com/dotnet/core/issues>.

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET Core or you publish a self-contained app, you'll need to make sure these libraries are installed:

- libc6

- libgcc-s1
- libgssapi-krb5-2
- libicu52 (for 8.x)
- libicu57 (for 9.x)
- libicu63 (for 10.x)
- libicu67 (for 11.x)
- libssl1.0.0 (for 8.x)
- libssl1.1 (for 9.x-11.x)
- libstdc++6
- zlib1g

For .NET Core apps that use the *System.Drawing.Common* assembly, you also need the following dependency:

- libgdipplus (version 6.0.1 or later)

WARNING

You can install a recent version of *libgdipplus* by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

Install the .NET SDK or the .NET Runtime on Fedora

9/20/2022 • 7 minutes to read • [Edit Online](#)

.NET is supported on Fedora and this article describes how to install .NET on Fedora. When a Fedora version falls out of support, .NET is no longer supported with that version.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

For more information on installing .NET without a package manager, see one of the following articles:

- [Install the .NET SDK or the .NET Runtime with Snap](#).
- [Install the .NET SDK or the .NET Runtime with a script](#).
- [Install the .NET SDK or the .NET Runtime manually](#).

Install .NET 6

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

Install .NET Core 3.1

Install the SDK

The .NET Core SDK allows you to develop apps with .NET Core. If you install the .NET Core SDK, you don't need to install the corresponding runtime. To install the .NET Core SDK, run the following command:

```
sudo dnf install dotnet-sdk-3.1
```

Install the runtime

The .NET Core Runtime allows you to run apps that were made with .NET Core that didn't include the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following command.

```
sudo dnf install aspnetcore-runtime-3.1
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Core Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-3.1` in the previous command with `dotnet-runtime-3.1`.

```
sudo dnf install dotnet-runtime-3.1
```

Supported distributions

The following table is a list of currently supported .NET releases and the versions of Fedora they're supported on. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of [Fedora reaches end-of-life](#).

- A ✓ indicates that the version of Fedora or .NET is still supported.
- A ✗ indicates that the version of Fedora or .NET isn't supported on that Fedora release.
- When both a version of Fedora and a version of .NET have ✓, that OS and .NET combination is supported.

.NET VERSION	FEDORA 36	35 ✓	34 ✗	33 ✗	32 ✗	31 ✗	30 ✗	29 ✗	28 ✗	27 ✗
.NET 6	✓	✓	✓	✗	✗	✗	✗	✗	✗	✗
.NET Core 3.1	✓	✓	✓	✓	✓	✓	✓	✓	✗	✗

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with `install-dotnet.sh`](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier

version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET Core or you publish a self-contained app, you'll need to make sure these libraries are installed:

- krb5-libs
- libicu
- openssl-libs
- zlib

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET Core apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- `libgdiplus` (version 6.0.1 or later)

WARNING

You can install a recent version of `libgdiplus` by adding the Mono repository to your system. For more information, see <https://www.monoproject.com/download/stable/>.

Install on older distributions

Older versions of Fedora don't contain .NET Core in the default package repositories. You can install .NET with `snap`, through the [`dotnet-install.sh` script](#), or use Microsoft's repository to install .NET:

1. First, add the Microsoft signing key to your list of trusted keys.

```
sudo rpm --import https://packages.microsoft.com/keys/microsoft.asc
```

2. Next, add the Microsoft package repository. The source of the repository is based on your version of Fedora.

FEDORA VERSION	PACKAGE REPOSITORY
33	https://packages.microsoft.com/config/fedora/33/prod.repo
32	https://packages.microsoft.com/config/fedora/32/prod.repo
31	https://packages.microsoft.com/config/fedora/31/prod.repo
30	https://packages.microsoft.com/config/fedora/30/prod.repo
29	https://packages.microsoft.com/config/fedora/29/prod.repo
28	https://packages.microsoft.com/config/fedora/28/prod.repo
27	https://packages.microsoft.com/config/fedora/27/prod.repo

```
sudo wget -O /etc/yum.repos.d/microsoft-prod.repo  
https://packages.microsoft.com/config/fedora/31/prod.repo
```

Install the SDK

The .NET Core SDK allows you to develop apps with .NET Core. If you install the .NET Core SDK, you don't need to install the corresponding runtime. To install the .NET Core SDK, run the following command:

```
sudo dnf install dotnet-sdk-3.1
```

Install the runtime

The .NET Core Runtime allows you to run apps that were made with .NET Core that didn't include the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following command.

```
sudo dnf install aspnetcore-runtime-3.1
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Core Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-3.1` in the previous command with `dotnet-runtime-3.1`.

```
sudo dnf install dotnet-runtime-3.1
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version} .
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET or .NET Core.

Unable to find package

For more information on installing .NET without a package manager, see one of the following articles:

- [Install the .NET SDK or the .NET Runtime with Snap](#).
- [Install the .NET SDK or the .NET Runtime with a script](#).
- [Install the .NET SDK or the .NET Runtime manually](#).

Failed to fetch

While installing the .NET package, you may see an error similar to

`signature verification failed for file 'repomd.xml' from repository 'packages-microsoft-com-prod'`. Generally speaking, this error means that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed should not be unavailable for more than 2 hours. If you continually receive this error for more than 2 hours, please file an issue at <https://github.com/dotnet/core/issues>.

Errors related to missing `fxr`, `libhostfxr.so`, or `FrameworkList.xml`

For more information about solving these problems, see [Troubleshoot `fxr`, `libhostfxr.so`, and `FrameworkList.xml` errors](#).

Next steps

- [Tutorial: Create a console application with .NET SDK using Visual Studio Code](#)

Install the .NET SDK or the .NET Runtime on openSUSE

9/20/2022 • 5 minutes to read • [Edit Online](#)

.NET is supported on openSUSE. This article describes how to install .NET on openSUSE.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET without a package manager, see one of the following articles:

- [Alternatively install .NET with Snap](#).
- [Alternatively install .NET with `install-dotnet` script](#).
- [Manually install .NET](#)

Supported distributions

The following table is a list of currently supported .NET releases on openSUSE 15. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of openSUSE is no longer supported.

- A ✓ indicates that the version of openSUSE or .NET is still supported.
- A ✗ indicates that the version of openSUSE or .NET isn't supported on that openSUSE release.
- When both a version of openSUSE and a version of .NET have ✓, that OS and .NET combination is supported.

OPEN SUSE	.NET CORE 3.1	.NET 6
✓ 15	✓ 3.1	✓ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

openSUSE 15 ✓

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

```
sudo zypper install libicu
sudo rpm --import https://packages.microsoft.com/keys/microsoft.asc
wget https://packages.microsoft.com/config/opensuse/15/prod.repo
sudo mv prod.repo /etc/zypp/repos.d/microsoft-prod.repo
sudo chown root:root /etc/zypp/repos.d/microsoft-prod.repo
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo zypper install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command installs the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo zypper install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo zypper install dotnet-runtime-6.0
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version}.
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET.

Unable to find package

IMPORTANT

Package manager installs are only supported on the **x64** architecture. Other architectures, such as **Arm**, must install .NET by some other means such as with Snap, an installer script, or through a manual binary installation.

For more information on installing .NET **without a package manager**, see one of the following articles:

- [Alternatively install .NET with Snap](#).
- [Alternatively install .NET with `install-dotnet` script](#).
- [Manually install .NET](#)

Failed to fetch

While installing the .NET package, you may see an error similar to

`signature verification failed for file 'repomd.xml' from repository 'packages-microsoft-com-prod'`. Generally

speaking, this error means that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed should not be unavailable for more than 2 hours. If you continually receive this error for more than 2 hours, please file an issue at <https://github.com/dotnet/core/issues>.

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET or you publish a self-contained app, you'll need to make sure these libraries are installed:

- krb5
- libicu
- libopenssl1_0_0

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install **compat-openssl10**.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET apps that use the *System.Drawing.Common* assembly, you'll also need the following dependency:

- [libgdiplus \(version 6.0.1 or later\)](#)

WARNING

You can install a recent version of *libgdiplus* by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

Install the .NET SDK or the .NET Runtime on RHEL and CentOS Stream

9/20/2022 • 8 minutes to read • [Edit Online](#)

.NET is supported on Red Hat Enterprise Linux (RHEL). This article describes how to install .NET on RHEL and CentOS Stream.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

Register your Red Hat subscription

To install .NET from Red Hat on RHEL, you first need to register using the Red Hat Subscription Manager. If this hasn't been done on your system, or if you're unsure, see the [Red Hat Product Documentation for .NET](#).

IMPORTANT

This doesn't apply to CentOS Stream.

Supported distributions

The following table is a list of currently supported .NET releases on both RHEL and CentOS Stream. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the Linux distribution is no longer supported.

- A ✓ indicates that the version of RHEL or .NET is still supported.
- A ✗ indicates that the version of RHEL or .NET isn't supported on that RHEL release.
- When both a version of Linux distribution and a version of .NET have ✓, that OS and .NET combination is supported.

DISTRIBUTION	.NET CORE 3.1	.NET 6
✓ RHEL 8	✓ 3.1	✓ 6.0
✓ RHEL 7	✓ 3.1	✓ 6.0
✓ CentOS Stream 9	✗ 3.1	✓ 6.0
✓ CentOS Stream 8	✓ 3.1	✓ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0

- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

RHEL 8 ✓

.NET is included in the AppStream repositories for RHEL 8.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

RHEL 7 ✓ .NET 6.0

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the

corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet60 -y  
scl enable rh-dotnet60 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet60` because it may affect other programs. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet60
```

Install the runtime

The .NET Runtime allows you to run apps that were made with .NET that didn't include the runtime. The commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet60-aspnetcore-runtime-6.0 -y  
scl enable rh-dotnet60 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet60` because it may affect other programs. If you want to enable `rh-dotnet60` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet60
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet60-aspnetcore-runtime-6.0` in the preceding command with `rh-dotnet60-dotnet-runtime-6.0`.

RHEL 7 ✓ .NET 5.0

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms  
yum install rh-dotnet50 -y  
scl enable rh-dotnet50 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet50` because it may affect other programs. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet50
```

Install the runtime

The .NET Runtime allows you to run apps that were made with .NET that didn't include the runtime. The

commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet50-aspnetcore-runtime-5.0 -y
scl enable rh-dotnet50 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet50` because it may affect other programs. If you want to enable `rh-dotnet50` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet50
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet50-aspnetcore-runtime-5.0` in the commands above with `rh-dotnet50-dotnet-runtime-5.0`.

RHEL 7 ✓ .NET Core 3.1

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

The following command installs the `scl-utils` package:

```
sudo yum install scl-utils
```

Install the SDK

.NET SDK allows you to develop apps with .NET Core. If you install .NET SDK, you don't need to install the corresponding runtime. To install .NET SDK, run the following commands:

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet31 -y
scl enable rh-dotnet31 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet31` because it may affect other programs. For example, `rh-dotnet31` includes a version of `libcurl` that differs from the base RHEL version. This may lead to issues in programs that do not expect a different version of `libcurl`. If you want to enable `rh-dotnet` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet31
```

Install the runtime

The .NET Core Runtime allows you to run apps that were made with .NET Core that didn't include the runtime. The commands below install the ASP.NET Core Runtime, which is the most compatible runtime for .NET Core. In your terminal, run the following commands.

```
subscription-manager repos --enable=rhel-7-server-dotnet-rpms
yum install rh-dotnet31-aspnetcore-runtime-3.1 -y
scl enable rh-dotnet31 bash
```

Red Hat does not recommend permanently enabling `rh-dotnet31` because it may affect other programs. For example, `rh-dotnet31` includes a version of `libcurl` that differs from the base RHEL version. This may lead to

issues in programs that do not expect a different version of `libcurl`. If you want to enable `rh-dotnet31` permanently, add the following line to your `~/.bashrc` file.

```
source scl_source enable rh-dotnet31
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Core Runtime that doesn't include ASP.NET Core support: replace `rh-dotnet31-aspnetcore-runtime-3.1` in the commands above with `rh-dotnet31-dotnet-runtime-3.1`.

CentOS Stream 9 ✓

.NET is included in the AppStream repositories for CentOS Stream 9. However, .NET Core 3.1 and .NET 5 have been removed from CentOS Stream 9 and you should use .NET 6. For more information, see the blog post [Using .NET with OpenSSL in CentOS Stream 9 | Omair Majid](#).

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

CentOS Stream 8 ✓

.NET is included in the AppStream repositories for CentOS Stream 8.

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo dnf install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command install the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo dnf install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo dnf install dotnet-runtime-6.0
```

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET Core or you publish a self-contained app, you'll need to make sure these libraries are installed:

- `krb5-libs`
- `libicu`
- `openssl-libs`
- `zlib`

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET Core apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- [libgdiplus \(version 6.0.1 or later\)](#)

WARNING

You can install a recent version of `libgdiplus` by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

How to install other versions

Consult the [Red Hat documentation for .NET](#) on the steps required to install other releases of .NET.

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET or .NET Core.

Errors related to missing `fxr`, `libhostfxr.so`, or `FrameworkList.xml`

For more information about solving these problems, see [Troubleshoot `fxr`, `libhostfxr.so`, and `FrameworkList.xml` errors](#).

Next steps

- [How to enable TAB completion for the .NET CLI](#)
- [Tutorial: Create a console application with .NET SDK using Visual Studio Code](#)

Install the .NET SDK or the .NET Runtime on SLES

9/20/2022 • 5 minutes to read • [Edit Online](#)

.NET is supported on SLES. This article describes how to install .NET on SLES.

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

Supported distributions

The following table is a list of currently supported .NET releases on both SLES 12 SP2 and SLES 15. These versions remain supported until either the version of [.NET reaches end-of-support](#) or the version of SLES is no longer supported.

- A ✓ indicates that the version of SLES or .NET is still supported.
- A ✗ indicates that the version of SLES or .NET isn't supported on that SLES release.
- When both a version of SLES and a version of .NET have ✓, that OS and .NET combination is supported.

SLES	.NET CORE 3.1	.NET 6
✓ 15	✓ 3.1	✓ 6.0
✓ 12 SP2	✓ 3.1	✓ 6.0

The following versions of .NET are ✗ no longer supported:

- .NET 5
- .NET Core 3.0
- .NET Core 2.2
- .NET Core 2.1
- .NET Core 2.0

Install preview versions

Preview and release candidate versions of .NET aren't available in package managers. You can install previews and release candidates of .NET in one of the following ways:

- [Snap package](#)
- [Scripted install with *install-dotnet.sh*](#)
- [Manual binary extraction](#)

Remove preview versions

When using a package manager to manage your installation of .NET, you may run into a conflict if you've previously installed a preview release. The package manager may interpret the non-preview release as an earlier

version of .NET. To install the non-preview release, first uninstall the preview versions. For more information about uninstalling .NET, see [How to remove the .NET Runtime and SDK](#).

SLES 15 ✓

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

```
sudo rpm -Uvh https://packages.microsoft.com/config/sles/15/packages-microsoft-prod.rpm
```

Currently, the SLES 15 Microsoft repository setup package installs the *microsoft-prod.repo* file to the wrong directory, preventing zypper from finding the .NET packages. To fix this problem, create a symlink in the correct directory.

```
sudo ln -s /etc/yum.repos.d/microsoft-prod.repo /etc/zypp/repos.d/microsoft-prod.repo
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo zypper install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command installs the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo zypper install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo zypper install dotnet-runtime-6.0
```

SLES 12 ✓

.NET requires SP2 as a minimum for the SLES 12 family.

Before you install .NET, run the following commands to add the Microsoft package signing key to your list of trusted keys and add the Microsoft package repository. Open a terminal and run the following commands:

```
sudo rpm -Uvh https://packages.microsoft.com/config/sles/12/packages-microsoft-prod.rpm
```

Install the SDK

The .NET SDK allows you to develop apps with .NET. If you install the .NET SDK, you don't need to install the corresponding runtime. To install the .NET SDK, run the following command:

```
sudo zypper install dotnet-sdk-6.0
```

Install the runtime

The ASP.NET Core Runtime allows you to run apps that were made with .NET that didn't provide the runtime. The following command installs the ASP.NET Core Runtime, which is the most compatible runtime for .NET. In your terminal, run the following command:

```
sudo zypper install aspnetcore-runtime-6.0
```

As an alternative to the ASP.NET Core Runtime, you can install the .NET Runtime, which doesn't include ASP.NET Core support: replace `aspnetcore-runtime-6.0` in the previous command with `dotnet-runtime-6.0`:

```
sudo zypper install dotnet-runtime-6.0
```

How to install other versions

All versions of .NET are available for download at <https://dotnet.microsoft.com/download/dotnet>, but require [manual installation](#). You can try and use the package manager to install a different version of .NET. However, the requested version may not be available.

The packages added to package manager feeds are named in a hackable format, for example:

```
{product}-{type}-{version}.
```

- **product**

The type of .NET product to install. Valid options are:

- dotnet
- aspnetcore

- **type**

Chooses the SDK or the runtime. Valid options are:

- sdk
- runtime

- **version**

The version of the SDK or runtime to install. This article will always give the instructions for the latest supported version. Valid options are any released version, such as:

- 5.0
- 3.1
- 3.0
- 2.1

It's possible the SDK/runtime you're trying to download is not available for your Linux distribution. For a list of supported distributions, see [Install .NET on Linux](#).

Examples

- Install the ASP.NET Core 5.0 runtime: `aspnetcore-runtime-5.0`
- Install the .NET Core 2.1 runtime: `dotnet-runtime-2.1`
- Install the .NET 5 SDK: `dotnet-sdk-5.0`
- Install the .NET Core 3.1 SDK: `dotnet-sdk-3.1`

Package missing

If the package-version combination doesn't work, it's not available. For example, there isn't an ASP.NET Core SDK, the SDK components are included with the .NET SDK. The value `aspnetcore-sdk-2.2` is incorrect and should be `dotnet-sdk-2.2`. For a list of Linux distributions supported by .NET, see [.NET dependencies and requirements](#).

Troubleshoot the package manager

This section provides information on common errors you may get while using the package manager to install .NET.

Failed to fetch

While installing the .NET package, you may see an error similar to

```
signature verification failed for file 'repomd.xml' from repository 'packages-microsoft-com-prod'
```

Generally speaking, this error means that the package feed for .NET is being upgraded with newer package versions, and that you should try again later. During an upgrade, the package feed should not be unavailable for more than 2 hours. If you continually receive this error for more than 2 hours, please file an issue at <https://github.com/dotnet/core/issues>.

Dependencies

When you install with a package manager, these libraries are installed for you. But, if you manually install .NET or you publish a self-contained app, you'll need to make sure these libraries are installed:

- krb5
- libicu
- libopenssl1_1

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

For more information about the dependencies, see [Self-contained Linux apps](#).

For .NET apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- [libgdiplus \(version 6.0.1 or later\)](#)

WARNING

You can install a recent version of `libgdiplus` by adding the Mono repository to your system. For more information, see <https://www.mono-project.com/download/stable/>.

Next steps

- [How to enable TAB completion for the .NET CLI](#)
- [Tutorial: Create a console application with .NET SDK using Visual Studio Code](#)

Install the .NET SDK or the .NET Runtime with Snap

9/20/2022 • 5 minutes to read • [Edit Online](#)

Use a Snap package to install the .NET SDK or .NET Runtime. Snaps are a great alternative to the package manager built into your Linux distribution. This article describes how to install .NET through [Snap](#).

A snap is a bundle of an app and its dependencies that works without modification across many different Linux distributions. Snaps are discoverable and installable from the Snap Store. For more information about Snap, see [Getting started with Snap](#).

Caution

Snap packages aren't supported in WSL2 on Windows 10. As an alternative, use the `dotnet-install` script or the package manager for the particular WSL2 distribution. It's not recommended but you can try to enable snap with an [unsupported workaround from the snapcraft forums](#).

.NET releases

Only ✓ supported versions of .NET SDK are available through Snap. All versions of the .NET Runtime are available through snap starting with version 2.1. The following table lists the .NET (and .NET Core) releases:

✓ SUPPORTED	✗ UNSUPPORTED
6 (LTS)	5
3.1 (LTS)	3.0
	2.2
	2.1
	2.0
	1.1
	1.0

For more information about the life cycle of .NET releases, see [.NET and .NET Core Support Policy](#).

SDK or Runtime

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

Install the SDK

Snap packages for the .NET SDK are all published under the same identifier: `dotnet-sdk`. A specific version of

the SDK can be installed by specifying the channel. The SDK includes the corresponding runtime. The following table lists the channels:

.NET VERSION	SNAP PACKAGE OR CHANNEL
6 (LTS)	6.0 or latest/stable or lts/stable
5	5.0
3.1 (LTS)	3.1

Use the `snap install` command to install a .NET SDK snap package. Use the `--channel` parameter to indicate which version to install. If this parameter is omitted, `latest/stable` is used. In this example, `6.0` is specified:

```
sudo snap install dotnet-sdk --classic --channel=6.0
```

Next, register the `dotnet` command for the system with the `snap alias` command:

```
sudo snap alias dotnet-sdk.dotnet dotnet
```

This command is formatted as: `sudo snap alias {package}.{command} {alias}`. You can choose any `{alias}` name you would like. For example, you could name the command after the specific version installed by snap: `sudo snap alias dotnet-sdk.dotnet dotnet60`. When you use the command `dotnet60`, you'll invoke this specific version of .NET. But choosing a different alias is incompatible with most tutorials and examples as they expect a `dotnet` command to be used.

Install the runtime

Snap packages for the .NET Runtime are each published under their own package identifier. The following table lists the package identifiers:

.NET VERSION	SNAP PACKAGE
6 (LTS)	dotnet-runtime-60
5	dotnet-runtime-50
3.1 (LTS)	dotnet-runtime-31
3.0	dotnet-runtime-30
2.2	dotnet-runtime-22
2.1	dotnet-runtime-21

Use the `snap install` command to install a .NET Runtime snap package. In this example, .NET 6 is installed:

```
sudo snap install dotnet-runtime-60 --classic
```

Next, register the `dotnet` command for the system with the `snap alias` command:

```
sudo snap alias dotnet-runtime-60.dotnet dotnet
```

The command is formatted as: `sudo snap alias {package}.{command} {alias}`. You can choose any `{alias}` name you would like. For example, you could name the command after the specific version installed by snap: `sudo snap alias dotnet-runtime-60.dotnet dotnet60`. When you use the command `dotnet60`, you'll invoke a specific version of .NET. But choosing a different alias is incompatible with most tutorials and examples as they expect a `dotnet` command to be available.

Export the install location

The `DOTNET_ROOT` environment variable is often used by tools to determine where .NET is installed. When .NET is installed through Snap, this environment variable isn't configured. You should configure the `DOTNET_ROOT` environment variable in your profile. The path to the snap uses the following format: `/snap/{package}/current`. For example, if you installed the `dotnet-sdk` snap, use the following command to set the environment variable to where .NET is located:

```
export DOTNET_ROOT=/snap/dotnet-sdk/current
```

TIP

The preceding `export` command only sets the environment variable for the terminal session in which it was run.

You can edit your shell profile to permanently add the commands. There are a number of different shells available for Linux and each has a different profile. For example:

- **Bash Shell:** `~/.bash_profile`, `~/.bashrc`
- **Korn Shell:** `~/.kshrc` or `.profile`
- **Z Shell:** `~/.zshrc` or `.zprofile`

Edit the appropriate source file for your shell and add `export DOTNET_ROOT=/snap/dotnet-sdk/current`.

TLS/SSL Certificate errors

When .NET is installed through Snap, it's possible that on some distros the .NET TLS/SSL certificates may not be found and you may receive an error during `restore`:

```
Processing post-creation actions...
Running 'dotnet restore' on /home/myhome/test/test.csproj...
Restoring packages for /home/myhome/test/test.csproj...
/snap/dotnet-sdk/27/sdk/2.2.103/NuGet.targets(114,5): error : Unable to load the service index for source
https://api.nuget.org/v3/index.json. [/home/myhome/test/test.csproj]
/snap/dotnet-sdk/27/sdk/2.2.103/NuGet.targets(114,5): error : The SSL connection could not be established,
see inner exception. [/home/myhome/test/test.csproj]
/snap/dotnet-sdk/27/sdk/2.2.103/NuGet.targets(114,5): error : The remote certificate is invalid according
to the validation procedure. [/home/myhome/test/test.csproj]
```

To resolve this problem, set a few environment variables:

```
export SSL_CERT_FILE=[path-to-certificate-file]
export SSL_CERT_DIR=/dev/null
```

The certificate location will vary by distro. Here are the locations for the distros where the issue has been experienced.

DISTRIBUTION	LOCATION
Fedora	/etc/pki/ca-trust/extracted/pem/tls-ca-bundle.pem
OpenSUSE	/etc/ssl/ca-bundle.pem
Solus	/etc/ssl/certs/ca-certificates.crt

Troubles resolving dotnet

It's common for other apps, such as the OmniSharp extension for Visual Studio Code, to try to resolve the location of the .NET SDK. Typically, this is done by figuring out where the `dotnet` executable is located. A snap-installed .NET SDK may confuse these apps. When these apps can't resolve the .NET SDK, you'll see an error similar to one of the following messages:

- The SDK 'Microsoft.NET.Sdk' specified could not be found
- The SDK 'Microsoft.NET.Sdk.Web' specified could not be found
- The SDK 'Microsoft.NET.Sdk.Razor' specified could not be found

To fix this problem, symlink the snap `dotnet` executable to the location that the program is looking for. Two common paths the `dotnet` command is looking for are `/usr/local/bin/dotnet` and `/usr/share/dotnet`. For example, to link the current .NET SDK snap package, use the following command:

```
ln -s /snap/dotnet-sdk/current/dotnet /usr/local/bin/dotnet
```

You can also review these GitHub issues for information about these problems:

- [SDK resolver doesn't work with snap installations of SDK on Linux](#)
- [It wasn't possible to find any installed .NET SDKs](#)

The `dotnet` alias

It's possible that if you created the `dotnet` alias for the snap-installed .NET, you'll have a conflict. Use the `snap unalias dotnet` command to remove it, and then add a different alias if you want.

Install .NET on Linux by using an install script or by extracting binaries

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article demonstrates how to install the .NET SDK or the .NET Runtime on Linux by using the install script or by extracting the binaries. For a list of distributions that support the built-in package manager, see [Install .NET on Linux](#).

You can also install .NET with snap. For more information, see [Install the .NET SDK or the .NET Runtime with Snap](#).

Install the SDK (which includes the runtime) if you want to develop .NET apps. Or, if you only need to run apps, install the Runtime. If you're installing the Runtime, we suggest you install the **ASP.NET Core Runtime** as it includes both .NET and ASP.NET Core runtimes.

If you've already installed the SDK or Runtime, use the `dotnet --list-sdks` and `dotnet --list-runtimes` commands to see which versions are installed. For more information, see [How to check that .NET is already installed](#).

.NET releases

The following table lists the .NET (and .NET Core) releases:

✓ SUPPORTED	✗ UNSUPPORTED
6 (LTS)	5
3.1 (LTS)	3.0
	2.2
	2.1
	2.0
	1.1
	1.0

For more information about the life cycle of .NET releases, see [.NET and .NET Core Support Policy](#).

Dependencies

It's possible that when you install .NET, specific dependencies may not be installed, such as when [manually installing](#). The following list details Linux distributions that are supported by Microsoft and have dependencies you may need to install. Check the distribution page for more information:

- [Alpine](#)
- [Debian](#)
- [CentOS](#)

- [Fedora](#)
- [RHEL and CentOS Stream](#)
- [SLES](#)
- [Ubuntu](#)

For generic information about the dependencies, see [Self-contained Linux apps](#).

RPM dependencies

If your distribution wasn't previously listed, and is RPM-based, you may need the following dependencies:

- krb5-libs
- libicu
- openssl-libs

If the target runtime environment's OpenSSL version is 1.1 or newer, you'll need to install `compat-openssl10`.

DEB dependencies

If your distribution wasn't previously listed, and is debian-based, you may need the following dependencies:

- libc6
- libgcc1
- libgssapi-krb5-2
- libicu67
- libssl1.1
- libstdc++6
- zlib1g

Common dependencies

For .NET apps that use the `System.Drawing.Common` assembly, you'll also need the following dependency:

- [libgdipplus \(version 6.0.1 or later\)](#)

WARNING

You can install a recent version of `libgdipplus` by adding the Mono repository to your system. For more information, see <https://www.monoproject.com/download/stable/>.

Scripted install

The [dotnet-install scripts](#) are used for automation and non-admin installs of the **SDK** and **Runtime**. You can download the script from <https://dot.net/v1/dotnet-install.sh>.

IMPORTANT

Bash is required to run the script.

Before running this script, you'll need to grant permission for this script to run as an executable:

```
sudo chmod +x ./dotnet-install.sh
```

The script defaults to installing the latest SDK [long term support \(LTS\)](#) version, which is .NET 6. To install the current release, which may not be an (LTS) version, use the `-c current` parameter.

```
./dotnet-install.sh -c Current
```

To install .NET Runtime instead of the SDK, use the `--runtime` parameter.

```
./dotnet-install.sh -c Current --runtime aspnetcore
```

You can install a specific version by altering the `-c` parameter to indicate the specific version. The following command installs .NET SDK 6.0.

```
./dotnet-install.sh -c 6.0
```

For more information, see [dotnet-install scripts reference](#).

Manual install

As an alternative to the package managers, you can download and manually install the SDK and runtime. Manual installation is commonly used as part of continuous integration testing or on an unsupported Linux distribution. For a developer or user, it's better to use a package manager.

First, download a **binary** release for either the SDK or the runtime from one of the following sites. If you install the .NET SDK, you will not need to install the corresponding runtime:

- ✓ [.NET 6 downloads](#)
- ✓ [.NET Core 3.1 downloads](#)
- [All .NET Core downloads](#)

Next, extract the downloaded file and use the `export` command to set `DOTNET_ROOT` to the extracted folder's location and then ensure .NET is in PATH. This should make the .NET CLI commands available at the terminal.

Alternatively, after downloading the .NET binary, the following commands may be run from the directory where the file is saved to extract the runtime. This will also make the .NET CLI commands available at the terminal and set the required environment variables. **Remember to change the `DOTNET_FILE` value to the name of the downloaded binary:**

```
DOTNET_FILE=dotnet-sdk-6.0.100-linux-x64.tar.gz
export DOTNET_ROOT=$(pwd)/.dotnet

mkdir -p "$DOTNET_ROOT" && tar zxf "$DOTNET_FILE" -C "$DOTNET_ROOT"

export PATH=$PATH:$DOTNET_ROOT:$DOTNET_ROOT/tools
```

This approach lets you install different versions into separate locations and choose explicitly which one to use by which application.

Set environment variables system-wide

If you used the previous install script, the variables set only apply to your current terminal session. Add them to your shell profile. There are a number of different shells available for Linux and each has a different profile. For example:

- **Bash Shell:** `~/.bash_profile`, `~/.bashrc`
- **Korn Shell:** `~/.kshrc` or `.profile`
- **Z Shell:** `~/.zshrc` or `.zprofile`

Set the following two environment variables in your shell profile:

- `DOTNET_ROOT`

This variable is set to the folder .NET was installed to, such as `$HOME/.dotnet`:

```
export DOTNET_ROOT=$HOME/.dotnet
```

- `PATH`

This variable should include both the `DOTNET_ROOT` folder and the user's `.dotnet/tools` folder:

```
export PATH=$PATH:$HOME/.dotnet:$HOME/.dotnet/tools
```

How to remove the .NET Runtime and SDK

9/20/2022 • 6 minutes to read • [Edit Online](#)

Over time, as you install updated versions of the .NET runtime and SDK, you may want to remove outdated versions of .NET from your machine. Removing older versions of the runtime may change the runtime chosen to run shared framework applications, as detailed in the article on [.NET version selection](#).

Should I remove a version?

The [.NET version selection](#) behaviors and the runtime compatibility of .NET across updates enables safe removal of previous versions. .NET runtime updates are compatible within a major version **band** such as 6.x and 5.x. Additionally, newer releases of the .NET SDK generally maintain the ability to build applications that target previous versions of the runtime in a compatible manner.

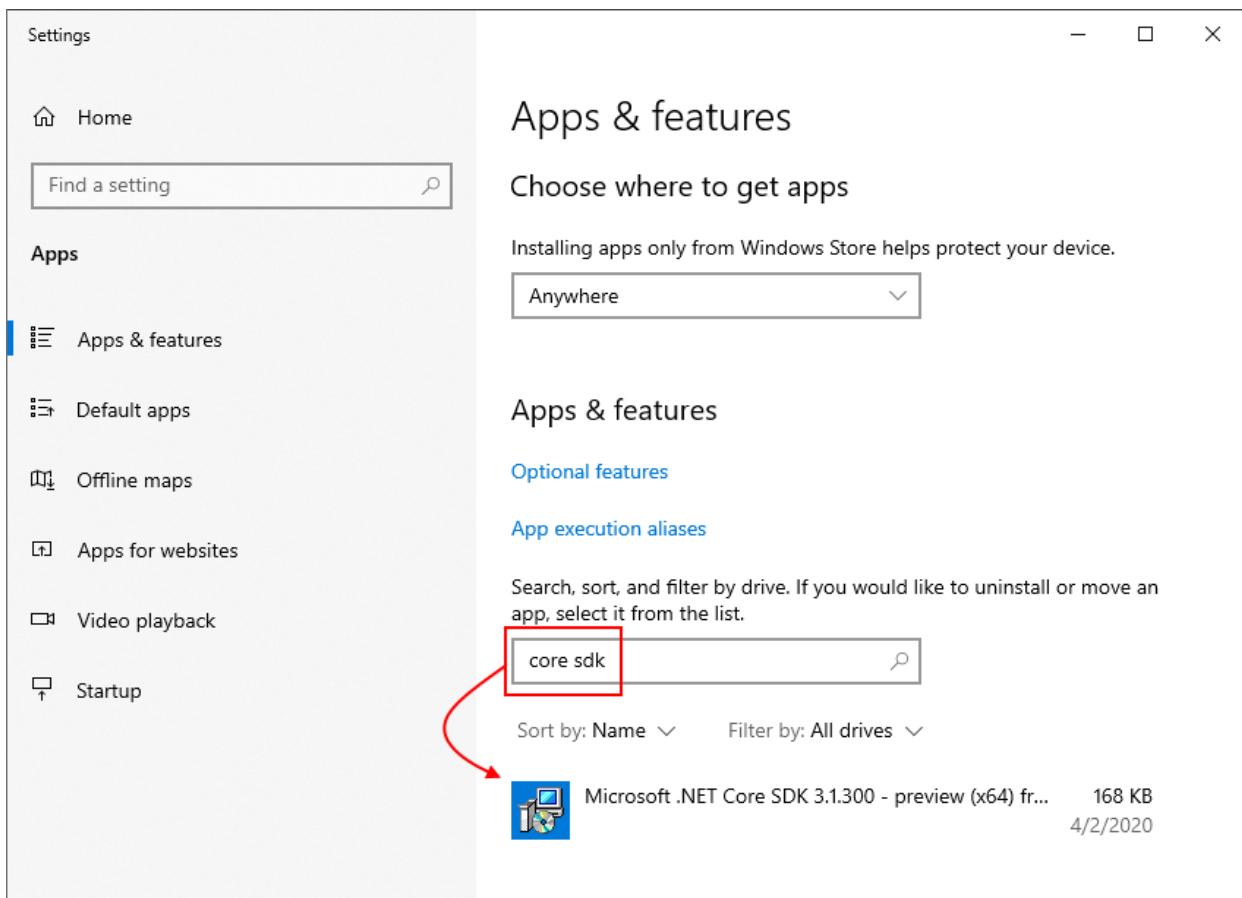

In general, you only need the latest SDK and latest patch version of the runtimes required for your application. Instances where you might want to keep older SDK or runtime versions include maintaining *project.json*-based applications. Unless your application has specific reasons for earlier SDKs or runtimes, you may safely remove older versions.

Determine what is installed

The .NET CLI has options you can use to list the versions of the SDK and runtime that are installed on your computer. Use `dotnet --list-sdks` to see the list of installed SDKs and `dotnet --list-runtimes` for the list of runtimes. For more information, see [How to check that .NET is already installed](#).

Uninstall .NET

.NET uses the Windows Apps & features dialog to remove versions of the .NET runtime and SDK. The following figure shows the Apps & features dialog. You can search for **core** or **.net** to filter and show installed versions of .NET.

Select any versions you want to remove from your computer and click **Uninstall**.

The best way for you to uninstall .NET is to mirror the action you used to install .NET. The specifics depend on your chosen Linux distribution and the installation method.

IMPORTANT

For Red Hat installations, consult the [Red Hat Product Documentation for .NET](#).

There's no need to first uninstall the .NET SDK when upgrading it using a package manager, unless you're upgrading from a preview version that was manually installed. The package manager `update` or `refresh` commands will automatically remove the older version upon the successful installation of a newer version. If you have a preview version installed, uninstall it.

If you installed .NET using a package manager, use that same package manager to uninstall the .NET SDK or runtime. .NET installations support most popular package managers. Consult the documentation for your distribution's package manager for the precise syntax in your environment:

- `apt-get(8)` is used by Debian based systems, including Ubuntu.
- `yum(8)` is used on Fedora, CentOS, and Oracle Linux.
- `zypper(8)` is used on openSUSE and SUSE Linux Enterprise System (SLES).
- `dnf(8)` is used on Fedora.

In almost all cases, the command to remove a package is `remove`.

The package name for the .NET SDK installation for most package managers is `dotnet-sdk`, followed by the version number. Starting with the version 2.1.300 of the .NET SDK and version 2.1 of the runtime, only the major and minor version numbers are necessary: for example, the .NET SDK version 2.1.300 can be referenced as the package `dotnet-sdk-2.1`. Prior versions require the entire version string: for example, `dotnet-sdk-2.1.200` would be required for version 2.1.200 of the .NET SDK.

For machines that have installed only the runtime, and not the SDK, the package name is `dotnet-runtime-<version>` for the .NET runtime, and `aspnetcore-runtime-<version>` for the entire runtime stack.

TIP

.NET Core installations earlier than 2.0 didn't uninstall the host application when the SDK was uninstalled using the package manager. Using `apt-get`, the command is:

```
apt-get remove dotnet-host
```

There's no version attached to `dotnet-host`.

If you installed using a tarball, you must remove .NET using the manual method.

On Linux, you must remove the SDKs and runtimes separately, by removing the versioned directories. These directories may vary depending on your Linux distribution. Removing them deletes the SDK and runtime from disk. For example, to remove the 1.0.1 SDK and runtime, you would use the following bash commands:

```
version="1.0.1"
sudo rm -rf /usr/share/dotnet/sdk/$version
sudo rm -rf /usr/share/dotnet/shared/Microsoft.NETCore.App/$version
sudo rm -rf /usr/share/dotnet/shared/Microsoft.AspNetCore.All/$version
sudo rm -rf /usr/share/dotnet/shared/Microsoft.AspNetCore.App/$version
sudo rm -rf /usr/share/dotnet/host/fxr/$version
```

IMPORTANT

The version folders may not match the "version" you're uninstalling. The individual runtimes and SDKs that are installed with a single .NET release may have different versions. For example, you may have installed ASP.NET Core 5 Runtime, which installed the 5.0.2 ASP.NET Core runtime and the 5.0.8 .NET runtime. Each has a different versioned folder. For more information, see [Overview of how .NET is versioned](#).

The parent directories for the SDK and runtime are listed in the output from the `dotnet --list-sdks` and `dotnet --list-runtimes` command, as shown in the earlier table.

On Mac, you must remove the SDKs and runtimes separately, by removing the versioned directories. Removing them deletes the SDK and runtime from disk. For example, to remove the 1.0.1 SDK and runtime, you would use the following bash commands:

```
version="1.0.1"
sudo rm -rf /usr/local/share/dotnet/sdk/$version
sudo rm -rf /usr/local/share/dotnet/shared/Microsoft.NETCore.App/$version
sudo rm -rf /usr/local/share/dotnet/shared/Microsoft.AspNetCore.All/$version
sudo rm -rf /usr/local/share/dotnet/shared/Microsoft.AspNetCore.App/$version
sudo rm -rf /usr/local/share/dotnet/host/fxr/$version
```

IMPORTANT

The version folders may not match the "version" you're uninstalling. The individual runtimes and SDKs that are installed with .NET may have different versions. For example, you may have installed .NET 5 Runtime, which installed the 5.0.2 ASP.NET Core runtime and the 5.0.8 .NET runtime. For more information, see [Overview of how .NET is versioned](#).

IMPORTANT

If you're using an Arm-based Mac, such as one with an M1 chip, review the folder paths described in [Install .NET on Arm-based Macs](#).

The parent directories for the SDK and runtime are listed in the output from the `dotnet --list-sdks` and `dotnet --list-runtimes` command, as shown in the earlier table.

.NET Uninstall Tool

The [.NET Uninstall Tool](#) (`dotnet-core-uninstall`) lets you remove .NET SDKs and runtimes from a system. A collection of options is available to specify which versions should be uninstalled.

Visual Studio dependency on .NET SDK versions

Before Visual Studio 2019 version 16.3, Visual Studio installers called the standalone SDK installer for .NET Core version 2.1 or 2.2. As a result, the SDK versions appear in the Windows **Apps & features** dialog. Removing .NET SDKs that were installed by Visual Studio using the standalone installer may break Visual Studio. If Visual Studio has problems after you uninstall SDKs, run Repair on that specific version of Visual Studio. The following table shows some of the Visual Studio dependencies on .NET Core SDK versions:

VISUAL STUDIO VERSION	.NET CORE SDK VERSION
Visual Studio 2019 version 16.2	.NET Core SDK 2.2.4xx, 2.1.8xx
Visual Studio 2019 version 16.1	.NET Core SDK 2.2.3xx, 2.1.7xx
Visual Studio 2019 version 16.0	.NET Core SDK 2.2.2xx, 2.1.6xx
Visual Studio 2017 version 15.9	.NET Core SDK 2.2.1xx, 2.1.5xx
Visual Studio 2017 version 15.8	.NET Core SDK 2.1.4xx

Starting with Visual Studio 2019 version 16.3, Visual Studio is in charge of its own copy of the .NET SDK. For that reason, you no longer see those SDK versions in the **Apps & features** dialog.

Remove the NuGet fallback folder

Before .NET Core 3.0 SDK, the .NET Core SDK installers used a folder named *NuGetFallbackFolder* to store a cache of NuGet packages. This cache was used during operations such as `dotnet restore` or `dotnet build /t:Restore`. The *NuGetFallbackFolder* is located at `C:\Program Files\dotnet\sdk` on Windows and at `/usr/local/share/dotnet/sdk` on macOS.

You may want to remove this folder, if:

- You're only developing using .NET Core 3.0 SDK or .NET 5 or later versions.
- You're developing using .NET Core SDK versions earlier than 3.0, but you can work online.

If you want to remove the NuGet fallback folder, you can delete it, but you'll need administrative privileges to do so.

It's not recommended to delete the *dotnet* folder. Doing so would remove any global tools you've previously installed. Also, on Windows:

- You'll break Visual Studio 2019 version 16.3 and later versions. You can run **Repair** to recover.
- If there are .NET Core SDK entries in the **Apps & features** dialog, they'll be orphaned.

Manage .NET project and item templates

9/20/2022 • 4 minutes to read • [Edit Online](#)

.NET Core provides a template system that enables users to install or uninstall templates from NuGet, a NuGet package file, or a file system directory. This article describes how to manage .NET Core templates through the .NET SDK CLI.

For more information about creating templates, see [Tutorial: Create templates](#).

Install template

Templates are installed through the `dotnet new` SDK command with the `-i` parameter. You can either provide the NuGet package identifier of a template, or a folder that contains the template files.

NuGet hosted package

.NET CLI templates are uploaded to [NuGet](#) for wide distribution. Templates can also be installed from a private feed. Instead of uploading a template to a NuGet feed, *nupkg* template files can be distributed and manually installed, as described in the [Local NuGet package](#) section.

For more information about configuring NuGet feeds, see [dotnet nuget add source](#).

To install a template pack from the default NuGet feed, use the `dotnet new -i {package-id}` command:

```
dotnet new -i Microsoft.DotNet.Web.Spa.ProjectTemplates
```

To install a template pack from the default NuGet feed with a specific version, use the

`dotnet new -i {package-id}::{version}` command:

```
dotnet new -i Microsoft.DotNet.Web.Spa.ProjectTemplates::2.2.6
```

Local NuGet package

When a template pack is created, a *nupkg* file is generated. If you have a *nupkg* file containing templates, you can install it with the `dotnet new -i {path-to-package}` command:

```
dotnet new -i c:\code\NuGet-Packages\Some.Templates.1.0.0.nupkg
```

```
dotnet new -i ~/code/NuGet-Packages/Some.Templates.1.0.0.nupkg
```

Folder

As an alternative to installing template from a *nupkg* file, you can also install templates from a folder directly with the `dotnet new -i {folder-path}` command. The folder specified is treated as the template pack identifier for any template found. Any template found in the specified folder's hierarchy is installed.

```
dotnet new -i c:\code\NuGet-Packages\some-folder\
```

```
dotnet new -i ~/code/NuGet-Packages/some-folder/
```

The `{folder-path}` specified on the command becomes the template pack identifier for all templates found. As specified in the [List templates](#) section, you can get a list of templates installed with the `dotnet new -u` command. In this example, the template pack identifier is shown as the folder used for install:

```
dotnet new -u
Template Instantiation Commands for .NET CLI

Currently installed items:

... cut to save space ...

c:\code\NuGet-Packages\some-folder
Templates:
A Template Console Class (templateconsole) C#
Project for some technology (contosoproject) C#
Uninstall Command:
dotnet new -u c:\code\NuGet-Packages\some-folder
```

```
dotnet new -u
Template Instantiation Commands for .NET CLI

Currently installed items:

... cut to save space ...

/home/username/code/templates
Templates:
A Template Console Class (templateconsole) C#
Project for some technology (contosoproject) C#
Uninstall Command:
dotnet new -u /home/username/code/templates
```

Uninstall template

Templates are uninstalled through the `dotnet new` SDK command with the `-u` parameter. You can either provide the NuGet package identifier of a template, or a folder that contains the template files.

NuGet package

After a NuGet template pack is installed, either from a NuGet feed or a `nupkg` file, you can uninstall it by referencing the NuGet package identifier.

To uninstall a template pack, use the `dotnet new -u {package-id}` command:

```
dotnet new -u Microsoft.DotNet.Web.Spa.ProjectTemplates
```

Folder

When templates are installed through a [folder path](#), the folder path becomes the template pack identifier.

To uninstall a template pack, use the `dotnet new -u {package-folder-path}` command:

```
dotnet new -u c:\code\NuGet-Packages\some-folder
```

```
dotnet new -u /home/username/code/templates
```

List templates

By using the standard `uninstall` command without a package identifier, you can see a list of installed templates along with the command that uninstalls each template.

```
dotnet new -u
Template Instantiation Commands for .NET CLI

Currently installed items:

... cut to save space ...

c:\code\NuGet-Packages\some-folder
Templates:
A Template Console Class (templateconsole) C#
Project for some technology (contosoproject) C#
Uninstall Command:
dotnet new -u c:\code\NuGet-Packages\some-folder
```

Install templates from other SDKs

If you've installed each version of the SDK sequentially, for example you installed SDK 2.0, then SDK 2.1, and so on, you'll have every SDK's templates installed. However, if you start with a later SDK version, like 3.1, only the templates for [LTS \(long term support\) releases](#) are included, which at the time of the SDK 3.1 release is SDK 2.1 and SDK 3.1. Templates for any other release aren't included.

The .NET Core templates are available on NuGet, and you can install them like any other template. For more information, see [Install NuGet hosted package](#).

SDK	NUGET PACKAGE IDENTIFIER
.NET Core 2.1	Microsoft.DotNet.Common.ProjectTemplates.2.1
.NET Core 2.2	Microsoft.DotNet.Common.ProjectTemplates.2.2
.NET Core 3.0	Microsoft.DotNet.Common.ProjectTemplates.3.0
.NET Core 3.1	Microsoft.DotNet.Common.ProjectTemplates.3.1
.NET 5.0	Microsoft.DotNet.Common.ProjectTemplates.5.0
.NET 6.0	Microsoft.DotNet.Common.ProjectTemplates.6.0
ASP.NET Core 2.1	Microsoft.DotNet.Web.ProjectTemplates.2.1
ASP.NET Core 2.2	Microsoft.DotNet.Web.ProjectTemplates.2.2
ASP.NET Core 3.0	Microsoft.DotNet.Web.ProjectTemplates.3.0
ASP.NET Core 3.1	Microsoft.DotNet.Web.ProjectTemplates.3.1
ASP.NET Core 5.0	Microsoft.DotNet.Web.ProjectTemplates.5.0
ASP.NET Core 6.0	Microsoft.DotNet.Web.ProjectTemplates.6.0

For example, the .NET Core SDK includes templates for a console app targeting .NET Core 2.1 and .NET Core 3.1. If you wanted to target .NET Core 3.0, you would need to install the 3.0 templates.

1. Try creating an app that targets .NET Core 3.0.

```
dotnet new console --framework netcoreapp3.0
```

If you see an error message, you need to install the templates.

Couldn't find an installed template that matches the input, searching online for one that does...

2. Install the .NET Core 3.0 project templates.

```
dotnet new -i Microsoft.DotNet.Common.ProjectTemplates.3.0
```

3. Try creating the app a second time.

```
dotnet new console --framework netcoreapp3.0
```

And you should see a message indicating the project was created.

The template "Console Application" was created successfully.

Processing post-creation actions... Running 'dotnet restore' on path-to-project-file.csproj...

Determining projects to restore... Restore completed in 1.05 sec for path-to-project-file.csproj.

Restore succeeded.

macOS Catalina Notarization and the impact on .NET downloads and projects

9/20/2022 • 4 minutes to read • [Edit Online](#)

Beginning with macOS Catalina (version 10.15), all software built after June 1, 2019, and distributed with Developer ID, must be notarized. This requirement applies to the .NET runtime, .NET SDK, and software created with .NET. This article describes the common scenarios you may face with .NET and macOS notarization.

Installing .NET

The installers for .NET (both runtime and SDK) have been notarized since February 18, 2020. Prior released versions aren't notarized. You can manually install a non-notarized version of .NET by first downloading the installer, and then using the `sudo installer` command. For more information, see [Download and manually install for macOS](#).

Native appHost

In .NET SDK 7 and later versions, an **appHost**, which is a native Mach-O executable, is produced for your app. This executable is usually invoked by .NET when your project compiles, publishes, or is run with the `dotnet run` command. The non-**appHost** version of your app is a *dll* file that can be invoked by the `dotnet <app.dll>` command.

When run locally, the SDK signs the apphost using [ad hoc signing](#), which allows the app to run locally. When distributing your app, you'll need to properly sign your app according to Apple guidance.

You can also distribute your app without the apphost and rely on users to run your app using `dotnet`. To turn off **appHost** generation, add the `UseAppHost` boolean setting in the project file and set it to `false`. You can also toggle the appHost with the `-p:UseAppHost` parameter on the command line for the specific `dotnet` command you run:

- Project file

```
<PropertyGroup>
  <UseAppHost>false</UseAppHost>
</PropertyGroup>
```

- Command-line parameter

```
dotnet run -p:UseAppHost=false
```

An **appHost** is required when you publish your app [self-contained](#) and you cannot disable it.

For more information about the `UseAppHost` setting, see [MSBuild properties for Microsoft.NET.Sdk](#).

Context of the appHost

When the appHost is enabled in your project, and you use the `dotnet run` command to run your app, the app is invoked in the context of the appHost and not the default host (the default host is the `dotnet` command). If the appHost is disabled in your project, the `dotnet run` command runs your app in the context of the default host. Even if the appHost is disabled, publishing your app as self-contained generates an appHost executable, and

users use that executable to run your app. Running your app with `dotnet <filename.dll>` invokes the app with the default host, the shared runtime.

When an app using the appHost is invoked, the certificate partition accessed by the app is different from the notarized default host. If your app must access the certificates installed through the default host, use the `dotnet run` command to run your app from its project file, or use the `dotnet <filename.dll>` command to start the app directly.

More information about this scenario is provided in the [ASP.NET Core and macOS and certificates](#) section.

ASP.NET Core, macOS, and certificates

.NET provides the ability to manage certificates in the macOS Keychain with the `System.Security.Cryptography.X509Certificates` class. Access to the macOS Keychain uses the application's identity as the primary key when deciding which partition to consider. For example, unsigned applications store secrets in the unsigned partition, but signed applications store their secrets in partitions only they can access. The source of execution that invokes your app decides which partition to use.

.NET provides three sources of execution: `appHost`, default host (the `dotnet` command), and a custom host. Each execution model may have different identities, either signed or unsigned, and has access to different partitions within the Keychain. Certificates imported by one mode may not be accessible from another. For example, the notarized versions of .NET have a default host that is signed. Certificates are imported into a secure partition based on its identity. These certificates aren't accessible from a generated appHost, as the appHost is ad-hoc signed.

Another example, by default, ASP.NET Core imports a default SSL certificate through the default host. ASP.NET Core applications that use an appHost won't have access to this certificate and will receive an error when .NET detects the certificate isn't accessible. The error message provides instructions on how to fix this problem.

If certificate sharing is required, macOS provides configuration options with the `security` utility.

For more information on how to troubleshoot ASP.NET Core certificate issues, see [Enforce HTTPS in ASP.NET Core](#).

Default entitlements

.NET's default host (the `dotnet` command) has a set of default entitlements. These entitlements are required for proper operation of .NET. It's possible that your application may need additional entitlements, in which case you'll need to generate and use an `appHost` and then add the necessary entitlements locally.

Default set of entitlements for .NET:

- `com.apple.security.cs.allow-jit`
- `com.apple.security.cs.allow-unsigned-executable-memory`
- `com.apple.security.cs.allow-dyld-environment-variables`
- `com.apple.security.cs.disable-library-validation`

Notarize a .NET app

If you want your application to run on macOS Catalina (version 10.15) or higher, you'll want to notarize your app. The appHost you submit with your application for notarization should be used with at least the same [default entitlements](#) for .NET Core.

Next steps

- [Install .NET on macOS](#).

Troubleshoot *fxr*, *libhostfxr.so*, and *FrameworkList.xml* errors

9/20/2022 • 3 minutes to read • [Edit Online](#)

When you try to use .NET 5+ (and .NET Core), commands such as `dotnet new` and `dotnet run` may fail with a message related to something not being found. Some of the error messages may be similar to the following:

- **System.IO.FileNotFoundException**

```
System.IO.FileNotFoundException: Could not find file  
'/usr/share/dotnet/packs/Microsoft.NETCore.App.Ref/5.0.0/data/FrameworkList.xml'.
```

- **A fatal error occurred.**

```
A fatal error occurred. The required library libhostfxr.so could not be found.
```

or

```
A fatal error occurred. The folder [/usr/share/dotnet/host/fxr] does not exist.
```

or

```
A fatal error occurred, the folder [/usr/share/dotnet/host/fxr] does not contain any version-numbered  
child folders.
```

- **Generic messages about dotnet not found**

A general message may appear that indicates the SDK isn't found, or that the package has already been installed.

One symptom of these problems is that both the `/usr/lib64/dotnet` and `/usr/share/dotnet` folders are on your system.

What's going on

This generally happens when two Linux package repositories provide .NET packages. While Microsoft provides a Linux package repository to source .NET packages, some Linux distributions also provide .NET packages, such as:

- Arch
- CentOS
- CentOS Stream
- Fedora
- RHEL

Mixing .NET packages from two different sources will most likely lead to issues since the packages may place things at different paths, and may be compiled differently.

Solutions

The solution to these problems is to use .NET from one package repository. Which repository to pick, and how to do it, varies by use-case and the Linux distribution.

If your distribution provides .NET packages, it's recommended that you use that package repository instead of Microsoft's.

- 1. I only use .NET and no other packages from the Microsoft repository, and my distribution provides .NET packages.**

If you only use the Microsoft repository for .NET packages and not for any other Microsoft package such as `mdatp`, `powershell`, or `mssql`, then:

- a. Remove the Microsoft repository
- b. Remove the .NET related packages from your OS
- c. Install the .NET packages from the distribution repository

For Fedora, CentOS 8+, RHEL 8+, use the following bash commands:

```
sudo dnf remove packages-microsoft-prod
sudo dnf remove 'dotnet*' 'aspnet*' 'netstandard*'
sudo dnf install dotnet-sdk-5.0
```

- 2. I want to use the distribution provided .NET packages, but I also use the Microsoft repository for other packages.**

If you use the Microsoft repository for Microsoft packages such as `mdatp`, `powershell`, or `mssql`, but you don't want to use the repository for .NET, then:

- a. Configure the Microsoft repository to exclude any .NET package
- b. Remove the .NET related packages from your OS
- c. Install the .NET packages from the distribution repository

For Fedora, CentOS 8+, RHEL 8+, use the following bash commands:

```
echo 'excludepkgs=dotnet*,aspnet*,netstandard*' | sudo tee -a /etc/yum.repos.d/microsoft-prod.repo
sudo dnf remove 'dotnet*' 'aspnet*' 'netstandard*'
sudo dnf install dotnet-sdk-5.0
```

- 3. I need a recent version of .NET that's not provided by the Linux distribution repositories.**

In this case, keep the Microsoft repository, but configure it so .NET packages from the Microsoft repository are considered a higher priority. Then, remove the already-installed .NET packages and then re-install the .NET packages from the Microsoft repository.

For Fedora, CentOS 8+, RHEL 8+, use the following bash commands:

```
echo 'priority=50' | sudo tee -a /etc/yum.repos.d/microsoft-prod.repo
sudo dnf remove 'dotnet*' 'aspnet*' 'netstandard*'
sudo dnf install dotnet-sdk-5.0
```

- 4. I've encountered a bug in the Linux distribution version of .NET, I need the latest Microsoft version.**

Use solution 3 to solve this problem.

Online references

Many of these problems have been reported by users such as yourself. The following is a list of those issues. You can read through them for insights on what may be happening:

How to check that .NET is already installed

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article teaches you how to check which versions of the .NET runtime and SDK are installed on your computer. If you have an integrated development environment, such as Visual Studio or Visual Studio for Mac, .NET may have already been installed.

Installing an SDK installs the corresponding runtime.

If any command in this article fails, you don't have the runtime or SDK installed. For more information, see the install articles for [Windows](#), [macOS](#), or [Linux](#).

Check SDK versions

You can see which versions of the .NET SDK are currently installed with a terminal. Open a terminal and run the following command.

```
dotnet --list-sdks
```

You get output similar to the following.

```
2.1.500 [C:\program files\dotnet\sdk]
2.1.502 [C:\program files\dotnet\sdk]
2.1.504 [C:\program files\dotnet\sdk]
2.1.600 [C:\program files\dotnet\sdk]
2.1.602 [C:\program files\dotnet\sdk]
3.1.100 [C:\program files\dotnet\sdk]
5.0.100 [C:\program files\dotnet\sdk]
6.0.100 [C:\program files\dotnet\sdk]
```

```
2.1.500 [/home/user/dotnet/sdk]
2.1.502 [/home/user/dotnet/sdk]
2.1.504 [/home/user/dotnet/sdk]
2.1.600 [/home/user/dotnet/sdk]
2.1.602 [/home/user/dotnet/sdk]
3.1.100 [/home/user/dotnet/sdk]
5.0.100 [/home/user/dotnet/sdk]
6.0.100 [/home/user/dotnet/sdk]
```

```
2.1.500 [/usr/local/share/dotnet/sdk]
2.1.502 [/usr/local/share/dotnet/sdk]
2.1.504 [/usr/local/share/dotnet/sdk]
2.1.600 [/usr/local/share/dotnet/sdk]
2.1.602 [/usr/local/share/dotnet/sdk]
3.1.100 [/usr/local/share/dotnet/sdk]
5.0.100 [/usr/local/share/dotnet/sdk]
6.0.100 [/usr/local/share/dotnet/sdk]
```

Check runtime versions

You can see which versions of the .NET runtime are currently installed with the following command.

```
dotnet --list-runtimes
```

You get output similar to the following.

```
Microsoft.AspNetCore.All 2.1.7 [c:\program files\dotnet\shared\Microsoft.AspNetCore.All]
Microsoft.AspNetCore.All 2.1.13 [c:\program files\dotnet\shared\Microsoft.AspNetCore.All]
Microsoft.AspNetCore.App 2.1.7 [c:\program files\dotnet\shared\Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 2.1.13 [c:\program files\dotnet\shared\Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 3.1.0 [c:\program files\dotnet\shared\Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 5.0.0 [c:\program files\dotnet\shared\Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 6.0.0 [c:\program files\dotnet\shared\Microsoft.AspNetCore.App]
Microsoft.NETCore.App 2.1.7 [c:\program files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.NETCore.App 2.1.13 [c:\program files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.NETCore.App 3.1.0 [c:\program files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.NETCore.App 5.0.0 [c:\program files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.NETCore.App 6.0.0 [c:\program files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.WindowsDesktop.App 3.0.0 [c:\program files\dotnet\shared\Microsoft.WindowsDesktop.App]
Microsoft.WindowsDesktop.App 3.1.0 [c:\program files\dotnet\shared\Microsoft.WindowsDesktop.App]
Microsoft.WindowsDesktop.App 5.0.0 [c:\program files\dotnet\shared\Microsoft.WindowsDesktop.App]
Microsoft.WindowsDesktop.App 6.0.0 [c:\program files\dotnet\shared\Microsoft.WindowsDesktop.App]
```

```
Microsoft.AspNetCore.All 2.1.7 [/home/user/dotnet/shared/Microsoft.AspNetCore.All]
Microsoft.AspNetCore.All 2.1.13 [/home/user/dotnet/shared/Microsoft.AspNetCore.All]
Microsoft.AspNetCore.App 2.1.7 [/home/user/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 2.1.13 [/home/user/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 3.1.0 [/home/user/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 5.0.0 [/home/user/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 6.0.0 [/home/user/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.NETCore.App 2.1.7 [/home/user/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 2.1.13 [/home/user/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 3.1.0 [/home/user/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 5.0.0 [/home/user/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 6.0.0 [/home/user/dotnet/shared/Microsoft.NETCore.App]
```

```
Microsoft.AspNetCore.All 2.1.7 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.All]
Microsoft.AspNetCore.All 2.1.13 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.All]
Microsoft.AspNetCore.App 2.1.7 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 2.1.13 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 3.1.0 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 5.0.0 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.AspNetCore.App 6.0.0 [/usr/local/share/dotnet/shared/Microsoft.AspNetCore.App]
Microsoft.NETCore.App 2.1.7 [/usr/local/share/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 2.1.13 [/usr/local/share/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 3.1.0 [/usr/local/share/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 5.0.0 [/usr/local/share/dotnet/shared/Microsoft.NETCore.App]
Microsoft.NETCore.App 6.0.0 [/usr/local/share/dotnet/shared/Microsoft.NETCore.App]
```

Check for install folders

It's possible that .NET is installed but not added to the `PATH` variable for your operating system or user profile. In this case, the commands from the previous sections may not work. As an alternative, you can check that the .NET install folders exist.

When you install .NET from an installer or script, it's installed to a standard folder. Much of the time the installer or script you're using to install .NET gives you an option to install to a different folder. If you choose to install to a different folder, adjust the start of the folder path.

- **dotnet executable**

C:\program files\dotnet\dotnet.exe

- **.NET SDK**

C:\program files\dotnet\sdk\{version}

- **.NET Runtime**

C:\program files\dotnet\shared\{runtime-type}\{version}

- **dotnet executable**

/home/user/share/dotnet/dotnet

- **.NET SDK**

/home/user/share/dotnet/sdk/{version}

- **.NET Runtime**

/home/user/share/dotnet/shared/{runtime-type}/{version}

- **dotnet executable**

/usr/local/share/dotnet/dotnet

- **.NET SDK**

/usr/local/share/dotnet/sdk/{version}

- **.NET Runtime**

/usr/local/share/dotnet/shared/{runtime-type}/{version}

More information

You can see both the SDK versions and runtime versions with the command `dotnet --info`. You'll also get other environmental related information, such as the operating system version and runtime identifier (RID).

Next steps

How to install localized IntelliSense files for .NET

9/20/2022 • 3 minutes to read • [Edit Online](#)

IntelliSense is a code-completion aid that's available in different integrated development environments (IDEs), such as Visual Studio. By default, when you're developing .NET projects, the SDK only includes the English version of the IntelliSense files. This article explains:

- How to install the localized version of those files.
- How to modify the Visual Studio installation to use a different language.

Prerequisites

- [.NET Core 3.1 SDK](#) or a later version, such as the [.NET 6 SDK](#).
- [Visual Studio 2019 version 16.3](#) or a later version.

Download and install the localized IntelliSense files

IMPORTANT

This procedure requires that you have administrator permission to copy the IntelliSense files to the .NET installation folder.

1. Go to the [Download IntelliSense files](#) page.
2. Download the IntelliSense file for the language and version you'd like to use.
3. Extract the contents of the zip file.
4. Navigate to the .NET Intellisense folder.
 - a. Navigate to the .NET installation folder. By default, it's under `%ProgramFiles%\dotnet\packs`.
 - b. Choose which SDK you want to install the IntelliSense for, and navigate to the associated path. You have the following options:

SDK TYPE	PATH
.NET 5+ and .NET Core	<code>Microsoft.NETCore.App.Ref</code>
Windows Desktop	<code>Microsoft.WindowsDesktop.App.Ref</code>
.NET Standard	<code>NETStandard.Library.Ref</code>

- c. Navigate to the version you want to install the localized IntelliSense for. For example, `6.0.0`.
- d. Open the `ref` folder.
- e. Open the moniker folder. For example, `net6.0`.

So, the full path that you'd navigate to would look similar to `C:\Program Files\dotnet\packs\Microsoft.NETCore.App.Ref\6.0.0\ref\net6.0`.

5. Create a subfolder inside the moniker folder you just opened. The name of the folder indicates which language you want to use. The following table specifies the different options:

LANGUAGE	FOLDER NAME
Brazilian Portuguese	<i>pt-br</i>
Chinese (simplified)	<i>zh-hans</i>
Chinese (traditional)	<i>zh-hant</i>
French	<i>fr</i>
German	<i>de</i>
Italian	<i>it</i>
Japanese	<i>ja</i>
Korean	<i>ko</i>
Russian	<i>ru</i>
Spanish	<i>es</i>

6. Copy the *.xm*/files you extracted in step 3 to this new folder. The *.xm*/files are broken down by SDK folders, so copy them to the matching SDK you chose in step 4.

Modify Visual Studio language

For Visual Studio to use a different language for IntelliSense, install the appropriate language pack. This can be done [during installation](#) or at a later time by modifying the Visual Studio installation. If you already have Visual Studio configured to the language of your choice, your IntelliSense installation is ready.

Install the language pack

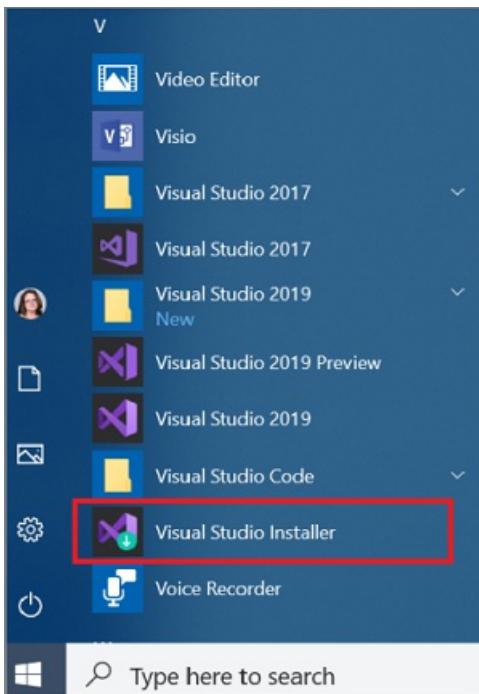

If you didn't install the desired language pack during setup, update Visual Studio as follows to install the language pack:

IMPORTANT

To install, update, or modify Visual Studio, you must log on with an account that has administrator permission. For more information, see [User permissions and Visual Studio](#).

1. Find the Visual Studio Installer on your computer.

For example, on a computer running Windows 10, select **Start**, and then scroll to the letter **V**, where it's listed as **Visual Studio Installer**.

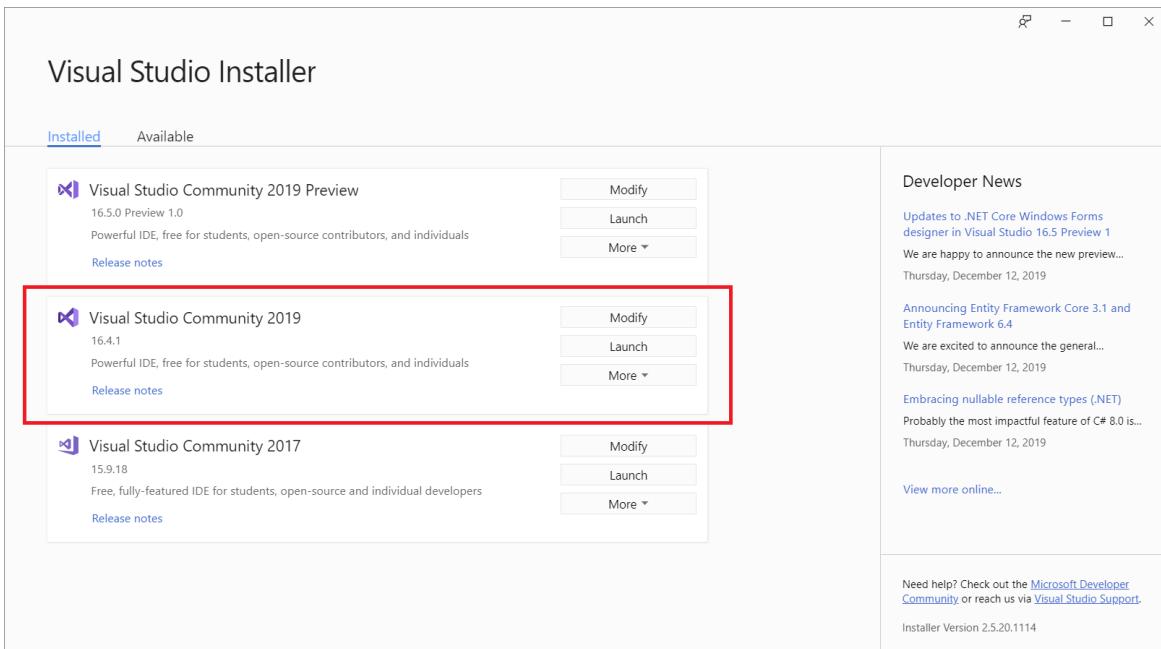

NOTE

You can also find the Visual Studio Installer in the following location:

```
C:\Program Files (x86)\Microsoft Visual Studio\Installer\vs_installer.exe
```

You might have to update the installer before continuing. If so, follow the prompts.

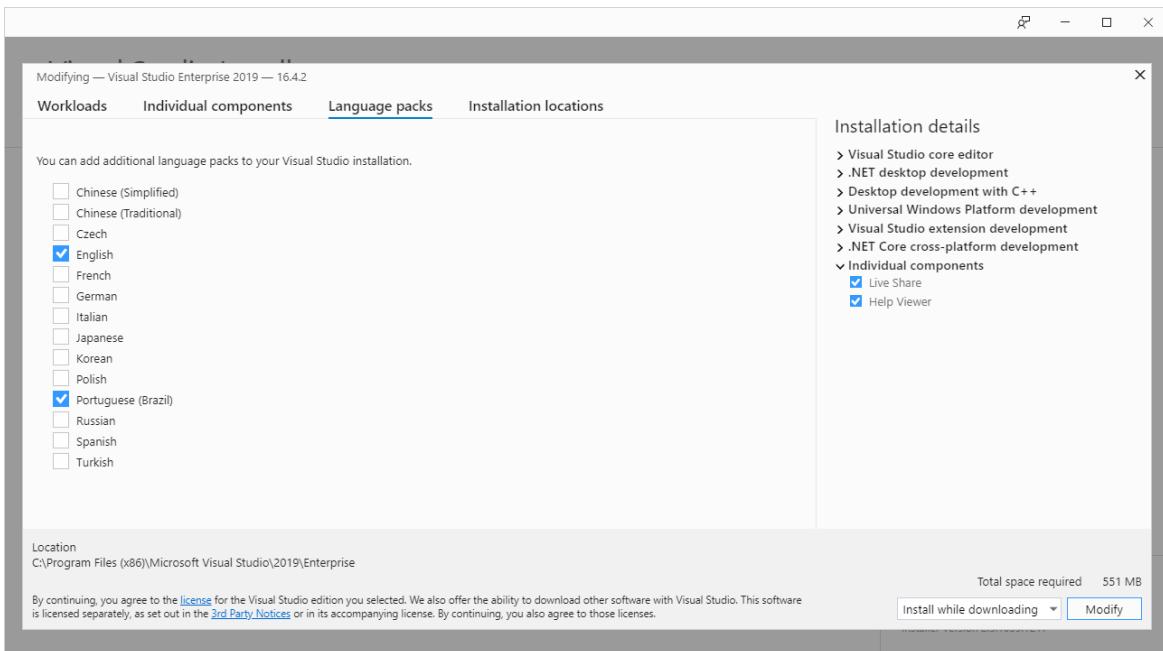

2. In the installer, look for the edition of Visual Studio that you want to add the language pack to, and then choose **Modify**.

IMPORTANT

If you don't see a **Modify** button but you see an **Update** one instead, you need to update your Visual Studio before you can modify your installation. After the update is finished, the **Modify** button should appear.

3. In the **Language packs** tab, select or deselect the languages you want to install or uninstall.

4. Choose **Modify**. The update starts.

Modify language settings in Visual Studio

Once you've installed the desired language packs, modify your Visual Studio settings to use a different language:

1. Open Visual Studio.
2. On the start window, choose **Continue without code**.
3. On the menu bar, select **Tools > Options**. The Options dialog opens.
4. Under the **Environment** node, choose **International Settings**.
5. On the **Language** drop-down, select the desired language. Choose **OK**.
6. A dialog informs you that you have to restart Visual Studio for the changes to take effect. Choose **OK**.
7. Restart Visual Studio.

After this, your IntelliSense should work as expected when you open a .NET project that targets the version of the IntelliSense files you just installed.

What is .NET? Introduction and overview

9/20/2022 • 8 minutes to read • [Edit Online](#)

.NET is a free, cross-platform, open source developer platform for building many kinds of applications. .NET is built on a high-performance runtime that is used in production by many high-scale apps.

Cloud apps

- [Cloud native apps](#)
- [Console apps](#)
- [Serverless functions in the cloud](#)
- [Web apps, web APIs, and microservices](#)

Cross-platform client apps

- [Desktop apps](#)
- [Games](#)
- [Mobile apps](#)

Windows apps

- [Windows Desktop apps](#)
 - [Windows Forms](#)
 - [Windows WPF](#)
 - [Universal Windows Platform \(UWP\)](#)
- [Windows services](#)

Other app types

- [Machine learning](#)
- [Internet of Things \(IoT\)](#)

Features

.NET features allow developers to productively write reliable and performant code.

- [Asynchronous code](#)
- [Attributes](#)
- [Reflection](#)
- [Code analyzers](#)
- [Delegates and lambdas](#)
- [Events](#)
- [Exceptions](#)
- [Garbage collection](#)
- [Generic types](#)
- [LINQ \(Language Integrated Query\).](#)
- [Parallel programming](#)
- Type inference - [C#](#), [F#](#), [Visual Basic](#).
- [Type system](#)
- [Unsafe code](#)

Using .NET

.NET apps and libraries are built from source code and a project file, using the [.NET CLI](#) or an Integrated Development Environment (IDE) like [Visual Studio](#).

The following example is a minimal .NET app:

Project file:

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
<OutputType>Exe</OutputType>
<TargetFramework>net6.0</TargetFramework>
</PropertyGroup>
</Project>
```

Source code:

```
Console.WriteLine("Hello, World!");
```

The app can be built and run with the [.NET CLI](#):

```
% dotnet run
Hello, World!
```

It can also be built and run as two separate steps. The following example is for an app that is named *app*:

```
% dotnet build
% ./bin/Debug/net6.0/app
Hello, World!
```

Binary distributions

- [.NET SDK](#) -- Set of tools, libraries, and runtimes for development, building, and testing apps.
- [.NET Runtimes](#) -- Set of runtimes and libraries, for running apps.

You can download .NET from:

- [The Microsoft download site](#).
- [Containers](#).
- [Linux package managers](#).

Free and open source

.NET is free, open source, and is a [.NET Foundation project](#). .NET is maintained by Microsoft and the community on GitHub in [several repositories](#).

.NET source and binaries are licensed with the [MIT license](#). Additional [licenses apply on Windows](#) for binary distributions.

Support

Microsoft supports .NET on Android, Apple, Linux, and Windows operating systems. It can be used on Arm64,

x64, and x86 architectures. It's also supported in emulated environments, like [macOS Rosetta 2](#).

New versions of .NET are released annually in November. .NET releases in odd-numbered years are Long-term Support (LTS) releases and are supported for three years. Releases in even-numbered years are Short-term Support (STS) releases and are supported for 18 months. The quality level, breaking change policies, and all other aspects of the releases are the same. For more information, see [Releases and support](#).

The .NET Team at Microsoft works collaboratively with other organizations to distribute and support .NET in various ways.

[Red Hat supports .NET](#) on Red Hat Enterprise Linux (RHEL).

[Samsung supports .NET](#) on Tizen platforms.

Runtime

The [Common Language Runtime \(CLR\)](#) is the foundation all .NET apps are built on. The [fundamental features of the runtime](#) are:

- Garbage collection.
- Memory safety and type safety.
- High level support for programming languages.
- Cross-platform design.

.NET is sometimes called a "managed code" runtime. It's called *managed* primarily because it uses a garbage collector for memory management and because it enforces type and memory safety. The CLR virtualizes (or abstracts) various operating system and hardware concepts, such as memory, threads, and exceptions.

The CLR was designed to be a cross-platform runtime from its inception. It has been ported to multiple operating systems and architectures. Cross-platform .NET code typically does not need to be recompiled to run in new environments. Instead, you just need to install a different runtime to run your app.

The runtime exposes various [diagnostics](#) services and APIs for debuggers, [dumps](#) and [tracing](#) tools, and [observability](#). The observability implementation is primarily [built around OpenTelemetry](#), enabling [flexible application monitoring](#) and site reliability engineering (SRE).

The runtime offers low-level C-style interop functionality, via a combination of [P/Invoke](#), value types, and the ability to [blit](#) values across the native/managed-code boundary.

Languages

The runtime is designed to support multiple programming languages. C#, F#, and Visual Basic languages are supported by Microsoft and are designed in collaboration with the community.

- [C#](#) is a modern, object-oriented, and type-safe programming language. It has its roots in the C family of languages and will be immediately familiar to C, C++, Java, and JavaScript programmers.
- [F#](#) is an interoperable programming language for writing succinct, robust, and performant code. F# programming is data-oriented, where code involves transforming data with functions.
- [Visual Basic](#) uses a more verbose syntax that is closer to ordinary human language. It can be an easier language to learn for people new to programming.

Compilation

.NET apps (as written in a high-level language like C#) are compiled to an [Intermediate Language \(IL\)](#). IL is a compact code format that can be supported on any operating system or architecture. Most .NET apps use APIs

that are supported in multiple environments, requiring only the .NET runtime to run.

IL needs to be compiled to native code in order to execute on a CPU, for example Arm64 or x64. .NET supports both Ahead-Of-Time (AOT) and Just-In-Time (JIT) compilation models.

- On Android, Linux, macOS, and Linux, JIT compilation is the default, and AOT is optional (for example, with [ReadyToRun](#)).
- On [iOS](#), AOT is mandatory (except when running in the simulator).
- In WebAssembly (Wasm) environments, AOT is mandatory.

The advantage of the JIT is that it can compile an app (unmodified) to the CPU instructions and calling conventions in a given environment, per the underlying operating system and hardware. It can also compile code at higher or lower levels of quality to enable better startup and steady-state throughput performance.

The advantage of AOT is that it provides the best app startup and can (in some cases) result in smaller deployments. The primary downside is that binaries must be built for each separate deployment target (the same as any other native code). AOT code is not compatible with some reflection patterns.

Runtime libraries

.NET has a comprehensive standard set of class libraries. These libraries provide implementations for many general-purpose and workload-specific types and utility functionality.

Here are some examples of types defined in the .NET runtime libraries:

- Every .NET type derives from the [System.Object](#) type.
- Primitive value types, such as [System.Boolean](#) and [System.Int32](#).
- Collections, such as [System.Collections.Generic.List<T>](#) and [System.Collections.Generic.Dictionary< TKey, TValue >](#).
- Data types, such as [System.Data.DataSet](#) and [System.Data.DataTable](#).
- Network utility types, such as [System.Net.Http.HttpClient](#).
- [File and stream I/O](#) utility types, such as [System.IO.FileStream](#) and [System.IO.TextWriter](#).
- [Serialization](#) utility types, such as [System.Text.Json.JsonSerializer](#) and [System.Xml.Serialization.XmlSerializer](#).
- High-performance types, such as [System.Span<T>](#), [System.Numerics.Vector](#), and [Pipelines](#).

For more information, see the [Runtime libraries overview](#).

NuGet Package Manager

[NuGet](#) is the package manager for .NET. It enables developers to share compiled binaries with each other.

[NuGet.org](#) offers many [popular packages](#) from the community.

Tools

The [.NET SDK](#) is a set of libraries and [tools](#) for developing and running .NET applications. It includes the [MSBuild](#) build engine, the [Roslyn](#) (C# and Visual Basic) compiler, and the [F#](#) compiler. Most commands are run by using the [dotnet](#) command. The CLI tools can be used for local development and continuous integration.

The [Visual Studio](#) family of IDEs offer excellent support for .NET and the C#, F#, and Visual Basic languages.

[GitHub Codespaces](#) and [GitHub security features](#) support .NET.

Notebooks

.NET Interactive is a group of CLI tools and APIs that enable users to create interactive experiences across the

web, markdown, and notebooks.

For more information, see the following resources:

- [.NET In-Browser Tutorial](#)
- [Using .NET notebooks with Jupyter on your machine](#)
- [.NET Interactive documentation](#)

CI/CD

MSBuild and the .NET CLI can be used with various continuous integration tools and environments, such as:

- [GitHub Actions](#)
- [Azure DevOps](#)
- [CAKE for C#](#)
- [FAKE for F#](#)

For more information, see [Use the .NET SDK in Continuous Integration \(CI\) environments](#).

Deployment models

.NET apps can be [published in two different modes](#):

- *Self-contained* apps include the .NET runtime and dependent libraries. They can be [single-file](#) or multi-file. Users of the application can run it on a machine that doesn't have the .NET runtime installed. Self-contained apps always target a single operating system and architecture configuration.
- *Framework-dependent* apps require a compatible version of the .NET runtime, typically installed globally. Framework-dependent apps can be published for a single operating system and architecture configuration or as "portable," targeting all supported configurations.

.NET apps are launched with a native executable, by default. The executable is both operating system and architecture-specific. Apps can also be launched with the `dotnet` command.

Apps can be [deployed in containers](#). Microsoft provides [container images](#) for various target environments.

.NET history

In 2002, Microsoft released [.NET Framework](#), a development platform for creating Windows apps. Today .NET Framework is at version 4.8 and remains [fully supported by Microsoft](#).

In 2014, Microsoft introduced .NET Core as a cross-platform, open-source successor to .NET Framework. This new [implementation of .NET](#) kept the name .NET Core through version 3.1. The next version after .NET Core 3.1 was named .NET 5.

New .NET versions continue to be released annually, each a major version number higher. They include significant new features and often enable new scenarios.

.NET ecosystem

There are multiple variants of .NET, each supporting a different type of app. The reason for multiple variants is part historical, part technical.

.NET implementations (historical order):

- **.NET Framework** -- It provides access to the broad capabilities of Windows and Windows Server. Also extensively used for Windows-based cloud computing. The original .NET.
- **Mono** -- A cross-platform implementation of .NET Framework. The original community and open source

.NET. Used for Android, iOS, and Wasm apps.

- **.NET (Core)** -- A cross-platform and open source implementation of .NET, rethought for the cloud age while remaining significantly compatible with .NET Framework. Used for Linux, macOS, and Windows apps.

- [Take a tour of F#](#)

.NET implementations

9/20/2022 • 2 minutes to read • [Edit Online](#)

A .NET app is developed for one or more *implementations of .NET*. Implementations of .NET include .NET Framework, .NET 5+ (and .NET Core), and Mono.

Each implementation of .NET includes the following components:

- One or more runtimes—for example, .NET Framework CLR and .NET 5 CLR.
- A class library—for example, .NET Framework Base Class Library and .NET 5 Base Class Library.
- Optionally, one or more application frameworks—for example, [ASP.NET](#), [Windows Forms](#), and [Windows Presentation Foundation \(WPF\)](#) are included in .NET Framework and .NET 5+.
- Optionally, development tools. Some development tools are shared among multiple implementations.

There are four .NET implementations that Microsoft supports:

- .NET 5 (and .NET Core) and later versions
- .NET Framework
- Mono
- UWP

.NET 6 is currently the primary implementation, and the one that's the focus of ongoing development. .NET 6 is built on a single code base that supports multiple platforms and many workloads, such as Windows desktop apps and cross-platform console apps, cloud services, and websites. [Some workloads](#), such as .NET WebAssembly build tools, are available as optional installations.

.NET 5 and later versions

.NET 5+, previously referred to as .NET Core, is a cross-platform implementation of .NET that's designed to handle server and cloud workloads at scale. It also supports other workloads, including desktop apps. It runs on Windows, macOS, and Linux. It implements .NET Standard, so code that targets .NET Standard can run on .NET 5+. [ASP.NET Core](#), [Windows Forms](#), and [Windows Presentation Foundation \(WPF\)](#) all run on .NET 5+.

.NET 6 is the latest version of this .NET implementation.

For more information, see the following resources:

- [.NET introduction](#)
- [.NET vs. .NET Framework for server apps](#)
- [.NET 5+ and .NET Standard](#)

.NET Framework

.NET Framework is the original .NET implementation that has existed since 2002. Versions 4.5 and later implement .NET Standard, so code that targets .NET Standard can run on those versions of .NET Framework. It contains additional Windows-specific APIs, such as APIs for Windows desktop development with Windows Forms and WPF. .NET Framework is optimized for building Windows desktop applications.

For more information, see the [.NET Framework guide](#).

Mono

Mono is a .NET implementation that is mainly used when a small runtime is required. It is the runtime that powers Xamarin applications on Android, macOS, iOS, tvOS, and watchOS and is focused primarily on a small footprint. Mono also powers games built using the Unity engine.

It supports all of the currently published .NET Standard versions.

Historically, Mono implemented the larger API of .NET Framework and emulated some of the most popular capabilities on Unix. It is sometimes used to run .NET applications that rely on those capabilities on Unix.

Mono is typically used with a just-in-time compiler, but it also features a full static compiler (ahead-of-time compilation) that is used on platforms like iOS.

For more information, see the [Mono documentation](#).

Universal Windows Platform (UWP)

UWP is an implementation of .NET that is used for building modern, touch-enabled Windows applications and software for the Internet of Things (IoT). It's designed to unify the different types of devices that you may want to target, including PCs, tablets, phones, and even the Xbox. UWP provides many services, such as a centralized app store, an execution environment (AppContainer), and a set of Windows APIs to use instead of Win32 (WinRT).

Apps can be written in C++, C#, Visual Basic, and JavaScript.

For more information, see [Introduction to the Universal Windows Platform](#).

.NET class libraries

9/20/2022 • 3 minutes to read • [Edit Online](#)

Class libraries are the [shared library](#) concept for .NET. They enable you to componentize useful functionality into modules that can be used by multiple applications. They can also be used as a means of loading functionality that is not needed or not known at application startup. Class libraries are described using the [.NET Assembly file format](#).

There are three types of class libraries that you can use:

- **Platform-specific** class libraries have access to all the APIs in a given platform (for example, .NET Framework on Windows, Xamarin iOS), but can only be used by apps and libraries that target that platform.
- **Portable** class libraries have access to a subset of APIs, and can be used by apps and libraries that target multiple platforms.
- **.NET Standard** class libraries are a merger of the platform-specific and portable library concept into a single model that provides the best of both.

Platform-specific class libraries

Platform-specific libraries are bound to a single .NET platform (for example, .NET Framework on Windows) and can therefore take significant dependencies on a known execution environment. Such an environment exposes a known set of APIs (.NET and OS APIs) and maintains and exposes expected state (for example, Windows registry).

Developers who create platform-specific libraries can fully exploit the underlying platform. The libraries will only ever run on that given platform, making platform checks or other forms of conditional code unnecessary (modulo single sourcing code for multiple platforms).

Platform-specific libraries have been the primary class library type for the .NET Framework. Even as other .NET implementations emerged, platform-specific libraries remained the dominant library type.

Portable class libraries

Portable libraries are supported on multiple .NET implementations. They can still take dependencies on a known execution environment, however, the environment is a synthetic one that's generated by the intersection of a set of concrete .NET implementations. Exposed APIs and platform assumptions are a subset of what would be available to a platform-specific library.

You choose a platform configuration when you create a portable library. The platform configuration is the set of platforms that you need to support (for example, .NET Framework 4.5+, Windows Phone 8.0+). The more platforms you opt to support, the fewer APIs and fewer platform assumptions you can make, the lowest common denominator. This characteristic can be confusing at first, since people often think "more is better" but find that more supported platforms results in fewer available APIs.

Many library developers have switched from producing multiple platform-specific libraries from one source (using conditional compilation directives) to portable libraries. There are [several approaches](#) for accessing platform-specific functionality within portable libraries, with bait-and-switch being the most widely accepted technique at this point.

.NET Standard class libraries

.NET Standard libraries are a replacement of the platform-specific and portable libraries concepts. They are platform-specific in the sense that they expose all functionality from the underlying platform (no synthetic platforms or platform intersections). They are portable in the sense that they work on all supporting platforms.

.NET Standard exposes a set of library *contracts*. .NET implementations must support each contract fully or not at all. Each implementation, therefore, supports a set of .NET Standard contracts. The corollary is that each .NET Standard class library is supported on the platforms that support its contract dependencies.

.NET Standard does not expose the entire functionality of .NET Framework (nor is that a goal), however, the libraries do expose many more APIs than Portable Class Libraries.

The following implementations support .NET Standard libraries:

- .NET Core
- .NET Framework
- Mono
- Universal Windows Platform (UWP)

For more information, see [.NET Standard](#).

Mono class libraries

Class libraries are supported on Mono, including the three types of libraries described previously. Mono is often viewed as a cross-platform implementation of .NET Framework. In part, this is because platform-specific .NET Framework libraries can run on the Mono runtime without modification or recompilation. This characteristic was in place before the creation of portable class libraries, so was an obvious choice to enable binary portability between .NET Framework and Mono (although it only worked in one direction).

.NET Standard

9/20/2022 • 14 minutes to read • [Edit Online](#)

.NET Standard is a formal specification of .NET APIs that are available on multiple .NET implementations. The motivation behind .NET Standard was to establish greater uniformity in the .NET ecosystem. .NET 5 and later versions adopt a different approach to establishing uniformity that eliminates the need for .NET Standard in most scenarios. However, if you want to share code between .NET Framework and any other .NET implementation, such as .NET Core, your library should target .NET Standard 2.0. [No new versions of .NET Standard will be released](#), but .NET 5, .NET 6, and all future versions will continue to support .NET Standard 2.1 and earlier.

For information about choosing between .NET 5+ and .NET Standard, see [.NET 5+ and .NET Standard](#) later in this article.

.NET Standard versions

.NET Standard is versioned. Each new version adds more APIs. When a library is built against a certain version of .NET Standard, it can run on any .NET implementation that implements that version of .NET Standard (or higher).

Targeting a higher version of .NET Standard allows a library to use more APIs but means it can only be used on more recent versions of .NET. Targeting a lower version reduces the available APIs but means the library can run in more places.

Select .NET Standard version

- [1.0](#)
- [1.1](#)
- [1.2](#)
- [1.3](#)
- [1.4](#)
- [1.5](#)
- [1.6](#)
- [2.0](#)
- [2.1](#)

.NET Standard 1.0 has 7,949 of the 37,118 available APIs.

.NET IMPLEMENTATION	VERSION SUPPORT
.NET and .NET Core	1.0, 1.1, 2.0, 2.1, 2.2, 3.0, 3.1, 5.0, 6.0
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8
Mono	4.6, 5.4, 6.4
Xamarin.iOS	10.0, 10.14, 12.16
Xamarin.Mac	3.0, 3.8, 5.16

.NET IMPLEMENTATION	VERSION SUPPORT
Xamarin.Android	7.0, 8.0, 10.0
Universal Windows Platform	8.0, 8.1, 10.0, 10.0.16299, TBD
Unity	2018.1

For more information, see [.NET Standard 1.0](#). For an interactive table, see [.NET Standard versions](#).

Which .NET Standard version to target

We recommend you target .NET Standard 2.0, unless you need to support an earlier version. Most general-purpose libraries should not need APIs outside of .NET Standard 2.0. .NET Standard 2.0 is supported by all modern platforms and is the recommended way to support multiple platforms with one target.

If you need to support .NET Standard 1.x, we recommend that you *also* target .NET Standard 2.0. .NET Standard 1.x is distributed as a granular set of NuGet packages, which creates a large package dependency graph and results in developers downloading a lot of packages when building. For more information, see [Cross-platform targeting](#) and [.NET 5+ and .NET Standard](#) later in this article.

.NET Standard versioning rules

There are two primary versioning rules:

- Additive: .NET Standard versions are logically concentric circles: higher versions incorporate all APIs from previous versions. There are no breaking changes between versions.
- Immutable: Once shipped, .NET Standard versions are frozen.

There will be no new .NET Standard versions after 2.1. For more information, see [.NET 5+ and .NET Standard](#) later in this article.

Specification

The .NET Standard specification is a standardized set of APIs. The specification is maintained by .NET implementers, specifically Microsoft (includes .NET Framework, .NET Core, and Mono) and Unity.

Official artifacts

The official specification is a set of .cs files that define the APIs that are part of the standard. The [ref directory](#) in the (now archived) [dotnet/standard repository](#) defines the .NET Standard APIs.

The [NETStandard.Library](#) metapackage ([source](#)) describes the set of libraries that define (in part) one or more .NET Standard versions.

A given component, like `System.Runtime`, describes:

- Part of .NET Standard (just its scope).
- Multiple versions of .NET Standard, for that scope.

Derivative artifacts are provided to enable more convenient reading and to enable certain developer scenarios (for example, using a compiler).

- [API list in markdown](#).
- Reference assemblies, distributed as NuGet packages and referenced by the [NETStandard.Library](#) metapackage.

Package representation

The primary distribution vehicle for the .NET Standard reference assemblies is NuGet packages.

Implementations are delivered in a variety of ways, appropriate for each .NET implementation.

NuGet packages target one or more [frameworks](#). .NET Standard packages target the ".NET Standard" framework. You can target the .NET Standard framework using the `netstandard` [compact TFM](#) (for example, `netstandard1.4`). Libraries that are intended to run on multiple implementations of .NET should target this framework. For the broadest set of APIs, target `netstandard2.0` since the number of available APIs more than doubled between .NET Standard 1.6 and 2.0.

The `NETStandard.Library` metapackage references the complete set of NuGet packages that define .NET Standard. The most common way to target `netstandard` is by referencing this metapackage. It describes and provides access to the ~40 .NET libraries and associated APIs that define .NET Standard. You can reference additional packages that target `netstandard` to get access to additional APIs.

Versioning

The specification is not singular, but a linearly versioned set of APIs. The first version of the standard establishes a baseline set of APIs. Subsequent versions add APIs and inherit APIs defined by previous versions. There is no established provision for removing APIs from the Standard.

.NET Standard is not specific to any one .NET implementation, nor does it match the versioning scheme of any of those implementations.

As noted earlier, there will be no new .NET Standard versions after 2.1.

Target .NET Standard

You can [build .NET Standard Libraries](#) using a combination of the `netstandard` framework and the `NETStandard.Library` metapackage.

.NET Framework compatibility mode

Starting with .NET Standard 2.0, the .NET Framework compatibility mode was introduced. This compatibility mode allows .NET Standard projects to reference .NET Framework libraries as if they were compiled for .NET Standard. Referencing .NET Framework libraries doesn't work for all projects, such as libraries that use Windows Presentation Foundation (WPF) APIs.

For more information, see [.NET Framework compatibility mode](#).

.NET Standard libraries and Visual Studio

In order to build .NET Standard libraries in Visual Studio, make sure you have [Visual Studio 2022](#), [Visual Studio 2019](#), or [Visual Studio 2017](#) version 15.3 or later installed on Windows, or [Visual Studio for Mac](#) version 7.1 or later installed on macOS.

If you only need to consume .NET Standard 2.0 libraries in your projects, you can also do that in Visual Studio 2015. However, you need NuGet client 3.6 or higher installed. You can download the NuGet client for Visual Studio 2015 from the [NuGet downloads](#) page.

.NET 5+ and .NET Standard

.NET 5 and .NET 6 are single products with a uniform set of capabilities and APIs that can be used for Windows desktop apps and cross-platform console apps, cloud services, and websites. The .NET 5 [TFMs](#), for example, reflect this broad range of scenarios:

- `net5.0`

This TFM is for code that runs everywhere. With a few exceptions, it includes only technologies that work

cross-platform. For .NET 5 code, `net5.0` replaces both `netcoreapp` and `netstandard` TFMs.

- `net5.0-windows`

This is an example of an [OS-specific TFM](#) that add OS-specific functionality to everything that `net5.0` refers to.

When to target `net5.0` or `net6.0` vs. `netstandard`

For existing code that targets `netstandard`, there's no need to change the TFM to `net5.0` or `net6.0`. .NET 5 and .NET 6 implement .NET Standard 2.1 and earlier. The only reason to retarget from .NET Standard to .NET 5+ would be to gain access to more runtime features, language features, or APIs. For example, in order to use C# 9, you need to target .NET 5 or a later version. You can multitarget .NET 5 or .NET 6 and .NET Standard to get access to newer features and still have your library available to other .NET implementations.

Here are some guidelines for new code for .NET 5+:

- App components

If you're using libraries to break down an application into several components, we recommend you target `net5.0` or `net6.0`. For simplicity, it's best to keep all projects that make up your application on the same version of .NET. Then you can assume the same BCL features everywhere.

- Reusable libraries

If you're building reusable libraries that you plan to ship on NuGet, consider the trade-off between reach and available feature set. .NET Standard 2.0 is the latest version that's supported by .NET Framework, so it gives good reach with a fairly large feature set. We don't recommend targeting .NET Standard 1.x, as you'd limit the available feature set for a minimal increase in reach.

If you don't need to support .NET Framework, you could go with .NET Standard 2.1 or .NET 5/6. We recommend you skip .NET Standard 2.1 and go straight to .NET 6. Most widely used libraries will multi-target for both .NET Standard 2.0 and .NET 5+. Supporting .NET Standard 2.0 gives you the most reach, while supporting .NET 5+ ensures you can leverage the latest platform features for customers that are already on .NET 5+.

.NET Standard problems

Here are some problems with .NET Standard that help explain why .NET 5 and later versions are the better way to share code across platforms and workloads:

- Slowness to add new APIs

.NET Standard was created as an API set that all .NET implementations would have to support, so there was a review process for proposals to add new APIs. The goal was to standardize only APIs that could be implemented in all current and future .NET platforms. The result was that if a feature missed a particular release, you might have to wait for a couple of years before it got added to a version of the Standard. Then you'd wait even longer for the new version of .NET Standard to be widely supported.

Solution in .NET 5+: When a feature is implemented, it's already available for every .NET 5+ app and library because the code base is shared. And since there's no difference between the API specification and its implementation, you're able to take advantage of new features much quicker than with .NET Standard.

- Complex versioning

The separation of the API specification from its implementations results in complex mapping between API specification versions and implementation versions. This complexity is evident in the table shown earlier in this article and the instructions for how to interpret it.

Solution in .NET 5+: There's no separation between a .NET 5+ API specification and its implementation.

The result is a simplified TFM scheme. There's one TFM prefix for all workloads: `net5.0` or `net6.0` is used for libraries, console apps, and web apps. The only variation is a [suffix that specifies platform-specific APIs](#) for a particular platform, such as `net5.0-windows` or `net6.0-windows`. Thanks to this TFM naming convention, you can easily tell whether a given app can use a given library. No version number equivalents table, like the one for .NET Standard, is needed.

- Platform-unsupported exceptions at run time

.NET Standard exposes platform-specific APIs. Your code might compile without errors and appear to be portable to any platform even if it isn't portable. When it runs on a platform that doesn't have an implementation for a given API, you get run-time errors.

Solution in .NET 5+: The .NET 5+ SDKs include code analyzers that are enabled by default. The platform compatibility analyzer detects unintentional use of APIs that aren't supported on the platforms you intend to run on. For more information, see [Platform compatibility analyzer](#).

.NET Standard not deprecated

.NET Standard is still needed for libraries that can be used by multiple .NET implementations. We recommend you target .NET Standard in the following scenarios:

- Use `netstandard2.0` to share code between .NET Framework and all other implementations of .NET.
- Use `netstandard2.1` to share code between Mono, Xamarin, and .NET Core 3.x.

Releases and support for .NET (.NET 5+ and .NET Core)

9/20/2022 • 7 minutes to read • [Edit Online](#)

Microsoft ships major releases, minor releases, and servicing updates (patches) for .NET 5 (and .NET Core) and later versions. This article explains release types, servicing updates, SDK feature bands, support periods, and support options.

Release types

Information about the type of each release is encoded in the version number in the form *major.minor.patch*.

For example:

- .NET 5 and NET 6 are major releases.
- .NET Core 3.1 is the first minor release after the .NET Core 3.0 major release.
- .NET Core 5.0.15 is the fifteenth patch for .NET 5.

Major releases

Major releases include new features, new public API surface area, and bug fixes. Examples include .NET 5 and .NET 6. Due to the nature of the changes, these releases are expected to have breaking changes. Major releases install side by side with previous major releases.

Minor releases

Minor releases also include new features, public API surface area, and bug fixes, and may also have breaking changes. An example is .NET Core 3.1. The difference between these and major releases is that the magnitude of the changes is smaller. An application upgrading from .NET Core 3.0 to 3.1 has a smaller jump to move forward. Minor releases install side by side with previous minor releases.

Servicing updates

Servicing updates (patches) ship almost every month, and these updates carry both security and non-security bug fixes. For example, .NET 5.0.8 is the eighth update for .NET 5. When these updates include security fixes, they're released on "patch Tuesday", which is always the second Tuesday of the month. Servicing updates are expected to maintain compatibility. Starting with .NET Core 3.1, servicing updates are upgrades that remove the preceding update. For example, the latest servicing update for 3.1 removes the previous 3.1 update upon successful installation.

Feature bands (SDK only)

Versioning for the .NET SDK works slightly differently from the .NET runtime. To align with new Visual Studio releases, .NET SDK updates sometimes include new features or new versions of components like MSBuild and NuGet. These new features or components may be incompatible with the versions that shipped in previous SDK updates for the same major or minor version.

To differentiate such updates, the .NET SDK uses the concept of feature bands. For example, the first .NET 5 SDK was 5.0.100. This release corresponds to the 3.1.1xx *feature band*. Feature bands are defined in the hundreds groups in the third section of the version number. For example, 5.0.101 and 5.0.201 are versions in two different feature bands while 5.0.101 and 5.0.199 are in the same feature band. When .NET SDK 5.0.101 is installed, .NET SDK 5.1.100 is removed from the machine if it exists. When .NET SDK 5.0.200 is installed on the same machine, .NET SDK 5.0.101 isn't removed.

Runtime roll-forward and compatibility

Major and minor updates install side by side with previous versions. An application built to target a specific *major:minor* version continues to use that targeted runtime even if a newer version is installed. The app doesn't automatically roll forward to use a newer *major:minor* version of the runtime unless you opt in for this behavior. An application that was built to target .NET Core 3.0 doesn't automatically start running on .NET Core 3.1. We recommend rebuilding the app and testing against a newer major or minor runtime version before deploying to production. For more information, see [Framework-dependent apps roll forward](#) and [Self-contained deployment runtime roll forward](#).

Servicing updates are treated differently from major and minor releases. An application built to target .NET 5.0.0 runs on the 5.0.0 runtime by default. It automatically rolls forward to use a newer 5.0.1 runtime when that servicing update is installed. This behavior is the default because we want security fixes to be used as soon as they're installed without any other action needed. You can opt out from this default roll forward behavior.

.NET version lifecycles

.NET Core, .NET 5, and later versions adopt the [modern lifecycle](#) rather than the [fixed lifecycle](#) that has been used for .NET Framework releases. Products with fixed lifecycles provide a long fixed period of support, for example, 5 years of mainstream support and another 5 years of extended support. Mainstream support includes security and non-security fixes, while extended support provides security fixes only. Products that adopt a modern lifecycle have a more service-like support model, with shorter support periods and more frequent releases.

Release tracks

There are two support tracks for releases:

- *Current* releases

These versions are supported until six months after the next major or minor release ships. Previously (.NET Core 3.0 and earlier), these releases were supported for only three months after the next major or minor release shipped.

Example:

- .NET Core 3.0 shipped in September 2019 and was followed by .NET Core 3.1 in December 2019.
- .NET Core 3.0 support ended in March 2020, 3 months after 3.1 shipped.

- *Long Term Support* (LTS) releases

These versions are supported for a minimum of 3 years, or 1 year after the next LTS release ships if that date is later.

Example:

- .NET Core 3.1 is an LTS release and was released in December 2019. It's supported for 3 years, until December, 2022.
- .NET 5 is a Current release and was released in November 2020. It's supported for 18 months, until May, 2022.
- .NET 6 is an LTS release and was released in November, 2021. It's supported for 3 years, until November, 2024.

Releases alternate between LTS and Current, so it's possible for an earlier release to be supported longer than a later release. For example, .NET Core 3.1 is an LTS release with support through December 2022. The .NET 5 release shipped almost a year later but goes out of support earlier, in May 2022.

Servicing updates ship monthly and include both security and non-security (reliability, compatibility, and stability) fixes. Servicing updates are supported until the next servicing update is released. Servicing updates have runtime roll forward behavior. That means that applications default to running on the latest installed

runtime servicing update.

How to choose a release

If you're building a service and expect to continue updating it on a regular basis, then a Current release like .NET 5 may be your best option to stay up to date with the latest features .NET has to offer.

If you're building a client application that will be distributed to consumers, stability may be more important than access to the latest features. Your application might need to be supported for a certain period before the consumer can upgrade to the next version of the application. In that case, an LTS release like .NET 6 might be the right option.

Servicing updates

.NET servicing updates are supported until the next servicing update is released. The release cadence is monthly.

You need to regularly install servicing updates to ensure that your apps are in a secure and supported state. For example, if the latest servicing update for .NET 5 is 5.0.8 and we ship 5.0.9, then 5.0.8 is no longer the latest. The supported servicing level for .NET 5 is then 5.0.9.

For information about the latest servicing updates for each major and minor version, see the [.NET downloads page](#).

End of support

End of support refers to the date after which Microsoft no longer provides fixes, updates, or technical assistance for a product version. Before this date, make sure you have moved to using a supported version. Versions that are out of support no longer receive security updates that protect your applications and data.

Supported operating systems

.NET 5 (and .NET Core) and later versions can be run on a range of operating systems. Each of these operating systems has a lifecycle defined by its sponsor organization (for example, Microsoft, Red Hat, or Apple). We take these lifecycle schedules into account when adding and removing support for operating system versions.

When an operating system version goes out of support, we stop testing that version and providing support for that version. Users need to move forward to a supported operating system version to get support.

For more information, see the [.NET OS Lifecycle Policy](#).

Microsoft support

For assisted support, [contact a Microsoft Support Professional](#).

You need to be on a supported servicing level (the latest available servicing update) to be eligible for support. If a system is running .NET 5 and the 5.0.8 servicing update has been released, then 5.0.8 needs to be installed as a first step.

Community support

For community support, see the [Community page](#).

See also

For more information, including supported date ranges for each version of .NET, see the [Support Policy](#).

Ecma standards

9/20/2022 • 2 minutes to read • [Edit Online](#)

The C# Language and the Common Language Infrastructure (CLI) specifications are standardized through [Ecma International](#). The first editions of these standards were published by Ecma in December 2001.

Subsequent revisions to the standards have been developed by the TC49-TG2 (C#) and TC49-TG3 (CLI) task groups within the Programming Languages Technical Committee ([TC49](#)), and adopted by the Ecma General Assembly and subsequently by ISO/IEC JTC 1 via the ISO Fast-Track process.

Latest standards

The following official Ecma documents are available for [C#](#) and the [CLI \(TR-84\)](#):

- **The C# Language Standard (version 6.0):** [ECMA-334.pdf](#)
- **The Common Language Infrastructure:** [ECMA-335.pdf](#).
- **Information Derived from the Partition IV XML File:** [ECMA-084.pdf](#) format.

The official ISO/IEC documents are available from the ISO/IEC [Publicly Available Standards](#) page. These links are direct from that page:

- **Information technology - Programming languages - C#:** [ISO/IEC 23270:2018](#)
- **Information technology — Common Language Infrastructure (CLI) Partitions I to VI:** [ISO/IEC 23271:2012](#)
- **Information technology — Common Language Infrastructure (CLI) — Technical Report on Information Derived from Partition IV XML File:** [ISO/IEC TR 23272:2011](#)

.NET Glossary

9/20/2022 • 14 minutes to read • [Edit Online](#)

The primary goal of this glossary is to clarify meanings of selected terms and acronyms that appear frequently in the .NET documentation.

AOT

Ahead-of-time compiler.

Similar to [JIT](#), this compiler also translates [IL](#) to machine code. In contrast to JIT compilation, AOT compilation happens before the application is executed and is usually performed on a different machine. Because AOT tool chains don't compile at run time, they don't have to minimize time spent compiling. That means they can spend more time optimizing. Since the context of AOT is the entire application, the AOT compiler also performs cross-module linking and whole-program analysis, which means that all references are followed and a single executable is produced.

See [CoreRT](#) and [.NET Native](#).

app model

A [workload](#)-specific API. Here are some examples:

- ASP.NET
- ASP.NET Web API
- Entity Framework (EF)
- Windows Presentation Foundation (WPF)
- Windows Communication Foundation (WCF)
- Windows Workflow Foundation (WF)
- Windows Forms (WinForms)

ASP.NET

The original ASP.NET implementation that ships with the .NET Framework, also known as ASP.NET 4.x.

Sometimes ASP.NET is an umbrella term that refers to both the original ASP.NET and ASP.NET Core. The meaning that the term carries in any given instance is determined by context. Refer to ASP.NET 4.x when you want to make it clear that you're not using ASP.NET to mean both implementations.

See [ASP.NET documentation](#).

ASP.NET Core

A cross-platform, high-performance, open-source implementation of ASP.NET.

See [ASP.NET Core documentation](#).

assembly

A [.dll](#) or [.exe](#) file that can contain a collection of APIs that can be called by applications or other assemblies.

An assembly may include types such as interfaces, classes, structures, enumerations, and delegates. Assemblies

in a project's *bin* folder are sometimes referred to as *binaries*. See also [library](#).

BCL

Base Class Library.

A set of libraries that comprise the System.* (and to a limited extent Microsoft.*) namespaces. The BCL is a general purpose, lower-level framework that higher-level application frameworks, such as ASP.NET Core, build on.

The source code of the BCL for [.NET 5 \(and .NET Core\) and later versions](#) is contained in the [.NET runtime repository](#). Most of these BCL APIs are also available in .NET Framework, so you can think of this source code as a fork of the .NET Framework BCL source code.

The following terms often refer to the same collection of APIs that BCL refers to:

- [core .NET libraries](#)
- [framework libraries](#)
- [runtime libraries](#)
- [shared framework](#)

CLR

Common Language Runtime.

The exact meaning depends on the context. Common Language Runtime usually refers to the runtime of [.NET Framework](#) or the runtime of [.NET 5 \(and .NET Core\) and later versions](#).

A CLR handles memory allocation and management. A CLR is also a virtual machine that not only executes apps but also generates and compiles code on-the-fly using a [JIT](#) compiler.

The CLR implementation for .NET Framework is Windows only.

The CLR implementation for .NET 5 and later versions (also known as the Core CLR) is built from the same code base as the .NET Framework CLR. Originally, the Core CLR was the runtime of Silverlight and was designed to run on multiple platforms, specifically Windows and OS X. It's still a [cross-platform](#) runtime, now including support for many Linux distributions.

See also [runtime](#).

Core CLR

The Common Language Runtime for [.NET 5 \(and .NET Core\) and later versions](#).

See [CLR](#).

CoreRT

In contrast to the [CLR](#), CoreRT is not a virtual machine, which means it doesn't include the facilities to generate and run code on-the-fly because it doesn't include a [JIT](#). It does, however, include the [GC](#) and the ability for runtime type identification (RTTI) and reflection. However, its type system is designed so that metadata for reflection isn't required. Not requiring metadata enables having an [AOT](#) tool chain that can link away superfluous metadata and (more importantly) identify code that the app doesn't use. CoreRT is in development.

See [Intro to CoreRT](#) and [.NET Runtime Lab](#).

cross-platform

The ability to develop and execute an application that can be used on multiple different operating systems, such as Linux, Windows, and iOS, without having to rewrite specifically for each one. This enables code reuse and consistency between applications on different platforms.

See [platform](#).

ecosystem

All of the runtime software, development tools, and community resources that are used to build and run applications for a given technology.

The term ".NET ecosystem" differs from similar terms such as ".NET stack" in its inclusion of third-party apps and libraries. Here's an example in a sentence:

- "The motivation behind [.NET Standard](#) was to establish greater uniformity in the .NET ecosystem."

framework

In general, a comprehensive collection of APIs that facilitates development and deployment of applications that are based on a particular technology. In this general sense, ASP.NET Core and Windows Forms are examples of application frameworks. The words **framework** and [library](#) are often used synonymously.

The word "framework" has a different meaning in the following terms:

- [framework libraries](#)
- [.NET Framework](#)
- [shared framework](#)
- [target framework](#)
- [TFM \(target framework moniker\)](#)
- [framework-dependent app](#)

Sometimes "framework" refers to an [implementation of .NET](#). For example, an article may call .NET 5+ a framework.

framework libraries

Meaning depends on context. May refer to the framework libraries for [.NET 5 \(and .NET Core\) and later versions](#), in which case it refers to the same libraries that [BCL](#) refers to. It may also refer to the [ASP.NET Core](#) framework libraries, which build on the BCL and provide additional APIs for web apps.

GC

Garbage collector.

The garbage collector is an implementation of automatic memory management. The GC frees memory occupied by objects that are no longer in use.

See [Garbage Collection](#).

IL

Intermediate language.

Higher-level .NET languages, such as C#, compile down to a hardware-agnostic instruction set, which is called Intermediate Language (IL). IL is sometimes referred to as MSIL (Microsoft IL) or CIL (Common IL).

JIT

Just-in-time compiler.

Similar to [AOT](#), this compiler translates [IL](#) to machine code that the processor understands. Unlike AOT, JIT compilation happens on demand and is performed on the same machine that the code needs to run on. Since JIT compilation occurs during execution of the application, compile time is part of the run time. Thus, JIT compilers have to balance time spent optimizing code against the savings that the resulting code can produce. But a JIT knows the actual hardware and can free developers from having to ship different implementations.

implementation of .NET

An implementation of .NET includes:

- One or more runtimes. Examples: [CLR](#), [CoreRT](#).
- A class library that implements a version of .NET Standard and may include additional APIs. Examples: the [BCLs](#) for [.NET Framework](#) and [.NET 5 \(and .NET Core\) and later versions](#).
- Optionally, one or more application frameworks. Examples: [ASP.NET](#), Windows Forms, and WPF are included in .NET Framework and .NET 5+.
- Optionally, development tools. Some development tools are shared among multiple implementations.

Examples of .NET implementations:

- [.NET Framework](#)
- [.NET 5 \(and .NET Core\) and later versions](#)
- [Universal Windows Platform \(UWP\)](#)
- [Mono](#)

For more information, see [.NET implementations](#).

library

A collection of APIs that can be called by apps or other libraries. A .NET library is composed of one or more [assemblies](#).

The words [library](#) and [framework](#) are often used synonymously.

Mono

Mono is an open source, [cross-platform .NET implementation](#) that is mainly used when a small runtime is required. It is the runtime that powers Xamarin applications on Android, Mac, iOS, tvOS, and watchOS and is focused primarily on apps that require a small footprint.

It supports all of the currently published .NET Standard versions.

Historically, Mono implemented the larger API of the .NET Framework and emulated some of the most popular capabilities on Unix. It is sometimes used to run .NET applications that rely on those capabilities on Unix.

Mono is typically used with a [just-in-time compiler](#), but it also features a full [static compiler \(ahead-of-time compilation\)](#) that is used on platforms like iOS.

See the [Mono documentation](#).

.NET

- In general, .NET is the umbrella term for [.NET Standard](#) and all [.NET implementations](#) and workloads.

- More specifically, .NET refers to the implementation of .NET that is recommended for all new development: [.NET 5 \(and .NET Core\) and later versions](#).

For example, the first meaning is intended in phrases such as "implementations of .NET" or "the .NET development platform." The second meaning is intended in names such as [.NET SDK](#) and [.NET CLI](#).

.NET is always fully capitalized, never ".Net".

See [.NET documentation](#)

.NET 5+

The plus sign after a version number means "and later versions." See [.NET 5 and later versions](#).

.NET 5 and later versions

A cross-platform, high-performance, open-source implementation of .NET. Also referred to as .NET 5+. Includes a Common Language Runtime ([CLR](#)), an AOT runtime ([CoreRT](#), in development), a Base Class Library ([BCL](#)), and the [.NET SDK](#).

Earlier versions of this .NET implementation are known as [.NET Core](#). .NET 5 is the next version following .NET Core 3.1. Version 4 was skipped to avoid confusing this newer implementation of .NET with the older implementation that is known as [.NET Framework](#). The current version of .NET Framework is 4.8.

See [.NET documentation](#).

.NET CLI

A cross-platform toolchain for developing applications and libraries for [.NET 5 \(and .NET Core\) and later versions](#). Also known as the .NET Core CLI.

See [.NET CLI](#).

.NET Core

See [.NET 5 and later versions](#).

.NET Framework

An [implementation of .NET](#) that runs only on Windows. Includes the Common Language Runtime ([CLR](#)), the Base Class Library ([BCL](#)), and application framework libraries such as [ASP.NET](#), Windows Forms, and WPF.

See [.NET Framework Guide](#).

.NET Native

A compiler tool chain that produces native code ahead-of-time ([AOT](#)), as opposed to just-in-time ([JIT](#)).

Compilation happens on the developer's machine similar to the way a C++ compiler and linker works. It removes unused code and spends more time optimizing it. It extracts code from libraries and merges them into the executable. The result is a single module that represents the entire app.

UWP is the application framework supported by .NET Native.

See [.NET Native documentation](#).

.NET SDK

A set of libraries and tools that allow developers to create .NET applications and libraries for [.NET 5 \(and .NET Core\) and later versions](#). Also known as the .NET Core SDK.

Includes the [.NET CLI](#) for building apps, .NET libraries and runtime for building and running apps, and the dotnet executable (`dotnet.exe`) that runs CLI commands and runs applications.

See [.NET SDK Overview](#).

.NET Standard

A formal specification of .NET APIs that are available in each [.NET implementation](#).

The .NET Standard specification is sometimes called a library. Because a library includes API implementations, not only specifications (interfaces), it's misleading to call .NET Standard a "library."

See [.NET Standard](#).

NGEN

Native (image) generation.

You can think of this technology as a persistent [JIT](#) compiler. It usually compiles code on the machine where the code is executed, but compilation typically occurs at install time.

package

A NuGet package—or just a package—is a `.zip` file with one or more assemblies of the same name along with additional metadata such as the author name.

The `.zip` file has a `.nupkg` extension and may contain assets, such as `.dll` files and `.xml` files, for use with multiple [target frameworks](#) and versions. When installed in an app or library, the appropriate assets are selected based on the target framework specified by the app or library. The assets that define the interface are in the `ref` folder, and the assets that define the implementation are in the `lib` folder.

platform

An operating system and the hardware it runs on, such as Windows, macOS, Linux, iOS, and Android.

Here are examples of usage in sentences:

- ".NET Core is a cross-platform implementation of .NET."
- "PCL profiles represent Microsoft platforms, while .NET Standard is agnostic to platform."

Legacy .NET documentation sometimes uses ".NET platform" to mean either an [implementation of .NET](#) or the [.NET stack](#) including all implementations. Both of these usages tend to get confused with the primary (OS/hardware) meaning, so we try to avoid these usages.

"Platform" has a different meaning in the phrase "developer platform," which refers to software that provides tools and libraries for building and running apps. .NET is a cross-platform, open-source developer platform for building many different types of applications.

POCO

A POCO—or a plain old class/[CLR](#) object—is a .NET data structure that contains only public properties or fields. A POCO shouldn't contain any other members, such as:

- methods

- events
- delegates

These objects are used primarily as data transfer objects (DTOs). A pure *POCO* will not inherit another object, or implement an interface. It's common for POCOs to be used with serialization.

runtime

In general, the execution environment for a managed program. The OS is part of the runtime environment but is not part of the .NET runtime. Here are some examples of .NET runtimes in this sense of the word:

- Common Language Runtime ([CLR](#))
- .NET Native (for UWP)
- Mono runtime

The word "runtime" has a different meaning in some contexts:

- *.NET runtime* on the [.NET 5 download page](#).

You can download the *.NET runtime* or other runtimes, such as the *ASP.NET Core runtime*. A *runtime* in this usage is the set of components that must be installed on a machine to run a [framework-dependent](#) app on the machine. The .NET runtime includes the [CLR](#) and the .NET [shared framework](#), which provides the [BCL](#).

- *.NET runtime libraries*

Refers to the same libraries that [BCL](#) refers to. However, other runtimes, such as the ASP.NET Core runtime, have different [shared frameworks](#), with additional libraries that build on the BCL.

- [Runtime Identifier \(RID\)](#).

Runtime here means the OS platform and CPU architecture that a .NET app runs on, for example:

`linux-x64`.

- Sometimes "runtime" is used in the sense of an [implementation of .NET](#), as in the following examples:

- "The various .NET runtimes implement specific versions of .NET Standard. ... Each .NET runtime version advertises the highest .NET Standard version it supports ..."
- "Libraries that are intended to run on multiple runtimes should target this framework." (referring to .NET Standard)

shared framework

Meaning depends on context. The *.NET shared framework* refers to the libraries included in the [.NET runtime](#). In this case, the *shared framework* for [.NET 5 \(and .NET Core\) and later versions](#) refers to the same libraries that [BCL](#) refers to.

There are other shared frameworks. The *ASP.NET Core shared framework* refers to the libraries included in the [ASP.NET Core runtime](#), which includes the BCL plus additional APIs for use by web apps.

For [framework-dependent apps](#), the shared framework consists of libraries that are contained in assemblies installed in a folder on the machine that runs the app. For [self-contained apps](#), the shared framework assemblies are included with the app.

For more information, see [Deep-dive into .NET Core primitives, part 2: the shared framework](#).

stack

A set of programming technologies that are used together to build and run applications.

"The .NET stack" refers to .NET Standard and all .NET implementations. The phrase "a .NET stack" may refer to one implementation of .NET.

target framework

The collection of APIs that a .NET app or library relies on.

An app or library can target a version of [.NET Standard](#) (for example, .NET Standard 2.0), which is a specification for a standardized set of APIs across all [.NET implementations](#). An app or library can also target a version of a specific .NET implementation, in which case it gets access to implementation-specific APIs. For example, an app that targets Xamarin.iOS gets access to Xamarin-provided iOS API wrappers.

For some target frameworks (for example, [.NET Framework](#)) the available APIs are defined by the assemblies that a .NET implementation installs on a system, which may include application framework APIs (for example, ASP.NET, WinForms). For package-based target frameworks, the framework APIs are defined by the packages installed in the app or library.

See [Target Frameworks](#).

TFM

Target framework moniker.

A standardized token format for specifying the [target framework](#) of a .NET app or library. Target frameworks are typically referenced by a short name, such as `net462`. Long-form TFMs (such as `.NETFramework,Version=4.6.2`) exist but are not generally used to specify a target framework.

See [Target Frameworks](#).

UWP

Universal Windows Platform.

An [implementation of .NET](#) that is used for building touch-enabled Windows applications and software for the Internet of Things (IoT). It's designed to unify the different types of devices that you may want to target, including PCs, tablets, phones, and even the Xbox. UWP provides many services, such as a centralized app store, an execution environment (AppContainer), and a set of Windows APIs to use instead of Win32 (WinRT). Apps can be written in C++, C#, Visual Basic, and JavaScript. When using C# and Visual Basic, the .NET APIs are provided by [.NET 5 \(and .NET Core\) and later versions](#).

workload

A type of app someone is building. More generic than [app model](#). For example, at the top of every .NET documentation page, including this one, is a drop-down list for **Workloads**, which lets you switch to documentation for **Web**, **Mobile**, **Cloud**, **Desktop**, and **Machine Learning & Data**.

In some contexts, *workload* refers to a collection of Visual Studio features that you can choose to install to support a particular type of app. For an example, see [Select a workload](#).

- [ASP.NET Core Overview](#)

.NET 6 C# console app template generates top-level statements

9/20/2022 • 5 minutes to read • [Edit Online](#)

Starting with .NET 6, the project template for new C# console apps generates the following code in the `Program.cs` file:

```
// See https://aka.ms/new-console-template for more information
Console.WriteLine("Hello, World!");
```

The new output uses recent C# features that simplify the code you need to write for a program. For .NET 5 and earlier versions, the console app template generates the following code:

```
using System;

namespace MyApp // Note: actual namespace depends on the project name.
{
    internal class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

These two forms represent the same program. Both are valid with C# 10.0. When you use the newer version, you only need to write the body of the `Main` method. The compiler synthesizes a `Program` class with a `Main` method and places all your top level statements in that `Main` method. You don't need to include the other program elements, the compiler generates them for you. You can learn more about the code the compiler generates when you use top level statements in the article on [top level statements](#) in the C# Guide's fundamentals section.

You have two options to work with tutorials that haven't been updated to use .NET 6+ templates:

- Use the new program style, adding new top-level statements as you add features.
- Convert the new program style to the older style, with a `Program` class and a `Main` method.

If you want to use the old templates, see [Use the old program style](#) later in this article.

Use the new program style

The features that make the new program simpler are *top-level statements*, *global using directives*, and *implicit using directives*.

The term [top-level statements](#) means the compiler generates the class and method elements for your main program. The compiler generated class and `Main` method are declared in the global namespace. You can look at the code for the new application and imagine that it contains the statements inside the `Main` method generated by earlier templates, but in the global namespace.

You can add more statements to the program, just like you can add more statements to your `Main` method in

the traditional style. You can access `args` (command-line arguments), use `await`, and set the exit code. You can even add functions. They're created as local functions nested inside the generated `Main` method. Local functions can't include any access modifiers (for example, `public` or `protected`).

Both top-level statements and `implicit using directives` simplify the code that makes up your application. To follow an existing tutorial, add any new statements to the `Program.cs` file generated by the template. You can imagine that the statements you write are between the open and closing braces in the `Main` method in the instructions of the tutorial.

If you'd prefer to use the older format, you can copy the code from the second example in this article, and continue the tutorial as before.

You can learn more about top-level statements in the tutorial exploration on [top-level statements](#).

Implicit `using` directives

The term *implicit using directives* means the compiler automatically adds a set of `using` directives based on the project type. For console applications, the following directives are implicitly included in the application:

- `using System;`
- `using System.IO;`
- `using System.Collections.Generic;`
- `using System.Linq;`
- `using System.Net.Http;`
- `using System.Threading;`
- `using System.Threading.Tasks;`

Other application types include more namespaces that are common for those application types.

If you need `using` directives that aren't implicitly included, you can add them to the `.cs` file that contains top-level statements or to other `.cs` files. For `using` directives that you need in all of the `.cs` files in an application, use [global using directives](#).

Disable implicit `using` directives

If you want to remove this behavior and manually control all namespaces in your project, add

`<ImplicitUsings>disable</ImplicitUsings>` to your project file in the `<PropertyGroup>` element, as shown in the following example:

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    ...
    <ImplicitUsings>disable</ImplicitUsings>
  </PropertyGroup>

</Project>
```

Global `using` directives

A *global using directive* imports a namespace for your whole application instead of a single file. These global directives can be added either by adding a `<Using>` item to the project file, or by adding the `global using` directive to a code file.

You can also add a `<Using>` item with a `Remove` attribute to your project file to remove a specific *implicit using*

[directive](#). For example, if the implicit `using` directives feature is turned on with `<ImplicitUsings>enable</ImplicitUsings>`, adding the following `<using>` item removes the `System.Net.Http` namespace from those that are implicitly imported:

```
<ItemGroup>
  <Using Remove="System.Net.Http" />
</ItemGroup>
```

Use the old program style

While a .NET 6 console app template generates the new style of top-level statements programs, using .NET 5 doesn't. By creating a .NET 5 project, you'll receive the old program style. Then, you can edit the project file to target .NET 6 but retain the old program style for the *Program.cs* file.

IMPORTANT

Creating a project that targets .NET 5 requires the .NET 5 templates. The .NET 5 templates can be installed manually with the `dotnet new --install` command or by [installing the .NET 5 SDK](#).

1. Create a new project that targets .NET 5.

```
dotnet new console --framework net5.0
```

2. Open the project file in a text editor and change `<TargetFramework>net5.0</TargetFramework>` to `<TargetFramework>net6.0</TargetFramework>`.

Here's a file diff that illustrates the changes:

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <OutputType>Exe</OutputType>
    - <TargetFramework>net5.0</TargetFramework>
    + <TargetFramework>net6.0</TargetFramework>
  </PropertyGroup>

</Project>
```

3. Optional step: you can still use some of the newer .NET 6 and C# features by adding the properties for implicit `using` directives and nullable context to the project file.

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <OutputType>Exe</OutputType>
    <TargetFramework>net6.0</TargetFramework>
    + <ImplicitUsings>enable</ImplicitUsings>
    + <Nullable>enable</Nullable>
  </PropertyGroup>

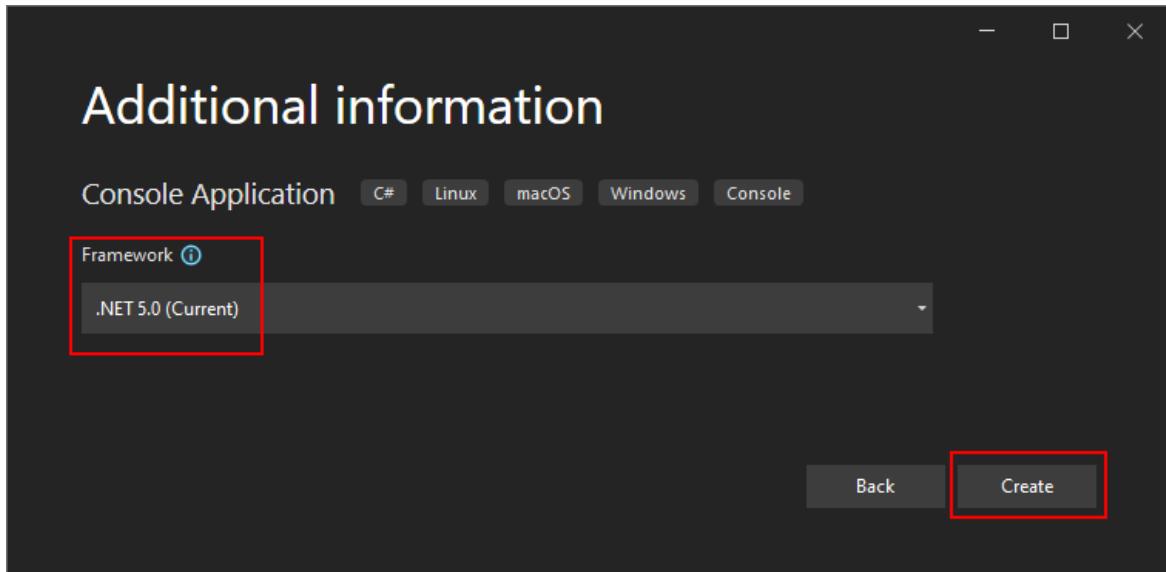

</Project>
```

Use the old program style in Visual Studio

When you create a new console project in Visual Studio, you're prompted with a dropdown box that identifies

which target framework you want to use. Change that value to **5.0**. After the project is created, edit the project file to change it back to **6.0**.

- When you create a new project, the setup steps will navigate to the **Additional information** setup page. On this page, change the framework setting from **.NET 6.0 (Long-term support)** to **.NET 5.0**, and then select the **Create** button.

- After your project is created, find the **Project Explorer** pane. Double-click on the project file and change `<TargetFramework>net5.0</TargetFramework>` to `<TargetFramework>net6.0</TargetFramework>`.

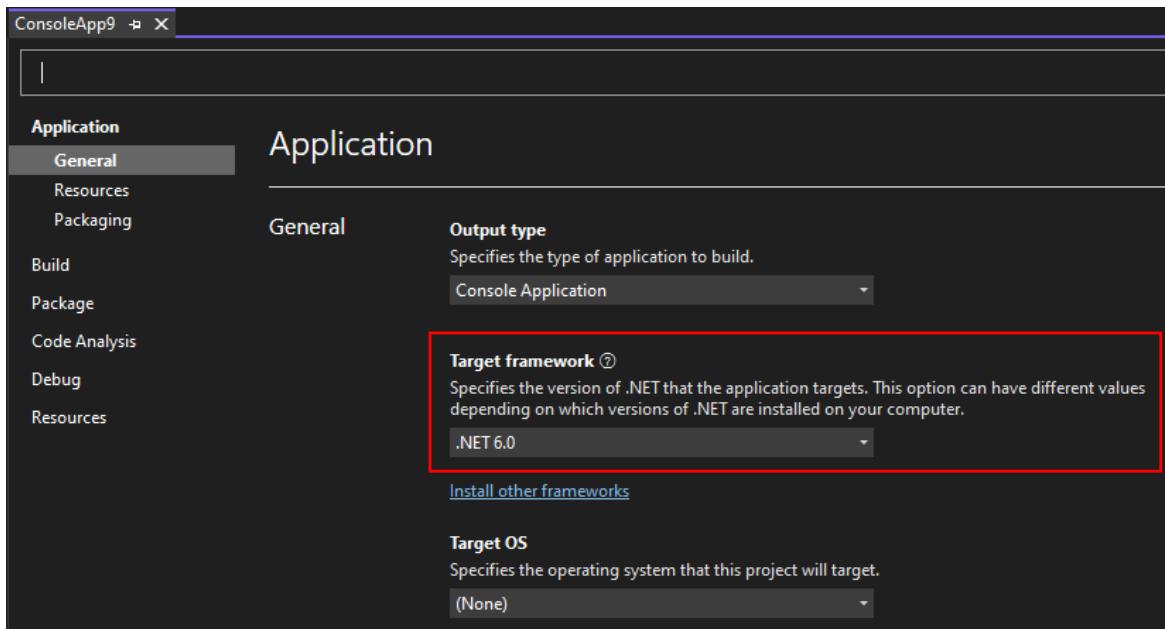

Here's a file diff that illustrates the changes:

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <OutputType>Exe</OutputType>
    - <TargetFramework>net5.0</TargetFramework>
    + <TargetFramework>net6.0</TargetFramework>
  </PropertyGroup>

</Project>
```

Alternatively, you can right-click on the project in the **Solution Explorer** pane, and select **Properties**. This opens up a settings page where you can change the **Target framework**.

3. Optional step: you can still use some of the newer .NET 6 and C# features by adding the properties for `implicit using` directives and `nullable context` to the project file.

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <OutputType>Exe</OutputType>
    <TargetFramework>net6.0</TargetFramework>
+   <ImplicitUsings>enable</ImplicitUsings>
+   <Nullable>enable</Nullable>
  </PropertyGroup>

</Project>
```

Template feedback

[Top-level statements](#) is a new feature in .NET 6. Add an up or down vote in [GitHub issue #27420](#) to let us know if you support the use of this feature in project templates.

Tutorial: Create a .NET console application using Visual Studio

9/20/2022 • 7 minutes to read • [Edit Online](#)

This tutorial shows how to create and run a .NET console application in Visual Studio 2022.

Prerequisites

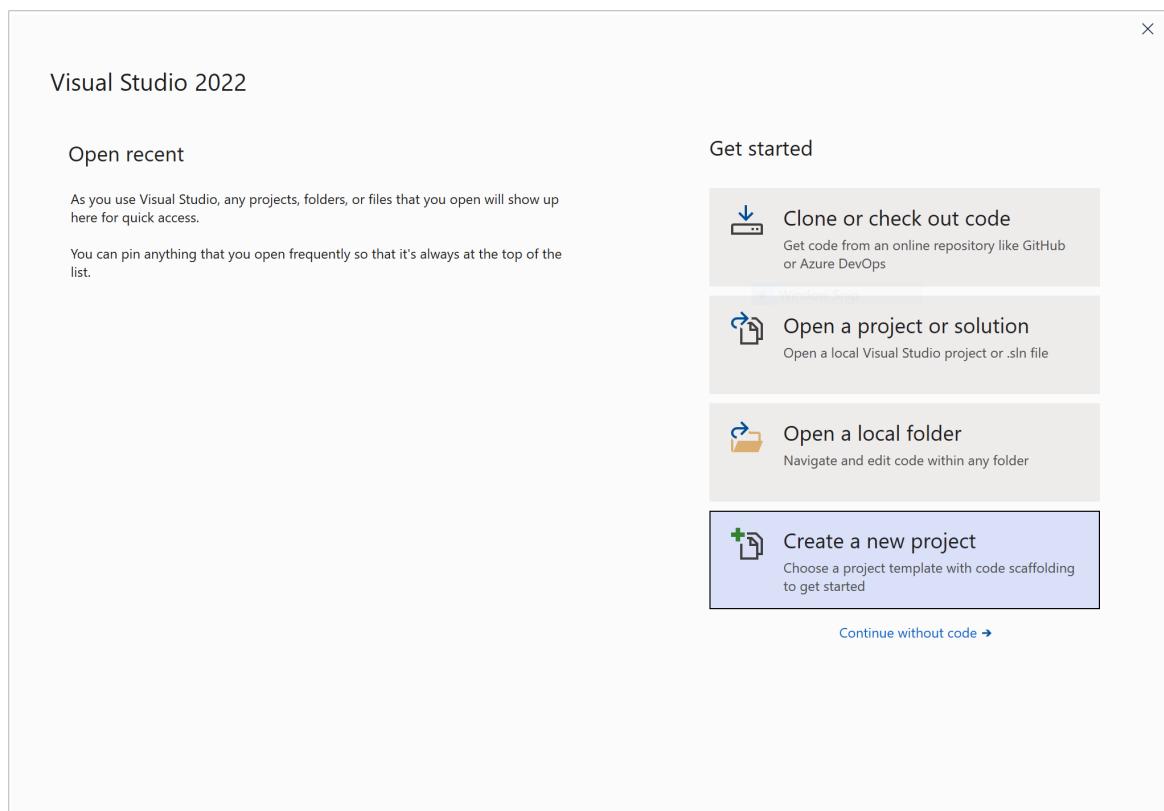

- [Visual Studio 2022 version 17.1 or later](#) with the **.NET desktop development** workload installed. The .NET 6 SDK is automatically installed when you select this workload.

For more information, see [Install the .NET SDK with Visual Studio](#).

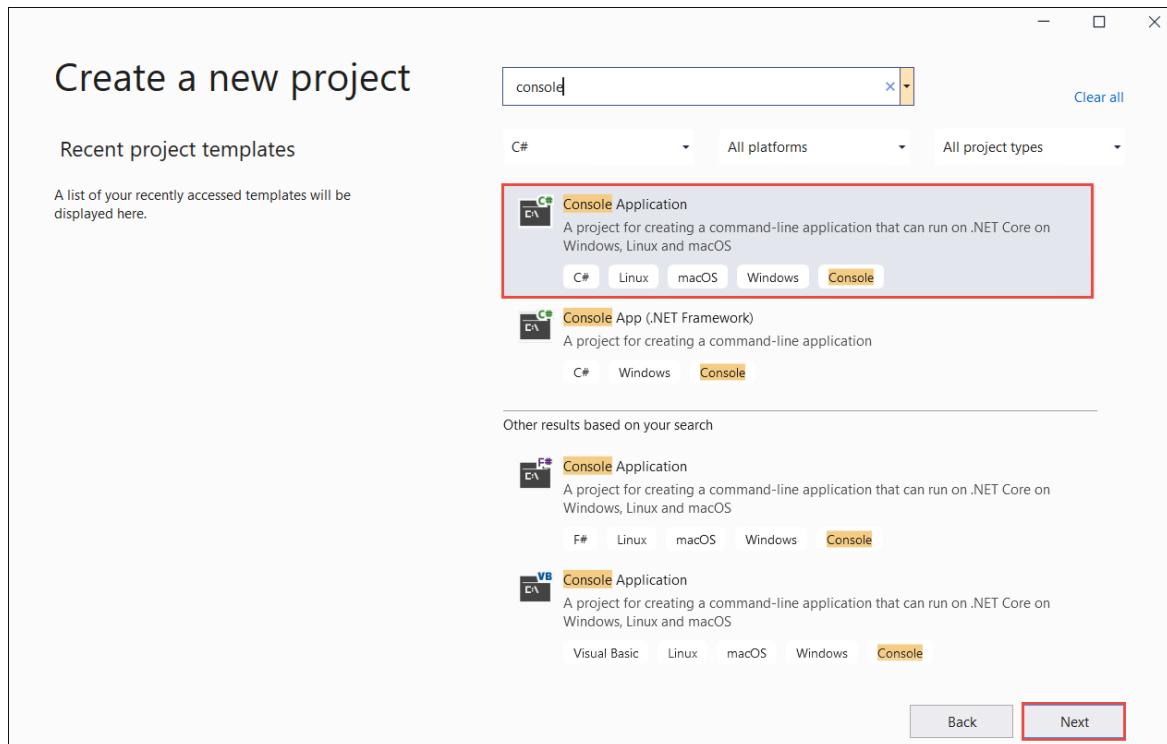

Create the app

Create a .NET console app project named "HelloWorld".

1. Start Visual Studio 2022.
2. On the start page, choose **Create a new project**.

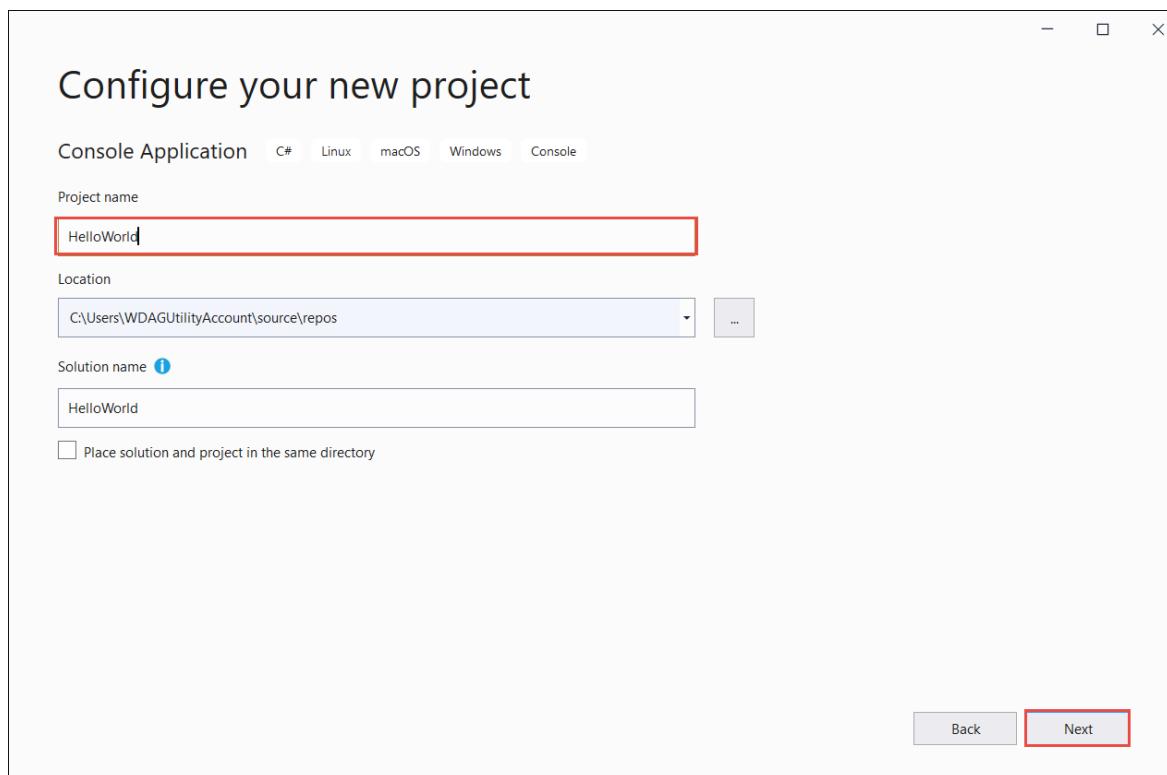

3. On the **Create a new project** page, enter **console** in the search box. Next, choose **C#** or **Visual Basic** from the language list, and then choose **All platforms** from the platform list. Choose the **Console Application** template, and then choose **Next**.

TIP

If you don't see the .NET templates, you're probably missing the required workload. Under the **Not finding what you're looking for?** message, choose the **Install more tools and features** link. The Visual Studio Installer opens. Make sure you have the **.NET desktop development** workload installed.

4. In the **Configure your new project** dialog, enter **HelloWorld** in the **Project name** box. Then choose **Next**.

5. In the **Additional information** dialog, select **.NET 6 (Long-term support)**, and then select **Create**.

The template creates a simple application that displays "Hello World" in the console window. The code is in the *Program.cs* or *Program.vb* file:

```
Console.WriteLine("Hello, World!");
```

```
Imports System

Module Program
    Sub Main(args As String())
        Console.WriteLine("Hello World!")
    End Sub
End Module
```

If the language you want to use is not shown, change the language selector at the top of the page.

6. For C#, the code is just a line that calls the [Console.WriteLine\(String\)](#) method to display "Hello World!" in the console window. Replace the contents of *Program.cs* with the following code:

```
namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

' This step of the tutorial applies only to C#.

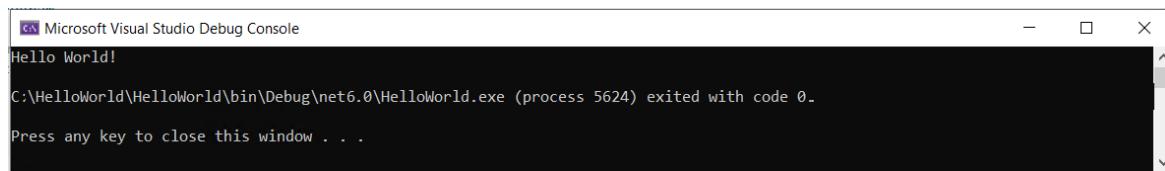

The code defines a class, `Program`, with a single method, `Main`, that takes a `String` array as an argument. `Main` is the application entry point, the method that's called automatically by the runtime when it launches the application. Any command-line arguments supplied when the application is launched are available in the `args` array.

In the latest version of C#, a new feature named [top-level statements](#) lets you omit the `Program` class and the `Main` method. Most existing C# programs don't use top-level statements, so this tutorial doesn't use this new feature. But it's available in C# 10, and whether you use it in your programs is a matter of style preference.

Run the app

1. Press **Ctrl+F5** to run the program without debugging.

A console window opens with the text "Hello World!" printed on the screen.

2. Press any key to close the console window.

Enhance the app

Enhance the application to prompt the user for their name and display it along with the date and time.

1. In *Program.cs* or *Program.vb*, replace the contents of the `Main` method, which is the line that calls `Console.WriteLine`, with the following code:

```
Console.WriteLine("What is your name?");
var name = Console.ReadLine();
var currentDate = DateTime.Now;
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}!");
Console.Write($"{Environment.NewLine}Press any key to exit...");
Console.ReadKey(true);
```

```
Console.WriteLine("What is your name?")
Dim name = Console.ReadLine()
Dim currentDate = DateTime.Now
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}")
Console.Write($"{Environment.NewLine}Press any key to exit...")
Console.ReadKey(True)
```

This code displays a prompt in the console window and waits until the user enters a string followed by the Enter key. It stores this string in a variable named `name`. It also retrieves the value of the `DateTime.Now` property, which contains the current local time, and assigns it to a variable named `currentDate`. And it displays these values in the console window. Finally, it displays a prompt in the console window and calls the `Console.ReadKey(Boolean)` method to wait for user input.

`Environment.NewLine` is a platform-independent and language-independent way to represent a line break. Alternatives are `\n` in C# and `vbcrlf` in Visual Basic.

The dollar sign (`$`) in front of a string lets you put expressions such as variable names in curly braces in the string. The expression value is inserted into the string in place of the expression. This syntax is referred to as [interpolated strings](#).

2. Press **Ctrl+F5** to run the program without debugging.
3. Respond to the prompt by entering a name and pressing the Enter key.

```
What is your name?
Maira

Hello, Maira, on 12/3/2019 at 3:36 AM!

Press any key to exit...
```

4. Press any key to close the console window.

Additional resources

- [Current releases and long-term support releases](#)

Next steps

In this tutorial, you created a .NET console application. In the next tutorial, you debug the app.

[Debug a .NET console application using Visual Studio](#)

This tutorial shows how to create and run a .NET console application in Visual Studio 2019.

Prerequisites

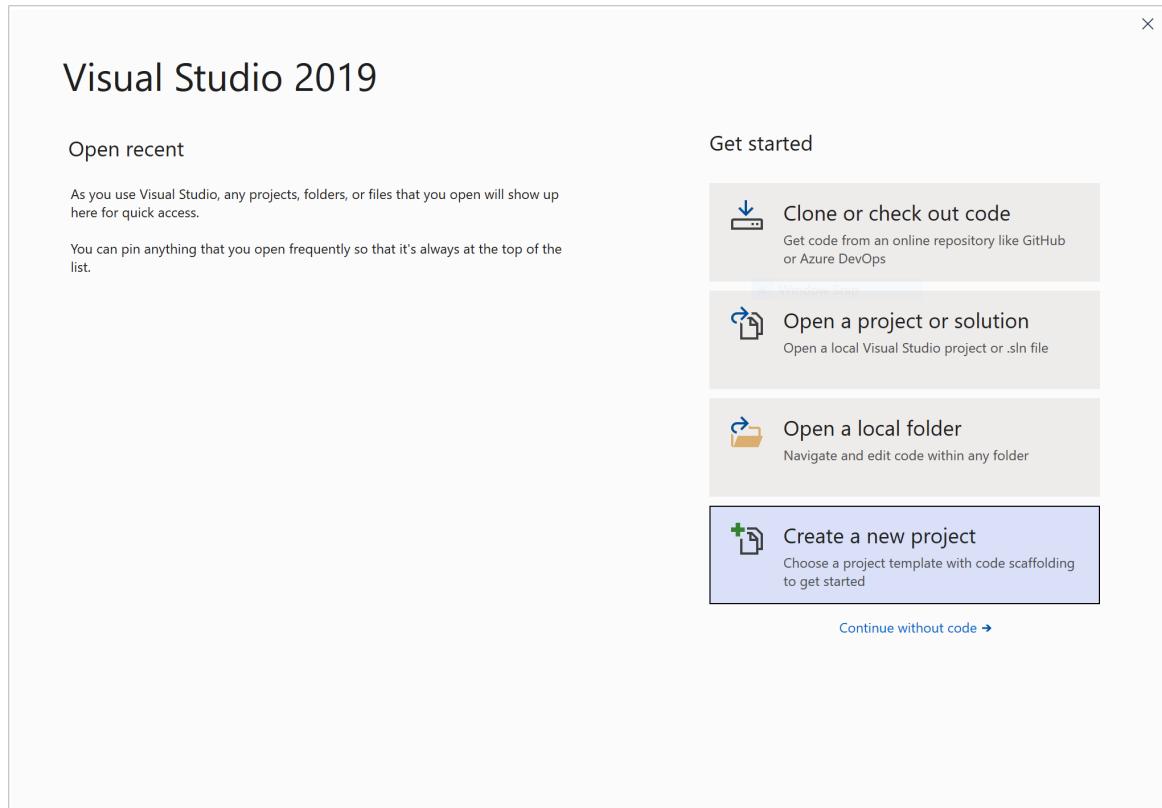

- [Visual Studio 2019 version 16.9.2 or a later version](#) with the **.NET Core cross-platform development** workload installed. The .NET 5.0 SDK is automatically installed when you select this workload.

For more information, see [Install the .NET SDK with Visual Studio](#).

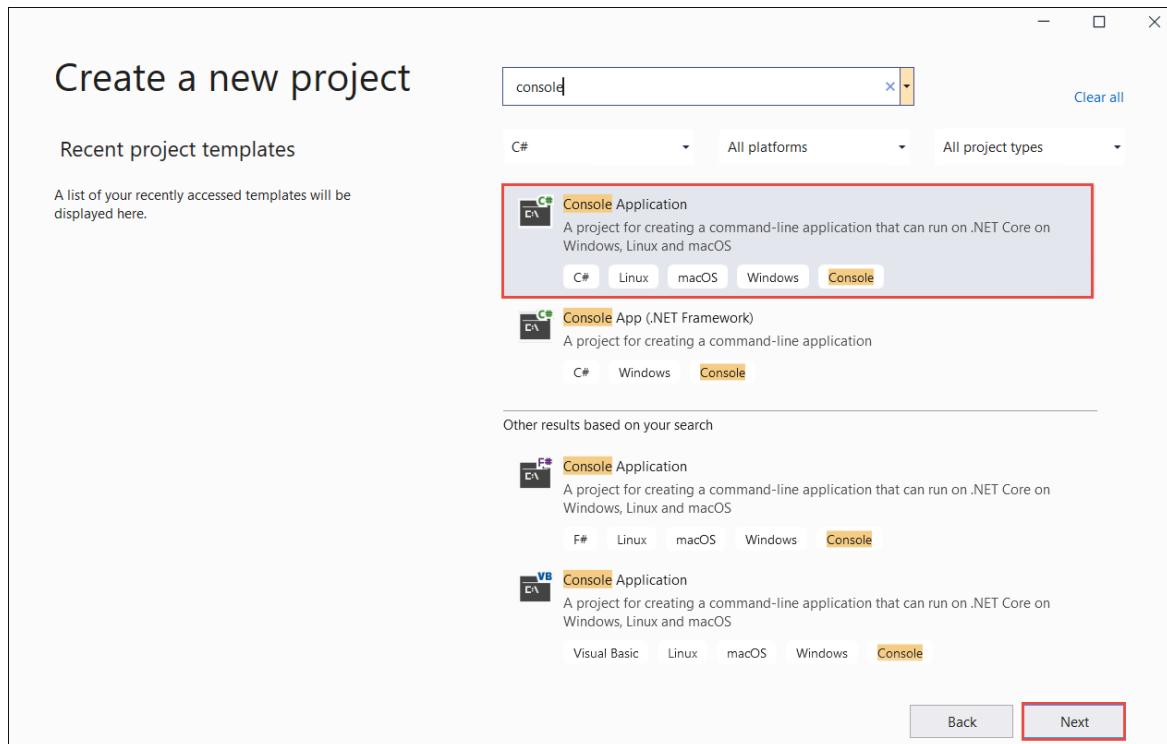

Create the app

Create a .NET console app project named "HelloWorld".

1. Start Visual Studio 2019.
2. On the start page, choose **Create a new project**.

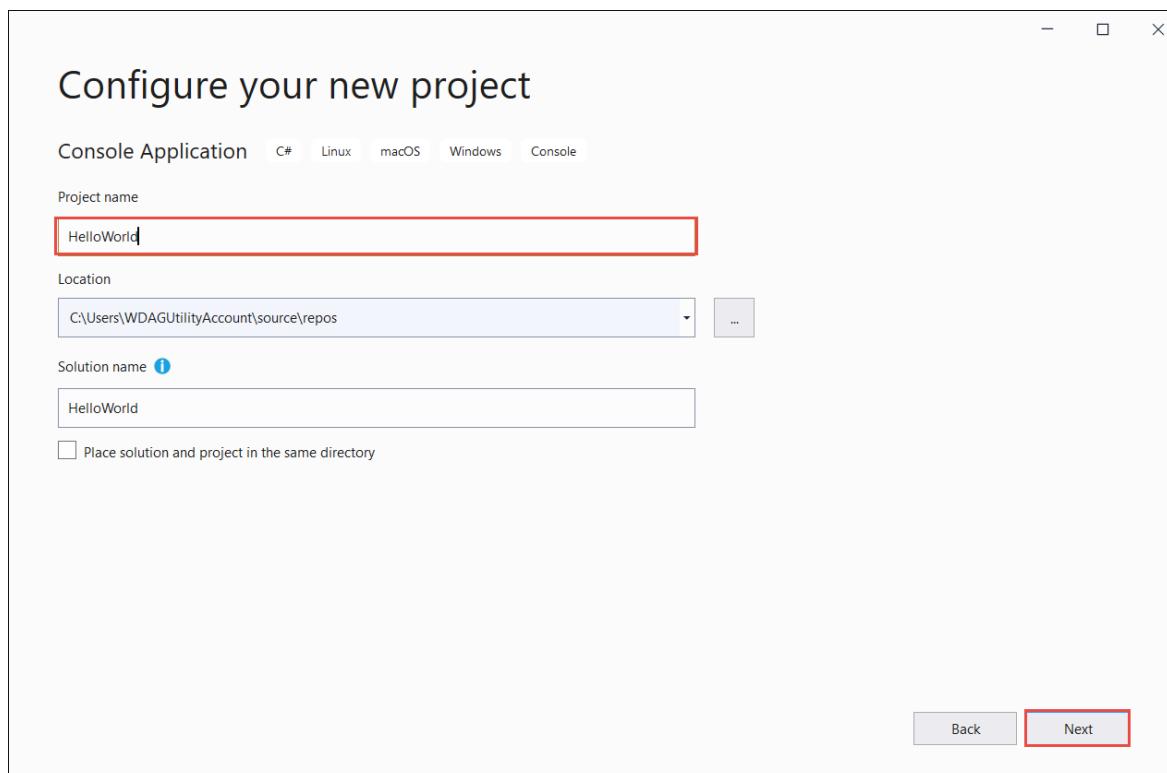

3. On the **Create a new project** page, enter **console** in the search box. Next, choose **C#** or **Visual Basic** from the language list, and then choose **All platforms** from the platform list. Choose the **Console Application** template, and then choose **Next**.

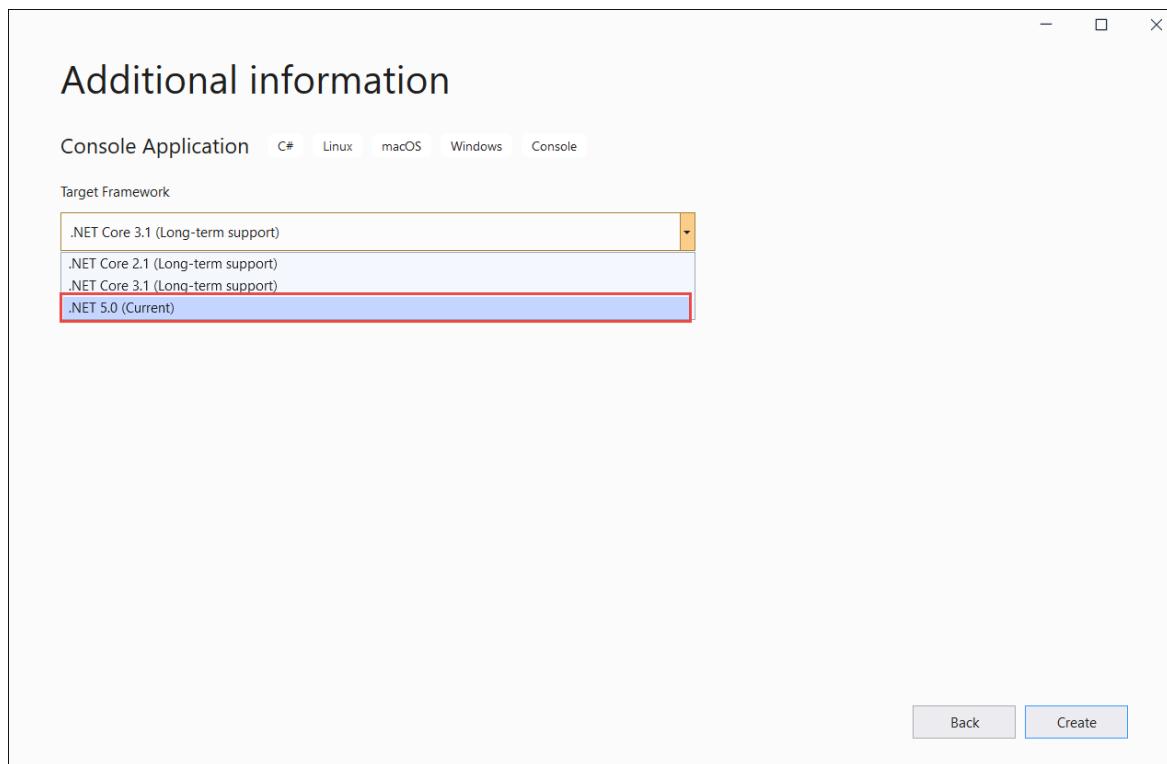

TIP

If you don't see the .NET templates, you're probably missing the required workload. Under the **Not finding what you're looking for?** message, choose the **Install more tools and features** link. The Visual Studio Installer opens. Make sure you have the **.NET Core cross-platform development** workload installed.

4. In the **Configure your new project** dialog, enter **HelloWorld** in the **Project name** box. Then choose **Next**.

5. In the **Additional information** dialog, select **.NET 5.0 (Current)**, and then select **Create**.

The template creates a simple "Hello World" application. It calls the `Console.WriteLine(String)` method to display "Hello World!" in the console window.

The template code defines a class, `Program`, with a single method, `Main`, that takes a `String` array as an argument:

```
using System;

namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

```
Imports System

Module Program
    Sub Main(args As String())
        Console.WriteLine("Hello World!")
    End Sub
End Module
```

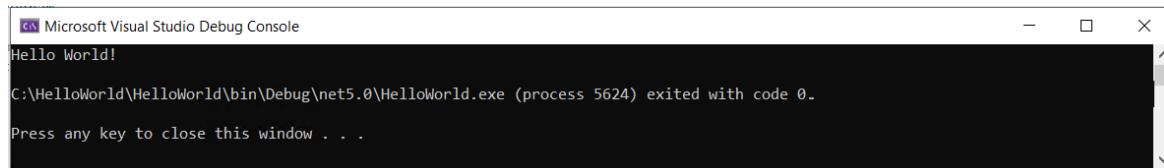

`Main` is the application entry point, the method that's called automatically by the runtime when it launches the application. Any command-line arguments supplied when the application is launched are available in the `args` array.

If the language you want to use is not shown, change the language selector at the top of the page.

Run the app

1. Press **Ctrl+F5** to run the program without debugging.

A console window opens with the text "Hello World!" printed on the screen.

The screenshot shows a Microsoft Visual Studio Debug Console window. The title bar says "Microsoft Visual Studio Debug Console". The main area displays the text "Hello World!". Below it, the command line shows the path "C:\HelloWorld\HelloWorld\bin\Debug\net5.0\HelloWorld.exe (process 5624) exited with code 0.". At the bottom, there is a prompt: "Press any key to close this window . . .".

2. Press any key to close the console window.

Enhance the app

Enhance the application to prompt the user for their name and display it along with the date and time.

1. In *Program.cs* or *Program.vb*, replace the contents of the `Main` method, which is the line that calls `Console.WriteLine`, with the following code:

```
Console.WriteLine("What is your name?");
var name = Console.ReadLine();
var currentDate = DateTime.Now;
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}!");
Console.Write($"{Environment.NewLine}Press any key to exit...");
Console.ReadKey(true);
```

```
Console.WriteLine("What is your name?")
Dim name = Console.ReadLine()
Dim currentDate = DateTime.Now
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}")
Console.Write($"{Environment.NewLine}Press any key to exit...")
Console.ReadKey(True)
```

This code displays a prompt in the console window and waits until the user enters a string followed by the Enter key. It stores this string in a variable named `name`. It also retrieves the value of the `DateTime.Now` property, which contains the current local time, and assigns it to a variable named `currentDate`. And it displays these values in the console window. Finally, it displays a prompt in the console window and calls the `Console.ReadKey(Boolean)` method to wait for user input.

`Environment.NewLine` is a platform-independent and language-independent way to represent a line break. Alternatives are `\n` in C# and `vbcrlf` in Visual Basic.

The dollar sign (`$`) in front of a string lets you put expressions such as variable names in curly braces in the string. The expression value is inserted into the string in place of the expression. This syntax is referred to as **interpolated strings**.

2. Press **Ctrl+F5** to run the program without debugging.
3. Respond to the prompt by entering a name and pressing the Enter key.

```
C:\Projects\HelloWorld\HelloWorld\bin\Debug\netcoreapp3.1\HelloWorld.exe
What is your name?
Maira
Hello, Maira, on 12/3/2019 at 3:36 AM!
Press any key to exit...
```

4. Press any key to close the console window.

Next steps

In this tutorial, you created a .NET console application. In the next tutorial, you debug the app.

[Debug a .NET console application using Visual Studio](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Debug a .NET console application using Visual Studio

9/20/2022 • 13 minutes to read • [Edit Online](#)

This tutorial introduces the debugging tools available in Visual Studio.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio](#).

Use Debug build configuration

Debug and *Release* are Visual Studio's built-in build configurations. You use the Debug build configuration for debugging and the Release configuration for the final release distribution.

In the Debug configuration, a program compiles with full symbolic debug information and no optimization. Optimization complicates debugging, because the relationship between source code and generated instructions is more complex. The release configuration of a program has no symbolic debug information and is fully optimized.

By default, Visual Studio uses the Debug build configuration, so you don't need to change it before debugging.

1. Start Visual Studio.
2. Open the project that you created in [Create a .NET console application using Visual Studio](#).

The current build configuration is shown on the toolbar. The following toolbar image shows that Visual Studio is configured to compile the Debug version of the app:

Set a breakpoint

A *breakpoint* temporarily interrupts the execution of the application before the line with the breakpoint is executed.

1. Set a *breakpoint* on the line that displays the name, date, and time, by clicking in the left margin of the code window on that line. The left margin is to the left of the line numbers. Other ways to set a breakpoint are by placing the cursor in the line of code and then pressing F9 or choosing **Debug > Toggle Breakpoint** from the menu bar.

As the following image shows, Visual Studio indicates the line on which the breakpoint is set by highlighting it and displaying a red dot in the left margin.

A screenshot of the Visual Studio IDE showing the code editor for a C# file named Program.cs. The code defines a namespace HelloWorld and a class Program with a Main method. A red rectangle highlights the line of code where the breakpoint is set: "Console.WriteLine(\$"Hello, {name}, on {currentDate:d} at {currentDate:t}!");". The status bar at the bottom shows "No issues found".

2. Press F5 to run the program in Debug mode. Another way to start debugging is by choosing **Debug > Start Debugging** from the menu.
3. Enter a string in the console window when the program prompts for a name, and then press Enter.
4. Program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes. The **Locals** window displays the values of variables that are defined in the currently executing method.

A screenshot of the Visual Studio IDE during a debug session. The code editor shows the same C# code as before. The Locals window is open, displaying variable values: args (string[0]), name ("jack"), and currentDate (4/26/2021 1:36:13 PM). The Diagnostic Tools window is also visible, showing a timeline of events and process memory usage. The status bar at the bottom shows "No issues found".

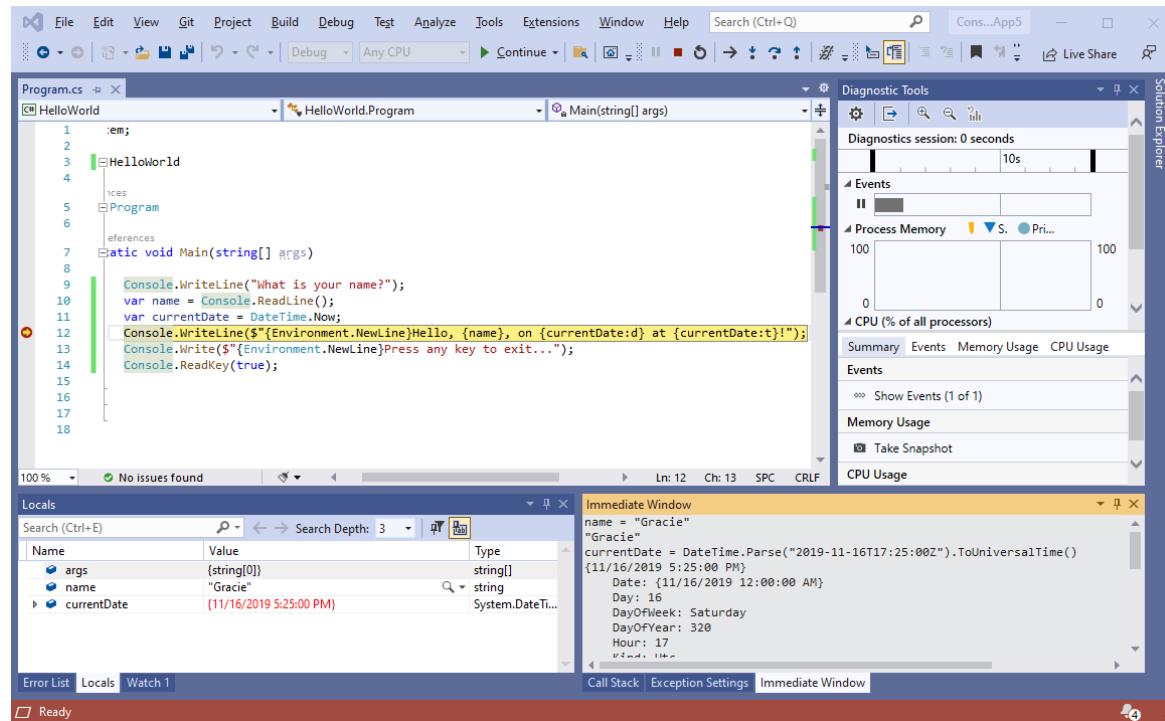

Use the Immediate window

The **Immediate** window lets you interact with the application you're debugging. You can interactively change the value of variables to see how it affects your program.

1. If the **Immediate** window is not visible, display it by choosing **Debug > Windows > Immediate**.
2. Enter `name = "Gracie"` in the **Immediate** window and press the Enter key.

3. Enter `currentDate = DateTime.Parse("2019-11-16T17:25:00Z").ToUniversalTime()` in the **Immediate** window and press the Enter key.

The **Immediate** window displays the value of the string variable and the properties of the `DateTime` value. In addition, the values of the variables are updated in the **Locals** window.

4. Press F5 to continue program execution. Another way to continue is by choosing **Debug > Continue** from the menu.

The values displayed in the console window correspond to the changes you made in the **Immediate** window.

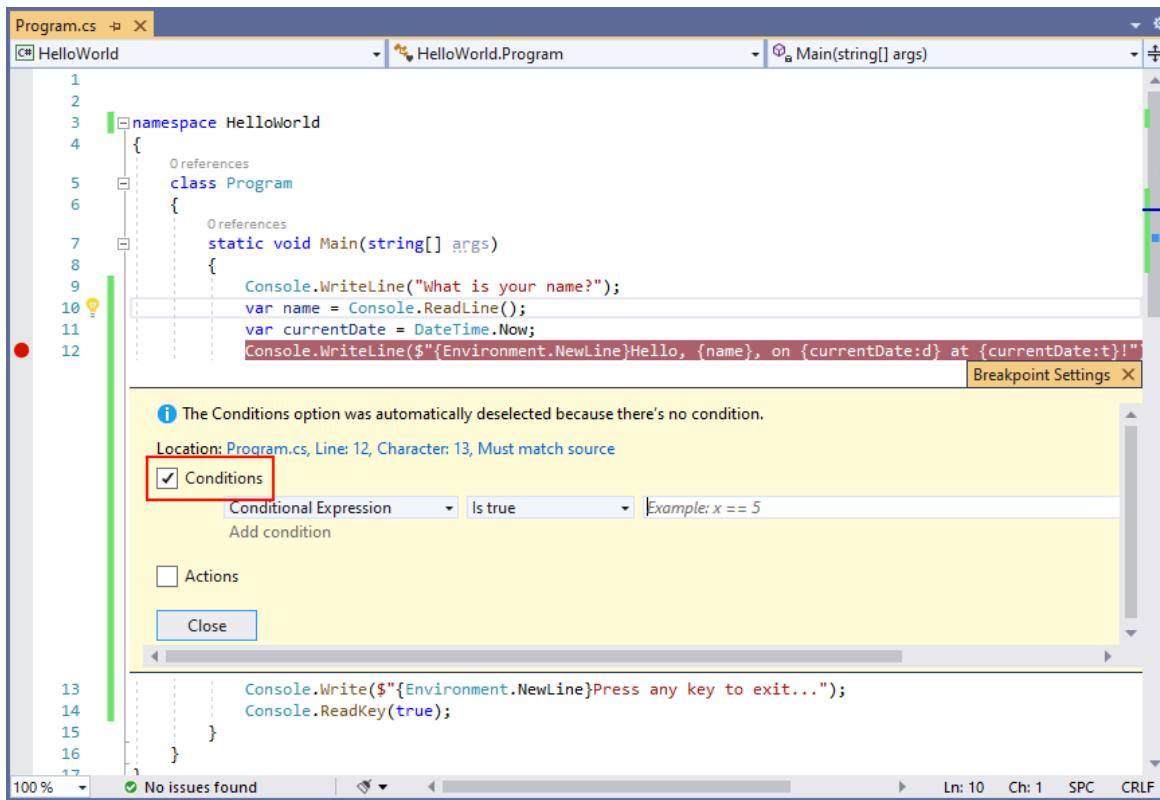

```
What is your name?  
jack  
  
Hello, Gracie, on 11/16/2019 at 5:25 PM!  
  
Press any key to exit...
```

5. Press any key to exit the application and stop debugging.

Set a conditional breakpoint

The program displays the string that the user enters. What happens if the user doesn't enter anything? You can test this with a useful debugging feature called a *conditional breakpoint*.

1. Right-click on the red dot that represents the breakpoint. In the context menu, select **Conditions** to open the **Breakpoint Settings** dialog. Select the box for **Conditions** if it's not already selected.

2. For the **Conditional Expression**, enter the following code in the field that shows example code that tests if `x` is 5.

```
String.IsNullOrEmpty(name)
```

```
String.IsNullOrEmpty(name)
```

Each time the breakpoint is hit, the debugger calls the `String.IsNullOrEmpty(name)` method, and it breaks on this line only if the method call returns `true`.

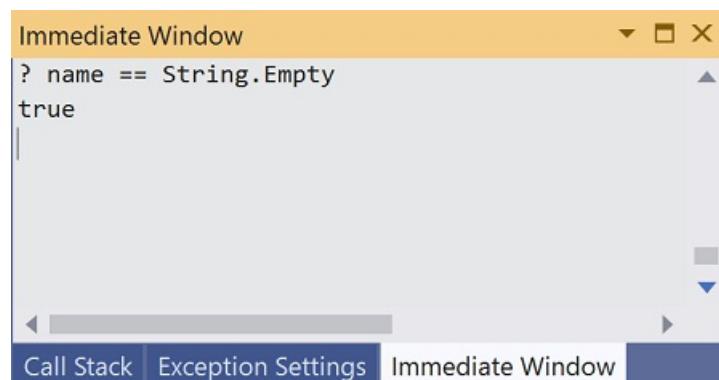

Instead of a conditional expression, you can specify a *hit count*, which interrupts program execution before a statement is executed a specified number of times. Another option is to specify a *filter condition*, which interrupts program execution based on such attributes as a thread identifier, process name, or thread name.

3. Select **Close** to close the dialog.
4. Start the program with debugging by pressing F5.
5. In the console window, press the Enter key when prompted to enter your name.
6. Because the condition you specified (`name` is either `null` or `String.Empty`) has been satisfied, program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes.
7. Select the **Locals** window, which shows the values of variables that are local to the currently executing method. In this case, `Main` is the currently executing method. Observe that the value of the `name` variable is `""`, or `String.Empty`.
8. Confirm the value is an empty string by entering the following statement in the **Immediate** window and pressing Enter. The result is `true`.

```
? name == String.Empty
```

```
? String.IsNullOrEmpty(name)
```

The question mark directs the immediate window to [evaluate an expression](#).

9. Press F5 to continue program execution.
10. Press any key to close the console window and stop debugging.
11. Clear the breakpoint by clicking on the dot in the left margin of the code window. Other ways to clear a breakpoint are by pressing F9 or choosing Debug > Toggle Breakpoint while the line of code is selected.

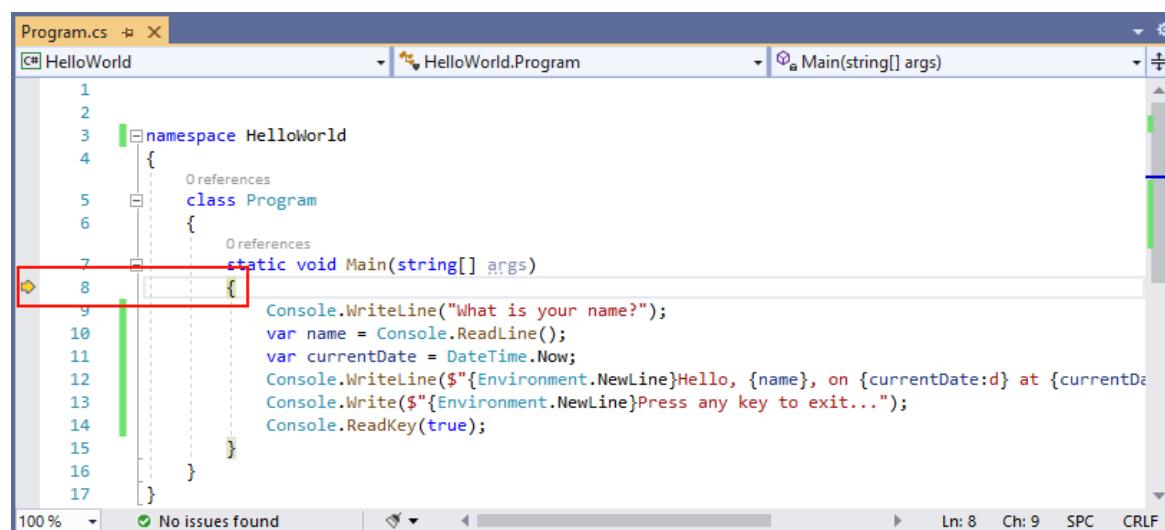

Step through a program

Visual Studio also allows you to step line by line through a program and monitor its execution. Ordinarily, you'd set a breakpoint and follow program flow through a small part of your program code. Since this program is small, you can step through the entire program.

1. Choose **Debug > Step Into**. Another way to debug one statement at a time is by pressing F11.

Visual Studio highlights and displays an arrow beside the next line of execution.

C#

Visual Basic

```
Imports System
Module Program
    Sub Main(args As String())
        Console.WriteLine("What is your name?")
        Dim name = Console.ReadLine()
        Dim currentDate = DateTime.Now
        Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}")
        Console.Write($"{Environment.NewLine}Press any key to exit...")
        Console.ReadKey(True)
    End Sub
End Module
```

At this point, the **Locals** window shows that the `args` array is empty, and `name` and `currentDate` have default values. In addition, Visual Studio has opened a blank console window.

2. Press F11. Visual Studio now highlights the next line of execution. The **Locals** window is unchanged, and the console window remains blank.

C#

```
namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("What is your name?"); ⏴1ms elapsed
            var name = Console.ReadLine();
            var currentDate = DateTime.Now;
            Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}");
            Console.Write($"{Environment.NewLine}Press any key to exit...");
            Console.ReadKey(true);
        }
    }
}
```

Visual Basic

```
Imports System
Module Program
    Sub Main(args As String())
        Console.WriteLine("What is your name?") ⏴1ms elapsed
        Dim name = Console.ReadLine()
        Dim currentDate = DateTime.Now
        Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}")
        Console.Write($"{Environment.NewLine}Press any key to exit...")
        Console.ReadKey(True)
    End Sub
End Module
```

3. Press F11. Visual Studio highlights the statement that includes the `name` variable assignment. The **Locals** window shows that `name` is `null`, and the console window displays the string "What is your name?".

4. Respond to the prompt by entering a string in the console window and pressing Enter. The console is unresponsive, and the string you entered isn't displayed in the console window, but the `Console.ReadLine` method will nevertheless capture your input.
5. Press F11. Visual Studio highlights the statement that includes the `currentDate` variable assignment. The **Locals** window shows the value returned by the call to the `Console.ReadLine` method. The console window also displays the string you entered at the prompt.
6. Press F11. The **Locals** window shows the value of the `currentDate` variable after the assignment from the `DateTime.Now` property. The console window is unchanged.
7. Press F11. Visual Studio calls the `Console.WriteLine(String, Object, Object)` method. The console window displays the formatted string.
8. Choose **Debug > Step Out**. Another way to stop step-by-step execution is by pressing **Shift+F11**.
The console window displays a message and waits for you to press a key.
9. Press any key to close the console window and stop debugging.

Use Release build configuration

Once you've tested the Debug version of your application, you should also compile and test the Release version. The Release version incorporates compiler optimizations that can sometimes negatively affect the behavior of an application. For example, compiler optimizations that are designed to improve performance can create race conditions in multithreaded applications.

To build and test the Release version of your console application, change the build configuration on the toolbar from **Debug** to **Release**.

When you press F5 or choose **Build Solution** from the **Build** menu, Visual Studio compiles the Release version of the application. You can test it as you did the Debug version.

Next steps

In this tutorial, you used Visual Studio debugging tools. In the next tutorial, you publish a deployable version of the app.

[Publish a .NET console application using Visual Studio](#)

This tutorial introduces the debugging tools available in Visual Studio.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio](#).

Use Debug build configuration

Debug and *Release* are Visual Studio's built-in build configurations. You use the Debug build configuration for debugging and the Release configuration for the final release distribution.

In the Debug configuration, a program compiles with full symbolic debug information and no optimization. Optimization complicates debugging, because the relationship between source code and generated instructions is more complex. The release configuration of a program has no symbolic debug information and is fully

optimized.

By default, Visual Studio uses the Debug build configuration, so you don't need to change it before debugging.

1. Start Visual Studio.
 2. Open the project that you created in [Create a .NET console application using Visual Studio](#).

The current build configuration is shown on the toolbar. The following toolbar image shows that Visual Studio is configured to compile the Debug version of the app:

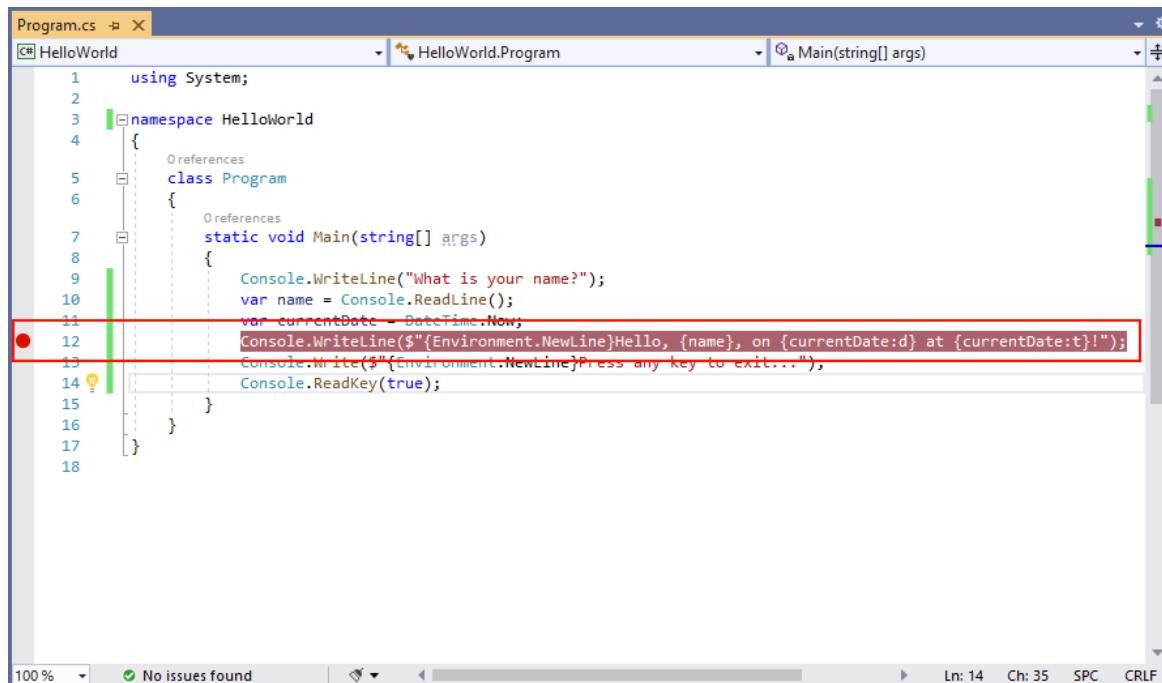

Set a breakpoint

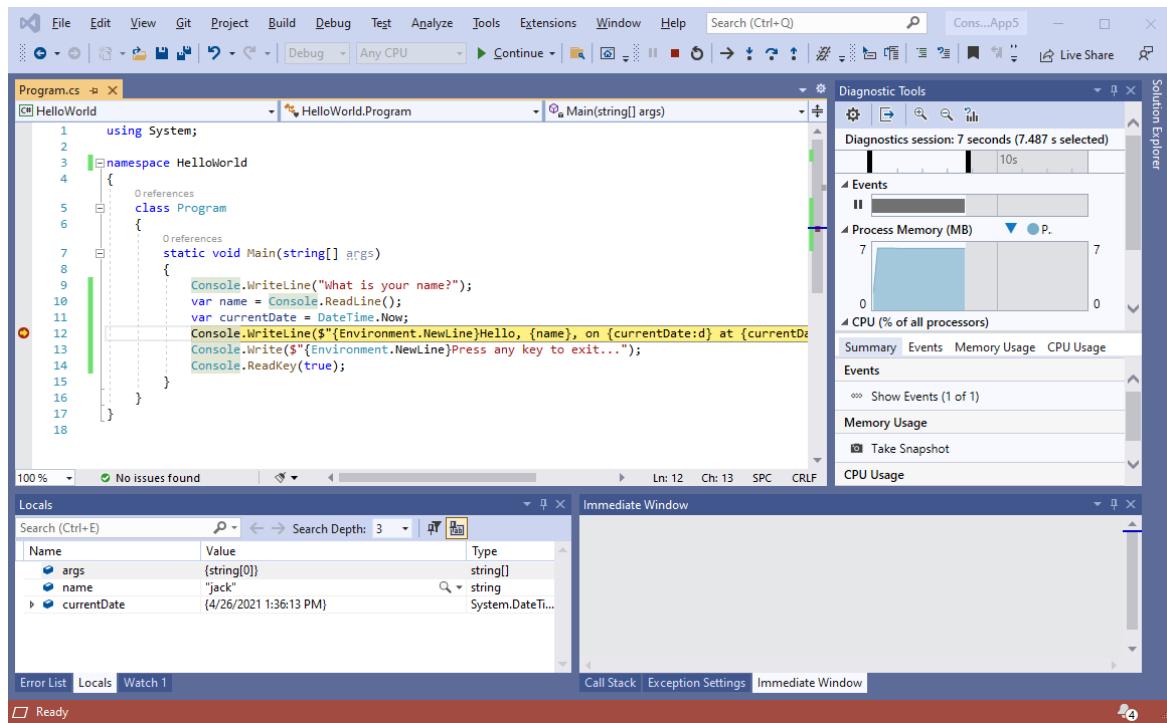

A *breakpoint* temporarily interrupts the execution of the application before the line with the breakpoint is executed.

1. Set a *breakpoint* on the line that displays the name, date, and time, by clicking in the left margin of the code window on that line. The left margin is to the left of the line numbers. Other ways to set a breakpoint are by placing the cursor in the line of code and then pressing F9 or choosing **Debug > Toggle Breakpoint** from the menu bar.

As the following image shows, Visual Studio indicates the line on which the breakpoint is set by highlighting it and displaying a red dot in the left margin.

2. Press F5 to run the program in Debug mode. Another way to start debugging is by choosing **Debug > Start Debugging** from the menu.
 3. Enter a string in the console window when the program prompts for a name, and then press Enter.
 4. Program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes. The **Locals** window displays the values of variables that are defined in the currently executing method.

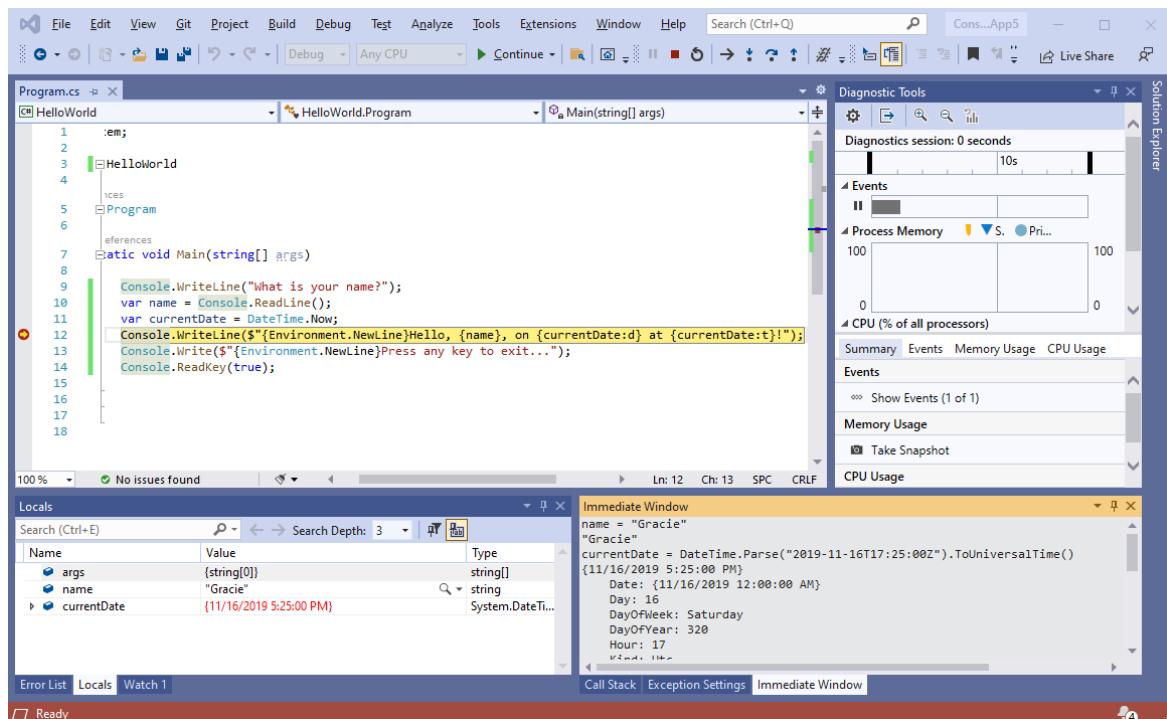

Use the Immediate window

The **Immediate** window lets you interact with the application you're debugging. You can interactively change the value of variables to see how it affects your program.

1. If the **Immediate** window is not visible, display it by choosing **Debug > Windows > Immediate**.
2. Enter `name = "Gracie"` in the **Immediate** window and press the **Enter** key.
3. Enter `currentDate = DateTime.Parse("2019-11-16T17:25:00Z").ToUniversalTime()` in the **Immediate** window and press the **Enter** key.

The **Immediate** window displays the value of the string variable and the properties of the **DateTime** value. In addition, the values of the variables are updated in the **Locals** window.

4. Press **F5** to continue program execution. Another way to continue is by choosing **Debug > Continue**

from the menu.

The values displayed in the console window correspond to the changes you made in the **Immediate** window.

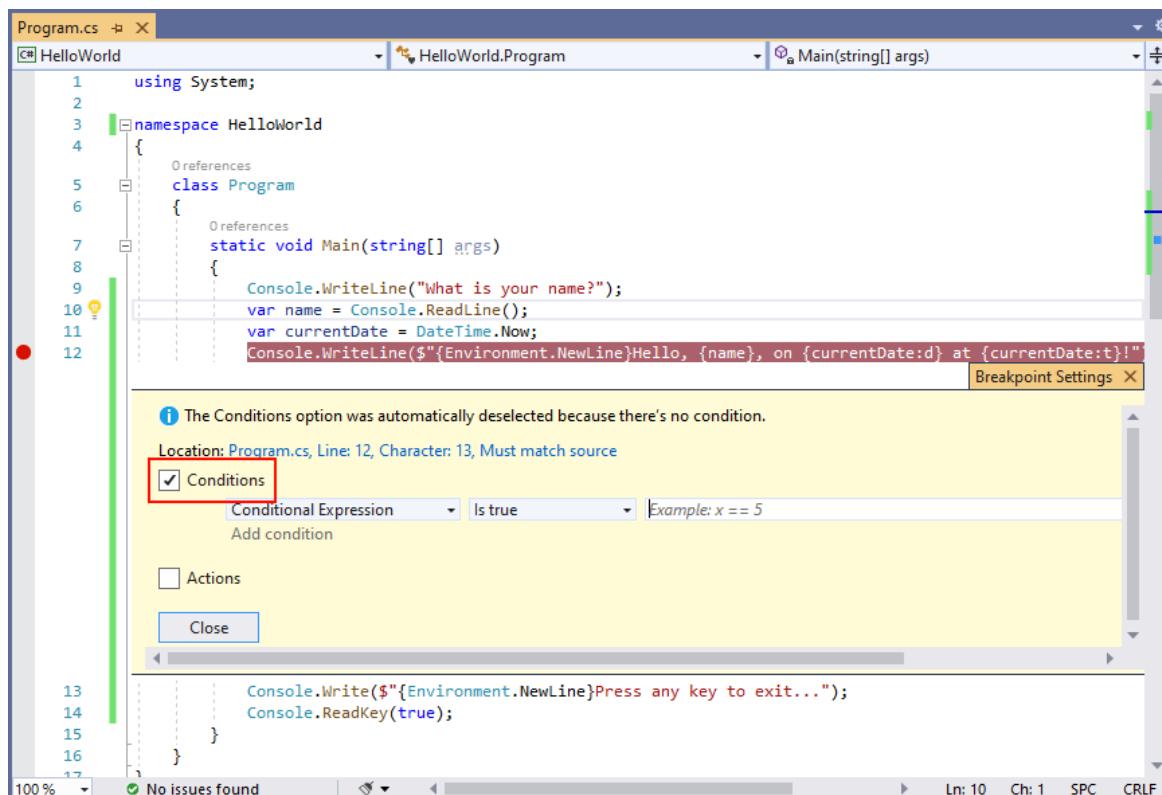

```
What is your name?  
jack  
  
Hello, Gracie, on 11/16/2019 at 5:25 PM!  
  
Press any key to exit...
```

5. Press any key to exit the application and stop debugging.

Set a conditional breakpoint

The program displays the string that the user enters. What happens if the user doesn't enter anything? You can test this with a useful debugging feature called a *conditional breakpoint*.

1. Right-click on the red dot that represents the breakpoint. In the context menu, select **Conditions** to open the **Breakpoint Settings** dialog. Select the box for **Conditions** if it's not already selected.

2. For the **Conditional Expression**, enter the following code in the field that shows example code that tests if `x` is 5. If the language you want to use is not shown, change the language selector at the top of the page.

```
String.IsNullOrEmpty(name)
```

```
String.IsNullOrEmpty(name)
```

Each time the breakpoint is hit, the debugger calls the `String.IsNullOrEmpty(name)` method, and it breaks on this line only if the method call returns `true`.

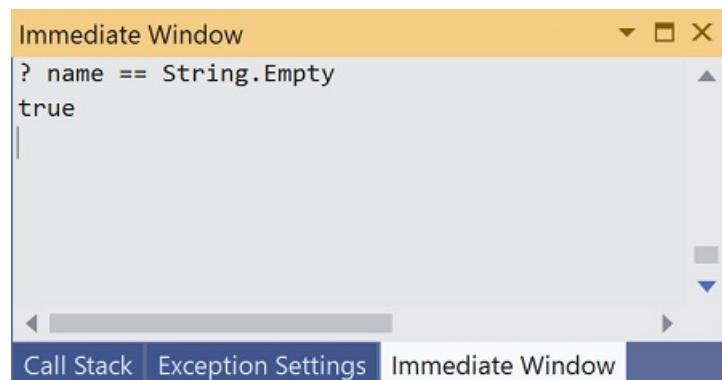

Instead of a conditional expression, you can specify a *hit count*, which interrupts program execution before a statement is executed a specified number of times. Another option is to specify a *filter condition*, which interrupts program execution based on such attributes as a thread identifier, process name, or thread name.

3. Select **Close** to close the dialog.
4. Start the program with debugging by pressing F5.
5. In the console window, press the Enter key when prompted to enter your name.
6. Because the condition you specified (`name` is either `null` or `String.Empty`) has been satisfied, program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes.
7. Select the **Locals** window, which shows the values of variables that are local to the currently executing method. In this case, `Main` is the currently executing method. Observe that the value of the `name` variable is `""`, or `String.Empty`.
8. Confirm the value is an empty string by entering the following statement in the **Immediate** window and pressing Enter. The result is `true`.

```
? name == String.Empty
```

```
? String.IsNullOrEmpty(name)
```

The question mark directs the immediate window to [evaluate an expression](#).

9. Press F5 to continue program execution.
10. Press any key to close the console window and stop debugging.
11. Clear the breakpoint by clicking on the dot in the left margin of the code window. Other ways to clear a breakpoint are by pressing F9 or choosing **Debug > Toggle Breakpoint** while the line of code is selected.

Step through a program

Visual Studio also allows you to step line by line through a program and monitor its execution. Ordinarily, you'd set a breakpoint and follow program flow through a small part of your program code. Since this program is small, you can step through the entire program.

1. Choose **Debug > Step Into**. Another way to debug one statement at a time is by pressing F11.

Visual Studio highlights and displays an arrow beside the next line of execution.

```
Program.cs # X
HelloWorld
    using System;
    namespace HelloWorld
    {
        class Program
        {
            static void Main(string[] args)
            {
                Console.WriteLine("What is your name?");
                var name = Console.ReadLine();
                var currentDate = DateTime.Now;
                Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}");
                Console.Write($"{Environment.NewLine}Press any key to exit...");
                Console.ReadKey(true);
            }
        }
    }
```

No issues found

Visual Basic

```
Program.vb # X
VB HelloWorld
    Imports System
    Module Program
        Sub Main(args As String())
            Console.WriteLine("What is your name?")
            Dim name = Console.ReadLine()
            Dim currentDate = DateTime.Now
            Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}");
            Console.Write($"{Environment.NewLine}Press any key to exit...")
            Console.ReadKey(True)
        End Sub
    End Module
```

No issues found

At this point, the **Locals** window shows that the `args` array is empty, and `name` and `currentDate` have default values. In addition, Visual Studio has opened a blank console window.

2. Press F11. Visual Studio now highlights the next line of execution. The **Locals** window is unchanged, and the console window remains blank.

C#

```
Program.cs # X
HelloWorld
    using System;
    namespace HelloWorld
    {
        class Program
        {
            static void Main(string[] args)
            {
                Console.WriteLine("What is your name?"); ≤1ms elapsed
                var name = Console.ReadLine();
                var currentDate = DateTime.Now;
                Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}");
                Console.Write($"{Environment.NewLine}Press any key to exit...");
                Console.ReadKey(true);
            }
        }
    }
```

No issues found

Visual Basic

```
Program.vb # X
VB HelloWorld      Program      Main
1 Imports System
2
3 Module Program
4 Sub Main(args As String())
5     Console.WriteLine("What is your name?")
6     Dim name = Console.ReadLine()
7     Dim currentDate = DateTime.Now
8     Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}")
9     Console.WriteLine($"{Environment.NewLine}Press any key to exit...")
10    Console.ReadKey(True)
11 End Sub
12 End Module
13
```

No issues found

3. Press F11. Visual Studio highlights the statement that includes the `name` variable assignment. The **Locals** window shows that `name` is `null`, and the console window displays the string "What is your name?".
4. Respond to the prompt by entering a string in the console window and pressing Enter. The console is unresponsive, and the string you entered isn't displayed in the console window, but the `Console.ReadLine` method will nevertheless capture your input.
5. Press F11. Visual Studio highlights the statement that includes the `currentDate` variable assignment. The **Locals** window shows the value returned by the call to the `Console.ReadLine` method. The console window also displays the string you entered at the prompt.
6. Press F11. The **Locals** window shows the value of the `currentDate` variable after the assignment from the `DateTime.Now` property. The console window is unchanged.
7. Press F11. Visual Studio calls the `Console.WriteLine(String, Object, Object)` method. The console window displays the formatted string.
8. Choose **Debug > Step Out**. Another way to stop step-by-step execution is by pressing Shift+F11.
The console window displays a message and waits for you to press a key.

9. Press any key to close the console window and stop debugging.

Use Release build configuration

Once you've tested the Debug version of your application, you should also compile and test the Release version. The Release version incorporates compiler optimizations that can sometimes negatively affect the behavior of an application. For example, compiler optimizations that are designed to improve performance can create race conditions in multithreaded applications.

To build and test the Release version of your console application, change the build configuration on the toolbar from **Debug** to **Release**.

When you press F5 or choose **Build Solution** from the **Build** menu, Visual Studio compiles the Release version of the application. You can test it as you did the Debug version.

Next steps

In this tutorial, you used Visual Studio debugging tools. In the next tutorial, you publish a deployable version of the app.

Publish a .NET console application using Visual Studio

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Publish a .NET console application using Visual Studio

9/20/2022 • 5 minutes to read • [Edit Online](#)

This tutorial shows how to publish a console app so that other users can run it. Publishing creates the set of files that are needed to run your application. To deploy the files, copy them to the target machine.

Prerequisites

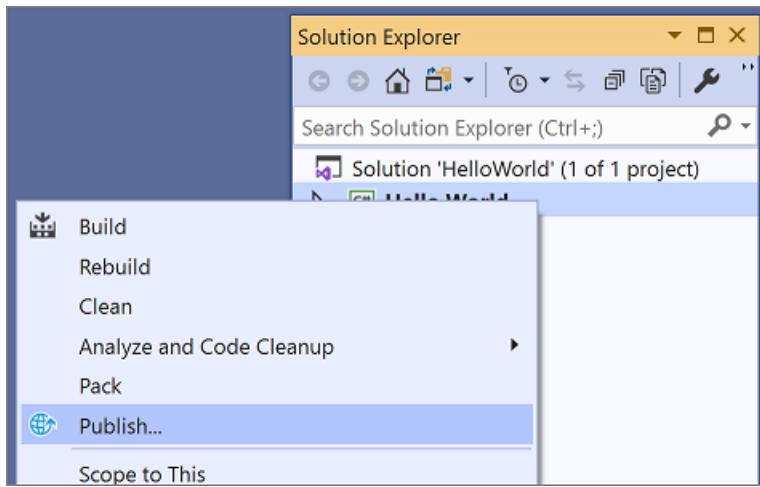

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio](#).

Publish the app

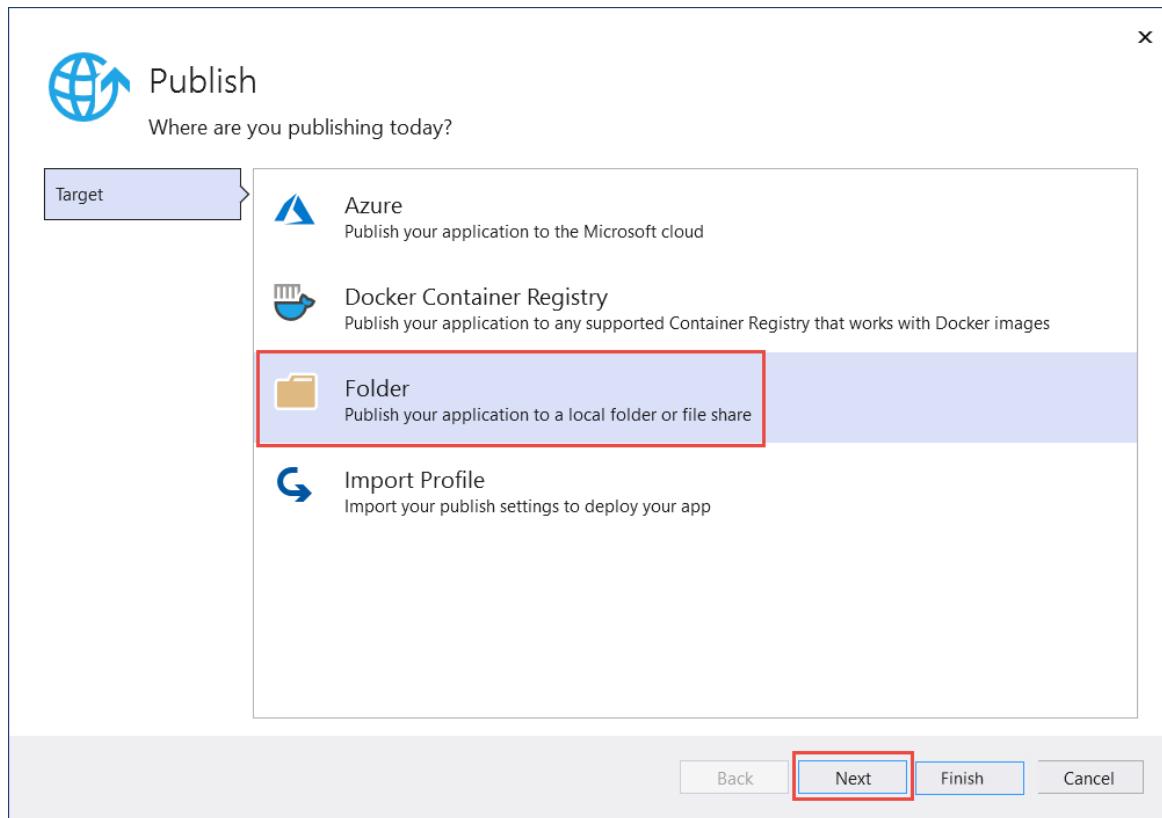

1. Start Visual Studio.
2. Open the *HelloWorld* project that you created in [Create a .NET console application using Visual Studio](#).
3. Make sure that Visual Studio is using the Release build configuration. If necessary, change the build configuration setting on the toolbar from **Debug** to **Release**.

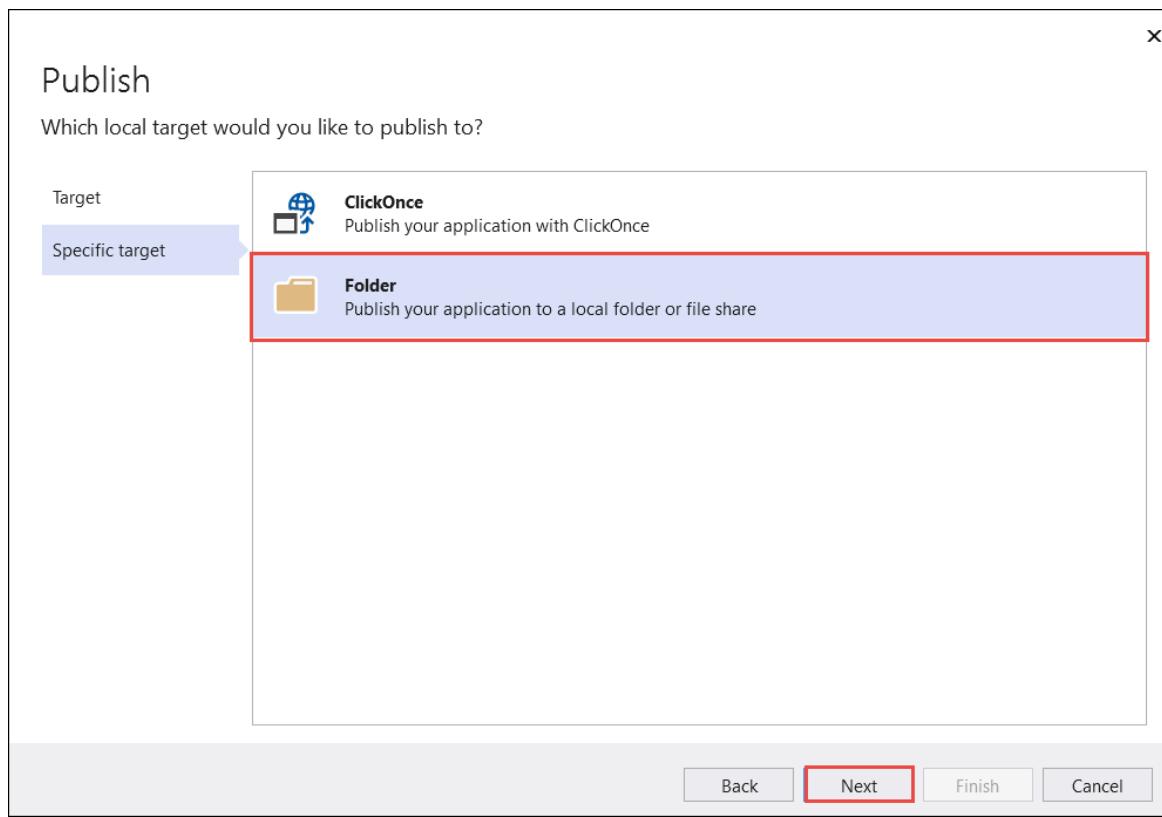

4. Right-click on the **HelloWorld** project (not the HelloWorld solution) and select **Publish** from the menu.

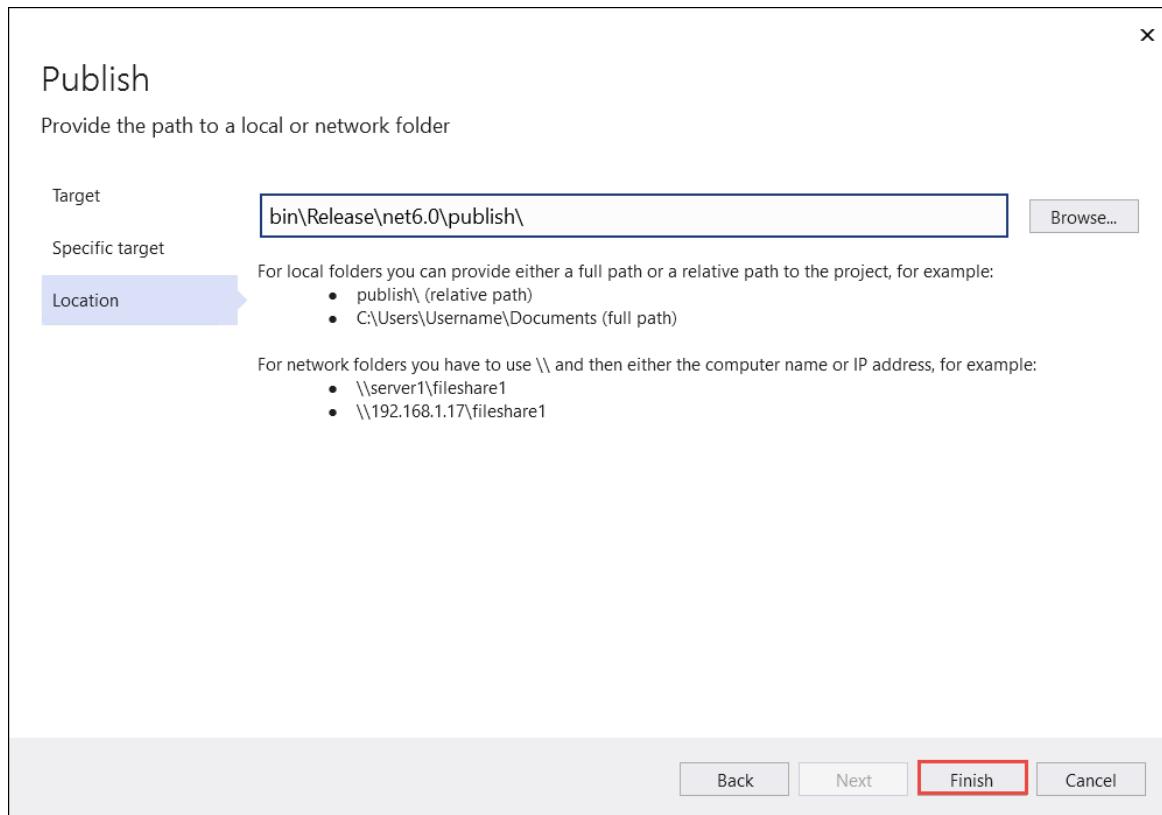

5. On the Target tab of the Publish page, select **Folder**, and then select **Next**.

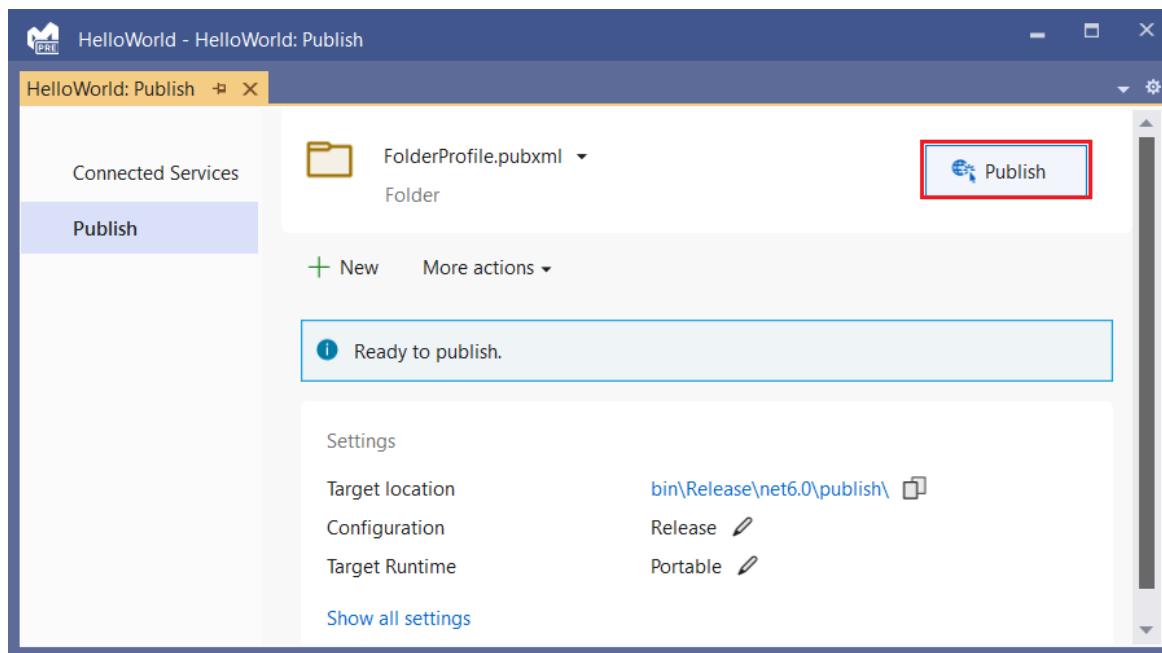

6. On the **Specific Target** tab of the **Publish** page, select **Folder**, and then select **Next**.

7. On the **Location** tab of the **Publish** page, select **Finish**.

8. On the **Publish** tab of the **Publish** window, select **Publish**.

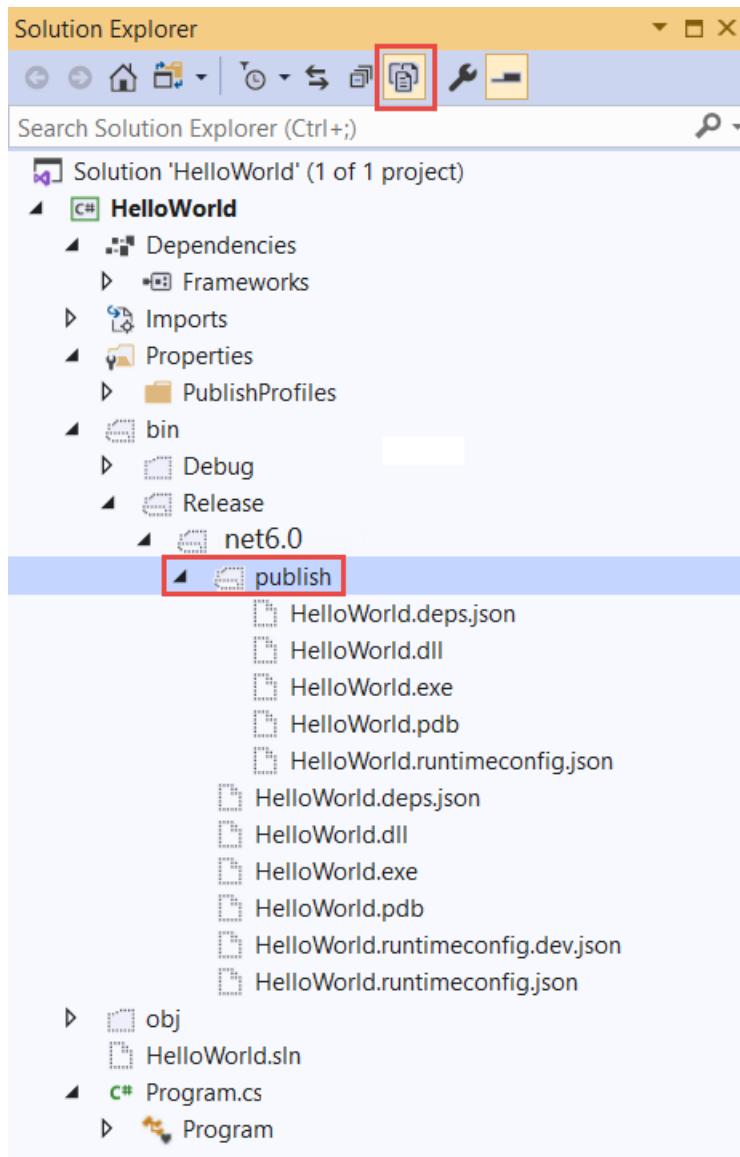

Inspect the files

By default, the publishing process creates a framework-dependent deployment, which is a type of deployment where the published application runs on machine that has the .NET runtime installed. Users can run the published app by double-clicking the executable or issuing the `dotnet HelloWorld.dll` command from a command prompt.

In the following steps, you'll look at the files created by the publish process.

1. In Solution Explorer, select **Show all files**.
2. In the project folder, expand *bin/Release/net6.0/publish*.

As the image shows, the published output includes the following files:

- *HelloWorld.deps.json*

This is the application's runtime dependencies file. It defines the .NET components and the libraries (including the dynamic link library that contains your application) needed to run the app. For more information, see [Runtime configuration files](#).

- *HelloWorld.dll*

This is the [framework-dependent deployment](#) version of the application. To execute this dynamic link library, enter `dotnet HelloWorld.dll` at a command prompt. This method of running the app works on any platform that has the .NET runtime installed.

- *HelloWorld.exe*

This is the [framework-dependent executable](#) version of the application. To run it, enter `HelloWorld.exe` at a command prompt. The file is operating-system-specific.

- *HelloWorld.pdb* (optional for deployment)

This is the debug symbols file. You aren't required to deploy this file along with your application, although you should save it in the event that you need to debug the published version of your application.

- *HelloWorld.runtimeconfig.json*

This is the application's runtime configuration file. It identifies the version of .NET that your application was built to run on. You can also add configuration options to it. For more information, see [.NET runtime configuration settings](#).

Run the published app

1. In **Solution Explorer**, right-click the *publish* folder, and select **Copy Full Path**.
2. Open a command prompt and navigate to the *publish* folder. To do that, enter `cd` and then paste the full path. For example:

```
cd C:\Projects\HelloWorld\bin\Release\net6.0\publish\
```
3. Run the app by using the executable:
 - a. Enter `HelloWorld.exe` and press **Enter**.
 - b. Enter a name in response to the prompt, and press any key to exit.
4. Run the app by using the `dotnet` command:
 - a. Enter `dotnet HelloWorld.dll` and press **Enter**.
 - b. Enter a name in response to the prompt, and press any key to exit.

Next steps

In this tutorial, you published a console app. In the next tutorial, you create a class library.

[Create a .NET class library using Visual Studio](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Create a .NET class library using Visual Studio

9/20/2022 • 12 minutes to read • [Edit Online](#)

In this tutorial, you create a simple class library that contains a single string-handling method.

A *class library* defines types and methods that are called by an application. If the library targets .NET Standard 2.0, it can be called by any .NET implementation (including .NET Framework) that supports .NET Standard 2.0. If the library targets .NET 6, it can be called by any application that targets .NET 6. This tutorial shows how to target .NET 6.

When you create a class library, you can distribute it as a NuGet package or as a component bundled with the application that uses it.

Prerequisites

- [Visual Studio 2022 version 17.0.0 Preview](#) with the **.NET desktop development** workload installed. The .NET 6 SDK is automatically installed when you select this workload.

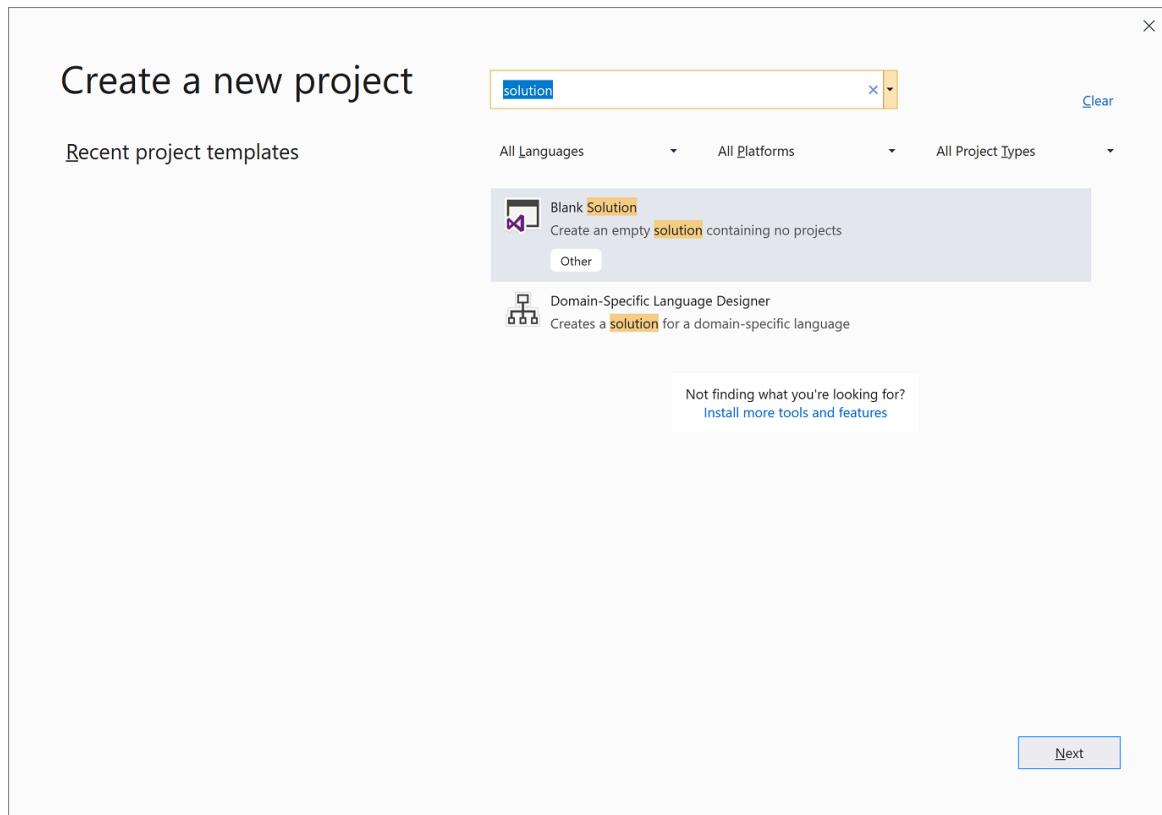

For more information, see [Install the .NET SDK with Visual Studio](#).

Create a solution

Start by creating a blank solution to put the class library project in. A Visual Studio solution serves as a container for one or more projects. You'll add additional, related projects to the same solution.

To create the blank solution:

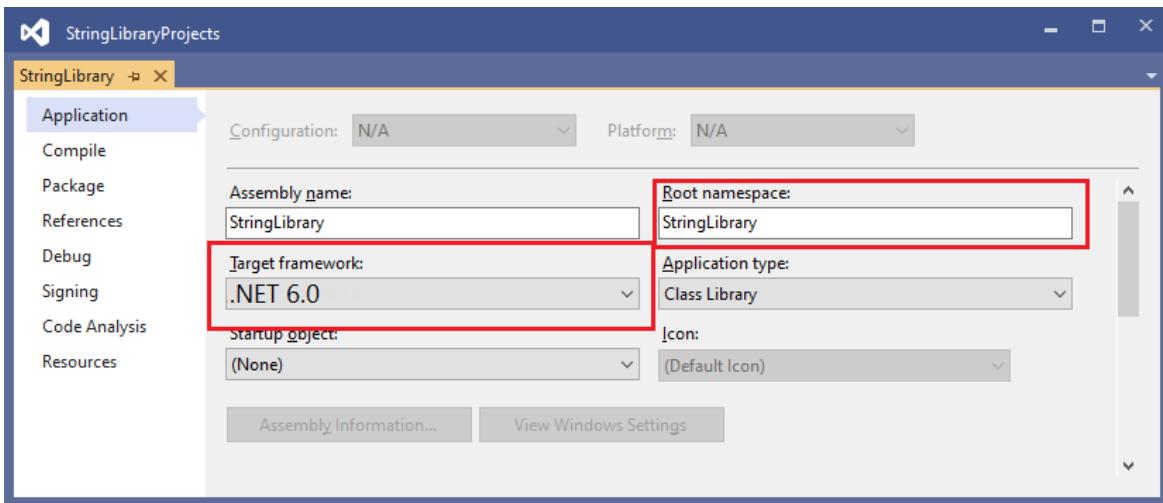

1. Start Visual Studio.
2. On the start window, choose **Create a new project**.
3. On the **Create a new project** page, enter **solution** in the search box. Choose the **Blank Solution** template, and then choose **Next**.

4. On the **Configure your new project** page, enter **ClassLibraryProjects** in the **Solution name** box. Then choose **Create**.

Create a class library project

1. Add a new .NET class library project named "StringLibrary" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New Project**.
 - b. On the **Add a new project** page, enter **library** in the search box. Choose **C# or Visual Basic** from the **Language** list, and then choose **All platforms** from the **Platform** list. Choose the **Class Library** template, and then choose **Next**.
 - c. On the **Configure your new project** page, enter **StringLibrary** in the **Project name** box, and then choose **Next**.
 - d. On the **Additional information** page, select **.NET 6 (Long-term support)**, and then choose **Create**.
2. Check to make sure that the library targets the correct version of .NET. Right-click on the library project in **Solution Explorer**, and then select **Properties**. The **Target Framework** text box shows that the project targets .NET 6.0.
3. If you're using Visual Basic, clear the text in the **Root namespace** text box.

For each project, Visual Basic automatically creates a namespace that corresponds to the project name. In this tutorial, you define a top-level namespace by using the `namespace` keyword in the code file.

4. Replace the code in the code window for *Class1.cs* or *Class1.vb* with the following code, and save the file. If the language you want to use isn't shown, change the language selector at the top of the page.

```
namespace UtilityLibraries;

public static class StringLibrary
{
    public static bool StartsWithUpper(this string? str)
    {
        if (string.IsNullOrWhiteSpace(str))
            return false;

        char ch = str[0];
        return char.IsUpper(ch);
    }
}
```

```
Imports System.Runtime.CompilerServices

Namespace UtilityLibraries
    Public Module StringLibrary
        <Extension>
        Public Function StartsWithUpper(str As String) As Boolean
            If String.IsNullOrWhiteSpace(str) Then
                Return False
            End If

            Dim ch As Char = str(0)
            Return Char.IsUpper(ch)
        End Function
    End Module
End Namespace
```

The class library, `UtilityLibraries.StringLibrary`, contains a method named `StartsWithUpper`. This method returns a `Boolean` value that indicates whether the current string instance begins with an uppercase character. The Unicode standard distinguishes uppercase characters from lowercase characters. The `Char.IsUpper(Char)` method returns `true` if a character is uppercase.

`StartsWithUpper` is implemented as an `extension method` so that you can call it as if it were a member of the `String` class. The question mark (?) after `string` in the C# code indicates that the string may be null.

5. On the menu bar, select **Build > Build Solution** or press **Ctrl+Shift+B** to verify that the project

compiles without error.

Add a console app to the solution

Add a console application that uses the class library. The app will prompt the user to enter a string and report whether the string begins with an uppercase character.

1. Add a new .NET console application named "ShowCase" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New project**.
 - b. On the **Add a new project** page, enter **console** in the search box. Choose **C# or Visual Basic** from the Language list, and then choose **All platforms** from the Platform list.
 - c. Choose the **Console Application** template, and then choose **Next**.
 - d. On the **Configure your new project** page, enter **ShowCase** in the **Project name** box. Then choose **Next**.
 - e. On the **Additional information** page, select **.NET 6 (Long-term support)** in the **Framework** box. Then choose **Create**.

2. In the code window for the *Program.cs* or *Program.vb* file, replace all of the code with the following code.

```
using UtilityLibraries;

class Program
{
    static void Main(string[] args)
    {
        int row = 0;

        do
        {
            if (row == 0 || row >= 25)
                ResetConsole();

            string? input = Console.ReadLine();
            if (string.IsNullOrEmpty(input)) break;
            Console.WriteLine($"Input: {input}");
            Console.WriteLine("Begins with uppercase? " +
                $"{(input.StartsWithUpper() ? "Yes" : "No")}");
            Console.WriteLine();
            row += 4;
        } while (true);
        return;

        // Declare a ResetConsole local method
        void ResetConsole()
        {
            if (row > 0)
            {
                Console.WriteLine("Press any key to continue...");
                Console.ReadKey();
            }
            Console.Clear();
            Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}");
            row = 3;
        }
    }
}
```

```

Imports UtilityLibraries

Module Program
    Dim row As Integer = 0

    Sub Main()
        Do
            If row = 0 OrElse row >= 25 Then ResetConsole()

            Dim input As String = Console.ReadLine()
            If String.IsNullOrEmpty(input) Then Return

            Console.WriteLine($"Input: {input} {"Begins with uppercase? ",30}: " +
                $"{If(input.StartsWithUpper(), "Yes", "No")}{Environment.NewLine}")
            row += 3
        Loop While True
    End Sub

    Private Sub ResetConsole()
        If row > 0 Then
            Console.WriteLine("Press any key to continue...")
            Console.ReadKey()
        End If
        Console.Clear()
        Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}")
        row = 3
    End Sub
End Module

```

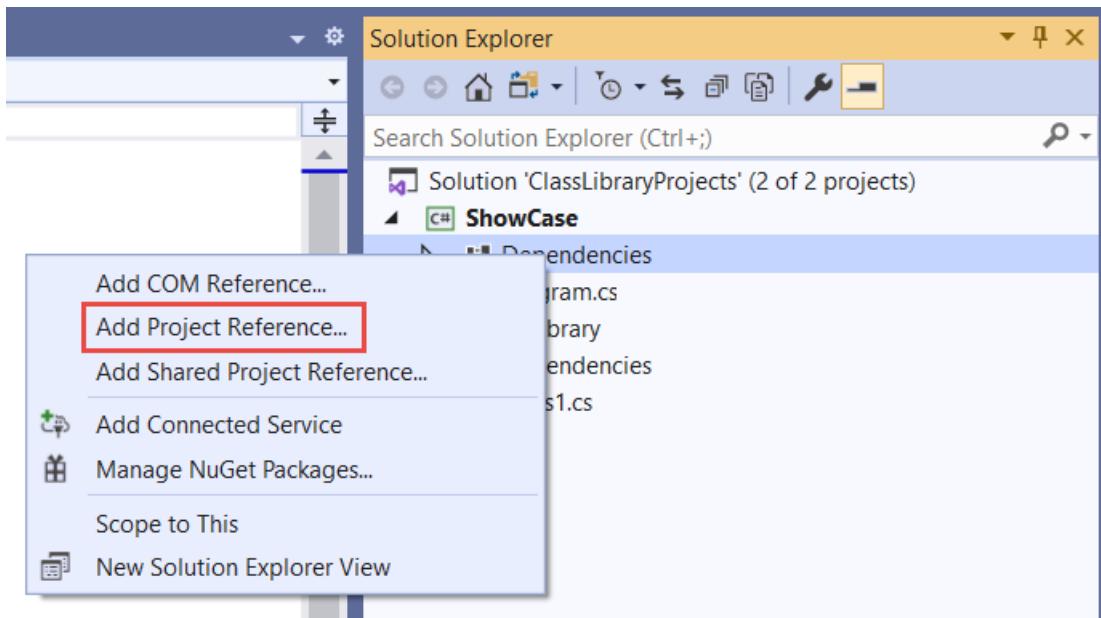

The code uses the `row` variable to maintain a count of the number of rows of data written to the console window. Whenever it's greater than or equal to 25, the code clears the console window and displays a message to the user.

The program prompts the user to enter a string. It indicates whether the string starts with an uppercase character. If the user presses the Enter key without entering a string, the application ends, and the console window closes.

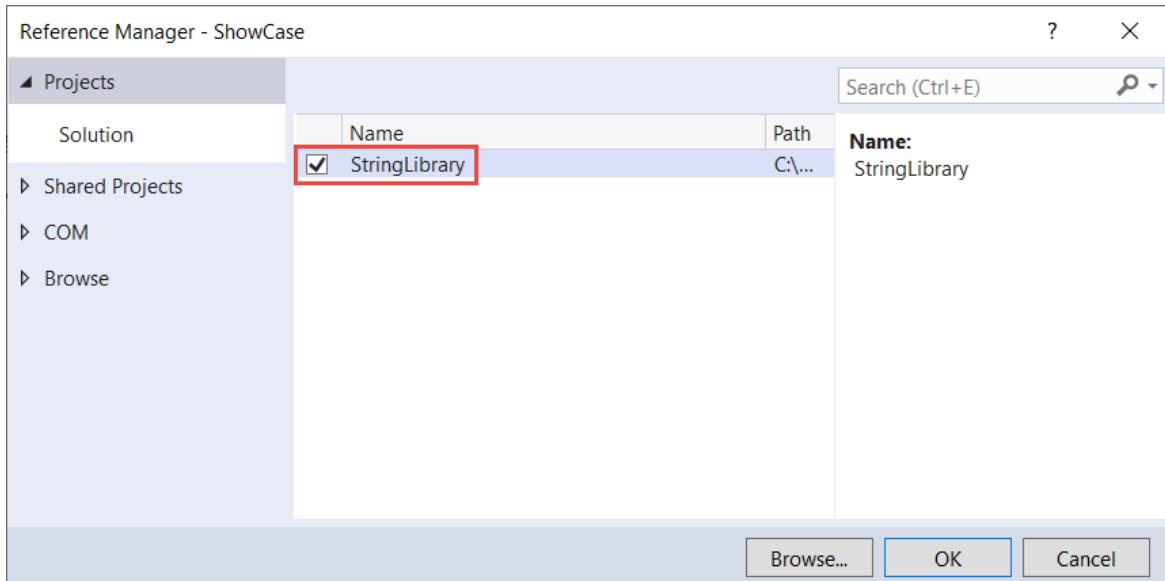

Add a project reference

Initially, the new console app project doesn't have access to the class library. To allow it to call methods in the class library, create a project reference to the class library project.

1. In **Solution Explorer**, right-click the `ShowCase` project's **Dependencies** node, and select **Add Project Reference**.

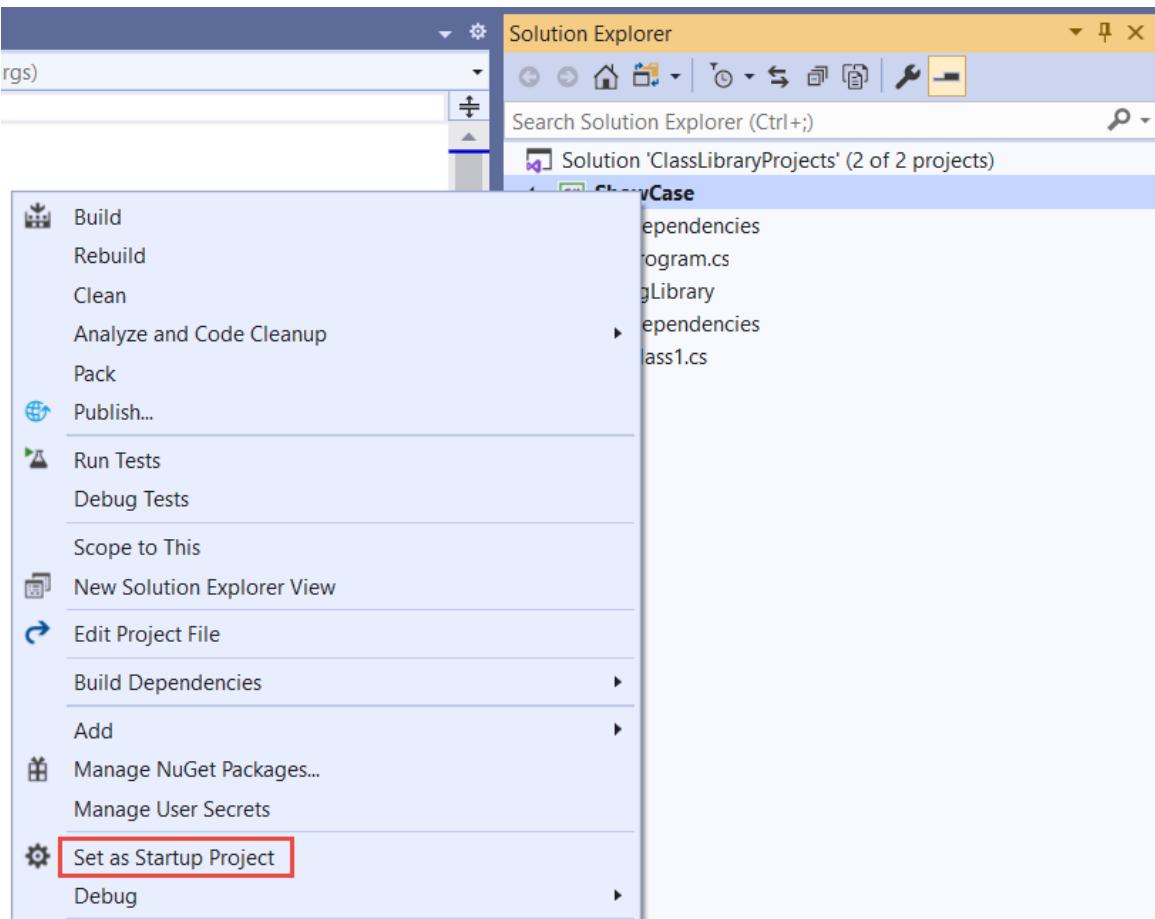

2. In the **Reference Manager** dialog, select the **StringLibrary** project, and select **OK**.

Run the app

1. In **Solution Explorer**, right-click the **ShowCase** project and select **Set as StartUp Project** in the context menu.

2. Press Ctrl+F5 to compile and run the program without debugging.

3. Try out the program by entering strings and pressing Enter, then press Enter to exit.

```
Press <Enter> only to exit; otherwise, enter a string and press <Enter>:  
  
Hello  
Input: Hello  
Begins with uppercase? Yes  
  
hello  
Input: hello  
Begins with uppercase? No
```

Next steps

In this tutorial, you created a class library. In the next tutorial, you learn how to unit test the class library.

[Unit test a .NET class library using Visual Studio](#)

Or you can skip automated unit testing and learn how to share the library by creating a NuGet package:

[Create and publish a package using Visual Studio](#)

Or learn how to publish a console app. If you publish the console app from the solution you created in this tutorial, the class library goes with it as a `.dll` file.

Publish a .NET console application using Visual Studio

In this tutorial, you create a simple class library that contains a single string-handling method.

A *class library* defines types and methods that are called by an application. If the library targets .NET Standard 2.0, it can be called by any .NET implementation (including .NET Framework) that supports .NET Standard 2.0. If the library targets .NET 5, it can be called by any application that targets .NET 5. This tutorial shows how to target .NET 5.

When you create a class library, you can distribute it as a NuGet package or as a component bundled with the application that uses it.

Prerequisites

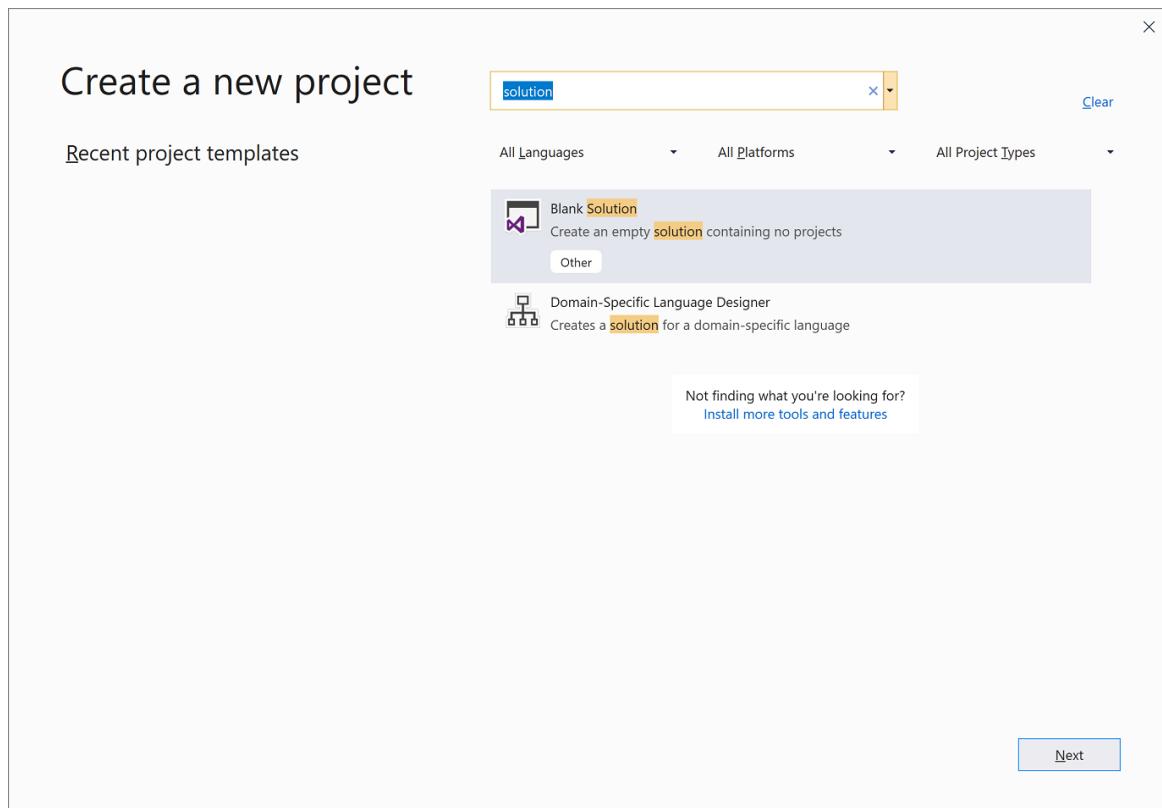

- [Visual Studio 2019 version 16.8 or a later version](#) with the **.NET Core cross-platform development** workload installed. The .NET 5.0 SDK is automatically installed when you select this workload. This tutorial assumes you have enabled **Show all .NET Core templates in the New project**, as shown in [Tutorial: Create a .NET console application using Visual Studio](#).

Create a solution

Start by creating a blank solution to put the class library project in. A Visual Studio solution serves as a container for one or more projects. You'll add additional, related projects to the same solution.

To create the blank solution:

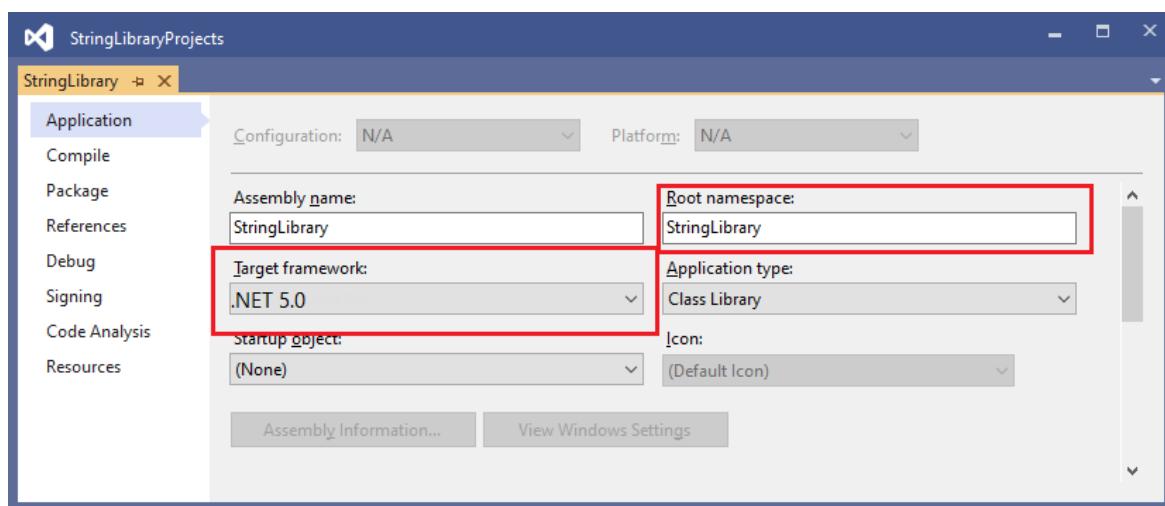

1. Start Visual Studio.
2. On the start window, choose **Create a new project**.
3. On the **Create a new project** page, enter `solution` in the search box. Choose the **Blank Solution** template, and then choose **Next**.

4. On the **Configure your new project** page, enter **ClassLibraryProjects** in the **Project name** box. Then choose **Create**.

Create a class library project

1. Add a new .NET class library project named "StringLibrary" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New Project**.
 - b. On the **Add a new project** page, enter **library** in the search box. Choose **C# or Visual Basic** from the Language list, and then choose **All platforms** from the Platform list. Choose the **Class Library** template, and then choose **Next**.
 - c. On the **Configure your new project** page, enter **StringLibrary** in the **Project name** box, and then choose **Next**.
 - d. On the **Additional information** page, select **.NET 5.0 (Current)**, and then choose **Create**.
2. Check to make sure that the library targets the correct version of .NET. Right-click on the library project in **Solution Explorer**, and then select **Properties**. The **Target Framework** text box shows that the project targets .NET 5.0.
3. If you're using Visual Basic, clear the text in the **Root namespace** text box.

For each project, Visual Basic automatically creates a namespace that corresponds to the project name. In this tutorial, you define a top-level namespace by using the `namespace` keyword in the code file.

4. Replace the code in the code window for *Class1.cs* or *Class1.vb* with the following code, and save the file. If the language you want to use is not shown, change the language selector at the top of the page.

```

using System;

namespace UtilityLibraries
{
    public static class StringLibrary
    {
        public static bool StartsWithUpper(this string str)
        {
            if (string.IsNullOrWhiteSpace(str))
                return false;

            char ch = str[0];
            return char.IsUpper(ch);
        }
    }
}

```

```

Imports System.Runtime.CompilerServices

Namespace UtilityLibraries
    Public Module StringLibrary
        <Extension>
        Public Function StartsWithUpper(str As String) As Boolean
            If String.IsNullOrWhiteSpace(str) Then
                Return False
            End If

            Dim ch As Char = str(0)
            Return Char.IsUpper(ch)
        End Function
    End Module
End Namespace

```

The class library, `UtilityLibraries.StringLibrary`, contains a method named `StartsWithUpper`. This method returns a `Boolean` value that indicates whether the current string instance begins with an uppercase character. The Unicode standard distinguishes uppercase characters from lowercase characters. The `Char.ToUpper(Char)` method returns `true` if a character is uppercase.

`StartsWithUpper` is implemented as an [extension method](#) so that you can call it as if it were a member of the `String` class.

5. On the menu bar, select **Build > Build Solution** or press **Ctrl+Shift+B** to verify that the project compiles without error.

Add a console app to the solution

Add a console application that uses the class library. The app will prompt the user to enter a string and report whether the string begins with an uppercase character.

1. Add a new .NET console application named "ShowCase" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New project**.
 - b. On the **Add a new project** page, enter **console** in the search box. Choose **C#** or **Visual Basic** from the Language list, and then choose **All platforms** from the Platform list.
 - c. Choose the **Console Application** template, and then choose **Next**.
 - d. On the **Configure your new project** page, enter **ShowCase** in the **Project name** box. Then choose **Next**.

- e. On the **Additional information** page, select **.NET 5.0 (Current)** in the **Target Framework** box. Then choose **Create**.
2. In the code window for the *Program.cs* or *Program.vb* file, replace all of the code with the following code.

```
using System;
using UtilityLibraries;

class Program
{
    static void Main(string[] args)
    {
        int row = 0;

        do
        {
            if (row == 0 || row >= 25)
                ResetConsole();

            string? input = Console.ReadLine();
            if (string.IsNullOrEmpty(input)) break;
            Console.WriteLine($"Input: {input} {"Begins with uppercase? ",30}: " +
                $"{{(input.StartsWithUpper() ? "Yes" : "No")}{Environment.NewLine}}");

            row += 3;
        } while (true);
        return;

        // Declare a ResetConsole local method
        void ResetConsole()
        {
            if (row > 0)
            {
                Console.WriteLine("Press any key to continue...");
                Console.ReadKey();
            }
            Console.Clear();
            Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}");
            row = 3;
        }
    }
}
```

```

Imports UtilityLibraries

Module Program
    Dim row As Integer = 0

    Sub Main()
        Do
            If row = 0 OrElse row >= 25 Then ResetConsole()

            Dim input As String = Console.ReadLine()
            If String.IsNullOrEmpty(input) Then Return

            Console.WriteLine($"Input: {input} {"Begins with uppercase? ",30}: " +
                $"{If(input.StartsWithUpper(), "Yes", "No")}{Environment.NewLine}")
            row += 3
        Loop While True
    End Sub

    Private Sub ResetConsole()
        If row > 0 Then
            Console.WriteLine("Press any key to continue...")
            Console.ReadKey()
        End If
        Console.Clear()
        Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}")
        row = 3
    End Sub
End Module

```

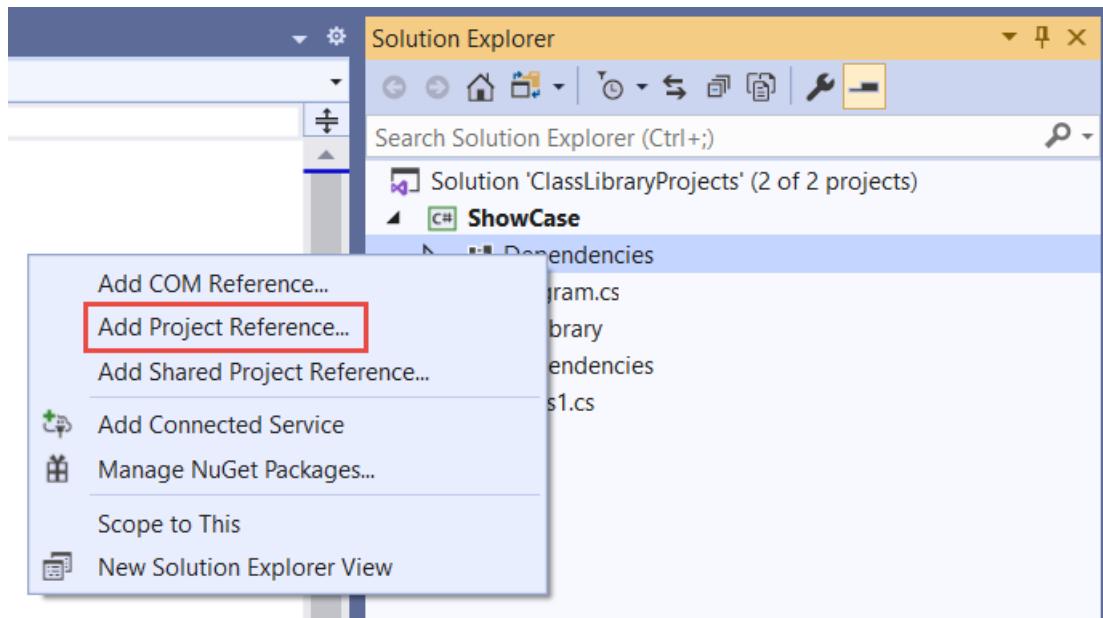

The code uses the `row` variable to maintain a count of the number of rows of data written to the console window. Whenever it's greater than or equal to 25, the code clears the console window and displays a message to the user.

The program prompts the user to enter a string. It indicates whether the string starts with an uppercase character. If the user presses the Enter key without entering a string, the application ends, and the console window closes.

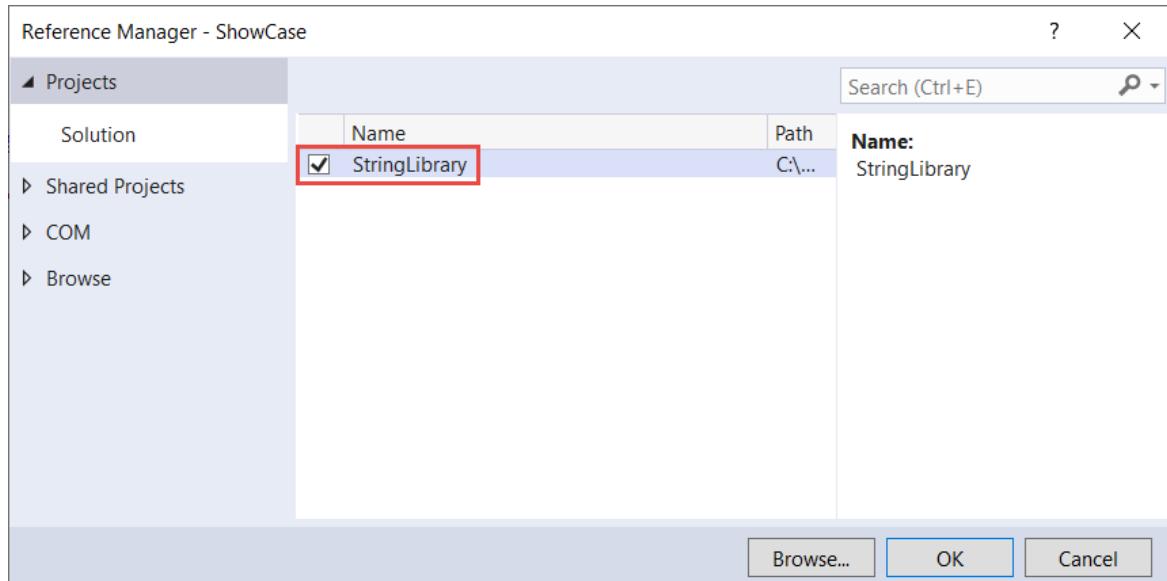

Add a project reference

Initially, the new console app project doesn't have access to the class library. To allow it to call methods in the class library, create a project reference to the class library project.

1. In **Solution Explorer**, right-click the `ShowCase` project's **Dependencies** node, and select **Add Project Reference**.

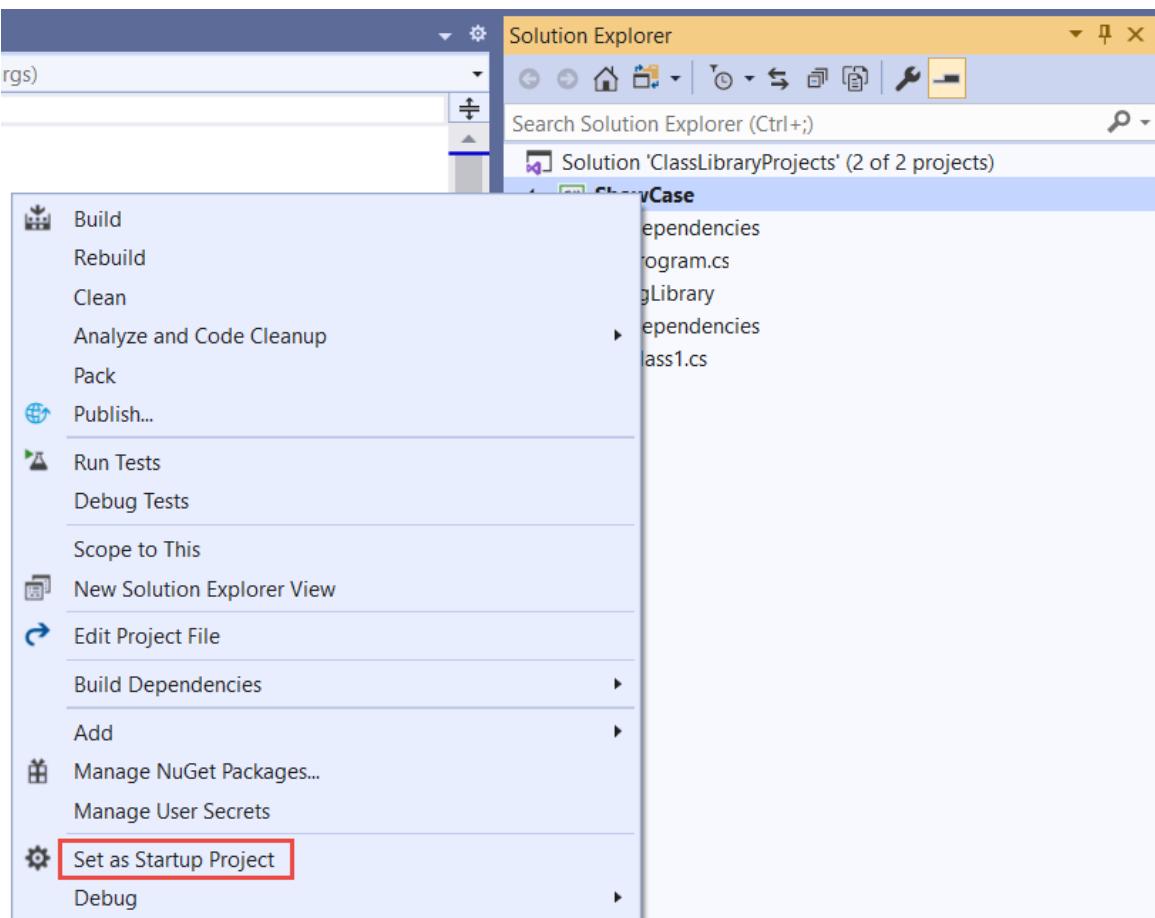

2. In the **Reference Manager** dialog, select the **StringLibrary** project, and select **OK**.

Run the app

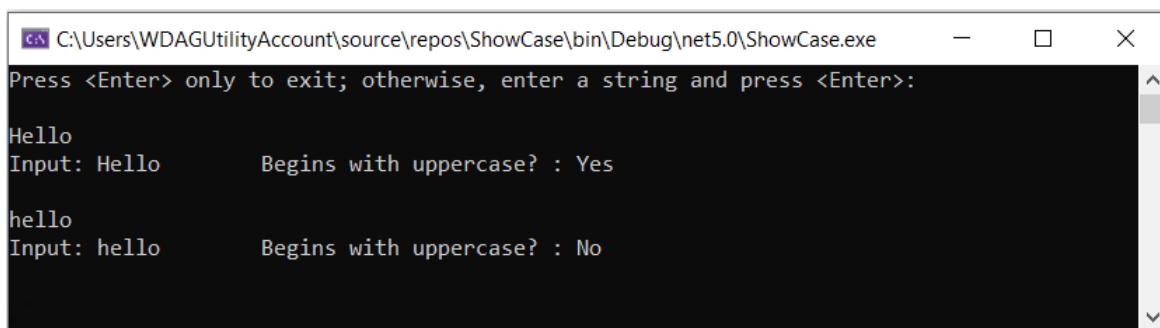

1. In **Solution Explorer**, right-click the **ShowCase** project and select **Set as StartUp Project** in the context menu.

2. Press Ctrl+F5 to compile and run the program without debugging.

3. Try out the program by entering strings and pressing Enter, then press Enter to exit.

Tutorial: Test a .NET class library with .NET using Visual Studio

9/20/2022 • 18 minutes to read • [Edit Online](#)

This tutorial shows how to automate unit testing by adding a test project to a solution.

Prerequisites

- This tutorial works with the solution that you create in [Create a .NET class library using Visual Studio](#).

Create a unit test project

Unit tests provide automated software testing during your development and publishing. [MSTest](#) is one of three test frameworks you can choose from. The others are [xUnit](#) and [nUnit](#).

1. Start Visual Studio.
2. Open the `ClassLibraryProjects` solution you created in [Create a .NET class library using Visual Studio](#).
3. Add a new unit test project named "StringLibraryTest" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New project**.
 - b. On the **Add a new project** page, enter **mstest** in the search box. Choose **C# or Visual Basic** from the Language list, and then choose **All platforms** from the Platform list.
 - c. Choose the **MSTest Test Project** template, and then choose **Next**.
 - d. On the **Configure your new project** page, enter **StringLibraryTest** in the **Project name** box. Then choose **Next**.
 - e. On the **Additional information** page, select **.NET 6 (Long-term support)** in the **Framework** box. Then choose **Create**.
4. Visual Studio creates the project and opens the class file in the code window with the following code. If the language you want to use is not shown, change the language selector at the top of the page.

```
using Microsoft.VisualStudio.TestTools.UnitTesting;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestMethod1()
        {
        }
    }
}
```

```

Imports Microsoft.VisualStudio.TestTools.UnitTesting

Namespace StringLibraryTest
    <TestClass>
    Public Class UnitTest1
        <TestMethod>
        Sub TestSub()

            End Sub
        End Class
    End Namespace

```

The source code created by the unit test template does the following:

- It imports the `Microsoft.VisualStudio.TestTools.UnitTesting` namespace, which contains the types used for unit testing.
- It applies the `TestClassAttribute` attribute to the `UnitTest1` class.
- It applies the `TestMethodAttribute` attribute to define `TestMethod1` in C# or `TestSub` in Visual Basic.

Each method tagged with `[TestMethod]` in a test class tagged with `[TestClass]` is executed automatically when the unit test is run.

Add a project reference

For the test project to work with the `StringLibrary` class, add a reference in the `StringLibraryTest` project to the `StringLibrary` project.

1. In **Solution Explorer**, right-click the **Dependencies** node of the `StringLibraryTest` project and select **Add Project Reference** from the context menu.
2. In the **Reference Manager** dialog, expand the **Projects** node, and select the box next to `StringLibrary`. Adding a reference to the `StringLibrary` assembly allows the compiler to find `StringLibrary` methods while compiling the `StringLibraryTest` project.
3. Select **OK**.

Add and run unit test methods

When Visual Studio runs a unit test, it executes each method that is marked with the `TestMethodAttribute` attribute in a class that is marked with the `TestClassAttribute` attribute. A test method ends when the first failure is found or when all tests contained in the method have succeeded.

The most common tests call members of the `Assert` class. Many assert methods include at least two parameters, one of which is the expected test result and the other of which is the actual test result. Some of the `Assert` class's most frequently called methods are shown in the following table:

ASSERT METHODS	FUNCTION
<code>Assert.AreEqual</code>	Verifies that two values or objects are equal. The assert fails if the values or objects aren't equal.
<code>Assert.AreSame</code>	Verifies that two object variables refer to the same object. The assert fails if the variables refer to different objects.
<code>Assert.IsFalse</code>	Verifies that a condition is <code>false</code> . The assert fails if the condition is <code>true</code> .

ASSERT METHODS	FUNCTION
<code>Assert.IsNotNull</code>	Verifies that an object isn't <code>null</code> . The assert fails if the object is <code>null</code> .

You can also use the `Assert.ThrowsException` method in a test method to indicate the type of exception it's expected to throw. The test fails if the specified exception isn't thrown.

In testing the `StringLibrary.StartsWithUpper` method, you want to provide a number of strings that begin with an uppercase character. You expect the method to return `true` in these cases, so you can call the `Assert.IsTrue` method. Similarly, you want to provide a number of strings that begin with something other than an uppercase character. You expect the method to return `false` in these cases, so you can call the `Assert.IsFalse` method.

Since your library method handles strings, you also want to make sure that it successfully handles an `empty string` (`String.Empty`), a valid string that has no characters and whose `Length` is 0, and a `null` string that hasn't been initialized. You can call `StartsWithUpper` directly as a static method and pass a single `String` argument. Or you can call `StartsWithUpper` as an extension method on a `string` variable assigned to `null`.

You'll define three methods, each of which calls an `Assert` method for each element in a string array. You'll call a method overload that lets you specify an error message to be displayed in case of test failure. The message identifies the string that caused the failure.

To create the test methods:

1. In the `UnitTest1.cs` or `UnitTest1.vb` code window, replace the code with the following code:

```

using Microsoft.VisualStudio.TestTools.UnitTesting;
using UtilityLibraries;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestStartsWithUpper()
        {
            // Tests that we expect to return true.
            string[] words = { "Alphabet", "Zebra", "ABC", "Αθήνα", "Москва" };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsTrue(result,
                    string.Format("Expected for '{0}': true; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void TestDoesNotStartWithUpper()
        {
            // Tests that we expect to return false.
            string[] words = { "alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                "1234", ".", ";", " " };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void DirectCallWithNullOrEmpty()
        {
            // Tests that we expect to return false.
            string?[] words = { string.Empty, null };
            foreach (var word in words)
            {
                bool result = StringLibrary.StartsWithUpper(word ?? string.Empty);
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word == null ? "<null>" : word, result));
            }
        }
    }
}

```

```

Imports Microsoft.VisualStudio.TestTools.UnitTesting
Imports UtilityLibraries

Namespace StringLibraryTest
    <TestClass>
    Public Class UnitTest1
        <TestMethod>
        Public Sub TestStartsWithUpper()
            ' Tests that we expect to return true.
            Dim words() As String = {"Alphabet", "Zebra", "ABC", "Αθήνα", "Москва"}
            For Each word In words
                Dim result As Boolean = word.StartsWithUpper()
                Assert.IsTrue(result,
                    $"Expected for '{word}': true; Actual: {result}")
            Next
        End Sub

        <TestMethod>
        Public Sub TestDoesNotStartWithUpper()
            ' Tests that we expect to return false.
            Dim words() As String = {"alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία",
"государство",
                "1234", ".", ";", " "}
            For Each word In words
                Dim result As Boolean = word.StartsWithUpper()
                Assert.IsFalse(result,
                    $"Expected for '{word}': false; Actual: {result}")
            Next
        End Sub

        <TestMethod>
        Public Sub DirectCallWithNullOrEmpty()
            ' Tests that we expect to return false.
            Dim words() As String = {String.Empty, Nothing}
            For Each word In words
                Dim result As Boolean = StringLibrary.StartsWithUpper(word)
                Assert.IsFalse(result,
                    $"Expected for '{If(word Is Nothing, "<null>", word)}': false; Actual:
{result}")
            Next
        End Sub
    End Class
End Namespace

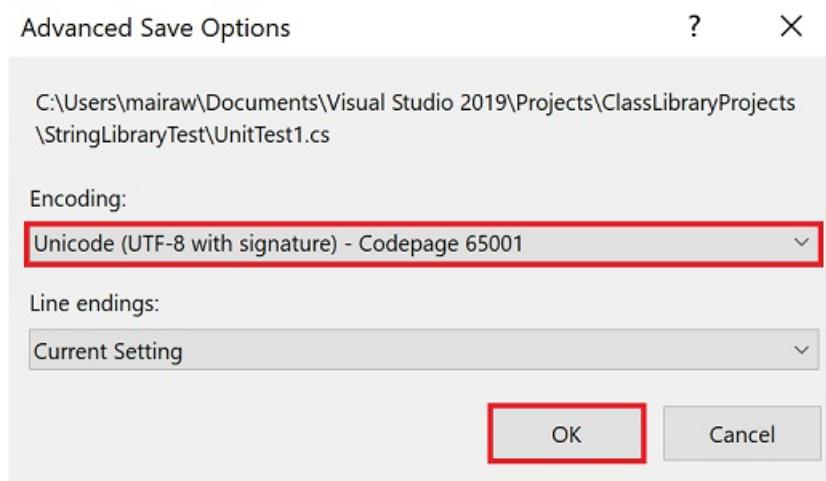

```

The test of uppercase characters in the `TestStartsWithUpper` method includes the Greek capital letter alpha (U+0391) and the Cyrillic capital letter EM (U+041C). The test of lowercase characters in the `TestDoesNotStartWithUpper` method includes the Greek small letter alpha (U+03B1) and the Cyrillic small letter Ghe (U+0433).

2. On the menu bar, select **File > Save UnitTest1.cs As** or **File > Save UnitTest1.vb As**. In the **Save File As** dialog, select the arrow beside the **Save** button, and select **Save with Encoding**.

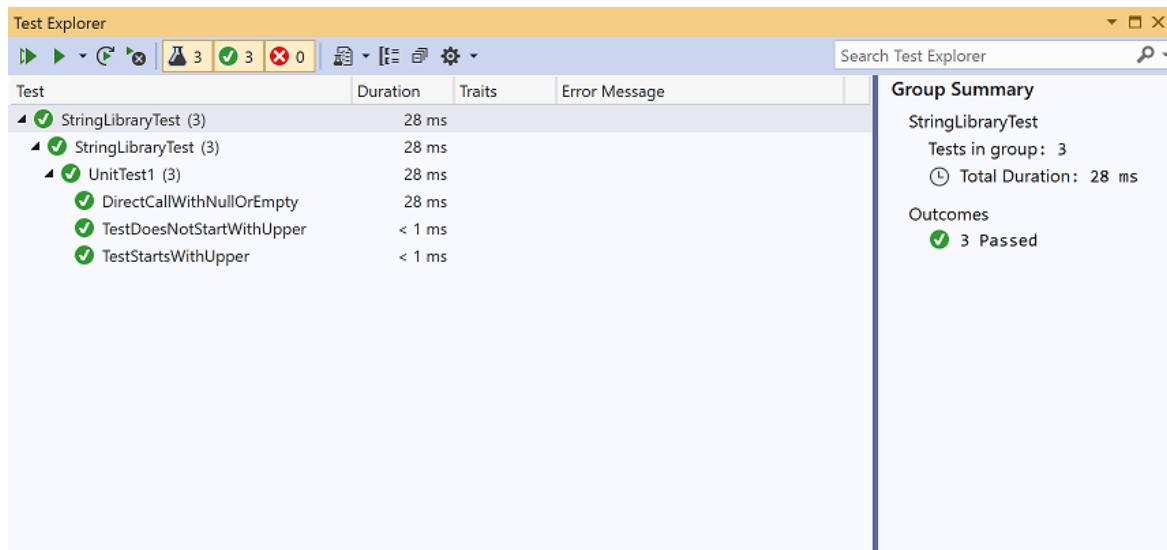

3. In the **Confirm Save As** dialog, select the **Yes** button to save the file.
4. In the **Advanced Save Options** dialog, select **Unicode (UTF-8 with signature) - Codepage 65001** from the **Encoding** drop-down list and select **OK**.

If you fail to save your source code as a UTF8-encoded file, Visual Studio may save it as an ASCII file. When that happens, the runtime doesn't accurately decode the UTF8 characters outside of the ASCII range, and the test results won't be correct.

5. On the menu bar, select **Test > Run All Tests**. If the **Test Explorer** window doesn't open, open it by choosing **Test > Test Explorer**. The three tests are listed in the **Passed Tests** section, and the **Summary** section reports the result of the test run.

Handle test failures

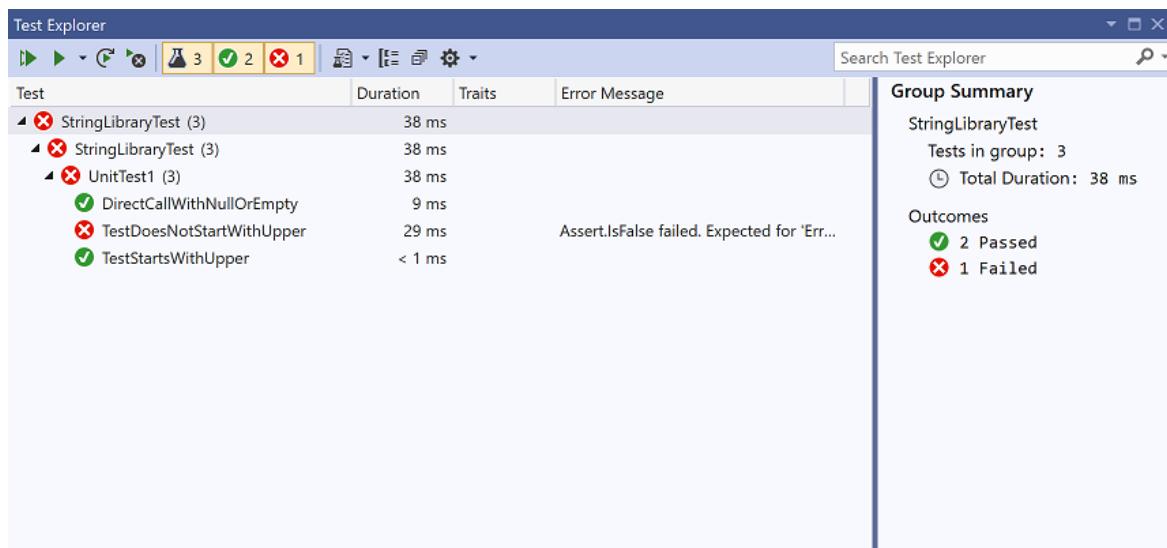

If you're doing test-driven development (TDD), you write tests first and they fail the first time you run them. Then you add code to the app that makes the test succeed. For this tutorial, you created the test after writing the app code that it validates, so you haven't seen the test fail. To validate that a test fails when you expect it to fail, add an invalid value to the test input.

1. Modify the `words` array in the `TestDoesNotStartWithUpper` method to include the string "Error". You don't need to save the file because Visual Studio automatically saves open files when a solution is built to run tests.

```
string[] words = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                   "1234", ".", ";" };
```

```
Dim words() As String = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                           "1234", ".", ";" };
```

2. Run the test by selecting **Test > Run All Tests** from the menu bar. The **Test Explorer** window indicates that two tests succeeded and one failed.

3. Select the failed test, `TestDoesNotStartWithUpper`.

The **Test Explorer** window displays the message produced by the assert: "Assert.IsFalse failed. Expected

for 'Error': false; actual: True". Because of the failure, no strings in the array after "Error" were tested.

Test Detail Summary

✖ TestDoesNotStartWithUpper

Source: [UnitTest1.cs](#) line 25

Duration: 29 ms

Message:

```
Assert.IsFalse failed. Expected for 'Error': false; Actual: True
```

Stack Trace:

```
UnitTest1.TestDoesNotStartWithUpper\(\) line 34
```

4. Remove the string "Error" that you added in step 1. Rerun the test and the tests pass.

Test the Release version of the library

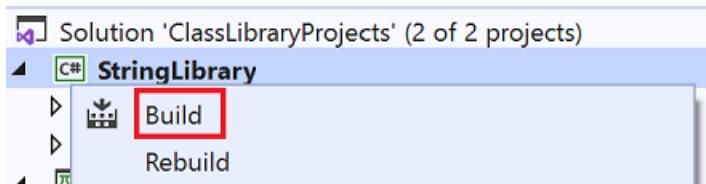

Now that the tests have all passed when running the Debug build of the library, run the tests an additional time against the Release build of the library. A number of factors, including compiler optimizations, can sometimes produce different behavior between Debug and Release builds.

To test the Release build:

1. In the Visual Studio toolbar, change the build configuration from **Debug** to **Release**.

2. In **Solution Explorer**, right-click the **StringLibrary** project and select **Build** from the context menu to recompile the library.

3. Run the unit tests by choosing **Test > Run All Tests** from the menu bar. The tests pass.

Debug tests

If you're using Visual Studio as your IDE, you can use the same process shown in [Tutorial: Debug a .NET console application using Visual Studio](#) to debug code using your unit test project. Instead of starting the *ShowCase* app project, right-click the **StringLibraryTests** project, and select **Debug Tests** from the context menu.

Visual Studio starts the test project with the debugger attached. Execution will stop at any breakpoint you've added to the test project or the underlying library code.

Next steps

In this tutorial, you unit tested a class library. You can make the library available to others by publishing it to

NuGet as a package. To learn how, follow a NuGet tutorial:

[Create and publish a NuGet package using Visual Studio](#)

If you publish a library as a NuGet package, others can install and use it. To learn how, follow a NuGet tutorial:

[Install and use a package in Visual Studio](#)

A library doesn't have to be distributed as a package. It can be bundled with a console app that uses it. To learn how to publish a console app, see the earlier tutorial in this series:

[Publish a .NET console application using Visual Studio](#)

This tutorial shows how to automate unit testing by adding a test project to a solution.

Prerequisites

- This tutorial works with the solution that you create in [Create a .NET class library using Visual Studio](#).

Create a unit test project

Unit tests provide automated software testing during your development and publishing. [MSTest](#) is one of three test frameworks you can choose from. The others are [xUnit](#) and [nUnit](#).

1. Start Visual Studio.
2. Open the `ClassLibraryProjects` solution you created in [Create a .NET class library using Visual Studio](#).
3. Add a new unit test project named "StringLibraryTest" to the solution.
 - a. Right-click on the solution in **Solution Explorer** and select **Add > New project**.
 - b. On the **Add a new project** page, enter `mstest` in the search box. Choose **C# or Visual Basic** from the Language list, and then choose **All platforms** from the Platform list.
 - c. Choose the **MSTest Test Project** template, and then choose **Next**.
 - d. On the **Configure your new project** page, enter `StringLibraryTest` in the **Project name** box. Then choose **Next**.
 - e. On the **Additional information** page, select **.NET 5.0 (Current)** in the **Target Framework** box. Then choose **Create**.
4. Visual Studio creates the project and opens the class file in the code window with the following code. If the language you want to use is not shown, change the language selector at the top of the page.

```
using Microsoft.VisualStudio.TestTools.UnitTesting;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestMethod1()
        {
        }
    }
}
```

```

Imports Microsoft.VisualStudio.TestTools.UnitTesting

Namespace StringLibraryTest
    <TestClass>
    Public Class UnitTest1
        <TestMethod>
        Sub TestSub()

            End Sub
        End Class
    End Namespace

```

The source code created by the unit test template does the following:

- It imports the `Microsoft.VisualStudio.TestTools.UnitTesting` namespace, which contains the types used for unit testing.
- It applies the `TestClassAttribute` attribute to the `UnitTest1` class.
- It applies the `TestMethodAttribute` attribute to define `TestMethod1` in C# or `TestSub` in Visual Basic.

Each method tagged with `[TestMethod]` in a test class tagged with `[TestClass]` is executed automatically when the unit test is run.

Add a project reference

For the test project to work with the `StringLibrary` class, add a reference in the `StringLibraryTest` project to the `StringLibrary` project.

1. In **Solution Explorer**, right-click the **Dependencies** node of the `StringLibraryTest` project and select **Add Project Reference** from the context menu.
2. In the **Reference Manager** dialog, expand the **Projects** node, and select the box next to `StringLibrary`. Adding a reference to the `StringLibrary` assembly allows the compiler to find `StringLibrary` methods while compiling the `StringLibraryTest` project.
3. Select **OK**.

Add and run unit test methods

When Visual Studio runs a unit test, it executes each method that is marked with the `TestMethodAttribute` attribute in a class that is marked with the `TestClassAttribute` attribute. A test method ends when the first failure is found or when all tests contained in the method have succeeded.

The most common tests call members of the `Assert` class. Many assert methods include at least two parameters, one of which is the expected test result and the other of which is the actual test result. Some of the `Assert` class's most frequently called methods are shown in the following table:

ASSERT METHODS	FUNCTION
<code>Assert.AreEqual</code>	Verifies that two values or objects are equal. The assert fails if the values or objects aren't equal.
<code>Assert.AreSame</code>	Verifies that two object variables refer to the same object. The assert fails if the variables refer to different objects.
<code>Assert.IsFalse</code>	Verifies that a condition is <code>false</code> . The assert fails if the condition is <code>true</code> .

ASSERT METHODS	FUNCTION
<code>Assert.IsNotNull</code>	Verifies that an object isn't <code>null</code> . The assert fails if the object is <code>null</code> .

You can also use the `Assert.ThrowsException` method in a test method to indicate the type of exception it's expected to throw. The test fails if the specified exception isn't thrown.

In testing the `StringLibrary.StartsWithUpper` method, you want to provide a number of strings that begin with an uppercase character. You expect the method to return `true` in these cases, so you can call the `Assert.IsTrue` method. Similarly, you want to provide a number of strings that begin with something other than an uppercase character. You expect the method to return `false` in these cases, so you can call the `Assert.IsFalse` method.

Since your library method handles strings, you also want to make sure that it successfully handles an `empty string` (`String.Empty`), a valid string that has no characters and whose `Length` is 0, and a `null` string that hasn't been initialized. You can call `StartsWithUpper` directly as a static method and pass a single `String` argument. Or you can call `StartsWithUpper` as an extension method on a `string` variable assigned to `null`.

You'll define three methods, each of which calls an `Assert` method for each element in a string array. You'll call a method overload that lets you specify an error message to be displayed in case of test failure. The message identifies the string that caused the failure.

To create the test methods:

1. In the `UnitTest1.cs` or `UnitTest1.vb` code window, replace the code with the following code:

```
using Microsoft.VisualStudio.TestTools.UnitTesting;
using UtilityLibraries;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestStartsWithUpper()
        {
            // Tests that we expect to return true.
            string[] words = { "Alphabet", "Zebra", "ABC", "Αθήνα", "Москва" };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsTrue(result,
                    string.Format("Expected for '{0}': true; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void TestDoesNotStartWithUpper()
        {
            // Tests that we expect to return false.
            string[] words = { "alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                "1234", ".", ";", " " };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void DirectCallWithNullOrEmpty()
        {
            // Tests that we expect to return false.
            string?[] words = { string.Empty, null };
            foreach (var word in words)
            {
                bool result = StringLibrary.StartsWithUpper(word ?? string.Empty);
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word == null ? "<null>" : word, result));
            }
        }
    }
}
```

```

Imports Microsoft.VisualStudio.TestTools.UnitTesting
Imports UtilityLibraries

Namespace StringLibraryTest
    <TestClass>
    Public Class UnitTest1
        <TestMethod>
        Public Sub TestStartsWithUpper()
            ' Tests that we expect to return true.
            Dim words() As String = {"Alphabet", "Zebra", "ABC", "Αθήνα", "Москва"}
            For Each word In words
                Dim result As Boolean = word.StartsWithUpper()
                Assert.IsTrue(result,
                    $"Expected for '{word}': true; Actual: {result}")
            Next
        End Sub

        <TestMethod>
        Public Sub TestDoesNotStartWithUpper()
            ' Tests that we expect to return false.
            Dim words() As String = {"alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία",
"государство",
                "1234", ".", ";", " "}
            For Each word In words
                Dim result As Boolean = word.StartsWithUpper()
                Assert.IsFalse(result,
                    $"Expected for '{word}': false; Actual: {result}")
            Next
        End Sub

        <TestMethod>
        Public Sub DirectCallWithNullOrEmpty()
            ' Tests that we expect to return false.
            Dim words() As String = {String.Empty, Nothing}
            For Each word In words
                Dim result As Boolean = StringLibrary.StartsWithUpper(word)
                Assert.IsFalse(result,
                    $"Expected for '{If(word Is Nothing, "<null>", word)}': false; Actual:
{result}")
            Next
        End Sub
    End Class
End Namespace

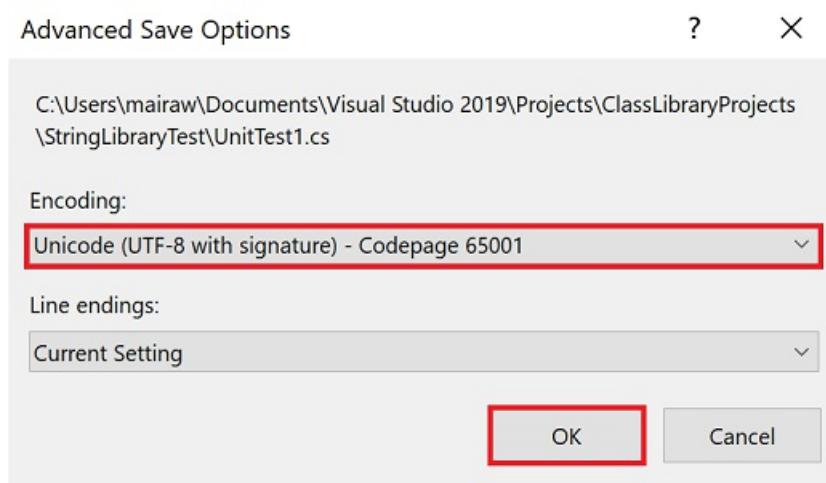

```

The test of uppercase characters in the `TestStartsWithUpper` method includes the Greek capital letter alpha (U+0391) and the Cyrillic capital letter EM (U+041C). The test of lowercase characters in the `TestDoesNotStartWithUpper` method includes the Greek small letter alpha (U+03B1) and the Cyrillic small letter Ghe (U+0433).

2. On the menu bar, select **File > Save UnitTest1.cs As** or **File > Save UnitTest1.vb As**. In the **Save File As** dialog, select the arrow beside the **Save** button, and select **Save with Encoding**.

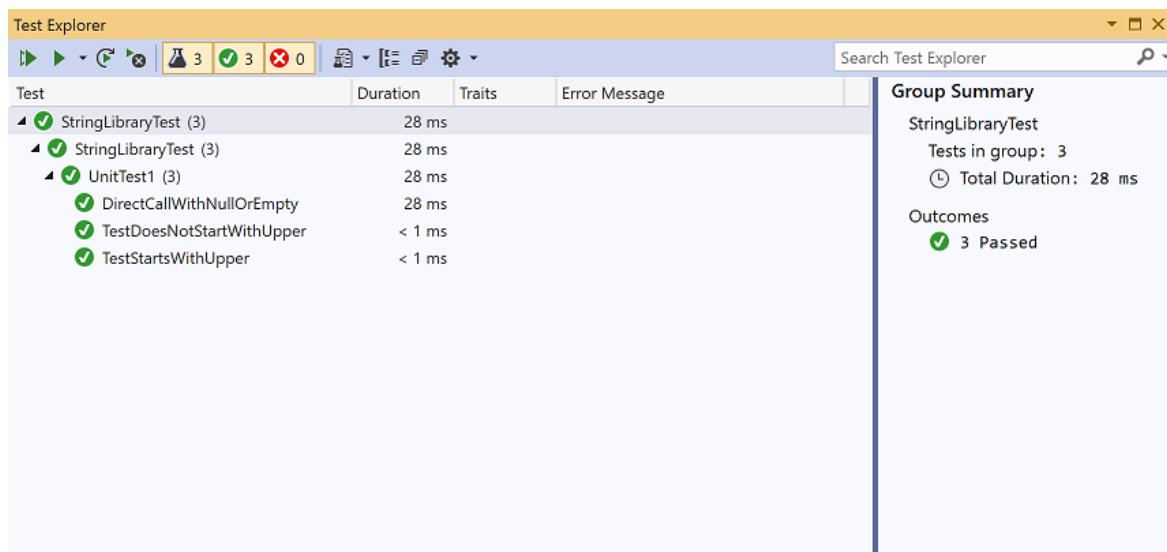

3. In the **Confirm Save As** dialog, select the **Yes** button to save the file.
4. In the **Advanced Save Options** dialog, select **Unicode (UTF-8 with signature) - Codepage 65001** from the **Encoding** drop-down list and select **OK**.

If you fail to save your source code as a UTF8-encoded file, Visual Studio may save it as an ASCII file. When that happens, the runtime doesn't accurately decode the UTF8 characters outside of the ASCII range, and the test results won't be correct.

5. On the menu bar, select **Test > Run All Tests**. If the **Test Explorer** window doesn't open, open it by choosing **Test > Test Explorer**. The three tests are listed in the **Passed Tests** section, and the **Summary** section reports the result of the test run.

Handle test failures

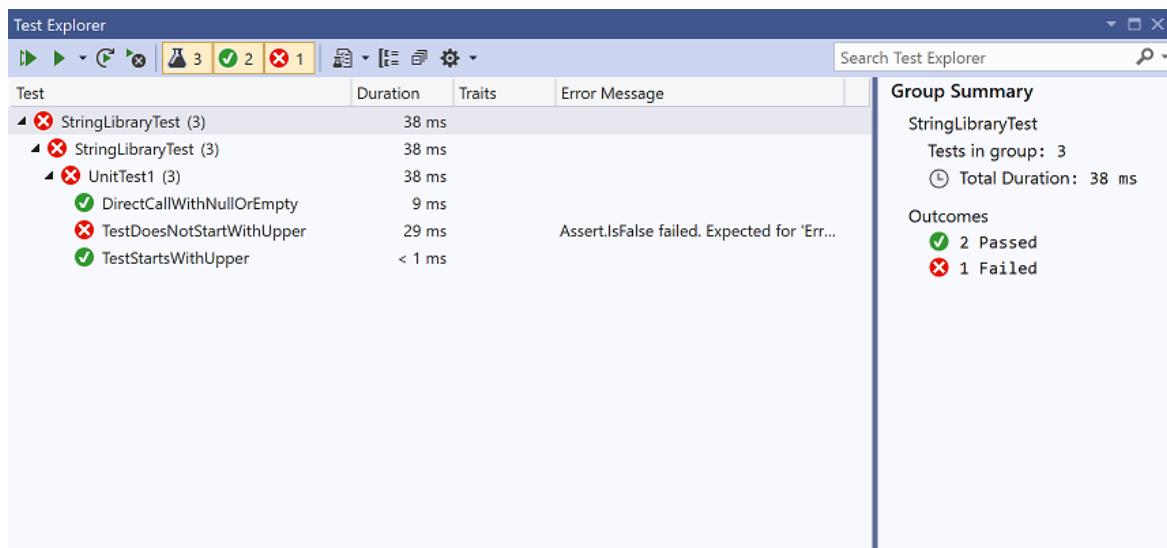

If you're doing test-driven development (TDD), you write tests first and they fail the first time you run them. Then you add code to the app that makes the test succeed. For this tutorial, you created the test after writing the app code that it validates, so you haven't seen the test fail. To validate that a test fails when you expect it to fail, add an invalid value to the test input.

1. Modify the `words` array in the `TestDoesNotStartWithUpper` method to include the string "Error". You don't need to save the file because Visual Studio automatically saves open files when a solution is built to run tests.

```
string[] words = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
    "1234", ".", ";" };
```

```
Dim words() As String = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
    "1234", ".", ";" };
```

2. Run the test by selecting **Test > Run All Tests** from the menu bar. The **Test Explorer** window indicates that two tests succeeded and one failed.

3. Select the failed test, `TestDoesNotStartWith`.

The **Test Explorer** window displays the message produced by the assert: "Assert.IsFalse failed. Expected

for 'Error': false; actual: True". Because of the failure, no strings in the array after "Error" were tested.

Test Detail Summary

✖ TestDoesNotStartWithUpper

Source: [UnitTest1.cs](#) line 25

Duration: 29 ms

Message:

 Assert.IsFalse failed. Expected for 'Error': false; Actual: True

Stack Trace:

[UnitTest1.TestDoesNotStartWithUpper\(\)](#) line 34

4. Remove the string "Error" that you added in step 1. Rerun the test and the tests pass.

Test the Release version of the library

Now that the tests have all passed when running the Debug build of the library, run the tests an additional time against the Release build of the library. A number of factors, including compiler optimizations, can sometimes produce different behavior between Debug and Release builds.

To test the Release build:

1. In the Visual Studio toolbar, change the build configuration from **Debug** to **Release**.

2. In **Solution Explorer**, right-click the **StringLibrary** project and select **Build** from the context menu to recompile the library.

3. Run the unit tests by choosing **Test Run > All Tests** from the menu bar. The tests pass.

Debug tests

If you're using Visual Studio as your IDE, you can use the same process shown in [Tutorial: Debug a .NET console application using Visual Studio](#) to debug code using your unit test project. Instead of starting the *ShowCase* app project, right-click the **StringLibraryTests** project, and select **Debug Tests** from the context menu.

Visual Studio starts the test project with the debugger attached. Execution will stop at any breakpoint you've added to the test project or the underlying library code.

- [Unit test basics - Visual Studio](#)
- [Unit testing in .NET](#)

Next steps

In this tutorial, you unit tested a class library. You can make the library available to others by publishing it to

NuGet as a package. To learn how, follow a NuGet tutorial:

[Create and publish a NuGet package using Visual Studio](#)

If you publish a library as a NuGet package, others can install and use it. To learn how, follow a NuGet tutorial:

[Install and use a package in Visual Studio](#)

A library doesn't have to be distributed as a package. It can be bundled with a console app that uses it. To learn how to publish a console app, see the earlier tutorial in this series:

[Publish a .NET console application using Visual Studio](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Create a .NET console application using Visual Studio Code

9/20/2022 • 7 minutes to read • [Edit Online](#)

This tutorial shows how to create and run a .NET console application by using Visual Studio Code and the .NET CLI. Project tasks, such as creating, compiling, and running a project are done by using the .NET CLI. You can follow this tutorial with a different code editor and run commands in a terminal if you prefer.

Prerequisites

- [Visual Studio Code](#) with the [C# extension](#) installed. For information about how to install extensions on Visual Studio Code, see [VS Code Extension Marketplace](#).
- The [.NET 6 SDK](#).

Create the app

Create a .NET console app project named "HelloWorld".

1. Start Visual Studio Code.
2. Select **File > Open Folder** (**File > Open...** on macOS) from the main menu.
3. In the **Open Folder** dialog, create a *HelloWorld* folder and select it. Then click **Select Folder** (**Open** on macOS).

The folder name becomes the project name and the namespace name by default. You'll add code later in the tutorial that assumes the project namespace is `HelloWorld`.

4. In the **Do you trust the authors of the files in this folder?** dialog, select **Yes, I trust the authors**.
5. Open the **Terminal** in Visual Studio Code by selecting **View > Terminal** from the main menu.

The **Terminal** opens with the command prompt in the *HelloWorld* folder.

6. In the **Terminal**, enter the following command:

```
dotnet new console --framework net6.0
```

The project template creates a simple application that displays "Hello World" in the console window by calling the [Console.WriteLine\(String\)](#) method in *Program.cs*.

```
Console.WriteLine("Hello, World!");
```

7. Replace the contents of *Program.cs* with the following code:

```
namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

The first time you edit a `.cs` file, Visual Studio Code prompts you to add the missing assets to build and debug your app. Select **Yes**, and Visual Studio Code creates a `.vscode` folder with `launch.json` and `tasks.json` files.

NOTE

If you don't get the prompt, or if you accidentally dismiss it without selecting **Yes**, do the following steps to create `launch.json` and `tasks.json`:

- Select **Run > Add Configuration** from the menu.
- Select **.NET 5+ and .NET Core** at the **Select environment** prompt.

The code defines a class, `Program`, with a single method, `Main`, that takes a `String` array as an argument. `Main` is the application entry point, the method that's called automatically by the runtime when it launches the application. Any command-line arguments supplied when the application is launched are available in the `args` array.

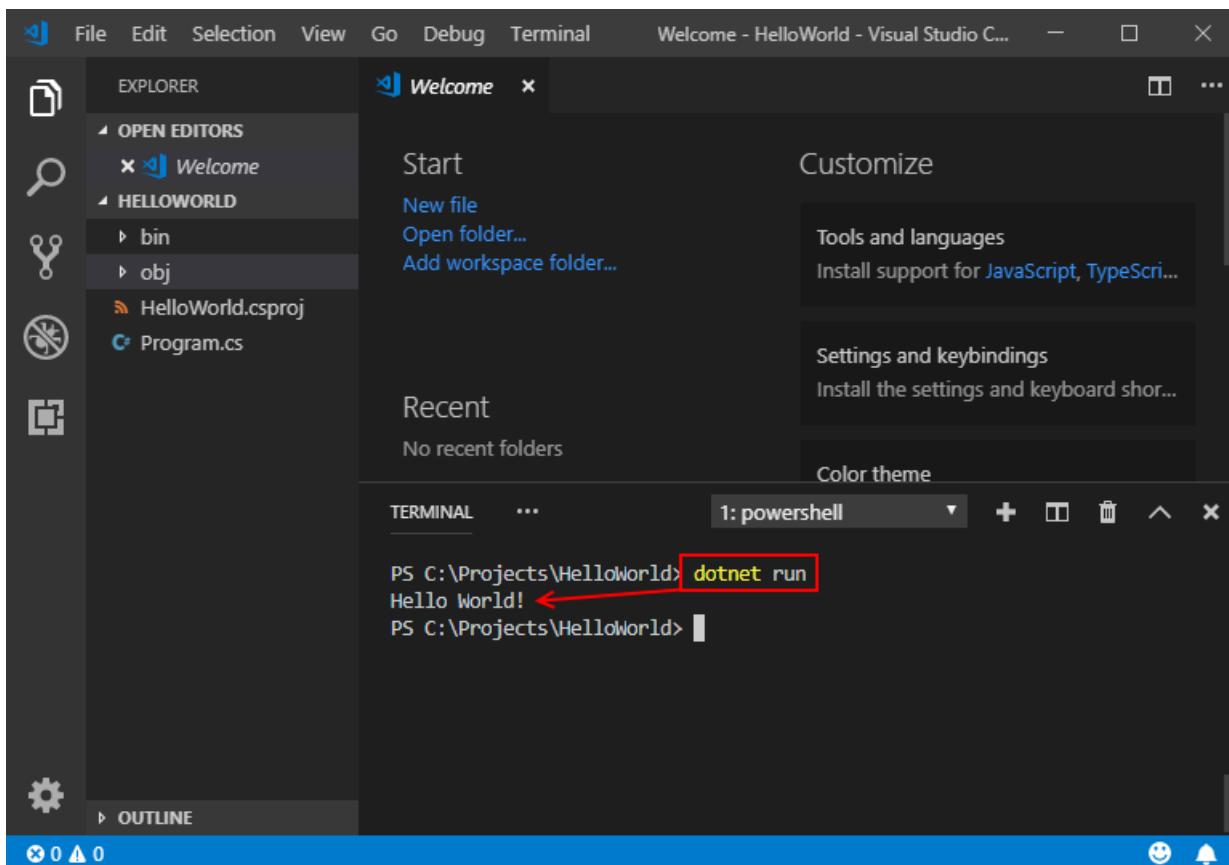

In the latest version of C#, a new feature named [top-level statements](#) lets you omit the `Program` class and the `Main` method. Most existing C# programs don't use top-level statements, so this tutorial doesn't use this new feature. But it's available in C# 10, and whether you use it in your programs is a matter of style preference.

Run the app

Run the following command in the **Terminal**:

```
dotnet run
```

The program displays "Hello World!" and ends.

Enhance the app

Enhance the application to prompt the user for their name and display it along with the date and time.

1. Open *Program.cs*.
2. Replace the contents of the `Main` method in *Program.cs*, which is the line that calls `Console.WriteLine`, with the following code:

```
Console.WriteLine("What is your name?");
var name = Console.ReadLine();
var currentDate = DateTime.Now;
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}!");
Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
Console.ReadKey(true);
```

This code displays a prompt in the console window and waits until the user enters a string followed by the Enter key. It stores this string in a variable named `name`. It also retrieves the value of the `DateTime.Now` property, which contains the current local time, and assigns it to a variable named `currentDate`. And it displays these values in the console window. Finally, it displays a prompt in the console window and calls the `Console.ReadKey(Boolean)` method to wait for user input.

`NewLine` is a platform-independent and language-independent way to represent a line break. Alternatives are `\n` in C# and `vbcrlf` in Visual Basic.

The dollar sign (`$`) in front of a string lets you put expressions such as variable names in curly braces in the string. The expression value is inserted into the string in place of the expression. This syntax is referred to as [interpolated strings](#).

3. Save your changes.

IMPORTANT

In Visual Studio Code, you have to explicitly save changes. Unlike Visual Studio, file changes are not automatically saved when you build and run an app.

- Run the program again:

```
dotnet run
```

- Respond to the prompt by entering a name and pressing the Enter key.

The screenshot shows the Visual Studio Code interface with the following details:

- File Bar:** File, Edit, Selection, View, Go, Run, Terminal, Help.
- Explorer:** Shows the project structure: OPEN EDITORS (Program.cs), CONSOLEAPP5 (vscode, bin, ConsoleApp5, obj, ConsoleApp5.sln, HelloWorld.csproj, Program.cs).
- Code Editor:** Displays the content of Program.cs:

```
1  using System;
2
3  namespace HelloWorld
4  {
5      class Program
6      {
7          static void Main(string[] args)
8          {
9              Console.WriteLine("What is your name?");
10             var name = Console.ReadLine();
11             var currentDate = DateTime.Now;
12             Console.WriteLine($"{Environment.NewLine}Hello, {name},
13             Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
14         }
15     }
}
```
- Terminal:** Shows the command `dotnet run` being run, followed by the user input "Nancy" and the application's response "Hello, Nancy, on 4/27/2021 at 8:52 AM!".
- Status Bar:** Shows the current file is Program.cs, encoding is C#, and the terminal has 2 tabs open.

- Press any key to exit the program.

Additional resources

- [Setting up Visual Studio Code](#)

Next steps

In this tutorial, you created a .NET console application. In the next tutorial, you debug the app.

Debug a .NET console application using Visual Studio Code

This tutorial shows how to create and run a .NET console application by using Visual Studio Code and the .NET CLI. Project tasks, such as creating, compiling, and running a project are done by using the .NET CLI. You can follow this tutorial with a different code editor and run commands in a terminal if you prefer.

Prerequisites

- Visual Studio Code with the [C# extension](#) installed. For information about how to install extensions on Visual Studio Code, see [VS Code Extension Marketplace](#).
- The [.NET 5 SDK](#). If you install the .NET 6 SDK, install the .NET 5 SDK also, or some of the tutorial instructions

won't work. For more information, see [New C# templates generate top-level statements](#).

Create the app

Create a .NET console app project named "HelloWorld".

1. Start Visual Studio Code.
2. Select **File > Open Folder** (**File > Open...** on macOS) from the main menu.
3. In the **Open Folder** dialog, create a *HelloWorld* folder and click **Select Folder** (Open on macOS).

The folder name becomes the project name and the namespace name by default. You'll add code later in the tutorial that assumes the project namespace is `HelloWorld`.

4. Open the **Terminal** in Visual Studio Code by selecting **View > Terminal** from the main menu.

The **Terminal** opens with the command prompt in the *HelloWorld* folder.

5. In the **Terminal**, enter the following command:

```
dotnet new console --framework net5.0
```

The template creates a simple "Hello World" application. It calls the `Console.WriteLine(String)` method to display "Hello World!" in the console window.

The template code defines a class, `Program`, with a single method, `Main`, that takes a `String` array as an argument:

```
using System;

namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

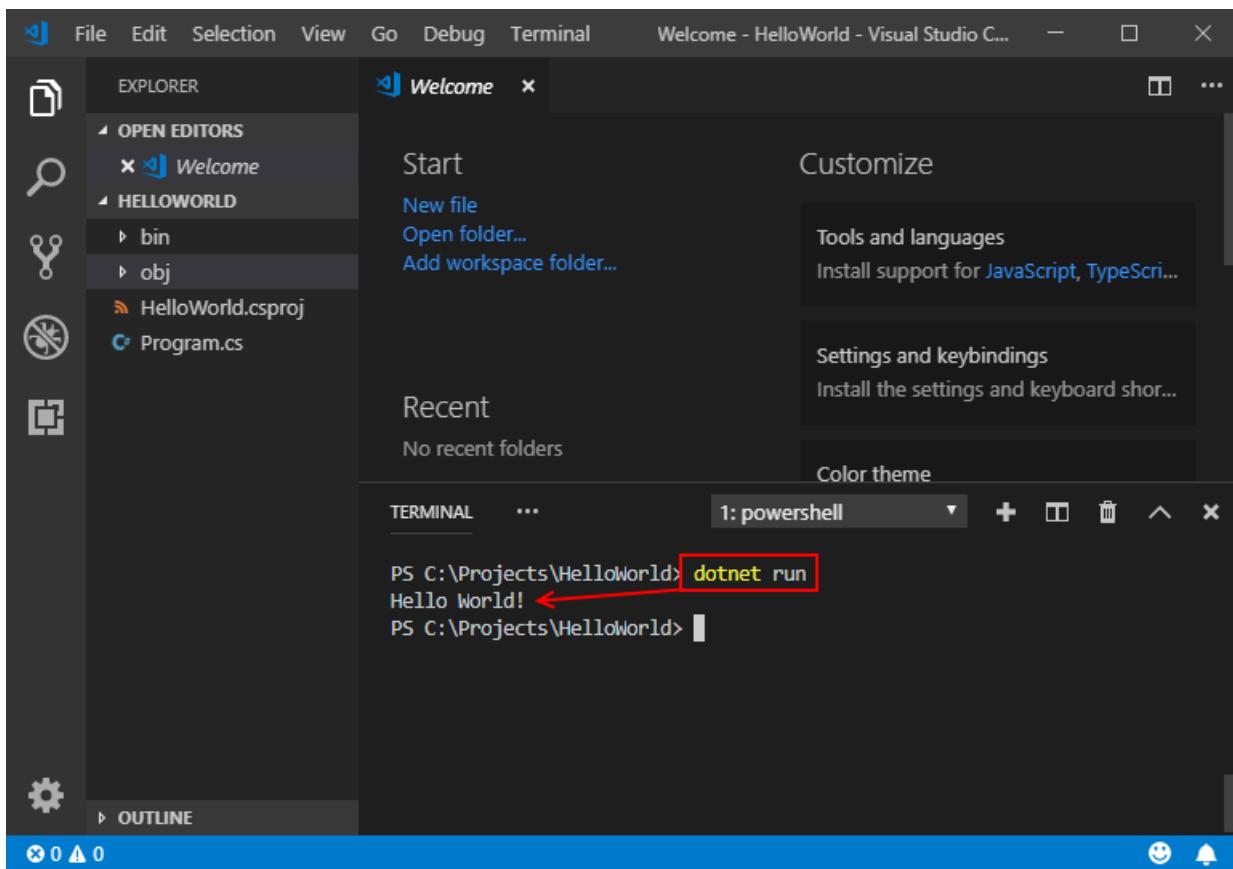

`Main` is the application entry point, the method that's called automatically by the runtime when it launches the application. Any command-line arguments supplied when the application is launched are available in the `args` array.

Run the app

Run the following command in the **Terminal**:

```
dotnet run
```

The program displays "Hello World!" and ends.

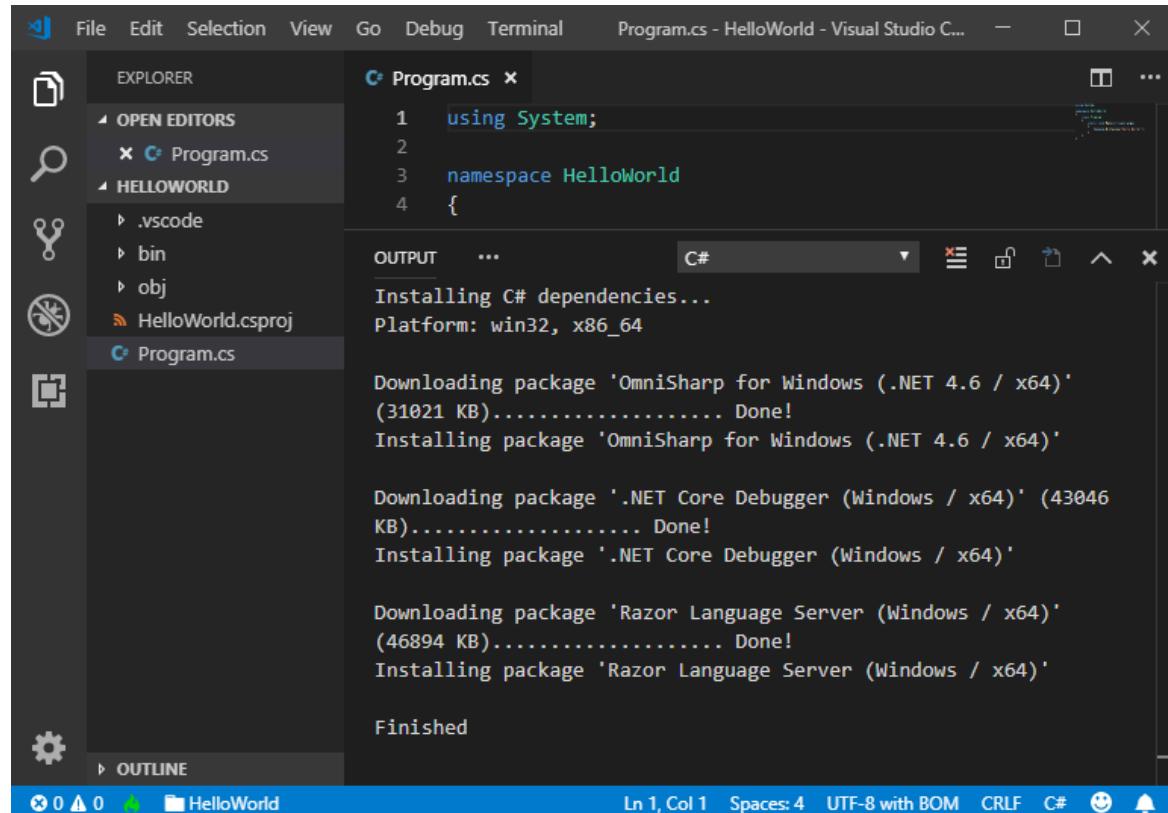

Enhance the app

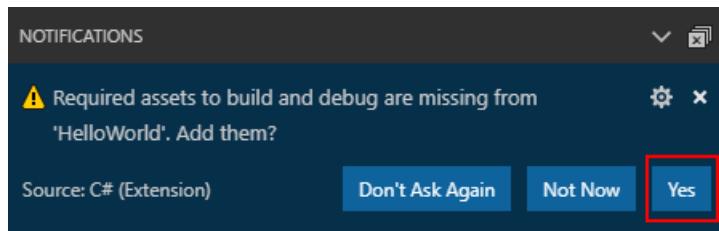

Enhance the application to prompt the user for their name and display it along with the date and time.

1. Open *Program.cs* by clicking on it.

The first time you open a C# file in Visual Studio Code, [OmniSharp](#) loads in the editor.

2. Select Yes when Visual Studio Code prompts you to add the missing assets to build and debug your app.

- Replace the contents of the `Main` method in `Program.cs`, which is the line that calls `Console.WriteLine`, with the following code:

```
Console.WriteLine("What is your name?");
var name = Console.ReadLine();
var currentDate = DateTime.Now;
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}!");
Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
Console.ReadKey(true);
```

This code displays a prompt in the console window and waits until the user enters a string followed by the Enter key. It stores this string in a variable named `name`. It also retrieves the value of the `DateTime.Now` property, which contains the current local time, and assigns it to a variable named `currentDate`. And it displays these values in the console window. Finally, it displays a prompt in the console window and calls the `Console.ReadKey(Boolean)` method to wait for user input.

`NewLine` is a platform-independent and language-independent way to represent a line break. Alternatives are `\n` in C# and `vbcrlf` in Visual Basic.

The dollar sign (`$`) in front of a string lets you put expressions such as variable names in curly braces in the string. The expression value is inserted into the string in place of the expression. This syntax is referred to as [interpolated strings](#).

- Save your changes.

IMPORTANT

In Visual Studio Code, you have to explicitly save changes. Unlike Visual Studio, file changes are not automatically saved when you build and run an app.

- Run the program again:

```
dotnet run
```

- Respond to the prompt by entering a name and pressing the Enter key.

The screenshot shows the Visual Studio Code interface with the following details:

- File Menu:** File, Edit, Selection, View, Go, Run, Terminal, Help.
- Title Bar:** Program.cs - ConsoleApp5 - Visual Studio Code.
- Sidebar (Left):** Explorer, Open Editors (Program.cs selected), Console Apps (ConsoleApp5 selected), and Solution Explorer (ConsoleApp5.sln selected).
- Editor Area:** Displays the contents of Program.cs:

```
1  using System;
2
3  namespace HelloWorld
4  {
5      // 0 references
6      class Program
7      {
8          // 0 references
9          static void Main(string[] args)
10         {
11             Console.WriteLine("What is your name?");
12             var name = Console.ReadLine();
13             var currentDate = DateTime.Now;
14             Console.WriteLine($"{Environment.NewLine}Hello, {name},");
15             Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
16             Console.ReadKey(true);
17         }
18     }
19 }
```
- Terminal:** Shows the command `dotnet run` being executed in the directory `C:\Users\thruk\source\repos\ConsoleApp5>`. The output shows the application prompting for a name ("What is your name?") and receiving "Nancy". It then outputs "Hello, Nancy, on 4/27/2021 at 8:52 AM!" followed by a prompt to press any key to exit.
- Bottom Status Bar:** Shows the status bar with icons for file operations, .NET Core Launch (console) (ConsoleApp5), Live Share, and file paths (ConsoleApp5.sln, csharp, Program.cs). It also shows CRLF, C#, and a bell icon.

7. Press any key to exit the program.

Additional resources

- Setting up Visual Studio Code

Next steps

In this tutorial, you created a .NET console application. In the next tutorial, you debug the app.

Debug a .NET console application using Visual Studio Code

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Debug a .NET console application using Visual Studio Code

9/20/2022 • 13 minutes to read • [Edit Online](#)

This tutorial introduces the debugging tools available in Visual Studio Code for working with .NET apps.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio Code](#).

Use Debug build configuration

Debug and *Release* are .NET's built-in build configurations. You use the Debug build configuration for debugging and the Release configuration for the final release distribution.

In the Debug configuration, a program compiles with full symbolic debug information and no optimization. Optimization complicates debugging, because the relationship between source code and generated instructions is more complex. The release configuration of a program has no symbolic debug information and is fully optimized.

By default, Visual Studio Code launch settings use the Debug build configuration, so you don't need to change it before debugging.

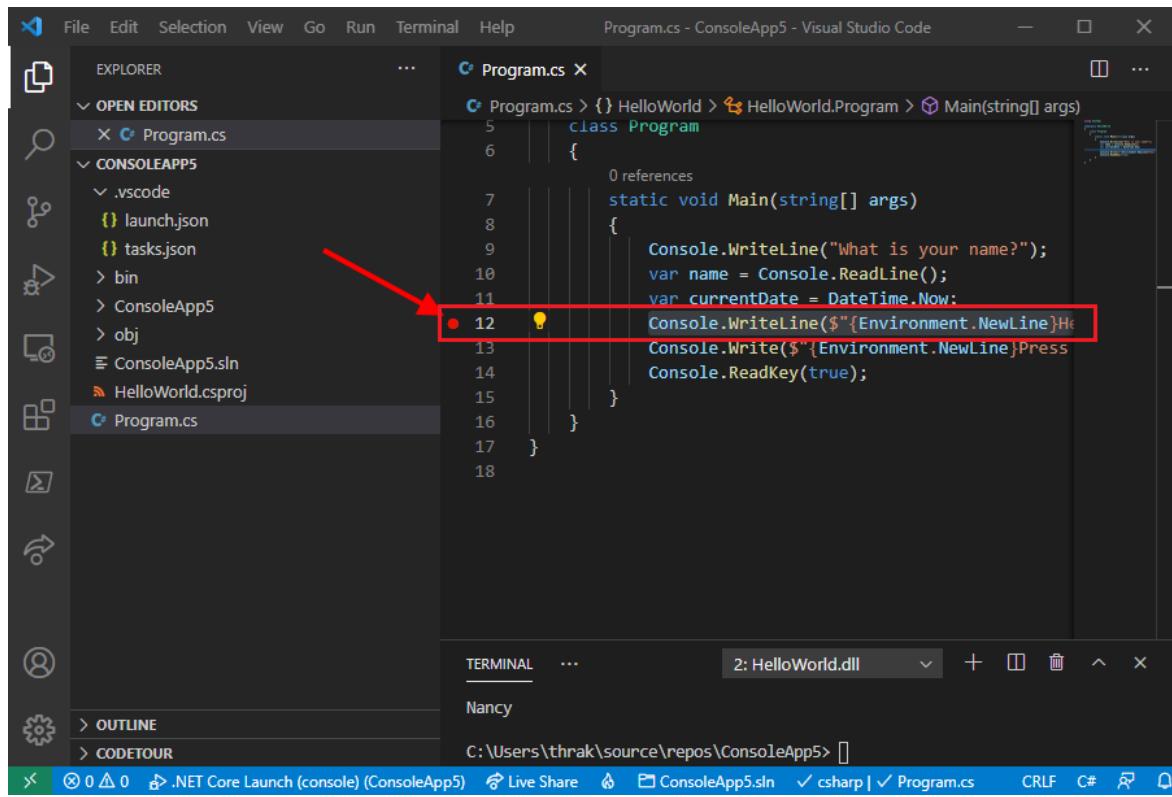

1. Start Visual Studio Code.
2. Open the folder of the project that you created in [Create a .NET console application using Visual Studio Code](#).

Set a breakpoint

A *breakpoint* temporarily interrupts the execution of the application before the line with the breakpoint is run.

1. Open the *Program.cs* file.
2. Set a *breakpoint* on the line that displays the name, date, and time, by clicking in the left margin of the code window. The left margin is to the left of the line numbers. Other ways to set a breakpoint are by pressing F9 or choosing **Run > Toggle Breakpoint** from the menu while the line of code is selected.

Visual Studio Code indicates the line on which the breakpoint is set by displaying a red dot in the left margin.

Set up for terminal input

The breakpoint is located after a `Console.ReadLine()` method call. The **Debug Console** doesn't accept terminal input for a running program. To handle terminal input while debugging, you can use the integrated terminal (one of the Visual Studio Code windows) or an external terminal. For this tutorial, you use the integrated terminal.

1. Open `.vscode/launch.json`.
2. Change the `console` setting from `internalConsole` to `integratedTerminal`:

```
"console": "integratedTerminal",
```

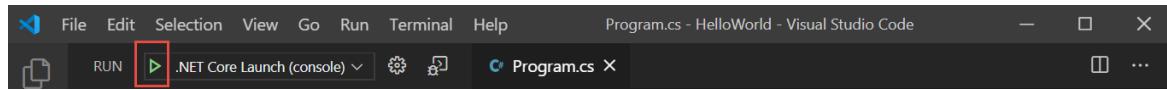

3. Save your changes.

Start debugging

1. Open the Debug view by selecting the Debugging icon on the left side menu.

A screenshot of Visual Studio Code showing the Debug sidebar open. The sidebar includes sections for VARIABLES, WATCH, CALL STACK, and BREAKPOINTS. A red box highlights the green arrow icon at the top of the sidebar, next to the ".NET Core Launch (console)" label. The main editor area shows a C# file named Program.cs with code for a HelloWorld application. The terminal at the bottom shows the path "C:\Users\thruk\source\repos\ConsoleApp5>".

2. Select the green arrow at the top of the pane, next to .NET Core Launch (console). Other ways to start the program in debugging mode are by pressing F5 or choosing Run > Start Debugging from the menu.

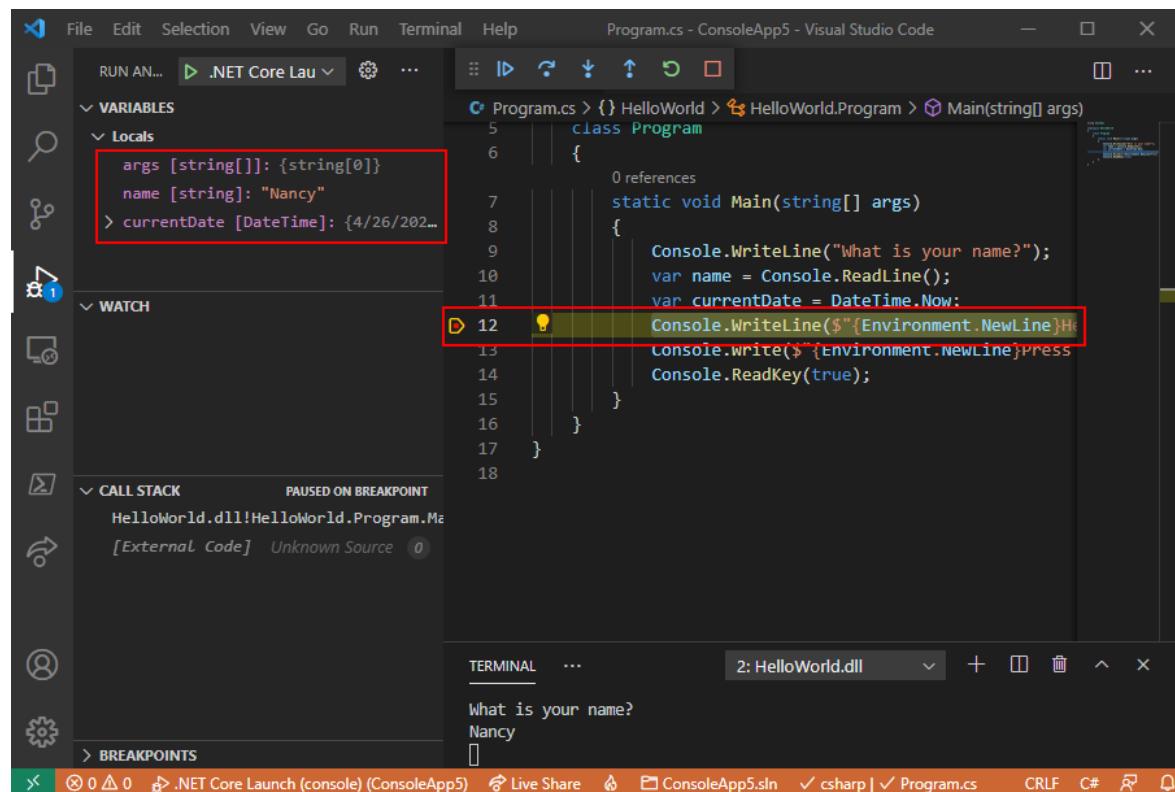

3. Select the Terminal tab to see the "What is your name?" prompt that the program displays before waiting for a response.

A screenshot of Visual Studio Code showing the Terminal tab selected in the bottom navigation bar. The main editor area shows the C# file (Program.cs) with the breakpoint at line 12. The terminal window at the bottom displays the text "What is your name?".

4. Enter a string in the Terminal window in response to the prompt for a name, and then press Enter.

Program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method runs.

The **Locals** section of the **Variables** window displays the values of variables that are defined in the currently running method.

Use the Debug Console

The **Debug Console** window lets you interact with the application you're debugging. You can change the value of variables to see how it affects your program.

1. Select the **Debug Console** tab.
2. Enter `name = "Gracie"` at the prompt at the bottom of the **Debug Console** window and press the Enter key.

A screenshot of Visual Studio Code showing the Debug Console tab selected. The code editor shows the same C# code as before. The terminal window shows the output: "What is your name? Nancy". A red box highlights the `DEBUG CONSOLE` tab. The bottom of the terminal window shows the prompt: "name = "Gracie"".

3. Enter `currentDate = DateTime.Parse("2019-11-16T17:25:00Z").ToUniversalTime()` at the bottom of the **Debug Console** window and press the Enter key.

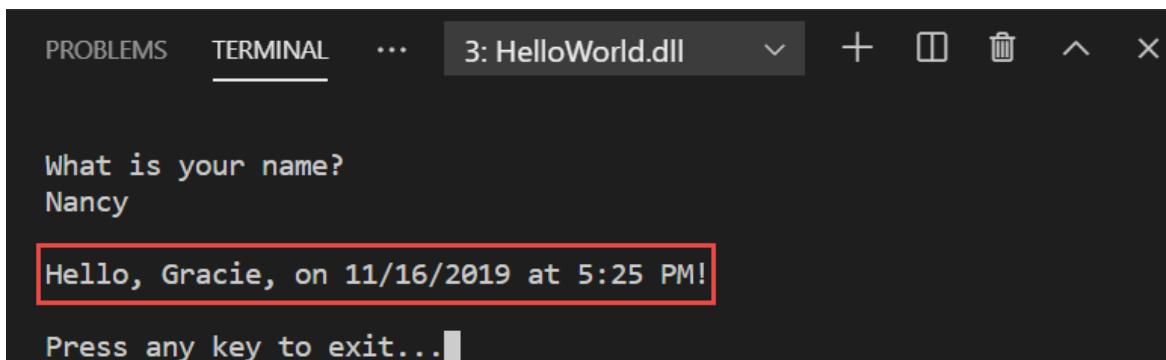

The **Variables** window displays the new values of the `name` and `currentDate` variables.

4. Continue program execution by selecting the **Continue** button in the toolbar. Another way to continue is by pressing F5.

5. Select the **Terminal** tab again.

The values displayed in the console window correspond to the changes you made in the **Debug Console**.

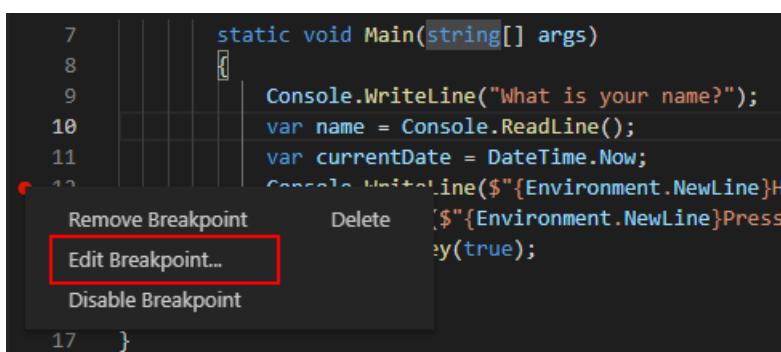

6. Press any key to exit the application and stop debugging.

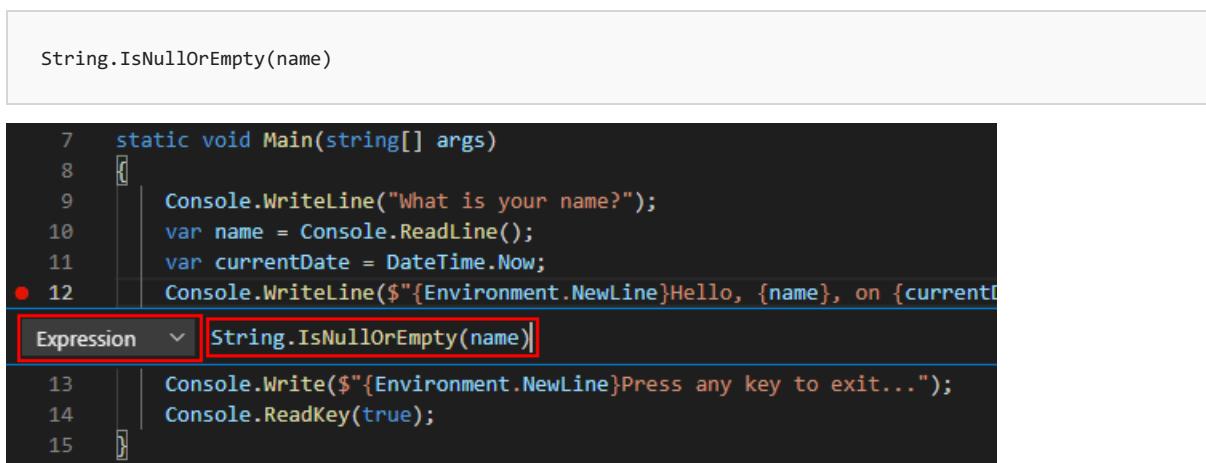

Set a conditional breakpoint

The program displays the string that the user enters. What happens if the user doesn't enter anything? You can test this with a useful debugging feature called a *conditional breakpoint*.

1. Right-click (Ctrl-click on macOS) on the red dot that represents the breakpoint. In the context menu, select **Edit Breakpoint** to open a dialog that lets you enter a conditional expression.

2. Select **Expression** in the drop-down, enter the following conditional expression, and press Enter.

Each time the breakpoint is hit, the debugger calls the `String.IsNullOrEmpty(name)` method, and it breaks

on this line only if the method call returns `true`.

Instead of a conditional expression, you can specify a *hit count*, which interrupts program execution before a statement is run a specified number of times. Another option is to specify a *filter condition*, which interrupts program execution based on such attributes as a thread identifier, process name, or thread name.

3. Start the program with debugging by pressing F5.
4. In the **Terminal** tab, press the Enter key when prompted to enter your name.

Because the condition you specified (`name` is either `null` or `String.Empty`) has been satisfied, program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method runs.

The **Variables** window shows that the value of the `name` variable is `""`, or `String.Empty`.

5. Confirm the value is an empty string by entering the following statement at the **Debug Console** prompt and pressing Enter. The result is `true`.

```
name == String.Empty
```

6. Select the **Continue** button on the toolbar to continue program execution.
7. Select the **Terminal** tab, and press any key to exit the program and stop debugging.
8. Clear the breakpoint by clicking on the dot in the left margin of the code window. Other ways to clear a breakpoint are by pressing F9 or choosing **Run > Toggle Breakpoint** from the menu while the line of code is selected.
9. If you get a warning that the breakpoint condition will be lost, select **Remove Breakpoint**.

Step through a program

Visual Studio Code also allows you to step line by line through a program and monitor its execution. Ordinarily, you'd set a breakpoint and follow program flow through a small part of your program code. Since this program is small, you can step through the entire program.

1. Set a breakpoint on the opening curly brace of the `Main` method.
2. Press F5 to start debugging.

Visual Studio Code highlights the breakpoint line.

At this point, the **Variables** window shows that the `args` array is empty, and `name` and `currentDate` have default values.

3. Select **Run > Step Into** or press F11.

Visual Studio Code highlights the next line.

4. Select **Run > Step Into** or press F11.

Visual Studio Code runs the `Console.WriteLine` for the name prompt and highlights the next line of execution. The next line is the `Console.ReadLine` for the `name`. The **Variables** window is unchanged, and the **Terminal** tab shows the "What is your name?" prompt.

5. Select **Run > Step Into** or press F11.

Visual Studio highlights the `name` variable assignment. The **Variables** window shows that `name` is still `null`.

6. Respond to the prompt by entering a string in the Terminal tab and pressing Enter.

The **Terminal** tab might not display the string you enter while you're entering it, but the `Console.ReadLine` method will capture your input.

7. Select **Run > Step Into** or press F11.

Visual Studio Code highlights the `currentDate` variable assignment. The **Variables** window shows the value returned by the call to the `Console.ReadLine` method. The **Terminal** tab displays the string you entered at the prompt.

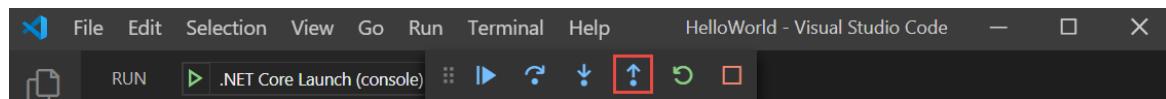

8. Select **Run > Step Into** or press F11.

The **Variables** window shows the value of the `currentDate` variable after the assignment from the `DateTime.Now` property.

9. Select **Run > Step Into** or press F11.

Visual Studio Code calls the `Console.WriteLine(String, Object, Object)` method. The console window displays the formatted string.

10. Select **Run > Step Out** or press Shift+F11.

11. Select the **Terminal** tab.

The terminal displays "Press any key to exit..."

12. Press any key to exit the program.

Use Release build configuration

Once you've tested the Debug version of your application, you should also compile and test the Release version. The Release version incorporates compiler optimizations that can affect the behavior of an application. For example, compiler optimizations that are designed to improve performance can create race conditions in multithreaded applications.

To build and test the Release version of your console application, open the **Terminal** and run the following command:

```
dotnet run --configuration Release
```

Additional resources

- [Debugging in Visual Studio Code](#)

Next steps

In this tutorial, you used Visual Studio Code debugging tools. In the next tutorial, you publish a deployable version of the app.

Publish a .NET console application using Visual Studio Code

This tutorial introduces the debugging tools available in Visual Studio Code for working with .NET apps.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio Code](#).

Use Debug build configuration

Debug and *Release* are .NET Core's built-in build configurations. You use the Debug build configuration for debugging and the Release configuration for the final release distribution.

In the Debug configuration, a program compiles with full symbolic debug information and no optimization. Optimization complicates debugging, because the relationship between source code and generated instructions is more complex. The release configuration of a program has no symbolic debug information and is fully optimized.

By default, Visual Studio Code launch settings use the Debug build configuration, so you don't need to change it before debugging.

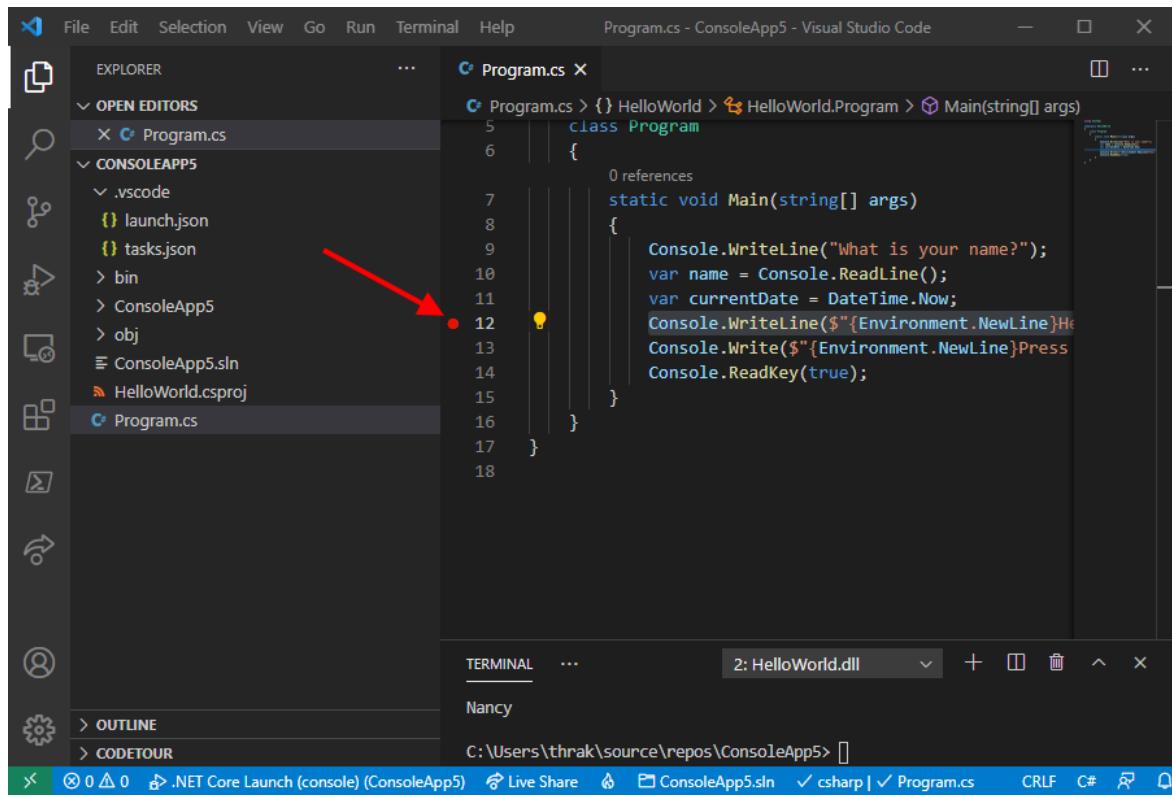

1. Start Visual Studio Code.
2. Open the folder of the project that you created in [Create a .NET console application using Visual Studio Code](#).

Set a breakpoint

A *breakpoint* temporarily interrupts the execution of the application before the line with the breakpoint is executed.

1. Open the *Program.cs* file.
2. Set a *breakpoint* on the line that displays the name, date, and time, by clicking in the left margin of the code window. The left margin is to the left of the line numbers. Other ways to set a breakpoint are by pressing F9 or choosing **Run > Toggle Breakpoint** from the menu while the line of code is selected.

Visual Studio Code indicates the line on which the breakpoint is set by displaying a red dot in the left margin.

Set up for terminal input

The breakpoint is located after a `Console.ReadLine()` method call. The **Debug** Console doesn't accept terminal input for a running program. To handle terminal input while debugging, you can use the integrated terminal (one of the Visual Studio Code windows) or an external terminal. For this tutorial, you use the integrated terminal.

1. Open `.vscode/launch.json`.
2. Change the `console` setting from `internalConsole` to `integratedTerminal`:

```
"console": "integratedTerminal",
```

3. Save your changes.

Start debugging

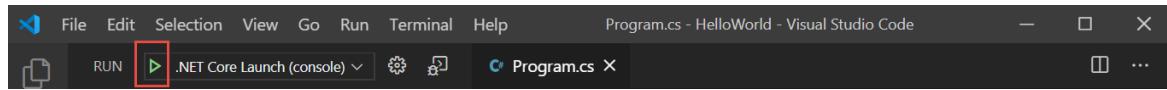

1. Open the Debug view by selecting the Debugging icon on the left side menu.

A screenshot of Visual Studio Code showing the Debug sidebar open. The sidebar includes sections for VARIABLES, WATCH, CALL STACK, and BREAKPOINTS. A red box highlights the green arrow icon at the top of the sidebar, next to the ".NET Core Launch (console)" button. The code editor shows a C# file named Program.cs with the following code:

```
1 using System;
2
3 namespace HelloWorld
4 {
5     0 references
6     class Program
7     {
8         0 references
9         static void Main(string[] args)
10        {
11            Console.WriteLine("What is your name?");
12            var name = Console.ReadLine();
13            var currentDate = DateTime.Now;
14            Console.WriteLine($"{Environment.NewLine}Hello, {name},");
15            Console.Write($"{Environment.NewLine}Press any key to exit...");
16            Console.ReadKey(true);
17        }
18    }
19 }
```

The terminal tab shows the path "C:\Users\thruk\source\repos\ConsoleApp5>".

2. Select the green arrow at the top of the pane, next to **.NET Core Launch (console)**. Other ways to start the program in debugging mode are by pressing F5 or choosing **Run > Start Debugging** from the menu.

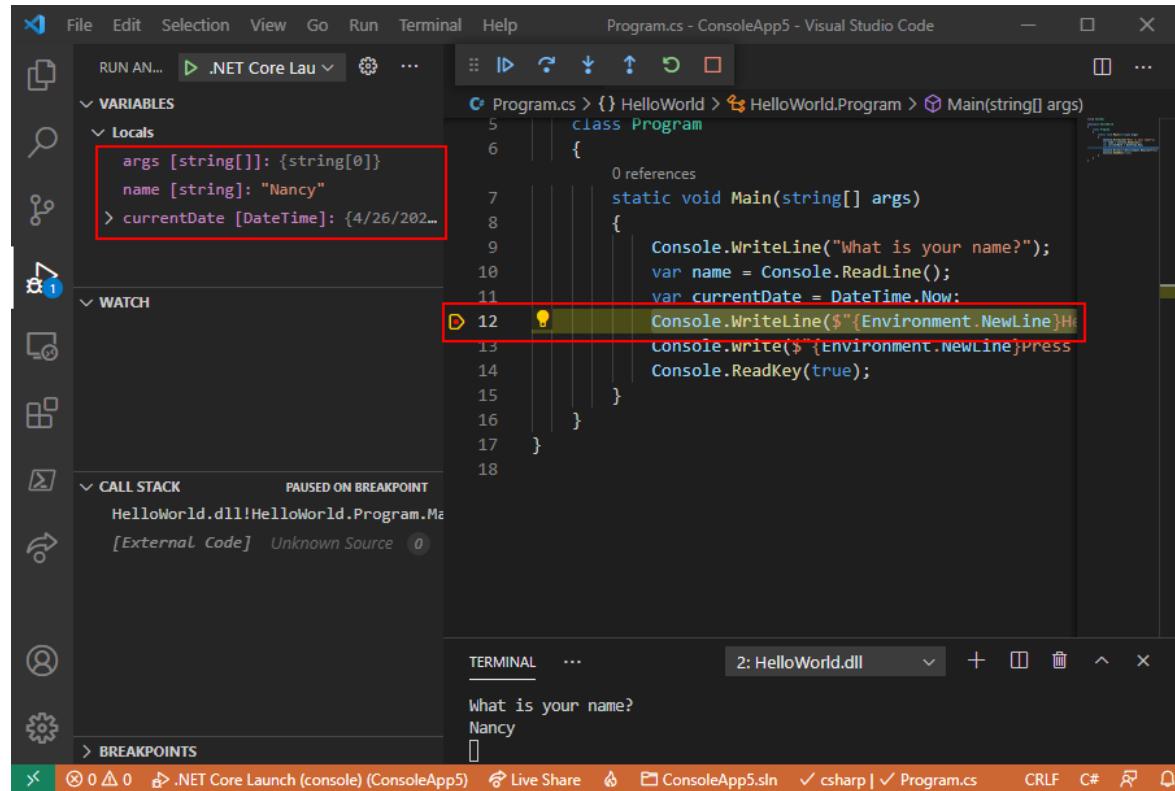

3. Select the **Terminal** tab to see the "What is your name?" prompt that the program displays before waiting for a response.

A screenshot of Visual Studio Code showing the program running. The terminal tab is active, displaying the message "What is your name?". The code editor shows the same C# code as the previous screenshot. The status bar at the bottom indicates "RUNNING" and shows the path "C:\Users\thruk\source\repos\ConsoleApp5>".

4. Enter a string in the **Terminal** window in response to the prompt for a name, and then press Enter.

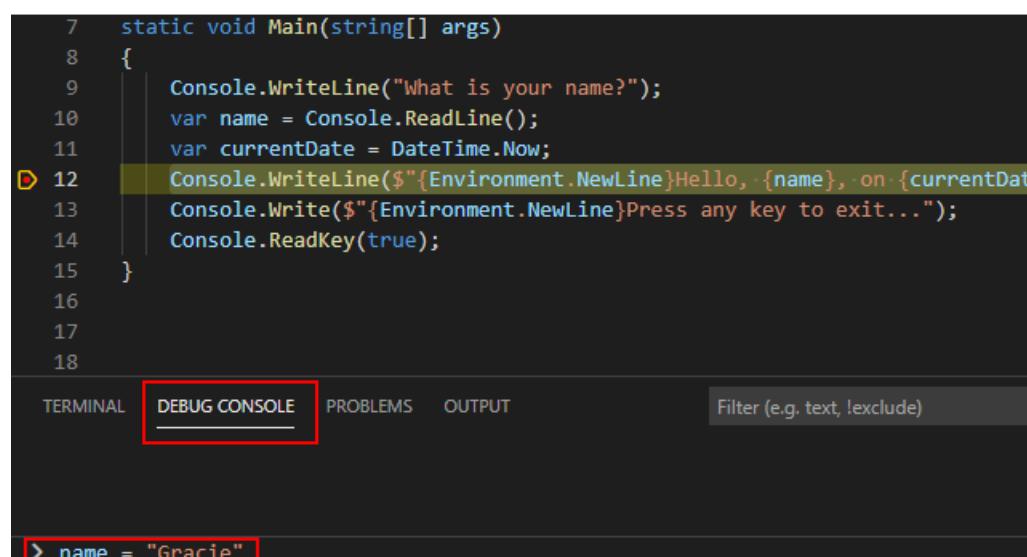

Program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes. The **Locals** section of the **Variables** window displays the values of variables that are defined in the currently executing method.

Use the Debug Console

The **Debug Console** window lets you interact with the application you're debugging. You can change the value of variables to see how it affects your program.

1. Select the **Debug Console** tab.
2. Enter `name = "Gracie"` at the prompt at the bottom of the **Debug Console** window and press the Enter key.

3. Enter `currentDate = DateTime.Parse("2019-11-16T17:25:00Z").ToUniversalTime()` at the bottom of the **Debug Console** window and press the Enter key.

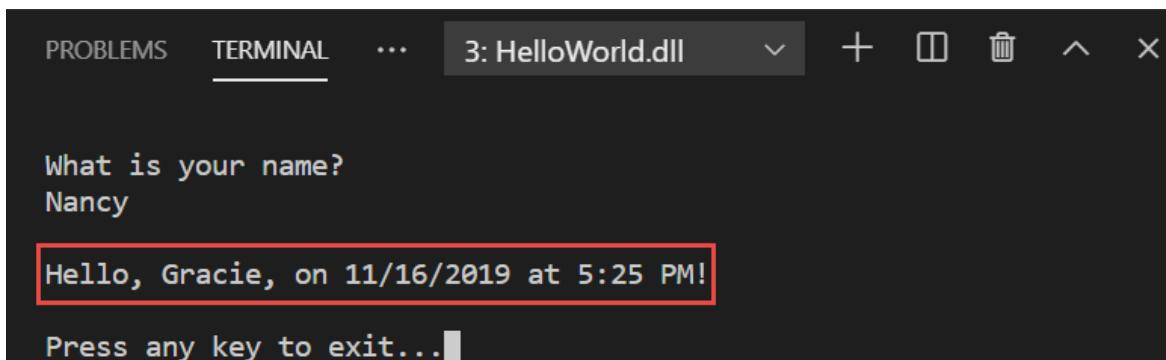

The **Variables** window displays the new values of the `name` and `currentDate` variables.

4. Continue program execution by selecting the **Continue** button in the toolbar. Another way to continue is by pressing F5.

5. Select the **Terminal** tab again.

The values displayed in the console window correspond to the changes you made in the **Debug Console**.

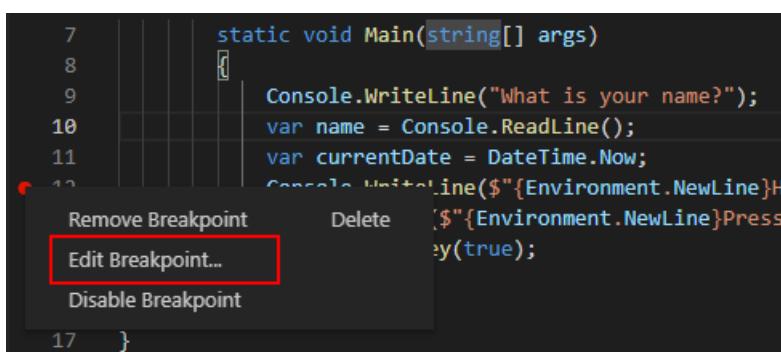

6. Press any key to exit the application and stop debugging.

Set a conditional breakpoint

The program displays the string that the user enters. What happens if the user doesn't enter anything? You can test this with a useful debugging feature called a *conditional breakpoint*.

1. Right-click (Ctrl-click on macOS) on the red dot that represents the breakpoint. In the context menu, select **Edit Breakpoint** to open a dialog that lets you enter a conditional expression.

2. Select **Expression** in the drop-down, enter the following conditional expression, and press Enter.

Each time the breakpoint is hit, the debugger calls the `String.IsNullOrEmpty(name)` method, and it breaks

on this line only if the method call returns `true`.

Instead of a conditional expression, you can specify a *hit count*, which interrupts program execution before a statement is executed a specified number of times. Another option is to specify a *filter condition*, which interrupts program execution based on such attributes as a thread identifier, process name, or thread name.

3. Start the program with debugging by pressing F5.
4. In the **Terminal** tab, press the Enter key when prompted to enter your name.

Because the condition you specified (`name` is either `null` or `String.Empty`) has been satisfied, program execution stops when it reaches the breakpoint and before the `Console.WriteLine` method executes.

The **Variables** window shows that the value of the `name` variable is `""`, or `String.Empty`.

5. Confirm the value is an empty string by entering the following statement at the **Debug Console** prompt and pressing Enter. The result is `true`.

A screenshot of the Visual Studio Code interface. The code editor shows a C# file with the following code:

```
7 static void Main(string[] args)
8 {
9     Console.WriteLine("What is your name?");
10    var name = Console.ReadLine();
11    var currentDate = DateTime.Now;
12    Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");
13    if (String.IsNullOrEmpty(name))
14        Console.WriteLine($"{Environment.NewLine}Press any key to exit..");
15    Console.ReadKey(true);
16 }
```

The line `12` is highlighted with a yellow background, indicating it is the current line of execution. The **DEBUG CONSOLE** tab is selected. The output pane shows the following:

```
→ name == String.Empty
true
```

The output `name == String.Empty` is highlighted with a red box.

6. Select the **Continue** button on the toolbar to continue program execution.
7. Select the **Terminal** tab, and press any key to exit the program and stop debugging.
8. Clear the breakpoint by clicking on the dot in the left margin of the code window. Other ways to clear a breakpoint are by pressing F9 or choosing **Run > Toggle Breakpoint** from the menu while the line of code is selected.
9. If you get a warning that the breakpoint condition will be lost, select **Remove Breakpoint**.

Step through a program

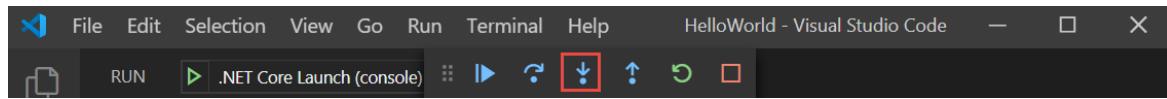

Visual Studio Code also allows you to step line by line through a program and monitor its execution. Ordinarily, you'd set a breakpoint and follow program flow through a small part of your program code. Since this program is small, you can step through the entire program.

1. Set a breakpoint on the opening curly brace of the `Main` method.
2. Press F5 to start debugging.

Visual Studio Code highlights the breakpoint line.

At this point, the **Variables** window shows that the `args` array is empty, and `name` and `currentDate` have default values.

3. Select **Run > Step Into** or press F11.

Visual Studio Code highlights the next line.

4. Select **Run > Step Into** or press F11.

Visual Studio Code executes the `Console.WriteLine` for the name prompt and highlights the next line of execution. The next line is the `Console.ReadLine` for the `name`. The **Variables** window is unchanged, and the **Terminal** tab shows the "What is your name?" prompt.

5. Select **Run > Step Into** or press F11.

Visual Studio highlights the `name` variable assignment. The **Variables** window shows that `name` is still `null`.

6. Respond to the prompt by entering a string in the Terminal tab and pressing Enter.

The **Terminal** tab might not display the string you enter while you're entering it, but the `Console.ReadLine` method will capture your input.

7. Select **Run > Step Into** or press F11.

Visual Studio Code highlights the `currentDate` variable assignment. The **Variables** window shows the value returned by the call to the `Console.ReadLine` method. The **Terminal** tab displays the string you entered at the prompt.

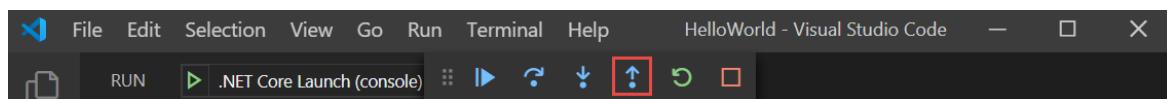

8. Select **Run > Step Into** or press F11.

The **Variables** window shows the value of the `currentDate` variable after the assignment from the `DateTime.Now` property.

9. Select **Run > Step Into** or press F11.

Visual Studio Code calls the `Console.WriteLine(String, Object, Object)` method. The console window displays the formatted string.

10. Select **Run > Step Out** or press Shift+F11.

11. Select the **Terminal** tab.

The terminal displays "Press any key to exit..."

12. Press any key to exit the program.

Use Release build configuration

Once you've tested the Debug version of your application, you should also compile and test the Release version. The Release version incorporates compiler optimizations that can affect the behavior of an application. For example, compiler optimizations that are designed to improve performance can create race conditions in multithreaded applications.

To build and test the Release version of your console application, open the **Terminal** and run the following command:

```
dotnet run --configuration Release
```

- [Debugging in Visual Studio Code](#)

Next steps

In this tutorial, you used Visual Studio Code debugging tools. In the next tutorial, you publish a deployable version of the app.

[Publish a .NET console application using Visual Studio Code](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Publish a .NET console application using Visual Studio Code

9/20/2022 • 6 minutes to read • [Edit Online](#)

This tutorial shows how to publish a console app so that other users can run it. Publishing creates the set of files that are needed to run an application. To deploy the files, copy them to the target machine.

The .NET CLI is used to publish the app, so you can follow this tutorial with a code editor other than Visual Studio Code if you prefer.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio Code](#).

Publish the app

1. Start Visual Studio Code.
2. Open the *HelloWorld* project folder that you created in [Create a .NET console application using Visual Studio Code](#).
3. Choose **View > Terminal** from the main menu.

The terminal opens in the *HelloWorld* folder.

4. Run the following command:

```
dotnet publish --configuration Release
```

The default build configuration is *Debug*, so this command specifies the *Release* build configuration. The output from the *Release* build configuration has minimal symbolic debug information and is fully optimized.

The command output is similar to the following example:

```
Microsoft (R) Build Engine version 16.7.0+b89cb5fde for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
HelloWorld -> C:\Projects\HelloWorld\bin\Release\net6.0\HelloWorld.dll
HelloWorld -> C:\Projects\HelloWorld\bin\Release\net6.0\publish\
```

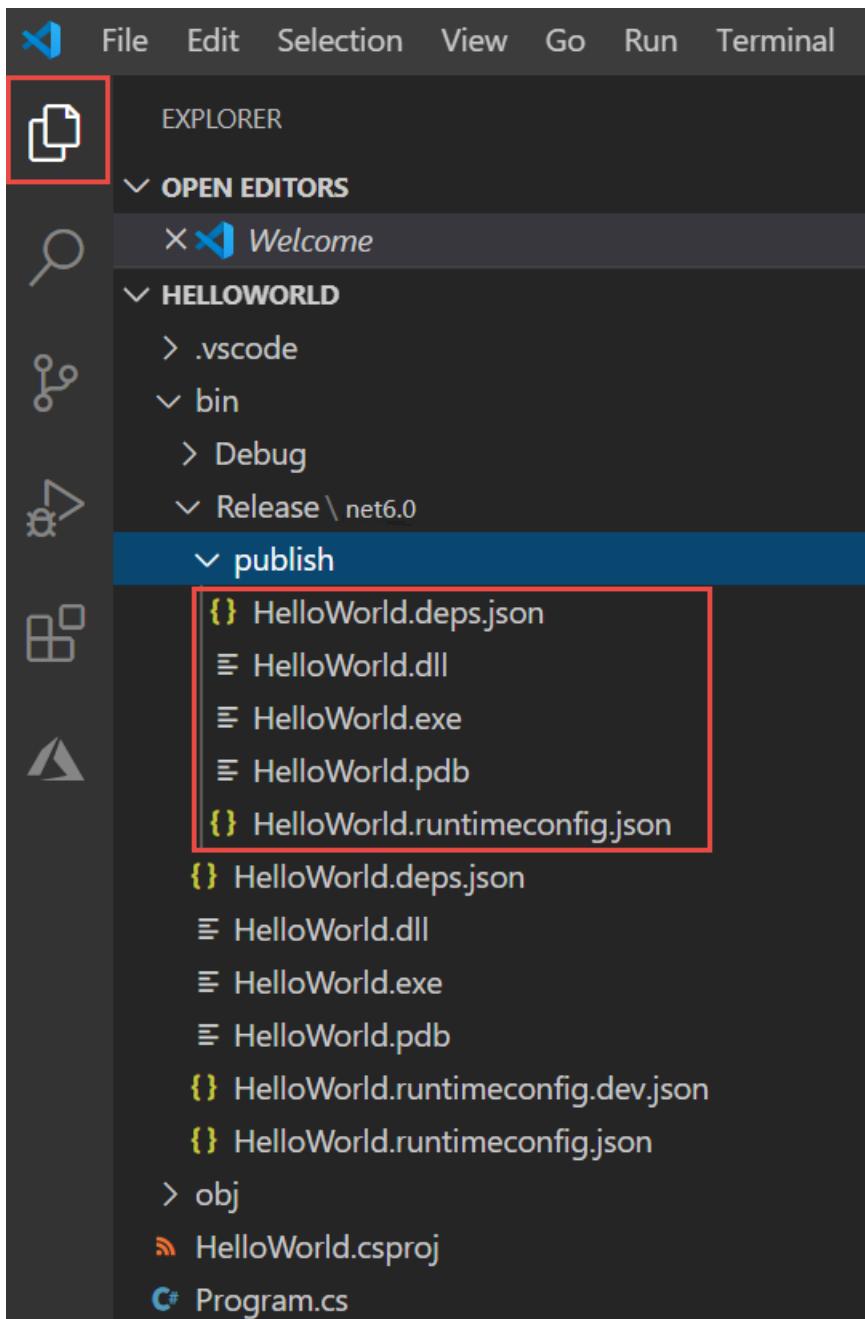

Inspect the files

By default, the publishing process creates a framework-dependent deployment, which is a type of deployment where the published application runs on a machine that has the .NET runtime installed. To run the published app you can use the executable file or run the `dotnet HelloWorld.dll` command from a command prompt.

In the following steps, you'll look at the files created by the publish process.

1. Select the **Explorer** in the left navigation bar.

2. Expand `bin/Release/net6.0/publish`.

As the image shows, the published output includes the following files:

- `HelloWorld.deps.json`

This is the application's runtime dependencies file. It defines the .NET components and the libraries (including the dynamic link library that contains your application) needed to run the app. For more information, see [Runtime configuration files](#).

- `HelloWorld.dll`

This is the [framework-dependent deployment](#) version of the application. To run this dynamic link library, enter `dotnet HelloWorld.dll` at a command prompt. This method of running the app works on any platform that has the .NET runtime installed.

- `HelloWorld.exe` (`HelloWorld` on Linux, not created on macOS.)

This is the [framework-dependent executable](#) version of the application. The file is operating-system-specific.

- *HelloWorld.pdb* (optional for deployment)

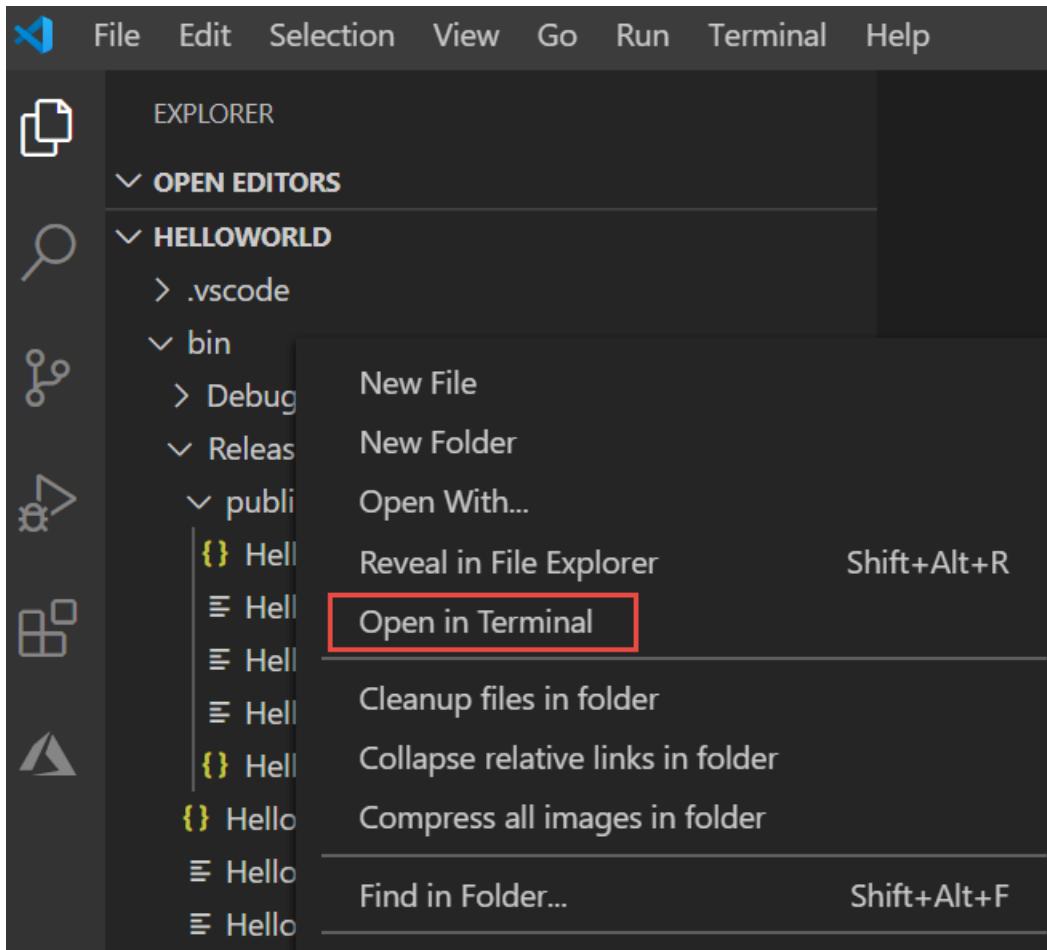

This is the debug symbols file. You aren't required to deploy this file along with your application, although you should save it in the event that you need to debug the published version of your application.

- *HelloWorld.runtimeconfig.json*

This is the application's runtime configuration file. It identifies the version of .NET that your application was built to run on. You can also add configuration options to it. For more information, see [.NET runtime configuration settings](#).

Run the published app

1. In Explorer, right-click the *publish* folder (Ctrl-click on macOS), and select **Open in Terminal**.

2. On Windows or Linux, run the app by using the executable.

- a. On Windows, enter `.\HelloWorld.exe` and press Enter.
- b. On Linux, enter `./HelloWorld` and press Enter.
- c. Enter a name in response to the prompt, and press any key to exit.

3. On any platform, run the app by using the `dotnet` command:

- a. Enter `dotnet HelloWorld.dll` and press Enter.
- b. Enter a name in response to the prompt, and press any key to exit.

Additional resources

- .NET application deployment

Next steps

In this tutorial, you published a console app. In the next tutorial, you create a class library.

[Create a .NET class library using Visual Studio Code](#)

This tutorial shows how to publish a console app so that other users can run it. Publishing creates the set of files that are needed to run an application. To deploy the files, copy them to the target machine.

The .NET CLI is used to publish the app, so you can follow this tutorial with a code editor other than Visual Studio Code if you prefer.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio Code](#).

Publish the app

1. Start Visual Studio Code.
2. Open the *HelloWorld* project folder that you created in [Create a .NET console application using Visual Studio Code](#).
3. Choose **View > Terminal** from the main menu.

The terminal opens in the *HelloWorld* folder.

4. Run the following command:

```
dotnet publish --configuration Release
```

The default build configuration is *Debug*, so this command specifies the *Release* build configuration. The output from the *Release* build configuration has minimal symbolic debug information and is fully optimized.

The command output is similar to the following example:

```
Microsoft (R) Build Engine version 16.7.0+b89cb5fde for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
HelloWorld -> C:\Projects\HelloWorld\bin\Release\net5.0\HelloWorld.dll
HelloWorld -> C:\Projects\HelloWorld\bin\Release\net5.0\publish\
```

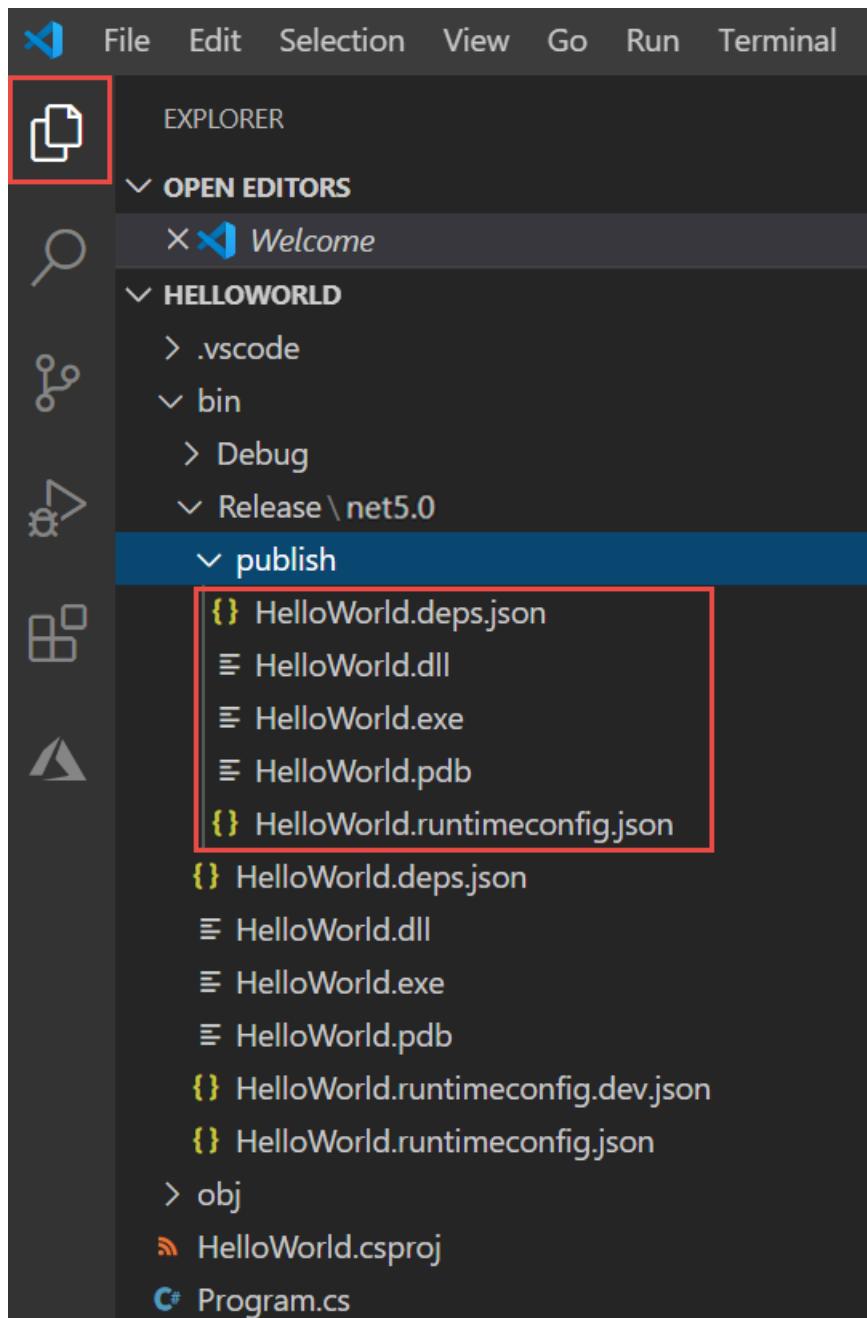

Inspect the files

By default, the publishing process creates a framework-dependent deployment, which is a type of deployment where the published application runs on a machine that has the .NET runtime installed. To run the published app you can use the executable file or run the `dotnet HelloWorld.dll` command from a command prompt.

In the following steps, you'll look at the files created by the publish process.

1. Select the **Explorer** in the left navigation bar.

2. Expand `bin/Release/net5.0/publish`.

As the image shows, the published output includes the following files:

- *HelloWorld.deps.json*

This is the application's runtime dependencies file. It defines the .NET components and the libraries (including the dynamic link library that contains your application) needed to run the app. For more information, see [Runtime configuration files](#).

- *HelloWorld.dll*

This is the [framework-dependent deployment](#) version of the application. To execute this dynamic link library, enter `dotnet HelloWorld.dll` at a command prompt. This method of running the app works on any platform that has the .NET runtime installed.

- *HelloWorld.exe* (*HelloWorld* on Linux, not created on macOS.)

This is the [framework-dependent executable](#) version of the application. The file is operating-system-specific.

- *HelloWorld.pdb* (optional for deployment)

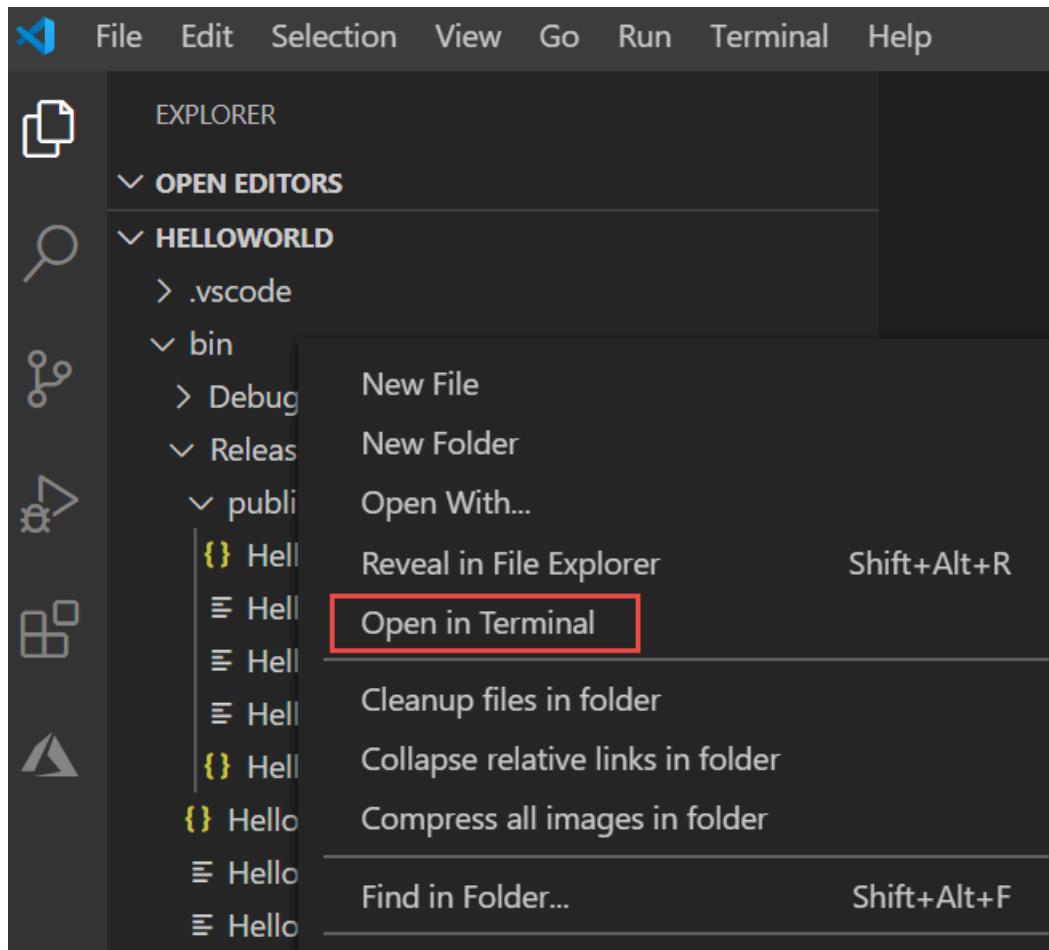

This is the debug symbols file. You aren't required to deploy this file along with your application, although you should save it in the event that you need to debug the published version of your application.

- *HelloWorld.runtimeconfig.json*

This is the application's runtime configuration file. It identifies the version of .NET that your application was built to run on. You can also add configuration options to it. For more information, see [.NET runtime configuration settings](#).

Run the published app

1. In Explorer, right-click the *publish* folder (Ctrl-click on macOS), and select Open in Integrated Terminal.

2. On Windows or Linux, run the app by using the executable.

- a. On Windows, enter `.\\HelloWorld.exe` and press Enter.
- b. On Linux, enter `./HelloWorld` and press Enter.
- c. Enter a name in response to the prompt, and press any key to exit.

3. On any platform, run the app by using the `dotnet` command:

- a. Enter `dotnet HelloWorld.dll` and press Enter.
- b. Enter a name in response to the prompt, and press any key to exit.

Next steps

In this tutorial, you published a console app. In the next tutorial, you create a class library.

[Create a .NET class library using Visual Studio Code](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Create a .NET class library using Visual Studio Code

9/20/2022 • 11 minutes to read • [Edit Online](#)

In this tutorial, you create a simple utility library that contains a single string-handling method.

A *class library* defines types and methods that are called by an application. If the library targets .NET Standard 2.0, it can be called by any .NET implementation (including .NET Framework) that supports .NET Standard 2.0. If the library targets .NET 6, it can be called by any application that targets .NET 6. This tutorial shows how to target .NET 6.

When you create a class library, you can distribute it as a third-party component or as a bundled component with one or more applications.

Prerequisites

- [Visual Studio Code](#) with the [C# extension](#) installed. For information about how to install extensions on Visual Studio Code, see [VS Code Extension Marketplace](#).
- The [.NET 6 SDK](#).

Create a solution

Start by creating a blank solution to put the class library project in. A solution serves as a container for one or more projects. You'll add additional, related projects to the same solution.

1. Start Visual Studio Code.
2. Select **File > Open Folder (Open... on macOS)** from the main menu
3. In the **Open Folder** dialog, create a *ClassLibraryProjects* folder and click **Select Folder (Open on macOS)**.
4. Open the **Terminal** in Visual Studio Code by selecting **View > Terminal** from the main menu.

The **Terminal** opens with the command prompt in the *ClassLibraryProjects* folder.

5. In the **Terminal**, enter the following command:

```
dotnet new sln
```

The terminal output looks like the following example:

```
The template "Solution File" was created successfully.
```

Create a class library project

Add a new .NET class library project named "StringLibrary" to the solution.

1. In the terminal, run the following command to create the library project:

```
dotnet new classlib -o StringLibrary
```

The `-o` or `--output` command specifies the location to place the generated output.

The terminal output looks like the following example:

```
The template "Class library" was created successfully.  
Processing post-creation actions...  
Running 'dotnet restore' on StringLibrary/StringLibrary.csproj...  
Determining projects to restore...  
Restored C:\Projects\ClassLibraryProjects\StringLibrary\StringLibrary.csproj (in 328 ms).  
Restore succeeded.
```

- Run the following command to add the library project to the solution:

```
dotnet sln add StringLibrary/StringLibrary.csproj
```

The terminal output looks like the following example:

```
Project `StringLibrary\StringLibrary.csproj` added to the solution.
```

- Check to make sure that the library targets .NET 6. In **Explorer**, open *StringLibrary/StringLibrary.csproj*.

The `TargetFramework` element shows that the project targets .NET 6.0.

```
<Project Sdk="Microsoft.NET.Sdk">  
  
<PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
</PropertyGroup>  
  
</Project>
```

- Open *Class1.cs* and replace the code with the following code.

```
namespace UtilityLibraries;  
  
public static class StringLibrary  
{  
    public static bool StartsToUpper(this string? str)  
    {  
        if (string.IsNullOrWhiteSpace(str))  
            return false;  
  
        char ch = str[0];  
        return char.IsUpper(ch);  
    }  
}
```

The class library, `UtilityLibraries.StringLibrary`, contains a method named `StartsToUpper`. This method returns a `Boolean` value that indicates whether the current string instance begins with an uppercase character. The Unicode standard distinguishes uppercase characters from lowercase characters. The `Char.IsUpper(Char)` method returns `true` if a character is uppercase.

`StartsToUpper` is implemented as an [extension method](#) so that you can call it as if it were a member of the `String` class.

5. Save the file.
6. Run the following command to build the solution and verify that the project compiles without error.

```
dotnet build
```

The terminal output looks like the following example:

```
Microsoft (R) Build Engine version 16.7.0+b89cb5fde for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
StringLibrary -> C:\Projects\ClassLibraryProjects\StringLibrary\bin\Debug\net6.0\StringLibrary.dll
Build succeeded.

0 Warning(s)
0 Error(s)

Time Elapsed 00:00:02.78
```

Add a console app to the solution

Add a console application that uses the class library. The app will prompt the user to enter a string and report whether the string begins with an uppercase character.

1. In the terminal, run the following command to create the console app project:

```
dotnet new console -o ShowCase
```

The terminal output looks like the following example:

```
The template "Console Application" was created successfully.
Processing post-creation actions...
Running 'dotnet restore' on ShowCase>ShowCase.csproj...
Determining projects to restore...
Restored C:\Projects\ClassLibraryProjects>ShowCase>ShowCase.csproj (in 210 ms).
Restore succeeded.
```

2. Run the following command to add the console app project to the solution:

```
dotnet sln add ShowCase>ShowCase.csproj
```

The terminal output looks like the following example:

```
Project `ShowCase>ShowCase.csproj` added to the solution.
```

3. Open *ShowCase/Program.cs* and replace all of the code with the following code.

```

using UtilityLibraries;

class Program
{
    static void Main(string[] args)
    {
        int row = 0;

        do
        {
            if (row == 0 || row >= 25)
                ResetConsole();

            string? input = Console.ReadLine();
            if (string.IsNullOrEmpty(input)) break;
            Console.WriteLine($"Input: {input}");
            Console.WriteLine("Begins with uppercase? " +
                $"{(input.StartsWithUpper() ? "Yes" : "No")}");
            Console.WriteLine();
            row += 4;
        } while (true);
        return;
    }

    // Declare a ResetConsole local method
    void ResetConsole()
    {
        if (row > 0)
        {
            Console.WriteLine("Press any key to continue...");
            Console.ReadKey();
        }
        Console.Clear();
        Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}");
        row = 3;
    }
}

```

The code uses the `row` variable to maintain a count of the number of rows of data written to the console window. Whenever it's greater than or equal to 25, the code clears the console window and displays a message to the user.

The program prompts the user to enter a string. It indicates whether the string starts with an uppercase character. If the user presses the Enter key without entering a string, the application ends, and the console window closes.

4. Save your changes.

Add a project reference

Initially, the new console app project doesn't have access to the class library. To allow it to call methods in the class library, create a project reference to the class library project.

1. Run the following command:

```
dotnet add ShowCase/ShowCase.csproj reference StringLibrary/StringLibrary.csproj
```

The terminal output looks like the following example:

```
Reference `..\StringLibrary\StringLibrary.csproj` added to the project.
```

Run the app

1. Run the following command in the terminal:

```
dotnet run --project ShowCase>ShowCase.csproj
```

2. Try out the program by entering strings and pressing Enter, then press Enter to exit.

The terminal output looks like the following example:

```
Press <Enter> only to exit; otherwise, enter a string and press <Enter>:  
  
A string that starts with an uppercase letter  
Input: A string that starts with an uppercase letter  
Begins with uppercase? : Yes  
  
a string that starts with a lowercase letter  
Input: a string that starts with a lowercase letter  
Begins with uppercase? : No
```

Additional resources

- [Develop libraries with the .NET CLI](#)
- [.NET Standard versions and the platforms they support](#).

Next steps

In this tutorial, you created a solution, added a library project, and added a console app project that uses the library. In the next tutorial, you add a unit test project to the solution.

[Test a .NET class library with .NET using Visual Studio Code](#)

In this tutorial, you create a simple utility library that contains a single string-handling method.

A *class library* defines types and methods that are called by an application. If the library targets .NET Standard 2.0, it can be called by any .NET implementation (including .NET Framework) that supports .NET Standard 2.0. If the library targets .NET 5, it can be called by any application that targets .NET 5. This tutorial shows how to target .NET 5.

When you create a class library, you can distribute it as a third-party component or as a bundled component with one or more applications.

Prerequisites

1. [Visual Studio Code](#) with the [C# extension](#) installed. For information about how to install extensions on Visual Studio Code, see [VS Code Extension Marketplace](#).
2. The [.NET 5.0 SDK or later](#)

Create a solution

Start by creating a blank solution to put the class library project in. A solution serves as a container for one or more projects. You'll add additional, related projects to the same solution.

1. Start Visual Studio Code.
2. Select **File > Open Folder** (**Open...** on macOS) from the main menu
3. In the **Open Folder** dialog, create a *ClassLibraryProjects* folder and click **Select Folder** (**Open** on macOS).
4. Open the **Terminal** in Visual Studio Code by selecting **View > Terminal** from the main menu.

The **Terminal** opens with the command prompt in the *ClassLibraryProjects* folder.

5. In the **Terminal**, enter the following command:

```
dotnet new sln
```

The terminal output looks like the following example:

```
The template "Solution File" was created successfully.
```

Create a class library project

Add a new .NET class library project named "StringLibrary" to the solution.

1. In the terminal, run the following command to create the library project:

```
dotnet new classlib -o StringLibrary
```

The `-o` or `--output` command specifies the location to place the generated output.

The terminal output looks like the following example:

```
The template "Class library" was created successfully.  
Processing post-creation actions...  
Running 'dotnet restore' on StringLibrary/StringLibrary.csproj...  
Determining projects to restore...  
Restored C:\Projects\ClassLibraryProjects\StringLibrary\StringLibrary.csproj (in 328 ms).  
Restore succeeded.
```

2. Run the following command to add the library project to the solution:

```
dotnet sln add StringLibrary/StringLibrary.csproj
```

The terminal output looks like the following example:

```
Project `StringLibrary\StringLibrary.csproj` added to the solution.
```

3. Check to make sure that the library targets .NET 5. In **Explorer**, open *StringLibrary/StringLibrary.csproj*.

The `TargetFramework` element shows that the project targets .NET 5.0.

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
<TargetFramework>net5.0</TargetFramework>
</PropertyGroup>

</Project>
```

4. Open *Class1.cs* and replace the code with the following code.

```
using System;

namespace UtilityLibraries
{
    public static class StringLibrary
    {
        public static bool StartsWithUpper(this string str)
        {
            if (string.IsNullOrWhiteSpace(str))
                return false;

            char ch = str[0];
            return char.IsUpper(ch);
        }
    }
}
```

The class library, `UtilityLibraries.StringLibrary`, contains a method named `StartsWithUpper`. This method returns a `Boolean` value that indicates whether the current string instance begins with an uppercase character. The Unicode standard distinguishes uppercase characters from lowercase characters. The `Char.IsUpper(Char)` method returns `true` if a character is uppercase.

`StartsWithUpper` is implemented as an [extension method](#) so that you can call it as if it were a member of the `String` class. The question mark (?) after `string` indicates that the string may be null.

5. Save the file.
6. Run the following command to build the solution and verify that the project compiles without error.

```
dotnet build
```

The terminal output looks like the following example:

```
Microsoft (R) Build Engine version 16.7.0+b89cb5fde for .NET
Copyright (C) Microsoft Corporation. All rights reserved.
Determining projects to restore...
All projects are up-to-date for restore.
StringLibrary -> C:\Projects\ClassLibraryProjects\StringLibrary\bin\Debug\net5.0\StringLibrary.dll
Build succeeded.
0 Warning(s)
0 Error(s)
Time Elapsed 00:00:02.78
```

Add a console app to the solution

Add a console application that uses the class library. The app will prompt the user to enter a string and report whether the string begins with an uppercase character.

1. In the terminal, run the following command to create the console app project:

```
dotnet new console -o ShowCase
```

The terminal output looks like the following example:

```
The template "Console Application" was created successfully.  
Processing post-creation actions...  
Running 'dotnet restore' on ShowCase>ShowCase.csproj...  
Determining projects to restore...  
Restored C:\Projects\ClassLibraryProjects>ShowCase>ShowCase.csproj (in 210 ms).  
Restore succeeded.
```

2. Run the following command to add the console app project to the solution:

```
dotnet sln add ShowCase>ShowCase.csproj
```

The terminal output looks like the following example:

```
Project `ShowCase>ShowCase.csproj` added to the solution.
```

3. Open *ShowCase/Program.cs* and replace all of the code with the following code.

```

using System;
using UtilityLibraries;

class Program
{
    static void Main(string[] args)
    {
        int row = 0;

        do
        {
            if (row == 0 || row >= 25)
                ResetConsole();

            string? input = Console.ReadLine();
            if (string.IsNullOrEmpty(input)) break;
            Console.WriteLine($"Input: {input} {"Begins with uppercase? ",30}: " +
                $"{{(input.StartsWithUpper() ? "Yes" : "No")}{Environment.NewLine}}");
            row += 3;
        } while (true);
        return;
    }

    // Declare a ResetConsole local method
    void ResetConsole()
    {
        if (row > 0)
        {
            Console.WriteLine("Press any key to continue...");
            Console.ReadKey();
        }
        Console.Clear();
        Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}");
        row = 3;
    }
}

```

The code uses the `row` variable to maintain a count of the number of rows of data written to the console window. Whenever it's greater than or equal to 25, the code clears the console window and displays a message to the user.

The program prompts the user to enter a string. It indicates whether the string starts with an uppercase character. If the user presses the Enter key without entering a string, the application ends, and the console window closes.

4. Save your changes.

Add a project reference

Initially, the new console app project doesn't have access to the class library. To allow it to call methods in the class library, create a project reference to the class library project.

1. Run the following command:

```
dotnet add ShowCase/ShowCase.csproj reference StringLibrary/StringLibrary.csproj
```

The terminal output looks like the following example:

```
Reference `..\StringLibrary\StringLibrary.csproj` added to the project.
```

Run the app

1. Run the following command in the terminal:

```
dotnet run --project ShowCase>ShowCase.csproj
```

2. Try out the program by entering strings and pressing Enter, then press Enter to exit.

The terminal output looks like the following example:

```
Press <Enter> only to exit; otherwise, enter a string and press <Enter>:  
  
A string that starts with an uppercase letter  
Input: A string that starts with an uppercase letter  
Begins with uppercase? : Yes  
  
a string that starts with a lowercase letter  
Input: a string that starts with a lowercase letter  
Begins with uppercase? : No
```

Next steps

In this tutorial, you created a solution, added a library project, and added a console app project that uses the library. In the next tutorial, you add a unit test project to the solution.

[Test a .NET class library with .NET using Visual Studio Code](#)

This tutorial is only available for .NET 5 and .NET 6. Select one of those options at the top of the page.

Tutorial: Test a .NET class library using Visual Studio Code

9/20/2022 • 14 minutes to read • [Edit Online](#)

This tutorial shows how to automate unit testing by adding a test project to a solution.

Prerequisites

- This tutorial works with the solution that you create in [Create a .NET class library using Visual Studio Code](#).

Create a unit test project

Unit tests provide automated software testing during your development and publishing. The testing framework that you use in this tutorial is MSTest. [MSTest](#) is one of three test frameworks you can choose from. The others are [xUnit](#) and [nUnit](#).

1. Start Visual Studio Code.
2. Open the `ClassLibraryProjects` solution you created in [Create a .NET class library using Visual Studio Code](#).
3. Create a unit test project named "StringLibraryTest".

```
dotnet new mstest -o StringLibraryTest
```

The project template creates a `UnitTest1.cs` file with the following code:

```
using Microsoft.VisualStudio.TestTools.UnitTesting;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestMethod1()
        {
        }
    }
}
```

The source code created by the unit test template does the following:

- It imports the [Microsoft.VisualStudio.TestTools.UnitTesting](#) namespace, which contains the types used for unit testing.
- It applies the [TestClassAttribute](#) attribute to the `UnitTest1` class.
- It applies the [TestMethodAttribute](#) attribute to define `TestMethod1`.

Each method tagged with [\[TestMethod\]](#) in a test class tagged with [\[TestClass\]](#) is run automatically when the unit test is invoked.

4. Add the test project to the solution.

```
dotnet sln add StringLibraryTest/StringLibraryTest.csproj
```

Add a project reference

For the test project to work with the `StringLibrary` class, add a reference in the `StringLibraryTest` project to the `StringLibrary` project.

1. Run the following command:

```
dotnet add StringLibraryTest/StringLibraryTest.csproj reference StringLibrary/StringLibrary.csproj
```

Add and run unit test methods

When Visual Studio invokes a unit test, it runs each method that is marked with the `TestMethodAttribute` attribute in a class that is marked with the `TestClassAttribute` attribute. A test method ends when the first failure is found or when all tests contained in the method have succeeded.

The most common tests call members of the `Assert` class. Many assert methods include at least two parameters, one of which is the expected test result and the other of which is the actual test result. Some of the `Assert` class's most frequently called methods are shown in the following table:

ASSERT METHODS	FUNCTION
<code>Assert.AreEqual</code>	Verifies that two values or objects are equal. The assert fails if the values or objects aren't equal.
<code>Assert.AreSame</code>	Verifies that two object variables refer to the same object. The assert fails if the variables refer to different objects.
<code>Assert.IsFalse</code>	Verifies that a condition is <code>false</code> . The assert fails if the condition is <code>true</code> .
<code>Assert.IsNotNull</code>	Verifies that an object isn't <code>null</code> . The assert fails if the object is <code>null</code> .

You can also use the `Assert.ThrowsException` method in a test method to indicate the type of exception it's expected to throw. The test fails if the specified exception isn't thrown.

In testing the `StringLibrary.StartsWithUpper` method, you want to provide a number of strings that begin with an uppercase character. You expect the method to return `true` in these cases, so you can call the `Assert.IsTrue` method. Similarly, you want to provide a number of strings that begin with something other than an uppercase character. You expect the method to return `false` in these cases, so you can call the `Assert.IsFalse` method.

Since your library method handles strings, you also want to make sure that it successfully handles an `empty string` (`String.Empty`) and a `null` string. An empty string is one that has no characters and whose `Length` is 0. A `null` string is one that hasn't been initialized. You can call `StartsWithUpper` directly as a static method and pass a single `String` argument. Or you can call `StartsWithUpper` as an extension method on a `string` variable assigned to `null`.

You'll define three methods, each of which calls an `Assert` method for each element in a string array. You'll call a method overload that lets you specify an error message to be displayed in case of test failure. The message identifies the string that caused the failure.

To create the test methods:

1. Open *StringLibraryTest/UnitTest1.cs* and replace all of the code with the following code.

```
using Microsoft.VisualStudio.TestTools.UnitTesting;
using UtilityLibraries;

namespace StringLibraryTest;

[TestClass]
public class UnitTest1
{
    [TestMethod]
    public void TestStartsWithUpper()
    {
        // Tests that we expect to return true.
        string[] words = { "Alphabet", "Zebra", "ABC", "Αθήνα", "Москва" };
        foreach (var word in words)
        {
            bool result = word.StartsWithUpper();
            Assert.IsTrue(result,
                string.Format("Expected for '{0}': true; Actual: {1}",
                    word, result));
        }
    }

    [TestMethod]
    public void TestDoesNotStartWithUpper()
    {
        // Tests that we expect to return false.
        string[] words = { "alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
            "1234", ".", ";", " " };
        foreach (var word in words)
        {
            bool result = word.StartsWithUpper();
            Assert.IsFalse(result,
                string.Format("Expected for '{0}': false; Actual: {1}",
                    word, result));
        }
    }

    [TestMethod]
    public void DirectCallWithNullOrEmpty()
    {
        // Tests that we expect to return false.
        string?[] words = { string.Empty, null };
        foreach (var word in words)
        {
            bool result = StringLibrary.StartsWithUpper(word);
            Assert.IsFalse(result,
                string.Format("Expected for '{0}': false; Actual: {1}",
                    word == null ? "<null>" : word, result));
        }
    }
}
```

The test of uppercase characters in the `TestStartsWithUpper` method includes the Greek capital letter alpha (U+0391) and the Cyrillic capital letter EM (U+041C). The test of lowercase characters in the `TestDoesNotStartWithUpper` method includes the Greek small letter alpha (U+03B1) and the Cyrillic small letter Ghe (U+0433).

2. Save your changes.

3. Run the tests:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj
```

The terminal output shows that all tests passed.

```
Starting test execution, please wait...
A total of 1 test files matched the specified pattern.

Passed! - Failed: 0, Passed: 3, Skipped: 0, Total: 3, Duration: 3 ms -
StringLibraryTest.dll (net6.0)
```

Handle test failures

If you're doing test-driven development (TDD), you write tests first and they fail the first time you run them. Then you add code to the app that makes the test succeed. For this tutorial, you created the test after writing the app code that it validates, so you haven't seen the test fail. To validate that a test fails when you expect it to fail, add an invalid value to the test input.

1. Modify the `words` array in the `TestDoesNotStartWithUpper` method to include the string "Error".

```
string[] words = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
    "1234", ".", ";" };
```

2. Run the tests:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj
```

The terminal output shows that one test fails, and it provides an error message for the failed test: "Assert.IsFalse failed. Expected for 'Error': false; actual: True". Because of the failure, no strings in the array after "Error" were tested.

```
Starting test execution, please wait...
A total of 1 test files matched the specified pattern.

Failed TestDoesNotStartWithUpper [28 ms]
Error Message:
  Assert.IsFalse failed. Expected for 'Error': false; Actual: True
Stack Trace:
  at StringLibraryTest.UnitTest1.TestDoesNotStartWithUpper() in
C:\ClassLibraryProjects\StringLibraryTest\UnitTest1.cs:line 33

Failed! - Failed: 1, Passed: 2, Skipped: 0, Total: 3, Duration: 31 ms -
StringLibraryTest.dll (net5.0)
```

3. Remove the string "Error" that you added in step 1. Rerun the test and the tests pass.

Test the Release version of the library

Now that the tests have all passed when running the Debug build of the library, run the tests an additional time against the Release build of the library. A number of factors, including compiler optimizations, can sometimes produce different behavior between Debug and Release builds.

1. Run the tests with the Release build configuration:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj --configuration Release
```

The tests pass.

Debug tests

If you're using Visual Studio Code as your IDE, you can use the same process shown in [Debug a .NET console application using Visual Studio Code](#) to debug code using your unit test project. Instead of starting the *ShowCase* app project, open *StringLibraryTest/UnitTest1.cs*, and select **Debug All Tests** between lines 7 and 8. If you're unable to find it, press **Ctrl+Shift+P** to open the command palette and enter **Reload Window**.

Visual Studio Code starts the test project with the debugger attached. Execution will stop at any breakpoint you've added to the test project or the underlying library code.

Additional resources

- [Unit testing in .NET](#)

Next steps

In this tutorial, you unit tested a class library. You can make the library available to others by publishing it to [NuGet](#) as a package. To learn how, follow a NuGet tutorial:

[Create and publish a package using the dotnet CLI](#)

If you publish a library as a NuGet package, others can install and use it. To learn how, follow a NuGet tutorial:

[Install and use a package using the dotnet CLI](#)

A library doesn't have to be distributed as a package. It can be bundled with a console app that uses it. To learn how to publish a console app, see the earlier tutorial in this series:

[Publish a .NET console application using Visual Studio Code](#)

This tutorial shows how to automate unit testing by adding a test project to a solution.

Prerequisites

- This tutorial works with the solution that you create in [Create a .NET class library using Visual Studio Code](#).

Create a unit test project

Unit tests provide automated software testing during your development and publishing. The testing framework that you use in this tutorial is MSTest. [MSTest](#) is one of three test frameworks you can choose from. The others are [xUnit](#) and [nUnit](#).

1. Start Visual Studio Code.
2. Open the `ClassLibraryProjects` solution you created in [Create a .NET class library using Visual Studio Code](#).
3. Create a unit test project named "StringLibraryTest".

```
dotnet new mstest -o StringLibraryTest
```

The project template creates a `UnitTest1.cs` file with the following code:

```

using Microsoft.VisualStudio.TestTools.UnitTesting;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestMethod1()
        {
        }
    }
}

```

The source code created by the unit test template does the following:

- It imports the `Microsoft.VisualStudio.TestTools.UnitTesting` namespace, which contains the types used for unit testing.
- It applies the `TestClassAttribute` attribute to the `UnitTest1` class.
- It applies the `TestMethodAttribute` attribute to define `TestMethod1`.

Each method tagged with `[TestMethod]` in a test class tagged with `[TestClass]` is executed automatically when the unit test is run.

4. Add the test project to the solution.

```
dotnet sln add StringLibraryTest/StringLibraryTest.csproj
```

Add a project reference

For the test project to work with the `StringLibrary` class, add a reference in the `StringLibraryTest` project to the `StringLibrary` project.

1. Run the following command:

```
dotnet add StringLibraryTest/StringLibraryTest.csproj reference StringLibrary/StringLibrary.csproj
```

Add and run unit test methods

When Visual Studio runs a unit test, it executes each method that is marked with the `TestMethodAttribute` attribute in a class that is marked with the `TestClassAttribute` attribute. A test method ends when the first failure is found or when all tests contained in the method have succeeded.

The most common tests call members of the `Assert` class. Many assert methods include at least two parameters, one of which is the expected test result and the other of which is the actual test result. Some of the `Assert` class's most frequently called methods are shown in the following table:

ASSERT METHODS	FUNCTION
<code>Assert.AreEqual</code>	Verifies that two values or objects are equal. The assert fails if the values or objects aren't equal.
<code>Assert.AreSame</code>	Verifies that two object variables refer to the same object. The assert fails if the variables refer to different objects.

ASSERT METHODS	FUNCTION
<code>Assert.IsFalse</code>	Verifies that a condition is <code>false</code> . The assert fails if the condition is <code>true</code> .
<code>Assert.IsNotNull</code>	Verifies that an object isn't <code>null</code> . The assert fails if the object is <code>null</code> .

You can also use the `Assert.ThrowsException` method in a test method to indicate the type of exception it's expected to throw. The test fails if the specified exception isn't thrown.

In testing the `StringLibrary.StartsWithUpper` method, you want to provide a number of strings that begin with an uppercase character. You expect the method to return `true` in these cases, so you can call the `Assert.IsTrue` method. Similarly, you want to provide a number of strings that begin with something other than an uppercase character. You expect the method to return `false` in these cases, so you can call the `Assert.IsFalse` method.

Since your library method handles strings, you also want to make sure that it successfully handles an `empty string` (`String.Empty`) and a `null` string. An empty string is one that has no characters and whose `Length` is 0. A `null` string is one that hasn't been initialized. You can call `StartsWithUpper` directly as a static method and pass a single `String` argument. Or you can call `StartsWithUpper` as an extension method on a `string` variable assigned to `null`.

You'll define three methods, each of which calls an `Assert` method for each element in a string array. You'll call a method overload that lets you specify an error message to be displayed in case of test failure. The message identifies the string that caused the failure.

To create the test methods:

1. Open `StringLibraryTest/UnitTest1.cs` and replace all of the code with the following code.

```

using Microsoft.VisualStudio.TestTools.UnitTesting;
using UtilityLibraries;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestStartsWithUpper()
        {
            // Tests that we expect to return true.
            string[] words = { "Alphabet", "Zebra", "ABC", "Αθήνα", "Москва" };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsTrue(result,
                    string.Format("Expected for '{0}': true; Actual: {1}",
                    word, result));
            }
        }

        [TestMethod]
        public void TestDoesNotStartWithUpper()
        {
            // Tests that we expect to return false.
            string[] words = { "alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                "1234", ".", ";", " " };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                    word, result));
            }
        }

        [TestMethod]
        public void DirectCallWithNullOrEmpty()
        {
            // Tests that we expect to return false.
            string?[] words = { string.Empty, null };
            foreach (var word in words)
            {
                bool result = StringLibrary.StartsWithUpper(word ?? string.Empty);
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                    word == null ? "<null>" : word, result));
            }
        }
    }
}

```

The test of uppercase characters in the `TestStartsWithUpper` method includes the Greek capital letter alpha (U+0391) and the Cyrillic capital letter EM (U+041C). The test of lowercase characters in the `TestDoesNotStartWithUpper` method includes the Greek small letter alpha (U+03B1) and the Cyrillic small letter Ghe (U+0433).

2. Save your changes.

3. Run the tests:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj
```

The terminal output shows that all tests passed.

```
Starting test execution, please wait...
A total of 1 test files matched the specified pattern.

Passed! - Failed: 0, Passed: 3, Skipped: 0, Total: 3, Duration: 3 ms -
StringLibraryTest.dll (net5.0)
```

Handle test failures

If you're doing test-driven development (TDD), you write tests first and they fail the first time you run them. Then you add code to the app that makes the test succeed. For this tutorial, you created the test after writing the app code that it validates, so you haven't seen the test fail. To validate that a test fails when you expect it to fail, add an invalid value to the test input.

1. Modify the `words` array in the `TestDoesNotStartWithUpper` method to include the string "Error".

```
string[] words = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
    "1234", ".", ";", " " };
```

2. Run the tests:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj
```

The terminal output shows that one test fails, and it provides an error message for the failed test: "Assert.IsFalse failed. Expected for 'Error': false; actual: True". Because of the failure, no strings in the array after "Error" were tested.

```
Starting test execution, please wait...
A total of 1 test files matched the specified pattern.
Failed TestDoesNotStartWithUpper [28 ms]
Error Message:
  Assert.IsFalse failed. Expected for 'Error': false; Actual: True
Stack Trace:
  at StringLibraryTest.UnitTest1.TestDoesNotStartWithUpper() in
C:\ClassLibraryProjects\StringLibraryTest\UnitTest1.cs:line 33

Failed! - Failed: 1, Passed: 2, Skipped: 0, Total: 3, Duration: 31 ms -
StringLibraryTest.dll (net5.0)
```

3. Remove the string "Error" that you added in step 1. Rerun the test and the tests pass.

Test the Release version of the library

Now that the tests have all passed when running the Debug build of the library, run the tests an additional time against the Release build of the library. A number of factors, including compiler optimizations, can sometimes produce different behavior between Debug and Release builds.

1. Run the tests with the Release build configuration:

```
dotnet test StringLibraryTest/StringLibraryTest.csproj --configuration Release
```

The tests pass.

Debug tests

If you're using Visual Studio Code as your IDE, you can use the same process shown in [Debug a .NET console application using Visual Studio Code](#) to debug code using your unit test project. Instead of starting the *ShowCase* app project, open *StringLibraryTest/UnitTest1.cs*, and select **Debug All Tests** between lines 7 and 8. If you're unable to find it, press **Ctrl+Shift+P** to open the command palette and enter **Reload Window**.

Visual Studio Code starts the test project with the debugger attached. Execution will stop at any breakpoint you've added to the test project or the underlying library code.

Tutorial: Create a .NET console application using Visual Studio for Mac

9/20/2022 • 3 minutes to read • [Edit Online](#)

This tutorial shows how to create and run a .NET console application using Visual Studio for Mac.

NOTE

Your feedback is highly valued. There are two ways you can provide feedback to the development team on Visual Studio for Mac:

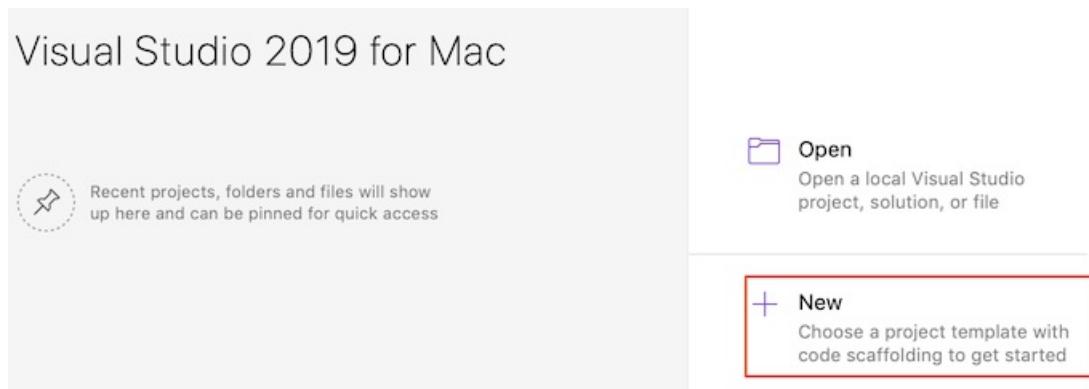

- In Visual Studio for Mac, select **Help > Report a Problem** from the menu or **Report a Problem** from the Welcome screen, which will open a window for filing a bug report. You can track your feedback in the [Developer Community portal](#).
- To make a suggestion, select **Help > Provide a Suggestion** from the menu or **Provide a Suggestion** from the Welcome screen, which will take you to the [Visual Studio for Mac Developer Community webpage](#).

Prerequisites

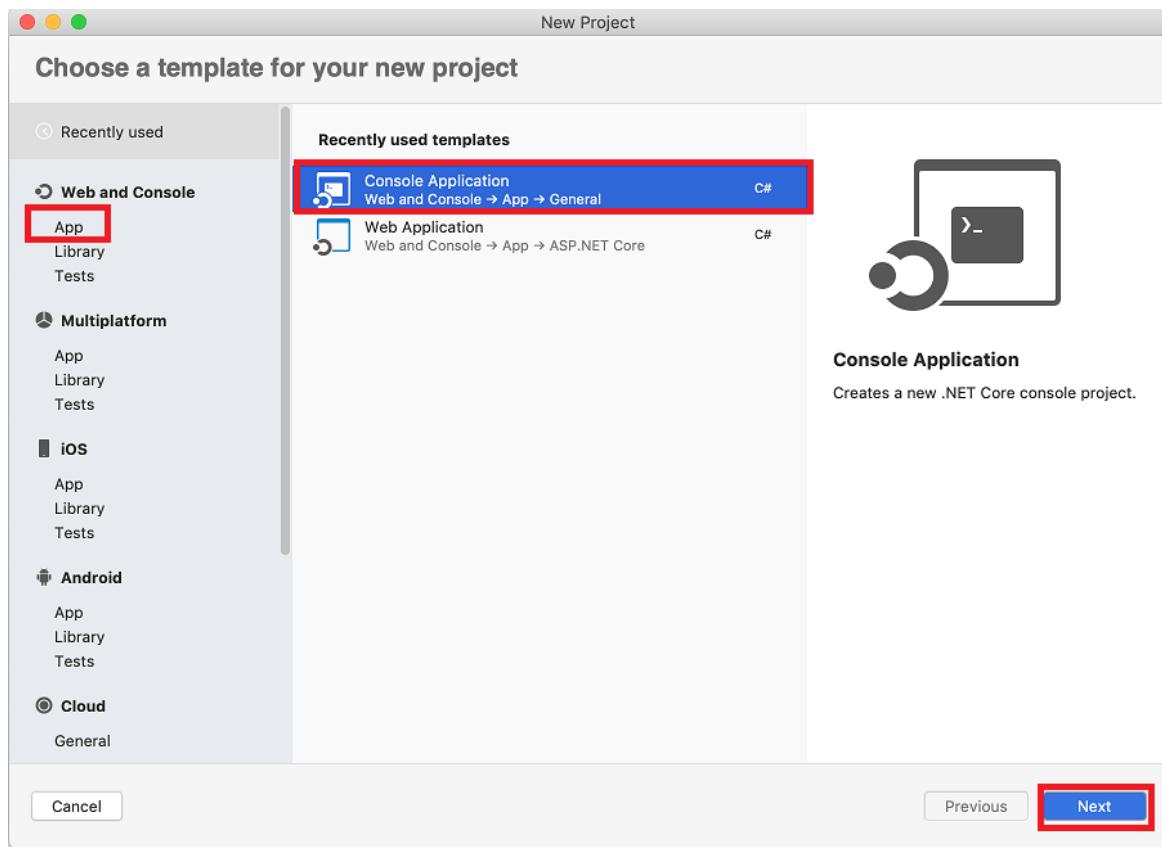

- [Visual Studio for Mac version 8.8 or later](#). Select the option to install .NET Core. Installing Xamarin is optional for .NET development. For more information, see the following resources:
 - [Tutorial: Install Visual Studio for Mac](#).
 - [Supported macOS versions](#).
 - [.NET versions supported by Visual Studio for Mac](#).

Create the app

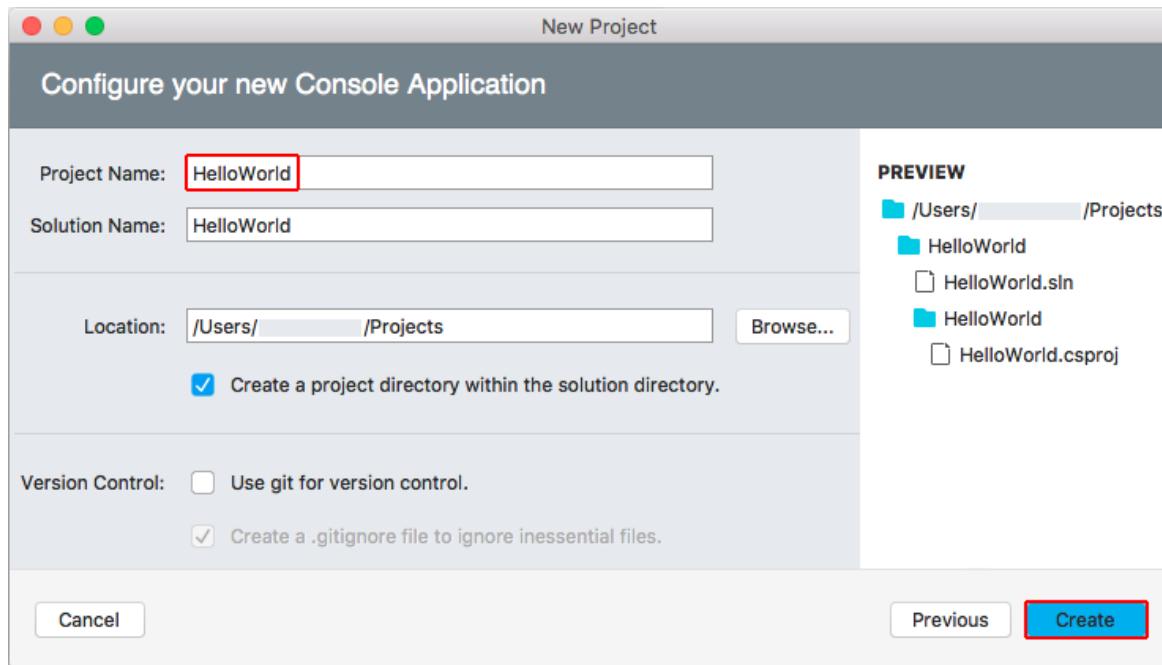

1. Start Visual Studio for Mac.
2. Select **New** in the start window.

3. In the **New Project** dialog, select **App** under the **Web and Console** node. Select the **Console Application** template, and select **Next**.

4. In the Target Framework drop-down of the Configure your new Console Application dialog, select .NET 5.0, and select Next.
5. Type "HelloWorld" for the Project Name, and select Create.

The template creates a simple "Hello World" application. It calls the `Console.WriteLine(String)` method to display "Hello World!" in the terminal window.

The template code defines a class, `Program`, with a single method, `Main`, that takes a `String` array as an argument:

```
using System;

namespace HelloWorld
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Hello World!");
        }
    }
}
```

Main is the application entry point, the method that's called automatically by the runtime when it launches the application. Any command-line arguments supplied when the application is launched are available in the args array.

Run the app

1. Press ⌘+option+command+enter to run the app without debugging.

The screenshot shows the Visual Studio interface on a Mac. The menu bar includes Apple, Visual Studio, File, Edit, View, Search, Project, Build, and Run. The toolbar has buttons for Stop, Start, Debug, and Default. A status bar message says "We'd love to hear about your .NET Core experience in Visual Studio for Mac." The code editor window is titled "Program.cs" and contains the provided C# code. The terminal window at the bottom is titled "Terminal - HelloWorld" and displays the output "Hello World!".

```
1 using System;
2
3 namespace HelloWorld
4 {
5     class Program
6     {
7         static void Main(string[] args)
8         {
9             Console.WriteLine("Hello World!");
10        }
11    }
12 }
13
```

```
Terminal - HelloWorld
Hello World!
```

2. Close the **Terminal** window.

Enhance the app

Enhance the application to prompt the user for their name and display it along with the date and time.

1. In *Program.cs*, replace the contents of the `Main` method, which is the line that calls `Console.WriteLine`, with the following code:

```
Console.WriteLine("What is your name?");
var name = Console.ReadLine();
var currentDate = DateTime.Now;
Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate:d} at {currentDate:t}!");
Console.Write($"{Environment.NewLine}Press any key to exit...");
Console.ReadKey(true);
```

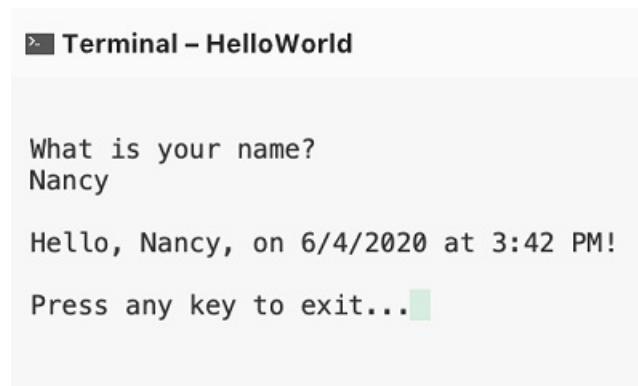

This code displays a prompt in the console window and waits until the user enters a string followed by the enter key. It stores this string in a variable named `name`. It also retrieves the value of the `DateTime.Now` property, which contains the current local time, and assigns it to a variable named `currentDate`. And it displays these values in the console window. Finally, it displays a prompt in the console window and calls the `Console.ReadKey(Boolean)` method to wait for user input.

`NewLine` is a platform-independent and language-independent way to represent a line break.

Alternatives are `\n` in C# and `vbcrlf` in Visual Basic.

The dollar sign (`$`) in front of a string lets you put expressions such as variable names in curly braces in the string. The expression value is inserted into the string in place of the expression. This syntax is referred to as [interpolated strings](#).

2. Press `⌘⌃⏎` (option+command+enter) to run the app.
3. Respond to the prompt by entering a name and pressing enter.

4. Close the terminal.

Next steps

In this tutorial, you created a .NET console application. In the next tutorial, you debug the app.

[Debug a .NET console application using Visual Studio for Mac](#)

Tutorial: Debug a .NET console application using Visual Studio for Mac

9/20/2022 • 6 minutes to read • [Edit Online](#)

This tutorial introduces the debugging tools available in Visual Studio for Mac.

Prerequisites

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio for Mac](#).

Use Debug build configuration

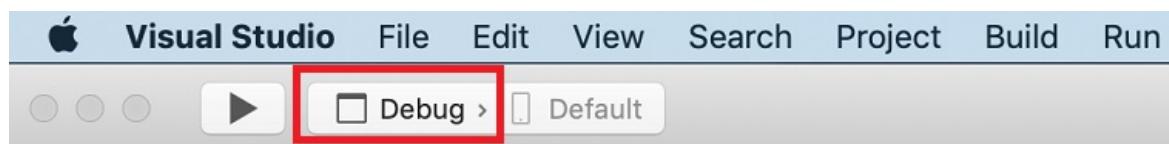

Debug and *Release* are Visual Studio's built-in build configurations. You use the Debug build configuration for debugging and the Release configuration for the final release distribution.

In the Debug configuration, a program compiles with full symbolic debug information and no optimization. Optimization complicates debugging, because the relationship between source code and generated instructions is more complex. The release configuration of a program has no symbolic debug information and is fully optimized.

By default, Visual Studio for Mac uses the Debug build configuration, so you don't need to change it before debugging.

1. Start Visual Studio for Mac.
2. Open the project that you created in [Create a .NET console application using Visual Studio for Mac](#).

The current build configuration is shown on the toolbar. The following toolbar image shows that Visual Studio is configured to compile the Debug version of the app:

Set a breakpoint

A *breakpoint* temporarily interrupts the execution of the application before the line with the breakpoint is executed.

1. Set a breakpoint on the line that displays the name, date, and time. To do that, place the cursor in the line of code and press $\text{⌘}\backslash$ ($\text{command} + \backslash$). Another way to set a breakpoint is by selecting **Run > Toggle Breakpoint** from the menu.

Visual Studio indicates the line on which the breakpoint is set by highlighting it and displaying a red dot in the left margin.

A screenshot of the Visual Studio code editor showing the file `Program.cs`. The code defines a `Program` class with a `Main` method. A red rectangle highlights the line `Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");`, which contains a breakpoint (indicated by a circled number 12). The code also includes a `Console.ReadKey(true);` statement at the end of the method.

```
1  using System;
2
3  namespace HelloWorld
4  {
5      class Program
6      {
7          static void Main(string[] args)
8          {
9              Console.WriteLine("What is your name?");
10             var name = Console.ReadLine();
11             var currentDate = DateTime.Now;
12             Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");
13             Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
14             Console.ReadKey(true);
15         }
16     }
17 }
```

2. Press ⌘+↑ (command+enter) to start the program in debugging mode. Another way to start debugging is by choosing Run > Start Debugging from the menu.
3. Enter a string in the terminal window when the program prompts for a name, and then press enter.
4. Program execution stops when it reaches the breakpoint, before the `Console.WriteLine` method executes.

A screenshot of the Visual Studio code editor showing the file `Program.cs`. The code is identical to the previous screenshot, but the line `Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");` does not have a red highlight or a breakpoint icon. The `Console.ReadKey(true);` statement is still present at the end of the method.

```
1  using System;
2
3  namespace HelloWorld
4  {
5      class Program
6      {
7          static void Main(string[] args)
8          {
9              Console.WriteLine("What is your name?");
10             var name = Console.ReadLine();
11             var currentDate = DateTime.Now;
12             Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");
13             Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
14             Console.ReadKey(true);
15         }
16     }
17 }
```

Use the Immediate window

The **Immediate** window lets you interact with the application you're debugging. You can interactively change the value of variables to see how it affects your program.

1. If the **Immediate** window is not visible, display it by choosing View > Debug Pads > **Immediate**.
2. Enter `name = "Gracie"` in the **Immediate** window and press enter.
3. Enter `currentDate = currentDate.AddDays(1)` in the **Immediate** window and press enter.

The **Immediate** window displays the new value of the string variable and the properties of the `DateTime` value.

```
[-] Immediate
name = "Gracie"
"Gracie"
currentDate = currentDate.AddDays(1)
{5/27/2021 11:15:29 AM}
    Date: {5/27/2021 12:00:00 AM}
    Day: 27
    DayOfWeek: System.DayOfWeek.Thursday
    DayOfYear: 147
    Hour: 11
    Kind: System.DateTimeKind.Local
    Millisecond: 799
    Minute: 15
    Month: 5
    Second: 29
    Ticks: 637577109297996840
    TimeOfDay: {11:15:29.7996840}
    Year: 2021
Static members:
Non-Public members:
```

The **Locals** window displays the values of variables that are defined in the currently executing method. The values of the variables that you just changed are updated in the **Locals** window.

Breakpoints		Locals	Watch	Threads
Name		Type		
args	{string[0]}	string[]		
name	Gracie	string		
▶ currentDate	{5/27/2021 11:15:29 AM}	System.DateTime		

4. Press ⌘← (command+enter) to continue debugging.

The values displayed in the terminal correspond to the changes you made in the **Immediate** window.

If you don't see the Terminal, select **Terminal - HelloWorld** in the bottom navigation bar.

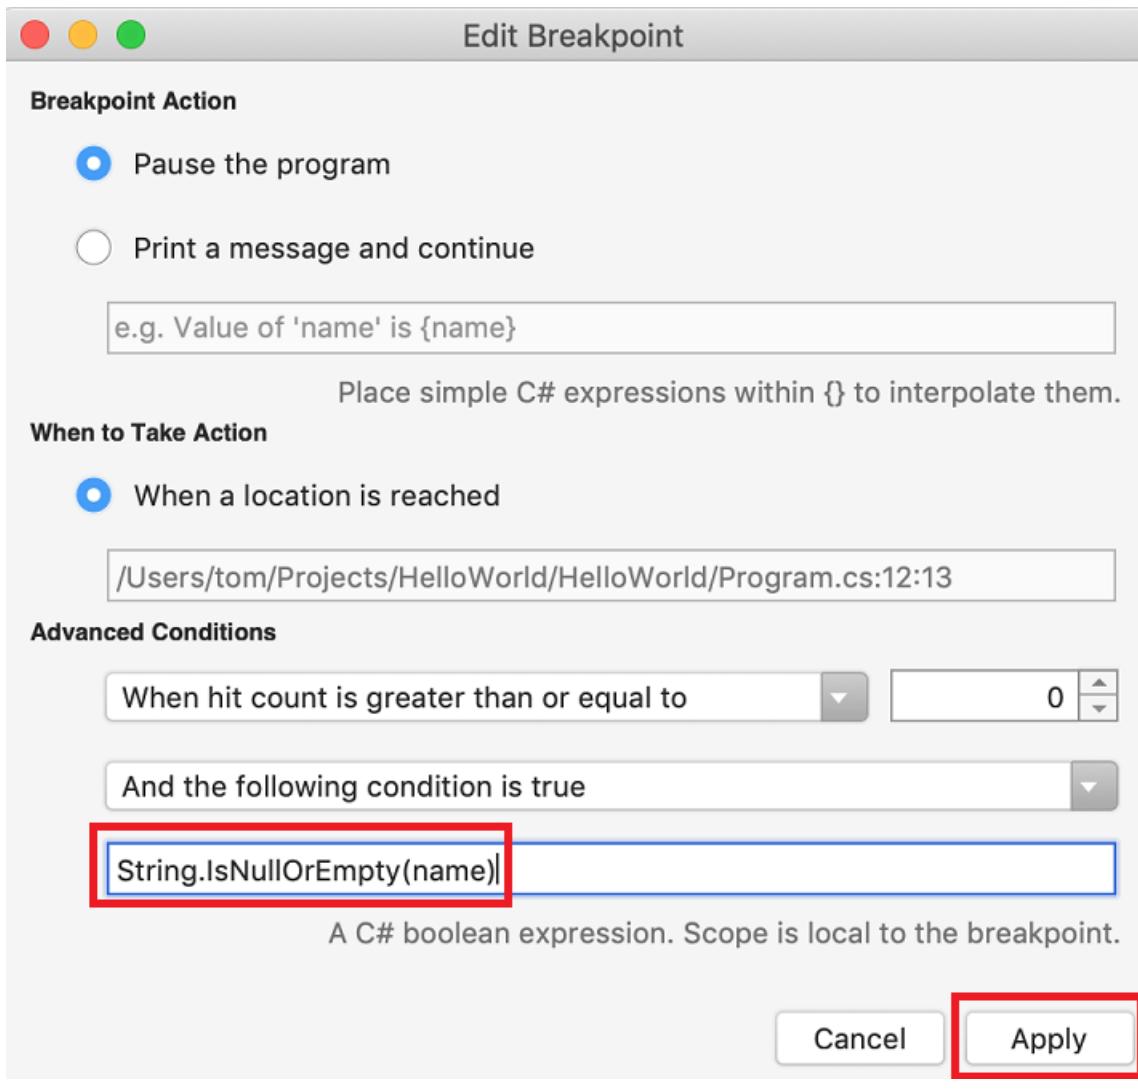

5. Press any key to exit the program.
6. Close the terminal window.

Set a conditional breakpoint

The program displays a string that the user enters. What happens if the user doesn't enter anything? You can test this with a useful debugging feature called a *conditional breakpoint*.

1. **ctrl-click** on the red dot that represents the breakpoint. In the context menu, select **Edit Breakpoint**.
2. In the **Edit Breakpoint** dialog, enter the following code in the field that follows **And the following condition is true**, and select **Apply**.

```
String.IsNullOrEmpty(name)
```

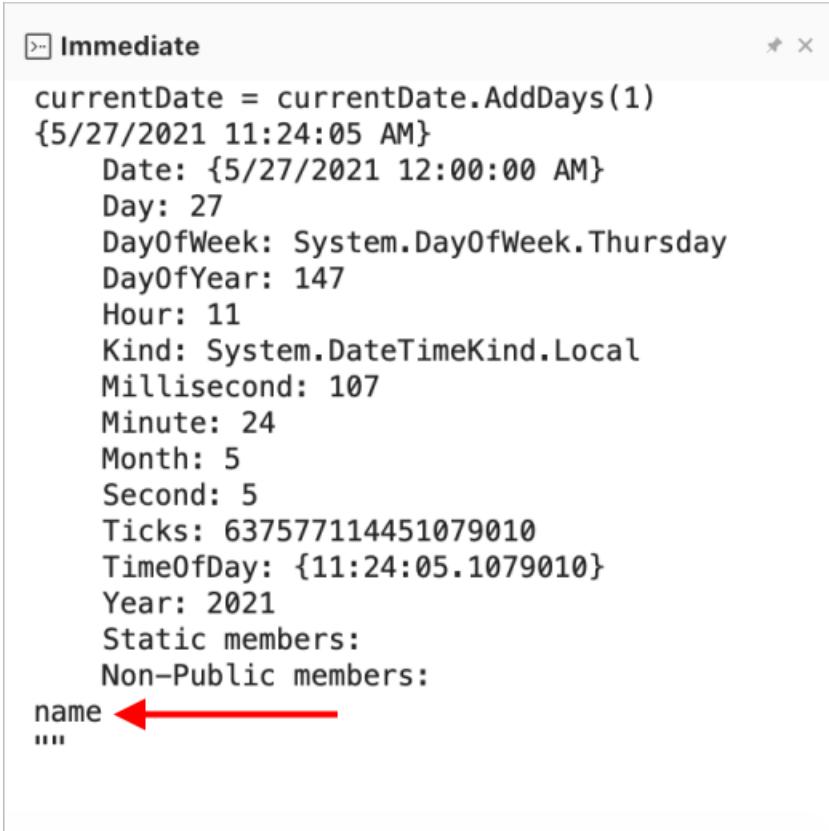

Each time the breakpoint is hit, the debugger calls the `String.IsNullOrEmpty(name)` method, and it breaks on this line only if the method call returns `true`.

Instead of a conditional expression, you can specify a *hit count*, which interrupts program execution before a statement is executed a specified number of times.

3. Press ⌘← (command+enter) to start debugging.
4. In the terminal window, press enter when prompted to enter your name.

Because the condition you specified (`name` is either `null` or `String.Empty`) has been satisfied, program execution stops when it reaches the breakpoint.

5. Select the **Locals** window, which shows the values of variables that are local to the currently executing method. In this case, `Main` is the currently executing method. Observe that the value of the `name` variable is `""`, that is, `String.Empty`.
6. You can also see that the value is an empty string by entering the `name` variable name in the **Immediate** window and pressing enter.

```
... Immediate ...
currentDate = currentDate.AddDays(1)
{5/27/2021 11:24:05 AM}
  Date: {5/27/2021 12:00:00 AM}
  Day: 27
  DayOfWeek: System.DayOfWeek.Thursday
  DayOfYear: 147
  Hour: 11
  Kind: System.DateTimeKind.Local
  Millisecond: 107
  Minute: 24
  Month: 5
  Second: 5
  Ticks: 637577114451079010
  TimeOfDay: {11:24:05.1079010}
  Year: 2021
  Static members:
  Non-Public members:
name ←
""
```

7. Press ⌘← (command+enter) to continue debugging.
8. In the terminal window, press any key to exit the program.
9. Close the terminal window.
10. Clear the breakpoint by clicking on the red dot in the left margin of the code window. Another way to clear a breakpoint is by choosing Run > Toggle Breakpoint while the line of code is selected.

Step through a program

Visual Studio also allows you to step line by line through a program and monitor its execution. Ordinarily, you'd set a breakpoint and follow program flow through a small part of your program code. Since this program is small, you can step through the entire program.

1. Set a breakpoint on the curly brace that marks the start of the `Main` method (press command+\).

2. Press ⌘← (command+enter) to start debugging.

Visual Studio stops on the line with the breakpoint.

3. Press ⇧⌘I (shift+command+I) or select Run > Step Into to advance one line.

Visual Studio highlights and displays an arrow beside the next line of execution.

```
1  using System;
2
3  namespace HelloWorld
4  {
5      class Program
6      {
7          static void Main(string[] args)
8          {
9              Console.WriteLine("What is your name?");
10             var name = Console.ReadLine();
11             var currentDate = DateTime.Now;
12             Console.WriteLine($"{Environment.NewLine}Hello, {name}, on {currentDate}");
13             Console.WriteLine($"{Environment.NewLine}Press any key to exit...");
14             Console.ReadKey(true);
15         }
16     }
17 }
```

At this point, the **Locals** window shows that the `args` array is empty, and `name` and `currentDate` have default values. In addition, Visual Studio has opened a blank terminal.

4. Press $\text{Shift} + \text{Command} + \text{I}$ (`shift+command+I`).

Visual Studio highlights the statement that includes the `name` variable assignment. The **Locals** window shows that `name` is `null`, and the terminal displays the string "What is your name?".

5. Respond to the prompt by entering a string in the console window and pressing enter.

6. Press $\text{Shift} + \text{Command} + \text{I}$ (`shift+command+I`).

Visual Studio highlights the statement that includes the `currentDate` variable assignment. The **Locals** window shows the value returned by the call to the `Console.ReadLine` method. The terminal displays the string you entered at the prompt.

7. Press $\text{Shift} + \text{Command} + \text{I}$ (`shift+command+I`).

The **Locals** window shows the value of the `currentDate` variable after the assignment from the `DateTime.Now` property. The terminal is unchanged.

8. Press $\text{Shift} + \text{Command} + \text{I}$ (`shift+command+I`).

Visual Studio calls the `Console.WriteLine(String, Object, Object)` method. The terminal displays the formatted string.

9. Press $\text{Shift} + \text{Command} + \text{U}$ (`shift+command+U`) or select **Run > Step Out**.

The terminal displays a message and waits for you to press a key.

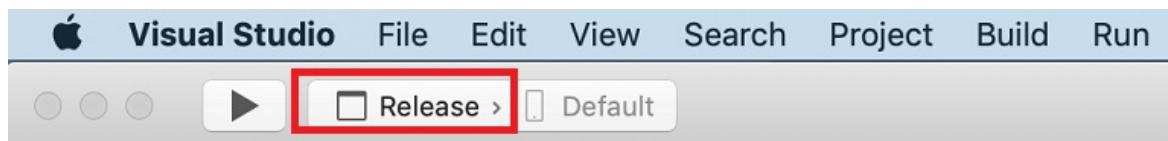

10. Press any key to exit the program.

Use Release build configuration

Once you've tested the Debug version of your application, you should also compile and test the Release version. The Release version incorporates compiler optimizations that can negatively affect the behavior of an application. For example, compiler optimizations that are designed to improve performance can create race conditions in multithreaded applications.

To build and test the Release version of the console application, do the following steps:

1. Change the build configuration on the toolbar from **Debug** to **Release**.

2. Press $\text{option} + \text{command} + \text{enter}$ (option+command+enter) to run without debugging.

Next steps

In this tutorial, you used Visual Studio debugging tools. In the next tutorial, you publish a deployable version of the app.

[Publish a .NET console application using Visual Studio for Mac](#)

Tutorial: Publish a .NET console application using Visual Studio for Mac

9/20/2022 • 2 minutes to read • [Edit Online](#)

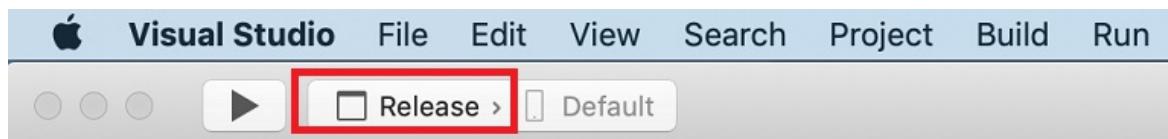

This tutorial shows how to publish a console app so that other users can run it. Publishing creates the set of files that are needed to run your application. To deploy the files, copy them to the target machine.

Prerequisites

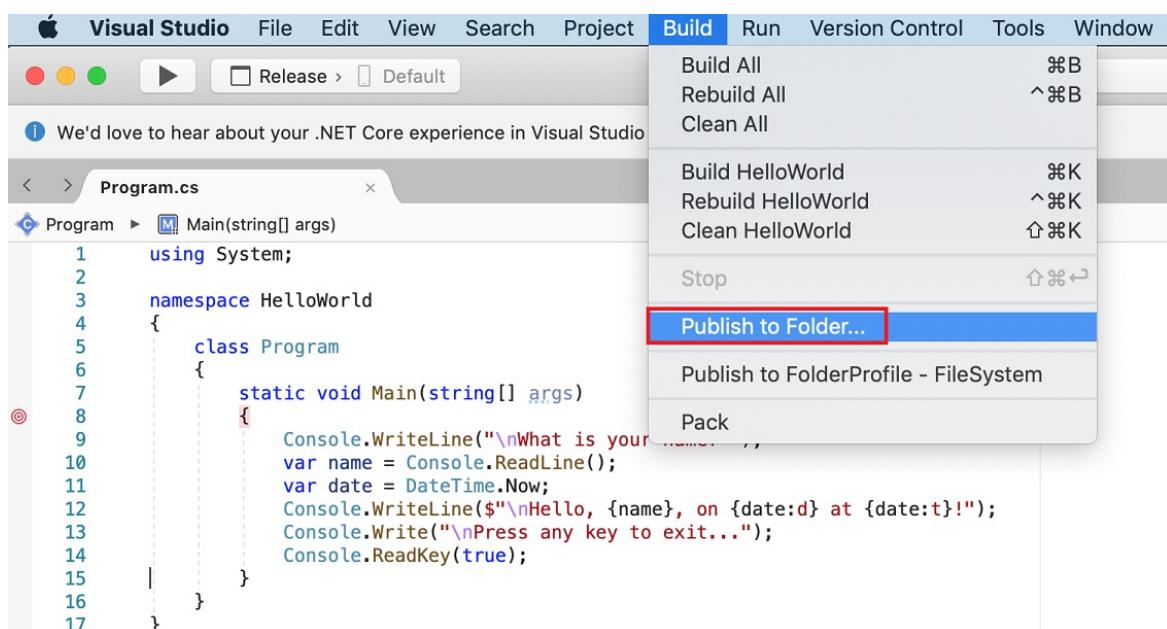

- This tutorial works with the console app that you create in [Create a .NET console application using Visual Studio for Mac](#).

Publish the app

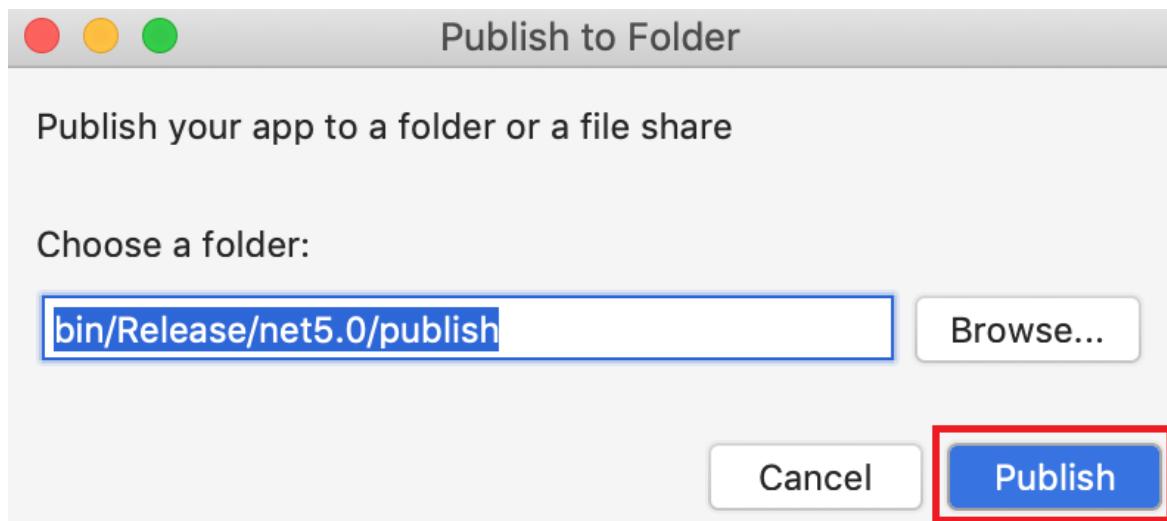

1. Start Visual Studio for Mac.
2. Open the HelloWorld project that you created in [Create a .NET console application using Visual Studio for Mac](#).
3. Make sure that Visual Studio is building the Release version of your application. If necessary, change the build configuration setting on the toolbar from **Debug** to **Release**.

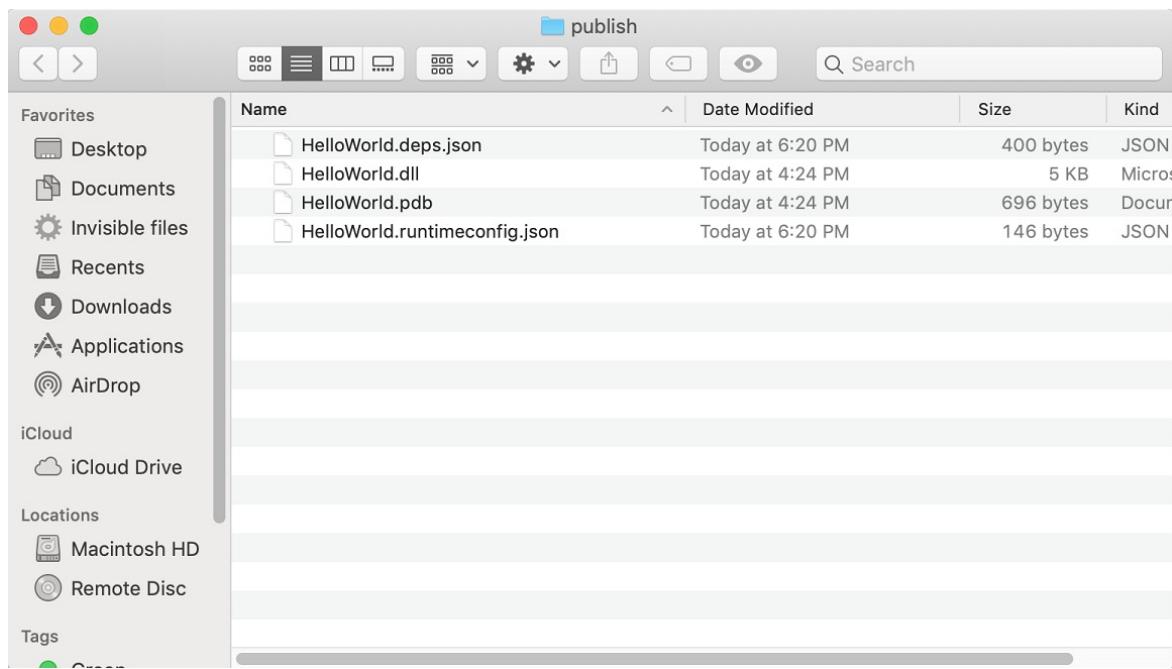

4. From the main menu, choose **Build > Publish to Folder....**

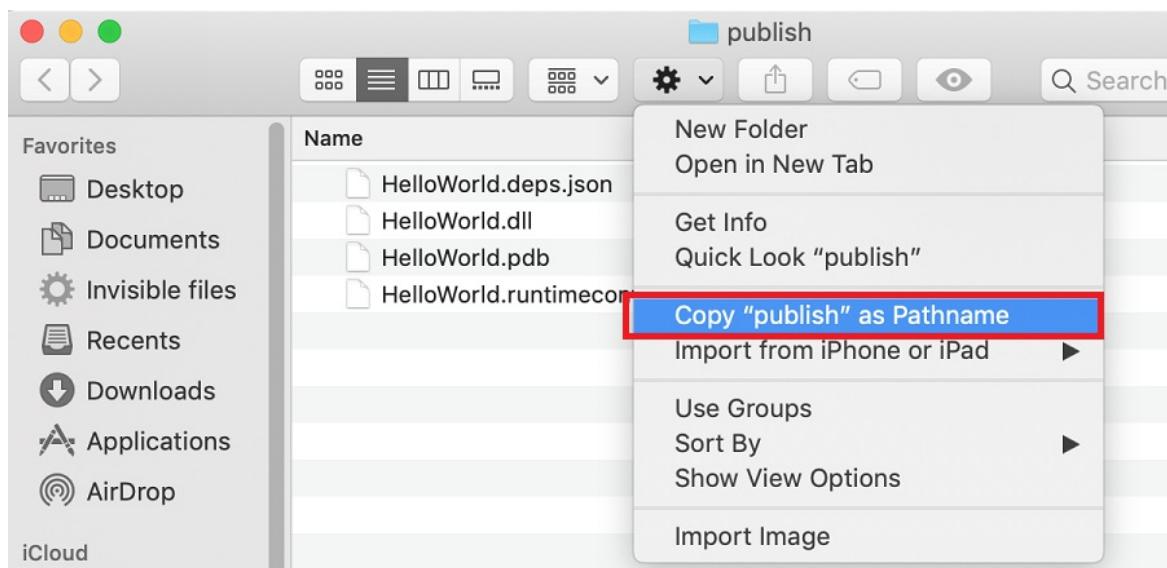

5. In the **Publish to Folder** dialog, select **Publish**.

The publish folder opens, showing the files that were created.

6. Select the gear icon, and select Copy "publish" as Pathname from the context menu.

Inspect the files

The publishing process creates a framework-dependent deployment, which is a type of deployment where the

published application runs on a machine that has the .NET runtime installed. Users can run the published app by running the `dotnet HelloWorld.dll` command from a command prompt.

As the preceding image shows, the published output includes the following files:

- *HelloWorlddeps.json*

This is the application's runtime dependencies file. It defines the .NET components and the libraries (including the dynamic link library that contains your application) needed to run the app. For more information, see [Runtime configuration files](#).

- *HelloWorld.dll*

This is the [framework-dependent deployment](#) version of the application. To execute this dynamic link library, enter `dotnet HelloWorld.dll` at a command prompt. This method of running the app works on any platform that has the .NET runtime installed.

- *HelloWorld.pdb* (optional for deployment)

This is the debug symbols file. You aren't required to deploy this file along with your application, although you should save it in the event that you need to debug the published version of your application.

- *HelloWorld.runtimeconfig.json*

This is the application's runtime configuration file. It identifies the version of .NET that your application was built to run on. You can also add configuration options to it. For more information, see [.NET runtime configuration settings](#).

Run the published app

1. Open a terminal and navigate to the *publish* folder. To do that, enter `cd` and then paste the path that you copied earlier. For example:

```
cd ~/Projects/HelloWorld/HelloWorld/bin/Release/net5.0/publish/
```

2. Run the app by using the `dotnet` command:

- a. Enter `dotnet HelloWorld.dll` and press enter.
- b. Enter a name in response to the prompt, and press any key to exit.

Additional resources

- [.NET application deployment](#)

Next steps

In this tutorial, you published a console app. In the next tutorial, you create a class library.

[Create a .NET library using Visual Studio for Mac](#)

Tutorial: Create a .NET class library using Visual Studio for Mac

9/20/2022 • 4 minutes to read • [Edit Online](#)

In this tutorial, you create a class library that contains a single string-handling method.

A *class library* defines types and methods that are called by an application. If the library targets .NET Standard 2.0, it can be called by any .NET implementation (including .NET Framework) that supports .NET Standard 2.0. If the library targets .NET 5, it can be called by any application that targets .NET 5. This tutorial shows how to target .NET 5.

NOTE

Your feedback is highly valued. There are two ways you can provide feedback to the development team on Visual Studio for Mac:

- In Visual Studio for Mac, select **Help > Report a Problem** from the menu or **Report a Problem** from the Welcome screen, which opens a window for filing a bug report. You can track your feedback in the [Developer Community](#) portal.
- To make a suggestion, select **Help > Provide a Suggestion** from the menu or **Provide a Suggestion** from the Welcome screen, which takes you to the [Visual Studio for Mac Developer Community webpage](#).

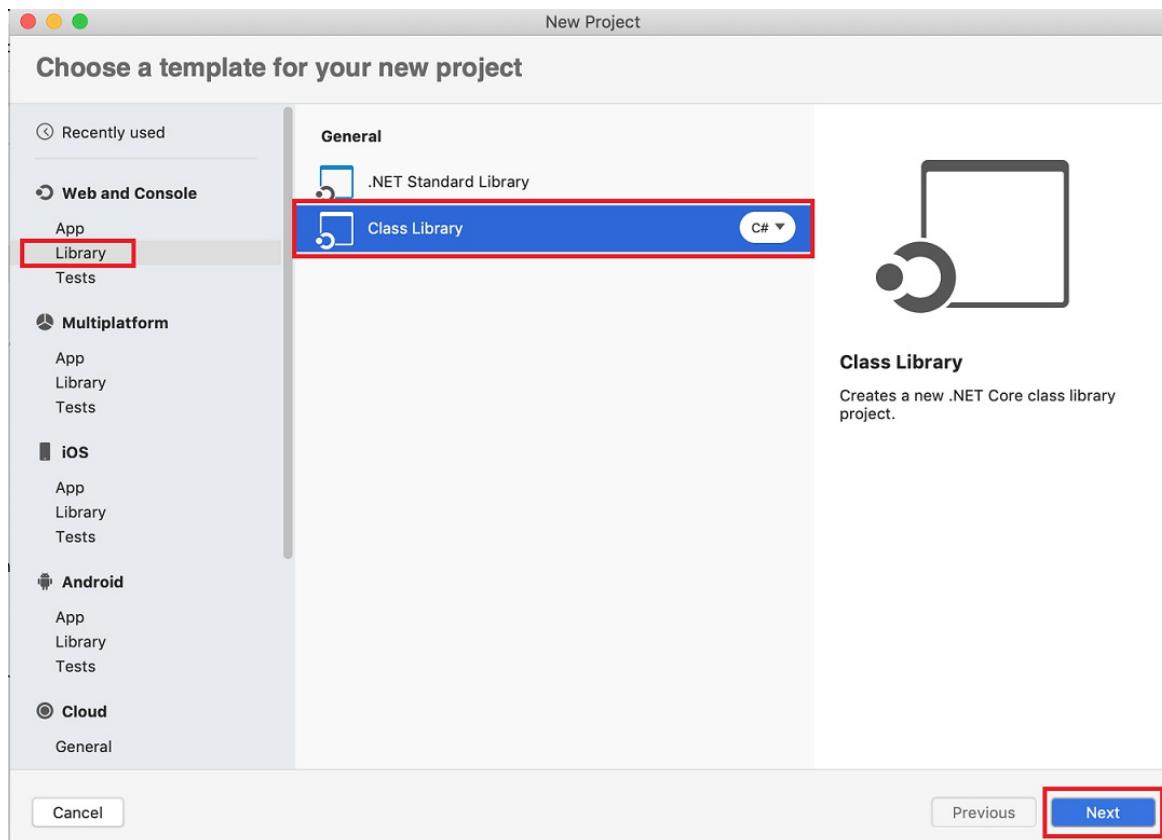

Prerequisites

- [Install Visual Studio for Mac version 8.8 or later](#). Select the option to install .NET Core. Installing Xamarin is optional for .NET development. For more information, see the following resources:
 - [Tutorial: Install Visual Studio for Mac](#).
 - [Supported macOS versions](#).
 - [.NET versions supported by Visual Studio for Mac](#).

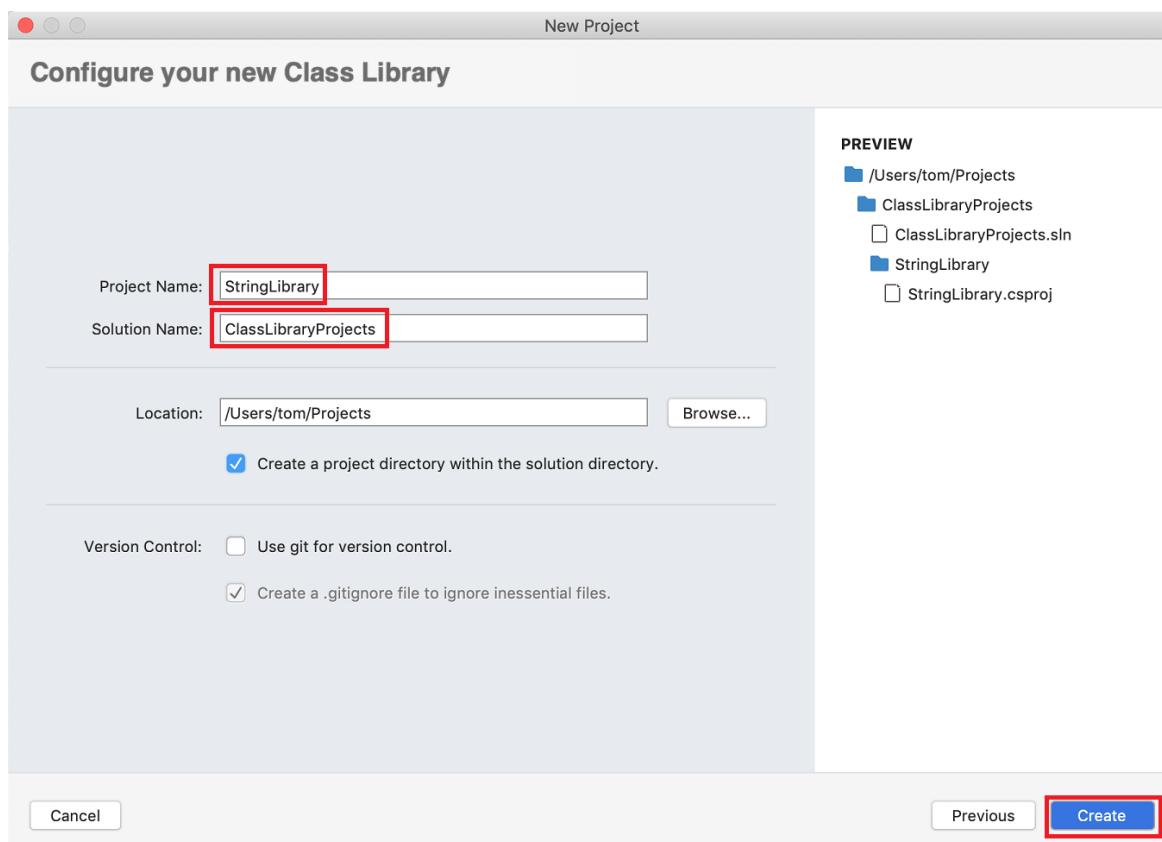

Create a solution with a class library project

A Visual Studio solution serves as a container for one or more projects. Create a solution and a class library project in the solution. You'll add additional, related projects to the same solution later.

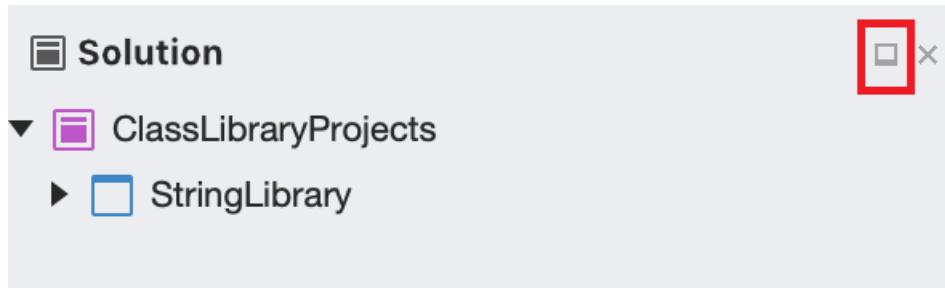

1. Start Visual Studio for Mac.
2. In the start window, select **New Project**.
3. In the **Choose a template for your new project** dialog select **Web and Console > Library > Class Library**, and then select **Next**.

4. In the **Configure your new Class Library** dialog, choose **.NET 5.0**, and select **Next**.
5. Name the project "StringLibrary" and the solution "ClassLibraryProjects". Leave **Create a project directory within the solution directory** selected. Select **Create**.

6. From the main menu, select **View > Solution**, and select the dock icon to keep the pad open.

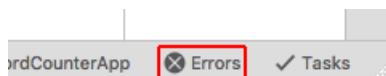

7. In the **Solution** pad, expand the `StringLibrary` node to reveal the class file provided by the template, `Class1.cs`. **ctrl**-click the file, select **Rename** from the context menu, and rename the file to `StringLibrary.cs`. Open the file and replace the contents with the following code:

```
using System;

namespace UtilityLibraries
{
    public static class StringLibrary
    {
        public static bool StartsWithUpper(this string str)
        {
            if (string.IsNullOrWhiteSpace(str))
                return false;

            char ch = str[0];
            return char.IsUpper(ch);
        }
    }
}
```

8. Press **⌘S** (command+S) to save the file.
9. Select **Errors** in the margin at the bottom of the IDE window to open the **Errors** panel. Select the **Build Output** button.

10. Select **Build > Build All** from the menu.

The solution builds. The build output panel shows that the build is successful.

```
Build succeeded.
  0 Warning(s)
  0 Error(s)

Time Elapsed 00:00:01.50

===== Build: 1 succeeded, 0 failed, 0 up-to-date, 0 skipped =====

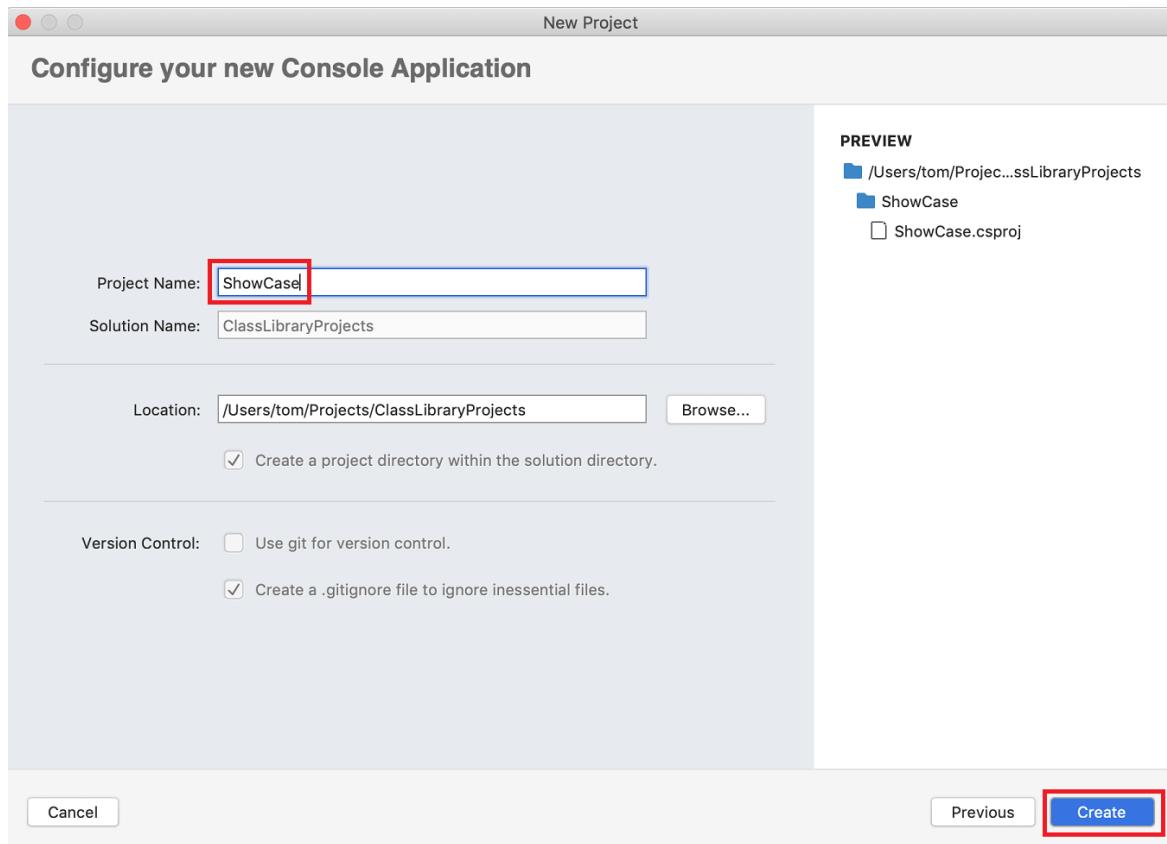

Build successful.
```

Add a console app to the solution

Add a console application that uses the class library. The app will prompt the user to enter a string and report whether the string begins with an uppercase character.

1. In the **Solution** pad, **ctrl**-click the `ClassLibraryProjects` solution. Add a new **Console Application** project by selecting the template from the **Web and Console > App** templates, and select **Next**.
2. Select **.NET 5.0** as the **Target Framework** and select **Next**.

3. Name the project **ShowCase**. Select **Create** to create the project in the solution.

4. Open the *Program.cs* file. Replace the code with the following code:

```

using System;
using UtilityLibraries;

class Program
{
    static void Main(string[] args)
    {
        int row = 0;

        do
        {
            if (row == 0 || row >= 25)
                ResetConsole();

            string? input = Console.ReadLine();
            if (string.IsNullOrEmpty(input)) break;
            Console.WriteLine($"Input: {input} {"Begins with uppercase? ",30}: " +
                $"{{(input.StartsWithUpper() ? "Yes" : "No")}{Environment.NewLine}}");
            row += 3;
        } while (true);
        return;
    }

    // Declare a ResetConsole local method
    void ResetConsole()
    {
        if (row > 0)
        {
            Console.WriteLine("Press any key to continue...");
            Console.ReadKey();
        }
        Console.Clear();
        Console.WriteLine($"{Environment.NewLine}Press <Enter> only to exit; otherwise, enter a
string and press <Enter>:{Environment.NewLine}");
        row = 3;
    }
}

```

The program prompts the user to enter a string. It indicates whether the string starts with an uppercase character. If the user presses the enter key without entering a string, the application ends, and the console window closes.

The code uses the `row` variable to maintain a count of the number of rows of data written to the console window. Whenever it's greater than or equal to 25, the code clears the console window and displays a message to the user.

Add a project reference

Initially, the new console app project doesn't have access to the class library. To allow it to call methods in the class library, create a project reference to the class library project.

1. In the **Solutions** pad, **ctrl-click** the **Dependencies** node of the new **ShowCase** project. In the context menu, select **Add Reference**.
2. In the **References** dialog, select **StringLibrary** and select **OK**.

Run the app

1. **ctrl-click** the **ShowCase** project and select **Run project** from the context menu.
2. Try out the program by entering strings and pressing enter, then press enter to exit.

Terminal – ShowCase

```
Press <Enter> only to exit; otherwise, enter a string and press <Enter>:
```

```
Begins with uppercase
```

```
Input: Begins with uppercase
```

```
Begins with uppercase? : Yes
```

```
begins with lowercase
```

```
Input: begins with lowercase
```

```
Begins with uppercase? : No
```

- [.NET Standard versions and the platforms they support.](#)

Next steps

In this tutorial, you created a solution and a library project, and added a console app project that uses the library. In the next tutorial, you add a unit test project to the solution.

[Test a .NET class library using Visual Studio for Mac](#)

Test a .NET class library using Visual Studio

9/20/2022 • 7 minutes to read • [Edit Online](#)

This tutorial shows how to automate unit testing by adding a test project to a solution.

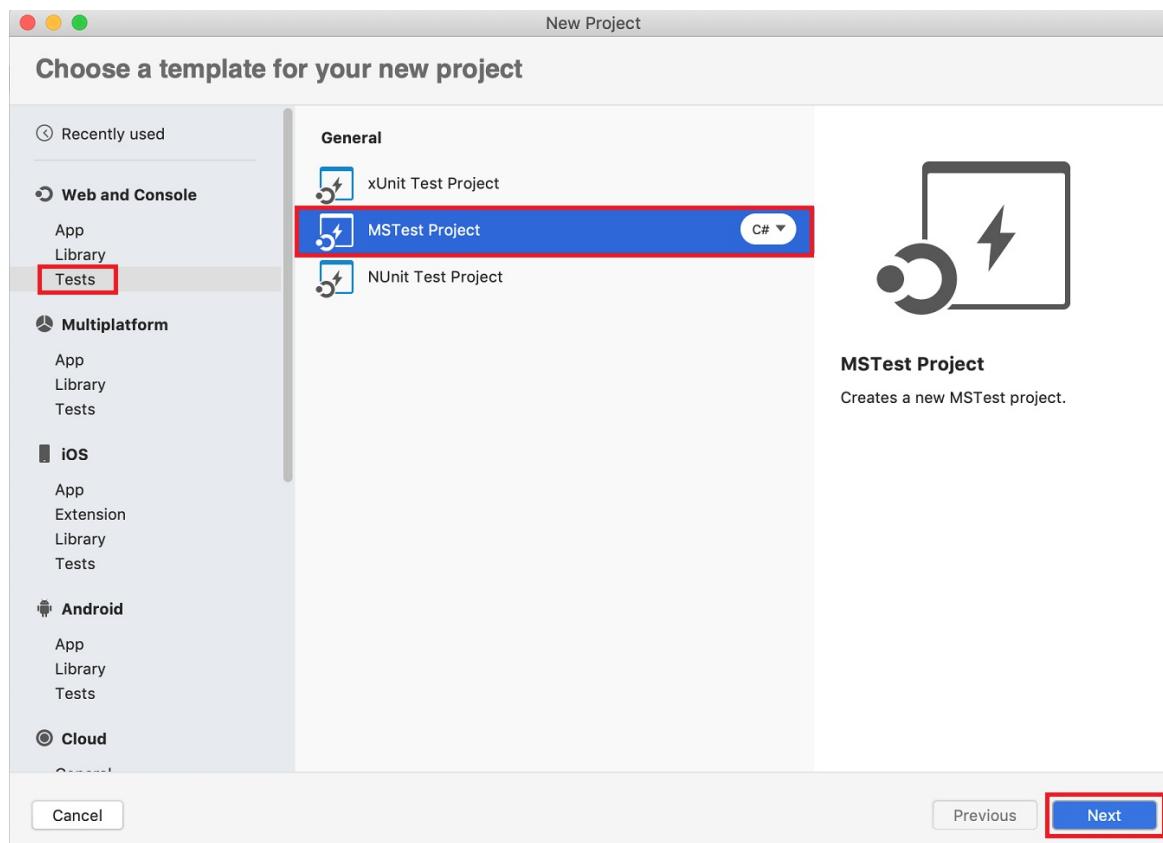

Prerequisites

- This tutorial works with the solution that you create in [Create a .NET class library using Visual Studio for Mac](#).

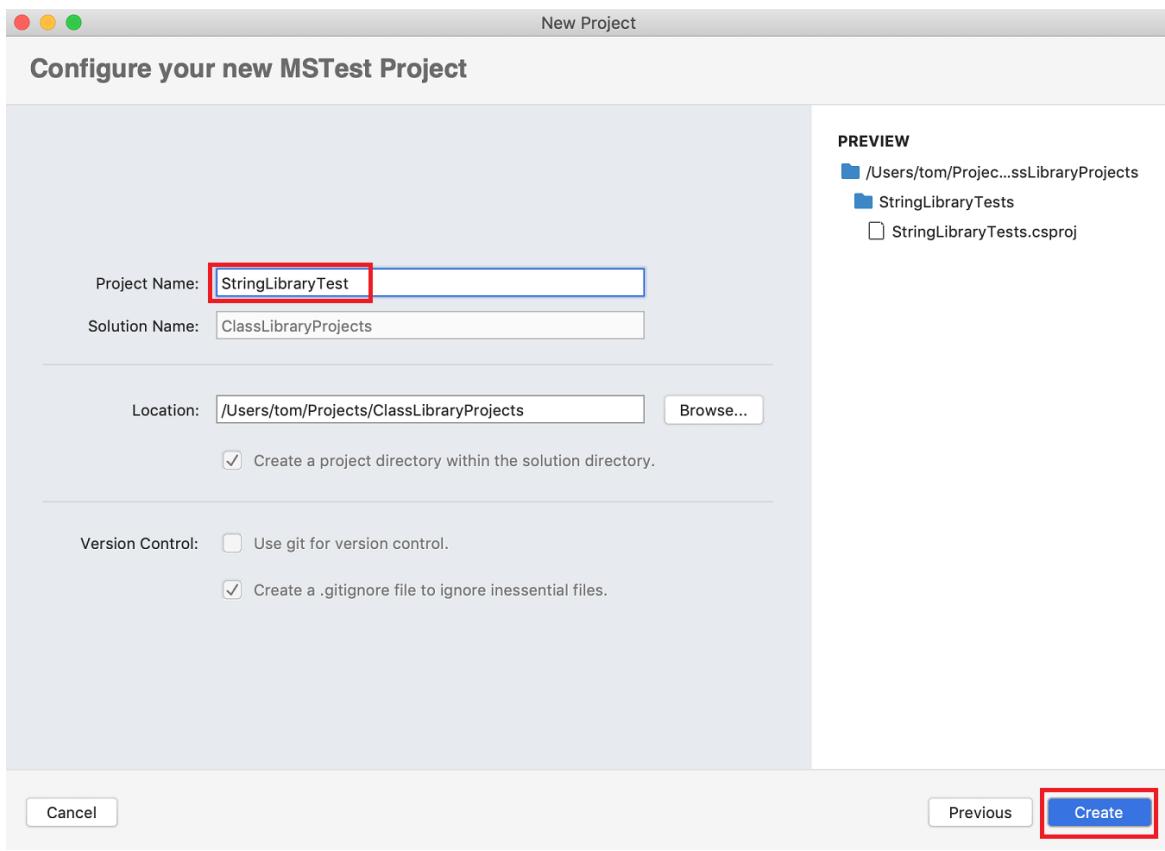

Create a unit test project

Unit tests provide automated software testing during your development and publishing. [MSTest](#) is one of three test frameworks you can choose from. The others are [xUnit](#) and [nUnit](#).

1. Start Visual Studio for Mac.
2. Open the `ClassLibraryProjects` solution you created in [Create a .NET class library using Visual Studio for Mac](#).
3. In the **Solution** pad, **ctrl**-click the `ClassLibraryProjects` solution and select **Add > New Project**.
4. In the **New Project** dialog, select **Tests** from the **Web and Console** node. Select the **MSTest Project** followed by **Next**.

5. Select .NET 5.0 as the **Target Framework** and select **Next**.
6. Name the new project "StringLibraryTest" and select **Create**.

Visual Studio creates a class file with the following code:

```
using Microsoft.VisualStudio.TestTools.UnitTesting;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestMethod1()
        {
        }
    }
}
```

The source code created by the unit test template does the following:

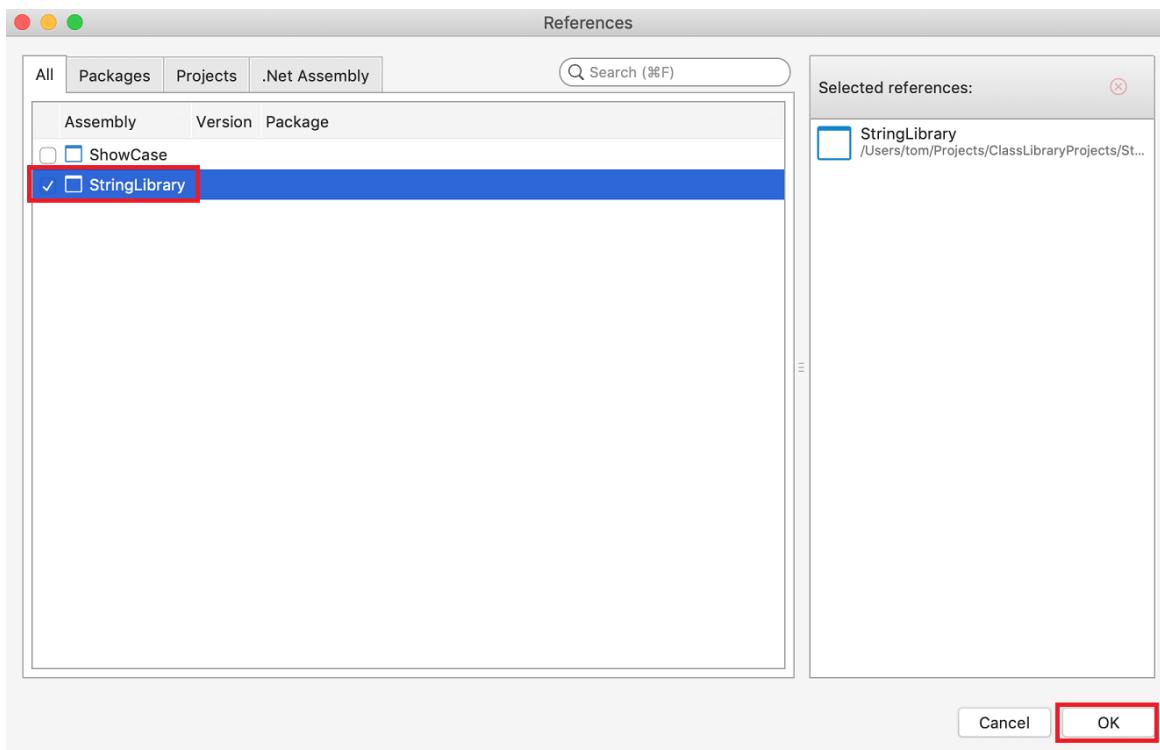

- It imports the `Microsoft.VisualStudio.TestTools.UnitTesting` namespace, which contains the types used for unit testing.
- It applies the `TestClassAttribute` attribute to the `UnitTest1` class.
- It applies the `TestMethodAttribute` attribute to `TestMethod1`.

Each method tagged with `[TestMethod]` in a test class tagged with `[TestClass]` is executed automatically when the unit test is run.

Add a project reference

For the test project to work with the `StringLibrary` class, add a reference to the `StringLibrary` project.

1. In the **Solution** pad, **ctrl+click** **Dependencies** under `StringLibraryTest`. Select **Add Reference** from the context menu.
2. In the **References** dialog, select the `StringLibrary` project. Select **OK**.

Add and run unit test methods

When Visual Studio runs a unit test, it executes each method that is marked with the `TestMethodAttribute` attribute in a class that is marked with the `TestClassAttribute` attribute. A test method ends when the first failure is found or when all tests contained in the method have succeeded.

The most common tests call members of the `Assert` class. Many assert methods include at least two parameters, one of which is the expected test result and the other of which is the actual test result. Some of the `Assert` class's most frequently called methods are shown in the following table:

ASSERT METHODS	FUNCTION
<code>Assert.AreEqual</code>	Vерифицирует, что два значения или объекта равны. Тестовый метод fails, если значения или объекты не равны.
<code>Assert.AreSame</code>	Верифицирует, что два объекта указывают на один и тот же объект. Тестовый метод fails, если объекты указывают на разные объекты.
<code>Assert.IsFalse</code>	Верифицирует, что условие равно <code>false</code> . Тестовый метод fails, если условие равно <code>true</code> .
<code>Assert.IsNotNull</code>	Верифицирует, что объект не равен <code>null</code> . Тестовый метод fails, если объект равен <code>null</code> .

You can also use the `Assert.ThrowsException` method in a test method to indicate the type of exception it's expected to throw. The test fails if the specified exception isn't thrown.

In testing the `StringLibrary.StartsWithUpper` method, you want to provide a number of strings that begin with an uppercase character. You expect the method to return `true` in these cases, so you can call the `Assert.IsTrue` method. Similarly, you want to provide a number of strings that begin with something other than an uppercase character. You expect the method to return `false` in these cases, so you can call the `Assert.IsFalse` method.

Since your library method handles strings, you also want to make sure that it successfully handles an `empty string` (`String.Empty`), a valid string that has no characters and whose `Length` is 0, and a `null` string that hasn't

been initialized. You can call `StartsWithUpper` directly as a static method and pass a single `String` argument. Or you can call `StartsWithUpper` as an extension method on a `string` variable assigned to `null`.

You'll define three methods, each of which calls an `Assert` method for each element in a string array. You'll call a method overload that lets you specify an error message to be displayed in case of test failure. The message identifies the string that caused the failure.

To create the test methods:

1. Open the `UnitTest1.cs` file and replace the code with the following code:

```
using Microsoft.VisualStudio.TestTools.UnitTesting;
using UtilityLibraries;

namespace StringLibraryTest
{
    [TestClass]
    public class UnitTest1
    {
        [TestMethod]
        public void TestStartsWithUpper()
        {
            // Tests that we expect to return true.
            string[] words = { "Alphabet", "Zebra", "ABC", "Αθήνα", "Москва" };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsTrue(result,
                    string.Format("Expected for '{0}': true; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void TestDoesNotStartWithUpper()
        {
            // Tests that we expect to return false.
            string[] words = { "alphabet", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",
                "1234", ".", ";", " " };
            foreach (var word in words)
            {
                bool result = word.StartsWithUpper();
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word, result));
            }
        }

        [TestMethod]
        public void DirectCallWithNullOrEmpty()
        {
            // Tests that we expect to return false.
            string?[] words = { string.Empty, null };
            foreach (var word in words)
            {
                bool result = StringLibrary.StartsWithUpper(word ?? string.Empty);
                Assert.IsFalse(result,
                    string.Format("Expected for '{0}': false; Actual: {1}",
                        word == null ? "<null>" : word, result));
            }
        }
    }
}
```

The test of uppercase characters in the `TestStartsWithUpper` method includes the Greek capital letter

alpha (U+0391) and the Cyrillic capital letter EM (U+041C). The test of lowercase characters in the `TestDoesNotStartWithUpper` method includes the Greek small letter alpha (U+03B1) and the Cyrillic small letter Ghe (U+0433).

2. On the menu bar, select **File > Save As**. In the dialog, make sure that **Encoding** is set to **Unicode (UTF-8)**.

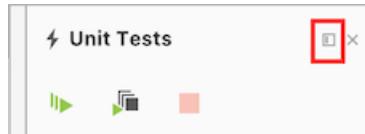

3. When you're asked if you want to replace the existing file, select **Replace**.

If you fail to save your source code as a UTF8-encoded file, Visual Studio may save it as an ASCII file. When that happens, the runtime doesn't accurately decode the UTF8 characters outside of the ASCII range, and the test results won't be correct.

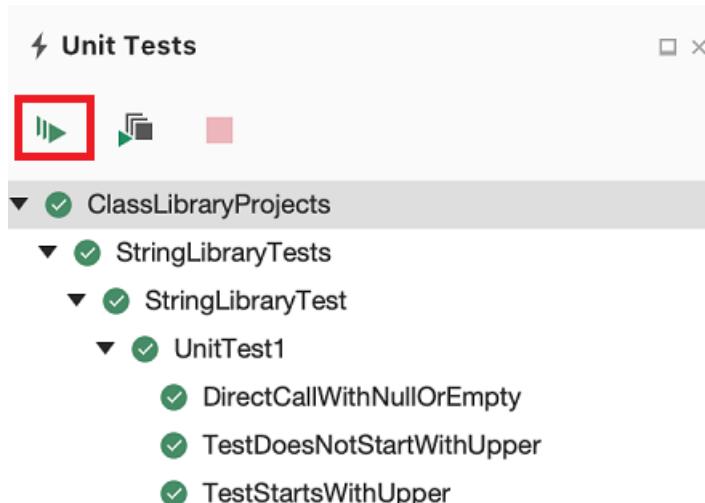

4. Open the **Unit Tests** panel on the right side of the screen. Select **View > Tests** from the menu.

5. Click the **Dock** icon to keep the panel open.

6. Click the **Run All** button.

All tests pass.

Handle test failures

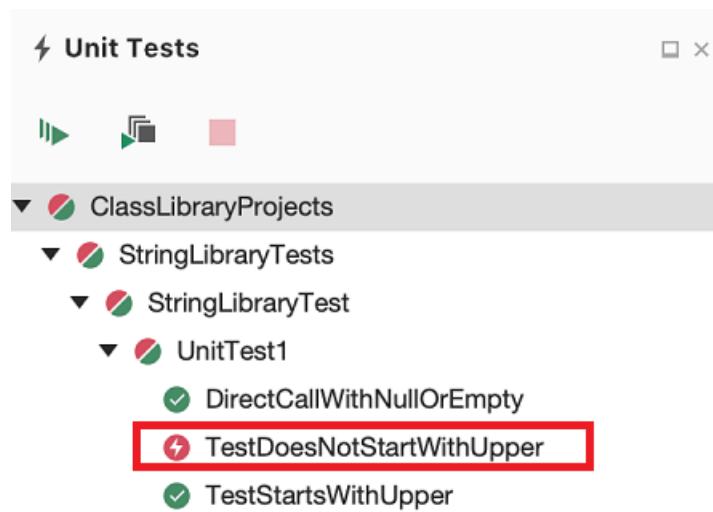

If you're doing test-driven development (TDD), you write tests first and they fail the first time you run them. Then you add code to the app that makes the test succeed. For this tutorial, you created the test after writing the app code that it validates, so you haven't seen the test fail. To validate that a test fails when you expect it to fail, add an invalid value to the test input.

1. Modify the `words` array in the `TestDoesNotStartWithUpper` method to include the string "Error". You don't need to save the file because Visual Studio automatically saves open files when a solution is built to run tests.

```
string[] words = { "alphabet", "Error", "zebra", "abc", "αυτοκινητοβιομηχανία", "государство",  
    "1234", ".", ";" };
```

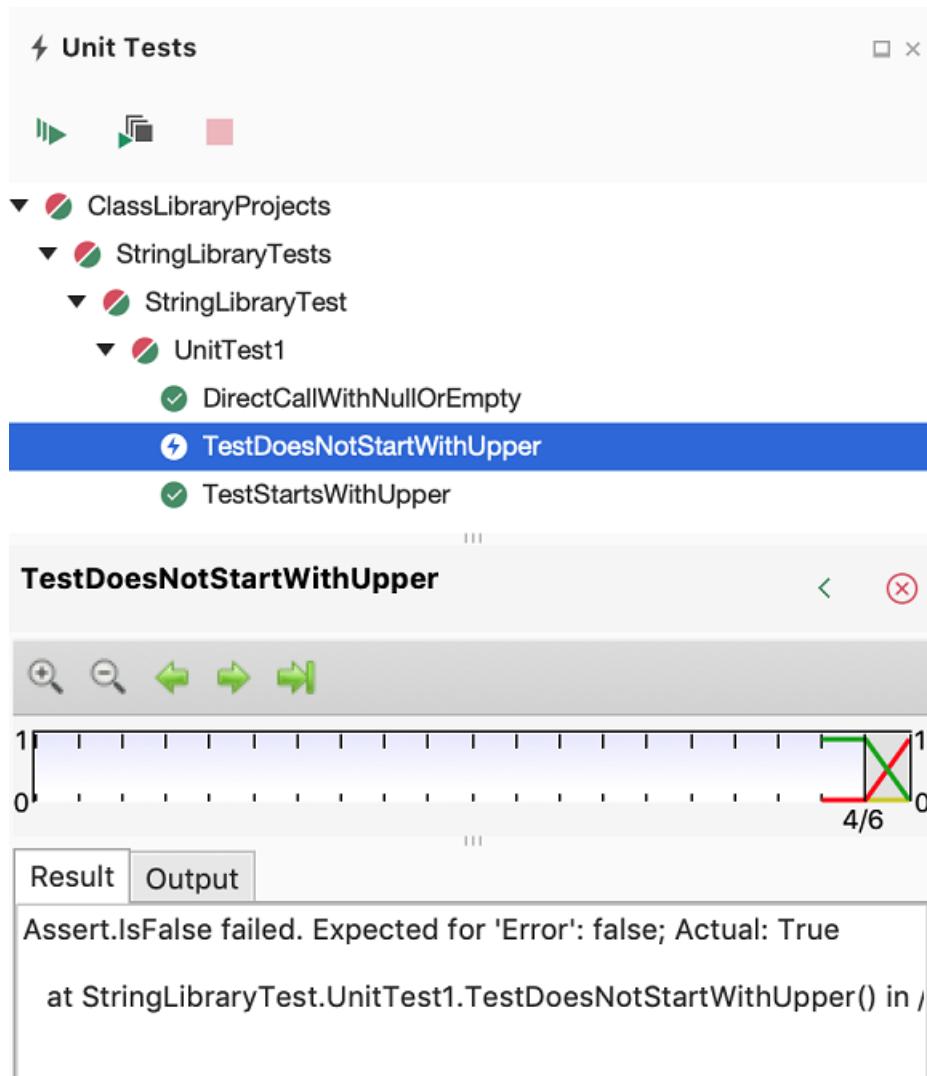

2. Run the tests again.

This time, the **Test Explorer** window indicates that two tests succeeded and one failed.

3. **ctrl-click** the failed test, `TestDoesNotStartWithUpper`, and select **Show Results Pad** from the context menu.

The **Results** pad displays the message produced by the assert: "Assert.IsFalse failed. Expected for 'Error': false; actual: True". Because of the failure, no strings in the array after "Error" were tested.

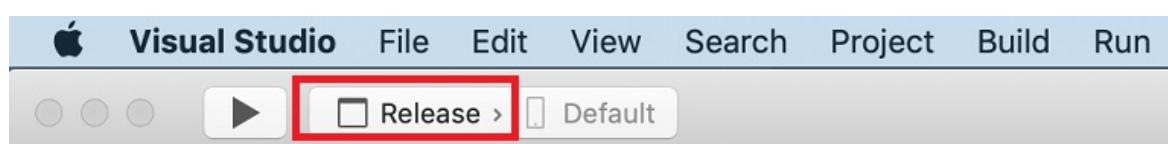

4. Remove the string "Error" that you added in step 1. Rerun the test and the tests pass.

Test the Release version of the library

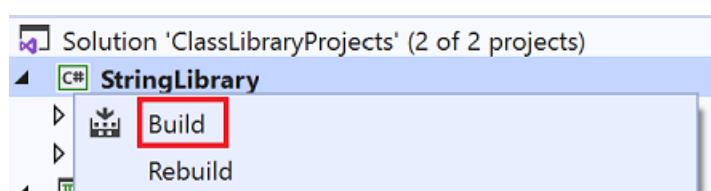

Now that the tests have all passed when running the Debug build of the library, run the tests an additional time against the Release build of the library. A number of factors, including compiler optimizations, can sometimes produce different behavior between Debug and Release builds.

To test the Release build:

1. In the Visual Studio toolbar, change the build configuration from Debug to Release.

2. In the Solution pad, **ctrl-click** the **StringLibrary** project and select **Build** from the context menu to recompile the library.

3. Run the unit tests again.

The tests pass.

Debug tests

If you're using Visual Studio for Mac as your IDE, you can use the same process shown in [Tutorial: Debug a .NET console application using Visual Studio for Mac](#) to debug code using your unit test project. Instead of starting the *ShowCase* app project, **ctrl-click** the **StringLibraryTests** project, and select **Start Debugging Project** from the context menu.

Visual Studio starts the test project with the debugger attached. Execution will stop at any breakpoint you've added to the test project or the underlying library code.

Next steps

In this tutorial, you unit tested a class library. You can make the library available to others by publishing it to [NuGet](#) as a package. To learn how, follow a NuGet tutorial:

[Create and publish a package \(dotnet CLI\)](#)

If you publish a library as a NuGet package, others can install and use it. To learn how, follow a NuGet tutorial:

[Install and use a package in Visual Studio for Mac](#)

A library doesn't have to be distributed as a package. It can be bundled with a console app that uses it. To learn how to publish a console app, see the earlier tutorial in this series:

[Publish a .NET console application using Visual Studio for Mac](#)

Learn .NET and the .NET SDK tools by exploring these tutorials

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following tutorials show how to develop console apps and libraries for .NET Core, .NET 5, and later versions. For other types of applications, see [Tutorials for getting started with .NET](#).

Use Visual Studio

- [Create a console app](#)
- [Debug an app](#)
- [Publish an app](#)
- [Create a class library](#)
- [Unit test a class library](#)
- [Install and use a package](#)
- [Create and publish a package](#)
- [Create an F# console app](#)

Use Visual Studio Code

Choose these tutorials if you want to use Visual Studio Code or some other code editor. All use the CLI for .NET Core development tasks, so all except the debugging tutorial can be used with any code editor.

- [Create a console app](#)
- [Debug an app](#)
- [Publish an app](#)
- [Create a class library](#)
- [Unit test a class library](#)
- [Install and use a package](#)
- [Create and publish a package](#)
- [Create an F# console app](#)

Use Visual Studio for Mac

- [Create a console app](#)
- [Debug an app](#)
- [Publish an app](#)
- [Create a class library](#)
- [Unit test a class library](#)
- [Install and use a package](#)
- [Create an F# console app](#)

What's new in .NET 6

9/20/2022 • 12 minutes to read • [Edit Online](#)

.NET 6 delivers the final parts of the .NET unification plan that started with [.NET 5](#). .NET 6 unifies the SDK, base libraries, and runtime across mobile, desktop, IoT, and cloud apps. In addition to this unification, the .NET 6 ecosystem offers:

- **Simplified development:** Getting started is easy. New language features in [C# 10](#) reduce the amount of code you need to write. And investments in the web stack and minimal APIs make it easy to quickly write smaller, faster microservices.
- **Better performance:** .NET 6 is the fastest full stack web framework, which lowers compute costs if you're running in the cloud.
- **Ultimate productivity:** .NET 6 and [Visual Studio 2022](#) provide hot reload, new git tooling, intelligent code editing, robust diagnostics and testing tools, and better team collaboration.

.NET 6 will be [supported for three years](#) as a long-term support (LTS) release.

Preview features are disabled by default. They are also not supported for use in production and may be removed in a future version. The new [RequiresPreviewFeaturesAttribute](#) is used to annotate preview APIs, and a corresponding analyzer alerts you if you're using these preview APIs.

.NET 6 is supported by Visual Studio 2022 and Visual Studio 2022 for Mac (and later versions).

This article does not cover all of the new features of .NET 6. To see all of the new features, and for further information about the features listed in this article, see the [Announcing .NET 6](#) blog post.

Performance

.NET 6 includes numerous performance improvements. This section lists some of the improvements—in [FileStream](#), [profile-guided optimization](#), and [AOT compilation](#). For detailed information, see the [Performance improvements in .NET 6](#) blog post.

FileStream

The [System.IO.FileStream](#) type has been rewritten for .NET 6 to provide better performance and reliability on Windows. Now, [FileStream](#) never blocks when created for asynchronous I/O on Windows. For more information, see the [File IO improvements in .NET 6](#) blog post.

Profile-guided optimization

Profile-guided optimization (PGO) is where the JIT compiler generates optimized code in terms of the types and code paths that are most frequently used. .NET 6 introduces *dynamic* PGO. Dynamic PGO works hand-in-hand with tiered compilation to further optimize code based on additional instrumentation that's put in place during tier 0. Dynamic PGO is disabled by default, but you can enable it with the `DOTNET_TieredPGO` environment variable. For more information, see [JIT performance improvements](#).

Crossgen2

.NET 6 introduces Crossgen2, the successor to Crossgen, which has been removed. Crossgen and Crossgen2 are tools that provide ahead-of-time (AOT) compilation to improve the startup time of an app. Crossgen2 is written in C# instead of C++, and can perform analysis and optimization that weren't possible with the previous version. For more information, see [Conversation about Crossgen2](#).

Arm64 support

The .NET 6 release includes support for macOS Arm64 (or "Apple Silicon") and Windows Arm64 operating systems, for both native Arm64 execution and x64 emulation. In addition, the x64 and Arm64 .NET installers now install side by side. For more information, see [.NET Support for macOS 11 and Windows 11 for Arm64 and x64](#).

Hot reload

Hot reload is a feature that lets you modify your app's source code and instantly apply those changes to your running app. The feature's purpose is to increase your productivity by avoiding app restarts between edits. Hot reload is available in Visual Studio 2022 and the `dotnet watch` command-line tool. Hot reload works with most types of .NET apps, and for C#, Visual Basic, and C++ source code. For more information, see the [Hot reload blog post](#).

.NET MAUI

.NET Multi-platform App UI (.NET MAUI) is still in *preview*, with a release candidate coming in the first quarter of 2022 and general availability (GA) in the second quarter of 2022. .NET MAUI makes it possible to build native client apps for desktop and mobile operating systems with a single codebase. For more information, see the [Update on .NET Multi-platform App UI](#) blog post.

C# 10 and templates

C# 10 includes innovations such as `global using` directives, file-scoped namespace declarations, and record structs. For more information, see [What's new in C# 10](#).

In concert with that work, the .NET SDK project templates for C# have been modernized to use some of the new language features:

- `async Main` method
- Top-level statements
- Target-typed new expressions
- `Implicit global using` directives
- File-scoped namespaces
- Nullable reference types

By adding these new language features to the project templates, new code starts with the features enabled. However, existing code isn't affected when you upgrade to .NET 6. For more information about these template changes, see the [.NET SDK: C# project templates modernized](#) blog post.

F# and Visual Basic

F# 6 adds several improvements to the F# language and F# Interactive. For more information, see [What's new in F# 6](#).

Visual Basic has improvements in the Visual Studio experience and Windows Forms project startup.

SDK Workloads

To keep the size of the .NET SDK smaller, some components have been placed in new, optional *SDK workloads*. These components include .NET MAUI and Blazor WebAssembly AOT. If you use Visual Studio, it will take care of installing any SDK workloads that you need. If you use the [.NET CLI](#), you can manage workloads using the new `dotnet workload` commands:

COMMAND	DESCRIPTION
<code>dotnet workload search</code>	Searches for available workloads.
<code>dotnet workload install</code>	Installs a specified workload.
<code>dotnet workload uninstall</code>	Removes a specified workload.
<code>dotnet workload update</code>	Updates installed workloads.
<code>dotnet workload repair</code>	Reinstalls all installed workloads to repair a broken installation.
<code>dotnet workload list</code>	Lists installed workloads.

For more information, see [Optional SDK workloads](#).

System.Text.Json APIs

Many improvements have been made in [System.Text.Json](#) in .NET 6, such that it is now an "industrial strength" serialization solution.

Source generator

.NET 6 adds a new [source generator](#) for [System.Text.Json](#). Source generation works with [JsonSerializer](#) and can be configured in multiple ways. It can improve performance, reduce memory usage, and facilitate assembly trimming. For more information, see [How to choose reflection or source generation in System.Text.Json](#) and [How to use source generation in System.Text.Json](#).

Writeable DOM

A new, writeable document object model (DOM) has been added, which supplements the pre-existing read-only DOM. The new API provides a lightweight serialization alternative for cases when use of plain old CLR object (POCO) types isn't possible. It also allows you to efficiently navigate to a subsection of a large JSON tree and read an array or deserialize a POCO from that subsection. The following new types have been added to support the writeable DOM:

- [JsonNode](#)
- [JsonArray](#)
- [JsonObject](#)
- [JsonValue](#)

For more information, see [JSON DOM choices](#).

IAsyncEnumerable serialization

[System.Text.Json](#) now supports serialization and deserialization with [IAsyncEnumerable<T>](#) instances. Asynchronous serialization methods enumerate any [IAsyncEnumerable<T>](#) instances in an object graph and then serialize them as JSON arrays. For deserialization, the new method [JsonSerializer.DeserializeAsyncEnumerable< TValue >\(Stream, JsonSerializerOptions, CancellationToken\)](#) was added. For more information, see [IAsyncEnumerable serialization](#).

Other new APIs

New serialization interfaces for validation and defaulting values:

- [IJsonOnDeserialized](#)
- [IJsonOnDeserializing](#)

- [IJsonOnSerialized](#)
- [IJsonOnSerializing](#)

For more information, see [Callbacks](#).

New property ordering attribute:

- [JsonPropertyOrderAttribute](#)

For more information, see [Configure the order of serialized properties](#).

New method to write "raw" JSON:

- [Utf8JsonWriter.WriteRawValue](#)

For more information, see [Write Raw JSON](#).

Synchronous serialization and deserialization to a stream:

- [JsonSerializer.Deserialize\(Stream, Type, JsonSerializerOptions\)](#)
- [JsonSerializer.Deserialize\(Stream, Type, JsonSerializerContext\)](#)
- [JsonSerializer.Deserialize< TValue >\(Stream, JsonSerializerOptions\)](#)
- [JsonSerializer.Deserialize< TValue >\(Stream, JsonTypeInfo< TValue >\)](#)
- [JsonSerializer.Serialize\(Stream, Object, Type, JsonSerializerOptions\)](#)
- [JsonSerializer.Serialize\(Stream, Object, Type, JsonSerializerContext\)](#)
- [JsonSerializer.Serialize< TValue >\(Stream, TValue, JsonSerializerOptions\)](#)
- [JsonSerializer.Serialize< TValue >\(Stream, TValue, JsonTypeInfo< TValue >\)](#)

New option to ignore an object when a reference cycle is detected during serialization:

- [ReferenceHandler.IgnoreCycles](#)

For more information, see [Ignore circular references](#).

For more information about serializing and deserializing with `System.Text.Json`, see [JSON serialization and deserialization in .NET](#).

HTTP/3

.NET 6 includes preview support for HTTP/3, a new version of HTTP. HTTP/3 solves some existing functional and performance challenges by using a new underlying connection protocol called QUIC. QUIC establishes connections more quickly, and connections are independent of the IP address, allowing mobile clients to roam between Wi-fi and cellular networks. For more information, see [Use HTTP/3 with HttpClient](#).

ASP.NET Core

ASP.NET Core includes improvements in minimal APIs, ahead-of-time (AOT) compilation for Blazor WebAssembly apps, and single-page apps. In addition, Blazor components can now be rendered from JavaScript and integrated with existing JavaScript based apps. For more information, see [What's new in ASP.NET Core 6](#).

OpenTelemetry

.NET 6 brings improved support for [OpenTelemetry](#), which is a collection of tools, APIs, and SDKs that help you analyze your software's performance and behavior. APIs in the `System.Diagnostics.Metrics` namespace implement the [OpenTelemetry Metrics API specification](#). For example, there are four instrument classes to support different metrics scenarios. The instrument classes are:

- [Counter< T >](#)

- [Histogram<T>](#)
- [ObservableCounter<T>](#)
- [ObservableGauge<T>](#)

Security

.NET 6 adds preview support for two key security mitigations: Control-flow Enforcement Technology (CET) and "write exclusive execute" (W^X).

CET is an Intel technology available in some newer Intel and AMD processors. It adds capabilities to the hardware that protect against some control-flow hijacking attacks. .NET 6 provides support for CET for Windows x64 apps, and you must explicitly enable it. For more information, see [.NET 6 compatibility with Intel CET shadow stacks](#).

W^X is available all operating systems with .NET 6 but only enabled by default on Apple Silicon. W^X blocks the simplest attack path by disallowing memory pages to be writeable and executable at the same time.

IL trimming

Trimming of self-contained deployments is improved. In .NET 5, only unused assemblies were trimmed. .NET 6 adds trimming of unused types and members too. In addition, trim warnings, which alert you to places where trimming may remove code that's used at run time, are now *enabled* by default. For more information, see [Trim self-contained deployments and executables](#).

Code analysis

The .NET 6 SDK includes a handful of new code analyzers that concern API compatibility, platform compatibility, trimming safety, use of span in string concatenation and splitting, faster string APIs, and faster collection APIs. For a full list of new (and removed) analyzers, see [Analyzer releases - .NET 6](#).

Custom platform guards

The [Platform compatibility analyzer](#) recognizes the `Is<Platform>` methods in the [OperatingSystem](#) class, for example, `OperatingSystem.IsWindows()`, as platform guards. To allow for custom platform guards, .NET 6 introduces two new attributes that you can use to annotate fields, properties, or methods with a supported or unsupported platform name:

- [SupportedOSPlatformGuardAttribute](#)
- [UnsupportedOSPlatformGuardAttribute](#)

Windows Forms

[Application.SetDefaultFont\(Font\)](#) is a new method in .NET 6 that sets the default font across your application.

The templates for C# Windows Forms apps have been updated to support `global using` directives, file-scoped namespaces, and nullable reference types. In addition, they include application bootstrap code, which reduces boilerplate code and allows the Windows Forms designer to render the design surface in the preferred font. The bootstrap code is a call to `ApplicationConfiguration.Initialize()`, which is a source-generated method that emits calls to other configuration methods, such as `Application.EnableVisualStyles()`. Additionally, if you set a non-default font via the `ApplicationDefaultFont` MSBuild property, `ApplicationConfiguration.Initialize()` emits a call to `SetDefaultFont(Font)`.

For more information, see the [What's new in Windows Forms](#) blog post.

Source build

The *source tarball*, which contains all the source for the .NET SDK, is now a product of the .NET SDK build. Other organizations, such as Red Hat, can build their own version of the SDK using this source tarball.

Target framework monikers

Additional OS-specific target framework monikers (TFMs) have been added for .NET 6, for example, `net6.0-android`, `net6.0-ios`, and `net6.0-macos`. For more information, see [.NET 5+ OS-specific TFMs](#).

Generic math

In *preview* is the ability to use operators on generic types in .NET 6. .NET 6 introduces numerous interfaces that make use of C# 10's new preview feature, `static abstract` interface members. These interfaces correspond to different operators, for example, `IAdditionOperators` represents the `+` operator. The interfaces are available in the `System.Runtime.Experimental` NuGet package. For more information, see the [Generic math](#) blog post.

NuGet package validation

If you're a NuGet library developer, new [package-validation tooling](#) enables you to validate that your packages are consistent and well-formed. You can determine if:

- There are any breaking changes across package versions.
- The package has the same set of public APIs for all runtime-specific implementations.
- There are any gaps for target-framework or runtime applicability.

For more information, see the [Package Validation](#) blog post.

Reflection APIs

.NET 6 introduces the following new APIs that inspect code and provide nullability information:

- `System.Reflection.NullabilityInfo`
- `System.Reflection.NullabilityInfoContext`
- `System.Reflection.NullabilityState`

These APIs are useful for reflection-based tools and serializers.

Microsoft.Extensions APIs

Several extensions namespaces have improvements in .NET 6, as the following table shows.

NAMESPACE	IMPROVEMENTS
<code>Microsoft.Extensions.DependencyInjection</code>	<code>CreateAsyncScope</code> lets you safely use a <code>using</code> statement for a service provider that registers an <code>IAsyncDisposable</code> service.
<code>Microsoft.Extensions.Hosting</code>	New <code>ConfigureHostOptions</code> methods simplify application setup.

NAMESPACE	IMPROVEMENTS
Microsoft.Extensions.Logging	<p>Microsoft.Extensions.Logging has a new source generator for performant logging APIs. The source generator is triggered if you add the new LoggerMessageAttribute to a <code>partial</code> logging method. At compile time, the generator generates the implementation of the <code>partial</code> method, which is typically faster at run time than existing logging solutions. For more information, see Compile-time logging source generation.</p>

New LINQ APIs

Numerous LINQ methods have been added in .NET 6. Most of the new methods listed in the following table have equivalent methods in the [System.Linq.Queryable](#) type.

METHOD	DESCRIPTION
<code>Enumerable.TryGetNonEnumeratedCount<TSource>(IEnumerable<TSource>, Int32)</code>	Attempts to determine the number of elements in a sequence without forcing an enumeration.
<code>Enumerable.Chunk<TSource>(IEnumerable<TSource>, Int32)</code>	Splits the elements of a sequence into chunks of a specified size.
<code>Enumerable.MaxBy</code> and <code>Enumerable.MinBy</code>	Finds maximal or minimal elements using a key selector.
<code>Enumerable.DistinctBy</code> , <code>Enumerable.ExceptBy</code> , <code>Enumerable.IntersectBy</code> , and <code>Enumerable.UnionBy</code>	These new variations of methods that perform set-based operations let you specify equality using a key selector function.
<code>Enumerable.ElementAt<TSource>(IEnumerable<TSource>, Index)</code> and <code>Enumerable.ElementAtOrDefault<TSource>(IEnumerable<TSource>, Index)</code>	Accepts indexes counted from the beginning or end of the sequence—for example, <code>Enumerable.Range(1, 10).ElementAt(^2)</code> returns <code>9</code> .
<code>Enumerable.FirstOrDefault<TSource>(IEnumerable<TSource>, TSource)</code> and <code>Enumerable.FirstOrDefault<TSource>(IEnumerable<TSource>, Func<TSource, Boolean>, TSource)</code> <code>Enumerable.LastOrDefault<TSource>(IEnumerable<TSource>, TSource)</code> and <code>Enumerable.LastOrDefault<TSource>(IEnumerable<TSource>, Func<TSource, Boolean>, TSource)</code> <code>Enumerable.SingleOrDefault<TSource>(IEnumerable<TSource>, TSource)</code> and <code>Enumerable.SingleOrDefault<TSource>(IEnumerable<TSource>, Func<TSource, Boolean>, TSource)</code>	New overloads let you specify a default value to use if the sequence is empty.
<code>Enumerable.Max<TSource>(IEnumerable<TSource>, IComparer<TSource>)</code> and <code>Enumerable.Min<TSource>(IEnumerable<TSource>, IComparer<TSource>)</code>	New overloads let you specify a comparer.
<code>Enumerable.Take<TSource>(IEnumerable<TSource>, Range)</code>	Accepts a <code>Range</code> argument to simplify taking a slice of a sequence—for example, you can use <code>source.Take(2..7)</code> instead of <code>source.Take(7).Skip(2)</code> .

METHOD	DESCRIPTION
<code>Enumerable.Zip<TFirst,TSecond,TThird>(IEnumerable<TFirst>, IEnumerable<TSecond>, IEnumerable<TThird>)</code>	Produces a sequence of tuples with elements from <i>three</i> specified sequences.

Date, time, and time zone improvements

The following two structs were added in .NET 6: [System.DateOnly](#) and [System.TimeOnly](#). These represent the date part and the time part of a [DateTime](#), respectively. [DateOnly](#) is useful for birthdays and anniversaries, and [TimeOnly](#) is useful for daily alarms and weekly business hours.

You can now use either Internet Assigned Numbers Authority (IANA) or Windows time zone IDs on any operating system that has time zone data installed. The [TimeZoneInfo.FindSystemTimeZoneById\(String\)](#) method has been updated to automatically convert its input from a Windows time zone to an IANA time zone (or vice versa) if the requested time zone is not found on the system. In addition, the new methods [TryConvertIanaIdToWindowsId\(String, String\)](#) and [TryConvertWindowsIdToIanaId](#) have been added for scenarios when you still need to manually convert from one time zone format to another.

There are a few other time zone improvements as well. For more information, see [Date, Time, and Time Zone Enhancements in .NET 6](#).

PriorityQueue class

The new [PriorityQueue<TElement,TPriority>](#) class represents a collection of items that have both a value and a priority. Items are dequeued in increasing priority order—that is, the item with the lowest priority value is dequeued first. This class implements a [min heap](#) data structure.

Breaking changes in .NET 6

9/20/2022 • 5 minutes to read • [Edit Online](#)

If you're migrating an app to .NET 6, the breaking changes listed here might affect you. Changes are grouped by technology area, such as ASP.NET Core or Windows Forms.

This article categorizes each breaking change as *binary incompatible* or *source incompatible*.

- **Binary incompatible** - Existing binaries may encounter a breaking change in behavior, such as failure to load or execute, or different run-time behavior.
- **Source incompatible** - Source code may encounter a breaking change in behavior when targeting the new runtime or using the new SDK or component. Behavior changes can include compile errors or different run-time behavior.

NOTE

This article is a work-in-progress. It's not a complete list of breaking changes in .NET 6. To query breaking changes that are still pending publication, see [Issues of .NET](#).

ASP.NET Core

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE	INTRODUCED
ActionResult<T> sets StatusCode to 200	✓	✗	
AddDataAnnotationsValidation method made obsolete	✓	✗	
Assemblies removed from Microsoft.AspNetCore.App shared framework	✗	✓	
Blazor: Parameter name changed in RequestImageFileAsync method	✓	✗	Preview 1
Blazor: WebEventDescriptorEventArgsType property replaced	✗	✗	
Blazor: Byte array interop	✓	✗	Preview 6
Changed MessagePack library in @microsoft/signalr-protocol-msgpack	✗	✓	

Title	Binary Compatible	Source Compatible	Introduced
ClientCertificate property doesn't trigger renegotiation for HttpSys	✓	✗	
EndpointName metadata not set automatically	✓	✗	RC 2
Identity: Default Bootstrap version of UI changed	✗	✗	
Kestrel: Log message attributes changed	✓	✗	
Microsoft.AspNetCore.Http. Features split	✗	✓	
Middleware: HTTPS Redirection Middleware throws exception on ambiguous HTTPS ports	✓	✗	
Middleware: New Use overload	✓	✗	Preview 4
Minimal API renames in RC 1	✗	✗	RC 1
Minimal API renames in RC 2	✗	✗	RC 2
MVC doesn't buffer IAsyncEnumerable types when using System.Text.Json	✓	✗	Preview 4
Nullable reference type annotations changed	✓	✗	
Obsolete and removed APIs	✓	✗	Preview 1
PreserveCompilationContext not configured by default	✗	✓	
Razor: Compiler no longer produces a Views assembly	✓	✗	Preview 3
Razor: Logging ID changes	✗	✓	RC1
Razor: RazorEngine APIs marked obsolete	✓	✗	Preview 1
SignalR: Java Client updated to RxJava3	✗	✓	Preview 4

Title	Binary Compatible	Source Compatible	Introduced
TryParse and BindAsync methods are validated	✗	✗	RC 2

Containers

Title	Binary Compatible	Source Compatible	Introduced
Default console logger formatting in container images	✓	✗	Servicing 6.0.6

For information on other breaking changes for containers in .NET 6, see [.NET 6 Container Release Notes](#).

Core .NET libraries

Title	Binary Compatible	Source Compatible	Introduced
API obsolesions with non-default diagnostic IDs	✓	✗	Preview 1
Changes to nullable reference type annotations	✓	✗	Preview 1-2
Conditional string evaluation in Debug methods	✓	✗	RC 1
Environment.ProcessorCount behavior on Windows	✓	✗	Preview 2
File.Replace on Unix throws exceptions to match Windows	✓	✗	Preview 7
FileStream locks files with shared lock on Unix	✗	✓	Preview 1
FileStream no longer synchronizes file offset with OS	✗	✗	Preview 4
FileStream.Position updates after ReadAsync or WriteAsync completes	✗	✗	Preview 4
New diagnostic IDs for obsoleted APIs	✓	✗	Preview 5
New nullable annotation in AssociatedMetadataTypeTypeDescriptionProvider	✓	✗	RC 2

Title	Binary Compatible	Source Compatible	Introduced
New System.Linq.Queryable method overloads	✓	✗	Preview 3-4
Older framework versions dropped from package	✗	✓	Preview 5
Parameter names changed	✓	✗	Preview 1
Parameter names in Stream-derived types	✓	✗	Preview 1
Partial and zero-byte reads in DeflateStream, GZipStream, and CryptoStream	✓	✗	Preview 6
Set timestamp on read-only file on Windows	✗	✓	Servicing 6.0.2
Standard numeric format parsing precision	✓	✗	Preview 2
Static abstract members in interfaces	✗	✓	Preview 7
StringBuilder.Append overloads and evaluation order	✗	✓	RC 1
Strong-name APIs throw PlatformNotSupportedException	✗	✓	Preview 4
System.Drawing.Common only supported on Windows	✗	✗	Preview 7

What's new in .NET 5

9/20/2022 • 4 minutes to read • [Edit Online](#)

.NET 5 is the next major release of .NET Core following 3.1. We named this new release .NET 5 instead of .NET Core 4 for two reasons:

- We skipped version numbers 4.x to avoid confusion with .NET Framework 4.x.
 - We dropped "Core" from the name to emphasize that this is the main implementation of .NET going forward.
- .NET 5 supports more types of apps and more platforms than .NET Core or .NET Framework.

ASP.NET Core 5.0 is based on .NET 5 but retains the name "Core" to avoid confusing it with ASP.NET MVC 5. Likewise, Entity Framework Core 5.0 retains the name "Core" to avoid confusing it with Entity Framework 5 and 6.

.NET 5 includes the following improvements and new features compared to .NET Core 3.1:

- [C# updates](#)
- [F# updates](#)
- [Visual Basic updates](#)
- [System.Text.Json new features](#)
- [Single file apps](#)
- [App trimming](#)
- Windows Arm64 and Arm64 intrinsics
- Tooling support for dump debugging
- The runtime libraries are 80% annotated for [nullable reference types](#)
- Performance improvements:
 - [Garbage Collection \(GC\)](#)
 - [System.Text.Json](#)
 - [System.Text.RegularExpressions](#)
 - [Async ValueTask pooling](#)
 - [Container size optimizations](#)
 - [Many more areas](#)

.NET 5 doesn't replace .NET Framework

.NET 5 and later versions are the main implementation of .NET going forward, but .NET Framework 4.x is still supported. There are no plans to port the following technologies from .NET Framework to .NET 5, but there are alternatives in .NET:

TECHNOLOGY	RECOMMENDED ALTERNATIVE
Web Forms	ASP.NET Core Blazor or Razor Pages
Windows Workflow (WF)	Elsa-Workflows

Windows Communication Foundation

The original implementation of [Windows Communication Foundation \(WCF\)](#) was only supported on Windows. However, there's a client port available from the .NET Foundation. It's entirely [open source](#), cross platform, and

supported by Microsoft. The core NuGet packages are listed below:

- [System.ServiceModel.Duplex](#)
- [System.ServiceModel.Federation](#)
- [System.ServiceModel.Http](#)
- [System.ServiceModel.NetTcp](#)
- [System.ServiceModel.Primitives](#)
- [System.ServiceModel.Security](#)

The server components that complement the aforementioned client libraries are available through [CoreWCF](#). As of April 2022, CoreWCF is officially supported by Microsoft. However, for an alternative to WCF, consider [gRPC](#).

.NET 5 doesn't replace .NET Standard

New application development can specify the `net5.0` Target Framework Moniker (TFM) for all project types, including class libraries. Sharing code between .NET 5 workloads is simplified: all you need is the `net5.0` TFM.

For .NET 5 apps and libraries, the `net5.0` TFM combines and replaces the `netcoreapp` and `netstandard` TFMs. However, if you plan to share code between .NET Framework, .NET Core, and .NET 5 workloads, you can do so by specifying `netstandard2.0` as your TFM. For more information, see [.NET Standard](#).

C# updates

Developers writing .NET 5 apps will have access to the latest C# version and features. .NET 5 is paired with C# 9, which brings many new features to the language. Here are a few highlights:

- **Records:** Reference types with value-based equality semantics and non-destructive mutation supported by a new `with` expression.
- **Relational pattern matching:** Extends pattern matching capabilities to relational operators for comparative evaluations and expressions, including logical patterns - new keywords `and`, `or`, and `not`.
- **Top-level statements:** As a means for accelerating the adoption and learning of C#, the `Main` method can be omitted, and an application as simple as the following example is valid:

```
System.Console.WriteLine("Hello world!");
```

- **Function pointers:** Language constructs that expose the following intermediate language (IL) opcodes: `ldftn` and `calli`.

For more information on the available C# 9 features, see [What's new in C# 9](#).

Source generators

In addition to some of the highlighted new C# features, source generators are making their way into developer projects. Source generators allow code that runs during compilation to inspect your program and produce additional files that are compiled together with the rest of your code.

For more information on source generators, see [Introducing C# source generators](#) and [C# source generator samples](#).

F# updates

F# is the .NET functional programming language, and with .NET 5, developers have access to F# 5. One of the new features is interpolated strings, similar to interpolated strings in C#, and even JavaScript.

```
let name = "David"
let age = 36
let message = $"{name} is {age} years old."
```

In addition to basic string interpolation, there's typed interpolation. With typed interpolation, a given type must match the format specifier.

```
let name = "David"
let age = 36
let message = $"{name} is {age} years old."
```

This format is similar to the `sprintf` function that formats a string based on type-safe inputs.

For more information, see [What's new in F# 5](#).

Visual Basic updates

There are no new language features for Visual Basic in .NET 5. However, with .NET 5, Visual Basic support is extended to:

DESCRIPTION	DOTNET NEW PARAMETER
Console Application	console
Class library	classlib
WPF Application	wpf
WPF Class library	wpflib
WPF Custom Control Library	wpfcustomcontrollib
WPF User Control Library	wpfusercontrollib
Windows Forms (WinForms) Application	winforms
Windows Forms (WinForms) Class library	winformslib
Unit Test Project	mstest
NUnit 3 Test Project	nunit
NUnit 3 Test Item	nunit-test
xUnit Test Project	xunit

For more information on project templates from the .NET CLI, see [dotnet new](#).

System.Text.Json new features

There are new features in and for [System.Text.Json](#):

- [Preserve references and handle circular references](#)
- [HttpClient and HttpContent extension methods](#)
- [Allow or write numbers in quotes](#)
- [Support immutable types and C# 9 Records](#)
- [Support non-public property accessors](#)
- [Support fields](#)
- [Conditionally ignore properties](#)
- [Support non-string-key dictionaries](#)
- [Allow custom converters to handle null](#)
- [Copy JsonSerializerOptions](#)
- [Create JsonSerializerOptions with web defaults](#)

Breaking changes in .NET 5

9/20/2022 • 5 minutes to read • [Edit Online](#)

If you're migrating an app to .NET 5, the breaking changes listed here might affect you. Changes are grouped by technology area, such as ASP.NET Core or cryptography.

This article categorizes each breaking change as *binary incompatible* or *source incompatible*.

- **Binary incompatible** - Existing binaries may encounter a breaking change in behavior, such as failure to load or execute, or different run-time behavior.
- **Source incompatible** - Source code may encounter a breaking change in behavior when targeting the new runtime or using the new SDK or component. Behavior changes can include compile errors or different run-time behavior.

ASP.NET Core

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
ASP.NET Core apps deserialize quoted numbers	✓	✗
AzureAD.UI and AzureADB2C.UI APIs obsolete	✓	✗
BinaryFormatter serialization methods are obsolete	✓	✗
Resource in endpoint routing is HttpContext	✓	✗
Microsoft-prefixed Azure integration packages removed	✗	✓
Blazor: Route precedence logic changed in Blazor apps	✓	✗
Blazor: Updated browser support	✓	✓
Blazor: Insignificant whitespace trimmed by compiler	✓	✗
Blazor: JObjectReference and JSInProcessObjectReference types are internal	✓	✗

Assembly-related API changes for single-file publishing	✗	✓
BinaryFormatter serialization methods are obsolete	✓	✗

Title	Binary Compatible	Source Compatible
Code access security APIs are obsolete	✓	✗
CreateCounterSetInstance throws InvalidOperationException	✓	✗
Default ActivityIdFormat is W3C	✗	✓
Environment.OSVersion returns the correct version	✗	✓
FrameworkDescription's value is .NET not .NET Core	✓	✗
GAC APIs are obsolete	✓	✗
Hardware intrinsic IsSupported checks	✗	✓
IntPtr and UIntPtr implement IFormattable	✓	✗
LastIndexOf handles empty search strings	✗	✓
URI paths with non-ASCII characters on Unix	✗	✓
API obsolesions with non-default diagnostic IDs	✓	✗
Obsolete properties on ConsoleLoggerOptions	✓	✗
Complexity of LINQ OrderBy.First	✗	✓
OSPlatform attributes renamed or removed	✓	✗
Microsoft.DotNet.PlatformAbstractions package removed	✗	✓
PrincipalPermissionAttribute is obsolete	✓	✗
Parameter name changes from preview versions	✓	✗
Parameter name changes in reference assemblies	✓	✗
Remoting APIs are obsolete	✗	✓
Order of Activity.Tags list is reversed	✓	✗

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
SSE and SSE2 comparison methods handle NaN	✓	✗
Thread.Abort is obsolete	✓	✗
Uri recognition of UNC paths on Unix	✗	✓
UTF-7 code paths are obsolete	✓	✗
Behavior change for Vector2.Lerp and Vector4.Lerp	✓	✗
Vector<T> throws NotSupportedException	✗	✓

Cryptography

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Cryptography APIs not supported on browser	✗	✓
Cryptography.Oid is init-only	✓	✗
Default TLS cipher suites on Linux	✗	✓
Create() overloads on cryptographic abstractions are obsolete	✓	✗
Default FeedbackSize value changed	✓	✗

Entity Framework Core

[Breaking changes in EF Core 5.0](#)

Globalization

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Use ICU libraries on Windows	✗	✓
StringInfo and TextElementEnumerator are UAX29-compliant	✗	✓
Unicode category changed for Latin-1 characters	✓	✗
TextInfo.ListSeparator values changed	✓	✗

Interop

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Support for WinRT is removed	✗	✓
Casting RCW to InterfacesInspectable throws exception	✗	✓
No A/W suffix probing on non-Windows platforms	✗	✓

Networking

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Cookie path handling conforms to RFC 6265	✓	✗
LocalEndPoint is updated after calling SendToAsync	✓	✗
MulticastOption.Group doesn't accept null	✓	✗
Streams allow successive Begin operations	✗	✓
WinHttpHandler removed from .NET runtime	✗	✓

SDK

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Directory.Packages.props files imported by default	✗	✓
Error generated when executable project references mismatched executable		✓
FrameworkReference replaced with WindowsSdkPackageVersion for Windows SDK	✓	✗
NETCOREAPP3_1 preprocessor symbol not defined	✓	✗
OutputType set to WinExe	✗	✓
PublishDepsFilePath behavior change	✗	✓
TargetFramework change from netcoreapp to net	✗	✓

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
WinForms and WPF apps use Microsoft.NETSdk	✗	✓

Security

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Code access security APIs are obsolete	✓	✗
PrincipalPermissionAttribute is obsolete	✓	✗
UTF-7 code paths are obsolete	✓	✗

Serialization

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
BinaryFormatter.Deserialize rewraps exceptions	✓	✗
JsonSerializer.Deserialize requires single-character string	✓	✗
ASP.NET Core apps deserialize quoted numbers	✓	✗
JsonSerializer.Serialize throws ArgumentNullException	✓	✗
Non-public, parameterless constructors not used for deserialization	✓	✗
Options are honored when serializing key-value pairs	✓	✗

Windows Forms

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Native code can't access Windows Forms objects	✓	✗
OutputType set to WinExe	✗	✓
DataGridView doesn't reset custom fonts	✓	✗
Methods throw ArgumentException	✓	✗

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
Methods throw ArgumentNullException	✓	✗
Properties throw ArgumentOutOfRangeException	✓	✗
TextFormatFlags.ModifyString is obsolete	✓	✗
DataGridView APIs throw InvalidOperationException	✓	✗
WinForms apps use Microsoft.NET.Sdk	✗	✓
Removed status bar controls	✓	✗

WPF

TITLE	BINARY COMPATIBLE	SOURCE COMPATIBLE
OutputType set to WinExe	✗	✓
WPF apps use Microsoft.NET.Sdk	✗	✓

What's new in .NET Core 3.1

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article describes what is new in .NET Core 3.1. This release contains minor improvements to .NET Core 3.0, focusing on small, but important, fixes. The most important feature about .NET Core 3.1 is that it's a [long-term support \(LTS\)](#) release.

If you're using Visual Studio 2019, you must update to [Visual Studio 2019 version 16.4 or later](#) to work with .NET Core 3.1 projects. For information on what's new in Visual Studio version 16.4, see [What's New in Visual Studio 2019 version 16.4](#).

Visual Studio for Mac also supports and includes .NET Core 3.1 in Visual Studio for Mac 8.4.

For more information about the release, see the [.NET Core 3.1 announcement](#).

- [Download and get started with .NET Core 3.1](#) on Windows, macOS, or Linux.

Long-term support

.NET Core 3.1 is an LTS release with support from Microsoft for three years after its release. It's highly recommended that you move your apps to the latest LTS release. See the [.NET and .NET Core support policy](#) page for a list of supported releases.

RELEASE	END OF LIFE DATE
.NET Core 3.1	End of life on December 13, 2022.
.NET Core 3.0	End of life on March 3, 2020.
.NET Core 2.2	End of life on December 23, 2019.
.NET Core 2.1	End of life on August 21, 2021.

For more information, see the [.NET and .NET Core support policy](#).

macOS appHost and notarization

macOS only

Starting with the notarized .NET Core SDK 3.1 for macOS, the appHost setting is disabled by default. For more information, see [macOS Catalina Notarization and the impact on .NET Core downloads and projects](#).

When the appHost setting is enabled, .NET Core generates a native Mach-O executable when you build or publish. Your app runs in the context of the appHost when it is run from source code with the `dotnet run` command, or by starting the Mach-O executable directly.

Without the appHost, the only way a user can start a [framework-dependent](#) app is with the `dotnet <filename.dll>` command. An appHost is always created when you publish your app [self-contained](#).

You can either configure the appHost at the project level, or toggle the appHost for a specific `dotnet` command with the `-p:UseAppHost` parameter:

- Project file

```
<PropertyGroup>
  <UseAppHost>true</UseAppHost>
</PropertyGroup>
```

- Command-line parameter

```
dotnet run -p:UseAppHost=true
```

For more information about the `UseAppHost` setting, see [MSBuild properties for Microsoft.NET.Sdk](#).

Windows Forms

Windows only

WARNING

There are breaking changes in Windows Forms.

Legacy controls were included in Windows Forms that have been unavailable in the Visual Studio Designer Toolbox for some time. These were replaced with new controls back in .NET Framework 2.0. These have been removed from the Desktop SDK for .NET Core 3.1.

REMOVED CONTROL	RECOMMENDED REPLACEMENT	ASSOCIATED APIs REMOVED
DataGrid	DataGridView	DataGridCell DataGridRow DataGridTableCollection DataGridColumnCollection DataGridTableStyle DataGridColumnStyle DataGridLineStyle DataGridParentRowsLabel DataGridParentRowsLabelStyle DataGridBoolColumn DataGridTextBox GridColumnStylesCollection GridTableStylesCollection HitTestType
ToolBar	ToolStrip	ToolBarAppearance
ToolBarButton	ToolStripButton	ToolBarButtonClickEventArgs ToolBarButtonClickEventHandler ToolBarButtonStyle ToolBarTextAlign
ContextMenu	ContextMenuStrip	
Menu	ToolStripDropDown ToolStripDropDownMenu	MenuItemCollection
MainMenu	MenuStrip	
MenuItem	ToolStripMenuItem	

We recommend you update your applications to .NET Core 3.1 and move to the replacement controls. Replacing the controls is a straightforward process, essentially "find and replace" on the type.

C++/CLI

Windows only

Support has been added for creating C++/CLI (also known as "managed C++") projects. Binaries produced from these projects are compatible with .NET Core 3.0 and later versions.

To add support for C++/CLI in Visual Studio 2019 version 16.4, install the [Desktop development with C++ workload](#). This workload adds two templates to Visual Studio:

- CLR Class Library (.NET Core)
- CLR Empty Project (.NET Core)

Next steps

- [Review the breaking changes in .NET Core 3.1 for Windows Forms apps.](#)

Breaking changes in .NET Core 3.1

9/20/2022 • 8 minutes to read • [Edit Online](#)

If you're migrating to version 3.1 of .NET Core or ASP.NET Core, the breaking changes listed in this article may affect your app.

ASP.NET Core

- [HTTP: Browser SameSite changes impact authentication](#)

HTTP: Browser SameSite changes impact authentication

Some browsers, such as Chrome and Firefox, made breaking changes to their implementations of `SameSite` for cookies. The changes impact remote authentication scenarios, such as OpenID Connect and WS-Federation, which must opt out by sending `SameSite=None`. However, `SameSite=None` breaks on iOS 12 and some older versions of other browsers. The app needs to sniff these versions and omit `sameSite`.

For discussion on this issue, see [dotnet/aspnetcore#14996](#).

Version introduced

3.1 Preview 1

Old behavior

`SameSite` is a 2016 draft standard extension to HTTP cookies. It's intended to mitigate Cross-Site Request Forgery (CSRF). This was originally designed as a feature the servers would opt into by adding the new parameters. ASP.NET Core 2.0 added initial support for `SameSite`.

New behavior

Google proposed a new draft standard that isn't backwards compatible. The standard changes the default mode to `Lax` and adds a new entry `None` to opt out. `Lax` suffices for most app cookies; however, it breaks cross-site scenarios like OpenID Connect and WS-Federation login. Most OAuth logins aren't affected because of differences in how the request flows. The new `None` parameter causes compatibility problems with clients that implemented the prior draft standard (for example, iOS 12). Chrome 80 will include the changes. See [SameSite Updates](#) for the Chrome product launch timeline.

ASP.NET Core 3.1 has been updated to implement the new `SameSite` behavior. The update redefines the behavior of `SameSiteMode.None` to emit `SameSite=None` and adds a new value `SameSiteMode.Unspecified` to omit the `SameSite` attribute. All cookie APIs now default to `Unspecified`, though some components that use cookies set values more specific to their scenarios such as the OpenID Connect correlation and nonce cookies.

For other recent changes in this area, see [HTTP: Some cookie SameSite defaults changed to None](#). In ASP.NET Core 3.0, most defaults were changed from `SameSiteMode.Lax` to `SameSiteMode.None` (but still using the prior standard).

Reason for change

Browser and specification changes as outlined in the preceding text.

Recommended action

Apps that interact with remote sites, such as through third-party login, need to:

- Test those scenarios on multiple browsers.
- Apply the cookie policy browser sniffing mitigation discussed in [Support older browsers](#).

For testing and browser sniffing instructions, see the following section.

Determine if you're affected

Test your web app using a client version that can opt into the new behavior. Chrome, Firefox, and Microsoft Edge Chromium all have new opt-in feature flags that can be used for testing. Verify that your app is compatible with older client versions after you've applied the patches, especially Safari. For more information, see [Support older browsers](#).

Chrome

Chrome 78 and later yield misleading test results. Those versions have a temporary mitigation in place and allow cookies less than two minutes old. With the appropriate test flags enabled, Chrome 76 and 77 yield more accurate results. To test the new behavior, toggle `chrome://flags/#same-site-by-default-cookies` to enabled. Chrome 75 and earlier are reported to fail with the new `None` setting. For more information, see [Support older browsers](#).

Google doesn't make older Chrome versions available. You can, however, download older versions of Chromium, which will suffice for testing. Follow the instructions at [Download Chromium](#).

- [Chromium 76 Win64](#)
- [Chromium 74 Win64](#)

Safari

Safari 12 strictly implemented the prior draft and fails if it sees the new `None` value in cookies. This must be avoided via the browser sniffing code shown in [Support older browsers](#). Ensure you test Safari 12 and 13 as well as WebKit-based, OS-style logins using Microsoft Authentication Library (MSAL), Active Directory Authentication Library (ADAL), or whichever library you're using. The problem is dependent on the underlying OS version. OSX Mojave 10.14 and iOS 12 are known to have compatibility problems with the new behavior. Upgrading to OSX Catalina 10.15 or iOS 13 fixes the problem. Safari doesn't currently have an opt-in flag for testing the new specification behavior.

Firefox

Firefox support for the new standard can be tested on version 68 and later by opting in on the `about:config` page with the feature flag `network.cookie.sameSite.laxByDefault`. No compatibility issues have been reported on older versions of Firefox.

Microsoft Edge

While Microsoft Edge supports the old `SameSite` standard, as of version 44 it didn't have any compatibility problems with the new standard.

Microsoft Edge Chromium

The feature flag is `edge://flags/#same-site-by-default-cookies`. No compatibility issues were observed when testing with Microsoft Edge Chromium 78.

Electron

Versions of Electron include older versions of Chromium. For example, the version of Electron used by Microsoft Teams is Chromium 66, which exhibits the older behavior. Perform your own compatibility testing with the version of Electron your product uses. For more information, see [Support older browsers](#).

Support older browsers

The 2016 `SameSite` standard mandated that unknown values be treated as `SameSite=Strict` values. Consequently, any older browsers that support the original standard may break when they see a `SameSite` property with a value of `None`. Web apps must implement browser sniffing if they intend to support these old browsers. ASP.NET Core doesn't implement browser sniffing for you because `User-Agent` request header values are highly unstable and change on a weekly basis. Instead, an extension point in the cookie policy allows you to add `User-Agent`-specific logic.

In `Startup.cs`, add the following code:

```

private void CheckSameSite(HttpContext httpContext, CookieOptions options)
{
    if (options.SameSite == SameSiteMode.None)
    {
        var userAgent = httpContext.Request.Headers["User-Agent"].ToString();
        // TODO: Use your User Agent library of choice here.
        if /* UserAgent doesn't support new behavior */
        {
            options.SameSite = SameSiteMode.Unspecified;
        }
    }
}

public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.MinimumSameSitePolicy = SameSiteMode.Unspecified;
        options.OnAppendCookie = cookieContext =>
            CheckSameSite(cookieContext.Context, cookieContext.CookieOptions);
        options.OnDeleteCookie = cookieContext =>
            CheckSameSite(cookieContext.Context, cookieContext.CookieOptions);
    });
}

public void Configure(IApplicationBuilder app)
{
    // Before UseAuthentication or anything else that writes cookies.
    app.UseCookiePolicy();

    app.UseAuthentication();
    // code omitted for brevity
}

```

Opt-out switches

The `Microsoft.AspNetCore.SuppressSameSiteNone` compatibility switch enables you to temporarily opt out of the new ASP.NET Core cookie behavior. Add the following JSON to a `runtimeconfig.template.json` file in your project:

```
{
  "configProperties": {
    "Microsoft.AspNetCore.SuppressSameSiteNone": "true"
  }
}
```

Other Versions

Related `SameSite` patches are forthcoming for:

- ASP.NET Core 2.1, 2.2, and 3.0
- `Microsoft.Owin` 4.1
- `System.Web` (for .NET Framework 4.7.2 and later)

Category

ASP.NET

Affected APIs

- `Microsoft.AspNetCore.Builder.CookiePolicyOptions.MinimumSameSitePolicy`
- `Microsoft.AspNetCore.Http.CookieBuilder.SameSite`
- `Microsoft.AspNetCore.Http.CookieOptions.SameSite`
- `Microsoft.AspNetCore.Http.SameSiteMode`

x86 host path on 64-bit Windows

MSBuild

- Design-time builds only return top-level package references

Design-time builds only return top-level package references

Starting in .NET Core SDK 3.1.400, only top-level package references are returned by the

`RunResolvePackageDependencies` target.

Version introduced

.NET Core SDK 3.1.400

Change description

In previous versions of the .NET Core SDK, the `RunResolvePackageDependencies` target created the following MSBuild items that contained information from the NuGet assets file:

- `PackageDefinitions`
- `PackageDependencies`
- `TargetDefinitions`
- `FileDefinitions`
- `FileDependencies`

This data is used by Visual Studio to populate the Dependencies node in Solution Explorer. However, it can be a large amount of data, and the data isn't needed unless the Dependencies node is expanded.

Starting in the .NET Core SDK version 3.1.400, most of these items aren't generated by default. Only items of type `Package` are returned. If Visual Studio needs the items to populate the Dependencies node, it reads the information directly from the assets file.

Reason for change

This change was introduced to improve solution-load performance inside of Visual Studio. Previously, all package references would be loaded, which involved loading many references that most users would never view.

Recommended action

If you have MSBuild logic that depends on these items being created, set the `EmitLegacyAssetsFileItems` property to `true` in your project file. This setting enables the previous behavior where all the items are created.

Windows Forms

- Removed controls
- CellFormatting event not raised if tooltip is shown

Removed controls

Starting in .NET Core 3.1, some Windows Forms controls are no longer available.

Change description

Starting with .NET Core 3.1, various Windows Forms controls are no longer available. Replacement controls that have better design and support were introduced in .NET Framework 2.0. The deprecated controls were previously removed from designer toolboxes but were still available to be used.

The following types are no longer available:

- [ContextMenu](#)
- [DataGridView](#)
- [DataGridView.HitTestType](#)
- [DataGridViewBoolColumn](#)
- [DataGridViewCell](#)
- [DataGridViewCellStyle](#)
- [DataGridViewLineStyle](#)
- [DataGridViewParentRowsLabelStyle](#)
- [DataGridViewPreferredColumnWidthTypeConverter](#)
- [DataGridViewTableStyle](#)
- [DataGridViewTextBox](#)
- [DataGridViewTextBoxColumn](#)
- [GridColumnStylesCollection](#)
- [GridTablesFactory](#)
- [GridTableStylesCollection](#)
- [IDataGridEditingService](#)
- [IMenuEditorService](#)
- [MainMenu](#)
- [Menu](#)
- [MenuItem.MenuItemCollection](#)
- [MenuItem](#)
- [ToolBar](#)
- [ToolBarAppearance](#)
- [ToolBarButton](#)
- [ToolBar.ToolBarButtonCollection](#)
- [ToolBarButtonClickEventArgs](#)
- [ToolBarButtonStyle](#)
- [ToolBar.TextAlign](#)

Version introduced

3.1

Recommended action

Each removed control has a recommended replacement control. Refer to the following table:

REMOVED CONTROL (API)	RECOMMENDED REPLACEMENT	ASSOCIATED APIs THAT ARE REMOVED
ContextMenu	ContextMenuStrip	

REMOVED CONTROL (API)	RECOMMENDED REPLACEMENT	ASSOCIATED APIs THAT ARE REMOVED
DataGridView	DataGridView	DataGridCell, DataGridRow, DataGridTableCollection, DataGridColumnCollection, DataGridTableStyle, DataGridColumnStyle, DataGridLineStyle, DataGridParentRowsLabel, DataGridParentRowsLabelStyle, DataGridBoolColumn, DataGridViewTextBox, GridColumnStylesCollection, GridTableStylesCollection, HitTestType
MainMenu	MenuStrip	
Menu	ToolStripDropDown, ToolStripDropDownMenu	MenuItemCollection
MenuItem	ToolStripMenuItem	
ToolBar	ToolStrip	ToolBarAppearance
ToolBarButton	ToolStripButton	ToolBarButtonClickEventArgs,ToolBarButtonClickEventHandler,ToolBarButtonStyle,ToolBarTextAlign

CellFormatting event not raised if tooltip is shown

A [DataGridView](#) now shows a cell's text and error tooltips when hovered by a mouse and when selected via the keyboard. If a tooltip is shown, the [DataGridView.CellFormatting](#) event is not raised.

Change description

Prior to .NET Core 3.1, a [DataGridView](#) that had the [ShowCellToolTips](#) property set to `true` showed a tooltip for a cell's text and errors when the cell was hovered by a mouse. Tooltips were not shown when a cell was selected via the keyboard (for example, by using the Tab key, shortcut keys, or arrow navigation). If the user edited a cell, and then, while the [DataGridView](#) was still in edit mode, hovered over a cell that did not have the [ToolTipText](#) property set, a [CellFormatting](#) event was raised to format the cell's text for display in the cell.

To meet accessibility standards, starting in .NET Core 3.1, a [DataGridView](#) that has the [ShowCellToolTips](#) property set to `true` shows tooltips for a cell's text and errors not only when the cell is hovered, but also when it's selected via the keyboard. As a consequence of this change, the [CellFormatting](#) event is *not* raised when cells that don't have the [ToolTipText](#) property set are hovered while the [DataGridView](#) is in edit mode. The event is not raised because the content of the hovered cell is shown as a tooltip instead of being displayed in the cell.

Version introduced

3.1

Recommended action

Refactor any code that depends on the [CellFormatting](#) event while the [DataGridView](#) is in edit mode.

What's new in .NET Core 3.0

9/20/2022 • 22 minutes to read • [Edit Online](#)

This article describes what is new in .NET Core 3.0. One of the biggest enhancements is support for Windows desktop applications (Windows only). By using the .NET Core 3.0 SDK component Windows Desktop, you can port your Windows Forms and Windows Presentation Foundation (WPF) applications. To be clear, the Windows Desktop component is only supported and included on Windows. For more information, see the [Windows desktop](#) section later in this article.

.NET Core 3.0 adds support for C# 8.0. It's highly recommended that you use [Visual Studio 2019 version 16.3](#) or newer, [Visual Studio for Mac 8.3](#) or newer, or [Visual Studio Code](#) with the latest C# extension.

[Download and get started with .NET Core 3.0](#) right now on Windows, macOS, or Linux.

For more information about the release, see the [.NET Core 3.0 announcement](#).

.NET Core 3.0 RC 1 was considered production ready by Microsoft and was fully supported. If you're using a preview release, you must move to the RTM version for continued support.

Language improvements C# 8.0

C# 8.0 is also part of this release, which includes the [nullable reference types](#) feature, [async streams](#), and more patterns. For more information about C# 8.0 features, see [What's new in C# 8.0](#).

Tutorials related to C# 8.0 language features:

- [Tutorial: Express your design intent more clearly with nullable and non-nullable reference types](#)
- [Tutorial: Generate and consume async streams using C# 8.0 and .NET Core 3.0](#)
- [Tutorial: Use pattern matching to build type-driven and data-driven algorithms](#)

Language enhancements were added to support the following API features detailed below:

- [Ranges and indices](#)
- [Async streams](#)

.NET Standard 2.1

.NET Core 3.0 implements [.NET Standard 2.1](#). However, the default `dotnet new classlib` template generates a project that still targets .NET Standard 2.0. To target .NET Standard 2.1, edit your project file and change the `TargetFramework` property to `netstandard2.1`:

```
<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <TargetFramework>netstandard2.1</TargetFramework>
  </PropertyGroup>

</Project>
```

If you're using Visual Studio, you need [Visual Studio 2019](#), as Visual Studio 2017 doesn't support .NET Standard 2.1 or .NET Core 3.0.

Compile/Deploy

Default executables

.NET Core now builds [framework-dependent executables](#) by default. This behavior is new for applications that use a globally installed version of .NET Core. Previously, only [self-contained deployments](#) would produce an executable.

During `dotnet build` or `dotnet publish`, an executable (known as the **appHost**) is created that matches the environment and platform of the SDK you're using. You can expect the same things with these executables as you would other native executables, such as:

- You can double-click on the executable.
- You can launch the application from a command prompt directly, such as `myapp.exe` on Windows, and `./myapp` on Linux and macOS.

macOS appHost and notarization

macOS only

Starting with the notarized .NET Core SDK 3.0 for macOS, the setting to produce a default executable (known as the **appHost**) is disabled by default. For more information, see [macOS Catalina Notarization and the impact on .NET Core downloads and projects](#).

When the **appHost** setting is enabled, .NET Core generates a native Mach-O executable when you build or publish. Your app runs in the context of the **appHost** when it is run from source code with the `dotnet run` command, or by starting the Mach-O executable directly.

Without the **appHost**, the only way a user can start a [framework-dependent](#) app is with the `dotnet <filename.dll>` command. An **appHost** is always created when you publish your app [self-contained](#).

You can either configure the **appHost** at the project level, or toggle the **appHost** for a specific `dotnet` command with the `-p:UseAppHost` parameter:

- Project file

```
<PropertyGroup>
  <UseAppHost>true</UseAppHost>
</PropertyGroup>
```

- Command-line parameter

```
dotnet run -p:UseAppHost=true
```

For more information about the `UseAppHost` setting, see [MSBuild properties for Microsoft.NET.Sdk](#).

Single-file executables

The `dotnet publish` command supports packaging your app into a platform-specific single-file executable. The executable is self-extracting and contains all dependencies (including native) that are required to run your app. When the app is first run, the application is extracted to a directory based on the app name and build identifier. Startup is faster when the application is run again. The application doesn't need to extract itself a second time unless a new version was used.

To publish a single-file executable, set the `PublishSingleFile` in your project or on the command line with the `dotnet publish` command:

```
<PropertyGroup>
  <RuntimeIdentifier>win10-x64</RuntimeIdentifier>
  <PublishSingleFile>true</PublishSingleFile>
</PropertyGroup>
```

-or-

```
dotnet publish -r win10-x64 -p:PublishSingleFile=true
```

For more information about single-file publishing, see the [single-file bundler design document](#).

Assembly trimming

The .NET core 3.0 SDK comes with a tool that can reduce the size of apps by analyzing IL and trimming unused assemblies.

Self-contained apps include everything needed to run your code, without requiring .NET to be installed on the host computer. However, many times the app only requires a small subset of the framework to function, and other unused libraries could be removed.

.NET Core now includes a setting that will use the [IL Trimmer](#) tool to scan the IL of your app. This tool detects what code is required, and then trims unused libraries. This tool can significantly reduce the deployment size of some apps.

To enable this tool, add the `<PublishTrimmed>` setting in your project and publish a self-contained app:

```
<PropertyGroup>
  <PublishTrimmed>true</PublishTrimmed>
</PropertyGroup>
```

```
dotnet publish -r <rid> -c Release
```

As an example, the basic "hello world" new console project template that is included, when published, hits about 70 MB in size. By using `<PublishTrimmed>`, that size is reduced to about 30 MB.

It's important to consider that applications or frameworks (including ASP.NET Core and WPF) that use reflection or related dynamic features, will often break when trimmed. This breakage occurs because the trimmer doesn't know about this dynamic behavior and can't determine which framework types are required for reflection. The IL Trimmer tool can be configured to be aware of this scenario.

Above all else, be sure to test your app after trimming.

For more information about the IL Trimmer tool, see the [documentation](#) or visit the [mono/linker](#) repo.

Tiered compilation

Tiered compilation (TC) is on by default with .NET Core 3.0. This feature enables the runtime to more adaptively use the just-in-time (JIT) compiler to achieve better performance.

The main benefit of tiered compilation is to provide two ways of jittering methods: in a lower-quality-but-faster tier or a higher-quality-but-slower tier. The quality refers to how well the method is optimized. TC helps to improve the performance of an application as it goes through various stages of execution, from startup through steady state. When tiered compilation is disabled, every method is compiled in a single way that's biased to steady-state performance over startup performance.

When TC is enabled, the following behavior applies for method compilation when an app starts up:

- If the method has ahead-of-time-compiled code, or [ReadyToRun](#), the pregenerated code is used.
- Otherwise, the method is jitted. Typically, these methods are generics over value types.
 - *Quick JIT* produces lower-quality (or less optimized) code more quickly. In .NET Core 3.0, Quick JIT is enabled by default for methods that don't contain loops and is preferred during startup.
 - The fully optimizing JIT produces higher-quality (or more optimized) code more slowly. For methods where Quick JIT would not be used (for example, if the method is attributed with [MethodImplOptions.AggressiveOptimization](#)), the fully optimizing JIT is used.

For frequently called methods, the just-in-time compiler eventually creates fully optimized code in the background. The optimized code then replaces the pre-compiled code for that method.

Code generated by Quick JIT may run slower, allocate more memory, or use more stack space. If there are issues, you can disable Quick JIT using this MSBuild property in the project file:

```
<PropertyGroup>
  <TieredCompilationQuickJit>false</TieredCompilationQuickJit>
</PropertyGroup>
```

To disable TC completely, use this MSBuild property in your project file:

```
<PropertyGroup>
  <TieredCompilation>false</TieredCompilation>
</PropertyGroup>
```

TIP

If you change these settings in the project file, you may need to perform a clean build for the new settings to be reflected (delete the `obj` and `bin` directories and rebuild).

For more information about configuring compilation at run time, see [Runtime configuration options for compilation](#).

ReadyToRun images

You can improve the startup time of your .NET Core application by compiling your application assemblies as ReadyToRun (R2R) format. R2R is a form of ahead-of-time (AOT) compilation.

R2R binaries improve startup performance by reducing the amount of work the just-in-time (JIT) compiler needs to do as your application loads. The binaries contain similar native code compared to what the JIT would produce. However, R2R binaries are larger because they contain both intermediate language (IL) code, which is still needed for some scenarios, and the native version of the same code. R2R is only available when you publish a self-contained app that targets specific runtime environments (RID) such as Linux x64 or Windows x64.

To compile your project as ReadyToRun, do the following:

1. Add the `<PublishReadyToRun>` setting to your project:

```
<PropertyGroup>
  <PublishReadyToRun>true</PublishReadyToRun>
</PropertyGroup>
```

2. Publish a self-contained app. For example, this command creates a self-contained app for the 64-bit version of Windows:

```
dotnet publish -c Release -r win-x64 --self-contained
```

Cross platform/architecture restrictions

The ReadyToRun compiler doesn't currently support cross-targeting. You must compile on a given target. For example, if you want R2R images for Windows x64, you need to run the publish command on that environment.

Exceptions to cross-targeting:

- Windows x64 can be used to compile Windows Arm32, Arm64, and x86 images.
- Windows x86 can be used to compile Windows Arm32 images.
- Linux x64 can be used to compile Linux Arm32 and Arm64 images.

For more information, see [Ready to Run](#).

Runtime/SDK

Major-version runtime roll forward

.NET Core 3.0 introduces an opt-in feature that allows your app to roll forward to the latest major version of .NET Core. Additionally, a new setting has been added to control how roll forward is applied to your app. This can be configured in the following ways:

- Project file property: `RollForward`
- Runtime configuration file property: `rollForward`
- Environment variable: `DOTNET_ROLL_FORWARD`
- Command-line argument: `--roll-forward`

One of the following values must be specified. If the setting is omitted, **Minor** is the default.

- **LatestPatch**

Roll forward to the highest patch version. This disables minor version roll forward.

- **Minor**

Roll forward to the lowest higher minor version, if requested minor version is missing. If the requested minor version is present, then the **LatestPatch** policy is used.

- **Major**

Roll forward to lowest higher major version, and lowest minor version, if requested major version is missing. If the requested major version is present, then the **Minor** policy is used.

- **LatestMinor**

Roll forward to highest minor version, even if requested minor version is present. Intended for component hosting scenarios.

- **LatestMajor**

Roll forward to highest major and highest minor version, even if requested major is present. Intended for component hosting scenarios.

- **Disable**

Don't roll forward. Only bind to specified version. This policy isn't recommended for general use because it disables the ability to roll forward to the latest patches. This value is only recommended for testing.

Besides the **Disable** setting, all settings will use the highest available patch version.

By default, if the requested version (as specified in `.runtimeconfig.json` for the application) is a release version, only release versions are considered for roll forward. Any pre-release versions are ignored. If there is no matching release version, then pre-release versions are taken into account. This behavior can be changed by setting `DOTNET_ROLL_FORWARD_TO_PRERELEASE=1`, in which case all versions are always considered.

Build copies dependencies

The `dotnet build` command now copies NuGet dependencies for your application from the NuGet cache to the build output folder. Previously, dependencies were only copied as part of `dotnet publish`.

There are some operations, like trimming and razor page publishing, that will still require publishing.

Local tools

.NET Core 3.0 introduces local tools. Local tools are similar to [global tools](#) but are associated with a particular location on disk. Local tools aren't available globally and are distributed as NuGet packages.

Local tools rely on a manifest file name `dotnet-tools.json` in your current directory. This manifest file defines the tools to be available at that folder and below. You can distribute the manifest file with your code to ensure that anyone who works with your code can restore and use the same tools.

For both global and local tools, a compatible version of the runtime is required. Many tools currently on NuGet.org target .NET Core Runtime 2.1. To install these tools globally or locally, you would still need to install the [NET Core 2.1 Runtime](#).

New `global.json` options

The `global.json` file has new options that provide more flexibility when you're trying to define which version of the .NET Core SDK is used. The new options are:

- `allowPrerelease` : Indicates whether the SDK resolver should consider prerelease versions when selecting the SDK version to use.
- `rollForward` : Indicates the roll-forward policy to use when selecting an SDK version, either as a fallback when a specific SDK version is missing or as a directive to use a higher version.

For more information about the changes including default values, supported values, and new matching rules, see [global.json overview](#).

Smaller Garbage Collection heap sizes

The Garbage Collector's default heap size has been reduced resulting in .NET Core using less memory. This change better aligns with the generation 0 allocation budget with modern processor cache sizes.

Garbage Collection Large Page support

Large Pages (also known as Huge Pages on Linux) is a feature where the operating system is able to establish memory regions larger than the native page size (often 4K) to improve performance of the application requesting these large pages.

The Garbage Collector can now be configured with the `GCLargePages` setting as an opt-in feature to choose to allocate large pages on Windows.

Windows Desktop & COM

.NET Core SDK Windows Installer

The MSI installer for Windows has changed starting with .NET Core 3.0. The SDK installers will now upgrade SDK feature-band releases in place. Feature bands are defined in the *hundreds* groups in the *patch* section of the version number. For example, `3.0.101` and `3.0.201` are versions in two different feature bands while `3.0.101` and `3.0.199` are in the same feature band. And, when .NET Core SDK `3.0.101` is installed, .NET Core SDK `3.0.100` will be removed from the machine if it exists. When .NET Core SDK `3.0.200` is installed on the same machine, .NET Core SDK `3.0.101` won't be removed.

For more information about versioning, see [Overview of how .NET Core is versioned](#).

Windows desktop

.NET Core 3.0 supports Windows desktop applications using Windows Presentation Foundation (WPF) and

Windows Forms. These frameworks also support using modern controls and Fluent styling from the Windows UI XAML Library (WinUI) via [XAML islands](#).

The Windows Desktop component is part of the Windows .NET Core 3.0 SDK.

You can create a new WPF or Windows Forms app with the following `dotnet` commands:

```
dotnet new wpf  
dotnet new winforms
```

Visual Studio 2019 adds [New Project](#) templates for .NET Core 3.0 Windows Forms and WPF.

For more information about how to port an existing .NET Framework application, see [Port WPF projects](#) and [Port Windows Forms projects](#).

WinForms high DPI

.NET Core Windows Forms applications can set high DPI mode with

[Application.SetHighDpiMode\(HighDpiMode\)](#). The `SetHighDpiMode` method sets the corresponding high DPI mode unless the setting has been set by other means like `App.Manifest` or P/Invoke before `Application.Run`.

The possible `highDpiMode` values, as expressed by the [System.Windows.Forms.HighDpiMode](#) enum are:

- `DpiUnaware`
- `SystemAware`
- `PerMonitor`
- `PerMonitorV2`
- `DpiUnawareGdiScaled`

For more information about high DPI modes, see [High DPI Desktop Application Development on Windows](#).

Create COM components

On Windows, you can now create COM-callable managed components. This capability is critical to use .NET Core with COM add-in models and also to provide parity with .NET Framework.

Unlike .NET Framework where the *mscoree.dll* was used as the COM server, .NET Core will add a native launcher dll to the *b/in* directory when you build your COM component.

For an example of how to create a COM component and consume it, see the [COM Demo](#).

Windows Native Interop

Windows offers a rich native API in the form of flat C APIs, COM, and WinRT. While .NET Core supports [P/Invoke](#), .NET Core 3.0 adds the ability to [CoCreate COM APIs](#) and [Activate WinRT APIs](#). For a code example, see the [Excel Demo](#).

MSIX Deployment

[MSIX](#) is a new Windows application package format. It can be used to deploy .NET Core 3.0 desktop applications to Windows 10.

The [Windows Application Packaging Project](#), available in Visual Studio 2019, allows you to create MSIX packages with [self-contained](#) .NET Core applications.

The .NET Core project file must specify the supported runtimes in the `<RuntimeIdentifiers>` property:

```
<RuntimeIdentifiers>win-x86;win-x64</RuntimeIdentifiers>
```

Linux improvements

SerialPort for Linux

.NET Core 3.0 provides basic support for `System.IO.Ports.SerialPort` on Linux.

Previously, .NET Core only supported using `SerialPort` on Windows.

For more information about the limited support for the serial port on Linux, see [GitHub issue #33146](#).

Docker and cgroup memory Limits

Running .NET Core 3.0 on Linux with Docker works better with cgroup memory limits. Running a Docker container with memory limits, such as with `docker run -m`, changes how .NET Core behaves.

- Default Garbage Collector (GC) heap size: maximum of 20 mb or 75% of the memory limit on the container.
- Explicit size can be set as an absolute number or percentage of cgroup limit.
- Minimum reserved segment size per GC heap is 16 mb. This size reduces the number of heaps that are created on machines.

GPIO Support for Raspberry Pi

Two packages have been released to NuGet that you can use for GPIO programming:

- `System.Device.Gpio`
- `Iot.Device.Bindings`

The GPIO packages include APIs for *GPIO*, *SPI*, *I2C*, and *PWM* devices. The IoT bindings package includes device bindings. For more information, see the [devices GitHub repo](#).

Arm64 Linux support

.NET Core 3.0 adds support for Arm64 for Linux. The primary use case for Arm64 is currently with IoT scenarios. For more information, see [.NET Core Arm64 Status](#).

Docker images for [.NET Core on Arm64](#) are available for Alpine, Debian, and Ubuntu.

NOTE

Support for the macOS Arm64 (or "Apple Silicon") and Windows Arm64 operating systems was later added in .NET 6.

Security

TLS 1.3 & OpenSSL 1.1.1 on Linux

.NET Core now takes advantage of [TLS 1.3 support in OpenSSL 1.1.1](#), when it's available in a given environment.

With TLS 1.3:

- Connection times are improved with reduced round trips required between the client and server.
- Improved security because of the removal of various obsolete and insecure cryptographic algorithms.

When available, .NET Core 3.0 uses `OpenSSL 1.1.1`, `OpenSSL 1.1.0`, or `OpenSSL 1.0.2` on a Linux system.

When `OpenSSL 1.1.1` is available, both `System.Net.Security.SslStream` and `System.Net.Http.HttpClient` types will use TLS 1.3 (assuming both the client and server support TLS 1.3).

IMPORTANT

Windows and macOS do not yet support TLS 1.3.

The following C# 8.0 example demonstrates .NET Core 3.0 on Ubuntu 18.10 connecting to

<https://www.cloudflare.com>:

```
using System;
using System.Net.Security;
using System.Net.Sockets;
using System.Threading.Tasks;

namespace whats_new
{
    public static class TLS
    {
        public static async Task ConnectCloudFlare()
        {
            var targetHost = "www.cloudflare.com";

            using TcpClient tcpClient = new TcpClient();

            await tcpClient.ConnectAsync(targetHost, 443);

            using SslStream sslStream = new SslStream(tcpClient.GetStream());

            await sslStream.AuthenticateAsClientAsync(targetHost);
            await Console.Out.WriteLineAsync($"Connected to {targetHost} with {sslStream.SslProtocol}");
        }
    }
}
```

Cryptography ciphers

.NET Core 3.0 adds support for AES-GCM and AES-CCM ciphers, implemented with [System.Security.Cryptography.AesGcm](#) and [System.Security.Cryptography.AesCcm](#) respectively. These algorithms are both [Authenticated Encryption with Association Data \(AEAD\) algorithms](#).

The following code demonstrates using `AesGcm` cipher to encrypt and decrypt random data.

```

using System;
using System.Linq;
using System.Security.Cryptography;

namespace whats_new
{
    public static class Cipher
    {
        public static void Run()
        {
            // key should be: pre-known, derived, or transported via another channel, such as RSA encryption
            byte[] key = new byte[16];
            RandomNumberGenerator.Fill(key);

            byte[] nonce = new byte[12];
            RandomNumberGenerator.Fill(nonce);

            // normally this would be your data
            byte[] dataToEncrypt = new byte[1234];
            byte[] associatedData = new byte[333];
            RandomNumberGenerator.Fill(dataToEncrypt);
            RandomNumberGenerator.Fill(associatedData);

            // these will be filled during the encryption
            byte[] tag = new byte[16];
            byte[] ciphertext = new byte[dataToEncrypt.Length];

            using (AesGcm aesGcm = new AesGcm(key))
            {
                aesGcm.Encrypt(nonce, dataToEncrypt, ciphertext, tag, associatedData);
            }

            // tag, nonce, ciphertext, associatedData should be sent to the other part

            byte[] decryptedData = new byte[ciphertext.Length];

            using (AesGcm aesGcm = new AesGcm(key))
            {
                aesGcm.Decrypt(nonce, ciphertext, tag, decryptedData, associatedData);
            }

            // do something with the data
            // this should always print that data is the same
            Console.WriteLine($"AES-GCM: Decrypted data is {(dataToEncrypt.SequenceEqual(decryptedData) ? "the same as" : "different than")}{original data."});
        }
    }
}

```

Cryptographic Key Import/Export

.NET Core 3.0 supports the import and export of asymmetric public and private keys from standard formats. You don't need to use an X.509 certificate.

All key types, such as *RSA*, *DSA*, *ECDsa*, and *ECDiffieHellman*, support the following formats:

- **Public Key**
 - X.509 SubjectPublicKeyInfo
- **Private key**
 - PKCS#8 PrivateKeyInfo
 - PKCS#8 EncryptedPrivateKeyInfo

RSA keys also support:

- **Public Key**

- PKCS#1 RSA PublicKey

- **Private key**

- PKCS#1 RSAPrivateKey

The export methods produce DER-encoded binary data, and the import methods expect the same. If a key is stored in the text-friendly PEM format, the caller will need to base64-decode the content before calling an import method.

```
using System;
using System.Security.Cryptography;

namespace whats_new
{
    public static class RSATest
    {
        public static void Run(string keyFile)
        {
            using var rsa = RSA.Create();

            byte[] keyBytes = System.IO.File.ReadAllBytes(keyFile);
            rsa.ImportRSAPrivateKey(keyBytes, out int bytesRead);

            Console.WriteLine($"Read {bytesRead} bytes, {keyBytes.Length - bytesRead} extra byte(s) in
file.");
            RSAParameters rsaParameters = rsa.ExportParameters(true);
            Console.WriteLine(BitConverter.ToString(rsaParameters.D));
        }
    }
}
```

PKCS#8 files can be inspected with [System.Security.Cryptography.Pkcs.Pkcs8PrivateKeyInfo](#) and PFX/PKCS#12 files can be inspected with [System.Security.Cryptography.Pkcs.Pkcs12Info](#). PFX/PKCS#12 files can be manipulated with [System.Security.Cryptography.Pkcs.Pkcs12Builder](#).

.NET Core 3.0 API changes

Ranges and indices

The new [System.Index](#) type can be used for indexing. You can create one from an `int` that counts from the beginning, or with a prefix `^` operator (C#) that counts from the end:

```
Index i1 = 3; // number 3 from beginning
Index i2 = ^4; // number 4 from end
int[] a = { 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 };
Console.WriteLine($"{a[i1]}, {a[i2]}"); // "3, 6"
```

There's also the [System.Range](#) type, which consists of two `Index` values, one for the start and one for the end, and can be written with a `x..y` range expression (C#). You can then index with a `Range`, which produces a slice:

```
var slice = a[i1..i2]; // { 3, 4, 5 }
```

For more information, see the [ranges and indices tutorial](#).

Async streams

The [IAsyncEnumerable<T>](#) type is a new asynchronous version of [IEnumerable<T>](#). The language lets you

`await foreach` over `IAsyncEnumerable<T>` to consume their elements, and use `yield return` to them to produce elements.

The following example demonstrates both production and consumption of async streams. The `foreach` statement is async and itself uses `yield return` to produce an async stream for callers. This pattern (using `yield return`) is the recommended model for producing async streams.

```
async IAsyncEnumerable<int> GetBigResultsAsync()
{
    await foreach (var result in GetResultsAsync())
    {
        if (result > 20) yield return result;
    }
}
```

In addition to being able to `await foreach`, you can also create async iterators, for example, an iterator that returns an `IAsyncEnumerable/IAsyncEnumerator` that you can both `await` and `yield` in. For objects that need to be disposed, you can use `IAsyncDisposable`, which various BCL types implement, such as `Stream` and `Timer`.

For more information, see the [async streams tutorial](#).

IEEE Floating-point

Floating point APIs are being updated to comply with [IEEE 754-2008 revision](#). The goal of these changes is to expose all **required** operations and ensure that they're behaviorally compliant with the IEEE spec. For more information about floating-point improvements, see the [Floating-Point Parsing and Formatting improvements in .NET Core 3.0](#) blog post.

Parsing and formatting fixes include:

- Correctly parse and round inputs of any length.
- Correctly parse and format negative zero.
- Correctly parse `Infinity` and `Nan` by doing a case-insensitive check and allowing an optional preceding `+` where applicable.

New `System.Math` APIs include:

- `BitIncrement(Double)` and `BitDecrement(Double)`

Corresponds to the `nextUp` and `nextDown` IEEE operations. They return the smallest floating-point number that compares greater or lesser than the input (respectively). For example, `Math.BitIncrement(0.0)` would return `double.Epsilon`.

- `MaxMagnitude(Double, Double)` and `MinMagnitude(Double, Double)`

Corresponds to the `maxNumMag` and `minNumMag` IEEE operations, they return the value that is greater or lesser in magnitude of the two inputs (respectively). For example, `Math.MaxMagnitude(2.0, -3.0)` would return `-3.0`.

- `ILogB(Double)`

Corresponds to the `logB` IEEE operation that returns an integral value, it returns the integral base-2 log of the input parameter. This method is effectively the same as `floor(log2(x))`, but done with minimal rounding error.

- `ScaleB(Double, Int32)`

Corresponds to the `scaleB` IEEE operation that takes an integral value, it returns effectively `x * pow(2, n)`, but is done with minimal rounding error.

- `Log2(Double)`

Corresponds to the `log2` IEEE operation, it returns the base-2 logarithm. It minimizes rounding error.

- [FusedMultiplyAdd\(Double, Double, Double\)](#)

Corresponds to the `fma` IEEE operation, it performs a fused multiply add. That is, it does $(x * y) + z$ as a single operation, thereby minimizing the rounding error. An example is `FusedMultiplyAdd(1e308, 2.0, -1e308)`, which returns `1e308`. The regular `(1e308 * 2.0) - 1e308` returns `double.PositiveInfinity`.

- [CopySign\(Double, Double\)](#)

Corresponds to the `copySign` IEEE operation, it returns the value of `x`, but with the sign of `y`.

.NET Platform-Dependent Intrinsics

APIs have been added that allow access to certain perf-oriented CPU instructions, such as the **SIMD** or **Bit Manipulation instruction** sets. These instructions can help achieve significant performance improvements in certain scenarios, such as processing data efficiently in parallel.

Where appropriate, the .NET libraries have begun using these instructions to improve performance.

For more information, see [.NET Platform-Dependent Intrinsics](#).

Improved .NET Core Version APIs

Starting with .NET Core 3.0, the version APIs provided with .NET Core now return the information you expect.

For example:

```
System.Console.WriteLine($"Environment.Version: {System.Environment.Version}");  
  
// Old result  
//   Environment.Version: 4.0.30319.42000  
//  
// New result  
//   Environment.Version: 3.0.0
```

```
System.Console.WriteLine($"RuntimeInformation.FrameworkDescription:  
{System.Runtime.InteropServices.RuntimeInformation.FrameworkDescription}");  
  
// Old result  
//   RuntimeInformation.FrameworkDescription: .NET Core 4.6.27415.71  
//  
// New result (notice the value includes any preview release information)  
//   RuntimeInformation.FrameworkDescription: .NET Core 3.0.0-preview4-27615-11
```

WARNING

Breaking change. This is technically a breaking change because the versioning scheme has changed.

Fast built-in JSON support

.NET users have largely relied on [Newtonsoft.Json](#) and other popular JSON libraries, which continue to be good choices. `Newtonsoft.Json` uses .NET strings as its base datatype, which is UTF-16 under the hood.

The new built-in JSON support is high-performance, low allocation, and works with UTF-8 encoded JSON text. For more information about the `System.Text.Json` namespace and types, see the following articles:

- [JSON serialization in .NET - overview](#)
- [How to serialize and deserialize JSON in .NET](#).
- [How to migrate from Newtonsoft.Json to System.Text.Json](#)

HTTP/2 support

The `System.Net.Http.HttpClient` type supports the HTTP/2 protocol. If HTTP/2 is enabled, the HTTP protocol

version is negotiated via TLS/ALPN, and HTTP/2 is used if the server elects to use it.

The default protocol remains HTTP/1.1, but HTTP/2 can be enabled in two different ways. First, you can set the HTTP request message to use HTTP/2:

```
var client = new HttpClient() { BaseAddress = new Uri("https://localhost:5001") };

// HTTP/1.1 request
using (var response = await client.GetAsync("/"))
    Console.WriteLine(response.Content);

// HTTP/2 request
using (var request = new HttpRequestMessage(HttpMethod.Get, "/") { Version = new Version(2, 0) })
using (var response = await client.SendAsync(request))
    Console.WriteLine(response.Content);
```

Second, you can change [HttpClient](#) to use HTTP/2 by default:

```
var client = new HttpClient()
{
    BaseAddress = new Uri("https://localhost:5001"),
    DefaultRequestVersion = new Version(2, 0)
};

// HTTP/2 is default
using (var response = await client.GetAsync("/"))
    Console.WriteLine(response.Content);
```

Many times when you're developing an application, you want to use an unencrypted connection. If you know the target endpoint will be using HTTP/2, you can turn on unencrypted connections for HTTP/2. You can turn it on by setting the `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_HTTP2UNENCRYPTEDSUPPORT` environment variable to `1` or by enabling it in the app context:

```
AppContext.SetSwitch("System.Net.Http.SocketsHttpHandler.Http2UnencryptedSupport", true);
```

Obsolete Antiforgery, CORS, Diagnostics, MVC, and Routing APIs removed

Obsolete members and compatibility switches in ASP.NET Core 2.2 were removed.

Version introduced

3.0

Reason for change

Improvement of API surface over time.

Recommended action

While targeting .NET Core 2.2, follow the guidance in the obsolete build messages to adopt new APIs instead.

Category

ASP.NET Core

Affected APIs

The following types and members were marked as obsolete for ASP.NET Core 2.1 and 2.2:

Types

- [Microsoft.AspNetCore.Diagnostics.Views.WelcomePage](#)
- [Microsoft.AspNetCore.DiagnosticsViewPage.Views.AttributeValue](#)
- [Microsoft.AspNetCore.DiagnosticsViewPage.Views.BaseView](#)
- [Microsoft.AspNetCore.DiagnosticsViewPage.Views.HelperResult](#)
- [Microsoft.AspNetCore.Mvc.Formatters.Xml.ProblemDetails21Wrapper](#)
- [Microsoft.AspNetCore.Mvc.Formatters.Xml.ValidationProblemDetails21Wrapper](#)
- [Microsoft.AspNetCore.Mvc.Razor.Compilation.ViewsFeatureProvider](#)
- [Microsoft.AspNetCore.Mvc.RazorPages.Infrastructure.PageArgumentBinder](#)
- [Microsoft.AspNetCore.Routing.IRouteValuesAddressMetadata](#)
- [Microsoft.AspNetCore.Routing.RouteValuesAddressMetadata](#)

Constructors

- [Microsoft.AspNetCore.Cors.Infrastructure.CorsService\(IOptions{CorsOptions}\)](#)
- [Microsoft.AspNetCore.Routing.Tree.TreeRouteBuilder\(ILoggerFactory,UrlEncoder,ObjectPool{UriBuildingContext},IInlineConstraintResolver\)](#)
- [Microsoft.AspNetCore.Mvc.Formatters.OutputFormatterCanWriteContext](#)
- [Microsoft.AspNetCore.Mvc.ApiExplorer.DefaultApiDescriptionProvider\(IOptions{MvcOptions},IInlineConstraintResolver,IModelMetadataProvider\)](#)
- [Microsoft.AspNetCore.Mvc.ApiExplorer.DefaultApiDescriptionProvider\(IOptions{MvcOptions},IInlineConstraintResolver,IModelMetadataProvider,IActionDescriptor\)](#)
- [Microsoft.AspNetCore.Mvc.Formatters.FormatFilter\(IOptions{MvcOptions}\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.ArrayModelBinder`1\(IModelBinder\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.ByteArrayModelBinder](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.CollectionModelBinder`1\(IModelBinder\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.ComplexTypeModelBinder\(IDictionary`2\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.DictionaryModelBinder`2\(IModelBinder,IModelBinder\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.DoubleModelBinder\(System.Globalization.NumberStyles\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.FloatModelBinder\(System.Globalization.NumberStyles\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.FormCollectionModelBinder](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.FormFileModelBinder](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.HeaderModelBinder](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.KeyValuePairModelBinder`2\(IModelBinder,IModelBinder\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.Binders.SimpleTypeModelBinder\(System.Type\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.ModelAttributes\(IEnumerable{System.Object}\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.ModelAttributes\(IEnumerable{System.Object}\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.ModelBinderFactory\(IModelMetadataProvider,IOptions{MvcOptions}\)](#)
- [Microsoft.AspNetCore.Mvc.ModelBinding.ParameterBinder\(IModelMetadataProvider,IModelBinderFactory,IObjectModelValidator\)](#)
- [Microsoft.AspNetCore.Mvc.Routing.KnownRouteValueConstraint](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlDataContractSerializerInputFormatter](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlDataContractSerializerInputFormatter\(System.Boolean\)](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlDataContractSerializerInputFormatter\(MvcOptions\)](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlSerializerInputFormatter](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlSerializerInputFormatter\(System.Boolean\)](#)
- [Microsoft.AspNetCore.Mvc.Formatters.XmlSerializerInputFormatter\(MvcOptions\)](#)
- [Microsoft.AspNetCore.Mvc.TagHelpers.ImageTagHelper\(IHostingEnvironment,IMemoryCache,HtmlEncoder,IUrlHelperFactory\)](#)

- `Microsoft.AspNetCore.Mvc.TagHelpers.LinkTagHelper(IHostingEnvironment, IMemoryCache, HtmlEncoder, JavaScriptEncoder, IUrlHelperFactory)`
- `Microsoft.AspNetCore.Mvc.TagHelpers.ScriptTagHelper(IHostingEnvironment, IMemoryCache, HtmlEncoder, JavaScriptEncoder, IUrlHelperFactory)`
- `Microsoft.AspNetCore.Mvc.RazorPages.Infrastructure.RazorPageAdapter(RazorPageBase)`

Properties

- `Microsoft.AspNetCore.Antiforgery.AntiforgeryOptions.CookieDomain`
- `Microsoft.AspNetCore.Antiforgery.AntiforgeryOptions.CookieName`
- `Microsoft.AspNetCore.Antiforgery.AntiforgeryOptions.CookiePath`
- `Microsoft.AspNetCore.Antiforgery.AntiforgeryOptions.RequireSsl`
- `Microsoft.AspNetCore.Mvc.ApiBehaviorOptions.AllowInferringBindingSourceForCollectionTypesAsFromQuery`
- `Microsoft.AspNetCore.Mvc.ApiBehaviorOptions.SuppressUseValidationProblemDetailsForInvalidModelStateResponses`
- `Microsoft.AspNetCore.Mvc.CookieTempDataProviderOptions.CookieName`
- `Microsoft.AspNetCore.Mvc.CookieTempDataProviderOptions.Domain`
- `Microsoft.AspNetCore.Mvc.CookieTempDataProviderOptions.Path`
- `Microsoft.AspNetCore.Mvc.DataAnnotations.MvcDataAnnotationsLocalizationOptions.AllowDataAnnotationsLocalizationForEnumDisplayAttributes`
- `Microsoft.AspNetCore.Mvc.Formatters.Xml.MvcXmlOptions.AllowRfc7807CompliantProblemDetailsFormat`
- `Microsoft.AspNetCore.Mvc.MvcOptions.AllowBindingHeaderValuesToNonStringModelTypes`
- `Microsoft.AspNetCore.Mvc.MvcOptions.AllowCombiningAuthorizeFilters`
- `Microsoft.AspNetCore.Mvc.MvcOptions.AllowShortCircuitingValidationWhenNoValidatorsArePresent`
- `Microsoft.AspNetCore.Mvc.MvcOptions.AllowValidatingTopLevelNodes`
- `Microsoft.AspNetCore.Mvc.MvcOptions.InputFormatterExceptionPolicy`
- `Microsoft.AspNetCore.Mvc.MvcOptions.SuppressBindingUndefinedValueToEnumType`
- `Microsoft.AspNetCore.Mvc.MvcViewOptions.AllowRenderingMaxLengthAttribute`
- `Microsoft.AspNetCore.Mvc.MvcViewOptions.SuppressTempDataAttributePrefix`
- `Microsoft.AspNetCore.Mvc.RazorPages.RazorPagesOptions.AllowAreas`
- `Microsoft.AspNetCore.Mvc.RazorPages.RazorPagesOptions.AllowDefaultHandlingForOptionsRequests`
- `Microsoft.AspNetCore.Mvc.RazorPages.RazorPagesOptions.AllowMappingHeadRequestsToGetHandler`

Methods

- `Microsoft.AspNetCore.Mvc.LocalRedirectResult.ExecuteResult(ActionContext)`
- `Microsoft.AspNetCore.Mvc.RedirectResult.ExecuteResult(ActionContext)`
- `Microsoft.AspNetCore.Mvc.RedirectToActionResult.ExecuteResult(ActionContext)`
- `Microsoft.AspNetCore.Mvc.RedirectToPageResult.ExecuteResult(ActionContext)`
- `Microsoft.AspNetCore.Mvc.RedirectToRouteResult.ExecuteResult(ActionContext)`
- `Microsoft.AspNetCore.Mvc.ModelBinding.ParameterBinder.BindModelAsync(ActionContext, IValueProvider, ParameterDescriptor)`
- `Microsoft.AspNetCore.Mvc.ModelBinding.ParameterBinder.BindModelAsync(ActionContext, IValueProvider, ParameterDescriptor, Object)`

"Pubternal" APIs removed

To better maintain the public API surface of ASP.NET Core, most of the types in `*.Internal` namespaces (referred to as "pubternal" APIs) have become truly internal. Members in these namespaces were never meant to be supported as public-facing APIs. The APIs could break in minor releases and often did. Code that depends on these APIs breaks when updating to ASP.NET Core 3.0.

For more information, see [dotnet/aspnetcore#4932](#) and [dotnet/aspnetcore#11312](#).

Version introduced

3.0

Old behavior

The affected APIs are marked with the `public` access modifier and exist in `*.Internal` namespaces.

New behavior

The affected APIs are marked with the `internal` access modifier and can no longer be used by code outside that assembly.

Reason for change

The guidance for these "pubternal" APIs was that they:

- Could change without notice.
- Weren't subject to .NET policies to prevent breaking changes.

Leaving the APIs `public` (even in the `*.Internal` namespaces) was confusing to customers.

Recommended action

Stop using these "pubternal" APIs. If you have questions about alternate APIs, open an issue in the [dotnet/aspnetcore](#) repository.

For example, consider the following HTTP request buffering code in an ASP.NET Core 2.2 project. The `EnableRewind` extension method exists in the `Microsoft.AspNetCore.Http.Internal` namespace.

```
HttpContext.Request.EnableRewind();
```

In an ASP.NET Core 3.0 project, replace the `EnableRewind` call with a call to the `EnableBuffering` extension method. The request buffering feature works as it did in the past. `EnableBuffering` calls the now `internal` API.

```
HttpContext.Request.EnableBuffering();
```

Category

ASP.NET Core

Affected APIs

All APIs in the `Microsoft.AspNetCore.*` and `Microsoft.Extensions.*` namespaces that have an `Internal` segment in the namespace name. For example:

- `Microsoft.AspNetCore.Authentication.Internal`
- `Microsoft.AspNetCore.Builder.Internal`
- `Microsoft.AspNetCore.DataProtection.Cng.Internal`
- `Microsoft.AspNetCore.DataProtection.Internal`
- `Microsoft.AspNetCore.Hosting.Internal`
- `Microsoft.AspNetCore.Http.Internal`
- `Microsoft.AspNetCore.Mvc.Core.Infrastructure`
- `Microsoft.AspNetCore.Mvc.Core.Internal`
- `Microsoft.AspNetCore.Mvc.Cors.Internal`
- `Microsoft.AspNetCore.Mvc.DataAnnotations.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Json.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Xml.Internal`
- `Microsoft.AspNetCore.Mvc.Internal`
- `Microsoft.AspNetCore.Mvc.ModelBinding.Internal`
- `Microsoft.AspNetCore.Mvc.Razor.Internal`
- `Microsoft.AspNetCore.Mvc.RazorPages.Internal`
- `Microsoft.AspNetCore.Mvc.TagHelpers.Internal`
- `Microsoft.AspNetCore.Mvc.ViewFeatures.Internal`
- `Microsoft.AspNetCore.Rewrite.Internal`
- `Microsoft.AspNetCore.Routing.Internal`
- `Microsoft.AspNetCore.Server.Kestrel.Core.Adapter.Internal`
- `Microsoft.AspNetCore.Server.Kestrel.Core.Internal.Http`
- `Microsoft.AspNetCore.Server.Kestrel.Core.Internal.Infrastructure`
- `Microsoft.AspNetCore.Server.Kestrel.Https.Internal`

Authentication: Google+ deprecated and replaced

Google is starting to [shut down](#) Google+ Sign-in for apps as early as January 28, 2019.

Change description

ASP.NET 4.x and ASP.NET Core have been using the Google+ Sign-in APIs to authenticate Google account users in web apps. The affected NuGet packages are `Microsoft.AspNetCore.Authentication.Google` for ASP.NET Core and `Microsoft.Owin.Security.Google` for `Microsoft.Owin` with ASP.NET Web Forms and MVC.

Google's replacement APIs use a different data source and format. The mitigations and solutions provided below account for the structural changes. Apps should verify the data itself still satisfies their requirements. For example, names, email addresses, profile links, and profile photos may provide subtly different values than before.

Version introduced

All versions. This change is external to ASP.NET Core.

Recommended action

Owin with ASP.NET Web Forms and MVC

For `Microsoft.Owin` 3.1.0 and later, a temporary mitigation is outlined [here](#). Apps should complete testing with the mitigation to check for changes in the data format. There are plans to release `Microsoft.Owin` 4.0.1 with a fix. Apps using any prior version should update to version 4.0.1.

ASP.NET Core 1.x

The mitigation in [Owin with ASP.NET Web Forms and MVC](#) can be adapted to ASP.NET Core 1.x. NuGet package

patches aren't planned because 1.x has reached [end of life](#) status.

ASP.NET Core 2.x

For `Microsoft.AspNetCore.Authentication.Google` version 2.x, replace your existing call to `AddGoogle` in `Startup.ConfigureServices` with the following code:

```
.AddGoogle(o =>
{
    o.ClientId = Configuration["Authentication:Google:ClientId"];
    o.ClientSecret = Configuration["Authentication:Google:ClientSecret"];
    o.UserInformationEndpoint = "https://www.googleapis.com/oauth2/v2/userinfo";
    o.ClaimActions.Clear();
    o.ClaimActions.MapJsonKey(ClaimTypes.NameIdentifier, "id");
    o.ClaimActions.MapJsonKey(ClaimTypes.Name, "name");
    o.ClaimActions.MapJsonKey(ClaimTypes.GivenName, "given_name");
    o.ClaimActions.MapJsonKey(ClaimTypes.Surname, "family_name");
    o.ClaimActions.MapJsonKey("urn:google:profile", "link");
    o.ClaimActions.MapJsonKey(ClaimTypes.Email, "email");
});
```

The February 2.1 and 2.2 patches incorporated the preceding reconfiguration as the new default. No patch is planned for ASP.NET Core 2.0 since it has reached [end of life](#).

ASP.NET Core 3.0

The mitigation given for ASP.NET Core 2.x can also be used for ASP.NET Core 3.0. In future 3.0 previews, the `Microsoft.AspNetCore.Authentication.Google` package may be removed. Users would be directed to `Microsoft.AspNetCore.Authentication.OpenIdConnect` instead. The following code shows how to replace `AddGoogle` with `AddOpenIdConnect` in `Startup.ConfigureServices`. This replacement can be used with ASP.NET Core 2.0 and later and can be adapted for ASP.NET Core 1.x as needed.

```
.AddOpenIdConnect("Google", o =>
{
    o.ClientId = Configuration["Authentication:Google:ClientId"];
    o.ClientSecret = Configuration["Authentication:Google:ClientSecret"];
    o.Authority = "https://accounts.google.com";
    o.ResponseType = OpenIdConnectResponseType.Code;
    o.CallbackPath = "/signin-google"; // Or register the default "/signin-oidc"
    o.Scope.Add("email");
});
JwtSecurityTokenHandler.DefaultInboundClaimTypeMap.Clear();
```

Category

ASP.NET Core

Affected APIs

[Microsoft.AspNetCore.Authentication.Google](#)

Authentication: `HttpContext.Authentication` property removed

The deprecated `Authentication` property on `HttpContext` has been removed.

Change description

As part of [dotnet/aspnetcore#6504](#), the deprecated `Authentication` property on `HttpContext` has been removed. The `Authentication` property has been deprecated since 2.0. A [migration guide](#) was published to migrate code using this deprecated property to the new replacement APIs. The remaining unused classes / APIs related to the old ASP.NET Core 1.x authentication stack were removed in commit [dotnet/aspnetcore@d7a7c65](#).

For discussion, see [dotnet/aspnetcore#6533](#).

Version introduced

3.0

Reason for change

ASP.NET Core 1.0 APIs have been replaced by extension methods in [Microsoft.AspNetCore.Authentication.AuthenticationHttpContextExtensions](#).

Recommended action

See the [migration guide](#).

Category

ASP.NET Core

Affected APIs

- [Microsoft.AspNetCore.Http.Authentication.AuthenticateInfo](#)
- [Microsoft.AspNetCore.Http.Authentication.AuthenticationManager](#)
- [Microsoft.AspNetCore.Http.Authentication.AuthenticationProperties](#)
- [Microsoft.AspNetCore.Http.Features.Authentication.AuthenticateContext](#)
- [Microsoft.AspNetCore.Http.Features.Authentication.ChallengeBehavior](#)
- [Microsoft.AspNetCore.Http.Features.Authentication.ChallengeContext](#)
- [Microsoft.AspNetCore.Http.Features.Authentication.DescribeSchemesContext](#)

- Microsoft.AspNetCore.Http.Features.Authentication.IAuthenticationHandler
- Microsoft.AspNetCore.Http.Features.Authentication.IHttpAuthenticationFeature.Handler
- Microsoft.AspNetCore.Http.Features.Authentication.SignInContext
- Microsoft.AspNetCore.Http.Features.Authentication.SignOutContext
- Microsoft.AspNetCore.Http.HttpContext.Authentication

Authentication: Newtonsoft.Json types replaced

In ASP.NET Core 3.0, `Newtonsoft.Json` types used in Authentication APIs have been replaced with `System.Text.Json` types. Except for the following cases, basic usage of the Authentication packages remains unaffected:

- Classes derived from the OAuth providers, such as those from `aspnet-contrib`.
- Advanced claim manipulation implementations.

For more information, see [dotnet/aspnetcore#7105](#). For discussion, see [dotnet/aspnetcore#7289](#).

Version introduced

3.0

Recommended action

For derived OAuth implementations, the most common change is to replace `JObject.Parse` with `JsonDocument.Parse` in the `CreateTicketAsync` override as shown [here](#). `JsonDocument` implements `IDisposable`.

The following list outlines known changes:

- `ClaimAction.Run(JObject, ClaimsIdentity, String)` becomes
`ClaimAction.Run(JsonElement userData, ClaimsIdentity identity, string issuer)`. All derived implementations of `ClaimAction` are similarly affected.
- `ClaimActionCollectionMapExtensions.MapCustomJson(ClaimActionCollection, String, Func<JObject, String>)` becomes
`MapCustomJson(this ClaimActionCollection collection, string claimType, Func<JsonElement, string> resolver)`
- `ClaimActionCollectionMapExtensions.MapCustomJson(ClaimActionCollection, String, String, Func<JObject, String>)` becomes
`MapCustomJson(this ClaimActionCollection collection, string claimType, string valueType, Func<JsonElement, string> resolver)`
- `OAuthCreatingTicketContext` has had one old constructor removed and the other replaced `JObject` with `JsonElement`. The `User` property and `RunClaimActions` method have been updated to match.
- `Success JObject` now accepts a parameter of type `JsonDocument` instead of `JObject`. The `Response` property has been updated to match. `OAuthTokenResponse` is now disposable and will be disposed by `OAuthHandler`. Derived OAuth implementations overriding `ExchangeCodeAsync` don't need to dispose the `JsonDocument` or `OAuthTokenResponse`.
- `UserInformationReceivedContext.User` changed from `JObject` to `JsonDocument`.
- `TwitterCreatingTicketContext.User` changed from `JObject` to `JsonElement`.
- The last parameter of `TwitterHandler.CreateTicketAsync(ClaimsIdentity, AuthenticationProperties, AccessToken, JObject)` changed from `JObject` to `JsonElement`. The replacement method is `TwitterHandler.CreateTicketAsync(ClaimsIdentity, AuthenticationProperties, AccessToken, JsonElement)`.

Category

ASP.NET Core

Affected APIs

- Microsoft.AspNetCore.Authentication.Facebook
- Microsoft.AspNetCore.Authentication.Google
- Microsoft.AspNetCore.Authentication.MicrosoftAccount
- Microsoft.AspNetCore.Authentication.OAuth
- Microsoft.AspNetCore.Authentication.OpenIdConnect
- Microsoft.AspNetCore.Authentication.Twitter

Authentication: OAuthHandler ExchangeCodeAsync signature changed

In ASP.NET Core 3.0, the signature of `OAuthHandler.ExchangeCodeAsync` was changed from:

```
protected virtual System.Threading.Tasks.Task<Microsoft.AspNetCore.Authentication.OAuth.OAuthTokenResponse>
ExchangeCodeAsync(string code, string redirectUri) { throw null; }
```

To:

```
protected virtual System.Threading.Tasks.Task<Microsoft.AspNetCore.Authentication.OAuth.OAuthTokenResponse>
ExchangeCodeAsync(Microsoft.AspNetCore.Authentication.OAuth.OAuthCodeExchangeContext context) { throw null;
}
```

Version introduced

3.0

Old behavior

The `code` and `redirectUri` strings were passed as separate arguments.

New behavior

`Code` and `RedirectUri` are properties on `OAuthCodeExchangeContext` that can be set via the `OAuthCodeExchangeContext` constructor. The new `OAuthCodeExchangeContext` type is the only argument passed to `OAuthHandler.ExchangeCodeAsync`.

Reason for change

This change allows additional parameters to be provided in a non-breaking manner. There's no need to create new `ExchangeCodeAsync` overloads.

Recommended action

Construct an `OAuthCodeExchangeContext` with the appropriate `code` and `redirectUri` values. An `AuthenticationProperties` instance must be provided. This single `OAuthCodeExchangeContext` instance can be passed to `OAuthHandler.ExchangeCodeAsync` instead of multiple arguments.

Category

ASP.NET Core

Affected APIs[OAuthHandler<TOptions>.ExchangeCodeAsync\(String, String\)](#)**Authorization: AddAuthorization overload moved to different assembly**

The core `AddAuthorization` methods that used to reside in `Microsoft.AspNetCore.Authorization` were renamed to `AddAuthorizationCore`. The old `AddAuthorization` methods still exist, but are in the `Microsoft.AspNetCore.Authorization.Policy` assembly instead. Apps using both methods should see no impact. Note that `Microsoft.AspNetCore.Authorization.Policy` now ships in the shared framework rather than a standalone package as discussed in [Shared framework: Assemblies removed from Microsoft.AspNetCore.App](#).

Version introduced

3.0

Old behavior

`AddAuthorization` methods existed in `Microsoft.AspNetCore.Authorization`.

New behavior

`AddAuthorization` methods exist in `Microsoft.AspNetCore.Authorization.Policy`. `AddAuthorizationCore` is the new name for the old methods.

Reason for change

`AddAuthorization` is a better method name for adding all common services needed for authorization.

Recommended action

Either add a reference to `Microsoft.AspNetCore.Authorization.Policy` or use `AddAuthorizationCore` instead.

Category

ASP.NET Core

Affected APIs[Microsoft.Extensions.DependencyInjection.AuthorizationServiceCollectionExtensions.AddAuthorization\(IServiceCollection collection, Action<AuthorizationOptions>\)](#)**Authorization: IAllowAnonymous removed from AuthorizationFilterContext.Filters**

As of ASP.NET Core 3.0, MVC doesn't add `AllowAnonymousFilters` for `[AllowAnonymous]` attributes that were discovered on controllers and action methods. This change is addressed locally for derivatives of `AuthorizeAttribute`, but it's a breaking change for `IAsyncAuthorizationFilter` and `IAuthorizationFilter` implementations. Such implementations wrapped in a `[TypeFilter]` attribute are a [popular](#) and supported way to achieve strongly-typed, attribute-based authorization when both configuration and dependency injection are required.

Version introduced

3.0

Old behavior

`IAllowAnonymous` appeared in the `AuthorizationFilterContext.Filters` collection. Testing for the interface's presence was a valid approach to override or disable the filter on individual controller methods.

New behavior

`IAllowAnonymous` no longer appears in the `AuthorizationFilterContext.Filters` collection.

`IAsyncAuthorizationFilter` implementations that are dependent on the old behavior typically cause intermittent HTTP 401 Unauthorized or HTTP 403 Forbidden responses.

Reason for change

A new endpoint routing strategy was introduced in ASP.NET Core 3.0.

Recommended action

Search the endpoint metadata for `IAllowAnonymous`. For example:

```
var endpoint = context.HttpContext.GetEndpoint();
if (endpoint?.Metadata?.GetMetadata<IAuthorizationPolicyProvider>() != null)
{
}
```

An example of this technique is seen in [this HasAllowAnonymous method](#).

Category

ASP.NET Core

Affected APIs

None

Authorization: IAuthorizationPolicyProvider implementations require new method

In ASP.NET Core 3.0, a new `GetFallbackPolicyAsync` method was added to `IAuthorizationPolicyProvider`. This fallback policy is used by the authorization middleware when no policy is specified.

For more information, see [dotnet/aspnetcore#9759](#).

Version introduced

3.0

Old behavior

Implementations of `IAuthorizationPolicyProvider` didn't require a `GetFallbackPolicyAsync` method.

New behavior

Implementations of `IAuthorizationPolicyProvider` require a `GetFallbackPolicyAsync` method.

Reason for change

A new method was needed for the new `AuthorizationMiddleware` to use when no policy is specified.

Recommended action

Add the `GetFallbackPolicyAsync` method to your implementations of `IAuthorizationPolicyProvider`.

Category

ASP.NET Core

Affected APIs

[Microsoft.AspNetCore.Authorization.IAuthorizationPolicyProvider](#)

Caching: CompactOnMemoryPressure property removed

The ASP.NET Core 3.0 release removed the [obsolete MemoryCacheOptions APIs](#).

Change description

This change is a follow-up to [aspnet/Caching#221](#). For discussion, see [dotnet/extensions#1062](#).

Version introduced

3.0

Old behavior

`MemoryCacheOptions.CompactOnMemoryPressure` property was available.

New behavior

The `MemoryCacheOptions.CompactOnMemoryPressure` property has been removed.

Reason for change

Automatically compacting the cache caused problems. To avoid unexpected behavior, the cache should only be compacted when needed.

Recommended action

To compact the cache, downcast to `MemoryCache` and call `Compact` when needed.

Category

ASP.NET Core

Affected APIs

[MemoryCacheOptions.CompactOnMemoryPressure](#)

Caching: Microsoft.Extensions.Caching.SqlServer uses new SqlClient package

The `Microsoft.Extensions.Caching.SqlServer` package will use the new `Microsoft.Data.SqlClient` package instead of `System.Data.SqlClient` package. This change could cause slight behavioral breaking changes. For more information, see [Introducing the new Microsoft.Data.SqlClient](#).

Version introduced

3.0

Old behavior

The `Microsoft.Extensions.Caching.SqlServer` package used the `System.Data.SqlClient` package.

New behavior

`Microsoft.Extensions.Caching.SqlServer` is now using the `Microsoft.Data.SqlClient` package.

Reason for change

`Microsoft.Data.SqlClient` is a new package that is built off of `System.Data.SqlClient`. It's where all new feature work will be done from now on.

Recommended action

Customers shouldn't need to worry about this breaking change unless they were using types returned by the `Microsoft.Extensions.Caching.SqlServer` package and casting them to `System.Data.SqlClient` types. For example, if someone was casting a `DbConnection` to the [old SqlConnection type](#), they would need to change the cast to the new `Microsoft.Data.SqlClient.SqlConnection` type.

Category

ASP.NET Core

Affected APIs

None

Caching: ResponseCaching "pubternal" types changed to internal

In ASP.NET Core 3.0, "pubternal" types in `ResponseCaching` have been changed to `internal`.

In addition, default implementations of `IResponseCachingPolicyProvider` and `IResponseCachingKeyProvider` are no longer added to services as part of the `AddResponseCaching` method.

Change description

In ASP.NET Core, "pubternal" types are declared as `public` but reside in a namespace suffixed with `.Internal`. While these types are public, they have no support policy and are subject to breaking changes. Unfortunately, accidental use of these types has been common, resulting in breaking changes to these projects and limiting the ability to maintain the framework.

Version introduced

3.0

Old behavior

These types were publicly visible, but unsupported.

New behavior

These types are now `internal`.

Reason for change

The `internal` scope better reflects the unsupported policy.

Recommended action

Copy types that are used by your app or library.

Category

ASP.NET Core

Affected APIs

- `Microsoft.AspNetCore.ResponseCaching.Internal.CachedResponse`
- `Microsoft.AspNetCore.ResponseCaching.Internal.CachedVaryByRules`
- `Microsoft.AspNetCore.ResponseCaching.Internal.IResponseCache`
- `Microsoft.AspNetCore.ResponseCaching.Internal.IResponseCacheEntry`
- `Microsoft.AspNetCore.ResponseCaching.Internal.IResponseCachingKeyProvider`
- `Microsoft.AspNetCore.ResponseCaching.Internal.IResponseCachingPolicyProvider`
- `Microsoft.AspNetCore.ResponseCaching.Internal.MemoryResponseCache`
- `Microsoft.AspNetCore.ResponseCaching.Internal.ResponseCachingContext`
- `Microsoft.AspNetCore.ResponseCaching.Internal.ResponseCachingKeyProvider`
- `Microsoft.AspNetCore.ResponseCaching.Internal.ResponseCachingPolicyProvider`
- `Microsoft.AspNetCore.ResponseCaching.ResponseCachingMiddleware.ResponseCachingMiddleware(RequestDelegate, IOptions<ResponseCachingOptions>, ILoggerFactory, IResponseCachingPolicyProvider, IResponseCache, IResponseCachingKeyProvider)`

Data Protection: DataProtection.Blobs uses new Azure Storage APIs

`Azure.Extensions.AspNetCore.DataProtection.Blobs` depends on the [Azure Storage libraries](#). These libraries renamed their assemblies, packages, and namespaces. Starting in ASP.NET Core 3.0,

`Azure.Extensions.AspNetCore.DataProtection.Blobs` uses the new `Azure.Storage.`-prefixed APIs and packages.

For questions about the Azure Storage APIs, use <https://github.com/Azure/azure-storage-net>. For discussion on this issue, see [dotnet/aspnetcore#19570](#).

Version introduced

3.0

Old behavior

The package referenced the `WindowsAzure.Storage` NuGet package. The package references the `Microsoft.Azure.Storage.Blob` NuGet package.

New behavior

The package references the `Azure.Storage.Blob` NuGet package.

Reason for change

This change allows `Azure.Extensions.AspNetCore.DataProtection.Blobs` to migrate to the recommended Azure Storage packages.

Recommended action

If you still need to use the older Azure Storage APIs with ASP.NET Core 3.0, add a direct dependency to the package `WindowsAzure.Storage` or `Microsoft.Azure.Storage`. This package can be installed alongside the new `Azure.Storage` APIs.

In many cases, the upgrade only involves changing the `using` statements to use the new namespaces:

```
- using Microsoft.WindowsAzure.Storage;
- using Microsoft.WindowsAzure.Storage.Blob;
- using Microsoft.Azure.Storage;
- using Microsoft.Azure.Storage.Blob;
+ using Azure.Storage;
+ using Azure.Storage.Blobs;
```

Category

ASP.NET Core

Affected APIs

None

Hosting: AspNetCoreModule V1 removed from Windows Hosting Bundle

Starting with ASP.NET Core 3.0, the Windows Hosting Bundle won't contain AspNetCoreModule (ANCM) V1.

ANCM V2 is backwards compatible with ANCM OutOfProcess and is recommended for use with ASP.NET Core 3.0 apps.

For discussion, see [dotnet/aspnetcore#7095](#).

Version introduced

3.0

Old behavior

ANCM V1 is included in the Windows Hosting Bundle.

New behavior

ANCM V1 isn't included in the Windows Hosting Bundle.

Reason for change

ANCM V2 is backwards compatible with ANCM OutOfProcess and is recommended for use with ASP.NET Core 3.0 apps.

Recommended action

Use ANCM V2 with ASP.NET Core 3.0 apps.

If ANCM V1 is required, it can be installed using the ASP.NET Core 2.1 or 2.2 Windows Hosting Bundle.

This change will break ASP.NET Core 3.0 apps that:

- Explicitly opted into using ANCM V1 with `<AspNetCoreModuleName>AspNetCoreModule</AspNetCoreModuleName>`.
- Have a custom `web.config` file with
`<add name="aspNetCore" path="*" verb="*" modules="AspNetCoreModule" resourceType="Unspecified" />`.

Category

ASP.NET Core

Affected APIs

None

Hosting: Generic host restricts Startup constructor injection

The only types the generic host supports for `Startup` class constructor injection are `IHostEnvironment`, `IWebHostEnvironment`, and `IConfiguration`. Apps using `WebHost` are unaffected.

Change description

Prior to ASP.NET Core 3.0, constructor injection could be used for arbitrary types in the `Startup` class's constructor. In ASP.NET Core 3.0, the web stack was replatformed onto the generic host library. You can see the change in the `Program.cs` file of the templates:

ASP.NET Core 2.x:

<https://github.com/dotnet/aspnetcore/blob/5cb615fcbe8559e49042e93394008077e30454c0/src/Templating/src/Microsoft.DotNet.Web.ProjectTemplates/content/EmptyWeb-CSharp/Program.cs#L20-L22>

ASP.NET Core 3.0:

<https://github.com/dotnet/aspnetcore/blob/b1ca2c1155da3920f0df5108b9fedbe82efaa11c/src/ProjectTemplates/src/Web.ProjectTemplates/content/EmptyWeb-CSharp/Program.cs#L19-L24>

`Host` uses one dependency injection (DI) container to build the app. `WebHost` uses two containers: one for the host and one for the app. As a result, the `Startup` constructor no longer supports custom service injection. Only `IHostEnvironment`, `IWebHostEnvironment`, and `IConfiguration` can be injected. This change prevents DI issues such as the duplicate creation of a singleton service.

Version introduced

3.0

Reason for change

This change is a consequence of replatforming the web stack onto the generic host library.

Recommended action

Inject services into the `Startup.Configure` method signature. For example:

```
public void Configure(IApplicationBuilder app, IOptions<MyOptions> options)
```

Category

Hosting: HTTPS redirection enabled for IIS out-of-process apps

Version 13.0.19218.0 of the [ASP.NET Core Module \(ANCM\)](#) for hosting via IIS out-of-process enables an existing HTTPS redirection feature for ASP.NET Core 3.0 and 2.2 apps.

For discussion, see [dotnet/AspNetCore#15243](#).

Version introduced

3.0

Old behavior

The ASP.NET Core 2.1 project template first introduced support for HTTPS middleware methods like `UseHttpsRedirection` and `UseHsts`. Enabling HTTPS redirection required the addition of configuration, since apps in development don't use the default port of 443. [HTTP Strict Transport Security \(HSTS\)](#) is active only if the request is already using HTTPS. Localhost is skipped by default.

New behavior

In ASP.NET Core 3.0, the IIS HTTPS scenario was [enhanced](#). With the enhancement, an app could discover the server's HTTPS ports and make `UseHttpsRedirection` work by default. The in-process component accomplished port discovery with the `I Server Addresses` feature, which only affects ASP.NET Core 3.0 apps because the in-process library is versioned with the framework. The out-of-process component changed to automatically add the `ASPNETCORE_HTTPS_PORT` environment variable. This change affected both ASP.NET Core 2.2 and 3.0 apps because the out-of-process component is shared globally. ASP.NET Core 2.1 apps aren't affected because they use a prior version of ANCM by default.

The preceding behavior was modified in ASP.NET Core 3.0.1 and 3.1.0 Preview 3 to reverse the behavior changes in ASP.NET Core 2.x. These changes only affect IIS out-of-process apps.

As detailed above, installing ASP.NET Core 3.0.0 had the side effect of also activating the `UseHttpsRedirection` middleware in ASP.NET Core 2.x apps. A change was made to ANCM in ASP.NET Core 3.0.1 and 3.1.0 Preview 3 such that installing them no longer has this effect on ASP.NET Core 2.x apps. The `ASPNETCORE_HTTPS_PORT` environment variable that ANCM populated in ASP.NET Core 3.0.0 was changed to `ASPNETCORE_ANCM_HTTPS_PORT` in ASP.NET Core 3.0.1 and 3.1.0 Preview 3. `UseHttpsRedirection` was also updated in these releases to understand both the new and old variables. ASP.NET Core 2.x won't be updated. As a result, it reverts to the previous behavior of being disabled by default.

Reason for change

Improved ASP.NET Core 3.0 functionality.

Recommended action

No action is required if you want all clients to use HTTPS. To allow some clients to use HTTP, take one of the following steps:

- Remove the calls to `UseHttpsRedirection` and `UseHsts` from your project's `Startup.Configure` method, and redeploy the app.
- In your `web.config` file, set the `ASPNETCORE_HTTPS_PORT` environment variable to an empty string. This change can occur directly on the server without redeploying the app. For example:

```
<aspNetCore processPath="dotnet" arguments=".\\WebApplication3.dll" stdoutLogEnabled="false"
stdoutLogFile="\\?\%home%\LogFiles\stdout" >
<environmentVariables>
<environmentVariable name="ASPNETCORE_HTTPS_PORT" value="" />
</environmentVariables>
</aspNetCore>
```

`UseHttpsRedirection` can still be:

- Activated manually in ASP.NET Core 2.x by setting the `ASPNETCORE_HTTPS_PORT` environment variable to the appropriate port number (443 in most production scenarios).
- Deactivated in ASP.NET Core 3.x by defining `ASPNETCORE_ANCM_HTTPS_PORT` with an empty string value. This value is set in the same fashion as the preceding `ASPNETCORE_HTTPS_PORT` example.

Machines running ASP.NET Core 3.0.0 apps should install the ASP.NET Core 3.0.1 runtime before installing the ASP.NET Core 3.1.0 Preview 3 ANCM. Doing so ensures that `UseHttpsRedirection` continues to operate as expected for the ASP.NET Core 3.0 apps.

In Azure App Service, ANCM deploys on a separate schedule from the runtime because of its global nature. ANCM was deployed to Azure with these changes after ASP.NET Core 3.0.1 and 3.1.0 were deployed.

Category

ASP.NET Core

Affected APIs

[HttpsPolicyBuilderExtensions.UseHttpsRedirection\(IApplicationBuilder\)](#)

Hosting: `IHostingEnvironment` and `IApplicationLifetime` types marked obsolete and replaced

New types have been introduced to replace existing `IHostingEnvironment` and `IApplicationLifetime` types.

Version introduced

3.0

Old behavior

There were two different `IHostingEnvironment` and `IApplicationLifetime` types from `Microsoft.Extensions.Hosting` and `Microsoft.AspNetCore.Hosting`.

New behavior

The old types have been marked as obsolete and replaced with new types.

Reason for change

When `Microsoft.Extensions.Hosting` was introduced in ASP.NET Core 2.1, some types like `IHostingEnvironment` and `IApplicationLifetime` were copied from `Microsoft.AspNetCore.Hosting`. Some ASP.NET Core 3.0 changes cause apps to include both the `Microsoft.Extensions.Hosting` and `Microsoft.AspNetCore.Hosting` namespaces. Any use of those duplicate types causes an "ambiguous reference" compiler error when both namespaces are referenced.

Recommended action

Replaced any usages of the old types with the newly introduced types as below:

Obsolete types (warning):

- `Microsoft.Extensions.Hosting.IHostingEnvironment`
- `Microsoft.AspNetCore.Hosting.IHostingEnvironment`
- `Microsoft.Extensions.Hosting.IApplicationLifetime`
- `Microsoft.AspNetCore.Hosting.IApplicationLifetime`
- `Microsoft.Extensions.Hosting.EnvironmentName`
- `Microsoft.AspNetCore.Hosting.EnvironmentName`

New types:

- `Microsoft.Extensions.Hosting.IHostEnvironment`
- `Microsoft.AspNetCore.Hosting.IWebHostEnvironment : IHostEnvironment`
- `Microsoft.Extensions.Hosting.IHostApplicationLifetime`
- `Microsoft.Extensions.Hosting.Environments`

The new `IHostEnvironment`, `IsDevelopment` and `IsProduction` extension methods are in the `Microsoft.Extensions.Hosting` namespace. That namespace may need to be added to your project.

Category

ASP.NET Core

Affected APIs

- `Microsoft.AspNetCore.Hosting.EnvironmentName`
- `Microsoft.AspNetCore.Hosting.IApplicationLifetime`
- `Microsoft.AspNetCore.Hosting.IHostingEnvironment`

- Microsoft.Extensions.Hosting.EnvironmentName
 - Microsoft.Extensions.Hosting.IApplicationLifetime
 - Microsoft.Extensions.Hosting.IHostingEnvironment
-

Hosting: ObjectPoolProvider removed from WebHostBuilder dependencies

As part of making ASP.NET Core more pay for play, the `ObjectPoolProvider` was removed from the main set of dependencies. Specific components relying on `ObjectPoolProvider` now add it themselves.

For discussion, see [dotnet/aspnetcore#5944](#).

Version introduced

3.0

Old behavior

`WebHostBuilder` provides `ObjectPoolProvider` by default in the DI container.

New behavior

`WebHostBuilder` no longer provides `ObjectPoolProvider` by default in the DI container.

Reason for change

This change was made to make ASP.NET Core more pay for play.

Recommended action

If your component requires `ObjectPoolProvider`, it needs to be added to your dependencies via the `IServiceCollection`.

Category

ASP.NET Core

Affected APIs

None

HTTP: DefaultHttpContext extensibility removed

As part of ASP.NET Core 3.0 performance improvements, the extensibility of `DefaultHttpContext` was removed. The class is now `sealed`. For more information, see [dotnet/aspnetcore#6504](#).

If your unit tests use `Mock<DefaultHttpContext>`, use `Mock<HttpContext>` or `new DefaultHttpContext()` instead.

For discussion, see [dotnet/aspnetcore#6534](#).

Version introduced

3.0

Old behavior

Classes can derive from `DefaultHttpContext`.

New behavior

Classes can't derive from `DefaultHttpContext`.

Reason for change

The extensibility was provided initially to allow pooling of the `HttpContext`, but it introduced unnecessary complexity and impeded other optimizations.

Recommended action

If you're using `Mock<DefaultHttpContext>` in your unit tests, begin using `Mock<HttpContext>` instead.

Category

ASP.NET Core

Affected APIs

[Microsoft.AspNetCore.Http.DefaultHttpContext](#)

HTTP: HeaderNames constants changed to static readonly

Starting in ASP.NET Core 3.0 Preview 5, the fields in [Microsoft.Net.Http.Headers.HeaderNames](#) changed from `const` to `static readonly`.

For discussion, see [dotnet/aspnetcore#9514](#).

Version introduced

3.0

Old behavior

These fields used to be `const`.

New behavior

These fields are now `static readonly`.

Reason for change

The change:

- Prevents the values from being embedded across assembly boundaries, allowing for value corrections as needed.
- Enables faster reference equality checks.

Recommended action

Recompile against 3.0. Source code using these fields in the following ways can no longer do so:

- As an attribute argument
- As a `case` in a `switch` statement
- When defining another `const`

To work around the breaking change, switch to using self-defined header name constants or string literals.

Category

ASP.NET Core

Affected APIs

[Microsoft.Net.Http.Headers.HeaderNames](#)

HTTP: Response body infrastructure changes

The infrastructure backing an HTTP response body has changed. If you're using `HttpResponse` directly, you shouldn't need to make any code changes. Read further if you're wrapping or replacing `HttpResponse.Body` or accessing `HttpContext.Features`.

Version introduced

3.0

Old behavior

There were three APIs associated with the HTTP response body:

- `IHttpResponseFeature.Body`
- `IHttpSendFileFeature.SendFileAsync`
- `IHttpBufferingFeature.DisableResponseBuffering`

New behavior

If you replace `HttpResponse.Body`, it replaces the entire `IHttpResponseBodyFeature` with a wrapper around your given stream using `StreamResponseBodyFeature` to provide default implementations for all of the expected APIs. Setting back the original stream reverts this change.

Reason for change

The motivation is to combine the response body APIs into a single new feature interface.

Recommended action

Use `IHttpResponseBodyFeature` where you previously were using `IHttpResponseFeature.Body`, `IHttpSendFileFeature`, or `IHttpBufferingFeature`.

Category

ASP.NET Core

Affected APIs

- [Microsoft.AspNetCore.Http.Features.IHttpBufferingFeature](#)
- [Microsoft.AspNetCore.Http.Features.IHttpResponseFeature.Body](#)
- [Microsoft.AspNetCore.Http.Features.IHttpSendFileFeature](#)

HTTP: Some cookie SameSite defaults changed to None

`SameSite` is an option for cookies that can help mitigate some Cross-Site Request Forgery (CSRF) attacks. When this option was initially introduced, inconsistent defaults were used across various ASP.NET Core APIs. The inconsistency has led to confusing results. As of ASP.NET Core 3.0, these defaults are better aligned. You must opt in to this feature on a per-component basis.

Version introduced

3.0

Old behavior

Similar ASP.NET Core APIs used different default `SameSiteMode` values. An example of the inconsistency is seen in `HttpResponse.Cookies.Append(String, String)` and `HttpResponse.Cookies.Append(String, String, CookieOptions)`, which defaulted to `SameSiteMode.None` and `SameSiteMode.Lax`, respectively.

New behavior

All the affected APIs default to `SameSiteMode.None`.

Reason for change

The default value was changed to make `SameSite` an opt-in feature.

Recommended action

Each component that emits cookies needs to decide if `SameSite` is appropriate for its scenarios. Review your

usage of the affected APIs and reconfigure `SameSite` as needed.

Category

ASP.NET Core

Affected APIs

- `IResponseCookies.Append(String, String, CookieOptions)`
- `CookiePolicyOptions.MinimumSameSitePolicy`

HTTP: Synchronous IO disabled in all servers

Starting with ASP.NET Core 3.0, synchronous server operations are disabled by default.

Change description

`AllowSynchronousIO` is an option in each server that enables or disables synchronous IO APIs like `HttpRequest.Body.Read`, `HttpResponse.Body.Write`, and `Stream.Flush`. These APIs have long been a source of thread starvation and app hangs. Starting in ASP.NET Core 3.0 Preview 3, these synchronous operations are disabled by default.

Affected servers:

- Kestrel
- HttpSys
- IIS in-process
- TestServer

Expect errors similar to:

- Synchronous operations are disallowed. Call `ReadAsync` or set `AllowSynchronousIO` to true instead.
- Synchronous operations are disallowed. Call `WriteAsync` or set `AllowSynchronousIO` to true instead.
- Synchronous operations are disallowed. Call `FlushAsync` or set `AllowSynchronousIO` to true instead.

Each server has an `AllowSynchronousIO` option that controls this behavior and the default for all of them is now `false`.

The behavior can also be overridden on a per-request basis as a temporary mitigation. For example:

```
var syncIOFeature = HttpContext.Features.Get< IHttpBodyControlFeature>();  
if (syncIOFeature != null)  
{  
    syncIOFeature.AllowSynchronousIO = true;  
}
```

If you have trouble with a `TextWriter` or another stream calling a synchronous API in `Dispose`, call the new `DisposeAsync` API instead.

For discussion, see [dotnet/aspnetcore#7644](#).

Version introduced

3.0

Old behavior

`HttpRequest.Body.Read`, `HttpResponse.Body.Write`, and `Stream.Flush` were allowed by default.

New behavior

These synchronous APIs are disallowed by default:

Expect errors similar to:

- Synchronous operations are disallowed. Call `ReadAsync` or set `AllowSynchronousIO` to true instead.
- Synchronous operations are disallowed. Call `WriteAsync` or set `AllowSynchronousIO` to true instead.
- Synchronous operations are disallowed. Call `FlushAsync` or set `AllowSynchronousIO` to true instead.

Reason for change

These synchronous APIs have long been a source of thread starvation and app hangs. Starting in ASP.NET Core 3.0 Preview 3, the synchronous operations are disabled by default.

Recommended action

Use the asynchronous versions of the methods. The behavior can also be overridden on a per-request basis as a temporary mitigation.

```
var syncIOFeature = HttpContext.Features.Get< IHttpBodyControlFeature>();  
if (syncIOFeature != null)  
{  
    syncIOFeature.AllowSynchronousIO = true;  
}
```

Category

ASP.NET Core

Affected APIs

- `Stream.Flush`
- `Stream.Read`
- `Stream.Write`

Identity: AddDefaultUI method overload removed

Starting with ASP.NET Core 3.0, the `IdentityBuilderUIExtensions.AddDefaultUI(IdentityBuilder, UIFramework)` method overload no longer exists.

Version introduced

3.0

Reason for change

This change was a result of adoption of the static web assets feature.

Recommended action

Call `IdentityBuilderUIExtensions.AddDefaultUI(IdentityBuilder)` instead of the overload that takes two arguments. If you're using Bootstrap 3, also add the following line to a `<PropertyGroup>` element in your project file:

```
<IdentityUIFrameworkVersion>Bootstrap3</IdentityUIFrameworkVersion>
```

Category

ASP.NET Core

Affected APIs

`IdentityBuilderUIExtensions.AddDefaultUI(IdentityBuilder, UIFramework)`

Identity: Default Bootstrap version of UI changed

Starting in ASP.NET Core 3.0, Identity UI defaults to using version 4 of Bootstrap.

Version introduced

3.0

Old behavior

The `services.AddDefaultIdentity<IdentityUser>().AddDefaultUI();` method call was the same as
`services.AddDefaultIdentity<IdentityUser>().AddDefaultUI(UIFramework.Bootstrap3);`

New behavior

The `services.AddDefaultIdentity<IdentityUser>().AddDefaultUI();` method call is the same as
`services.AddDefaultIdentity<IdentityUser>().AddDefaultUI(UIFramework.Bootstrap4);`

Reason for change

Bootstrap 4 was released during ASP.NET Core 3.0 timeframe.

Recommended action

You're impacted by this change if you use the default Identity UI and have added it in `Startup.ConfigureServices` as shown in the following example:

```
services.AddDefaultIdentity<IdentityUser>().AddDefaultUI();
```

Take one of the following actions:

- Migrate your app to use Bootstrap 4 using their [migration guide](#).
- Update `Startup.ConfigureServices` to enforce usage of Bootstrap 3. For example:

```
services.AddDefaultIdentity<IdentityUser>().AddDefaultUI(UIFramework.Bootstrap3);
```

Identity: SignInAsync throws exception for unauthenticated identity

By default, `SignInAsync` throws an exception for principals / identities in which `IsAuthenticated` is `false`.

Version introduced

3.0

Old behavior

`SignInAsync` accepts any principals / identities, including identities in which `IsAuthenticated` is `false`.

New behavior

By default, `SignInAsync` throws an exception for principals / identities in which `IsAuthenticated` is `false`.

There's a new flag to suppress this behavior, but the default behavior has changed.

Reason for change

The old behavior was problematic because, by default, these principals were rejected by `[Authorize]` / `RequireAuthenticatedUser()`.

Recommended action

In ASP.NET Core 3.0 Preview 6, there's a `RequireAuthenticatedSignIn` flag on `AuthenticationOptions` that is `true` by default. Set this flag to `false` to restore the old behavior.

Category

ASP.NET Core

Affected APIs

None

Identity: SignInManager constructor accepts new parameter

Starting with ASP.NET Core 3.0, a new `IUserConfirmation<TUser>` parameter was added to the `SignInManager` constructor. For more information, see [dotnet/aspnetcore#8356](#).

Version introduced

3.0

Reason for change

The motivation for the change was to add support for new email / confirmation flows in Identity.

Recommended action

If manually constructing a `SignInManager`, provide an implementation of `IUserConfirmation` or grab one from dependency injection to provide.

Category

ASP.NET Core

Affected APIs

`SignInManager<TUser>`

Identity: UI uses static web assets feature

ASP.NET Core 3.0 introduced a static web assets feature, and Identity UI has adopted it.

Change description

As a result of Identity UI adopting the static web assets feature:

- Framework selection is accomplished by using the `IdentityUIFrameworkVersion` property in your project file.
- Bootstrap 4 is the default UI framework for Identity UI. Bootstrap 3 has reached end of life, and you should consider migrating to a supported version.

Version introduced

3.0

Old behavior

The default UI framework for Identity UI was **Bootstrap 3**. The UI framework could be configured using a parameter to the `AddDefaultUI` method call in `Startup.ConfigureServices`.

New behavior

The default UI framework for Identity UI is **Bootstrap 4**. The UI framework must be configured in your project file, instead of in the `AddDefaultUI` method call.

Reason for change

Adoption of the static web assets feature required that the UI framework configuration move to MSBuild. The decision on which framework to embed is a build-time decision, not a runtime decision.

Recommended action

Review your site UI to ensure the new Bootstrap 4 components are compatible. If necessary, use the `IdentityUIFrameworkVersion` MSBuild property to revert to Bootstrap 3. Add the property to a `<PropertyGroup>` element in your project file:

```
<IdentityUIFrameworkVersion>Bootstrap3</IdentityUIFrameworkVersion>
```

Category

ASP.NET Core

Affected APIs

`IdentityBuilderUIExtensions.AddDefaultUI(IdentityBuilder, UIFramework)`

Kestrel: Connection adapters removed

As part of the move to move "pubternal" APIs to `public`, the concept of an `IConnectionAdapter` was removed from Kestrel. Connection adapters are being replaced with connection middleware (similar to HTTP middleware in the ASP.NET Core pipeline, but for lower-level connections). HTTPS and connection logging have moved from connection adapters to connection middleware. Those extension methods should continue to work seamlessly,

but the implementation details have changed.

For more information, see [dotnet/aspnetcore#11412](#). For discussion, see [dotnet/aspnetcore#11475](#).

Version introduced

3.0

Old behavior

Kestrel extensibility components were created using `IConnectionAdapter`.

New behavior

Kestrel extensibility components are created as [middleware](#).

Reason for change

This change is intended to provide a more flexible extensibility architecture.

Recommended action

Convert any implementations of `IConnectionAdapter` to use the new middleware pattern as shown [here](#).

Category

ASP.NET Core

Affected APIs

`Microsoft.AspNetCore.Server.Kestrel.Core.Adapter.Internal.IConnectionAdapter`

Kestrel: Empty HTTPS assembly removed

The assembly [Microsoft.AspNetCore.Server.Kestrel.Https](#) has been removed.

Version introduced

3.0

Reason for change

In ASP.NET Core 2.1, the contents of `Microsoft.AspNetCore.Server.Kestrel.Https` were moved to `Microsoft.AspNetCore.Server.Kestrel.Core`. This change was done in a non-breaking way using `[TypeForwardedTo]` attributes.

Recommended action

- Libraries referencing `Microsoft.AspNetCore.Server.Kestrel.Https` 2.0 should update all ASP.NET Core dependencies to 2.1 or later. Otherwise, they may break when loaded into an ASP.NET Core 3.0 app.
- Apps and libraries targeting ASP.NET Core 2.1 and later should remove any direct references to the `Microsoft.AspNetCore.Server.Kestrel.Https` NuGet package.

Category

ASP.NET Core

Affected APIs

None

Kestrel: Request trailer headers moved to new collection

In prior versions, Kestrel added HTTP/1.1 chunked trailer headers into the request headers collection when the request body was read to the end. This behavior caused concerns about ambiguity between headers and trailers. The decision was made to move the trailers to a new collection.

HTTP/2 request trailers were unavailable in ASP.NET Core 2.2 but are now also available in this new collection in ASP.NET Core 3.0.

New request extension methods have been added to access these trailers.

HTTP/1.1 trailers are available once the entire request body has been read.

HTTP/2 trailers are available once they're received from the client. The client won't send the trailers until the entire request body has been at least buffered by the server. You may need to read the request body to free up buffer space. Trailers are always available if you read the request body to the end. The trailers mark the end of the body.

Version introduced

3.0

Old behavior

Request trailer headers would be added to the `HttpRequest.Headers` collection.

New behavior

Request trailer headers aren't present in the `HttpRequest.Headers` collection. Use the following extension methods on `HttpRequest` to access them:

- `GetDeclaredTrailers()` - Gets the request "Trailer" header that lists which trailers to expect after the body.
- `SupportsTrailers()` - Indicates if the request supports receiving trailer headers.
- `CheckTrailersAvailable()` - Determines if the request supports trailers and if they're available for reading.
- `GetTrailer(string trailerName)` - Gets the requested trailing header from the response.

Reason for change

Trailers are a key feature in scenarios like gRPC. Merging the trailers in to request headers was confusing to users.

Recommended action

Use the trailer-related extension methods on `HttpRequest` to access trailers.

Category

ASP.NET Core

Affected APIs

[HttpRequest.Headers](#)

Kestrel: Transport abstractions removed and made public

As part of moving away from "pubternal" APIs, the Kestrel transport layer APIs are exposed as a public interface in the `Microsoft.AspNetCore.Connections.Abstractions` library.

Version introduced

3.0

Old behavior

- Transport-related abstractions were available in the `Microsoft.AspNetCore.Server.Kestrel.Transport.Abstractions` library.
- The `ListenOptions.NoDelay` property was available.

New behavior

- The `IConnectionListener` interface was introduced in the `Microsoft.AspNetCore.Connections.Abstractions` library to expose the most used functionality from the `...Transport.Abstractions` library.
- The `NoDelay` is now available in transport options (`LibuvTransportOptions` and `SocketTransportOptions`).
- `SchedulingMode` is no longer available.

Reason for change

ASP.NET Core 3.0 has moved away from "pubternal" APIs.

Recommended action

Category

ASP.NET Core

Affected APIs

None

Localization: ResourceManagerWithCultureStringLocalizer and WithCulture marked obsolete

The `ResourceManagerWithCultureStringLocalizer` class and `WithCulture` interface member are often sources of confusion for users of localization, especially when creating their own `IStringLocalizer` implementation. These items give the user the impression that an `IStringLocalizer` instance is "per-language, per-resource". In reality, the instances should only be "per-resource". The language searched for is determined by the `CultureInfo.CurrentCulture` at execution time. To eliminate the source of confusion, the APIs were marked as obsolete in ASP.NET Core 3.0 Preview 3. The APIs will be removed in a future release.

For context, see [dotnet/aspnetcore#3324](#). For discussion, see [dotnet/aspnetcore#7756](#).

Version introduced

3.0

Old behavior

Methods weren't marked as `Obsolete`.

New behavior

Methods are marked `Obsolete`.

Reason for change

The APIs represented a use case that isn't recommended. There was confusion about the design of localization.

Recommended action

The recommendation is to use `ResourceManagerStringLocalizer` instead. Let the culture be set by the `CurrentCulture`. If that isn't an option, create and use a copy of `ResourceManagerWithCultureStringLocalizer`.

Category

ASP.NET Core

Affected APIs

- `ResourceManagerWithCultureStringLocalizer`
 - `ResourceManagerStringLocalizer.WithCulture`
-

Logging: DebugLogger class made internal

Prior to ASP.NET Core 3.0, `DebugLogger`'s access modifier was `public`. In ASP.NET Core 3.0, the access modifier changed to `internal`.

Version introduced

3.0

Reason for change

The change is being made to:

- Enforce consistency with other logger implementations such as `ConsoleLogger`.
- Reduce the API surface.

Recommended action

Use the `AddDebug` `ILoggingBuilder` extension method to enable debug logging. `DebugLoggerProvider` is also still `public` in the event the service needs to be registered manually.

Category

ASP.NET Core

Affected APIs`Microsoft.Extensions.Logging.Debug.DebugLogger`**MVC: Async suffix trimmed from controller action names**

As part of addressing [dotnet/aspnetcore#4849](#), ASP.NET Core MVC trims the suffix `Async` from action names by default. Starting with ASP.NET Core 3.0, this change affects both routing and link generation.

Version introduced

3.0

Old behavior

Consider the following ASP.NET Core MVC controller:

```
public class ProductController : Controller
{
    public async IActionResult ListAsync()
    {
        var model = await DbContext.Products.ToListAsync();
        return View(model);
    }
}
```

The action is routable via `Product/ListAsync`. Link generation requires specifying the `Async` suffix. For example:

```
<a asp-controller="Product" asp-action="ListAsync">List</a>
```

New behavior

In ASP.NET Core 3.0, the action is routable via `Product>List`. Link generation code should omit the `Async` suffix. For example:

```
<a asp-controller="Product" asp-action="List">List</a>
```

This change doesn't affect names specified using the `[ActionName]` attribute. The new behavior can be disabled by setting `MvcOptions.SuppressAsyncSuffixInActionNames` to `false` in `Startup.ConfigureServices`:

```
services.AddMvc(options =>
{
    options.SuppressAsyncSuffixInActionNames = false;
});
```

Reason for change

By convention, asynchronous .NET methods are suffixed with `Async`. However, when a method defines an MVC action, it's undesirable to use the `Async` suffix.

Recommended action

If your app depends on MVC actions preserving the name's `Async` suffix, choose one of the following mitigations:

- Use the `[ActionName]` attribute to preserve the original name.
- Disable the renaming entirely by setting `MvcOptions.SuppressAsyncSuffixInActionNames` to `false` in `Startup.ConfigureServices`:

```
services.AddMvc(options =>
{
    options.SuppressAsyncSuffixInActionNames = false;
});
```

Category

MVC: JsonResult moved to Microsoft.AspNetCore.Mvc.Core

`JsonResult` has moved to the `Microsoft.AspNetCore.Mvc.Core` assembly. This type used to be defined in `Microsoft.AspNetCore.Mvc.Formatters.Json`. An assembly-level `[TypeForwardedTo]` attribute was added to `Microsoft.AspNetCore.Mvc.Formatters.Json` to address this issue for the majority of users. Apps that use third-party libraries may encounter issues.

Version introduced

3.0 Preview 6

Old behavior

An app using a 2.2-based library builds successfully.

New behavior

An app using a 2.2-based library fails compilation. An error containing a variation of the following text is provided:

```
The type 'JsonResult' exists in both 'Microsoft.AspNetCore.Mvc.Core, Version=3.0.0.0, Culture=neutral, PublicKeyToken=adb9793829ddae60' and 'Microsoft.AspNetCore.Mvc.Formatters.Json, Version=2.0.0.0, Culture=neutral, PublicKeyToken=adb9793829ddae60'
```

For an example of such an issue, see [dotnet/aspnetcore#7220](#).

Reason for change

Platform-level changes to the composition of ASP.NET Core as described at [aspnet/Announcements#325](#).

Recommended action

Libraries compiled against the 2.2 version of `Microsoft.AspNetCore.Mvc.Formatters.Json` may need to recompile to address the problem for all consumers. If affected, contact the library author. Request recompilation of the library to target ASP.NET Core 3.0.

Category

ASP.NET Core

Affected APIs

[Microsoft.AspNetCore.Mvc.JsonResult](#)

MVC: Precompilation tool deprecated

In ASP.NET Core 1.1, the `Microsoft.AspNetCore.Mvc.Razor.ViewCompilation` (MVC precompilation tool) package was introduced to add support for publish-time compilation of Razor files (`.cshtml` files). In ASP.NET Core 2.1, the [Razor SDK](#) was introduced to expand upon features of the precompilation tool. The Razor SDK added support for build- and publish-time compilation of Razor files. The SDK verifies the correctness of `.cshtml` files at build time while improving on app startup time. The Razor SDK is on by default, and no gesture is required to start using it.

In ASP.NET Core 3.0, the ASP.NET Core 1.1-era MVC precompilation tool was removed. Earlier package versions will continue receiving important bug and security fixes in the patch release.

Version introduced

3.0

Old behavior

The `Microsoft.AspNetCore.Mvc.Razor.ViewCompilation` package was used to pre-compile MVC Razor views.

New behavior

The Razor SDK natively supports this functionality. The `Microsoft.AspNetCore.Mvc.Razor.ViewCompilation` package is no longer updated.

Reason for change

The Razor SDK provides more functionality and verifies the correctness of `.cshtml` files at build time. The SDK also improves app startup time.

Recommended action

For users of ASP.NET Core 2.1 or later, update to use the native support for precompilation in the [Razor SDK](#). If bugs or missing features prevent migration to the Razor SDK, open an issue at [dotnet/aspnetcore](#).

Category

ASP.NET Core

Affected APIs

MVC: "Pubternal" types changed to internal

In ASP.NET Core 3.0, all "pubternal" types in MVC were updated to either be `public` in a supported namespace or `internal` as appropriate.

Change description

In ASP.NET Core, "pubternal" types are declared as `public` but reside in a `.Internal`-suffixed namespace. While these types are `public`, they have no support policy and are subject to breaking changes. Unfortunately, accidental use of these types has been common, resulting in breaking changes to these projects and limiting the ability to maintain the framework.

Version introduced

3.0

Old behavior

Some types in MVC were `public` but in a `.Internal` namespace. These types had no support policy and were subject to breaking changes.

New behavior

All such types are updated either to be `public` in a supported namespace or marked as `internal`.

Reason for change

Accidental use of the "pubternal" types has been common, resulting in breaking changes to these projects and limiting the ability to maintain the framework.

Recommended action

If you're using types that have become truly `public` and have been moved into a new, supported namespace, update your references to match the new namespaces.

If you're using types that have become marked as `internal`, you'll need to find an alternative. The previously "pubternal" types were never supported for public use. If there are specific types in these namespaces that are critical to your apps, file an issue at [dotnet/aspnetcore](#). Considerations may be made for making the requested types `public`.

Category

ASP.NET Core

Affected APIs

This change includes types in the following namespaces:

- `Microsoft.AspNetCore.Mvc.Cors.Internal`
- `Microsoft.AspNetCore.Mvc.DataAnnotations.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Json.Internal`
- `Microsoft.AspNetCore.Mvc.Formatters.Xml.Internal`
- `Microsoft.AspNetCore.Mvc.Internal`
- `Microsoft.AspNetCore.Mvc.ModelBinding.Internal`
- `Microsoft.AspNetCore.Mvc.Razor.Internal`
- `Microsoft.AspNetCore.Mvc.RazorPages.Internal`
- `Microsoft.AspNetCore.Mvc.TagHelpers.Internal`
- `Microsoft.AspNetCore.Mvc.ViewFeatures.Internal`

MVC: Web API compatibility shim removed

Starting with ASP.NET Core 3.0, the `Microsoft.AspNetCore.Mvc.WebApiCompatShim` package is no longer available.

Change description

The `Microsoft.AspNetCore.Mvc.WebApiCompatShim` (WebApiCompatShim) package provides partial compatibility in ASP.NET Core with ASP.NET 4.x Web API 2 to simplify migrating existing Web API implementations to ASP.NET Core. However, apps using the WebApiCompatShim don't benefit from the API-related features shipping in recent ASP.NET Core releases. Such features include improved Open API specification generation, standardized error handling, and client code generation. To better focus the API efforts in 3.0, WebApiCompatShim was removed. Existing apps using the WebApiCompatShim should migrate to the newer `[ApiController]` model.

Version introduced

3.0

Reason for change

The Web API compatibility shim was a migration tool. It restricts user access to new functionality added in ASP.NET Core.

Recommended action

Remove usage of this shim and migrate directly to the similar functionality in ASP.NET Core itself.

Category

ASP.NET Core

Affected APIs

[Microsoft.AspNetCore.Mvc.WebApiCompatShim](#)

Razor: RazorTemplateEngine API removed

The `RazorTemplateEngine` API was removed and replaced with

```
Microsoft.AspNetCore.Razor.Language.RazorProjectEngine .
```

For discussion, see GitHub issue [dotnet/aspnetcore#25215](#).

Version introduced

3.0

Old behavior

A template engine can be created and used to parse and generate code for Razor files.

New behavior

`RazorProjectEngine` can be created and provided the same type of information as `RazorTemplateEngine` to parse and generate code for Razor files. `RazorProjectEngine` also provides extra levels of configuration.

Reason for change

`RazorTemplateEngine` was too tightly coupled to the existing implementations. This tight coupling led to more questions when trying to properly configure a Razor parsing/generation pipeline.

Recommended action

Use `RazorProjectEngine` instead of `RazorTemplateEngine`. Consider the following examples.

`Create and configure the RazorProjectEngine`

```
RazorProjectEngine projectEngine =
    RazorProjectEngine.Create(RazorConfiguration.Default,
        RazorProjectFileSystem.Create(@"C:\source\repos\ConsoleApp4\ConsoleApp4"),
        builder =>
    {
        builder.ConfigureClass((document, classNode) =>
        {
            classNode.ClassName = "MyClassName";

            // Can also configure other aspects of the class here.
        });

        // More configuration can go here
    });
}
```

`Generate code for a Razor file`

```
RazorProjectItem item = projectEngine.FileSystem.GetItem(
    @"C:\source\repos\ConsoleApp4\ConsoleApp4\Example.cshtml",
    FileKinds.Legacy);
RazorCodeDocument output = projectEngine.Process(item);

// Things available
RazorSyntaxTree syntaxTree = output.GetSyntaxTree();
DocumentIntermediateNode intermediateDocument =
    output.GetDocumentIntermediateNode();
RazorCSharpDocument csharpDocument = output.GetCSharpDocument();
```

Category

ASP.NET Core

Affected APIs

- `RazorTemplateEngine`
- `RazorTemplateEngineOptions`

Razor: Runtime compilation moved to a package

Support for runtime compilation of Razor views and Razor Pages has moved to a separate package.

Version introduced

3.0

Old behavior

Runtime compilation is available without needing additional packages.

New behavior

The functionality has been moved to the `Microsoft.AspNetCore.Mvc.Razor.RuntimeCompilation` package.

The following APIs were previously available in `Microsoft.AspNetCore.Mvc.Razor.RazorViewEngineOptions` to support runtime compilation. The APIs are now available via

`Microsoft.AspNetCore.Mvc.Razor.RuntimeCompilation.MvcRazorRuntimeCompilationOptions`.

- `RazorViewEngineOptions.FileProviders` is now `MvcRazorRuntimeCompilationOptions.FileProviders`
- `RazorViewEngineOptions.AdditionalCompilationReferences` is now `MvcRazorRuntimeCompilationOptions.AdditionalReferencePaths`

In addition, `Microsoft.AspNetCore.Mvc.Razor.RazorViewEngineOptions.AllowRecompilingViewsOnFileChange` has been removed. Recompilation on file changes is enabled by default by referencing the `Microsoft.AspNetCore.Mvc.Razor.RuntimeCompilation` package.

Reason for change

This change was necessary to remove the ASP.NET Core shared framework dependency on Roslyn.

Recommended action

Apps that require runtime compilation or recompilation of Razor files should take the following steps:

1. Add a reference to the `Microsoft.AspNetCore.Mvc.Razor.RuntimeCompilation` package.
2. Update the project's `Startup.ConfigureServices` method to include a call to `AddRazorRuntimeCompilation`.
For example:

```
services.AddMvc()
    .AddRazorRuntimeCompilation();
```

Category

ASP.NET Core

Affected APIs

`Microsoft.AspNetCore.Mvc.Razor.RazorViewEngineOptions`

Session state: Obsolete APIs removed

Obsolete APIs for configuring session cookies were removed. For more information, see [aspnet/Announcements#257](#).

Version introduced

3.0

Reason for change

This change enforces consistency across APIs for configuring features that use cookies.

Recommended action

Migrate usage of the removed APIs to their newer replacements. Consider the following example in

```
Startup.ConfigureServices :
```

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddSession(options =>
    {
        // Removed obsolete APIs
        options.CookieName = "SessionCookie";
        options.CookieDomain = "contoso.com";
        options.CookiePath = "/";
        options.CookieHttpOnly = true;
        options.CookieSecure = CookieSecurePolicy.Always;

        // new API
        options.Cookie.Name = "SessionCookie";
        options.Cookie.Domain = "contoso.com";
        options.Cookie.Path = "/";
        options.Cookie.HttpOnly = true;
        options.Cookie.SecurePolicy = CookieSecurePolicy.Always;
    });
}
```

Category

ASP.NET Core

Affected APIs

- `Microsoft.AspNetCore.Builder.SessionOptions.CookieDomain`
- `Microsoft.AspNetCore.Builder.SessionOptions.CookieHttpOnly`
- `Microsoft.AspNetCore.Builder.SessionOptions.CookieName`
- `Microsoft.AspNetCore.Builder.SessionOptions.CookiePath`
- `Microsoft.AspNetCore.Builder.SessionOptions.CookieSecure`

Shared framework: Assemblies removed from Microsoft.AspNetCore.App

Starting in ASP.NET Core 3.0, the ASP.NET Core shared framework (`Microsoft.AspNetCore.App`) only contains first-party assemblies that are fully developed, supported, and serviceable by Microsoft.

Change description

Think of the change as the redefining of boundaries for the ASP.NET Core "platform." The shared framework will be [source-buildable by anybody via GitHub](#) and will continue to offer the existing benefits of .NET Core shared frameworks to your apps. Some benefits include smaller deployment size, centralized patching, and faster startup time.

As part of the change, some notable breaking changes are introduced in `Microsoft.AspNetCore.App`.

Version introduced

3.0

Old behavior

Projects referenced `Microsoft.AspNetCore.App` via a `<PackageReference>` element in the project file.

Additionally, `Microsoft.AspNetCore.App` contained the following subcomponents:

- Json.NET (`Newtonsoft.Json`)
- Entity Framework Core (assemblies prefixed with `Microsoft.EntityFrameworkCore.`)
- Roslyn (`Microsoft.CodeAnalysis`)

New behavior

A reference to `Microsoft.AspNetCore.App` no longer requires a `<PackageReference>` element in the project file.

The .NET Core SDK supports a new element called `<FrameworkReference>`, which replaces the use of `<PackageReference>`.

For more information, see [dotnet/aspnetcore#3612](#).

Entity Framework Core ships as NuGet packages. This change aligns the shipping model with all other data access libraries on .NET. It provides Entity Framework Core the simplest path to continue innovating while supporting the various .NET platforms. The move of Entity Framework Core out of the shared framework has no impact on its status as a Microsoft-developed, supported, and serviceable library. The [.NET Core support policy](#) continues to cover it.

Json.NET and Entity Framework Core continue to work with ASP.NET Core. They won't, however, be included in the shared framework.

For more information, see [The future of JSON in .NET Core 3.0](#). Also see [the complete list of binaries](#) removed from the shared framework.

Reason for change

This change simplifies the consumption of `Microsoft.AspNetCore.App` and reduces the duplication between NuGet packages and shared frameworks.

For more information on the motivation for this change, see [this blog post](#).

Recommended action

Starting with ASP.NET Core 3.0, it is no longer necessary for projects to consume assemblies in `Microsoft.AspNetCore.App` as NuGet packages. To simplify the targeting and usage of the ASP.NET Core shared framework, many NuGet packages shipped since ASP.NET Core 1.0 are no longer produced. The APIs those packages provide are still available to apps by using a `<FrameworkReference>` to `Microsoft.AspNetCore.App`. Common API examples include Kestrel, MVC, and Razor.

This change doesn't apply to all binaries referenced via `Microsoft.AspNetCore.App` in ASP.NET Core 2.x. Notable exceptions include:

- `Microsoft.Extensions` libraries that continue to target .NET Standard are available as NuGet packages (see <https://github.com/dotnet/extensions>).
- APIs produced by the ASP.NET Core team that aren't part of `Microsoft.AspNetCore.App`. For example, the following components are available as NuGet packages:
 - Entity Framework Core
 - APIs that provide third-party integration
 - Experimental features
 - APIs with dependencies that couldn't fulfill the requirements to be in the shared framework
- Extensions to MVC that maintain support for Json.NET. An API is provided as a [NuGet package](#) to support using Json.NET and MVC. See the [ASP.NET Core migration guide for more details](#).
- The SignalR .NET client continues to support .NET Standard and ships as a [NuGet package](#). It's intended for use on many .NET runtimes, such as Xamarin and UWP.

For more information, see [Stop producing packages for shared framework assemblies in 3.0](#). For discussion, see [dotnet/aspnetcore#3757](#).

Category

ASP.NET Core

Affected APIs

- `Microsoft.CodeAnalysis`
- `Microsoft.EntityFrameworkCore`

Shared framework: Removed `Microsoft.AspNetCore.All`

Starting in ASP.NET Core 3.0, the `Microsoft.AspNetCore.All` metapackage and the matching `Microsoft.AspNetCore.All` shared framework are no longer produced. This package is available in ASP.NET Core 2.2 and will continue to receive servicing updates in ASP.NET Core 2.1.

Version introduced

3.0

Old behavior

Apps could use the `Microsoft.AspNetCore.All` metapackage to target the `Microsoft.AspNetCore.All` shared

framework on .NET Core.

New behavior

.NET Core 3.0 doesn't include a `Microsoft.AspNetCore.All` shared framework.

Reason for change

The `Microsoft.AspNetCore.All` metapackage included a large number of external dependencies.

Recommended action

Migrate your project to use the `Microsoft.AspNetCore.App` framework. Components that were previously available in `Microsoft.AspNetCore.All` are still available on NuGet. Those components are now deployed with your app instead of being included in the shared framework.

Category

ASP.NET Core

Affected APIs

SignalR: HandshakeProtocol.SuccessHandshakeData replaced

The `HandshakeProtocol.SuccessHandshakeData` field was removed and replaced with a helper method that generates a successful handshake response given a specific `IHubProtocol`.

Version introduced

3.0

Old behavior

`HandshakeProtocol.SuccessHandshakeData` was a `public static ReadOnlyMemory<byte>` field.

New behavior

`HandshakeProtocol.SuccessHandshakeData` has been replaced by a `static GetSuccessfulHandshake(IHubProtocol protocol)` method that returns a `ReadOnlyMemory<byte>` based on the specified protocol.

Reason for change

Additional fields were added to the handshake *response* that are non-constant and change depending on the selected protocol.

Recommended action

None. This type isn't designed for use from user code. It's `public`, so it can be shared between the SignalR server and client. It may also be used by customer SignalR clients written in .NET. **Users** of SignalR shouldn't be affected by this change.

Category

ASP.NET Core

Affected APIs

`HandshakeProtocol.SuccessHandshakeData`

SignalR: HubConnection ResetSendPing and ResetTimeout methods removed

The `ResetSendPing` and `ResetTimeout` methods were removed from the SignalR `HubConnection` API. These methods were originally intended only for internal use but were made public in ASP.NET Core 2.2. These methods won't be available starting in the ASP.NET Core 3.0 Preview 4 release. For discussion, see [dotnet/aspnetcore#8543](#).

Version introduced

3.0

Old behavior

APIs were available.

New behavior

APIs are removed.

Reason for change

These methods were originally intended only for internal use but were made public in ASP.NET Core 2.2.

Recommended action

Don't use these methods.

Category

ASP.NET Core

Affected APIs

- `HubConnection.ResetSendPing()`
 - `HubConnection.ResetTimeout()`
-

SignalR: HubConnectionContext constructors changed

SignalR's `HubConnectionContext` constructors changed to accept an options type, rather than multiple

parameters, to future-proof adding options. This change replaces two constructors with a single constructor that accepts an options type.

Version introduced

3.0

Old behavior

`HubConnectionContext` has two constructors:

```
public HubConnectionContext(ConnectionContext connectionContext, TimeSpan keepAliveInterval, ILoggerFactory loggerFactory);
public HubConnectionContext(ConnectionContext connectionContext, TimeSpan keepAliveInterval, ILoggerFactory loggerFactory, TimeSpan clientTimeoutInterval);
```

New behavior

The two constructors were removed and replaced with one constructor:

```
public HubConnectionContext(ConnectionContext connectionContext, HubConnectionContextOptions contextOptions, ILoggerFactory loggerFactory)
```

Reason for change

The new constructor uses a new options object. Consequently, the features of `HubConnectionContext` can be expanded in the future without making more constructors and breaking changes.

Recommended action

Instead of using the following constructor:

```
HubConnectionContext connectionContext = new HubConnectionContext(
    connectionContext,
    keepAliveInterval: TimeSpan.FromSeconds(15),
    loggerFactory,
    clientTimeoutInterval: TimeSpan.FromSeconds(15));
```

Use the following constructor:

```
HubConnectionContextOptions contextOptions = new HubConnectionContextOptions()
{
    KeepAliveInterval = TimeSpan.FromSeconds(15),
    ClientTimeoutInterval = TimeSpan.FromSeconds(15)
};
HubConnectionContext connectionContext = new HubConnectionContext(connectionContext, contextOptions,
    loggerFactory);
```

- [HubConnectionContext\(ConnectionContext, TimeSpan, ILoggerFactory, TimeSpan\)](#)

SignalR: JavaScript client package name changed

In ASP.NET Core 3.0 Preview 7, the SignalR JavaScript client package name changed from `@aspnet/signalr` to `@microsoft/signalr`. The name change reflects the fact that SignalR is useful in more than just ASP.NET Core apps, thanks to the Azure SignalR Service.

To react to this change, change references in your `package.json` files, `require` statements, and ECMAScript `import` statements. No API will change as part of this rename.

For discussion, see [dotnet/aspnetcore#11637](#).

Version introduced

3.0

Old behavior

The client package was named `@aspnet/signalr`.

New behavior

The client package is named `@microsoft/signalr`.

Reason for change

The name change clarifies that SignalR is useful beyond ASP.NET Core apps, thanks to the Azure SignalR Service.

Recommended action

Switch to the new package `@microsoft/signalr`.

Category

ASP.NET Core

Affected APIs

None

SignalR: UseSignalR and UseConnections methods marked obsolete

The methods `UseConnections` and `UseSignalR` and the classes `ConnectionsRouteBuilder` and `HubRouteBuilder` are marked as obsolete in ASP.NET Core 3.0.

Version introduced

3.0

Old behavior

SignalR hub routing was configured using `UseSignalR` or `UseConnections`.

New behavior

The old way of configuring routing has been obsoleted and replaced with endpoint routing.

Reason for change

Middleware is being moved to the new endpoint routing system. The old way of adding middleware is being obsoleted.

Recommended action

Replace `UseSignalR` with `UseEndpoints`:

Old code:

```
app.UseSignalR(routes =>
{
    routes.MapHub<SomeHub>("/path");
});
```

New code:

```
app.UseEndpoints(endpoints =>
{
    endpoints.MapHub<SomeHub>("/path");
});
```

Category

ASP.NET Core

Affected APIs

- [Microsoft.AspNetCore.Builder.ConnectionsApplicationBuilderExtensions.UseConnections\(IApplicationBuilder, Action<ConnectionsRouteBuilder>\)](#)
- [Microsoft.AspNetCore.Builder.SignalRApplicationBuilderExtensions.UseSignalR\(IApplicationBuilder, Action<HubRouteBuilder>\)](#)
- [Microsoft.AspNetCore.Http.Connections.ConnectionsRouteBuilder](#)
- [Microsoft.AspNetCore.SignalR.HubRouteBuilder](#)

SPAs: SpaServices and NodeServices marked obsolete

The contents of the following NuGet packages have all been unnecessary since ASP.NET Core 2.1. Consequently, the following packages are being marked as obsolete:

- [Microsoft.AspNetCore.SpaServices](#)
- [Microsoft.AspNetCore.NodeServices](#)

For the same reason, the following npm modules are being marked as deprecated:

- [aspnet-angular](#)
- [aspnet-prerendering](#)
- [aspnet-webpack](#)
- [aspnet-webpack-react](#)
- [domain-task](#)

The preceding packages and npm modules will later be removed in .NET 5.

Version introduced

3.0

Old behavior

The deprecated packages and npm modules were intended to integrate ASP.NET Core with various Single-Page App (SPA) frameworks. Such frameworks include Angular, React, and React with Redux.

New behavior

A new integration mechanism exists in the [Microsoft.AspNetCore.SpaServices.Extensions](#) NuGet package. The package remains the basis of the Angular and React project templates since ASP.NET Core 2.1.

Reason for change

ASP.NET Core supports integration with various Single-Page App (SPA) frameworks, including Angular, React,

and React with Redux. Initially, integration with these frameworks was accomplished with ASP.NET Core-specific components that handled scenarios like server-side prerendering and integration with Webpack. As time went on, industry standards changed. Each of the SPA frameworks released their own standard command-line interfaces. For example, Angular CLI and create-react-app.

When ASP.NET Core 2.1 was released in May 2018, the team responded to the change in standards. A newer and simpler way to integrate with the SPA frameworks' own toolchains was provided. The new integration mechanism exists in the package `Microsoft.AspNetCore.SpaServices.Extensions` and remains the basis of the Angular and React project templates since ASP.NET Core 2.1.

To clarify that the older ASP.NET Core-specific components are irrelevant and not recommended:

- The pre-2.1 integration mechanism is marked as obsolete.
- The supporting npm packages are marked as deprecated.

Recommended action

If you're using these packages, update your apps to use the functionality:

- In the `Microsoft.AspNetCore.SpaServices.Extensions` package.
- Provided by the SPA frameworks you're using

To enable features like server-side prerendering and hot module reload, see the documentation for the corresponding SPA framework. The functionality in `Microsoft.AspNetCore.SpaServices.Extensions` is *not* obsolete and will continue to be supported.

Category

ASP.NET Core

Affected APIs

- `Microsoft.AspNetCore.Builder.SpaRouteExtensions`
- `Microsoft.AspNetCore.Builder.WebpackDevMiddleware`
- `Microsoft.AspNetCore.NodeServices.EmbeddedResourceReader`
- `Microsoft.AspNetCore.NodeServices.INodeServices`
- `Microsoft.AspNetCore.NodeServices.NodeServicesFactory`
- `Microsoft.AspNetCore.NodeServices.NodeServicesOptions`
- `Microsoft.AspNetCore.NodeServices.StringAsTempFile`
- `Microsoft.AspNetCore.NodeServices.HostingModels.INodeInstance`
- `Microsoft.AspNetCore.NodeServices.HostingModels.NodeInvocationException`
- `Microsoft.AspNetCore.NodeServices.HostingModels.NodeInvocationInfo`
- `Microsoft.AspNetCore.NodeServices.HostingModels.NodeServicesOptionsExtensions`
- `Microsoft.AspNetCore.NodeServices.HostingModels.OutOfProcessNodeInstance`
- `Microsoft.AspNetCore.SpaServices.Prerendering.ISpaPrerenderer`
- `Microsoft.AspNetCore.SpaServices.Prerendering.ISpaPrerendererBuilder`
- `Microsoft.AspNetCore.SpaServices.Prerendering.JavaScriptModuleExport`
- `Microsoft.AspNetCore.SpaServices.Prerendering.Prefixer`
- `Microsoft.AspNetCore.SpaServices.Prerendering.PrefixerBuilder`
- `Microsoft.AspNetCore.SpaServices.Prerendering.RenderToStringResult`
- `Microsoft.AspNetCore.SpaServices.Webpack.WebpackDevMiddlewareOptions`
- `Microsoft.Extensions.DependencyInjection.NodeServicesServiceCollectionExtensions`
- `Microsoft.Extensions.DependencyInjection.PrerenderingServiceCollectionExtensions`

SPAs: `SpaServices` and `NodeServices` no longer fall back to console logger

`Microsoft.AspNetCore.SpaServices` and `Microsoft.AspNetCore.NodeServices` won't display console logs unless logging is configured.

Version introduced

3.0

Old behavior

`Microsoft.AspNetCore.SpaServices` and `Microsoft.AspNetCore.NodeServices` used to automatically create a console logger when logging isn't configured.

New behavior

`Microsoft.AspNetCore.SpaServices` and `Microsoft.AspNetCore.NodeServices` won't display console logs unless

logging is configured.

Reason for change

There's a need to align with how other ASP.NET Core packages implement logging.

Recommended action

If the old behavior is required, to configure console logging, add

```
services.AddLogging(builder => builder.AddConsole())
```

Category

Target framework: .NET Framework support dropped

Starting with ASP.NET Core 3.0, .NET Framework is an unsupported target framework.

Change description

.NET Framework 4.8 is the last major version of .NET Framework. New ASP.NET Core apps should be built on .NET Core. Starting with the .NET Core 3.0 release, you can think of ASP.NET Core 3.0 as being part of .NET Core.

Customers using ASP.NET Core with .NET Framework can continue in a fully supported fashion using the [2.1 LTS release](#). Support and servicing for 2.1 continues until at least August 21, 2021. This date is three years after declaration of the LTS release per the [.NET Support Policy](#). Support for ASP.NET Core 2.1 packages on .NET Framework will extend indefinitely, similar to the [servicing policy for other package-based ASP.NET frameworks](#).

For more information about porting from .NET Framework to .NET Core, see [Porting to .NET Core](#).

`Microsoft.Extensions` packages (such as logging, dependency injection, and configuration) and Entity Framework Core aren't affected. They'll continue to support .NET Standard.

For more information on the motivation for this change, see [the original blog post](#).

Version introduced

3.0

Old behavior

ASP.NET Core apps could run on either .NET Core or .NET Framework.

New behavior

ASP.NET Core apps can only be run on .NET Core.

Recommended action

Take one of the following actions:

- Keep your app on ASP.NET Core 2.1.
- Migrate your app and dependencies to .NET Core.

Category

ASP.NET Core

Affected APIs

None

Core .NET libraries

- APIs that report version now report product and not file version
- Custom EncoderFallbackBuffer instances cannot fall back recursively
- Floating point formatting and parsing behavior changes
- Floating-point parsing operations no longer fail or throw an `OverflowException`
- `InvalidOperationException` moved to another assembly
- Replacing ill-formed UTF-8 byte sequences follows Unicode guidelines
- `TypeDescriptionProviderAttribute` moved to another assembly
- `ZipArchiveEntry` no longer handles archives with inconsistent entry sizes
- `FieldInfo.SetValue` throws exception for static, init-only fields
- Passing `GroupCollection` to extension methods taking `IEnumerable<T>` requires disambiguation

APIs that report version now report product and not file version

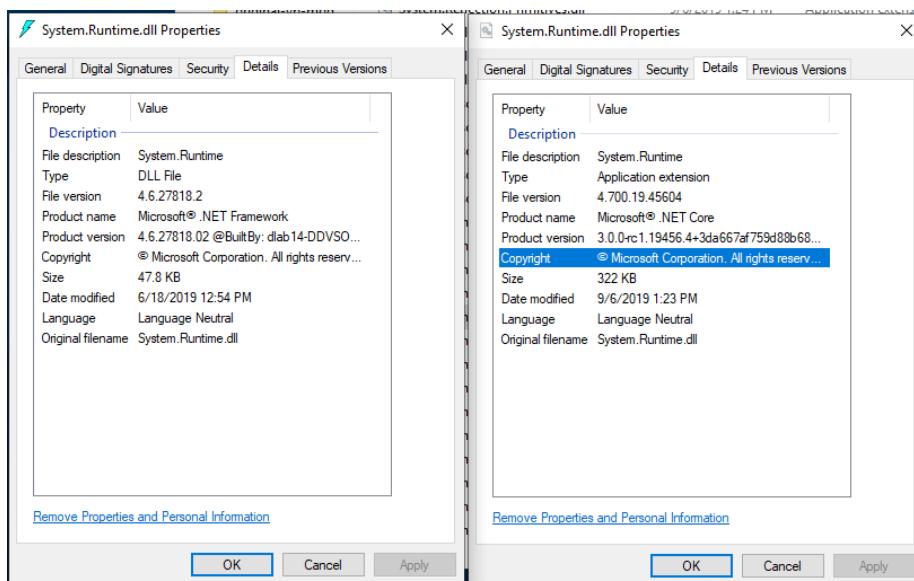

Many of the APIs that return versions in .NET Core now return the product version rather than the file version.

Change description

In .NET Core 2.2 and previous versions, methods such as `Environment.Version`, `RuntimelInformation.FrameworkDescription`, and the file properties dialog for .NET Core assemblies reflect the file version. Starting with .NET Core 3.0, they reflect the product version.

The following figure illustrates the difference in version information for the `System.Runtime.dll` assembly for

.NET Core 2.2 (on the left) and .NET Core 3.0 (on the right) as displayed by the Windows Explorer file properties dialog.

Version introduced

3.0

Recommended action

None. This change should make version detection intuitive rather than obtuse.

Category

Core .NET libraries

Affected APIs

- [Environment.Version](#)
- [RuntimeInformation.FrameworkDescription](#)

Custom EncoderFallbackBuffer instances cannot fall back recursively

Custom [EncoderFallbackBuffer](#) instances cannot fall back recursively. The implementation of [EncoderFallbackBuffer.GetNextChar\(\)](#) must result in a character sequence that is convertible to the destination encoding. Otherwise, an exception occurs.

Change description

During a character-to-byte transcoding operation, the runtime detects ill-formed or nonconvertible UTF-16 sequences and provides those characters to the [EncoderFallbackBuffer.Fallback](#) method. The [Fallback](#) method determines which characters should be substituted for the original nonconvertible data, and these characters are drained by calling [EncoderFallbackBuffer.GetNextChar](#) in a loop.

The runtime then attempts to transcode these substitution characters to the target encoding. If this operation succeeds, the runtime continues transcoding from where it left off in the original input string.

Previously, custom implementations of [EncoderFallbackBuffer.GetNextChar\(\)](#) can return character sequences that are not convertible to the destination encoding. If the substituted characters cannot be transcoded to the target encoding, the runtime invokes the [EncoderFallbackBuffer.Fallback](#) method once again with the substitution characters, expecting the [EncoderFallbackBuffer.GetNextChar\(\)](#) method to return a new substitution sequence. This process continues until the runtime eventually sees a well-formed, convertible substitution, or until a maximum recursion count is reached.

Starting with .NET Core 3.0, custom implementations of [EncoderFallbackBuffer.GetNextChar\(\)](#) must return character sequences that are convertible to the destination encoding. If the substituted characters cannot be transcoded to the target encoding, an [ArgumentException](#) is thrown. The runtime will no longer make recursive calls into the [EncoderFallbackBuffer](#) instance.

This behavior only applies when all three of the following conditions are met:

- The runtime detects an ill-formed UTF-16 sequence or a UTF-16 sequence that cannot be converted to the target encoding.
- A custom [EncoderFallback](#) has been specified.
- The custom [EncoderFallback](#) attempts to substitute a new ill-formed or nonconvertible UTF-16 sequence.

Version introduced

3.0

Recommended action

Most developers needn't take any action.

If an application uses a custom [EncoderFallback](#) and [EncoderFallbackBuffer](#) class, ensure the implementation of

`EncoderFallbackBuffer.Fallback` populates the fallback buffer with well-formed UTF-16 data that is directly convertible to the target encoding when the `Fallback` method is first invoked by the runtime.

Category

Core .NET libraries

Affected APIs

- `EncoderFallbackBuffer.Fallback`
- `EncoderFallbackBuffer.GetNextChar()`

Floating-point formatting and parsing behavior changed

Floating-point parsing and formatting behavior (by the `Double` and `Single` types) are now [IEEE-compliant](#). This ensures that the behavior of floating-point types in .NET matches that of other IEEE-compliant languages. For example, `double.Parse("SomeLiteral")` should always match what C# produces for `double x = SomeLiteral`.

Change description

In .NET Core 2.2 and earlier versions, formatting with `Double.ToString` and `Single.ToString`, and parsing with `Double.Parse`, `Double.TryParse`, `Single.Parse`, and `Single.TryParse` are not IEEE-compliant. As a result, it's impossible to guarantee that a value will roundtrip with any supported standard or custom format string. For some inputs, the attempt to parse a formatted value can fail, and for others, the parsed value doesn't equal the original value.

Starting with .NET Core 3.0, floating-point parsing and formatting operations are IEEE 754-compliant.

The following table shows two code snippets and how the output changes between .NET Core 2.2 and .NET Core 3.1.

CODE SNIPPET	OUTPUT ON .NET CORE 2.2	OUTPUT ON .NET CORE 3.1
<code>Console.WriteLine((-0.0).ToString());</code>	0	-0
<code>var value = -3.123456789123456789; Console.WriteLine(value == double.Parse(value.ToString()));</code>	False	True

For more information, see the [Floating-point parsing and formatting improvements in .NET Core 3.0](#) blog post.

Version introduced

3.0

Recommended action

The [Potential impact to existing code](#) section of the [Floating-point parsing and formatting improvements in .NET Core 3.0](#) blog post suggests some changes you can make to your code if you want to maintain the previous behavior.

- For some differences in formatting, you can get behavior equivalent to the previous behavior by specifying a different format string.
- For differences in parsing, there's no mechanism to fall back to the previous behavior.

Category

Core .NET libraries

Affected APIs

- `Double.ToString`
- `Single.ToString`
- `Double.Parse`
- `Double.TryParse`
- `Single.Parse`
- `Single.TryParse`

Floating-point parsing operations no longer fail or throw an `OverflowException`

The floating-point parsing methods no longer throw an `OverflowException` or return `false` when they parse a string whose numeric value is outside the range of the `Single` or `Double` floating-point type.

Change description

In .NET Core 2.2 and earlier versions, the `Double.Parse` and `Single.Parse` methods throw an `OverflowException` for values that outside the range of their respective type. The `Double.TryParse` and `Single.TryParse` methods return `false` for the string representations of out-of-range numeric values.

Starting with .NET Core 3.0, the `Double.Parse`, `Double.TryParse`, `Single.Parse`, and `Single.TryParse` methods no longer fail when parsing out-of-range numeric strings. Instead, the `Double` parsing methods return `Double.PositiveInfinity` for values that exceed `Double.MaxValue`, and they return `Double.NegativeInfinity` for values that are less than `Double.MinValue`. Similarly, the `Single` parsing methods return `Single.PositiveInfinity` for values that exceed `Single.MaxValue`, and they return `Single.NegativeInfinity` for values that are less than

`Single.MinValue`.

This change was made for improved IEEE 754:2008 compliance.

Version introduced

3.0

Recommended action

This change can affect your code in either of two ways:

- Your code depends on the handler for the `OverflowException` to execute when an overflow occurs. In this case, you should remove the `catch` statement and place any necessary code in an `If` statement that tests whether `Double.IsInfinity` or `Single.IsInfinity` is `true`.
- Your code assumes that floating-point values are not `Infinity`. In this case, you should add the necessary code to check for floating-point values of `PositiveInfinity` and `NegativeInfinity`.

Category

Core .NET libraries

Affected APIs

- `Double.Parse`
- `Double.TryParse`
- `Single.Parse`
- `Single.TryParse`

InvalidAsynchronousStateException moved to another assembly

The `InvalidAsynchronousStateException` class has been moved.

Change description

In .NET Core 2.2 and earlier versions, the `InvalidAsynchronousStateException` class is found in the `System.ComponentModel.TypeConverter` assembly.

Starting with .NET Core 3.0, it is found in the `System.ComponentModel.Primitives` assembly.

Version introduced

3.0

Recommended action

This change only affects applications that use reflection to load the `InvalidAsynchronousStateException` by calling a method such as `Assembly.GetType` or an overload of `Activator.CreateInstance` that assumes the type is in a particular assembly. If that is the case, update the assembly referenced in the method call to reflect the type's new assembly location.

Category

Core .NET libraries

Affected APIs

None.

Replacing ill-formed UTF-8 byte sequences follows Unicode guidelines

When the `UTF8Encoding` class encounters an ill-formed UTF-8 byte sequence during a byte-to-character transcoding operation, it replaces that sequence with a ' REPLACEMENT CHARACTER' character in the output string. .NET Core 3.0 differs from previous versions of .NET Core and the .NET Framework by following the Unicode best practice for performing this replacement during the transcoding operation.

This is part of a larger effort to improve UTF-8 handling throughout .NET, including by the new `System.Text.Unicode.Utf8` and `System.Text.Rune` types. The `UTF8Encoding` type was given improved error handling mechanics so that it produces output consistent with the newly introduced types.

Change description

Starting with .NET Core 3.0, when transcoding bytes to characters, the `UTF8Encoding` class performs character substitution based on Unicode best practices. The substitution mechanism used is described by [The Unicode Standard, Version 12.0, Sec. 3.9 \(PDF\)](#) in the heading titled *U+FFFD Substitution of Maximal Subparts*.

This behavior *only* applies when the input byte sequence contains ill-formed UTF-8 data. Additionally, if the `UTF8Encoding` instance has been constructed with `throwOnInvalidBytes: true`, the `UTF8Encoding` instance will continue to throw on invalid input rather than perform U+FFFD replacement. For more information about the `UTF8Encoding` constructor, see [UTF8Encoding\(Boolean, Boolean\)](#).

The following table illustrates the impact of this change with an invalid 3-byte input:

ILL-FORMED 3-BYTE INPUT	OUTPUT BEFORE .NET CORE 3.0	OUTPUT STARTING WITH .NET CORE 3.0
[ED A0 90]	[FFFD FFFD] (2-character output)	[FFFD FFFD FFFD] (3-character output)

The 3-char output is the preferred output, according to *Table 3-9* of the previously linked Unicode Standard PDF.

Version introduced

3.0

Recommended action

No action is required on the part of the developer.

Category

Core .NET libraries

Affected APIs

- [UTF8Encoding.GetCharCount](#)
- [UTF8Encoding.GetChars](#)
- [UTF8Encoding.GetString\(Byte\[\], Int32, Int32\)](#)

TypeDescriptionProviderAttribute moved to another assembly

The [TypeDescriptionProviderAttribute](#) class has been moved.

Change description

In .NET Core 2.2 and earlier versions, The [TypeDescriptionProviderAttribute](#) class is found in the [System.ComponentModel.TypeConverter](#) assembly.

Starting with .NET Core 3.0, it is found in the [System.ObjectModel](#) assembly.

Version introduced

3.0

Recommended action

This change only affects applications that use reflection to load the [TypeDescriptionProviderAttribute](#) type by calling a method such as [Assembly.GetType](#) or an overload of [Activator.CreateInstance](#) that assumes the type is in a particular assembly. If that is the case, the assembly referenced in the method call should be updated to reflect the type's new assembly location.

Category

Windows Forms

Affected APIs

None.

ZipArchiveEntry no longer handles archives with inconsistent entry sizes

Zip archives list both compressed size and uncompressed size in the central directory and local header. The entry data itself also indicates its size. In .NET Core 2.2 and earlier versions, these values were never checked for consistency. Starting with .NET Core 3.0, they now are.

Change description

In .NET Core 2.2 and earlier versions, [ZipArchiveEntry.Open\(\)](#) succeeds even if the local header disagrees with the central header of the zip file. Data is decompressed until the end of the compressed stream is reached, even if its length exceeds the uncompressed file size listed in the central directory/local header.

Starting with .NET Core 3.0, the [ZipArchiveEntry.Open\(\)](#) method checks that local header and central header agree on compressed and uncompressed sizes of an entry. If they do not, the method throws an [InvalidOperationException](#) if the archive's local header and/or data descriptor list sizes that disagree with the central directory of the zip file. When reading an entry, decompressed data is truncated to the uncompressed file size listed in the header.

This change was made to ensure that a [ZipArchiveEntry](#) correctly represents the size of its data and that only that amount of data is read.

Version introduced

3.0

Recommended action

Repackage any zip archive that exhibits these problems.

Category

Core .NET libraries

Affected APIs

- [ZipArchiveEntry.Open\(\)](#)
- [ZipFileExtensions.ExtractToDirectory](#)
- [ZipFileExtensions.ExtractToFile](#)
- [ZipFile.ExtractToDirectory](#)

FieldInfo.SetValue throws exception for static, init-only fields

Starting in .NET Core 3.0, an exception is thrown when you attempt to set a value on a static, [InitOnly](#) field by calling [System.Reflection.FieldInfo.SetValue](#).

Change description

In .NET Framework and versions of .NET Core prior to 3.0, you could set the value of a static field that's constant after it is initialized ([readonly in C#](#)) by calling `System.Reflection.FieldInfo.SetValue`. However, setting such a field in this way resulted in unpredictable behavior based on the target framework and optimization settings.

In .NET Core 3.0 and later versions, when you call `SetValue` on a static, `InitOnly` field, a `System.FieldAccessException` exception is thrown.

TIP

An `InitOnly` field is one that can only be set at the time it's declared or in the constructor for the containing class. In other words, it's constant after it is initialized.

Version introduced

3.0

Recommended action

Initialize static, `InitOnly` fields in a static constructor. This applies to both dynamic and non-dynamic types.

Alternatively, you can remove the `FieldAttributes.InitOnly` attribute from the field, and then call `FieldInfo.SetValue`.

Category

Core .NET libraries

Affected APIs

- `FieldInfo.SetValue(Object, Object)`
- `FieldInfo.SetValue(Object, Object, BindingFlags, CultureInfo)`

Passing GroupCollection to extension methods taking `IEnumerable<T>` requires disambiguation

When calling an extension method that takes an `IEnumerable<T>` on a `GroupCollection`, you must disambiguate the type using a cast.

Change description

Starting in .NET Core 3.0, `System.Text.RegularExpressions.GroupCollection` implements `IEnumerable<KeyValuePair<String, Group>>` in addition to the other types it implements, including `IEnumerable<Group>`. This results in ambiguity when calling an extension method that takes an `IEnumerable<T>`. If you call such an extension method on a `GroupCollection` instance, for example, `Enumerable.Count`, you'll see the following compiler error:

`CS1061: 'GroupCollection' does not contain a definition for 'Count' and no accessible extension method 'Count' accepting a first argument of type 'GroupCollection' could be found (are you missing a using directive or an assembly reference?)`

In previous versions of .NET, there was no ambiguity and no compiler error.

Version introduced

3.0

Reason for change

This was an [unintentional breaking change](#). Because it has been like this for some time, we don't plan to revert it. In addition, such a change would itself be breaking.

Recommended action

For `GroupCollection` instances, disambiguate calls to extension methods that accept an `IEnumerable<T>` with a cast.

```
// Without a cast - causes CS1061.  
match.Groups.Count(_ => true)  
  
// With a disambiguating cast.  
((IEnumerable<Group>)m.Groups).Count(_ => true);
```

Category

Core .NET libraries

Affected APIs

Any extension method that accepts an `IEnumerable<T>` is affected. For example:

- `System.Collections.Immutable.ImmutableArray.TolImmutableArray<TSource>(IEnumerable<TSource>)`
- `System.Collections.Immutable.ImmutableDictionary.TolImmutableDictionary`
- `System.Collections.Immutable.ImmutableHashSet.TolImmutableHashSet`
- `System.Collections.Immutable.ImmutableList.TolImmutableList<TSource>(IEnumerable<TSource>)`
- `System.Collections.Immutable.ImmutableSortedDictionary.TolImmutableSortedDictionary`
- `System.Collections.Immutable.ImmutableSortedSet.TolImmutableSortedSet`
- `System.Data.DataTableExtensions.Copy ToDataTable`

- Most of the `System.Linq.Enumerable` methods, for example, `System.Linq.Enumerable.Count`
- `System.Linq.ParallelEnumerable.AsParallel`
- `System.Linq.Queryable.AsQueryable`

Cryptography

- `BEGIN TRUSTED CERTIFICATE` syntax no longer supported on Linux
- `EnvelopedCms` defaults to AES-256 encryption
- Minimum size for RSAOpenSsl key generation has increased
- .NET Core 3.0 prefers OpenSSL 1.1.x to OpenSSL 1.0.x
- `CryptoStream.Dispose` transforms final block only when writing

"BEGIN TRUSTED CERTIFICATE" syntax no longer supported for root certificates on Linux

Root certificates on Linux and other Unix-like systems (but not macOS) can be presented in two forms: the standard `BEGIN CERTIFICATE` PEM header, and the OpenSSL-specific `BEGIN TRUSTED CERTIFICATE` PEM header. The latter syntax allows for additional configuration that has caused compatibility issues with .NET Core's `System.Security.Cryptography.X509Certificates.X509Chain` class. `BEGIN TRUSTED CERTIFICATE` root certificate contents are no longer loaded by the chain engine starting in .NET Core 3.0.

Change description

Previously, both the `BEGIN CERTIFICATE` and `BEGIN TRUSTED CERTIFICATE` syntaxes were used to populate the root trust list. If the `BEGIN TRUSTED CERTIFICATE` syntax was used and additional options were specified in the file, `X509Chain` may have reported that the chain trust was explicitly disallowed (`X509ChainStatusFlags.ExplicitDistrust`). However, if the certificate was also specified with the `BEGIN CERTIFICATE` syntax in a previously loaded file, the chain trust was allowed.

Starting in .NET Core 3.0, `BEGIN TRUSTED CERTIFICATE` contents are no longer read. If the certificate is not also specified via a standard `BEGIN CERTIFICATE` syntax, the `X509Chain` reports that the root is not trusted (`X509ChainStatusFlags.UntrustedRoot`).

Version introduced

3.0

Recommended action

Most applications are unaffected by this change, but applications that cannot see both root certificate sources because of permissions problems may experience unexpected `UntrustedRoot` errors after upgrading.

Many Linux distributions (or distros) write root certificates into two locations: a one-certificate-per-file directory, and a one-file concatenation. On some distros, the one-certificate-per-file directory uses the `BEGIN TRUSTED CERTIFICATE` syntax while the file concatenation uses the standard `BEGIN CERTIFICATE` syntax. Ensure that any custom root certificates are added as `BEGIN CERTIFICATE` in at least one of these locations, and that both locations can be read by your application.

The typical directory is `/etc/ssl/certs/` and the typical concatenated file is `/etc/ssl/cert.pem`. Use the command `openssl version -d` to determine the platform-specific root, which may differ from `/etc/ssl/`. For example, on Ubuntu 18.04, the directory is `/usr/lib/ssl/certs/` and the file is `/usr/lib/ssl/cert.pem`. However, `/usr/lib/ssl/certs/` is a symlink to `/etc/ssl/certs/` and `/usr/lib/ssl/cert.pem` does not exist.

```
$ openssl version -d
OPENSSLDIR: "/usr/lib/ssl"
$ ls -al /usr/lib/ssl
total 12
drwxr-xr-x  3 root root 4096 Dec 12 17:10 .
drwxr-xr-x 73 root root 4096 Feb 20 15:18 ..
lrwxrwxrwx  1 root root   14 Mar 27  2018 certs -> /etc/ssl/certs
drwxr-xr-x  2 root root 4096 Dec 12 17:10 misc
lrwxrwxrwx  1 root root   20 Nov 12 16:58 openssl.cnf -> /etc/ssl/openssl.cnf
lrwxrwxrwx  1 root root   16 Mar 27  2018 private -> /etc/ssl/private
```

Affected APIs

- `System.Security.Cryptography.X509Certificates.X509Chain`

EnvelopedCms defaults to AES-256 encryption

The default symmetric encryption algorithm used by `EnvelopedCms` has changed from TripleDES to AES-256.

Change description

In previous versions, when `EnvelopedCms` is used to encrypt data without specifying a symmetric encryption algorithm via a constructor overload, the data is encrypted with the TripleDES/3DES/3DEA/DES3-EDE algorithm.

Starting with .NET Core 3.0 (via version 4.6.0 of the `System.Security.Cryptography.Pkcs` NuGet package), the default algorithm has been changed to AES-256 for algorithm modernization and to improve the security of default options. If a message recipient certificate has a (non-EC) Diffie-Hellman public key, the encryption

operation may fail with a [CryptographicException](#) due to limitations in the underlying platform.

In the following sample code, the data is encrypted with TripleDES if running on .NET Core 2.2 or earlier. If running on .NET Core 3.0 or later, it's encrypted with AES-256.

```
EnvelopedCms cms = new EnvelopedCms(content);
cms.Encrypt(recipient);
return cms.Encode();
```

Version introduced

3.0

Recommended action

If you are negatively impacted by the change, you can restore TripleDES encryption by explicitly specifying the encryption algorithm identifier in an [EnvelopedCms](#) constructor that includes a parameter of type [AlgorithmIdentifier](#), such as:

```
Oid tripleDesOid = new Oid("1.2.840.113549.3.7", null);
AlgorithmIdentifier tripleDesIdentifier = new AlgorithmIdentifier(tripleDesOid);
EnvelopedCms cms = new EnvelopedCms(content, tripleDesIdentifier);

cms.Encrypt(recipient);
return cms.Encode();
```

- [EnvelopedCms\(SubjectIdentifierType, ContentInfo\)](#)

Minimum size for RSAOpenSsl key generation has increased

The minimum size for generating new RSA keys on Linux has increased from 384-bit to 512-bit.

Change description

Starting with .NET Core 3.0, the minimum legal key size reported by the [LegalKeySizes](#) property on RSA instances from [RSA.Create](#), [RSAOpenSsl](#), and [RSACryptoServiceProvider](#) on Linux has increased from 384 to 512.

As a result, in .NET Core 2.2 and earlier versions, a method call such as `RSA.Create(384)` succeeds. In .NET Core 3.0 and later versions, the method call `RSA.Create(384)` throws an exception indicating the size is too small.

This change was made because OpenSSL, which performs the cryptographic operations on Linux, raised its minimum between versions 1.0.2 and 1.1.0. .NET Core 3.0 prefers OpenSSL 1.1.x to 1.0.x, and the minimum reported version was raised to reflect this new higher dependency limitation.

Version introduced

3.0

Recommended action

If you call any of the affected APIs, ensure that the size of any generated keys is not less than the provider minimum.

NOTE

384-bit RSA is already considered insecure (as is 512-bit RSA). Modern recommendations, such as [NIST Special Publication 800-57 Part 1 Revision 4](#), suggest 2048-bit as the minimum size for newly generated keys.

.NET Core 3.0 prefers OpenSSL 1.1.x to OpenSSL 1.0.x

.NET Core for Linux, which works across multiple Linux distributions, can support both OpenSSL 1.0.x and OpenSSL 1.1.x. .NET Core 2.1 and .NET Core 2.2 look for 1.0.x first, then fall back to 1.1.x; .NET Core 3.0 looks for 1.1.x first. This change was made to add support for new cryptographic standards.

This change may impact libraries or applications that do platform interop with the OpenSSL-specific interop types in .NET Core.

Change description

In .NET Core 2.2 and earlier versions, the runtime prefers loading OpenSSL 1.0.x over 1.1.x. This means that the `IntPtr` and `SafeHandle` types for interop with OpenSSL are used with `libcrypto.so.1.0.0 / libcrypto.so.1.0 / libcrypto.so.10` by preference.

Starting with .NET Core 3.0, the runtime prefers loading OpenSSL 1.1.x over OpenSSL 1.0.x, so the `IntPtr` and `SafeHandle` types for interop with OpenSSL are used with `libcrypto.so.1.1 / libcrypto.so.11 / libcrypto.so.1.1.0 / libcrypto.so.1.1.1` by preference. As a result, libraries and applications that interoperate with OpenSSL directly may have incompatible pointers with the .NET Core-exposed values when upgrading from .NET Core 2.1 or .NET Core 2.2.

Version introduced

3.0

Recommended action

Libraries and applications that do direct operations with OpenSSL need to be careful to ensure they are using the same version of OpenSSL as the .NET Core runtime.

All libraries or applications that use `IntPtr` or `SafeHandle` values from the .NET Core cryptographic types directly with OpenSSL should compare the version of the library they use with the new `SafeEvpPKeyHandle.OpenSslVersion` property to ensure the pointers are compatible.

CryptoStream.Dispose transforms final block only when writing

The `CryptoStream.Dispose` method, which is used to finish `CryptoStream` operations, no longer attempts to transform the final block when reading.

Change description

In previous .NET versions, if a user performed an incomplete read when using `CryptoStream` in `Read` mode, the `Dispose` method could throw an exception (for example, when using AES with padding). The exception was thrown because the final block was attempted to be transformed but the data was incomplete.

In .NET Core 3.0 and later versions, `Dispose` no longer tries to transform the final block when reading, which allows for incomplete reads.

Reason for change

This change enables incomplete reads from the crypto stream when a network operation is canceled, without the need to catch an exception.

Version introduced

3.0

Recommended action

Most apps should not be affected by this change.

If your application previously caught an exception in case of an incomplete read, you can delete that `catch` block. If your app used transforming of the final block in hashing scenarios, you might need to ensure that the entire stream is read before it's disposed.

Globalization

- "C" locale maps to the invariant locale

"C" locale maps to the invariant locale

.NET Core 2.2 and earlier versions depend on the default ICU behavior, which maps the "C" locale to the en_US_POSIX locale. The en_US_POSIX locale has an undesirable collation behavior, because it doesn't support case-insensitive string comparisons. Because some Linux distributions set the "C" locale as the default locale, users were experiencing unexpected behavior.

Change description

Starting with .NET Core 3.0, the "C" locale mapping has changed to use the Invariant locale instead of en_US_POSIX. The "C" locale to Invariant mapping is also applied to Windows for consistency.

Mapping "C" to en_US_POSIX culture caused customer confusion, because en_US_POSIX doesn't support case insensitive sorting/searching string operations. Because the "C" locale is used as a default locale in some of the Linux distros, customers experienced this undesired behavior on these operating systems.

Version introduced

3.0

Recommended action

Nothing specific more than the awareness of this change. This change affects only applications that use the "C" locale mapping.

Category

Globalization

Affected APIs

All collation and culture APIs are affected by this change.

MSBuild

- Resource manifest file name change

Resource manifest file name change

Starting in .NET Core 3.0, in the default case, MSBuild generates a different manifest file name for resource files.

Version introduced

3.0

Change description

Prior to .NET Core 3.0, if no `LogicalName`, `ManifestResourceName`, or `DependentUpon` metadata was specified for an `EmbeddedResource` item in the project file, MSBuild generated a manifest file name in the pattern `<RootNamespace>.<ResourceFilePathFromProjectRoot>.resources`. If `RootNamespace` is not defined in the project file, it defaults to the project name. For example, the generated manifest name for a resource file named `Form1.resx` in the root project directory was `MyProject.Form1.resources`.

Starting in .NET Core 3.0, if a resource file is colocated with a source file of the same name (for example, `Form1.resx` and `Form1.cs`), MSBuild uses type information from the source file to generate the manifest file name in the pattern `<Namespace>.<ClassName>.resources`. The namespace and class name are extracted from the first type in the colocated source file. For example, the generated manifest name for a resource file named `Form1.resx` that's colocated with a source file named `Form1.cs` is `MyNamespace.Form1.resources`. The key thing to note is that the first part of the file name is different to prior versions of .NET Core (`MyNamespace` instead of `MyProject`).

NOTE

If you have `LogicalName`, `ManifestResourceName`, or `DependentUpon` metadata specified on an `EmbeddedResource` item in the project file, then this change does not affect that resource file.

This breaking change was introduced with the addition of the `EmbeddedResourceUseDependentUponConvention` property to .NET Core projects. By default, resource files aren't explicitly listed in a .NET Core project file, so they have no `DependentUpon` metadata to specify how to name the generated `.resources` file. When `EmbeddedResourceUseDependentUponConvention` is set to `true`, which is the default, MSBuild looks for a colocated source file and extracts a namespace and class name from that file. If you set `EmbeddedResourceUseDependentUponConvention` to `false`, MSBuild generates the manifest name according to the previous behavior, which combines `RootNamespace` and the relative file path.

Recommended action

In most cases, no action is required on the part of the developer, and your app should continue to work. However, if this change breaks your app, you can either:

- Change your code to expect the new manifest name.

- Opt out of the new naming convention by setting `EmbeddedResourceUseDependentUponConvention` to `false` in your project file.

```
<PropertyGroup>
  <EmbeddedResourceUseDependentUponConvention>false</EmbeddedResourceUseDependentUponConvention>
</PropertyGroup>
```

Networking

- Default value of `HttpRequestMessage.Version` changed to 1.1

Default value of `HttpRequestMessage.Version` changed to 1.1

The default value of the `System.Net.Http.HttpRequestMessage.Version` property has changed from 2.0 to 1.1.

Version introduced

3.0

Change description

In .NET Core 1.0 through 2.0, the default value of the `System.Net.Http.HttpRequestMessage.Version` property is 1.1. Starting with .NET Core 2.1, it was changed to 2.1.

Starting with .NET Core 3.0, the default version number returned by the `System.Net.Http.HttpRequestMessage.Version` property is once again 1.1.

Recommended action

Update your code if it depends on the `System.Net.Http.HttpRequestMessage.Version` property returning a default value of 2.0.

What's new in .NET Core 2.2

9/20/2022 • 3 minutes to read • [Edit Online](#)

.NET Core 2.2 includes enhancements in application deployment, event handling for runtime services, authentication to Azure SQL databases, JIT compiler performance, and code injection prior to the execution of the `Main` method.

New deployment mode

Starting with .NET Core 2.2, you can deploy [framework-dependent executables](#), which are `.exe` files instead of `.dll` files. Functionally similar to framework-dependent deployments, framework-dependent executables (FDE) still rely on the presence of a shared system-wide version of .NET Core to run. Your app contains only your code and any third-party dependencies. Unlike framework-dependent deployments, FDEs are platform-specific.

This new deployment mode has the distinct advantage of building an executable instead of a library, which means you can run your app directly without invoking `dotnet` first.

Core

Handling events in runtime services

You may often want to monitor your application's use of runtime services, such as the GC, JIT, and ThreadPool, to understand how they impact your application. On Windows systems, this is commonly done by monitoring the ETW events of the current process. While this continues to work well, it's not always possible to use ETW if you're running in a low-privilege environment or on Linux or macOS.

Starting with .NET Core 2.2, CoreCLR events can now be consumed using the [System.Diagnostics.Tracing.EventListener](#) class. These events describe the behavior of such runtime services as GC, JIT, ThreadPool, and interop. These are the same events that are exposed as part of the CoreCLR ETW provider. This allows for applications to consume these events or use a transport mechanism to send them to a telemetry aggregation service. You can see how to subscribe to events in the following code sample:

```

internal sealed class SimpleEventListener : EventListener
{
    // Called whenever an EventSource is created.
    protected override void OnEventSourceCreated(EventSource eventSource)
    {
        // Watch for the .NET runtime EventSource and enable all of its events.
        if (eventSource.Name.Equals("Microsoft-Windows-DotNETRuntime"))
        {
            EnableEvents(eventSource, EventLevel.Verbose, (EventKeywords)(-1));
        }
    }

    // Called whenever an event is written.
    protected override void OnEventWritten(EventWrittenEventArgs eventData)
    {
        // Write the contents of the event to the console.
        Console.WriteLine($"ThreadID = {eventData.OSThreadId} ID = {eventData.EventId} Name =
{eventData.EventName}");
        for (int i = 0; i < eventData.Payload.Count; i++)
        {
            string payloadString = eventData.Payload[i]?.ToString() ?? string.Empty;
            Console.WriteLine($" \tName = \"{eventData.PayloadNames[i]}\" Value = \"{payloadString}\"");
        }
        Console.WriteLine("\n");
    }
}

```

In addition, .NET Core 2.2 adds the following two properties to the [EventWrittenEventArgs](#) class to provide additional information about ETW events:

- [EventWrittenEventArgs.OSThreadId](#)
- [EventWrittenEventArgs.TimeStamp](#)

Data

AAD authentication to Azure SQL databases with the `SqlConnection.AccessToken` property

Starting with .NET Core 2.2, an access token issued by Azure Active Directory can be used to authenticate to an Azure SQL database. To support access tokens, the [AccessToken](#) property has been added to the [SqlConnection](#) class. To take advantage of AAD authentication, download version 4.6 of the System.Data.SqlClient NuGet package. In order to use the feature, you can obtain the access token value using the [Active Directory Authentication Library for .NET](#) contained in the [Microsoft.IdentityModel.Clients.ActiveDirectory](#) NuGet package.

JIT compiler improvements

Tiered compilation remains an opt-in feature

In .NET Core 2.1, the JIT compiler implemented a new compiler technology, *tiered compilation*, as an opt-in feature. The goal of tiered compilation is improved performance. One of the important tasks performed by the JIT compiler is optimizing code execution. For little-used code paths, however, the compiler may spend more time optimizing code than the runtime spends executing unoptimized code. Tiered compilation introduces two stages in JIT compilation:

- A **first tier**, which generates code as quickly as possible.
- A **second tier**, which generates optimized code for those methods that are executed frequently. The second tier of compilation is performed in parallel for enhanced performance.

For information on the performance improvement that can result from tiered compilation, see [Announcing .NET Core 2.2 Preview 2](#).

For information about opting in to tiered compilation, see [Jit compiler improvements](#) in [What's new in .NET Core 2.1](#).

Runtime

Injecting code prior to executing the Main method

Starting with .NET Core 2.2, you can use a startup hook to inject code prior to running an application's Main method. Startup hooks make it possible for a host to customize the behavior of applications after they have been deployed without needing to recompile or change the application.

We expect hosting providers to define custom configuration and policy, including settings that potentially influence the load behavior of the main entry point, such as the [`System.Runtime.Loader.AssemblyLoadContext`](#) behavior. The hook can be used to set up tracing or telemetry injection, to set up callbacks for handling, or to define other environment-dependent behavior. The hook is separate from the entry point, so that user code doesn't need to be modified.

See [Host startup hook](#) for more information.

What's new in .NET Core 2.1

9/20/2022 • 10 minutes to read • [Edit Online](#)

.NET Core 2.1 includes enhancements and new features in the following areas:

- [Tooling](#)
- [Roll forward](#)
- [Deployment](#)
- [Windows Compatibility Pack](#)
- [JIT compilation improvements](#)
- [API changes](#)

Tooling

The .NET Core 2.1 SDK (v 2.1.300), the tooling included with .NET Core 2.1, includes the following changes and enhancements:

Build performance improvements

A major focus of .NET Core 2.1 is improving build-time performance, particularly for incremental builds. These performance improvements apply to both command-line builds using `dotnet build` and to builds in Visual Studio. Some individual areas of improvement include:

- For package asset resolution, resolving only assets used by a build rather than all assets.
- Caching of assembly references.
- Use of long-running SDK build servers, which are processes that span across individual `dotnet build` invocations. They eliminate the need to JIT-compile large blocks of code every time `dotnet build` is run. Build server processes can be automatically terminated with the following command:

```
dotnet buildserver shutdown
```

New CLI commands

A number of tools that were available only on a per project basis using `DotnetCliToolReference` are now available as part of the .NET Core SDK. These tools include:

- `dotnet watch` provides a file system watcher that waits for a file to change before executing a designated set of commands. For example, the following command automatically rebuilds the current project and generates verbose output whenever a file in it changes:

```
dotnet watch -- --verbose build
```

Note the `--` option that precedes the `--verbose` option. It delimits the options passed directly to the `dotnet watch` command from the arguments that are passed to the child `dotnet` process. Without it, the `--verbose` option applies to the `dotnet watch` command, not the `dotnet build` command.

For more information, see [Develop ASP.NET Core apps using dotnet watch](#).

- `dotnet dev-certs` generates and manages certificates used during development in ASP.NET Core applications.

- `dotnet user-secrets` manages the secrets in a user secret store in ASP.NET Core applications.
- `dotnet sql-cache` creates a table and indexes in a Microsoft SQL Server database to be used for distributed caching.
- `dotnet ef` is a tool for managing databases, `DbContext` objects, and migrations in Entity Framework Core applications. For more information, see [EF Core .NET Command-line Tools](#).

Global Tools

.NET Core 2.1 supports *Global Tools* -- that is, custom tools that are available globally from the command line. The extensibility model in previous versions of .NET Core made custom tools available on a per project basis only by using `DotnetCliToolReference`.

To install a Global Tool, you use the `dotnet tool install` command. For example:

```
dotnet tool install -g dotnetsay
```

Once installed, the tool can be run from the command line by specifying the tool name. For more information, see [.NET Core Global Tools overview](#).

Tool management with the `dotnet tool` command

In .NET Core 2.1 SDK, all tools operations use the `dotnet tool` command. The following options are available:

- `dotnet tool install` to install a tool.
- `dotnet tool update` to uninstall and reinstall a tool, which effectively updates it.
- `dotnet tool list` to list currently installed tools.
- `dotnet tool uninstall` to uninstall currently installed tools.

Roll forward

All .NET Core applications starting with .NET Core 2.0 automatically roll forward to the latest *minor version* installed on a system.

Starting with .NET Core 2.0, if the version of .NET Core that an application was built with is not present at run time, the application automatically runs against the latest installed *minor version* of .NET Core. In other words, if an application is built with .NET Core 2.0, and .NET Core 2.0 is not present on the host system but .NET Core 2.1 is, the application runs with .NET Core 2.1.

IMPORTANT

This roll-forward behavior doesn't apply to preview releases. By default, it also doesn't apply to major releases, but this can be changed with the settings below.

You can modify this behavior by changing the setting for the roll-forward on no candidate shared framework.

The available settings are:

- `0` - disable minor version roll-forward behavior. With this setting, an application built for .NET Core 2.0.0 will roll forward to .NET Core 2.0.1, but not to .NET Core 2.2.0 or .NET Core 3.0.0.
- `1` - enable minor version roll-forward behavior. This is the default value for the setting. With this setting, an application built for .NET Core 2.0.0 will roll forward to either .NET Core 2.0.1 or .NET Core 2.2.0, depending on which one is installed, but it will not roll forward to .NET Core 3.0.0.
- `2` - enable minor and major version roll-forward behavior. If set, even different major versions are

considered, so an application built for .NET Core 2.0.0 will roll forward to .NET Core 3.0.0.

You can modify this setting in any of three ways:

- Set the `DOTNET_ROLL_FORWARD_ON_NO_CANDIDATE_FX` environment variable to the desired value.
- Add the following line with the desired value to the `.runtimeconfig.json` file:

```
"rollForwardOnNoCandidateFx" : 0
```

- When using the [.NET Core CLI](#), add the following option with the desired value to a .NET Core command such as `run`:

```
dotnet run --rollForwardOnNoCandidateFx=0
```

Patch version roll forward is independent of this setting and is done after any potential minor or major version roll forward is applied.

Deployment

Self-contained application servicing

`dotnet publish` now publishes self-contained applications with a serviced runtime version. When you publish a self-contained application with the .NET Core 2.1 SDK (v 2.1.300), your application includes the latest serviced runtime version known by that SDK. When you upgrade to the latest SDK, you'll publish with the latest .NET Core runtime version. This applies for .NET Core 1.0 runtimes and later.

Self-contained publishing relies on runtime versions on NuGet.org. You do not need to have the serviced runtime on your machine.

Using the .NET Core 2.0 SDK, self-contained applications are published with the .NET Core 2.0.0 runtime unless a different version is specified via the `RuntimeFrameworkVersion` property. With this new behavior, you'll no longer need to set this property to select a higher runtime version for a self-contained application. The easiest approach going forward is to always publish with .NET Core 2.1 SDK (v 2.1.300).

For more information, see [Self-contained deployment runtime roll forward](#).

Windows Compatibility Pack

When you port existing code from the .NET Framework to .NET Core, you can use the [Windows Compatibility Pack](#). It provides access to 20,000 more APIs than are available in .NET Core. These APIs include types in the `System.Drawing` namespace, the `EventLog` class, WMI, Performance Counters, Windows Services, and the Windows registry types and members.

JIT compiler improvements

.NET Core incorporates a new JIT compiler technology called *tiered compilation* (also known as *adaptive optimization*) that can significantly improve performance. Tiered compilation is an opt-in setting.

One of the important tasks performed by the JIT compiler is optimizing code execution. For little-used code paths, however, the compiler may spend more time optimizing code than the runtime spends running unoptimized code. Tiered compilation introduces two stages in JIT compilation:

- A **first tier**, which generates code as quickly as possible.
- A **second tier**, which generates optimized code for those methods that are executed frequently. The

second tier of compilation is performed in parallel for enhanced performance.

You can opt into tiered compilation in either of two ways.

- To use tiered compilation in all projects that use the .NET Core 2.1 SDK, set the following environment variable:

```
COMPlus_TieredCompilation="1"
```

- To use tiered compilation on a per-project basis, add the `<TieredCompilation>` property to the `<PropertyGroup>` section of the MSBuild project file, as the following example shows:

```
<PropertyGroup>
    <!-- other property definitions -->

    <TieredCompilation>true</TieredCompilation>
</PropertyGroup>
```

API changes

`Span<T>` and `Memory<T>`

.NET Core 2.1 includes some new types that make working with arrays and other types of memory much more efficient. The new types include:

- `System.Span<T>` and `System.ReadOnlySpan<T>`.
- `System.Memory<T>` and `System.ReadOnlyMemory<T>`.

Without these types, when passing such items as a portion of an array or a section of a memory buffer, you have to make a copy of some portion of the data before passing it to a method. These types provide a virtual view of that data that eliminates the need for the additional memory allocation and copy operations.

The following example uses a `Span<T>` and `Memory<T>` instance to provide a virtual view of 10 elements of an array.

```
using System;

class Program
{
    static void Main()
    {
        int[] numbers = new int[100];
        for (int i = 0; i < 100; i++)
        {
            numbers[i] = i * 2;
        }

        var part = new Span<int>(numbers, start: 10, length: 10);
        foreach (var value in part)
            Console.Write($"{value} ");
    }
}

// The example displays the following output:
//      20 22 24 26 28 30 32 34 36 38
```

```

Module Program
Sub Main()
    Dim numbers As Integer() = New Integer(99) {}

    For i As Integer = 0 To 99
        numbers(i) = i * 2
    Next

    Dim part = New Memory(Of Integer)(numbers, start:=10, length:=10)

    For Each value In part.Span
        Console.WriteLine($"{value} ")
    Next
End Sub
End Module
' The example displays the following output:
'      20  22  24  26  28  30  32  34  36  38

```

Brotli compression

.NET Core 2.1 adds support for Brotli compression and decompression. Brotli is a general-purpose lossless compression algorithm that is defined in [RFC 7932](#) and is supported by most web browsers and major web servers. You can use the stream-based [System.IO.Compression.BrotliStream](#) class or the high-performance span-based [System.IO.Compression.BrotliEncoder](#) and [System.IO.Compression.BrotliDecoder](#) classes. The following example illustrates compression with the [BrotliStream](#) class:

```

public static Stream DecompressWithBrotli(Stream toDecompress)
{
    MemoryStream decompressedStream = new MemoryStream();
    using (BrotliStream decompressionStream = new BrotliStream(toDecompress, CompressionMode.Decompress))
    {
        decompressionStream.CopyTo(decompressedStream);
    }
    decompressedStream.Position = 0;
    return decompressedStream;
}

```

```

Public Function DecompressWithBrotli(toDecompress As Stream) As Stream
    Dim decompressedStream As New MemoryStream()
    Using decompressionStream As New BrotliStream(toDecompress, CompressionMode.Decompress)
        decompressionStream.CopyTo(decompressedStream)
    End Using
    decompressedStream.Position = 0
    Return decompressedStream
End Function

```

The [BrotliStream](#) behavior is the same as [DeflateStream](#) and [GZipStream](#), which makes it easy to convert code that calls these APIs to [BrotliStream](#).

New cryptography APIs and cryptography improvements

.NET Core 2.1 includes numerous enhancements to the cryptography APIs:

- [System.Security.Cryptography.Pkcs.SignedCms](#) is available in the [System.Security.Cryptography.Pkcs](#) package. The implementation is the same as the [SignedCms](#) class in the .NET Framework.
- New overloads of the [X509Certificate.GetCertHash](#) and [X509Certificate.GetCertHashString](#) methods accept a hash algorithm identifier to enable callers to get certificate thumbprint values using algorithms other than SHA-1.
- New [Span<T>](#)-based cryptography APIs are available for hashing, HMAC, cryptographic random number

generation, asymmetric signature generation, asymmetric signature processing, and RSA encryption.

- The performance of [System.Security.Cryptography.Rfc2898DeriveBytes](#) has improved by about 15% by using a [Span<T>](#)-based implementation.
- The new [System.Security.Cryptography.CryptographicOperations](#) class includes two new methods:
 - [FixedTimeEquals](#) takes a fixed amount of time to return for any two inputs of the same length, which makes it suitable for use in cryptographic verification to avoid contributing to timing side-channel information.
 - [ZeroMemory](#) is a memory-clearing routine that cannot be optimized.
- The static [RandomNumberGenerator.Fill](#) method fills a [Span<T>](#) with random values.
- The [System.Security.Cryptography.Pkcs.EnvelopedCms](#) is now supported on Linux and macOS.
- Elliptic-Curve Diffie-Hellman (ECDH) is now available in the [System.Security.Cryptography.ECDiffieHellman](#) class family. The surface area is the same as in the .NET Framework.
- The instance returned by [RSA.Create](#) can encrypt or decrypt with OAEP using a SHA-2 digest, as well as generate or validate signatures using RSA-PSS.

Sockets improvements

.NET Core includes a new type, [System.Net.Http.SocketsHttpHandler](#), and a rewritten [System.Net.Http.HttpMessageHandler](#), that form the basis of higher-level networking APIs. [System.Net.Http.SocketsHttpHandler](#), for example, is the basis of the [HttpClient](#) implementation. In previous versions of .NET Core, higher-level APIs were based on native networking implementations.

The sockets implementation introduced in .NET Core 2.1 has a number of advantages:

- A significant performance improvement when compared with the previous implementation.
- Elimination of platform dependencies, which simplifies deployment and servicing.
- Consistent behavior across all .NET Core platforms.

[SocketsHttpHandler](#) is the default implementation in .NET Core 2.1. However, you can configure your application to use the older [HttpClientHandler](#) class by calling the [AppContext.SetSwitch](#) method:

```
AppContext.SetSwitch("System.Net.Http.UseSocketsHttpHandler", false);
```

```
AppContext.SetSwitch("System.Net.Http.UseSocketsHttpHandler", False)
```

You can also use an environment variable to opt out of using sockets implementations based on [SocketsHttpHandler](#). To do this, set the `DOTNET_SYSTEM_NET_HTTP_USESOCKETSHTTPHANDLER` to either `false` or 0.

On Windows, you can also choose to use [System.Net.Http.WinHttpHandler](#), which relies on a native implementation, or the [SocketsHttpHandler](#) class by passing an instance of the class to the [HttpClient](#) constructor.

On Linux and macOS, you can only configure [HttpClient](#) on a per-process basis. On Linux, you need to deploy [libcurl](#) if you want to use the old [HttpClient](#) implementation. (It is installed with .NET Core 2.0.)

Breaking changes

Breaking changes in .NET Core 2.1

9/20/2022 • 6 minutes to read • [Edit Online](#)

If you're migrating to version 2.1 of .NET Core, the breaking changes listed in this article may affect your app.

Core .NET libraries

- [Path APIs don't throw an exception for invalid characters](#)
- [Private fields added to built-in struct types](#)
- [OpenSSL versions on macOS](#)

Path APIs don't throw an exception for invalid characters

APIs that involve file paths no longer validate path characters or throw an [ArgumentException](#) if an invalid character is found.

Change description

In .NET Framework and .NET Core 1.0 - 2.0, the methods listed in the [Affected APIs](#) section throw an [ArgumentException](#) if the path argument contains an invalid path character. Starting in .NET Core 2.1, these methods no longer check for [invalid path characters](#) or throw an exception if an invalid character is found.

Reason for change

Aggressive validation of path characters blocks some cross-platform scenarios. This change was introduced so that .NET does not try to replicate or predict the outcome of operating system API calls. For more information, see the [System.IO in .NET Core 2.1 sneak peek](#) blog post.

Version introduced

.NET Core 2.1

Recommended action

If your code relied on these APIs to check for invalid characters, you can add a call to [Path.GetInvalidPathChars](#).

Private fields added to built-in struct types

Private fields were added to [certain struct types](#) in [reference assemblies](#). As a result, in C#, those struct types must always be instantiated by using the [new operator](#) or [default literal](#).

Change description

In .NET Core 2.0 and previous versions, some provided struct types, for example, [ConsoleKeyInfo](#), could be instantiated without using the [new](#) operator or [default literal](#) in C#. This was because the [reference assemblies](#) used by the C# compiler didn't contain the private fields for the structs. All private fields for .NET struct types are added to the reference assemblies starting in .NET Core 2.1.

For example, the following C# code compiles in .NET Core 2.0, but not in .NET Core 2.1:

```
ConsoleKeyInfo key; // Struct type

if (key.ToString() == "y")
{
    Console.WriteLine("Yes!");
}
```

In .NET Core 2.1, the previous code results in the following compiler error: [CS0165 - Use of unassigned local variable 'key'](#)

Version introduced

2.1

Recommended action

Instantiate struct types by using the [new](#) operator or [default literal](#).

For example:

```
ConsoleKeyInfo key = new ConsoleKeyInfo(); // Struct type.

if (key.ToString() == "y")
    Console.WriteLine("Yes!");
```

```
ConsoleKeyInfo key = default; // Struct type.  
  
if (key.ToString() == "y")  
    Console.WriteLine("Yes!");
```

OpenSSL versions on macOS

The .NET Core 3.0 and later runtimes on macOS now prefer OpenSSL 1.1.x versions to OpenSSL 1.0.x versions for the [AesCcm](#), [AesGcm](#), [DSAOpenSsl](#), [ECDiffieHellmanOpenSsl](#), [ECDsaOpenSsl](#), [RSAOpenSsl](#), and [SafeEvpPKeyHandle](#) types.

The .NET Core 2.1 runtime now supports OpenSSL 1.1.x versions, but still prefers OpenSSL 1.0.x versions.

Change description

Previously, the .NET Core runtime used OpenSSL 1.0.x versions on macOS for types that interact with OpenSSL. The most recent OpenSSL 1.0.x version, OpenSSL 1.0.2, is now out of support. To keep types that use OpenSSL on supported versions of OpenSSL, the .NET Core 3.0 and later runtimes now use newer versions of OpenSSL on macOS.

With this change, the behavior for the .NET Core runtimes on macOS is as follows:

- The .NET Core 3.0 and later version runtimes use OpenSSL 1.1.x, if available, and fall back to OpenSSL 1.0.x only if there's no 1.1.x version available.

For callers that use the OpenSSL interop types with custom P/Invokes, follow the guidance in the [SafeEvpPKeyHandle.OpenSslVersion](#) remarks. Your app may crash if you don't check the [OpenSslVersion](#) value.

- The .NET Core 2.1 runtime uses OpenSSL 1.0.x, if available, and falls back to OpenSSL 1.1.x if there's no 1.0.x version available.

The 2.1 runtime prefers the earlier version of OpenSSL because the [SafeEvpPKeyHandle.OpenSslVersion](#) property does not exist in .NET Core 2.1, so the OpenSSL version cannot be reliably determined at run time.

Version introduced

- .NET Core 2.1.16
- .NET Core 3.0.3
- .NET Core 3.1.2

Recommended action

- Uninstall OpenSSL version 1.0.2 if it's no longer needed.
- Install OpenSSL 1.1.x if you use the [AesCcm](#), [AesGcm](#), [DSAOpenSsl](#), [ECDiffieHellmanOpenSsl](#), [ECDsaOpenSsl](#), [RSAOpenSsl](#), or [SafeEvpPKeyHandle](#) types.
- If you use the OpenSSL interop types with custom P/Invokes, follow the guidance in the [SafeEvpPKeyHandle.OpenSslVersion](#) remarks.

Category

Core .NET libraries

Affected APIs

- [System.Security.Cryptography.AesCcm](#)
- [System.Security.Cryptography.AesGcm](#)
- [System.Security.Cryptography.DSAOpenSsl](#)
- [System.Security.Cryptography.ECDiffieHellmanOpenSsl](#)
- [System.Security.Cryptography.ECDsaOpenSsl](#)
- [System.Security.Cryptography.RSAOpenSsl](#)
- [System.Security.Cryptography.SafeEvpPKeyHandle](#)

MSBuild

- [Project tools now included in SDK](#)

Project tools now included in SDK

The .NET Core 2.1 SDK now includes common CLI tooling, and you no longer need to reference these tools from the project.

Change description

In .NET Core 2.0, projects reference external .NET tools with the `<DotNetCliToolReference>` project setting. In .NET Core 2.1, some of these tools are included with the .NET Core SDK, and the setting is no longer needed. If you include references to these tools in your project, you'll receive an error similar to the following: **The tool 'Microsoft.EntityFrameworkCore.Tools.DotNet' is now included in the .NET Core SDK.**

Tools now included in .NET Core 2.1 SDK:

<DOTNETCLITOOLREFERENCE> VALUE	TOOL
<code>Microsoft.DotNet.Watcher.Tools</code>	<code>dotnet-watch</code>
<code>Microsoft.Extensions.SecretManager.Tools</code>	<code>dotnet-user-secrets</code>

<DOTNETCLITOOLREFERENCE> VALUE	TOOL
Microsoft.Extensions.Caching.SqlConfig.Tools	dotnet-sql-cache
Microsoft.EntityFrameworkCore.Tools.DotNet	dotnet-ef

Version introduced

.NET Core SDK 2.1.300

Recommended action

Remove the <DotNetCliToolReference> setting from your project.

What's new in .NET Core 2.0

9/20/2022 • 6 minutes to read • [Edit Online](#)

.NET Core 2.0 includes enhancements and new features in the following areas:

- [Tooling](#)
- [Language support](#)
- [Platform improvements](#)
- [API changes](#)
- [Visual Studio integration](#)
- [Documentation improvements](#)

Tooling

dotnet restore runs implicitly

In previous versions of .NET Core, you had to run the `dotnet restore` command to download dependencies immediately after you created a new project with the `dotnet new` command, as well as whenever you added a new dependency to your project.

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

You can also disable the automatic invocation of `dotnet restore` by passing the `--no-restore` switch to the `new`, `run`, `build`, `publish`, `pack`, and `test` commands.

Retargeting to .NET Core 2.0

If the .NET Core 2.0 SDK is installed, projects that target .NET Core 1.x can be retargeted to .NET Core 2.0.

To retarget to .NET Core 2.0, edit your project file by changing the value of the `<TargetFramework>` element (or the `<TargetFrameworks>` element if you have more than one target in your project file) from 1.x to 2.0:

```
<PropertyGroup>
  <TargetFramework>netcoreapp2.0</TargetFramework>
</PropertyGroup>
```

You can also retarget .NET Standard libraries to .NET Standard 2.0 the same way:

```
<PropertyGroup>
  <TargetFramework>netstandard2.0</TargetFramework>
</PropertyGroup>
```

For more information about migrating your project to .NET Core 2.0, see [Migrating from ASP.NET Core 1.x to ASP.NET Core 2.0](#).

Language support

In addition to supporting C# and F#, .NET Core 2.0 also supports Visual Basic.

Visual Basic

With version 2.0, .NET Core now supports Visual Basic 2017. You can use Visual Basic to create the following project types:

- .NET Core console apps
- .NET Core class libraries
- .NET Standard class libraries
- .NET Core unit test projects
- .NET Core xUnit test projects

For example, to create a Visual Basic "Hello World" application, do the following steps from the command line:

1. Open a console window, create a directory for your project, and make it the current directory.
2. Enter the command `dotnet new console -lang vb`.

The command creates a project file with a `.vbproj` file extension, along with a Visual Basic source code file named `Program.vb`. This file contains the source code to write the string "Hello World!" to the console window.

3. Enter the command `dotnet run`. The [.NET Core CLI](#) automatically compiles and executes the application, which displays the message "Hello World!" in the console window.

Support for C# 7.1

.NET Core 2.0 supports C# 7.1, which adds a number of new features, including:

- The `Main` method, the application entry point, can be marked with the `async` keyword.
- Inferred tuple names.
- Default expressions.

Platform improvements

.NET Core 2.0 includes a number of features that make it easier to install .NET Core and to use it on supported operating systems.

.NET Core for Linux is a single implementation

.NET Core 2.0 offers a single Linux implementation that works on multiple Linux distributions. .NET Core 1.x required that you download a distribution-specific Linux implementation.

You can also develop apps that target Linux as a single operating system. .NET Core 1.x required that you target each Linux distribution separately.

Support for the Apple cryptographic libraries

.NET Core 1.x on macOS required the OpenSSL toolkit's cryptographic library. .NET Core 2.0 uses the Apple cryptographic libraries and doesn't require OpenSSL, so you no longer need to install it.

API changes and library support

Support for .NET Standard 2.0

.NET Standard defines a versioned set of APIs that must be available on .NET implementations that comply with that version of the standard. .NET Standard is targeted at library developers. It aims to guarantee the functionality that is available to a library that targets a version of .NET Standard on each .NET implementation.

.NET Core 1.x supports .NET Standard version 1.6; .NET Core 2.0 supports the latest version, .NET Standard 2.0. For more information, see [.NET Standard](#).

.NET Standard 2.0 includes over 20,000 more APIs than were available in .NET Standard 1.6. Much of this expanded surface area results from incorporating APIs that are common to the .NET Framework and Xamarin into .NET Standard.

.NET Standard 2.0 class libraries can also reference .NET Framework class libraries, provided that they call APIs that are present in .NET Standard 2.0. No recompilation of the .NET Framework libraries is required.

For a list of the APIs that have been added to .NET Standard since its last version, .NET Standard 1.6, see [.NET Standard 2.0 vs. 1.6](#).

Expanded surface area

The total number of APIs available on .NET Core 2.0 has more than doubled in comparison with .NET Core 1.1.

And with the [Windows Compatibility Pack](#) porting from .NET Framework has also become much simpler.

Support for .NET Framework libraries

.NET Core code can reference existing .NET Framework libraries, including existing NuGet packages. Note that the libraries must use APIs that are found in .NET Standard.

Visual Studio integration

Visual Studio 2017 version 15.3 and in some cases Visual Studio for Mac offer a number of significant enhancements for .NET Core developers.

Retargeting .NET Core apps and .NET Standard libraries

If the .NET Core 2.0 SDK is installed, you can retarget .NET Core 1.x projects to .NET Core 2.0 and .NET Standard 1.x libraries to .NET Standard 2.0.

To retarget your project in Visual Studio, you open the **Application** tab of the project's properties dialog and change the **Target framework** value to **.NET Core 2.0** or **.NET Standard 2.0**. You can also change it by right-clicking on the project and selecting the **Edit *.csproj** file option. For more information, see the [Tooling](#) section earlier in this topic.

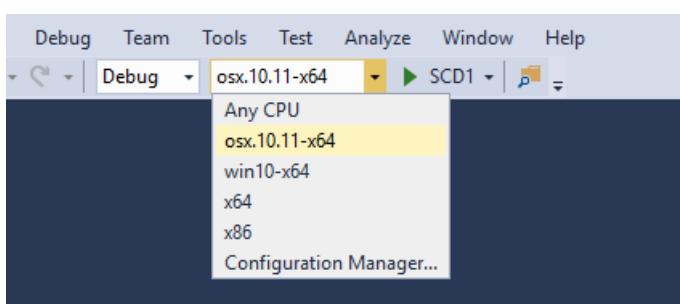

Live Unit Testing support for .NET Core

Whenever you modify your code, Live Unit Testing automatically runs any affected unit tests in the background and displays the results and code coverage live in the Visual Studio environment. .NET Core 2.0 now supports Live Unit Testing. Previously, Live Unit Testing was available only for .NET Framework applications.

For more information, see [Live Unit Testing with Visual Studio](#) and the [Live Unit Testing FAQ](#).

Better support for multiple target frameworks

If you're building a project for multiple target frameworks, you can now select the target platform from the top-level menu. In the following figure, a project named SCD1 targets 64-bit macOS X 10.11 (`osx.10.11-x64`) and 64-bit Windows 10/Windows Server 2016 (`win10-x64`). You can select the target framework before selecting the project button, in this case to run a debug build.

Side-by-side support for .NET Core SDKs

You can now install the .NET Core SDK independently of Visual Studio. This makes it possible for a single version of Visual Studio to build projects that target different versions of .NET Core. Previously, Visual Studio and the .NET Core SDK were tightly coupled; a particular version of the SDK accompanied a particular version of Visual Studio.

Documentation improvements

.NET Application Architecture

[.NET Application Architecture](#) gives you access to a set of e-books that provide guidance, best practices, and sample applications when using .NET to build:

- [Microservices and Docker containers](#)
- [Web applications with ASP.NET](#)
- [Mobile applications with Xamarin](#)
- [Applications that are deployed to the Cloud with Azure](#)

See also

- [What's new in ASP.NET Core 2.0](#)

What's new in .NET Standard

9/20/2022 • 3 minutes to read • [Edit Online](#)

.NET Standard is a formal specification that defines a versioned set of APIs that must be available on .NET implementations that comply with that version of the standard. .NET Standard is targeted at library developers. A library that targets a .NET Standard version can be used on any .NET or Xamarin implementation that supports that version of the standard.

.NET Standard is included with the .NET SDK. It's also included with Visual Studio if you select the .NET workload.

.NET Standard 2.1 is the last version of .NET Standard that will be released. For more information, see [.NET 5+ and .NET Standard](#).

Supported .NET implementations

.NET Standard 2.1 is supported by the following .NET implementations:

- .NET Core 3.0 or later (including .NET 5 and later)
- Mono 6.4 or later
- Xamarin.iOS 12.16 or later
- Xamarin.Android 10.0 or later

.NET Standard 2.0 is supported by the following .NET implementations:

- .NET Core 2.0 or later (including .NET 5 and later)
- .NET Framework 4.6.1 or later
- Mono 5.4 or later
- Xamarin.iOS 10.14 or later
- Xamarin.Mac 3.8 or later
- Xamarin.Android 8.0 or later
- Universal Windows Platform 10.0.16299 or later

What's new in .NET Standard 2.1

.NET Standard 2.1 adds many APIs to the standard. Some of them are new APIs, and others are existing APIs that help to converge the .NET implementations even further. For a list of the APIs that have been added to .NET Standard 2.1, see [.NET Standard 2.1 vs 2.0](#).

For more information, see the [Announcing .NET Standard 2.1](#) blog post.

What's new in .NET Standard 2.0

.NET Standard 2.0 includes the following new features.

A vastly expanded set of APIs

Through version 1.6, .NET Standard included a comparatively small subset of APIs. Among those excluded were many APIs that were commonly used in .NET Framework or Xamarin. This complicates development, since it requires that developers find suitable replacements for familiar APIs when they develop applications and libraries that target multiple .NET implementations. .NET Standard 2.0 addresses this limitation by adding over 20,000 more APIs than were available in .NET Standard 1.6, the previous version of the standard. For a list of the APIs that have been added to .NET Standard 2.0, see [.NET Standard 2.0 vs 1.6](#).

Some of the additions to the [System](#) namespace in .NET Standard 2.0 include:

- Support for the [AppDomain](#) class.
- Better support for working with arrays from additional members in the [Array](#) class.
- Better support for working with attributes from additional members in the [Attribute](#) class.
- Better calendar support and additional formatting options for [DateTime](#) values.
- Additional [Decimal](#) rounding functionality.
- Additional functionality in the [Environment](#) class.
- Enhanced control over the garbage collector through the [GC](#) class.
- Enhanced support for string comparison, enumeration, and normalization in the [String](#) class.
- Support for daylight saving adjustments and transition times in the [TimeZoneInfo.AdjustmentRule](#) and [TimeZoneInfo.TransitionTime](#) classes.
- Significantly enhanced functionality in the [Type](#) class.
- Better support for deserialization of exception objects by adding an exception constructor with [SerializationInfo](#) and [StreamingContext](#) parameters.

Support for .NET Framework libraries

Many libraries target .NET Framework rather than .NET Standard. However, most of the calls in those libraries are to APIs that are included in .NET Standard 2.0. Starting with .NET Standard 2.0, you can access .NET Framework libraries from a .NET Standard library by using a [compatibility shim](#). This compatibility layer is transparent to developers; you don't have to do anything to take advantage of .NET Framework libraries.

The single requirement is that the APIs called by the .NET Framework class library must be included in .NET Standard 2.0.

Support for Visual Basic

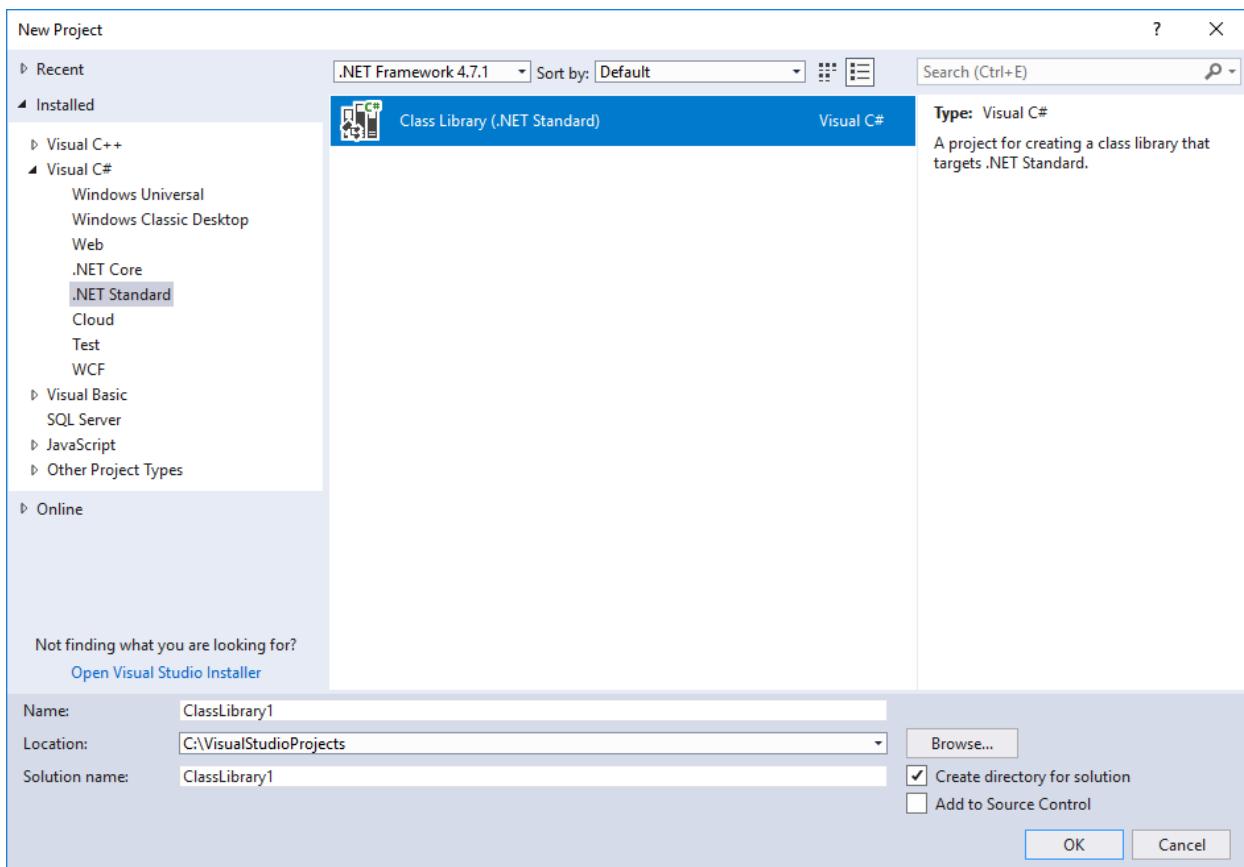

You can now develop .NET Standard libraries in Visual Basic. Visual Studio 2019 and Visual Studio 2017 version 15.3 or later with the .NET Core workload installed include a .NET Standard Class Library template. For Visual Basic developers who use other development tools and environments, you can use the [dotnet new](#) command to create a .NET Standard Library project. For more information, see the [Tooling support for .NET Standard libraries](#).

Tooling support for .NET Standard libraries

With the release of .NET Core 2.0 and .NET Standard 2.0, both Visual Studio 2017 and the [.NET CLI](#) include tooling support for creating .NET Standard libraries.

If you install Visual Studio with the [.NET Core cross-platform development](#) workload, you can create a .NET Standard 2.0 library project by using a project template, as the following figure shows:

- [C#](#)
- [Visual Basic](#)

If you're using the .NET CLI, the following `dotnet new` command creates a class library project that targets .NET Standard 2.0:

```
dotnet new classlib
```

Tools and diagnostics in .NET

9/20/2022 • 2 minutes to read • [Edit Online](#)

In this article, you'll learn about the various tools available to .NET developers. With .NET, you have a robust software development kit (SDK) that includes a command-line interface (CLI). The .NET CLI enables many of the features throughout the .NET-ready integrated development environments (IDEs). This article also provides resources to productivity capabilities, such as .NET CLI tools for diagnosing performance issues, memory leaks, high CPU, deadlocks, and tooling support for code analysis.

.NET SDK

The .NET SDK includes both the .NET Runtime and the .NET CLI. You can download the [.NET SDK](#) for Windows, Linux, macOS, or Docker. For more information, see [.NET SDK overview](#).

.NET CLI

The .NET CLI is a cross-platform toolchain for developing, building, running, and publishing .NET applications. The .NET CLI is included with the .NET SDK. For more information, see [.NET CLI overview](#).

IDEs

You can write .NET applications in [Visual Studio Code](#), [Visual Studio](#), or [Visual Studio for Mac](#).

Additional tools

In addition to the more common tools, .NET also provides tools for specific scenarios. Some of the use cases include uninstalling the .NET SDK or the .NET Runtime, retrieving Windows Communication Foundation (WCF) metadata, generating proxy source code, and serializing XML. For more information, see [.NET additional tools overview](#).

Diagnostics and instrumentation

As a .NET developer, you can make use of common performance diagnostic tools to monitor app performance, profile apps with tracing, collect performance metrics, and analyze dump files. You collect performance metrics with event counters, and use profiling tools to gain insights into how apps perform. For more information, see [.NET diagnostics tools](#).

Code analysis

The .NET compiler platform (Roslyn) analyzers inspect your C# or Visual Basic code for code quality and code style issues. For more information, see [.NET source code analysis overview](#).

Package Validation

The .NET SDK allows library developers to validate that their packages are consistent and well formed. For more information, see [.NET SDK package validation](#).

What is the .NET SDK?

9/20/2022 • 2 minutes to read • [Edit Online](#)

The .NET SDK is a set of libraries and tools that allow developers to create .NET applications and libraries. It contains the following components that are used to build and run applications:

- The [.NET CLI](#).
- The [.NET runtime and libraries](#).
- The `dotnet` driver.

How to install the .NET SDK

As with any tooling, the first thing is to get the tools on your machine. Depending on your scenario, you can install the SDK using one of the following methods:

- Use the native installers.
- Use the installation shell script.

The native installers are primarily meant for developers' machines. The SDK is distributed using each supported platform's native install mechanism, such as DEB packages on Ubuntu or MSI bundles on Windows. These installers install and set up the environment as needed for the user to use the SDK immediately after the install. However, they also require administrative privileges on the machine. You can find the SDK to install on the [.NET downloads](#) page.

Install scripts, on the other hand, don't require administrative privileges. However, they also don't install any prerequisites on the machine; you need to install all of the prerequisites manually. The scripts are meant mostly for setting up build servers or when you wish to install the tools without admin privileges (do note the prerequisites caveat above). You can find more information in the [install script reference](#) article. If you're interested in how to set up the SDK on your CI build server, see [Use the .NET SDK in Continuous Integration \(CI\) environments](#).

By default, the SDK installs in a "side-by-side" (SxS) manner, which means multiple versions can coexist at any given time on a single machine. For information about how the version gets picked when you're running CLI commands, see [Select the .NET version to use](#).

- [Select the .NET version to use](#)

.NET environment variables

9/20/2022 • 11 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

In this article, you'll learn about the environment variables used by .NET SDK, .NET CLI, and .NET runtime. Some environment variables are used by the .NET runtime, while others are only used by the .NET SDK and .NET CLI. Some environment variables are used by all.

.NET runtime environment variables

`DOTNET_SYSTEM_NET_HTTP_*`

There are several global HTTP environment variable settings:

- `DOTNET_SYSTEM_NET_HTTP_ENABLEACTIVITYPROPAGATION`
 - Indicates whether or not to enable activity propagation of the diagnostic handler for global HTTP settings.
- `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_HTTP2SUPPORT`
 - When set to `false` or `0`, disables HTTP/2 support, which is enabled by default.
- `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_HTTP3SUPPORT`
 - When set to `true` or `1`, enables HTTP/3 support, which is disabled by default.
- `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_HTTP2FLOWCONTROL_DISABLEDYYNAMICWINDOWSIZING`
 - When set to `false` or `0`, overrides the default and disables the HTTP/2 dynamic window scaling algorithm.
- `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_FLOWCONTROL_MAXSTREAMWINDOWSIZE`
 - Defaults to 16 MB. When overridden, the maximum size of the HTTP/2 stream receive window cannot be less than 65,535.
- `DOTNET_SYSTEM_NET_HTTP_SOCKETSHTTPHANDLER_FLOWCONTROL_STREAMWINDOWSCALETHRESHOLDMULTIPLIER`
 - Defaults to 1.0. When overridden, higher values result in a shorter window but slower downloads.
Can't be less than 0.

`DOTNET_SYSTEM_GLOBALIZATION_*`

- `DOTNET_SYSTEM_GLOBALIZATION_INVARIANT` : See [set invariant mode](#).
- `DOTNET_SYSTEM_GLOBALIZATION_PREDEFINED_CULTURES_ONLY` : Specifies whether to load only predefined cultures.
- `DOTNET_SYSTEM_GLOBALIZATION_APPLOCALICU` : Indicates whether to use the app-local International Components of Unicode (ICU). For more information, see [App-local ICU](#).

Set invariant mode

Applications can enable the invariant mode in any of the following ways:

1. In the project file:

```
<PropertyGroup>
    <InvariantGlobalization>true</InvariantGlobalization>
</PropertyGroup>
```

2. In the `runtimedataconfig.json` file:

```
{  
    "runtimeOptions": {  
        "configProperties": {  
            "System.Globalization.Invariant": true  
        }  
    }  
}
```

3. By setting environment variable value `DOTNET_SYSTEM_GLOBALIZATION_INVARIANT` to `true` or `1`.

IMPORTANT

A value set in the project file or *runtimeconfig.json* has a higher priority than the environment variable.

For more information, see [.NET Globalization Invariant Mode](#).

`DOTNET_SYSTEM_GLOBALIZATION_USENLS`

This applies to Windows only. For globalization to use National Language Support (NLS), set

`DOTNET_SYSTEM_GLOBALIZATION_USENLS` to either `true` or `1`. To not use it, set `DOTNET_SYSTEM_GLOBALIZATION_USENLS` to either `false` or `0`.

`DOTNET_SYSTEM_NET_SOCKETS_*`

This section focuses on two `System.Net.Sockets` environment variables:

- `DOTNET_SYSTEM_NET_SOCKETS_INLINE_COMPLETIONS`
- `DOTNET_SYSTEM_NET_SOCKETS_THREAD_COUNT`

Socket continuations are dispatched to the `System.Threading.ThreadPool` from the event thread. This avoids continuations blocking the event handling. To allow continuations to run directly on the event thread, set

`DOTNET_SYSTEM_NET_SOCKETS_INLINE_COMPLETIONS` to `1`. It's disabled by default.

NOTE

This setting can make performance worse if there is expensive work that will end up holding onto the IO thread for longer than needed. Test to make sure this setting helps performance.

Using TechEmpower benchmarks that generate a lot of small socket reads and writes under a very high load, a single socket engine is capable of keeping busy up to thirty x64 and eight Arm64 CPU cores. The vast majority of real-life scenarios will never generate such a huge load (hundreds of thousands of requests per second), and having a single producer is almost always enough. However, to be sure that extreme loads can be handled, you can use `DOTNET_SYSTEM_NET_SOCKETS_THREAD_COUNT` to override the calculated value. When not overridden, the following value is used:

- When `DOTNET_SYSTEM_NET_SOCKETS_INLINE_COMPLETIONS` is `1`, the `Environment.ProcessorCount` value is used.
- When `DOTNET_SYSTEM_NET_SOCKETS_INLINE_COMPLETIONS` is not `1`, `RuntimelInformation.ProcessArchitecture` is evaluated:
 - When Arm or Arm64 the cores per engine value is set to `8`, otherwise `30`.
- Using the determined cores per engine, the maximum value of either `1` or `Environment.ProcessorCount` over the cores per engine.

`DOTNET_SYSTEM_NET_DISABLEIPV6`

Helps determine whether or not Internet Protocol version 6 (IPv6) is disabled. When set to either `true` or `1`, IPv6 is disabled unless otherwise specified in the `System.AppContext`.

`DOTNET_SYSTEM_NET_HTTP_USESOCKETSHTTPHANDLER`

You can use one of the following mechanisms to configure a process to use the older `HttpClientHandler`:

From code, use the `ApplicationContext` class:

```
ApplicationContext.SetSwitch("System.Net.Http.UseSocketsHttpHandler", false);
```

The `ApplicationContext` switch can also be set by a config file. For more information configuring switches, see [ApplicationContext for library consumers](#).

The same can be achieved via the environment variable `DOTNET_SYSTEM_NET_HTTP_USESOCKETSHTTPHANDLER`. To opt-out, set the value to either `false` or `0`.

NOTE

Starting in .NET 5, this setting to use `HttpClientHandler` is no longer available.

`DOTNET_Jit*` and `DOTNET_GC*`

There are two stressing-related features for the JIT and JIT-generated GC information: JIT Stress and GC Hole Stress. These features provide a way during development to discover edge cases and more "real world" scenarios without having to develop complex applications. The following environment variables are available:

- `DOTNET_JitStress`
- `DOTNET_JitStressModeNamesOnly`
- `DOTNET_GCStress`

JIT stress

Enabling JIT Stress can be done in several ways. Set `DOTNET_JitStress` to a non-zero integer value to generate varying levels of JIT optimizations based on a hash of the method's name. To apply all optimizations set `DOTNET_JitStress=2`, for example. Another way to enable JIT Stress is by setting `DOTNET_JitStressModeNamesOnly=1` and then requesting the stress modes, space-delimited, in the `DOTNET_JitStressModeNames` variable.

As an example, consider:

```
DOTNET_JitStressModeNames=STRESS_USE_CMOV STRESS_64RSLT_MUL STRESS_LCL_FLDS
```

GC Hole stress

Enabling GC Hole Stress causes GCs to always occur in specific locations and that helps to track down GC holes. GC Hole Stress can be enabled using the `DOTNET_GCStress` environment variable.

For more information, see [Investigating JIT and GC Hole stress](#).

JIT memory barriers

The code generator for Arm64 allows all `MemoryBarriers` instructions to be removed by setting `DOTNET_JitNoMemoryBarriers` to `1`.

`DOTNET_RUNNING_IN_CONTAINER` and `DOTNET_RUNNING_IN_CONTAINERS`

The official .NET images (Windows and Linux) set the well-known environment variables:

- `DOTNET_RUNNING_IN_CONTAINER`
- `DOTNET_RUNNING_IN_CONTAINERS`

These values are used to determine when your ASP.NET Core workloads are running in the context of a

container.

`DOTNET_SYSTEM_CONSOLE_ALLOW_ANSI_COLOR_REDIRECTION`

When `Console.IsOutputRedirected` is `true`, you can emit ANSI color code by setting

`DOTNET_SYSTEM_CONSOLE_ALLOW_ANSI_COLOR_REDIRECTION` to either `1` or `true`.

`DOTNET_SYSTEM_DIAGNOSTICS` and related variables

- `DOTNET_SYSTEM_DIAGNOSTICS_DEFAULTACTIVITYIDFORMATISHIERARCHIAL`: When `1` or `true`, the default *Activity Id* format is hierarchical.
- `DOTNET_SYSTEM_RUNTIME_CACHING_TRACING`: When running as Debug, tracing can be enabled when this is `true`.

`DOTNET_DiagnosticPorts`

Configures alternate endpoints where diagnostic tools can communicate with the .NET runtime. See the [Diagnostic Port documentation](#) for more information.

`DOTNET_DefaultDiagnosticPortSuspend`

Configures the runtime to pause during startup and wait for the *Diagnostics IPC ResumeStartup* command from the specified diagnostic port when set to 1. Defaults to 0. See the [Diagnostic Port documentation](#) for more information.

`DOTNET_EnableDiagnostics`

When set to `1`, enables debugging, profiling, and other diagnostics via the [Diagnostic Port](#). Defaults to 1.

EventPipe variables

See [EventPipe environment variables](#) for more information.

- `DOTNET_EnableEventPipe`: When set to `1`, enables tracing via EventPipe.
- `DOTNET_EventPipeOutputPath`: The output path where the trace will be written.
- `DOTNET_EventPipeOutputStreaming`: When set to `1`, enables streaming to the output file while the app is running. By default trace information is accumulated in a circular buffer and the contents are written at app shutdown.

.NET SDK and CLI environment variables

`DOTNET_ROOT`, `DOTNET_ROOT(x86)`

Specifies the location of the .NET runtimes, if they are not installed in the default location. The default location on Windows is `C:\Program Files\dotnet`. The default location on Linux and macOS is `/usr/local/share/dotnet`. This environment variable is used only when running apps via generated executables (apphosts). `DOTNET_ROOT(x86)` is used instead when running a 32-bit executable on a 64-bit OS.

`NUGET_PACKAGES`

The global packages folder. If not set, it defaults to `~/.nuget/packages` on Unix or `%userprofile%\.nuget\packages` on Windows.

`DOTNET_SERVICING`

Specifies the location of the servicing index to use by the shared host when loading the runtime.

`DOTNET_NOLOGO`

Specifies whether .NET welcome and telemetry messages are displayed on the first run. Set to `true` to mute these messages (values `true`, `1`, or `yes` accepted) or set to `false` to allow them (values `false`, `0`, or `no` accepted). If not set, the default is `false` and the messages will be displayed on the first run. This flag does not affect telemetry (see `DOTNET_CLI_TELEMETRY_OPTOUT` for opting out of sending telemetry).

`DOTNET_CLI_PERF_LOG`

Specifies whether performance details about the current CLI session are logged. Enabled when set to `1`, `true`, or `yes`. This is disabled by default.

`DOTNET_GENERATE_APNET_CERTIFICATE`

Specifies whether to generate an ASP.NET Core certificate. The default value is `true`, but this can be overridden by setting this environment variable to either `0`, `false`, or `no`.

`DOTNET_ADD_GLOBAL_TOOLS_TO_PATH`

Specifies whether to add global tools to the `PATH` environment variable. The default is `true`. To not add global tools to the path, set to `0`, `false`, or `no`.

`DOTNET_CLI_TELEMETRY_OPTOUT`

Specifies whether data about the .NET tools usage is collected and sent to Microsoft. Set to `true` to opt-out of the telemetry feature (values `true`, `1`, or `yes` accepted). Otherwise, set to `false` to opt into the telemetry features (values `false`, `0`, or `no` accepted). If not set, the default is `false` and the telemetry feature is active.

`DOTNET_SKIP_FIRST_TIME_EXPERIENCE`

If `DOTNET_SKIP_FIRST_TIME_EXPERIENCE` is set to `true`, the `NuGetFallbackFolder` won't be expanded to disk and a shorter welcome message and telemetry notice will be shown.

`DOTNET_MULTILEVEL_LOOKUP`

Specifies whether the .NET runtime, shared framework, or SDK are resolved from the global location. If not set, it defaults to 1 (logical `true`). Set the value to 0 (logical `false`) to not resolve from the global location and have isolated .NET installations. For more information about multi-level lookup, see [Multi-level SharedFX Lookup](#).

NOTE

This environment variable only applies to applications that target .NET 6 and earlier versions. Starting in .NET 7, .NET only looks for frameworks in one location. For more information, see [Multi-level lookup is disabled](#).

`DOTNET_ROLL_FORWARD`

Determines roll forward behavior. For more information, see the `--roll-forward` option for the `dotnet` command.

`DOTNET_ROLL_FORWARD_TO_PRERELEASE`

If set to `1` (enabled), enables rolling forward to a pre-release version from a release version. By default (`0` - disabled), when a release version of .NET runtime is requested, roll-forward will only consider installed release versions.

For more information, see the `--roll-forward` option for the `dotnet` command

`DOTNET_ROLL_FORWARD_ON_NO_CANDIDATE_FX`

Disables minor version roll forward, if set to `0`. This setting is superseded in .NET Core 3.0 by `DOTNET_ROLL_FORWARD`. The new settings should be used instead.

`DOTNET_CLI_UI_LANGUAGE`

Sets the language of the CLI UI using a locale value such as `en-us`. The supported values are the same as for Visual Studio. For more information, see the section on changing the installer language in the [Visual Studio installation documentation](#). The .NET resource manager rules apply, so you don't have to pick an exact match—you can also pick descendants in the `CultureInfo` tree. For example, if you set it to `fr-CA`, the CLI will find and use the `fr` translations. If you set it to a language that is not supported, the CLI falls back to English.

`DOTNET_DISABLE_GUI_ERRORS`

For GUI-enabled generated executables - disables dialog popup, which normally shows for certain classes of errors. It only writes to `stderr` and exits in those cases.

`DOTNET_ADDITIONAL_DEPS`

Equivalent to CLI option `--additional-deps`.

`DOTNET_RUNTIME_ID`

Overrides the detected RID.

`DOTNET_SHARED_STORE`

Location of the "shared store" which assembly resolution falls back to in some cases.

`DOTNET_STARTUP_HOOKS`

List of assemblies to load and execute startup hooks from.

`DOTNET_BUNDLE_EXTRACT_BASE_DIR`

Specifies a directory to which a single-file application is extracted before it is executed.

For more information, see [Single-file executables](#).

`DOTNET_CLI_CONTEXT_*`

- `DOTNET_CLI_CONTEXT_VERBOSE` : To enable a verbose context, set to `true`.
- `DOTNET_CLI_CONTEXT_ANSI_PASS_THRU` : To enable an ANSI pass-through, set to `true`.

`DOTNET_CLI_WORKLOAD_UPDATE_NOTIFY_DISABLE`

Disables background download of advertising manifests for workloads. Default is `false` - not disabled. If set to `true`, downloading is disabled. For more information, see [Advertising manifests](#).

`DOTNET_CLI_WORKLOAD_UPDATE_NOTIFY_INTERVAL_HOURS`

Specifies the minimum number of hours between background downloads of advertising manifests for workloads. Default is `24` - no more frequently than once a day. For more information, see [Advertising manifests](#).

`COREHOST_TRACE`

Controls diagnostics tracing from the hosting components, such as `dotnet.exe`, `hostfxr`, and `hostpolicy`.

- `COREHOST_TRACE=[0/1]` - default is `0` - tracing disabled. If set to `1`, diagnostics tracing is enabled.
- `COREHOST_TRACEFILE=<file path>` - has an effect only if tracing is enabled by setting `COREHOST_TRACE=1`. When set, the tracing information is written to the specified file; otherwise, the trace information is written to `stderr`.
- `COREHOST_TRACE_VERBOSITY=[1/2/3/4]` - default is `4`. The setting is used only when tracing is enabled via `COREHOST_TRACE=1`.
 - `4` - all tracing information is written
 - `3` - only informational, warning, and error messages are written
 - `2` - only warning and error messages are written
 - `1` - only error messages are written

The typical way to get detailed trace information about application startup is to set `COREHOST_TRACE=1` and `COREHOST_TRACEFILE=host_trace.txt` and then run the application. A new file `host_trace.txt` will be created in the current directory with the detailed information.

SuppressNETCoreSdkPreviewMessage

If set to `true`, invoking `dotnet` won't produce a warning when a preview SDK is being used.

Configure MSBuild in the .NET CLI

To execute MSBuild out-of-process, set the `DOTNET_CLI_RUN_MSBUILD_OUTOFPROC` environment variable to either `1`, `true`, or `yes`. By default, MSBuild will execute in-proc. To force MSBuild to use an external working node long-living process for building projects, set `DOTNET_CLI_USE_MSBUILDNOINPROCNODE` to `1`, `true`, or `yes`. This will set the `MSBUILDNOINPROCNODE` environment variable to `1`, which is referred to as *MSBuild Server V1*, as the entry process forwards most of the work to it.

DOTNET_MSBUILD_SDK_RESOLVER_*

These are overrides that are used to force the resolved SDK tasks and targets to come from a given base directory and report a given version to MSBuild, which may be `null` if unknown. One key use case for this is to test SDK tasks and targets without deploying them by using the .NET Core SDK.

- `DOTNET_MSBUILD_SDK_RESOLVER_SDKS_DIR` : Overrides the .NET SDK directory.
- `DOTNET_MSBUILD_SDK_RESOLVER_SDKS_VER` : Overrides the .NET SDK version.
- `DOTNET_MSBUILD_SDK_RESOLVER_CLI_DIR` : Overrides the `dotnet.exe` directory path.

DOTNET_NEW_PREFERRED_LANG

Configures the default programming language for the `dotnet new` command when the `-lang|--language` switch is omitted. The default value is `c#`. Valid values are `c#`, `F#`, or `vb`. For more information, see [dotnet new](#).

dotnet watch environment variables

For information about `dotnet watch` settings that are available as environment variables, see [dotnet watch environment variables](#).

dotnet-install scripts reference

9/20/2022 • 7 minutes to read • [Edit Online](#)

Name

`dotnet-install.ps1` | `dotnet-install.sh` - Script used to install the .NET SDK and the shared runtime.

Synopsis

Windows:

```
dotnet-install.ps1 [-Architecture <ARCHITECTURE>] [-AzureFeed]
  [-Channel <CHANNEL>] [-DryRun] [-FeedCredential]
  [-InstallDir <DIRECTORY>] [-JsonFile <JSONFILE>]
  [-NoCdn] [-NoPath] [-ProxyAddress] [-ProxyBypassList <LIST_OF_URLS>]
  [-ProxyUseDefaultCredentials] [-Quality <QUALITY>] [-Runtime <RUNTIME>]
  [-SkipNonVersionedFiles] [-UncachedFeed] [-Verbose]
  [-Version <VERSION>]

Get-Help ./dotnet-install.ps1
```

Linux/macOS:

```
dotnet-install.sh [--architecture <ARCHITECTURE>] [--azure-feed]
  [--channel <CHANNEL>] [--dry-run] [--feed-credential]
  [--install-dir <DIRECTORY>] [--jsonfile <JSONFILE>]
  [--no-cdn] [--no-path] [--quality <QUALITY>]
  [--runtime <RUNTIME>] [--runtime-id <RID>]
  [--skip-non-versioned-files] [--uncached-feed] [--verbose]
  [--version <VERSION>]

dotnet-install.sh --help
```

The bash script also reads PowerShell switches, so you can use PowerShell switches with the script on Linux/macOS systems.

Description

The `dotnet-install` scripts perform a non-admin installation of the .NET SDK, which includes the .NET CLI and the shared runtime. There are two scripts:

- A PowerShell script that works on Windows.
- A bash script that works on Linux/macOS.

NOTE

.NET collects telemetry data. To learn more and how to opt out, see [.NET SDK telemetry](#).

Purpose

The intended use of the scripts is for Continuous Integration (CI) scenarios, where:

- The SDK needs to be installed without user interaction and without admin rights.

- The SDK installation doesn't need to persist across multiple CI runs.

The typical sequence of events:

- CI is triggered.
- CI installs the SDK using one of these scripts.
- CI finishes its work and clears temporary data including the SDK installation.

To set up a development environment or to run apps, use the installers rather than these scripts.

Recommended version

We recommend that you use the stable version of the scripts:

- Bash (Linux/macOS): <https://dot.net/v1/dotnet-install.sh>
- PowerShell (Windows): <https://dot.net/v1/dotnet-install.ps1>

Script behavior

Both scripts have the same behavior. They download the ZIP/tarball file from the CLI build drops and proceed to install it in either the default location or in a location specified by `-InstallDir|--install-dir`.

By default, the installation scripts download the SDK and install it. If you wish to only obtain the shared runtime, specify the `-Runtime|--runtime` argument.

By default, the script adds the install location to the \$PATH for the current session. Override this default behavior by specifying the `-NoPath|--no-path` argument. The script doesn't set the `DOTNET_ROOT` environment variable.

Before running the script, install the required [dependencies](#).

You can install a specific version using the `-Version|--version` argument. The version must be specified as a three-part version number, such as `2.1.0`. If the version isn't specified, the script installs the `latest` version.

The install scripts do not update the registry on Windows. They just download the zipped binaries and copy them to a folder. If you want registry key values to be updated, use the .NET installers.

Options

- `-Architecture|--architecture <ARCHITECTURE>`

Architecture of the .NET binaries to install. Possible values are `<auto>`, `amd64`, `x64`, `x86`, `arm64`, `arm`, and `s390x`. The default value is `<auto>`, which represents the currently running OS architecture.

- `-AzureFeed|--azure-feed`

For internal use only. Allows using a different storage to download SDK archives from. This parameter is only used if `--no-cdn` is false. The default is <https://dotnetcli.azureedge.net/dotnet>.

- `-Channel|--channel <CHANNEL>`

Specifies the source channel for the installation. The possible values are:

- `Current` - Most current release.
- `LTS` - Long-Term Support channel (most current supported release).
- Two-part version in A.B format, representing a specific release (for example, `3.1` or `6.0`).
- Three-part version in A.B.Cxx format, representing a specific SDK release (for example, `6.0.1xx` or `6.0.2xx`). Available since the 5.0 release.

The `version` parameter overrides the `channel` parameter when any version other than `latest` is used.

The default value is `LTS`. For more information on .NET support channels, see the [.NET Support Policy](#)

page.

- `-DryRun|--dry-run`

If set, the script won't perform the installation. Instead, it displays what command line to use to consistently install the currently requested version of the .NET CLI. For example, if you specify version `latest`, it displays a link with the specific version so that this command can be used deterministically in a build script. It also displays the binary's location if you prefer to install or download it yourself.

- `-FeedCredential|--feed-credential`

Used as a query string to append to the Azure feed. It allows changing the URL to use non-public blob storage accounts.

- `--help`

Prints out help for the script. Applies only to bash script. For PowerShell, use

```
Get-Help ./dotnet-install.ps1 .
```

- `-InstallDir|--install-dir <DIRECTORY>`

Specifies the installation path. The directory is created if it doesn't exist. The default value is `%LocalAppData%\Microsoft\dotnet` on Windows and `$HOME/.dotnet` on Linux/macOS. Binaries are placed directly in this directory.

- `-JsonFile|--jsonfile <JSONFILE>`

Specifies a path to a [global.json](#) file that will be used to determine the SDK version. The *global.json* file must have a value for `sdk:version`.

- `-NoCdn|--no-cdn`

Disables downloading from the [Azure Content Delivery Network \(CDN\)](#) and uses the uncached feed directly.

- `-NoPath|--no-path`

If set, the installation folder isn't exported to the path for the current session. By default, the script modifies the PATH, which makes the .NET CLI available immediately after install.

- `-ProxyAddress`

If set, the installer uses the proxy when making web requests. (Only valid for Windows.)

- `-ProxyBypassList <LIST_OF_URLS>`

If set with `ProxyAddress`, provides a list of comma-separated urls that will bypass the proxy. (Only valid for Windows.)

- `ProxyUseDefaultCredentials`

If set, the installer uses the credentials of the current user when using proxy address. (Only valid for Windows.)

- `-Quality|--quality <QUALITY>`

Downloads the latest build of the specified quality in the channel. The possible values are: `daily`, `signed`, `validated`, `preview`, `GA`. Works only in combination with `channel`. Not applicable for current and LTS channels and will be ignored if one of those channels is used.

For an SDK installation, use `channel` in `A.B` or `A.B.Cxx` format. For a runtime installation, use `channel`

in `A.B` format.

Don't use both `version` and `quality` parameters. When `quality` is specified, the script determines the proper version on its own.

Available since the 5.0 release.

- `-Runtime|--runtime <RUNTIME>`

Installs just the shared runtime, not the entire SDK. The possible values are:

- `dotnet` - the `Microsoft.NETCore.App` shared runtime.
- `aspnetcore` - the `Microsoft.AspNetCore.App` shared runtime.
- `windowsdesktop` - the `Microsoft.WindowsDesktop.App` shared runtime.

- `--os <OPERATING_SYSTEM>`

Specifies the operating system for which the tools are being installed. Possible values are: `osx`, `linux`, `linux-musl`, `freebsd`.

The parameter is optional and should only be used when it's required to override the operating system that is detected by the script.

- `-SharedRuntime|--shared-runtime`

NOTE

This parameter is obsolete and may be removed in a future version of the script. The recommended alternative is the `-Runtime|--runtime` option.

Installs just the shared runtime bits, not the entire SDK. This option is equivalent to specifying

`-Runtime|--runtime dotnet`.

- `-SkipNonVersionedFiles|--skip-non-versioned-files`

Skips installing non-versioned files, such as `dotnet.exe`, if they already exist.

- `-UncachedFeed|--uncached-feed`

For internal use only. Allows using a different storage to download SDK archives from. This parameter is only used if `--no-cdn` is true.

- `-Verbose|--verbose`

Displays diagnostics information.

- `-Version|--version <VERSION>`

Represents a specific build version. The possible values are:

- `Latest` - Latest build on the channel (used with the `-Channel` option).
- Three-part version in X.Y.Z format representing a specific build version; supersedes the `-channel` option. For example: `2.0.0-preview2-006120`.

If not specified, `-Version` defaults to `latest`.

Examples

- Install the latest long-term supported (LTS) version to the default location:

Windows:

```
./dotnet-install.ps1 -Channel LTS
```

macOS/Linux:

```
./dotnet-install.sh --channel LTS
```

- Install the latest preview version of the 6.0.1xx SDK to the specified location:

Windows:

```
./dotnet-install.ps1 -Channel 6.0.1xx -Quality preview -InstallDir C:\cli
```

macOS/Linux:

```
./dotnet-install.sh --channel 6.0.1xx --quality preview --install-dir ~/cli
```

- Install the 6.0.0 version of the shared runtime:

Windows:

```
./dotnet-install.ps1 -Runtime dotnet -Version 6.0.0
```

macOS/Linux:

```
./dotnet-install.sh --runtime dotnet --version 6.0.0
```

- Obtain script and install the 6.0.2 version behind a corporate proxy (Windows only):

```
Invoke-WebRequest 'https://dot.net/v1/dotnet-install.ps1' -Proxy $env:HTTP_PROXY -  
ProxyUseDefaultCredentials -OutFile 'dotnet-install.ps1';  
./dotnet-install.ps1 -InstallDir '~/.dotnet' -Version '6.0.2' -Runtime 'dotnet' -ProxyAddress  
$env:HTTP_PROXY -ProxyUseDefaultCredentials;
```

- Obtain script and install .NET CLI one-liner examples:

Windows:

```
# Run a separate PowerShell process because the script calls exit, so it will end the current  
PowerShell session.  
&powershell -NoProfile -ExecutionPolicy unrestricted -Command "  
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12; &  
([scriptblock]::Create((Invoke-WebRequest -UseBasicParsing 'https://dot.net/v1/dotnet-install.ps1')))  
<additional install-script args>"
```

macOS/Linux:

```
curl -sSL https://dot.net/v1/dotnet-install.sh | bash /dev/stdin <additional install-script args>
```

Set environment variables

Manually installing .NET doesn't add the environment variables system-wide, and generally only works for the session in which .NET was installed. There are two environment variables you should set for your operating system:

- **DOTNET_ROOT**

This variable is set to the folder .NET was installed to, such as `$HOME/.dotnet` for Linux and macOS, and `$HOME\.dotnet` in PowerShell for Windows.

- **PATH**

This variable should include both the `DOTNET_ROOT` folder and the user's `.dotnet/tools` folder. Generally this is `$HOME/.dotnet/tools` on Linux and macOS, and `$HOME\.dotnet\tools` in PowerShell on Windows.

TIP

For Linux and macOS, use the `echo` command to set the variables in your shell profile, such as `.bashrc`.

```
echo 'export DOTNET_ROOT=$HOME/.dotnet' >> ~/.bashrc
echo 'export PATH=$PATH:$DOTNET_ROOT:$DOTNET_ROOT/tools' >> ~/.bashrc
```

global.json overview

9/20/2022 • 8 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

The *global.json* file allows you to define which .NET SDK version is used when you run .NET CLI commands. Selecting the .NET SDK version is independent from specifying the runtime version a project targets. The .NET SDK version indicates which version of the .NET CLI is used. This article explains how to select the SDK version by using *global.json*.

If you always want to use the latest SDK version that is installed on your machine, no *global.json* file is needed. In CI (continuous integration) scenarios, however, you typically want to specify an acceptable range for the SDK version that is used. The *global.json* file has a `rollForward` feature that provides flexible ways to specify an acceptable range of versions. For example, the following *global.json* file selects 6.0.300 or any later [feature band](#) or [patch](#) for 6.0 that is installed on the machine:

```
{  
  "sdk": {  
    "version": "6.0.300",  
    "rollForward": "latestFeature"  
  }  
}
```

The .NET SDK looks for a *global.json* file in the current working directory (which isn't necessarily the same as the project directory) or one of its parent directories.

For information about specifying the runtime version instead of the SDK version, see [Target frameworks](#).

global.json schema

sdk

Type: `object`

Specifies information about the .NET SDK to select.

version

- Type: `string`

The version of the .NET SDK to use.

This field:

- Doesn't have wildcard support; that is, you must specify the full version number.
- Doesn't support version ranges.

allowPrerelease

- Type: `boolean`
- Available since: .NET Core 3.0 SDK.

Indicates whether the SDK resolver should consider prerelease versions when selecting the SDK version to use.

If you don't set this value explicitly, the default value depends on whether you're running from Visual Studio:

- If you're **not** in Visual Studio, the default value is `true`.

- If you are in Visual Studio, it uses the prerelease status requested. That is, if you're using a Preview version of Visual Studio or you set the **Use previews of the .NET SDK** option (under Tools > Options > Environment > Preview Features), the default value is `true`. Otherwise, the default value is `false`.

`rollForward`

- Type: `string`
- Available since: .NET Core 3.0 SDK.

The roll-forward policy to use when selecting an SDK version, either as a fallback when a specific SDK version is missing or as a directive to use a higher version. A [version](#) must be specified with a `rollForward` value, unless you're setting it to `latestMajor`. The default roll forward behavior is determined by the [matching rules](#).

To understand the available policies and their behavior, consider the following definitions for an SDK version in the format `x.y.znn`:

- `x` is the major version.
- `y` is the minor version.
- `z` is the feature band.
- `nn` is the patch version.

The following table shows the possible values for the `rollForward` key:

VALUE	BEHAVIOR
<code>patch</code>	Uses the specified version. If not found, rolls forward to the latest patch level. If not found, fails.
<code>feature</code>	This value is the legacy behavior from the earlier versions of the SDK. Uses the latest patch level for the specified major, minor, and feature band. If not found, rolls forward to the next higher feature band within the same major/minor and uses the latest patch level for that feature band. If not found, fails.
<code>minor</code>	Uses the latest patch level for the specified major, minor, and feature band. If not found, rolls forward to the next higher feature band within the same major/minor version and uses the latest patch level for that feature band. If not found, rolls forward to the next higher minor and feature band within the same major and uses the latest patch level for that feature band. If not found, fails.

VALUE	BEHAVIOR
major	Uses the latest patch level for the specified major, minor, and feature band. If not found, rolls forward to the next higher feature band within the same major/minor version and uses the latest patch level for that feature band. If not found, rolls forward to the next higher minor and feature band within the same major and uses the latest patch level for that feature band. If not found, rolls forward to the next higher major, minor, and feature band and uses the latest patch level for that feature band. If not found, fails.
latestPatch	Uses the latest installed patch level that matches the requested major, minor, and feature band with a patch level and that is greater or equal than the specified value. If not found, fails.
latestFeature	Uses the highest installed feature band and patch level that matches the requested major and minor with a feature band and patch level that is greater or equal than the specified value. If not found, fails.
latestMinor	Uses the highest installed minor, feature band, and patch level that matches the requested major with a minor, feature band, and patch level that is greater or equal than the specified value. If not found, fails.
latestMajor	Uses the highest installed .NET SDK with a version that is greater or equal than the specified value. If not found, fail.
disable	Doesn't roll forward. Exact match required.

msbuild-sdks

Type: `object`

Lets you control the project SDK version in one place rather than in each individual project. For more information, see [How project SDKs are resolved](#).

Examples

The following example shows how to not use prerelease versions:

```
{
  "sdk": {
    "allowPrerelease": false
  }
}
```

The following example shows how to use the highest version installed that's greater or equal than the specified version. The JSON shown disallows any SDK version earlier than 2.2.200 and allows 2.2.200 or any later version, including 3.0.xxx and 3.1.xxx.

```
{  
  "sdk": {  
    "version": "2.2.200",  
    "rollForward": "latestMajor"  
  }  
}
```

The following example shows how to use the exact specified version:

```
{  
  "sdk": {  
    "version": "3.1.100",  
    "rollForward": "disable"  
  }  
}
```

The following example shows how to use the latest feature band and patch version installed of a specific major and minor version. The JSON shown disallows any SDK version earlier than 3.1.102 and allows 3.1.102 or any later 3.1.xxx version, such as 3.1.103 or 3.1.200.

```
{  
  "sdk": {  
    "version": "3.1.102",  
    "rollForward": "latestFeature"  
  }  
}
```

The following example shows how to use the highest patch version installed of a specific version. The JSON shown disallows any SDK version earlier than 3.1.102 and allows 3.1.102 or any later 3.1.1xx version, such as 3.1.103 or 3.1.199.

```
{  
  "sdk": {  
    "version": "3.1.102",  
    "rollForward": "latestPatch"  
  }  
}
```

global.json and the .NET CLI

To set an SDK version in the *global.json* file, it's helpful to know which SDK versions are installed on your machine. For information on how to do that, see [How to check that .NET is already installed](#).

To install additional .NET SDK versions on your machine, visit the [Download .NET](#) page.

You can create a new *global.json* file in the current directory by executing the `dotnet new` command, similar to the following example:

```
dotnet new globaljson --sdk-version 6.0.100
```

Matching rules

NOTE

The matching rules are governed by the `dotnet.exe` entry point, which is common across all installed .NET installed runtimes. The matching rules for the latest installed version of the .NET Runtime are used when you have multiple runtimes installed side-by-side or if you're using a `global.json` file.

The following rules apply when determining which version of the SDK to use:

- If no `global.json` file is found, or `global.json` doesn't specify an SDK version nor an `allowPrerelease` value, the highest installed SDK version is used (equivalent to setting `rollForward` to `latestMajor`). Whether prerelease SDK versions are considered depends on how `dotnet` is being invoked.
 - If you're **not** in Visual Studio, prerelease versions are considered.
 - If you are in Visual Studio, it uses the prerelease status requested. That is, if you're using a Preview version of Visual Studio or you set the **Use previews of the .NET SDK** option (under **Tools > Options > Environment > Preview Features**), prerelease versions are considered; otherwise, only release versions are considered.
- If a `global.json` file is found that doesn't specify an SDK version but it specifies an `allowPrerelease` value, the highest installed SDK version is used (equivalent to setting `rollForward` to `latestMajor`). Whether the latest SDK version can be release or prerelease depends on the value of `allowPrerelease`. `true` indicates prerelease versions are considered; `false` indicates that only release versions are considered.
- If a `global.json` file is found and it specifies an SDK version:
 - If no `rollForward` value is set, it uses `latestPatch` as the default `rollForward` policy. Otherwise, check each value and their behavior in the `rollForward` section.
 - Whether prerelease versions are considered and what's the default behavior when `allowPrerelease` isn't set is described in the `allowPrerelease` section.

Troubleshoot build warnings

- The following warnings indicate that your project was compiled using a prerelease version of the .NET SDK:

You are working with a preview version of the .NET Core SDK. You can define the SDK version via a `global.json` file in the current project. More at <https://go.microsoft.com/fwlink/?linkid=869452>.

You are using a preview version of .NET. See: <https://aka.ms/dotnet-core-preview>

.NET SDK versions have a history and commitment of being high quality. However, if you don't want to use a prerelease version, check the different strategies you can use in the `allowPrerelease` section. For machines that have never had a .NET Core 3.0 or higher runtime or SDK installed, you need to create a `global.json` file and specify the exact version you want to use.

- The following warning indicates that your project targets EF Core 1.0 or 1.1, which isn't compatible with .NET Core 2.1 SDK and later versions:

Startup project '{startupProject}' targets framework '.NETCoreApp' version '{targetFrameworkVersion}'. This version of the Entity Framework Core .NET Command-line Tools only supports version 2.0 or higher. For information on using older versions of the tools, see <https://go.microsoft.com/fwlink/?linkid=871254>.

Starting with .NET Core 2.1 SDK (version 2.1.300), the `dotnet ef` command comes included in the SDK.

To compile your project, install .NET Core 2.0 SDK (version 2.1.201) or earlier on your machine and define the desired SDK version using the *global.json* file. For more information about the `dotnet ef` command, see [EF Core .NET Command-line Tools](#).

.NET SDK and .NET CLI telemetry

9/20/2022 • 7 minutes to read • [Edit Online](#)

The [.NET SDK](#) includes a telemetry feature that collects usage data and sends it to Microsoft when you use [.NET CLI](#) commands. The usage data includes exception information when the .NET CLI crashes. The .NET CLI comes with the .NET SDK and is the set of verbs that enable you to build, test, and publish your .NET apps. Telemetry data helps the .NET team understand how the tools are used so they can be improved. Information on failures helps the team resolve problems and fix bugs.

The collected data is published in aggregate under the [Creative Commons Attribution License](#). Some of the collected data is published at [.NET CLI Telemetry Data](#).

Scope

`dotnet` has two functions: to run apps and to execute CLI commands. Telemetry *isn't collected* when using `dotnet` to start an application in the following format:

- `dotnet [path-to-app].dll`

Telemetry *is collected* when using any of the [.NET CLI commands](#), such as:

- `dotnet build`
- `dotnet pack`
- `dotnet run`

How to opt out

The .NET SDK telemetry feature is enabled by default. To opt out of the telemetry feature, set the `DOTNET_CLI_TELEMETRY_OPTOUT` environment variable to `1` or `true`.

A single telemetry entry is also sent by the .NET SDK installer when a successful installation happens. To opt out, set the `DOTNET_CLI_TELEMETRY_OPTOUT` environment variable before you install the .NET SDK.

IMPORTANT

To opt out after you started the installer: close the installer, set the environment variable, and then run the installer again with that value set.

Disclosure

The .NET SDK displays text similar to the following when you first run one of the [.NET CLI commands](#) (for example, `dotnet build`). Text may vary slightly depending on the version of the SDK you're running. This "first run" experience is how Microsoft notifies you about data collection.

```
Telemetry
-----
The .NET tools collect usage data in order to help us improve your experience. The data is collected by
Microsoft and shared with the community. You can opt-out of telemetry by setting the
DOTNET_CLI_TELEMETRY_OPTOUT environment variable to '1' or 'true' using your favorite shell.

Read more about .NET CLI Tools telemetry: https://aka.ms/dotnet-cli-telemetry
```

To disable this message and the .NET welcome message, set the `DOTNET_NOLOGO` environment variable to `true`. Note that this variable has no effect on telemetry opt out.

Data points

The telemetry feature doesn't collect personal data, such as usernames or email addresses. It doesn't scan your code and doesn't extract project-level data, such as name, repository, or author. The data is sent securely to Microsoft servers using [Azure Monitor](#) technology, held under restricted access, and published under strict security controls from secure [Azure Storage](#) systems.

Protecting your privacy is important to us. If you suspect the telemetry is collecting sensitive data or the data is being insecurely or inappropriately handled, file an issue in the [dotnet/sdk](#) repository or send an email to dotnet@microsoft.com for investigation.

The telemetry feature collects the following data:

SDK VERSIONS	DATA
All	Timestamp of invocation.
All	Command invoked (for example, "build"), hashed starting in 2.1.
All	Three octet IP address used to determine the geographical location.
All	Operating system and version.
All	Runtime ID (RID) the SDK is running on.
All	.NET SDK version.
All	Telemetry profile: an optional value only used with explicit user opt-in and used internally at Microsoft.
>=2.0	Command arguments and options: several arguments and options are collected (not arbitrary strings). See collected options . Hashed after 2.1.300.
>=2.0	Whether the SDK is running in a container.
>=2.0	Target frameworks (from the <code>TargetFramework</code> event), hashed starting in 2.1.
>=2.0	Hashed Media Access Control (MAC) address (SHA256).
>=2.0	Hashed current working directory.
>=2.0	Install success report, with hashed installer exe filename.
>=2.1.300	Kernel version.
>=2.1.300	Libc release/version.

SDK VERSIONS	DATA
>=3.0.100	Whether the output was redirected (true or false).
>=3.0.100	On a CLI/SDK crash, the exception type and its stack trace (only CLI/SDK code is included in the stack trace sent). For more information, see Crash exception telemetry .
>=5.0.100	Hashed TargetFrameworkVersion used for build (MSBuild property)
>=5.0.100	Hashed RuntimeIdentifier used for build (MSBuild property)
>=5.0.100	Hashed SelfContained used for build (MSBuild property)
>=5.0.100	Hashed UseApphost used for build (MSBuild property)
>=5.0.100	Hashed OutputType used for build (MSBuild property)
>=5.0.201	Hashed PublishReadyToRun used for build (MSBuild property)
>=5.0.201	Hashed PublishTrimmed used for build (MSBuild property)
>=5.0.201	Hashed PublishSingleFile used for build (MSBuild property)
>=5.0.202	Elapsed time from process start until entering the CLI program's main method, measuring host and runtime startup.
>=5.0.202	Elapsed time for the step that adds .NET Tools to the path on first run.
>=5.0.202	Elapsed time to display first time use notice on first run.
>=5.0.202	Elapsed time for generating ASP.NET Certificate on first run.
>=5.0.202	Elapsed time to parse the CLI input.
>=6.0.100	OS architecture
>=6.0.104	Hashed PublishReadyToRunUseCrossgen2 used for build (MSBuild property)
>=6.0.104	Hashed Crossgen2PackVersion used for build (MSBuild property)
>=6.0.104	Hashed CompileListCount used for build (MSBuild property)
>=6.0.104	Hashed _ReadyToRunCompilationFailures used for build (MSBuild property)

SDK VERSIONS	DATA
>=6.0.300	If the CLI was invoked from a Continuous Integration environment. For more information, see Continuous Integration Detection .
>=7.0.100	Hashed PublishAot used for build (MSBuild property)
>=7.0.100	Hashed PublishProtocol used for build (MSBuild property)

Collected options

Certain commands send additional data. A subset of commands sends the first argument:

COMMAND	FIRST ARGUMENT DATA SENT
<code>dotnet help <arg></code>	The command help is being queried for.
<code>dotnet new <arg></code>	The template name (hashed).
<code>dotnet add <arg></code>	The word <code>package</code> or <code>reference</code> .
<code>dotnet remove <arg></code>	The word <code>package</code> or <code>reference</code> .
<code>dotnet list <arg></code>	The word <code>package</code> or <code>reference</code> .
<code>dotnet sln <arg></code>	The word <code>add</code> , <code>list</code> , or <code>remove</code> .
<code>dotnet nuget <arg></code>	The word <code>delete</code> , <code>locals</code> , or <code>push</code> .
<code>dotnet workload <subcommand> <arg></code>	The word <code>install</code> , <code>update</code> , <code>list</code> , <code>search</code> , <code>uninstall</code> , <code>repair</code> , <code>restore</code> and the workload name (hashed).
<code>dotnet tool <subcommand> <arg></code>	The word <code>install</code> , <code>update</code> , <code>list</code> , <code>search</code> , <code>uninstall</code> , <code>run</code> and the dotnet tool name (hashed).

A subset of commands sends selected options if they're used, along with their values:

OPTION	COMMANDS
<code>--verbosity</code>	All commands
<code>--language</code>	<code>dotnet new</code>
<code>--configuration</code>	<code>dotnet build</code> , <code>dotnet clean</code> , <code>dotnet publish</code> , <code>dotnet run</code> , <code>dotnet test</code>
<code>--framework</code>	<code>dotnet build</code> , <code>dotnet clean</code> , <code>dotnet publish</code> , <code>dotnet run</code> , <code>dotnet test</code> , <code>dotnet vstest</code>
<code>--runtime</code>	<code>dotnet build</code> , <code>dotnet publish</code>

OPTION	COMMANDS
--platform	dotnet vstest
--logger	dotnet vstest
--sdk-package-version	dotnet migrate

Except for `--verbosity` and `--sdk-package-version`, all the other values are hashed starting with .NET Core 2.1.100 SDK.

Template engine telemetry

The `dotnet new` template instantiation command collects additional data for Microsoft-authored templates, starting with .NET Core 2.1.100 SDK:

- `--framework`
- `--auth`

Crash exception telemetry

If the .NET CLI/SDK crashes, it collects the name of the exception and stack trace of the CLI/SDK code. This information is collected to assess problems and improve the quality of the .NET SDK and CLI. This article provides information about the data we collect. It also provides tips on how users building their own version of the .NET SDK can avoid inadvertent disclosure of personal or sensitive information.

The .NET CLI collects information for CLI/SDK exceptions only, not exceptions in your application. The collected data contains the name of the exception and the stack trace. This stack trace is of CLI/SDK code.

The following example shows the kind of data that is collected:

```
System.IO.IOException
at System.ConsolePal.WindowsConsoleStream.Write(Byte[] buffer, Int32 offset, Int32 count)
at System.IO.StreamWriter.Flush(Boolean flushStream, Boolean flushEncoder)
at System.IO.StreamWriter.Write(Char[] buffer)
at System.IO.TextWriter.WriteLine()
at System.IO.TextWriter.SyncTextWriter.WriteLine()
at Microsoft.DotNet.Cli.Utils.Reporter.WriteLine()
at Microsoft.DotNet.Tools.Run.RunCommand.EnsureProjectIsBuilt()
at Microsoft.DotNet.Tools.Run.RunCommand.Execute()
at Microsoft.DotNet.Tools.Run.RunCommand.Run(String[] args)
at Microsoft.DotNet.Cli.Program.ProcessArgs(String[] args, ITelemetry telemetryClient)
at Microsoft.DotNet.Cli.Program.Main(String[] args)
```

Continuous Integration Detection

In order to detect if the .NET CLI is running in a Continuous Integration environment, the .NET CLI probes for the presence and values of several well-known environment variables that common CI providers set.

The full list of environment variables, and what is done with their values, is shown below. Note that in every case, the value of the environment variable is never collected, only used to set a boolean flag.

VARIABLE(S)	PROVIDER	ACTION
TF_BUILD	Azure Pipelines	Parse boolean value

VARIABLE(S)	PROVIDER	ACTION
GITHUB_ACTIONS	GitHub Actions	Parse boolean value
APPVEYOR	Appveyor	Parse boolean value
CI	Many/Most	Parse boolean value
TRAVIS	Travis CI	Parse boolean value
CIRCLECI	Circle CI	Parse boolean value
CODEBUILD_BUILD_ID, AWS_REGION	Amazon Web Services CodeBuild	Check if all are present and non-null
BUILD_ID, BUILD_URL	Jenkins	Check if all are present and non-null
BUILD_ID, PROJECT_ID	Google Cloud Build	Check if all are present and non-null
TEAMCITY_VERSION	TeamCity	Check if present and non-null
JB_SPACE_API_URL	JetBrains Space	Check if present and non-null

Avoid inadvertent disclosure of information

.NET contributors and anyone else running a version of the .NET SDK that they built themselves should consider the path to their SDK source code. If a crash occurs while using a .NET SDK that is a custom debug build or configured with custom build symbol files, the SDK source file path from the build machine is collected as part of the stack trace and isn't hashed.

Because of this, custom builds of the .NET SDK shouldn't be located in directories whose path names expose personal or sensitive information.

.NET SDK error list

9/20/2022 • 15 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

This is a complete list of the errors that you might get from the .NET SDK while developing .NET apps. If more info is available for a particular error, the error number is a link.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1001	At least one possible target framework must be specified.
NETSDK1002	Project '{0}' targets '{2}'. It cannot be referenced by a project that targets '{1}'.
NETSDK1003	Invalid framework name: '{0}'.
NETSDK1004	Assets file '{0}' not found. Run a NuGet package restore to generate this file.
NETSDK1005	Assets file '{0}' doesn't have a target for '{1}'. Ensure that restore has run and that you have included '{2}' in the TargetFrameworks for your project.
NETSDK1006	Assets file path '{0}' is not rooted. Only full paths are supported.
NETSDK1007	Cannot find project info for '{0}'. This can indicate a missing project reference.
NETSDK1008	Missing '{0}' metadata on '{1}' item '{2}'.
NETSDK1009	Unrecognized preprocessor token '{0}' in '{1}'.
NETSDK1010	The '{0}' task must be given a value for parameter '{1}' in order to consume preprocessed content.
NETSDK1011	Assets are consumed from project '{0}', but no corresponding MSBuild project path was found in '{1}'.
NETSDK1012	Unexpected file type for '{0}'. Type is both '{1}' and '{2}'.
NETSDK1013	The TargetFramework value '{0}' was not recognized. It may be misspelled. If not, then the TargetFrameworkIdentifier and/or TargetFrameworkVersion properties must be specified explicitly.
NETSDK1014	Content item for '{0}' sets '{1}', but does not provide '{2}' or '{3}'.
NETSDK1015	The preprocessor token '{0}' has been given more than one value. Choosing '{1}' as the value.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1016	Unable to find resolved path for '{0}'.
NETSDK1017	Asset preprocessor must be configured before assets are processed.
NETSDK1018	Invalid NuGet version string: '{0}'.
NETSDK1019	{0} is an unsupported framework.
NETSDK1020	Package Root {0} was incorrectly given for Resolved library {1}.
NETSDK1021	More than one file found for {0}
NETSDK1022	Duplicate '{0}' items were included. The .NET SDK includes '{0}' items from your project directory by default. You can either remove these items from your project file, or set the '{1}' property to '{2}' if you want to explicitly include them in your project file. For more information, see {4}. The duplicate items were: {3}.
NETSDK1023	A PackageReference for '{0}' was included in your project. This package is implicitly referenced by the .NET SDK and you do not typically need to reference it from your project. For more information, see {1}.
NETSDK1024	Folder '{0}' already exists - either delete it or provide a different ComposeWorkingDir.
NETSDK1025	The target manifest {0} provided is of not the correct format.
NETSDK1028	Specify a Runtimeldentifier.
NETSDK1029	Unable to use '{0}' as application host executable as it does not contain the expected placeholder byte sequence '{1}' that would mark where the application name would be written.
NETSDK1030	Given file name '{0}' is longer than 1024 bytes.
NETSDK1031	It is not supported to build or publish a self-contained application without specifying a Runtimeldentifier. You must either specify a Runtimeldentifier or set SelfContained to false.
NETSDK1032	The Runtimeldentifier platform '{0}' and the PlatformTarget '{1}' must be compatible.
NETSDK1042	Could not load PlatformManifest from '{0}' because it did not exist.
NETSDK1043	Error parsing PlatformManifest from '{0}' line {1}. Lines must have the format {2}.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1044	Error parsing PlatformManifest from '{0}' line {1}. {2} '{3}' was invalid.
NETSDK1045	The current .NET SDK does not support targeting {0} {1}. Either target {0} {2} or lower, or use a version of the .NET SDK that supports {0} {1}.
NETSDK1046	The TargetFramework value '{0}' is not valid. To multi-target, use the 'TargetFrameworks' property instead.
NETSDK1047	Assets file '{0}' doesn't have a target for '{1}'. Ensure that restore has run and that you have included '{2}' in the TargetFrameworks for your project. You may also need to include '{3}' in your project's RuntimeIdentifiers.
NETSDK1048	'AdditionalProbingPaths' were specified for GenerateRuntimeConfigurationFiles, but are being skipped because 'RuntimeConfigDevPath' is empty.
NETSDK1049	Resolved file has a bad image, no metadata, or is otherwise inaccessible. {0} {1}.
NETSDK1050	The version of Microsoft.NET.Sdk used by this project is insufficient to support references to libraries targeting .NET Standard 1.5 or higher. Please install version 2.0 or higher of the .NET Core SDK.
NETSDK1051	Error parsing FrameworkList from '{0}'. {1} '{2}' was invalid.
NETSDK1052	Framework list file path '{0}' is not rooted. Only full paths are supported.
NETSDK1053	Pack as tool does not support self contained.
NETSDK1054	Only supports .NET Core.
NETSDK1055	DotnetTool does not support target framework lower than netcoreapp2.1.
NETSDK1056	Project is targeting runtime '{0}' but did not resolve any runtime-specific packages. This runtime may not be supported by the target framework.
NETSDK1057	You are using a preview version of .NET. See https://aka.ms/dotnet-support-policy .
NETSDK1058	Invalid value for ItemSpecToUse parameter: '{0}'. This property must be blank or set to 'Left' or 'Right'
NETSDK1059	The tool '{0}' is now included in the .NET SDK. Information on resolving this warning is available at https://aka.ms/dotnetclitools-in-box .
NETSDK1060	Error reading assets file: {0}

SDK MESSAGE NUMBER	MESSAGE
NETSDK1061	The project was restored using {0} version {1}, but with current settings, version {2} would be used instead. To resolve this issue, make sure the same settings are used for restore and for subsequent operations such as build or publish. Typically this issue can occur if the RuntimeIdentifier property is set during build or publish but not during restore. For more information, see https://aka.ms/dotnet-runtime-patch-selection .
NETSDK1063	The path to the project assets file was not set. Run a NuGet package restore to generate this file.
NETSDK1064	Package {0}, version {1} was not found. It might have been deleted since NuGet restore. Otherwise, NuGet restore might have only partially completed, which might have been due to maximum path length restrictions.
NETSDK1065	Cannot find app host for {0}. {0} could be an invalid runtime identifier (RID). For more information about RID, see https://aka.ms/rid-catalog .
NETSDK1067	Self-contained applications are required to use the application host. Either set SelfContained to false or set UseAppHost to true.
NETSDK1068	The framework-dependent application host requires a target framework of at least 'netcoreapp2.1'.
NETSDK1069	This project uses a library that targets .NET Standard 1.5 or higher, and the project targets a version of .NET Framework that doesn't have built-in support for that version of .NET Standard. Visit https://aka.ms/net-standard-known-issues for a set of known issues. Consider retargeting to .NET Framework 4.7.2.
NETSDK1070	The application configuration file must have root configuration element.
NETSDK1071	A PackageReference to '{0}' specified a Version of {1}. Specifying the version of this package is not recommended. For more information, see https://aka.ms/sdkimplicitrefs .
NETSDK1072	Unable to use '{0}' as application host executable because it's not a Windows executable for the CUI (Console) subsystem.
NETSDK1073	The FrameworkReference '{0}' was not recognized.
NETSDK1074	The application host executable will not be customized because adding resources requires that the build be performed on Windows (excluding Nano Server).
NETSDK1075	Update handle is invalid. This instance may not be used for further updates.
NETSDK1076	AddResource can only be used with integer resource types.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1077	Failed to lock resource.
NETSDK1078	Unable to use '{0}' as application host executable because it's not a Windows PE file.
NETSDK1079	The Microsoft.AspNetCore.All package is not supported when targeting .NET Core 3.0 or higher. A FrameworkReference to Microsoft.AspNetCore.App should be used instead, and will be implicitly included by Microsoft.NET.Sdk.Web.
NETSDK1080	A PackageReference to Microsoft.AspNetCore.App is not necessary when targeting .NET Core 3.0 or higher. If Microsoft.NET.Sdk.Web is used, the shared framework will be referenced automatically. Otherwise, the PackageReference should be replaced with a FrameworkReference.
NETSDK1081	The targeting pack for {0} was not found. You may be able to resolve this by running a NuGet restore on the project.
NETSDK1082	There was no runtime pack for {0} available for the specified RuntimeIdentifier '{1}'.
NETSDK1083	The specified RuntimeIdentifier '{0}' is not recognized.
NETSDK1084	There is no application host available for the specified RuntimeIdentifier '{0}'.
NETSDK1085	The 'NoBuild' property was set to true but the 'Build' target was invoked.
NETSDK1086	A FrameworkReference for '{0}' was included in the project. This is implicitly referenced by the .NET SDK and you do not typically need to reference it from your project. For more information, see {1}.
NETSDK1087	Multiple FrameworkReference items for '{0}' were included in the project.
NETSDK1088	The COMVisible class '{0}' must have a GuidAttribute with the CLSID of the class to be made visible to COM in .NET Core.
NETSDK1089	The '{0}' and '{1}' types have the same CLSID '{2}' set in their GuidAttribute. Each COMVisible class needs to have a distinct guid for their CLSID.
NETSDK1090	The supplied assembly '{0}' is not valid. Cannot generate a CLSIDMap from it.
NETSDK1091	Unable to find a .NET Core COM host. The .NET Core COM host is only available on .NET Core 3.0 or higher when targeting Windows.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1092	The CLSIDMap cannot be embedded on the COM host because adding resources requires that the build be performed on Windows (excluding Nano Server).
NETSDK1093	Project tools (DotnetCliTool) only support targeting .NET Core 2.2 and lower.
NETSDK1094	Unable to optimize assemblies for performance: a valid runtime package was not found. Either set the PublishReadyToRun property to false, or use a supported runtime identifier when publishing. When targeting .NET 6 or higher, make sure to restore packages with the PublishReadyToRun property set to true.
NETSDK1095	Optimizing assemblies for performance is not supported for the selected target platform or architecture. Please verify you are using a supported runtime identifier, or set the PublishReadyToRun property to false.
NETSDK1096	Optimizing assemblies for performance failed. You can either exclude the failing assemblies from being optimized, or set the PublishReadyToRun property to false.
NETSDK1097	It is not supported to publish an application to a single-file without specifying a Runtimeldentifier. You must either specify a Runtimeldentifier or set PublishSingleFile to false.
NETSDK1098	Applications published to a single-file are required to use the application host. You must either set PublishSingleFile to false or set UseAppHost to true.
NETSDK1099	Publishing to a single-file is only supported for executable applications.
NETSDK1100	To build a project targeting Windows on this operating system, set the EnableWindowsTargeting property to true.
NETSDK1102	Optimizing assemblies for size is not supported for the selected publish configuration. Please ensure that you are publishing a self-contained app.
NETSDK1103	RollForward setting is only supported on .NET Core 3.0 or higher.
NETSDK1104	RollForward value '{0}' is invalid. Allowed values are {1}.
NETSDK1105	Windows desktop applications are only supported on .NET Core 3.0 or higher.
NETSDK1106	Microsoft.NET.Sdk.WindowsDesktop requires 'UseWpf' or 'UseWindowsForms' to be set to 'true'.
NETSDK1107	Microsoft.NET.Sdk.WindowsDesktop is required to build Windows desktop applications. 'UseWpf' and 'UseWindowsForms' are not supported by the current SDK.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1109	Runtime list file '{0}' was not found. Report this error to the .NET team here: https://aka.ms/dotnet-sdk-issue .
NETSDK1110	More than one asset in the runtime pack has the same destination sub-path of '{0}'. Report this error to the .NET team here: https://aka.ms/dotnet-sdk-issue .
NETSDK1111	Failed to delete output apphost: {0}.
NETSDK1112	The runtime pack for {0} was not downloaded. Try running a NuGet restore with the RuntimeIdentifier '{1}'.
NETSDK1113	Failed to create apphost (attempt {0} out of {1}): {2}.
NETSDK1114	Unable to find a .NET Core IJW host. The .NET Core IJW host is only available on .NET Core 3.1 or higher when targeting Windows.
NETSDK1115	The current .NET SDK does not support .NET Framework without using .NET SDK Defaults. It is likely due to a mismatch between C++/CLI project CLRSupport property and TargetFramework.
NETSDK1116	C++/CLI projects targeting .NET Core must be dynamic libraries.
NETSDK1117	Does not support publish of C++/CLI project targeting dotnet core.
NETSDK1118	C++/CLI projects targeting .NET Core cannot be packed.
NETSDK1119	C++/CLI projects targeting .NET Core cannot use EnableComHosting=true.
NETSDK1120	C++/CLI projects targeting .NET Core require a target framework of at least 'netcoreapp3.1'.
NETSDK1121	C++/CLI projects targeting .NET Core cannot use SelfContained=true.
NETSDK1122	ReadyToRun compilation will be skipped because it is only supported for .NET Core 3.0 or higher.
NETSDK1123	Publishing an application to a single-file requires .NET Core 3.0 or higher.
NETSDK1124	Trimming assemblies requires .NET Core 3.0 or higher.
NETSDK1125	Publishing to a single-file is only supported for netcoreapp target.
NETSDK1126	Publishing ReadyToRun using Crossgen2 is only supported for self-contained applications.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1127	The targeting pack {0} is not installed. Please restore and try again.
NETSDK1128	COM hosting does not support self-contained deployments.
NETSDK1129	The 'Publish' target is not supported without specifying a target framework. The current project targets multiple frameworks, you must specify the framework for the published application.
NETSDK1130	{1} cannot be referenced. Referencing a Windows Metadata component directly when targeting .NET 5 or higher is not supported. For more information, see https://aka.ms/netsdk1130 .
NETSDK1131	Producing a managed Windows Metadata component with WinMDExp is not supported when targeting {0}.
NETSDK1132	No runtime pack information was available for {0}.
NETSDK1133	There was conflicting information about runtime packs available for {0}.
NETSDK1134	Building a solution with a specific RuntimeIdentifier is not supported. If you would like to publish for a single RID, specify the RID at the individual project level instead.
NETSDK1135	SupportedOSPlatformVersion {0} cannot be higher than TargetPlatformVersion {1}.
NETSDK1136	The target platform must be set to Windows (usually by including '-windows' in the TargetFramework property) when using Windows Forms or WPF, or referencing projects or packages that do so.
NETSDK1137	It is no longer necessary to use the Microsoft.NET.Sdk.WindowsDesktop SDK. Consider changing the Sdk attribute of the root Project element to 'Microsoft.NET.Sdk'.
NETSDK1138	The target framework '{0}' is out of support and will not receive security updates in the future. Please refer to https://aka.ms/dotnet-core-support for more information about the support policy.
NETSDK1139	The target platform identifier {0} was not recognized.
NETSDK1140	{0} is not a valid TargetPlatformVersion for {1}. Valid versions include:
NETSDK1141	Unable to resolve the .NET SDK version as specified in the global.json located at {0}.
NETSDK1142	Including symbols in a single file bundle is not supported when publishing for .NET5 or higher.

SDK MESSAGE NUMBER	MESSAGE
NETSDK1143	Including all content in a single file bundle also includes native libraries. If <code>IncludeAllContentForSelfExtract</code> is true, <code>IncludeNativeLibrariesForSelfExtract</code> must not be false.
NETSDK1144	Optimizing assemblies for size failed. Optimization can be disabled by setting the <code>PublishTrimmed</code> property to false.
NETSDK1145	The {0} pack is not installed and NuGet package restore is not supported. Upgrade Visual Studio, remove <code>global.json</code> if it specifies a certain SDK version, and uninstall the newer SDK. For more options visit https://aka.ms/targeting-apphost-pack-missing . Pack Type:{0}, Pack directory: {1}, targetframework: {2}, Pack PackageId: {3}, Pack Package Version: {4}.
NETSDK1146	PackAsTool does not support <code>TargetPlatformIdentifier</code> being set. For example, <code>TargetFramework</code> cannot be <code>net5.0-windows</code> , only <code>net5.0</code> . PackAsTool also does not support <code>UseWPF</code> or <code>UseWindowsForms</code> when targeting .NET 5 and higher.
NETSDK1147	To build this project, the following workloads must be installed: {0}.
NETSDK1148	A referenced assembly was compiled using a newer version of <code>Microsoft.Windows.SDK.NET.dll</code> . Please update to a newer .NET SDK in order to reference this assembly.
NETSDK1149	{0} cannot be referenced because it uses built-in support for WinRT, which is no longer supported in .NET 5 and higher. An updated version of the component supporting .NET 5 is needed. For more information, see https://aka.ms/netsdk1149 .
NETSDK1150	The referenced project '{0}' is a non self-contained executable. A non self-contained executable cannot be referenced by a self-contained executable. For more information, see https://aka.ms/netsdk1150 .
NETSDK1151	The referenced project '{0}' is a self-contained executable. A self-contained executable cannot be referenced by a non self-contained executable. For more information, see https://aka.ms/netsdk1151 .
NETSDK1152	Found multiple publish output files with the same relative path: {0}.
NETSDK1153	CrossgenTool not specified in PDB compilation mode.
NETSDK1154	Crossgen2Tool must be specified when <code>UseCrossgen2</code> is set to true.

NETSDK1183	Unable to optimize assemblies for Ahead of time compilation: a valid runtime package was not found. Either set the PublishAot property to false, or use a supported runtime identifier when publishing. When targeting .NET 7 or higher, make sure to restore packages with the PublishAot property set to true.
NETSDK1184	The Targeting Pack for FrameworkReference '{0}' was not available. This may be because DisableTransitiveFrameworkReferenceDownloads was set to true.
NETSDK1185	The Runtime Pack for FrameworkReference '{0}' was not available. This may be because DisableTransitiveFrameworkReferenceDownloads was set to true.
NETSDK1186	This project depends on Maui Essentials through a project or NuGet package reference, but doesn't declare that dependency explicitly. To build this project, you must set the UseMauiEssentials property to true (and install the Maui workload if necessary).

NETSDK1004: Assets file not found

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

NuGet writes a file named *project.assets.json* in the *obj* folder, and the .NET SDK uses it to get information about packages to pass into the compiler. This error occurs when the assets file *project.assets.json* is not found during build. The full error message is similar to the following example:

NETSDK1004: Assets file 'C:\path\to\project.assets.json' not found. Run a NuGet package restore to generate this file.

Here are some possible causes of the error:

- You are running the `dotnet build` command from a directory path that contains a `%` character. To resolve the error, remove the `%` from the folder name, and rerun `dotnet build`.
- A change to the project file wasn't automatically detected and restored by the project system. To resolve the error, open a command prompt and run `dotnet restore` on the project.
- A project was restored separately by an older version of Nuget.exe. To resolve the error, open a command prompt and run `dotnet restore` on the project.
- An earlier error, such as NETSDK1045 (the version of the SDK you're using doesn't support the project's target framework), prevented NuGet from creating the project assets file. To resolve the NETSDK1004 error, resolve the earlier error, and then run `dotnet restore` on the project.
- App Center CI is building a project that has an external assembly that is not in NuGet. To resolve the error, use a NuGet package for the assembly.
- You added a solution folder in Visual Studio with a name that starts with a period. To resolve the error, remove the leading period from the folder name.
- You have a source in the `<packageSources>` section in the *NuGet.Config* file with a path that doesn't exist. To resolve the error, edit the *NuGet.Config* file to correct the package source path.

NETSDK1005 and NETSDK1047: Asset file is missing target

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

When the .NET SDK issues error NETSDK1005 or NETSDK1047, the project's assets file is missing information on one of your target frameworks. NuGet writes a file named `project.assets.json` in the `obj` folder, and the .NET SDK uses it to get information about packages to pass into the compiler. In .NET 5, NuGet added a new field named `TargetFrameworkAlias`, so earlier versions of MSBuild or NuGet generate an assets file without the new field. For more information, see [error NETSDK1005](#).

Here are some actions you can take that may resolve the error:

- Make sure that you're using MSBuild version 16.8 or later and NuGet version 5.8 or later, and restore the project after updating your tools. When you're using NuGet version 5.8 or later, you should be using Visual Studio 2019 version 16.8 or later, MSBuild version 16.8 or later, and .NET 5 SDK or later.
- If you get the error while building a project in Visual Studio 2019 for the first time after installing version 16.8 or after changing the project's target framework, build the project a second time.
- Delete the `obj` folder before building the project.
- Make sure that the missing target value is included in the `TargetFrameworks` property of your project.
- If you're building a Docker image, make sure the `.dockerignore` file ignores the `bin` and `obj` directories. For more information, see GitHub pull request [dotnet/docs #29530](#).

NETSDK1013: The TargetFramework value was not recognized

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.100 SDK and later versions

The SDK tries to parse the values provided in the project file for `<TargetFramework>` or `<TargetFrameworks>` into a well known value. If the value is not recognized, the `TargetFrameworkIdentifier` or `TargetFrameworkVersion` value may be set to an empty string or `Unsupported`.

To resolve this, check the spelling of your `TargetFramework` value from the list of [supported frameworks](#). You can also set the `TargetFrameworkIdentifier` and `TargetFrameworkVersion` properties directly in your project file.

```
<PropertyGroup Condition="$(TargetFrameworkIdentifier)' == ''">
  <TargetFrameworkIdentifier>.NETCOREAPP</TargetFrameworkIdentifier>
  <TargetFrameworkVersion>3.1</TargetFrameworkVersion>
</PropertyGroup>
```

NETSDK1022: Duplicate items were included.

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

Starting in Visual Studio 2017 / MSBuild version 15.3, the .NET SDK automatically includes items from the project directory by default. This includes `Compile` and `Content` targets. This should greatly clean up your project file and reduce the complexity you have there.

You can revert to the earlier behavior by setting the correct property to false.

Example for `Compile` items:

```
<PropertyGroup>
    <EnableDefaultCompileItems>false</EnableDefaultCompileItems>
</PropertyGroup>
```

NETSDK1045: The current .NET SDK does not support 'newer version' as a target.

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

This error occurs when the build tools can't find the version of the .NET SDK that's needed to build a project. This is typically due to a .NET SDK installation or configuration issue. The full error message is similar to the following example:

```
NETSDK1045: The current .NET SDK does not support 'newer version' as a target. Either target 'older version' or lower, or use a .NET SDK version that supports 'newer version'.
```

The following sections describe some of the possible reasons for this error. Check each one and see which one applies to you. Keep in mind that when making changes to the environment or the configuration files, you might have to restart command windows, restart Visual Studio, or reboot your machine, for your changes to take effect.

.NET SDK version

Open the project file (.csproj, .vbproj, or .fsproj) and check the target framework. This is the version of the framework that your app is trying to use.

```
<TargetFramework>netcoreapp3.0</TargetFramework>
```

Make sure that the version of .NET listed is installed on the machine. You can list the installed versions by using the following command (open a Developer Command Prompt and run this command):

```
dotnet --list-sdks
```

x86 or x64 architecture

Each version of the .NET SDK is available in both x86 and x64 architecture. The project might be trying to find the .NET SDK for the wrong architecture, or the .NET SDK for the architecture your project needs might not be installed. Check the installation folders for the architecture you need. For example, on Windows, the x86 version of the .NET SDK is installed in *C:\Program Files (x86)\dotnet* and the x64 version is installed in *C:\Program Files\dotnet*. See [How to check that .NET is already installed](#) and choose your operating system to find out how to detect what's installed on your machine.

If the version you need isn't installed, find the one you need at the [.NET Downloads](#) page.

Preview not enabled

If you have a preview installed of the requested .NET SDK version, you also need to set the option to enable previews in Visual Studio. Go to **Tools > Options > Environment > Preview Features**, and make sure that **Use previews of the .NET Core SDK** is checked.

Visual Studio version

For example, .NET Core 3.0 and later require Visual Studio 2019. Upgrade to [Visual Studio 2019 version 16.3](#) or later to build your project.

PATH environment variable

The build tools use the PATH environment variable to find the right version of the .NET build tools. If the PATH environment variable contains direct paths to older build tools, this error message could appear. Make sure the only path to the .NET tools in the PATH environment variable is to the top-level *dotnet* folder, for example, *C:\Program Files\dotnet*. An example of an incorrect PATH would be something like *C:\Program Files\dotnet\2.1.0\sdk*.

MSBuildSDKPath environment variable

Check the MSBuildSDKPath environment variable. This optional environment variable is recognized by MSBuild and if set, overrides the default value. It might be set to a specific older version of the .NET SDK. If it's set, try deleting it and rebuilding your project.

global.json file

Check for a *global.json* file in the root folder in your project and up the directory chain to the root of the volume, since it can be anywhere in the folder structure. If it contains an SDK version, delete the `sdk` node and all its children, or update it to the desired newer .NET Core version.

```
{  
  "sdk": {  
    "version": "2.1.0"  
  }  
}
```

The *global.json* file is not required, so if it doesn't contain anything other than the `sdk` node, you can delete the whole file.

Directory.build.props file

The *Directory.build.props* file is an optional MSBuild file that can set global properties. Check for these files in the solution folder and up the directory chain to the root of the volume, since they can be anywhere in the folder structure. Look for `TargetFramework` elements, or settings of `MSBuildSDKPath` that could override your desired settings.

NETSDK1059: Project contains obsolete .NET CLI tool

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

When the .NET SDK issues warning NETSDK1059, your project contains an obsolete .NET CLI tool. As of .NET Core 2.1, these tools are included in the .NET SDK and do not need to be explicitly referenced by the project. For more information, see [Project tools now included in SDK](#).

NETSDK1064: Package not found

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

This error occurs when the build tools can't find a NuGet package that's needed to build a project. This is typically due to a package restore issue. The full error message is similar to the following example:

NETSDK1064: Package 'PackageName', version x.x.x was not found. It might have been deleted since NuGet restore. Otherwise, NuGet restore might have only partially completed, which might have been due to maximum path length restrictions.

Here are some actions you can take to resolve this error:

- Add the `/restore` option to your *MSBuild.exe* command. Don't use `/t:Restore;Build`, as that can result in subtle bugs. An alternative is to use the `dotnet build` command, since it automatically does a package restore.
- If you're running package restore by using Visual Studio 2019 or *MSBuild.exe*, the error may be caused by maximum path length restrictions. For more information, see [Long Path Support \(NuGet CLI\)](#) and [NuGet/Home issue #3324](#).
- If you're restoring with x86 *nuget.exe* and building with x64 *MSBuild.exe*, the mismatched bitness could cause this error. The build can't find the packages that the restore claims it acquired because the path in *project.assets.json* doesn't work in a process of different bitness. To resolve the error, use tools of the same bitness for restore and build, or configure NuGet to restore packages to a folder that doesn't virtualize between x86 and x64. For more information, see [dotnet/core issue #4332](#).
- If you're building a Docker image, make sure the *.dockerignore* file ignores the *bin* and *obj* directories. For more information, see [NETSDK1064: Package DnsClient, 1.2.0 was not found](#).

NETSDK1071: Explicitly versioned PackageReference to a metapackage that would be included with the framework.

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 5.0.100 SDK and later versions

When the .NET SDK issues warning NETSDK1071, it suggests there may be a version conflict in the future between the version of a metapackage specified in a PackageReference and the version of that metapackage as implicitly referenced via a TargetFramework property:

```
<PropertyGroup>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>
```

Since the TargetFramework automatically brings in a version of the metapackage, the versions will conflict should they ever differ.

To resolve this:

1. Consider, when targeting .NET Core or .NET Standard, avoiding explicit references to `Microsoft.NETCore.App` or `NETStandard.Library` in your project file.
2. If you need a specific version of the runtime when targeting .NET Core, use the `<RuntimeFrameworkVersion>` property instead of referencing the metapackage directly. As an example, this could happen if you're using [self-contained deployments](#) and need a specific patch of the 1.0.0 LTS runtime.
3. If you need a specific version of `NetStandard.Library` when targeting .NET Standard, you can use the `<NetStandardImplicitPackageVersion>` property and set it to the version you need.
4. Don't explicitly add or update references to either `Microsoft.NETCore.App` or `NETStandard.Library` in .NET Framework projects. NuGet automatically installs any version of `NETStandard.Library` you need when using a .NET Standard-based NuGet package.
5. Do not specify a version for `Microsoft.AspNetCore.App` or `Microsoft.AspNetCore.All` when using .NET Core 2.1+, as the .NET SDK automatically selects the appropriate version. (Note: This only works when targeting .NET Core 2.1 if the project also uses `Microsoft.NET.Sdk.Web`. This problem was resolved in the .NET Core 2.2 SDK.)
6. If you want the warning to go away, you can also disable it:

```
<PackageReference Include="Microsoft.NetCore.App" Version="2.2.8" >
  <AllowExplicitVersion>true</AllowExplicitVersion>
</PackageReference>
```

NETSDK1073: The FrameworkReference was not recognized

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1.100 SDK and later versions

This error typically means there is a version of a particular FrameworkReference that the SDK cannot find. Try deleting your *obj* and *bin* folders and running `dotnet restore` to redownload the latest targeting packs.

Alternatively, there could be an issue with your install, so ensure you're on the latest versions of .NET and Visual Studio

NETSDK1079: The Microsoft.AspNetCore.All package is not supported when targeting .NET Core 3.0 or higher.

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core SDK 3.1.100 and later versions

You may receive this error message when:

- You retarget an ASP.NET Core project from .NET Core 2.2 or earlier to .NET Core 3.0 or later.
- The project uses the Microsoft.AspNetCore.All package.

Remove the `PackageReference` for Microsoft.AspNetCore.All. You may also need to add package references for packages that were referenced from Microsoft.AspNetCore.All but are not included in the ASP.NET Core shared framework. These packages are listed here: [Migrating from Microsoft.AspNetCore.All to Microsoft.AspNetCore.App](#).

See also [Migrate from ASP.NET Core 2.2 to 3.0](#)

NETSDK1080: PackageReference to Microsoft.AspNetCore.App is not necessary

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1080 warns you that the `PackageReference` element for `Microsoft.AspNetCore.App` in your project file is not necessary. The full error message is similar to the following example:

```
warning NETSDK1080: A PackageReference to Microsoft.AspNetCore.App is not necessary when targeting .NET Core 3.0 or higher. If Microsoft.NET.Sdk.Web is used, the shared framework will be referenced automatically. Otherwise, the PackageReference should be replaced with a FrameworkReference.
```

This error typically occurs after you've upgraded a project to .NET Core 3.0 or later, from an earlier version that required `PackageReference` entries in the project file.

ASP.NET Core project files

For example, your original project file might look like this example:

```
<Project Sdk="Microsoft.NET.Sdk.Web">

<PropertyGroup>
  <TargetFramework>netcoreapp2.2</TargetFramework>
  <AspNetCoreHostingModel>InProcess</AspNetCoreHostingModel>
</PropertyGroup>

<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.App"/>
  <PackageReference Include="Microsoft.AspNetCore.Razor.Design" Version="2.2.0" PrivateAssets="All" />
</ItemGroup>

</Project>
```

After updating to .NET Core 3.1 the project file for the same project should look like the following example:

```
<Project Sdk="Microsoft.NET.Sdk.Web">

<PropertyGroup>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>

</Project>
```

Make these changes, in particular delete the `PackageReference` element, to eliminate the warning. For more information, see [Remove obsolete package references](#).

Class library project

In a class library project that uses ASP.NET Core APIs, replace the `PackageReference` with a `FrameworkReference`, as shown in the following example:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>

<ItemGroup>
  <FrameworkReference Include="Microsoft.AspNetCore.App" />
</ItemGroup>

</Project>
```

For more information, see [Use ASP.NET Core APIs in a class library](#).

NETSDK1082: PackageReference to Microsoft.AspNetCore.App is not necessary

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1082 warns you that the runtime pack for your [runtime identifier](#) (RID) could not be found in your NuGet feed. The full error message is similar to the following example:

```
There was no runtime pack for <RuntimePack> available for the specified RuntimeIdentifier '<RID>'.
```

.NET automatically downloads known runtime packs for self-contained applications but there could be a pointer to one that's not available to you. Investigate your NuGet configuration and feeds to find out why the required runtime pack is missing. In some scenarios, you might have to override the `LatestRuntimeFrameworkVersion` value to one that's available on your NuGet feeds by adding markup like the following example to the project file:

```
<ItemGroup>
  <KnownRuntimePack Update="@{KnownRuntimePack}">
    <LatestRuntimeFrameworkVersion Condition="'%(TargetFramework)' == 'TARGETFRAMEWORK'">EXISTINGVERSION</LatestRuntimeFrameworkVersion>
  </KnownRuntimePack>
</ItemGroup>
```

In this example, `TARGETFRAMEWORK` represents values like `net6.0`, `net5.0`, or `netcoreapp3.1` – basically anything that's in the [NET 5+ \(and .NET Core\)](#) list in [Supported target frameworks](#). `EXISTINGVERSION` would need to be a valid version that has been released. For example, `6.0.7` for `net6.0`, `5.0.17` for `net5.0`, and so forth. For information about released versions, see [Download .NET 6.0](#) and [Download .NET 5.0](#).

NETSDK1100: Set the `EnableWindowsTargeting` property to true

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1100 indicates that you're building a project that targets Windows on Linux or macOS. The full error message is similar to the following example:

To build a project targeting Windows on this operating system, set the `EnableWindowsTargeting` property to true.

To resolve this error, set the `EnableWindowsTargeting` property to true. You can set it in the project file or by passing `/p:EnableWindowsTargeting=true` to a .NET CLI command, such as `dotnet build`. Here's an example project file:

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <OutputType>Exe</OutputType>
    <TargetFramework>net6.0</TargetFramework>
    <EnableWindowsTargeting>true</EnableWindowsTargeting>
  </PropertyGroup>
</Project>
```

If you want to apply this setting to your whole solution or repository, you can set it in a `Directory.Build.props` file.

By default, .NET downloads all targeting packs (and runtime packs for self-contained builds) for the current target framework whether they're needed or not, because they might be brought in by a transitive framework reference. We didn't want to ship the Windows targeting packs with the non-Windows SDK builds, but we also didn't want a vanilla Console or ASP.NET Core app to automatically download these targeting and runtime packs the first time you build. The `EnableWindowsTargeting` property enables them to only be downloaded if you opt in.

NETSDK1112: The runtime pack was not downloaded

9/20/2022 • 2 minutes to read • [Edit Online](#)

A runtime pack that your project requires was not downloaded. The full error message is similar to the following example:

```
The runtime pack for <Runtime> was not downloaded. Try running a NuGet restore with the  
RuntimeIdentifier '<RID>'.
```

This can happen in the following scenarios:

- The publish parameters are different than what's in the project file. Review publish parameters and change any instances where publish parameters differ from the project file.
- You used Debug configuration to build an app that is set up to require Release configuration. Try building with Release configuration.

NETSDK1130: Can't reference a Windows Metadata component directly

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1130 indicates that you're trying to reference a Windows Metadata component directly from an app that targets .NET 5 or later. The full error message is similar to the following example:

```
<Component name> cannot be referenced. Referencing a Windows Metadata component directly when targeting .NET 5 or higher is not supported.
```

To resolve this error:

- Remove references to the [Microsoft.Windows.SDK.Contracts package](#). Instead, specify the version of the Windows APIs that you want to access via the `TargetFramework` property of the project. For example:

```
<TargetFramework>net5.0-windows10.0.19041.0</TargetFramework>
```

- If you're consuming a third-party runtime component that's defined in a `.winmd` file, add a reference to the [Microsoft.Windows.CsWinRT NuGet package](#). For information on how to generate the C# projection, see the [C#/WinRT](#) documentation.

For more information, see [Built-in support for WinRT is removed from .NET](#) and [Call Windows Runtime APIs in desktop apps](#).

NETSDK1135: SupportedOSPlatformVersion can't be higher than TargetPlatformVersion

9/20/2022 • 2 minutes to read • [Edit Online](#)

The value that your project file specifies for `SupportedOSPlatformVersion` is too high. The full error message is similar to the following example:

`SupportedOSPlatformVersion <version> cannot be higher than TargetPlatformVersion <version>.`

Check your project files for `SupportedOSPlatformVersion`, `TargetPlatformVersion` (TPV) is inferred from the `TargetFramework` value. For example, `net6.0-windows10.0.19041` will set the TPV to be `10.0.19041`. .NET uses `TargetPlatformVersion` to determine which APIs are available at compile time.

NETSDK1136: The target framework must be Windows

9/20/2022 • 2 minutes to read • [Edit Online](#)

If `UseWindowsForms` or `UseWPF` is `true`, .NET assumes that your project is a Windows app, and so the platform has to be set to Windows. This error can happen if you have a project-to-project reference where one is set to Windows and the other is not. The full error message is similar to the following example:

The target platform must be set to Windows (usually by including `-windows` in the `TargetFramework` property) when using Windows Forms or WPF, or referencing projects or packages that do so.

For example, set `TargetFramework` to `net6.0-windows`, as shown in this project file:

```
<Project Sdk="Microsoft.NET.Sdk.Web">
  <PropertyGroup>
    <TargetFramework>net6.0-windows</TargetFramework>
  </PropertyGroup>
</Project>
```

NETSDK1137: Don't use the Microsoft.NET.Sdk.WindowsDesktop SDK

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1137 indicates that your project specifies an outdated project SDK. The full error message is similar to the following example:

It is no longer necessary to use the Microsoft.NET.Sdk.WindowsDesktop SDK. Consider changing the Sdk attribute of the root Project element to 'Microsoft.NET.Sdk'.

To resolve this error, modify your project file to have `<Project Sdk="Microsoft.NET.Sdk">` instead of the `WindowsDesktop` SDK.

NETSDK1138: The target framework is out of support

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1138 indicates that your project targets a version of the framework that is out of support. The full error message is similar to the following example:

```
The target framework '<framework>' is out of support and will not receive security updates in the future.  
Please refer to https://aka.ms/dotnet-core-support for more information about the support policy.
```

Out-of-support versions include 1.0, 1.1, 2.0, 2.1, 2.2, and 3.0. In November 2022, .NET 5 will be added to this list.

To resolve this error, change your project to target a supported version of .NET Core or .NET 5+.

If you want to suppress the message without targeting a later framework, set the MSBuild property `CheckEolTargetFramework` to false. You can set it in the project file or by passing `/p:CheckEolTargetFramework=false` to a .NET CLI command, such as `dotnet build`. Here's an example project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <OutputType>Exe</OutputType>  
    <TargetFramework>netcoreapp3.0</TargetFramework>  
    <CheckEolTargetFramework>false</CheckEolTargetFramework>  
  </PropertyGroup>  
</Project>
```

Here's an example .NET CLI command:

```
dotnet build /p:CheckEolTargetFramework=false
```

NETSDK1141: Unable to resolve the .NET SDK version as specified in the `global.json`

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 5.0 SDK and later versions

There was a problem with the version of the SDK specified in the `global.json` file.

NETSDK1141: Unable to resolve the .NET SDK version as specified in the `global.json` located at C:\path\global.json.

Cause

- The SDK version in the `global.json` file is incorrectly specified.
- The SDK version specified in the `global.json` file was not installed.
- The SDK version specified in `global.json` could not be found, due to an incorrect path.

How to fix the error

- Install the SDK version requested in `global.json`.
- Specify a different SDK version in `global.json`.
- Check for typos or other problems in `global.json`. See [global.json](#) for the correct structure of that file.
- Delete `global.json`. In this case, the latest installed version of the SDK is used.

When you're working on a shared project, developers need to agree on the SDK version that will be used for the project. Without `global.json`, if developers on different dev machines don't have the same SDK versions, the build environment might be inconsistent across the dev team. To solve this, the SDK version can be specified in `global.json` and checked into source control as a common file which would be the same for all developers and ensure that the same SDK version is being used in all development environments. Therefore, to resolve this issue in a shared project, you might need to agree as a team on a particular SDK version and update all the code to use this version.

[global.json How to check that the .NET SDK is installed](#)

NETSDK1145: Targeting or apphost pack missing

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 5.0.100 SDK and later versions

When the .NET SDK issues error NETSDK1145, the targeting or apphost pack is not installed and NuGet package restore is not supported. This is typically caused by having a newer SDK than the one included in Visual Studio for C++/CLI projects. Upgrade Visual Studio, remove *global.json* if it specifies a certain SDK version, and uninstall the newer SDK. Alternatively, you could override the targeting or apphost version. Find the version that exists under the pack directory from the error message and matches the target framework of the project. Add the following to the project:

For apphost pack

```
<ItemGroup>
  <KnownAppHostPack Update="@{KnownAppHostPack}">
    <AppHostPackVersion Condition="'%(TargetFramework)' ==
'TARGETFRAMEWORK'">EXISTINGVERSION</AppHostPackVersion>
  </KnownAppHostPack>
</ItemGroup>
```

For targeting pack

```
<ItemGroup>
  <KnownFrameworkReference Update="@{KnownFrameworkReference}">
    <TargetingPackVersion Condition="'%(TargetFramework)' ==
'TARGETFRAMEWORK'">EXISTINGVERSION</TargetingPackVersion>
  </KnownFrameworkReference>
</ItemGroup>
```

NETSDK1147: Missing workload for specified target framework

9/20/2022 • 2 minutes to read • [Edit Online](#)

This error is caused by trying to compile a project that requires an optional workload, but you don't have the workload installed. The full error message is similar to the following example:

NETSDK1147: To build this project, the following workloads must be installed: <workload ID>

To install these workloads, run the following command: dotnet workload install <workload ID>

For example, if your project targets `net6.0-android`, you might have to run the `dotnet workload install` command and specify workload ID `android`:

```
dotnet workload install android
```

For more information, see [dotnet workload install](#).

NETSDK1149: Built-in WinRT support not provided in .NET 5 and later

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1149 indicates that you're trying to reference a component that requires WinRT in an application that targets .NET 5 or a later version. These .NET versions don't have built-in support for WinRT. The full error message is similar to the following example:

<Component name> cannot be referenced because it uses built-in support for WinRT, which is no longer supported in .NET 5 and higher. An updated version of the component supporting .NET 5 is needed.

If your application calls Windows Runtime APIs, resolve this error by changing the application's Target Framework Moniker (TFM) to a value that targets Windows 10. For more information, see [Call Windows Runtime APIs in desktop apps](#).

If your application calls a 3rd party WinRT component, get an updated version of the component that supports .NET 5. You can generate an updated version by using [C#/WinRT](#).

For more information, see [Built-in support for WinRT is removed from .NET](#).

NETSDK1174: -p abbreviation for --project in dotnet run is deprecated

9/20/2022 • 2 minutes to read • [Edit Online](#)

The full error message is similar to the following example:

The abbreviation of -p for --project is deprecated. Please use --project.

The use of `-p` in `dotnet run` is deprecated because of the close relationship `dotnet run` has with `dotnet build` and `dotnet publish`. In `dotnet build` and `dotnet publish`, `p` is used to set MSBuild properties. This deprecation is the first step in aligning abbreviations for these three commands.

For more information, see [-p option for dotnet run is deprecated](#).

NETSDK1182: Targeting .NET 6.0 or higher in Visual Studio 2019 is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

NETSDK1182 indicates that you're trying to open a .NET 6+ project in Visual Studio 2019. Or you might be trying to build from the command line using MSBuild from Visual Studio 2019. The full error message is similar to the following example:

Targeting .NET 6.0 or higher in Visual Studio 2019 is not supported.

To resolve this error switch to Visual Studio 2022, or change your project to target .NET 5 or earlier.

.NET CLI overview

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

The .NET command-line interface (CLI) is a cross-platform toolchain for developing, building, running, and publishing .NET applications.

The .NET CLI is included with the [.NET SDK](#). To learn how to install the .NET SDK, see [Install .NET Core](#).

CLI commands

The following commands are installed by default:

Basic commands

- [new](#)
- [restore](#)
- [build](#)
- [publish](#)
- [run](#)
- [test](#)
- [vstest](#)
- [pack](#)
- [migrate](#)
- [clean](#)
- [sln](#)
- [help](#)
- [store](#)

Project modification commands

- [add package](#)
- [add reference](#)
- [remove package](#)
- [remove reference](#)
- [list reference](#)

Advanced commands

- [nuget delete](#)
- [nuget locals](#)
- [nuget push](#)
- [msbuild](#)
- [dotnet install script](#)

Tool management commands

- [tool install](#)
- [tool list](#)
- [tool update](#)

- `tool restore` Available since .NET Core SDK 3.0.
- `tool run` Available since .NET Core SDK 3.0.
- `tool uninstall`

Tools are console applications that are installed from NuGet packages and are invoked from the command prompt. You can write tools yourself or install tools written by third parties. Tools are also known as global tools, tool-path tools, and local tools. For more information, see [.NET tools overview](#).

Command structure

CLI command structure consists of **the driver ("dotnet")**, **the command**, and possibly command **arguments** and **options**. You see this pattern in most CLI operations, such as creating a new console app and running it from the command line as the following commands show when executed from a directory named *my_app*:

```
dotnet new console  
dotnet build --output ./build_output  
dotnet ./build_output/my_app.dll
```

Driver

The driver is named **dotnet** and has two responsibilities, either running a [framework-dependent app](#) or executing a command.

To run a framework-dependent app, specify the app after the driver, for example, `dotnet /path/to/my_app.dll`. When executing the command from the folder where the app's DLL resides, simply execute `dotnet my_app.dll`. If you want to use a specific version of the .NET Runtime, use the `--fx-version <VERSION>` option (see the [dotnet command reference](#)).

When you supply a command to the driver, `dotnet.exe` starts the CLI command execution process. For example:

```
dotnet build
```

First, the driver determines the version of the SDK to use. If there is no [global.json](#) file, the latest version of the SDK available is used. This might be either a preview or stable version, depending on what is latest on the machine. Once the SDK version is determined, it executes the command.

Command

The command performs an action. For example, `dotnet build` builds code. `dotnet publish` publishes code. The commands are implemented as a console application using a `dotnet {command}` convention.

Arguments

The arguments you pass on the command line are the arguments to the command invoked. For example, when you execute `dotnet publish my_app.csproj`, the `my_app.csproj` argument indicates the project to publish and is passed to the `publish` command.

Options

The options you pass on the command line are the options to the command invoked. For example, when you execute `dotnet publish --output /build_output`, the `--output` option and its value are passed to the `publish` command.

dotnet command

9/20/2022 • 7 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet` - The generic driver for the .NET CLI.

Synopsis

To get information about the available commands and the environment:

```
dotnet [--version] [--info] [--list-runtimes] [--list-sdks]  
dotnet -h|--help
```

To run a command (requires SDK installation):

```
dotnet <COMMAND> [-d|--diagnostics] [-h|--help] [--verbosity <LEVEL>]  
[command-options] [arguments]
```

To run an application:

```
dotnet [--additionalprobingpath <PATH>] [--additional-deps <PATH>]  
[--fx-version <VERSION>] [--roll-forward <SETTING>]  
<PATH_TO_APPLICATION> [arguments]  
  
dotnet exec [--additionalprobingpath] [--additional-deps <PATH>]  
[--depsfile <PATH>]  
[--fx-version <VERSION>] [--roll-forward <SETTING>]  
[--runtimeconfig <PATH>]  
<PATH_TO_APPLICATION> [arguments]
```

Description

The `dotnet` command has two functions:

- It provides commands for working with .NET projects.

For example, `dotnet build` builds a project. Each command defines its own options and arguments. All commands support the `--help` option for printing out brief documentation about how to use the command.

- It runs .NET applications.

You specify the path to an application `.dll` file to run the application. To run the application means to find and execute the entry point, which in the case of console apps is the `Main` method. For example, `dotnet myapp.dll` runs the `myapp` application. See [.NET application deployment](#) to learn about deployment options.

Options

Different options are available for:

- Displaying information about the environment.
- Running a command.
- Running an application.

Options for displaying environment information and available commands

The following options are available when `dotnet` is used by itself, without specifying a command or an application to run. For example, `dotnet --info` or `dotnet --version`. They print out information about the environment.

- `--info`

Prints out detailed information about a .NET installation and the machine environment, such as the current operating system, and commit SHA of the .NET version.

- `--version`

Prints out the version of the .NET SDK used by `dotnet` commands, which may be affected by a *global.json* file. Available only when the SDK is installed.

- `--list-runtimes`

Prints out a list of the installed .NET runtimes. An x86 version of the SDK lists only x86 runtimes, and an x64 version of the SDK lists only x64 runtimes.

- `--list-sdks`

Prints out a list of the installed .NET SDKs.

- `-?|-h|--help`

Prints out a list of available commands.

Options for running a command

The following options are for `dotnet` with a command. For example, `dotnet build --help` or `dotnet build --verbosity diagnostic`.

- `-d|--diagnostics`

Enables diagnostic output.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. Not supported in every command. See specific command page to determine if this option is available.

- `-?|-h|--help`

Prints out documentation for a given command. For example, `dotnet build --help` displays help for the `build` command.

- `command options`

Each command defines options specific to that command. See specific command page for a list of available options.

Options for running an application

The following options are available when `dotnet` runs an application. For example,

```
dotnet --roll-forward Major myapp.dll .
```

- `--additionalprobingpath <PATH>`

Path containing probing policy and assemblies to probe. Repeat the option to specify multiple paths.

- `--additional-deps <PATH>`

Path to an additional `.deps.json` file. A `.deps.json` file contains a list of dependencies, compilation dependencies, and version information used to address assembly conflicts. For more information, see [Runtime Configuration Files](#) on GitHub.

- `--roll-forward <SETTING> **`

Controls how roll forward is applied to the app. The `<SETTING>` can be one of the following values. If not specified, `Minor` is the default.

- `LatestPatch` - Roll forward to the highest patch version. This disables minor version roll forward.
- `Minor` - Roll forward to the lowest higher minor version, if requested minor version is missing. If the requested minor version is present, then the `LatestPatch` policy is used.
- `Major` - Roll forward to lowest higher major version, and lowest minor version, if requested major version is missing. If the requested major version is present, then the `Minor` policy is used.
- `LatestMinor` - Roll forward to highest minor version, even if requested minor version is present. Intended for component hosting scenarios.
- `LatestMajor` - Roll forward to highest major and highest minor version, even if requested major is present. Intended for component hosting scenarios.
- `Disable` - Don't roll forward. Only bind to specified version. This policy isn't recommended for general use because it disables the ability to roll forward to the latest patches. This value is only recommended for testing.

With the exception of `Disable`, all settings will use the highest available patch version.

Roll forward behavior can also be configured in a project file property, a runtime configuration file property, and an environment variable. For more information, see [Major-version runtime roll forward](#).

- `--fx-version <VERSION>`

Version of the .NET runtime to use to run the application.

This option overrides the version of the first framework reference in the application's `.runtimeconfig.json` file. This means it only works as expected if there's just one framework reference. If the application has more than one framework reference, using this option may cause errors.

Options for running an application with the `exec` command

The following options are available only when `dotnet` runs an application by using the `exec` command. For example, `dotnet exec --runtimeconfig myapp.runtimeconfig.json myapp.dll .`

- `--depsfile <PATH>`

Path to a `deps.json` file. A `deps.json` file is a configuration file that contains information about dependencies necessary to run the application. This file is generated by the .NET SDK.

- `--runtimeconfig <PATH>`

Path to a `runtimeconfig.json` file. A `runtimeconfig.json` file contains run-time settings and is typically

named `<applicationname>.runtimeconfig.json`. For more information, see [.NET runtime configuration settings](#).

dotnet commands

General

COMMAND	FUNCTION
<code>dotnet build</code>	Builds a .NET application.
<code>dotnet build-server</code>	Interacts with servers started by a build.
<code>dotnet clean</code>	Clean build outputs.
<code>dotnet exec</code>	Runs a .NET application.
<code>dotnet help</code>	Shows more detailed documentation online for the command.
<code>dotnet migrate</code>	Migrates a valid Preview 2 project to a .NET Core SDK 1.0 project.
<code>dotnet msbuild</code>	Provides access to the MSBuild command line.
<code>dotnet new</code>	Initializes a C# or F# project for a given template.
<code>dotnet pack</code>	Creates a NuGet package of your code.
<code>dotnet publish</code>	Publishes a .NET framework-dependent or self-contained application.
<code>dotnet restore</code>	Restores the dependencies for a given application.
<code>dotnet run</code>	Runs the application from source.
<code>dotnet sdk check</code>	Shows up-to-date status of installed SDK and Runtime versions.
<code>dotnet sln</code>	Options to add, remove, and list projects in a solution file.
<code>dotnet store</code>	Stores assemblies in the runtime package store.
<code>dotnet test</code>	Runs tests using a test runner.

Project references

COMMAND	FUNCTION
<code>dotnet add reference</code>	Adds a project reference.
<code>dotnet list reference</code>	Lists project references.
<code>dotnet remove reference</code>	Removes a project reference.

NuGet packages

COMMAND	FUNCTION
dotnet add package	Adds a NuGet package.
dotnet remove package	Removes a NuGet package.

NuGet commands

COMMAND	FUNCTION
dotnet nuget delete	Deletes or unlists a package from the server.
dotnet nuget push	Pushes a package to the server and publishes it.
dotnet nuget locals	Clears or lists local NuGet resources such as http-request cache, temporary cache, or machine-wide global packages folder.
dotnet nuget add source	Adds a NuGet source.
dotnet nuget disable source	Disables a NuGet source.
dotnet nuget enable source	Enables a NuGet source.
dotnet nuget list source	Lists all configured NuGet sources.
dotnet nuget remove source	Removes a NuGet source.
dotnet nuget update source	Updates a NuGet source.

Workload commands

COMMAND	FUNCTION
dotnet workload install	Installs an optional workload.
dotnet workload list	Lists all installed workloads.
dotnet workload repair	Repairs all installed workloads.
dotnet workload search	List selected workloads or all available workloads.
dotnet workload uninstall	Uninstalls a workload.
dotnet workload update	Reinstalls all installed workloads.

Global, tool-path, and local tools commands

Tools are console applications that are installed from NuGet packages and are invoked from the command prompt. You can write tools yourself or install tools written by third parties. Tools are also known as global tools, tool-path tools, and local tools. For more information, see [.NET tools overview](#).

COMMAND	FUNCTION
<code>dotnet tool install</code>	Installs a tool on your machine.
<code>dotnet tool list</code>	Lists all global, tool-path, or local tools currently installed on your machine.
<code>dotnet tool search</code>	Searches NuGet.org for tools that have the specified search term in their name or metadata.
<code>dotnet tool uninstall</code>	Uninstalls a tool from your machine.
<code>dotnet tool update</code>	Updates a tool that is installed on your machine.

Additional tools

The following additional tools are available as part of the .NET SDK:

TOOL	FUNCTION
<code>dev-certs</code>	Creates and manages development certificates.
<code>ef</code>	Entity Framework Core command-line tools.
<code>user-secrets</code>	Manages development user secrets.
<code>watch</code>	A file watcher that restarts or hot reloads an application when it detects changes in the source code.

For more information about each tool, type `dotnet <tool-name> --help`.

Examples

Create a new .NET console application:

```
dotnet new console
```

Build a project and its dependencies in a given directory:

```
dotnet build
```

Run an application:

```
dotnet exec myapp.dll
```

```
dotnet myapp.dll
```

dotnet add package

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet add package` - Adds or updates a package reference in a project file.

Synopsis

```
dotnet add [<PROJECT>] package <PACKAGE_NAME>
  [-f|--framework <FRAMEWORK>] [--interactive]
  [-n|--no-restore] [--package-directory <PACKAGE_DIRECTORY>]
  [--prerelease] [-s|--source <SOURCE>] [-v|--version <VERSION>]

dotnet add package -h|--help
```

Description

The `dotnet add package` command provides a convenient option to add or update a package reference in a project file. When you run the command, there's a compatibility check to ensure the package is compatible with the frameworks in the project. If the check passes and the package isn't referenced in the project file, a `<PackageReference>` element is added to the project file. If the check passes and the package is already referenced in the project file, the `<PackageReference>` element is updated to the latest compatible version. After the project file is updated, `dotnet restore` is run.

For example, adding `Microsoft.EntityFrameworkCore` to `ToDo.csproj` produces output similar to the following example:

```
Determining projects to restore...
Writing C:\Users\username\AppData\Local\Temp\tmp24A8.tmp
info : Adding PackageReference for package 'Microsoft.EntityFrameworkCore' into project
'C:\ToDo\ToDo.csproj'.
info : CACHE https://api.nuget.org/v3/registration5-gz-semver2/microsoft.entityframeworkcore/index.json
info : GET https://pkgs.dev.azure.com/dnceng/9ee6d478-d288-47f7-aacc-f6e6d082ae6d/_packaging/516521bf-
6417-457e-9a9c-0a4bdfde03e7/nuget/v3/registrations2-semver2/microsoft.entityframeworkcore/index.json
info : CACHE https://api.nuget.org/v3/registration5-gz-semver2/microsoft.entityframeworkcore/page/0.0.1-
alpha/3.1.3.json
info : CACHE https://api.nuget.org/v3/registration5-gz-
semver2/microsoft.entityframeworkcore/page/3.1.4/7.0.0-preview.2.22153.1.json
info : CACHE https://api.nuget.org/v3/registration5-gz-semver2/microsoft.entityframeworkcore/page/7.0.0-
preview.3.22175.1/7.0.0-preview.3.22175.1.json
info : NotFound https://pkgs.dev.azure.com/dnceng/9ee6d478-d288-47f7-aacc-
f6e6d082ae6d/_packaging/516521bf-6417-457e-9a9c-0a4bdfde03e7/nuget/v3/registrations2-
semver2/microsoft.entityframeworkcore/index.json 257ms
info : Restoring packages for C:\ToDo\ToDo.csproj...
info : Package 'Microsoft.EntityFrameworkCore' is compatible with all the specified frameworks in project
'C:\ToDo\ToDo.csproj'.
info : PackageReference for package 'Microsoft.EntityFrameworkCore' version '6.0.4' added to file
'C:\ToDo\ToDo.csproj'.
info : Writing assets file to disk. Path: C:\ToDo\obj\project.assets.json
log : Restored C:\ToDo\ToDo.csproj (in 171 ms).
```

The `ToDo.csproj` file now contains a `<PackageReference>` element for the referenced package.

```
<PackageReference Include="Microsoft.EntityFrameworkCore" Version="6.0.4" />
```

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore](#) documentation.

Arguments

- `PROJECT`

Specifies the project file. If not specified, the command searches the current directory for one.

- `PACKAGE_NAME`

The package reference to add.

Options

- `-f|--framework <FRAMEWORK>`

Adds a package reference only when targeting a specific [framework](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `-n|--no-restore`

Adds a package reference without performing a restore preview and compatibility check.

- `--package-directory <PACKAGE_DIRECTORY>`

The directory where to restore the packages. The default package restore location is `%userprofile%\.nuget\packages` on Windows and `~/.nuget/packages` on macOS and Linux. For more information, see [Managing the global packages, cache, and temp folders in NuGet](#).

- `--prerelease`

Allows prerelease packages to be installed. Available since .NET Core 5 SDK

- `-s|--source <SOURCE>`

The URI of the NuGet package source to use during the restore operation.

- `-v|--version <VERSION>`

Version of the package. See [NuGet package versioning](#).

Examples

- Add `Microsoft.EntityFrameworkCore` NuGet package to a project:

```
dotnet add package Microsoft.EntityFrameworkCore
```

- Add a specific version of a package to a project:

```
dotnet add ToDo.csproj package Microsoft.Azure.DocumentDB.Core -v 1.0.0
```

- Add a package using a specific NuGet source:

```
dotnet add package Microsoft.AspNetCore.StaticFiles -s https://dotnet.myget.org/F/dotnet-core/api/v3/index.json
```

See also

- [Managing the global packages, cache, and temp folders in NuGet](#)
- [NuGet package versioning](#)

dotnet list package

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet list package` - Lists the package references for a project or solution.

Synopsis

```
dotnet list [<PROJECT>|<SOLUTION>] package [--config <SOURCE>]
  [--deprecated]
  [--framework <FRAMEWORK>] [--highest-minor] [--highest-patch]
  [--include-prerelease] [--include-transitive] [--interactive]
  [--outdated] [--source <SOURCE>] [-v|--verbosity <LEVEL>]
  [--vulnerable]

dotnet list package -h|--help
```

Description

The `dotnet list package` command provides a convenient option to list all NuGet package references for a specific project or a solution. You first need to build the project in order to have the assets needed for this command to process. The following example shows the output of the `dotnet list package` command for the [SentimentAnalysis](#) project:

```
Project 'SentimentAnalysis' has the following package references
[netcoreapp2.1]:
  Top-level Package      Requested   Resolved
  > Microsoft.ML          1.4.0       1.4.0
  > Microsoft.NETCore.App (A) [2.1.0, )  2.1.0

(A) : Auto-referenced package.
```

The **Requested** column refers to the package version specified in the project file and can be a range. The **Resolved** column lists the version that the project is currently using and is always a single value. The packages displaying an `(A)` right next to their names represent implicit package references that are inferred from your project settings (`Sdk` type, or `<TargetFramework>` or `<TargetFrameworks>` property).

Use the `--outdated` option to find out if there are newer versions available of the packages you're using in your projects. By default, `--outdated` lists the latest stable packages unless the resolved version is also a prerelease version. To include prerelease versions when listing newer versions, also specify the `--include-prerelease` option. To update a package to the latest version, use [dotnet add package](#).

The following example shows the output of the `dotnet list package --outdated --include-prerelease` command for the same project as the previous example:

```
The following sources were used:  
https://api.nuget.org/v3/index.json  
C:\Program Files (x86)\Microsoft SDKs\NuGetPackages\
```

```
Project `SentimentAnalysis` has the following updates to its packages  
[netcoreapp2.1]:  
Top-level Package Requested Resolved Latest  
> Microsoft.ML 1.4.0 1.4.0 1.5.0-preview
```

If you need to find out whether your project has transitive dependencies, use the `--include-transitive` option. Transitive dependencies occur when you add a package to your project that in turn relies on another package. The following example shows the output from running the `dotnet list package --include-transitive` command for the [HelloPlugin](#) project, which displays top-level packages and the packages they depend on:

```
Project 'HelloPlugin' has the following package references  
[netcoreapp3.0]:  
Transitive Package Resolved  
> PluginBase 1.0.0
```

Arguments

[PROJECT](#) | [SOLUTION](#)

The project or solution file to operate on. If not specified, the command searches the current directory for one. If more than one solution or project is found, an error is thrown.

Options

- `--config <SOURCE>`
The NuGet sources to use when searching for newer packages. Requires the `--outdated` option.
- `--deprecated`
Displays packages that have been deprecated.
- `--framework <FRAMEWORK>`
Displays only the packages applicable for the specified [target framework](#). To specify multiple frameworks, repeat the option multiple times. For example: `--framework net6.0 --framework netstandard2.0`.
- `-?|-h|--help`
Prints out a description of how to use the command.
- `--highest-minor`
Considers only the packages with a matching major version number when searching for newer packages. Requires the `--outdated` or `--deprecated` option.
- `--highest-patch`
Considers only the packages with a matching major and minor version numbers when searching for newer packages. Requires the `--outdated` or `--deprecated` option.
- `--include-prerelease`
Considers packages with prerelease versions when searching for newer packages. Requires the

--outdated or --deprecated option.

- --include-transitive

Lists transitive packages, in addition to the top-level packages. When specifying this option, you get a list of packages that the top-level packages depend on.

- --interactive

Allows the command to stop and wait for user input or action. For example, to complete authentication.

Available since .NET Core 3.0 SDK.

- --outdated

Lists packages that have newer versions available.

- -s|--source <SOURCE>

The NuGet sources to use when searching for newer packages. Requires the --outdated or --deprecated option.

- -v|--verbosity <LEVEL>

Sets the verbosity level of the command. Allowed values are q[uiet], m[inimal], n[ormal], d[etailed], and diag[nostic]. The default is minimal. For more information, see [LoggerVerbosity](#).

- --vulnerable

Lists packages that have known vulnerabilities. Cannot be combined with --deprecated or --outdated options. Nuget.org is the source of information about vulnerabilities. For more information, see [Vulnerabilities](#) and [How to Scan NuGet Packages for Security Vulnerabilities](#).

Examples

- List package references of a specific project:

```
dotnet list SentimentAnalysis.csproj package
```

- List package references that have newer versions available, including prerelease versions:

```
dotnet list package --outdated --include-prerelease
```

- List package references for a specific target framework:

```
dotnet list package --framework netcoreapp3.0
```

dotnet remove package

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet remove package` - Removes package reference from a project file.

Synopsis

```
dotnet remove [<PROJECT>] package <PACKAGE_NAME>
```

```
dotnet remove package -h|--help
```

Description

The `dotnet remove package` command provides a convenient option to remove a NuGet package reference from a project.

Arguments

`PROJECT`

Specifies the project file. If not specified, the command searches the current directory for one.

`PACKAGE_NAME`

The package reference to remove.

Options

• `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Remove `Newtonsoft.Json` NuGet package from a project in the current directory:

```
dotnet remove package Newtonsoft.Json
```

dotnet add reference

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet add reference` - Adds project-to-project (P2P) references.

Synopsis

```
dotnet add [<PROJECT>] reference [-f|--framework <FRAMEWORK>]
```

```
[--interactive] <PROJECT_REFERENCES>
```

```
dotnet add reference -h|--help
```

Description

The `dotnet add reference` command provides a convenient option to add project references to a project. After running the command, the `<ProjectReference>` elements are added to the project file.

```
<ItemGroup>
  <ProjectReference Include="app.csproj" />
  <ProjectReference Include=".\\lib2\\lib2.csproj" />
  <ProjectReference Include=".\\lib1\\lib1.csproj" />
</ItemGroup>
```

Arguments

- `PROJECT`

Specifies the project file. If not specified, the command searches the current directory for one.

- `PROJECT_REFERENCES`

Project-to-project (P2P) references to add. Specify one or more projects. [Glob patterns](#) are supported on Unix/Linux-based systems.

Options

- `-f|--framework <FRAMEWORK>`

Adds project references only when targeting a specific [framework](#) using the TFM format.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

Examples

- Add a project reference:

```
dotnet add app/app.csproj reference lib/lib.csproj
```

- Add multiple project references to the project in the current directory:

```
dotnet add reference lib1/lib1.csproj lib2/lib2.csproj
```

- Add multiple project references using a globbing pattern on Linux/Unix:

```
dotnet add app/app.csproj reference **/*.csproj
```

dotnet list reference

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet list reference` - Lists project-to-project references.

Synopsis

```
dotnet list [<PROJECT>] reference
```

```
dotnet list -h|--help
```

Description

The `dotnet list reference` command provides a convenient option to list project references for a given project.

Arguments

- `PROJECT`

The project file to operate on. If a file is not specified, the command will search the current directory for one.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- List the project references for the specified project:

```
dotnet list app/app.csproj reference
```

- List the project references for the project in the current directory:

```
dotnet list reference
```

dotnet remove reference

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet remove reference` - Removes project-to-project (P2P) references.

Synopsis

```
dotnet remove [<PROJECT>] reference [-f|--framework <FRAMEWORK>]  
<PROJECT_REFERENCES>  
  
dotnet remove reference -h|--help
```

Description

The `dotnet remove reference` command provides a convenient option to remove project references from a project.

Arguments

`PROJECT`

Target project file. If not specified, the command searches the current directory for one.

`PROJECT_REFERENCES`

Project-to-project (P2P) references to remove. You can specify one or multiple projects. [Glob patterns](#) are supported on Unix/Linux based terminals.

Options

• `-?|-h|--help`

Prints out a description of how to use the command.

• `-f|--framework <FRAMEWORK>`

Removes the reference only when targeting a specific [framework](#) using the TFM format.

Examples

- Remove a project reference from the specified project:

```
dotnet remove app/app.csproj reference lib/lib.csproj
```

- Remove multiple project references from the project in the current directory:

```
dotnet remove reference lib1/lib1.csproj lib2/lib2.csproj
```

- Remove multiple project references using a glob pattern on Unix/Linux:

```
dotnet remove app/app.csproj reference **/*.csproj`
```

dotnet build

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet build` - Builds a project and all of its dependencies.

Synopsis

```
dotnet build [<PROJECT>|<SOLUTION>] [-a|--arch <ARCHITECTURE>]
  [-c|--configuration <CONFIGURATION>] [-f|--framework <FRAMEWORK>]
  [--force] [--interactive] [--no-dependencies] [--no-incremental]
  [--no-restore] [--nologo] [--no-self-contained] [--os <OS>]
  [-o|--output <OUTPUT_DIRECTORY>] [-r|--runtime <RUNTIME_IDENTIFIER>]
  [--self-contained [true|false]] [--source <SOURCE>]
  [-v|--verbosity <LEVEL>] [--version-suffix <VERSION_SUFFIX>]

dotnet build -h|--help
```

Description

The `dotnet build` command builds the project and its dependencies into a set of binaries. The binaries include the project's code in Intermediate Language (IL) files with a `.dll` extension. Depending on the project type and settings, other files may be included, such as:

- An executable that can be used to run the application, if the project type is an executable targeting .NET Core 3.0 or later.
- Symbol files used for debugging with a `.pdb` extension.
- A `.deps.json` file, which lists the dependencies of the application or library.
- A `.runtimeconfig.json` file, which specifies the shared runtime and its version for an application.
- Other libraries that the project depends on (via project references or NuGet package references).

For executable projects targeting versions earlier than .NET Core 3.0, library dependencies from NuGet are typically NOT copied to the output folder. They're resolved from the NuGet global packages folder at run time. With that in mind, the product of `dotnet build` isn't ready to be transferred to another machine to run. To create a version of the application that can be deployed, you need to publish it (for example, with the `dotnet publish` command). For more information, see [.NET Application Deployment](#).

For executable projects targeting .NET Core 3.0 and later, library dependencies are copied to the output folder. This means that if there isn't any other publish-specific logic (such as Web projects have), the build output should be deployable.

Implicit restore

Building requires the `project.assets.json` file, which lists the dependencies of your application. The file is created when `dotnet restore` is executed. Without the assets file in place, the tooling can't resolve reference assemblies, which results in errors.

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable

implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

This command supports the `dotnet restore` options when passed in the long form (for example, `--source`). Short form options, such as `-s`, are not supported.

Executable or library output

Whether the project is executable or not is determined by the `<OutputType>` property in the project file. The following example shows a project that produces executable code:

```
<PropertyGroup>
  <OutputType>Exe</OutputType>
</PropertyGroup>
```

To produce a library, omit the `<OutputType>` property or change its value to `Library`. The IL DLL for a library doesn't contain entry points and can't be executed.

MSBuild

`dotnet build` uses MSBuild to build the project, so it supports both parallel and incremental builds. For more information, see [Incremental Builds](#).

In addition to its options, the `dotnet build` command accepts MSBuild options, such as `-p` for setting properties or `-l` to define a logger. For more information about these options, see the [MSBuild Command-Line Reference](#). Or you can also use the `dotnet msbuild` command.

NOTE

When `dotnet build` is run automatically by `dotnet run`, arguments like `-property:property=value` aren't respected.

Running `dotnet build` is equivalent to running `dotnet msbuild -restore`; however, the default verbosity of the output is different.

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Arguments

PROJECT | SOLUTION

The project or solution file to build. If a project or solution file isn't specified, MSBuild searches the current working directory for a file that has a file extension that ends in either `proj` or `sln` and uses that file.

Options

- `-a|--arch <ARCHITECTURE>`

Specifies the target architecture. This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where

the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--arch x86` sets the RID to `win-x86`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6 Preview 7.

- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project.

- `-f|--framework <FRAMEWORK>`

Compiles for a specific [framework](#). The framework must be defined in the [project file](#).

- `--force`

Forces all dependencies to be resolved even if the last restore was successful. Specifying this flag is the same as deleting the `project.assets.json` file.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

- `--no-dependencies`

Ignores project-to-project (P2P) references and only builds the specified root project.

- `--no-incremental`

Marks the build as unsafe for incremental build. This flag turns off incremental compilation and forces a clean rebuild of the project's dependency graph.

- `--no-restore`

Doesn't execute an implicit restore during build.

- `--nologo`

Doesn't display the startup banner or the copyright message.

- `--no-self-contained`

Publishes the application as a framework dependent application. A compatible .NET runtime must be installed on the target machine to run the application. Available since .NET 6 SDK.

- `-o|--output <OUTPUT_DIRECTORY>`

Directory in which to place the built binaries. If not specified, the default path is `./bin/<configuration>/<framework>/`. For projects with multiple target frameworks (via the `TargetFrameworks` property), you also need to define `--framework` when you specify this option.

- `--os <OS>`

Specifies the target operating system (OS). This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--os linux` sets the RID to `linux-x64`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6.

- `-r|--runtime <RUNTIME_IDENTIFIER>`

Specifies the target runtime. For a list of Runtime Identifiers (RIDs), see the [RID catalog](#). If you use this option with .NET 6 SDK, use `--self-contained` or `--no-self-contained` also. If not specified, the default is to build for the current OS and architecture.

- `--self-contained [true|false]`

Publishes the .NET runtime with the application so the runtime doesn't need to be installed on the target machine. The default is `true` if a runtime identifier is specified. Available since .NET 6 SDK.

- `--source <SOURCE>`

The URI of the NuGet package source to use during the restore operation.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

- `--version-suffix <VERSION_SUFFIX>`

Sets the value of the `$(VersionSuffix)` property to use when building the project. This only works if the `$(Version)` property isn't set. Then, `$(Version)` is set to the `$(VersionPrefix)` combined with the `$(VersionSuffix)`, separated by a dash.

Examples

- Build a project and its dependencies:

```
dotnet build
```

- Build a project and its dependencies using Release configuration:

```
dotnet build --configuration Release
```

- Build a project and its dependencies for a specific runtime (in this example, Ubuntu 18.04):

```
dotnet build --runtime ubuntu.18.04-x64
```

- Build the project and use the specified NuGet package source during the restore operation:

```
dotnet build --source c:\packages\mypackages
```

- Build the project and set version 1.2.3.4 as a build parameter using the `-p` [MSBuild option](#):

```
dotnet build -p:Version=1.2.3.4
```

dotnet build-server

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet build-server` - Interacts with servers started by a build.

Synopsis

```
dotnet build-server shutdown [--msbuild] [--razor] [--vbcscompiler]  
dotnet build-server shutdown -h|--help  
dotnet build-server -h|--help
```

Commands

- `shutdown`

Shuts down build servers that are started from dotnet. By default, all servers are shut down.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--msbuild`

Shuts down the MSBuild build server.

- `--razor`

Shuts down the Razor build server.

- `--vbcscompiler`

Shuts down the VB/C# compiler build server.

dotnet clean

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet clean` - Cleans the output of a project.

Synopsis

```
dotnet clean [<PROJECT>|<SOLUTION>] [-c|--configuration <CONFIGURATION>]
    [-f|--framework <FRAMEWORK>] [--interactive]
    [--nologo] [-o|--output <OUTPUT_DIRECTORY>]
    [-r|--runtime <RUNTIME_IDENTIFIER>] [-v|--verbosity <LEVEL>]

dotnet clean -h|--help
```

Description

The `dotnet clean` command cleans the output of the previous build. It's implemented as an [MSBuild target](#), so the project is evaluated when the command is run. Only the outputs created during the build are cleaned. Both intermediate (*obj*) and final output (*bin*) folders are cleaned.

Arguments

`PROJECT | SOLUTION`

The MSBuild project or solution to clean. If a project or solution file is not specified, MSBuild searches the current working directory for a file that has a file extension that ends in *proj* or *sln*, and uses that file.

Options

- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project. This option is only required when cleaning if you specified it during build time.

- `-f|--framework <FRAMEWORK>`

The [framework](#) that was specified at build time. The framework must be defined in the [project file](#). If you specified the framework at build time, you must specify the framework when cleaning.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

- `--nologo`
Doesn't display the startup banner or the copyright message.
- `-o|--output <OUTPUT_DIRECTORY>`
The directory that contains the build artifacts to clean. Specify the `-f|--framework <FRAMEWORK>` switch with the output directory switch if you specified the framework when the project was built.
- `-r|--runtime <RUNTIME_IDENTIFIER>`
Cleans the output folder of the specified runtime. This is used when a [self-contained deployment](#) was created.
- `-v|--verbosity <LEVEL>`
Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `normal`. For more information, see [LoggerVerbosity](#).

Examples

- Clean a default build of the project:

```
dotnet clean
```

- Clean a project built using the Release configuration:

```
dotnet clean --configuration Release
```

dotnet dev-certs

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet dev-certs` - Generates a self-signed certificate to enable HTTPS use in development.

Synopsis

```
dotnet dev-certs https  
[-c|--check] [--clean] [-ep|--export-path <PATH>]  
[--format] [-i|--import] [-np|--no-password]  
[-p|--password] [-q|--quiet] [-t|--trust]  
[-v|--verbose] [--version]  
  
dotnet dev-certs https -h|--help
```

Description

The `dotnet dev-certs` command manages a self-signed certificate to enable HTTPS use in local web app development. Its main functions are:

- Generating a certificate for use with HTTPS endpoints during development.
- Trusting the generated certificate on the local machine.
- Removing the generated certificate from the local machine.
- Exporting a certificate in various formats so that it can be used by other tools.
- Importing an existing certificate generated by the tool into the local machine.

Commands

- `https`

`dotnet dev-certs` has only one command: `https`. The `dotnet dev-certs https` command with no options checks if a development certificate is present in the current user's certificate store on the machine. If the command finds a development certificate, it displays a message like the following example:

```
A valid HTTPS certificate is already present.
```

If the command doesn't find a development certificate, it creates one in the current user's certificate store, the store named `My` in the location `CurrentUser`. The physical location of the certificate is an implementation detail of the .NET runtime that could change at any time. On macOS in .NET 7.0, the certificate is stored in the user key chain and as a PFX file: `~/.aspnet/https-aspnetcore-localhost-<Thumbprint[0..5]>.pfx`.

After creating a certificate, the command displays a message like the following example:

```
The HTTPS developer certificate was generated successfully.
```

By default, the newly created certificate is not trusted. To trust the certificate, use the `--trust` option.

To create a file that you can use with other tools, use the `--export-path` option.

Options

- `-c|--check`

Checks for the existence of the development certificate but doesn't perform any action. Use this option with the `--trust` option to check if the certificate is not only valid but also trusted.

- `--clean`

Removes all HTTPS development certificates from the certificate store by using the .NET certificate store API. Doesn't remove any physical files that were created by using the `--export-path` option. On macOS in .NET 7.0, the `dotnet dev-certs` command creates the certificate on a path on disk, and the clean operation removes that certificate file.

If there's at least one certificate in the certificate store, the command displays a message like the following example:

```
Cleaning HTTPS development certificates
from the machine.
A prompt might get displayed to confirm
the removal of some of the certificates.

HTTPS development certificates
successfully removed from the machine.
```

- `-ep|--export-path <PATH>`

Exports the certificate to a file so that it can be used by other tools. Specify the full path to the exported certificate file, including the file name. The type of certificate files that are created depends on which options are used with `--export-path`:

OPTIONS	WHAT IS EXPORTED
<code>--export-path</code>	The public part of the certificate as a PFX file.
<code>--export-path --format PEM</code>	The public part of the certificate in PEM format. No separate <code>.key</code> file is created.
<code>--export-path --password</code>	The public and private parts of the certificate as a PFX file.
<code>--export-path --password --format PEM</code>	The public and private parts of the certificate as a pair of files in PEM format. The key file has the <code>.key</code> extension and is protected by the given password.
<code>--export-path --no-password --format PEM</code>	The public and private parts of the certificate as a pair of files in PEM format. The key file has the <code>.key</code> extension and is exported in plain text. The <code>--no-password</code> option is intended for internal testing use only.

- `--format`

When used with `--export-path`, specifies the format of the exported certificate file. Valid values are `PFX` and `PEM`, case-insensitive. `PFX` is the default.

The file format is independent of the file name extension. For example, if you specify `--format pfx` and `--export-path ./cert.pem`, you'll get a file named `cert.pem` in `PFX` format.

For information about the effect of this option when used with `--password`, `--no-password`, or without either of those options, see [--export-path](#) earlier in this article.

- `-i|--import <PATH>`

Imports the provided HTTPS development certificate into the local machine. Requires that you also specify the `--clean` option, which clears out any existing HTTPS developer certificates.

`PATH` specifies a path to a PFX certificate file. Provide the password with the `--password` option.

- `-np| --no-password`

Doesn't use a password for the key when exporting a certificate to PEM format files. The key file is exported in plain text. This option is not applicable to PFX files and is intended for internal testing use only.

- `-p| --password`

Specifies the password to use:

- When exporting the development certificate to a PFX or PEM file.
- When importing a PFX file.

When exporting with `--format PEM`, the public and private parts of the certificate are exported as a pair of files in PEM format. The key file has the `.key` extension and is protected by the given password. In addition to the file name specified for the `--export-path` option, the command creates another file in the same directory with the same name but a `.key` extension. For example, the following command will generate a file named `/localhost.pem` and a file named `/localhost.key` in the `/home/user` directory:

```
dotnet dev-certs https --format pem -ep /home/user/localhost.pem -p $CREDENTIAL_PLACEHOLDER$
```

In the example, `$CREDENTIAL_PLACEHOLDER$` represents a password.

- `-q| --quiet`

Display warnings and errors only.

- `-t| --trust`

Trusters the certificate on the local machine.

If this option isn't specified, the certificate is added to the certificate store but not to a trusted list.

When combined with the `--check` option, validates that the certificate is trusted.

- `-v| --verbose`

Display debug information.

Examples

- Check for the presence of a development certificate, and create one in the default certificate store if one doesn't exist yet. But don't trust the certificate.

```
dotnet dev-certs https
```

- Remove any development certificates that already exist on the local machine.

```
dotnet dev-certs https --clean
```

- Import a PFX file.

```
dotnet dev-certs https --clean --import ./certificate.pfx -p $CREDENTIAL_PLACEHOLDER$
```

In the preceding example, `$CREDENTIAL_PLACEHOLDER$` represents a password.

- Check if a trusted development certificate is present on the local machine.

```
dotnet dev-certs https --check --trust
```

- Create a certificate, trust it, and export it to a PFX file.

```
dotnet dev-certs https -ep ./certificate.pfx -p $CREDENTIAL_PLACEHOLDER$ --trust
```

- Create a certificate, trust it, and export it to a PEM file.

```
dotnet dev-certs https -ep ./certificate.crt --trust --format PEM
```

- Create a certificate, trust it, and export it to a PEM file including the private key:

```
dotnet dev-certs https -ep ./certificate.crt -p $CREDENTIAL_PLACEHOLDER$ --trust --format PEM
```

dotnet format

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6.x SDK and later versions

Name

`dotnet format` - Formats code to match `editorconfig` settings.

Synopsis

```
dotnet format [options] [<PROJECT | SOLUTION>]
```

```
dotnet format -h|--help
```

Description

`dotnet format` is a code formatter that applies style preferences to a project or solution. Preferences will be read from an `.editorconfig` file, if present, otherwise a default set of preferences will be used. For more information, see the [EditorConfig documentation](#).

Arguments

`PROJECT | SOLUTION`

The MSBuild project or solution to run code formatting on. If a project or solution file is not specified, MSBuild searches the current working directory for a file that has a file extension that ends in `proj` or `sln`, and uses that file.

Options

None of the options below are required for the `dotnet format` command to succeed, but you can use them to further customize what is formatted and by which rules.

- `--diagnostics <DIAGNOSTICS>`

A space-separated list of diagnostic IDs to use as a filter when fixing code style or third-party issues.

Default value is whichever IDs are listed in the `.editorconfig` file. For a list of built-in analyzer rule IDs that you can specify, see the [list of IDs for code-analysis style rules](#).

- `--severity`

The minimum severity of diagnostics to fix. Allowed values are `info`, `warn`, and `error`. The default value is `warn`.

- `--no-restore`

Doesn't execute an implicit restore before formatting. Default is to do implicit restore.

- `--verify-no-changes`

Verifies that no formatting changes would be performed. Terminates with a non zero exit code if any files

would have been formatted.

- `--include <INCLUDE>`

A space-separated list of relative file or folder paths to include in formatting. The default is all files in the solution or project.

- `--exclude <EXCLUDE>`

A space-separated list of relative file or folder paths to exclude from formatting. The default is none.

- `--include-generated`

Formats files generated by the SDK.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. Default value is `m[inimal]`.

- `--binarylog <BINARY-LOG-PATH>`

Logs all project or solution load information to a binary log file.

- `--report <REPORT-PATH>`

Produces a JSON report in the directory specified by `<REPORT_PATH>`.

- `-h|--help`

Shows help and usage information

Subcommands

Whitespace

`dotnet format whitespace` - Formats code to match `editorconfig` settings for whitespace.

Description

The `dotnet format whitespace` subcommand will only run formatting rules associated with whitespace formatting. For a complete list of possible formatting options that you can specify in your `.editorconfig` file, see the [C# formatting options](#).

Options

- `--folder`

Treat the `<PROJECT | SOLUTION>` argument as a path to a simple folder of code files.

Style

`dotnet format style` - Formats code to match EditorConfig settings for code style.

Description

The `dotnet format style` subcommand will only run formatting rule associated with code style formatting. For a complete list of formatting options that you can specify in your `editorconfig` file, see [Code style rules](#).

Options

- `--diagnostics <DIAGNOSTICS>`

A space-separated list of diagnostic IDs to use as a filter when fixing code style or third-party issues.

Default value is whichever IDs are listed in the `.editorconfig` file. For a list of built-in analyzer rule IDs that you can specify, see the [list of IDs for code-analysis style rules](#).

- `--severity`

The minimum severity of diagnostics to fix. Allowed values are `info`, `warn`, and `error`. The default value is `warn`.

Analyzers

```
dotnet format analyzers
```

 - Formats code to match `editorconfig` settings for analyzers.

Description

The `dotnet format analyzers` subcommand will only run formatting rule associated with analyzers. For a list of analyzer rules that you can specify in your `editorconfig` file, see [Code style rules](#).

Options

- `--diagnostics <DIAGNOSTICS>`

A space-separated list of diagnostic IDs to use as a filter when fixing code style or third-party issues.

Default value is whichever IDs are listed in the `.editorconfig` file. For a list of built-in analyzer rule IDs that you can specify, see the [list of IDs for code-analysis style rules](#).

- `--severity`

The minimum severity of diagnostics to fix. Allowed values are `info`, `warn`, and `error`. The default value is `warn`.

Examples

- Format all code in the solution:

```
dotnet format ./solution.sln
```

- Clean up all code in the application project:

```
dotnet format ./src/application.csproj
```

- Verify that all code is correctly formatted:

```
dotnet format --verify-no-changes
```

- Clean up all code in the `src` and `tests` directory but not in `src/submodule-a`:

```
dotnet format --include ./src/ ./tests/ --exclude ./src/submodule-a/
```

dotnet help reference

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet help` - Shows more detailed documentation online for the specified command.

Synopsis

```
dotnet help <COMMAND_NAME> [-h|--help]
```

Description

The `dotnet help` command opens up the reference page for more detailed information about the specified command.

Arguments

- `COMMAND_NAME`

Name of the .NET CLI command. For a list of the valid CLI commands, see [CLI commands](#).

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Opens the documentation page for the `dotnet new` command:

```
dotnet help new
```

dotnet migrate

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.x SDK

Name

`dotnet migrate` - Migrates a Preview 2 .NET Core project to a .NET Core SDK-style project.

Synopsis

```
dotnet migrate [<SOLUTION_FILE|PROJECT_DIR>] [--format-report-file-json <REPORT_FILE>]
  [-r|--report-file <REPORT_FILE>] [-s|--skip-project-references [Debug|Release]]
  [--skip-backup] [-t|--template-file <TEMPLATE_FILE>] [-v|--sdk-package-version]
  [-x|--xproj-file]

dotnet migrate -h|--help
```

Description

This command is deprecated. The `dotnet migrate` command is no longer available starting with .NET Core 3.0 SDK. It can only migrate a Preview 2 .NET Core project to a 1.x .NET Core project, which is out of support.

By default, the command migrates the root project and any project references that the root project contains. This behavior is disabled using the `--skip-project-references` option at run time.

Migration can be performed on the following assets:

- A single project by specifying the *project.json* file to migrate.
- All of the directories specified in the *global.json* file by passing in a path to the *global.json* file.
- A *solution.sln* file, where it migrates the projects referenced in the solution.
- On all subdirectories of the given directory recursively.

The `dotnet migrate` command keeps the migrated *project.json* file inside a `backup` directory, which it creates if the directory doesn't exist. This behavior is overridden using the `--skip-backup` option.

By default, the migration operation outputs the state of the migration process to standard output (STDOUT). If you use the `--report-file <REPORT_FILE>` option, the output is saved to the file specify.

The `dotnet migrate` command only supports valid Preview 2 *project.json*-based projects. This means that you cannot use it to migrate DNX or Preview 1 *project.json*-based projects directly to MSBuild/csproj projects. You first need to manually migrate the project to a Preview 2 *project.json*-based project and then use the `dotnet migrate` command to migrate the project.

Arguments

`PROJECT_JSON/GLOBAL_JSON/SOLUTION_FILE/PROJECT_DIR`

The path to one of the following:

- a *project.json* file to migrate.
- a *global.json* file: the folders specified in *global.json* are migrated.

- a *solution.sln* file: the projects referenced in the solution are migrated.
- a directory to migrate: recursively searches for *project.json* files to migrate inside the specified directory.

Defaults to current directory if nothing is specified.

Options

```
--format-report-file-json <REPORT_FILE>
```

Output migration report file as JSON rather than user messages.

```
-h|--help
```

Prints out a short help for the command.

```
-r|--report-file <REPORT_FILE>
```

Output migration report to a file in addition to the console.

```
-s|--skip-project-references [Debug|Release]
```

Skip migrating project references. By default, project references are migrated recursively.

```
--skip-backup
```

Skip moving *project.json*, *global.json*, and **.xproj* to a `backup` directory after successful migration.

```
-t|--template-file <TEMPLATE_FILE>
```

Template csproj file to use for migration. By default, the same template as the one dropped by `dotnet new console` is used.

```
-v|--sdk-package-version <VERSION>
```

The version of the sdk package that's referenced in the migrated app. The default is the version of the SDK in `dotnet new .`

```
-x|--xproj-file <FILE>
```

The path to the xproj file to use. Required when there is more than one xproj in a project directory.

Examples

Migrate a project in the current directory and all of its project-to-project dependencies:

```
dotnet migrate
```

Migrate all projects that *global.json* file includes:

```
dotnet migrate path/to/global.json
```

Migrate only the current project and no project-to-project (P2P) dependencies. Also, use a specific SDK version:

```
dotnet migrate -s -v 1.0.0-preview4
```

dotnet msbuild

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet msbuild` - Builds a project and all of its dependencies. Note: A solution or project file may need to be specified if there are multiple.

Synopsis

```
dotnet msbuild <MSBUILD_ARGUMENTS>  
dotnet msbuild -h
```

Description

The `dotnet msbuild` command allows access to a fully functional MSBuild.

The command has the exact same capabilities as the existing MSBuild command-line client for SDK-style projects only. The options are all the same. For more information about the available options, see the [MSBuild command-line reference](#).

The `dotnet build` command is equivalent to `dotnet msbuild -restore`. When you don't want to build the project and you have a specific target you want to run, use `dotnet build` or `dotnet msbuild` and specify the target.

Examples

- Build a project and its dependencies:

```
dotnet msbuild
```

- Build a project and its dependencies using Release configuration:

```
dotnet msbuild -property:Configuration=Release
```

- Run the publish target and publish for the `osx.10.11-x64` RID:

```
dotnet msbuild -target:Publish -property:RuntimeIdentifiers=osx.10.11-x64
```

- See the whole project with all targets included by the SDK:

```
dotnet msbuild -preprocess  
dotnet msbuild -preprocess:<fileName>.xml
```

dotnet new <TEMPLATE>

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet new` - Creates a new project, configuration file, or solution based on the specified template.

Synopsis

```
dotnet new <TEMPLATE> [--dry-run] [--force] [-lang|--language {"C#"|"F#"|VB"}]
[-n|--name <OUTPUT_NAME>] [--no-update-check] [-o|--output <OUTPUT_DIRECTORY>] [Template options]

dotnet new -h|--help
```

Description

The `dotnet new` command creates a .NET project or other artifacts based on a template.

The command calls the [template engine](#) to create the artifacts on disk based on the specified template and options.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore](#) documentation.

Arguments

- **TEMPLATE**

The template to instantiate when the command is invoked. Each template might have specific options you can pass. For more information, see [Template options](#).

You can run `dotnet new --list` to see a list of all installed templates.

Starting with .NET Core 3.0 SDK and ending with .NET Core 5.0.300 SDK, the CLI searches for templates in NuGet.org when you invoke the `dotnet new` command in the following conditions:

- If the CLI can't find a template match when invoking `dotnet new`, not even partial.
- If there's a newer version of the template available. In this case, the project or artifact is created but the CLI warns you about an updated version of the template.

Starting with .NET Core 5.0.300 SDK, the `--search` option should be used to search for templates in NuGet.org..

The following table shows the templates that come pre-installed with the .NET SDK. The default language for the template is shown inside the brackets. Click on the short name link to see the specific template options.

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
Console Application	console	[C#], F#, VB	Common/Console	1.0
Class library	classlib	[C#], F#, VB	Common/Library	1.0
WPF Application	wpf	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF Class library	wpfclib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF Custom Control Library	wpfcustomcontrollib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF User Control Library	wpfusercontrollib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
Windows Forms (WinForms) Application	winforms	[C#], VB	Common/WinForms	3.0 (5.0 for VB)
Windows Forms (WinForms) Class library	winformslib	[C#], VB	Common/WinForms	3.0 (5.0 for VB)
Worker Service	worker	[C#]	Common/Worker/Web	3.0
Unit Test Project	mstest	[C#], F#, VB	Test/MSTest	1.0
NUnit 3 Test Project	nunit	[C#], F#, VB	Test/NUnit	2.1.400
NUnit 3 Test Item	nunit-test	[C#], F#, VB	Test/NUnit	2.2

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
xUnit Test Project	xunit	[C#], F#, VB	Test/xUnit	1.0
Razor Component	razorcomponent	[C#]	Web/ASP.NET	3.0
Razor Page	page	[C#]	Web/ASP.NET	2.0
MVC ViewImports	viewimports	[C#]	Web/ASP.NET	2.0

ASP.NET Core with React.js and Redux	reactredux	[C#]	Web/MVC/SPA	2.0
Razor Class Library	razorclasslib	[C#]	Web/Razor/Library/Razor Class Library	2.1
ASP.NET Core Web API	webapi	[C#], F#	Web/WebAPI	1.0
ASP.NET Core gRPC Service	grpc	[C#]	Web/gRPC	3.0
dotnet gitignore file	gitignore		Config	3.0
global.json file	globaljson		Config	2.0
NuGet Config	nugetconfig		Config	1.0
Dotnet local tool manifest file	tool-manifest		Config	3.0

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
Web Config	webconfig		Config	1.0
Solution File	sln		Solution	1.0
Protocol Buffer File	proto		Web/gRPC	3.0
EditorConfig file	editorconfig		Config	6.0

Options

- `--dry-run`

Displays a summary of what would happen if the given command were run if it would result in a template creation. Available since .NET Core 2.2 SDK.

- `--force`

Forces content to be generated even if it would change existing files. This is required when the template chosen would override existing files in the output directory.

- `-?|-h|--help`

Prints out help for the command. It can be invoked for the `dotnet new` command itself or for any template. For example, `dotnet new mvc --help`.

- `-lang|--language {C#|F#|VB}`

The language of the template to create. The language accepted varies by the template (see defaults in the [arguments](#) section). Not valid for some templates.

NOTE

Some shells interpret `#` as a special character. In those cases, enclose the language parameter value in quotes. For example, `dotnet new console -lang "F#"`.

- `-n|--name <OUTPUT_NAME>`

The name for the created output. If no name is specified, the name of the current directory is used.

- `-no-update-check`

Disables checking for template package updates when instantiating a template. Available since .NET 6.0.100 SDK. When instantiating the template from a template package that was installed by using `dotnet new --install`, `dotnet new` checks if there is an update for the template. Starting with .NET 6, no update checks are done for .NET default templates. To update .NET default templates, install the patch version of the .NET SDK.

- `-o|--output <OUTPUT_DIRECTORY>`

Location to place the generated output. The default is the current directory.

Template options

Each template may have additional options defined. For more information, see [.NET default templates for](#)

```
dotnet new .
```

Examples

- Create a C# console application project:

```
dotnet new console
```

- Create an F# console application project in the current directory:

```
dotnet new console --language "F#"
```

- Create a .NET Standard 2.0 class library project in the specified directory:

```
dotnet new classlib --framework "netstandard2.0" -o MyLibrary
```

- Create a new ASP.NET Core C# MVC project in the current directory with no authentication:

```
dotnet new mvc -au None
```

- Create a new xUnit project:

```
dotnet new xunit
```

- Create a *global.json* in the current directory setting the SDK version to 3.1.101:

```
dotnet new globaljson --sdk-version 3.1.101
```

- Show help for the C# console application template:

```
dotnet new console -h
```

- Show help for the F# console application template:

```
dotnet new console --language "F#" -h
```

dotnet new list

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet new --list` - Lists available templates to be run using `dotnet new`.

Synopsis

```
dotnet new [<TEMPLATE_NAME>] -l|--list [--author <AUTHOR>] [-lang|--language {"C#"|"F#"|VB"}]
[--tag <TAG>] [--type <TYPE>] [--columns <COLUMNS>] [--columns-all]
```

Description

The `dotnet new --list` option lists available templates to use with `dotnet new`. If the `<TEMPLATE_NAME>` is specified, lists templates containing the specified name. This option lists only default and installed templates. To find templates in NuGet that you can install locally, use the `--search` option.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Examples of the new syntax:

- Show help for `list` subcommand

```
dotnet new list --help
```

- List all templates matching the `we` substring that support the F# language.

```
dotnet new list we --language "F#"
```

Arguments

- `TEMPLATE_NAME`

If the argument is specified, only the templates containing `<TEMPLATE_NAME>` in template name or short name will be shown.

NOTE

Starting with .NET SDK 6.0.100, you can put the `<TEMPLATE_NAME>` argument after the `--list` option. For example, `dotnet new --list web` provides the same result as `dotnet new web --list`. Using more than one argument is not allowed.

Options

- `--author <AUTHOR>`

Filters templates based on template author. Partial match is supported. Available since .NET Core 5.0.300 SDK.

- `--columns <COLUMNS>`

Comma-separated list of columns to display in the output. The supported columns are:

- `language` - A comma-separated list of languages supported by the template.
- `tags` - The list of template tags.
- `author` - The template author.
- `type` - The template type: project or item.

The template name and short name are always shown. The default list of columns is template name, short name, language, and tags. This list is equivalent to specifying `--columns=language,tags`. Available since .NET Core 5.0.300 SDK.

- `--columns-all`

Displays all columns in the output. Available since .NET Core 5.0.300 SDK.

- `-lang|--language {C#|F#|VB}`

Filters templates based on language supported by the template. The language accepted varies by the template. Not valid for some templates.

NOTE

Some shells interpret `#` as a special character. In those cases, enclose the language parameter value in quotes.

For example, `dotnet new --list --language "F#"`.

- `--tag <TAG>`

Filters templates based on template tags. To be selected, a template must have at least one tag that exactly matches the criteria. Available since .NET Core 5.0.300 SDK.

- `--type <TYPE>`

Filters templates based on template type. Predefined values are `project`, `item`, and `solution`.

Examples

- List all templates

```
dotnet new --list
```

- List all Single Page Application (SPA) templates:

- since .NET SDK 6.0.100

```
dotnet new --list spa
```

- before .NET SDK 6.0.100

```
dotnet new spa --list
```

- List all templates matching the *we* substring.

- since .NET SDK 6.0.100

```
dotnet new --list we
```

- before .NET SDK 6.0.100

```
dotnet new we --list
```

- List all templates matching the *we* substring that support the F# language.

```
dotnet new --list we --language "F#"
```

- List all item templates.

```
dotnet new --list --type item
```

- List all C# templates, showing the author and the type in the output.

```
dotnet new --list --language "C#" --columns "author,type"
```

See also

- [dotnet new command](#)
- [dotnet new --search option](#)
- [Custom templates for dotnet new](#)

dotnet new search

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 5.0.300 SDK and later versions

Name

`dotnet new --search` - searches for the templates supported by `dotnet new` on NuGet.org.

Synopsis

```
dotnet new <TEMPLATE_NAME> --search

dotnet new [<TEMPLATE_NAME>] --search [--author <AUTHOR>] [-lang|--language {"C#"|"F#"|VB}]
  [--package <PACKAGE>] [--tag <TAG>] [--type <TYPE>]
  [--columns <COLUMNS>] [--columns-all]
```

Description

The `dotnet new --search` option searches for templates supported by `dotnet new` on NuGet.org. When the `<TEMPLATE_NAME>` is specified, searches for templates containing the specified name.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Examples of the new syntax:

- Show help for the `search` subcommand.

```
dotnet new search --help
```

- Search for all templates available on NuGet.org matching the "we" substring and supporting the F# language

```
dotnet new search we --language "F#"
```

Arguments

- `<TEMPLATE_NAME>`

If the argument is specified, only templates containing `<TEMPLATE_NAME>` in the template name or short name will be shown. The argument is mandatory when `--author`, `--language`, `--package`, `--tag` or `--type` options are not specified.

NOTE

Starting with .NET SDK 6.0.100, you can put the `<TEMPLATE_NAME>` argument after the `--search` option. For example, `dotnet new --search web` provides the same result as `dotnet new web --search`. Using more than one argument is not allowed.

Options

- `--author <AUTHOR>`

Filters templates based on template author. Partial match is supported.

- `--columns <COLUMNS>`

Comma-separated list of columns to display in the output. The supported columns are:

- `language` - A comma-separated list of languages supported by the template.
- `tags` - The list of template tags.
- `author` - The template author.
- `type` - The template type: project or item.

The template name, short name, package name and total downloads count are always shown. The default list of columns is template name, short name, author, language, package, and total downloads. This list is equivalent to specifying `--columns=author,language`.

- `--columns-all`

Displays all columns in the output.

- `-lang|--language {C#|F#|VB}`

Filters templates based on language supported by the template. The language accepted varies by the template. Not valid for some templates.

NOTE

Some shells interpret `#` as a special character. In those cases, enclose the language parameter value in quotes.

For example, `dotnet new --search --language "F#"`.

- `--package <PACKAGE>`

Filters templates based on NuGet package ID. Partial match is supported.

- `--tag <TAG>`

Filters templates based on template tags. To be selected, a template must have at least one tag that exactly matches the criteria.

- `--type <TYPE>`

Filters templates based on template type. Predefined values are `project`, `item`, and `solution`.

NOTE

To ensure that the template package appears in `dotnet new --search` result, set the NuGet package type to `Template`.

Examples

- Search for all templates available on NuGet.org matching the `spa` substring.

- since .NET SDK 6.0.100

```
dotnet new --search spa
```

- before .NET SDK 6.0.100

```
dotnet new spa --search
```

- Search for all templates available on NuGet.org matching the `we` substring and supporting the F# language.

- since .NET SDK 6.0.100

```
dotnet new --search we --language "F#"
```

- before .NET SDK 6.0.100

```
dotnet new we --search --language "F#"
```

- Search for item templates.

```
dotnet new --search --type item
```

- Search for all C# templates, showing the type and tags in the output.

```
dotnet new --search --language "C#" --columns "type,tags"
```

- [dotnet new --list option](#)
- [Custom templates for dotnet new](#)

dotnet new install

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet new --install` - installs a template package.

Synopsis

```
dotnet new --install <PATH|NUGET_ID> [--interactive] [--nuget-source <SOURCE>]
```

Description

The `dotnet new --install` command installs a template package from the `PATH` or `NUGET_ID` provided. If you want to install a specific version or prerelease version of a template package, specify the version in the format `<package-name>:<package-version>`. By default, `dotnet new` passes * for the version, which represents the latest stable package version. For more information, see the [Examples](#) section.

If a version of the template package was already installed when you run this command, the template package will be updated to the specified version. If no version is specified, the package is updated to the latest stable version. Starting with .NET SDK 6.0.100, if the argument specifies the version, and that version of the NuGet package is already installed, it won't be reinstalled. If the argument is a `PATH` and it's already installed, it won't be reinstalled.

Prior to .NET SDK 6.0.100, template packages were managed individually for each .NET SDK version, including [patch versions](#). For example, if you install the template package using `dotnet new --install` in .NET SDK 5.0.100, it will be installed only for .NET SDK 5.0.100. Templates from the package won't be available in other .NET SDK versions installed on your machine.

Starting with .NET SDK 6.0.100, installed template packages are available in later .NET SDK versions installed on your machine. A template package installed in .NET SDK 6.0.100 will also be available in .NET SDK 6.0.101, .NET SDK 6.0.200, and so on. However, these template packages won't be available in .NET SDK versions prior to .NET SDK 6.0.100. To use a template package installed in .NET SDK 6.0.100 or later in earlier .NET SDK versions, you need to install it using `dotnet new --install` in that .NET SDK version.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Examples of new syntax:

- Show help for `install` subcommand

```
dotnet new install --help
```

- Install the latest version of Azure web jobs project template package:

```
dotnet new install Microsoft.Azure.WebJobs.ProjectTemplates
```

Options

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.
Available since .NET 5.0 SDK.

- `--nuget-source <SOURCE>`

By default, `dotnet new --install` uses the hierarchy of NuGet configuration files from the current directory to determine the NuGet source the package can be installed from. If `--nuget-source` is specified, the source will be added to the list of sources to be checked.

To check the configured sources for the current directory use `dotnet nuget list source`. For more information, see [Common NuGet Configurations](#)

Examples

- Install the latest version of SPA templates for ASP.NET Core:

```
dotnet new --install Microsoft.DotNet.Web.Spa.ProjectTemplates
```

- Install version 2.0 of the SPA templates for ASP.NET Core:

```
dotnet new --install Microsoft.DotNet.Web.Spa.ProjectTemplates::2.0.0
```

- Install version 2.0 of the SPA templates for ASP.NET Core from a custom NuGet source using interactive mode:

```
dotnet new --install Microsoft.DotNet.Web.Spa.ProjectTemplates::2.0.0 --nuget-source "https://api.my-
custom-nuget.com/v3/index.json" --interactive
```

dotnet new uninstall

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet new --uninstall` - uninstalls a template package.

Synopsis

```
dotnet new --uninstall <PATH|NUGET_ID>
```

Description

The `dotnet new --uninstall` command uninstalls a template package at the `<PATH|NUGET_ID>` provided. When the `<PATH|NUGET_ID>` value isn't specified, all currently installed template packages and their associated templates are displayed. When specifying `NUGET_ID`, don't include the version number.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Examples of the new syntax:

- Show help for the `uninstall` subcommand.

```
dotnet new uninstall --help
```

- List the installed templates and details about them, including how to uninstall them:

```
dotnet new uninstall
```

- Uninstall the Azure web jobs project template package:

```
dotnet new uninstall Microsoft.Azure.WebJobs.ProjectTemplates
```

Examples

- List the installed templates and details about them, including how to uninstall them:

```
dotnet new --uninstall
```

- Uninstall the SPA templates for ASP.NET Core:

```
dotnet new --uninstall Microsoft.DotNet.Web.Spa.ProjectTemplates
```

dotnet new update

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet new --update-check` - Checks for available updates for installed template packages.

`dotnet new --update-apply` - Applies updates to installed template packages.

Synopsis

```
dotnet new --update-check
```

```
dotnet new --update-apply
```

Description

The `dotnet new --update-check` option checks if there are updates available for the template packages that are currently installed. The `dotnet new --update-apply` option checks if there are updates available for the template packages that are currently installed and installs them.

NOTE

Starting with .NET SDK 7.0.100 Preview 2, the `dotnet new` syntax has changed:

- The `--list`, `--search`, `--install`, and `--uninstall` options became `list`, `search`, `install` and `uninstall` subcommands.
- The `--update-apply` option became the `update` subcommand.
- to use `--update-check`, use the `update` subcommand with the `--check` option.

Other options that were available before are still available to use with their respective subcommands. Separate help for each subcommand is available via the `-h` or `--help` option: `dotnet new <subcommand> --help` lists all supported options for the subcommand.

Additionally, tab completion is now available for `dotnet new`. It supports completion for installed template names, as well as completion for the options a selected template provides. To activate tab completion for the .NET SDK, see [Enable tab completion](#).

Examples of the new syntax:

- Show help for the `update` subcommand.

```
dotnet new update --help
```

- Check for updates for installed template packages:

```
dotnet new update --check
```

- Update installed template packages:

```
dotnet new update
```

.NET default templates for dotnet new

9/20/2022 • 17 minutes to read • [Edit Online](#)

When you install the [.NET SDK](#), you receive over a dozen built-in templates for creating projects and files, including console apps, class libraries, unit test projects, ASP.NET Core apps (including [Angular](#) and [React](#) projects), and configuration files. To list the built-in templates, run the `dotnet new` command with the `-l|--list` option:

```
dotnet new --list
```

The following table shows the templates that come pre-installed with the .NET SDK. The default language for the template is shown inside the brackets. Click on the short name link to see the specific template options.

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
Console Application	console	[C#], F#, VB	Common/Console	1.0
Class library	classlib	[C#], F#, VB	Common/Library	1.0
WPF Application	wpf	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF Class library	wpflib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF Custom Control Library	wpfcustomcontrollib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
WPF User Control Library	wpfusercontrollib	[C#], VB	Common/WPF	3.0 (5.0 for VB)
Windows Forms (WinForms) Application	winforms	[C#], VB	Common/WinForms	3.0 (5.0 for VB)
Windows Forms (WinForms) Class library	winformslib	[C#], VB	Common/WinForms	3.0 (5.0 for VB)
Worker Service	worker	[C#]	Common/Worker/Web	3.0
Unit Test Project	mstest	[C#], F#, VB	Test/MSTest	1.0
NUnit 3 Test Project	nunit	[C#], F#, VB	Test/NUnit	2.1.400
NUnit 3 Test Item	nunit-test	[C#], F#, VB	Test/NUnit	2.2
xUnit Test Project	xunit	[C#], F#, VB	Test/xUnit	1.0
Razor Component	razorcomponent	[C#]	Web/ASP.NET	3.0

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
Razor Page	<code>page</code>	[C#]	Web/ASP.NET	2.0
MVC ViewImports	<code>viewimports</code>	[C#]	Web/ASP.NET	2.0
MVC ViewStart	<code>viewstart</code>	[C#]	Web/ASP.NET	2.0
Blazor Server App	<code>blazorserver</code>	[C#]	Web/Blazor	3.0

NuGet Config	<code>nugetconfig</code>		Config	1.0
Dotnet local tool manifest file	<code>tool-manifest</code>		Config	3.0

TEMPLATES	SHORT NAME	LANGUAGE	TAGS	INTRODUCED
Web Config	webconfig		Config	1.0
Solution File	sln		Solution	1.0
Protocol Buffer File	proto		Web/gRPC	3.0
EditorConfig file	editorconfig (#editorconfig)		Config	6.0

Template options

Each template may have additional options available. The core templates have the following additional options:

console

- f|--framework <FRAMEWORK>

Specifies the [framework](#) to target. Available since .NET Core 3.0 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	net6.0
5.0	net5.0
3.1	netcoreapp3.1

The ability to create a project for an earlier TFM depends on having that version of the SDK installed. For example, if you have only the .NET 6 SDK installed, then the only value available for `--framework` is `net6.0`. If you install the .NET 5 SDK, the value `net5.0` becomes available for `--framework`. If you install the .NET Core 3.1 SDK, `netcoreapp3.1` becomes available, and so on. So by specifying `--framework netcoreapp3.1` you can target .NET Core 3.1 even while running `dotnet new` in the .NET 6 SDK.

Alternatively, to create a project that targets a framework earlier than the SDK that you're using, you might be able to do it by installing the NuGet package for the template. [Common](#), [web](#), and [SPA](#) project types use different packages per target framework moniker (TFM). For example, to create a `console` project that targets `netcoreapp1.0`, run `dotnet new --install Microsoft.DotNet.Common.ProjectTemplates.1.x`.

- langVersion <VERSION_NUMBER>

Sets the `LangVersion` property in the created project file. For example, use `--langVersion 7.3` to use C# 7.3. Not supported for F#. Available since .NET Core 2.2 SDK.

For a list of default C# versions, see [Defaults](#).

- no-restore

If specified, doesn't execute an implicit restore during project creation. Available since .NET Core 2.2 SDK.

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

`classlib`

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Values: `net6.0`, `net5.0`, or `netcoreapp3.1` to create a .NET Class Library or `netstandard<version>` to create a .NET Standard Class Library. The default value for .NET 6 SDK is `net6.0`.

To create a project that targets a framework earlier than the SDK that you're using, see [--framework for console projects](#) earlier in this article.

- `--langVersion <VERSION_NUMBER>`

Sets the `LangVersion` property in the created project file. For example, use `--langVersion 7.3` to use C# 7.3. Not supported for F#. Available since .NET Core 2.2 SDK.

For a list of default C# versions, see [Defaults](#).

- `--no-restore`

Doesn't execute an implicit restore during project creation.

`wpf`, `wpflib`, `wpfcustomcontrollib`, `wpfusercontrollib`

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. For the .NET 6 SDK, the default value is `net6.0`. Available since .NET Core 3.1 SDK.

- `--langVersion <VERSION_NUMBER>`

Sets the `LangVersion` property in the created project file. For example, use `--langVersion 7.3` to use C# 7.3.

For a list of default C# versions, see [Defaults](#).

- `--no-restore`

Doesn't execute an implicit restore during project creation.

`winforms`, `winformslib`

- `--langVersion <VERSION_NUMBER>`

Sets the `LangVersion` property in the created project file. For example, use `--langVersion 7.3` to use C# 7.3.

For a list of default C# versions, see [Defaults](#).

- `--no-restore`

Doesn't execute an implicit restore during project creation.

worker , grpc

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. The default value is `netcoreapp3.1`. Available since .NET Core 3.1 SDK.

To create a project that targets a framework earlier than the SDK that you're using, see [--framework for console projects](#) earlier in this article.

- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

mstest , xunit

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Option available since .NET Core 3.0 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>

The ability to create a project for an earlier TFM depends on having that version of the SDK installed. For example, if you have only the .NET 6 SDK installed, then the only value available for `--framework` is `net6.0`. If you install the .NET 5 SDK, the value `net5.0` becomes available for `--framework`. If you install the .NET Core 3.1 SDK, `netcoreapp3.1` becomes available, and so on. So by specifying `--framework netcoreapp3.1` you can target .NET Core 3.1 even while running `dotnet new` in the .NET 6 SDK.

- `-p|--enable-pack`

Enables packaging for the project using [dotnet pack](#).

- `--no-restore`

Doesn't execute an implicit restore during project creation.

nunit

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	net6.0
5.0	net5.0
3.1	netcoreapp3.1

The ability to create a project for an earlier TFM depends on having that version of the SDK installed. For example, if you have only the .NET 6 SDK installed, then the only value available for `--framework` is `net6.0`. If you install the .NET 5 SDK, the value `net5.0` becomes available for `--framework`. If you install the .NET Core 3.1 SDK, `netcoreapp3.1` becomes available, and so on. So by specifying `--framework netcoreapp3.1` you can target .NET Core 3.1 even while running `dotnet new` in the .NET 6 SDK.

- `-p|--enable-pack`

Enables packaging for the project using [dotnet pack](#).

- `--no-restore`

Doesn't execute an implicit restore during project creation.

page

- `-na|--namespace <NAMESPACE_NAME>`

Namespace for the generated code. The default value is `MyApp.Namespace`.

- `-np|--no-pagemodel`

Creates the page without a PageModel.

viewimports , proto

- `-na|--namespace <NAMESPACE_NAME>`

Namespace for the generated code. The default value is `MyApp.Namespace`.

blazorserver

- `-au|--auth <AUTHENTICATION_TYPE>`

The type of authentication to use. The possible values are:

- `None` - No authentication (Default).
- `Individual` - Individual authentication.
- `IndividualB2C` - Individual authentication with Azure AD B2C.
- `SingleOrg` - Organizational authentication for a single tenant.
- `MultiOrg` - Organizational authentication for multiple tenants.

- `Windows` - Windows authentication.
- `--aad-b2c-instance <INSTANCE>`

The Azure Active Directory B2C instance to connect to. Use with `IndividualB2C` authentication. The default value is `https://login.microsoftonline.com/tfp/`.
- `-ssp|--susi-policy-id <ID>`

The sign-in and sign-up policy ID for this project. Use with `IndividualB2C` authentication.
- `-rp|--reset-password-policy-id <ID>`

The reset password policy ID for this project. Use with `IndividualB2C` authentication.
- `-ep|--edit-profile-policy-id <ID>`

The edit profile policy ID for this project. Use with `IndividualB2C` authentication.
- `--aad-instance <INSTANCE>`

The Azure Active Directory instance to connect to. Use with `SingleOrg` or `MultiOrg` authentication. The default value is `https://login.microsoftonline.com/`.
- `--client-id <ID>`

The Client ID for this project. Use with `IndividualB2C`, `SingleOrg`, or `MultiOrg` authentication. The default value is `11111111-1111-1111-1111-111111111111`.
- `--domain <DOMAIN>`

The domain for the directory tenant. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `qualified.domain.name`.
- `--tenant-id <ID>`

The TenantId ID of the directory to connect to. Use with `SingleOrg` authentication. The default value is `22222222-2222-2222-2222-222222222222`.
- `--callback-path <PATH>`

The request path within the application's base path of the redirect URI. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `/signin-oidc`.
- `-r|--org-read-access`

Allows this application read-access to the directory. Only applies to `SingleOrg` or `MultiOrg` authentication.
- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.
- `--no-https`

Turns off HTTPS. This option only applies if `Individual`, `IndividualB2C`, `SingleOrg`, or `MultiOrg` aren't being used for `--auth`.
- `-uld|--use-local-db`

Specifies LocalDB should be used instead of SQLite. Only applies to `Individual` or `IndividualB2C` authentication.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in *launchSettings.json*.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in *launchSettings.json*. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

blazorwasm

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
7.0	<code>net7.0</code>
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>

To create a project that targets a framework earlier than the SDK that you're using, see [--framework for console projects](#) earlier in this article.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `-ho|--hosted`

Includes an ASP.NET Core host for the Blazor WebAssembly app.

- `-au|--auth <AUTHENTICATION_TYPE>`

The type of authentication to use. The possible values are:

- `None` - No authentication (Default).
- `Individual` - Individual authentication.
- `IndividualB2C` - Individual authentication with Azure AD B2C.
- `SingleOrg` - Organizational authentication for a single tenant.

- `--authority <AUTHORITY>`

The authority of the OIDC provider. Use with `Individual` authentication. The default value is `https://login.microsoftonline.com/`.

- `--aad-b2c-instance <INSTANCE>`

The Azure Active Directory B2C instance to connect to. Use with `IndividualB2C` authentication. The default value is `https://aadB2CInstance.b2clogin.com/`.

- `-ssp|--sus-i-policy-id <ID>`

The sign-in and sign-up policy ID for this project. Use with `IndividualB2C` authentication.

- `--aad-instance <INSTANCE>`

The Azure Active Directory instance to connect to. Use with `SingleOrg` authentication. The default value is `https://login.microsoftonline.com/`.

- `--client-id <ID>`

The Client ID for this project. Use with `IndividualB2C`, `SingleOrg`, or `Individual` authentication in standalone scenarios. The default value is `33333333-3333-3333-3333333333333333`.

- `--domain <DOMAIN>`

The domain for the directory tenant. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `qualified.domain.name`.

- `--app-id-uri <URI>`

The App ID Uri for the server API you want to call. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `api.id.uri`.

- `--api-client-id <ID>`

The Client ID for the API that the server hosts. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `11111111-1111-1111-1111111111111111`.

- `-s|--default-scope <SCOPE>`

The API scope the client needs to request to provision an access token. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `user_impersonation`.

- `--tenant-id <ID>`

The TenantId ID of the directory to connect to. Use with `SingleOrg` authentication. The default value is `22222222-2222-2222-2222-222222222222`.

- `-r|--org-read-access`

Allows this application read-access to the directory. Only applies to `SingleOrg` authentication.

- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.

- `-p|--pwa`

produces a Progressive Web Application (PWA) supporting installation and offline use.

- `--no-https`

Turns off HTTPS. This option only applies if `Individual`, `IndividualB2C`, or `SingleOrg` aren't being used

for `--auth`.

- `-uld|--use-local-db`

Specifies LocalDB should be used instead of SQLite. Only applies to `Individual` or `IndividualB2C` authentication.

- `--called-api-url <URL>`

URL of the API to call from the web app. Only applies to `SingleOrg` or `IndividualB2C` authentication without an ASP.NET Core host specified. The default value is `https://graph.microsoft.com/v1.0/me`.

- `--calls-graph`

Specifies if the web app calls Microsoft Graph. Only applies to `SingleOrg` authentication.

- `--called-api-scopes <SCOPES>`

Scopes to request to call the API from the web app. Only applies to `SingleOrg` or `IndividualB2C` authentication without an ASP.NET Core host specified. The default is `user.read`.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in `launchSettings.json`.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in `launchSettings.json`. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements. Available since .NET SDK 6.0.300. Default value: `false`.

web

- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.

- `-f|--framework <FRAMEWORK>`

Specifies the `framework` to target. Option not available in .NET Core 2.2 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>
3.0	<code>netcoreapp3.0</code>

SDK VERSION	DEFAULT VALUE
2.1	netcoreapp2.1

To create a project that targets a framework earlier than the SDK that you're using, see [--framework](#) for [console](#) projects earlier in this article.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--no-https`

Turns off HTTPS.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in *launchSettings.json*.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in *launchSettings.json*. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

`mvc` , `webapp`

- `-au|--auth <AUTHENTICATION_TYPE>`

The type of authentication to use. The possible values are:

- `None` - No authentication (Default).
- `Individual` - Individual authentication.
- `IndividualB2C` - Individual authentication with Azure AD B2C.
- `SingleOrg` - Organizational authentication for a single tenant.
- `MultiOrg` - Organizational authentication for multiple tenants.
- `Windows` - Windows authentication.

- `--aad-b2c-instance <INSTANCE>`

The Azure Active Directory B2C instance to connect to. Use with `IndividualB2C` authentication. The default value is `https://login.microsoftonline.com/tfp/`.

- `-ssp|--sus-i-policy-id <ID>`

The sign-in and sign-up policy ID for this project. Use with `IndividualB2C` authentication.

- `-rp|--reset-password-policy-id <ID>`

The reset password policy ID for this project. Use with `IndividualB2C` authentication.

- `-ep|--edit-profile-policy-id <ID>`

The edit profile policy ID for this project. Use with `IndividualB2C` authentication.

- `--aad-instance <INSTANCE>`

The Azure Active Directory instance to connect to. Use with `SingleOrg` or `MultiOrg` authentication. The default value is `https://login.microsoftonline.com/`.

- `--client-id <ID>`

The Client ID for this project. Use with `IndividualB2C`, `SingleOrg`, or `MultiOrg` authentication. The default value is `11111111-1111-1111-1111-111111111111`.

- `--domain <DOMAIN>`

The domain for the directory tenant. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `qualified.domain.name`.

- `--tenant-id <ID>`

The TenantId ID of the directory to connect to. Use with `SingleOrg` authentication. The default value is `22222222-2222-2222-2222-222222222222`.

- `--callback-path <PATH>`

The request path within the application's base path of the redirect URI. Use with `SingleOrg` or `IndividualB2C` authentication. The default value is `/signin-oidc`.

- `-r|--org-read-access`

Allows this application read-access to the directory. Only applies to `SingleOrg` or `MultiOrg` authentication.

- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.

- `--no-https`

Turns off HTTPS. This option only applies if `Individual`, `IndividualB2C`, `SingleOrg`, or `MultiOrg` aren't being used.

- `-uld|--use-local-db`

Specifies LocalDB should be used instead of SQLite. Only applies to `Individual` or `IndividualB2C` authentication.

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Option available since .NET Core 3.0 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>

SDK VERSION	DEFAULT VALUE
3.0	netcoreapp3.0

To create a project that targets a framework earlier than the SDK that you're using, see [--framework](#) for [console projects](#) earlier in this article.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--use-browserlink`

Includes BrowserLink in the project. Option not available in .NET Core 2.2 and 3.1 SDK.

- `-rrc|--razor-runtime-compilation`

Determines if the project is configured to use [Razor runtime compilation](#) in Debug builds. Option available since .NET Core 3.1.201 SDK.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in *launchSettings.json*.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in *launchSettings.json*. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

`angular` , `react`

- `-au|--auth <AUTHENTICATION_TYPE>`

The type of authentication to use. Available since .NET Core 3.0 SDK.

The possible values are:

- `None` - No authentication (Default).
- `Individual` - Individual authentication.

- `--exclude-launch-settings`

Excludes *launchSettings.json* from the generated template.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--no-https`

Turns off HTTPS. This option only applies if authentication is `None`.

- `-uld|--use-local-db`

Specifies LocalDB should be used instead of SQLite. Only applies to `Individual` or `IndividualB2C` authentication. Available since .NET Core 3.0 SDK.

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Option not available in .NET Core 2.2 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>
3.0	<code>netcoreapp3.0</code>
2.1	<code>netcoreapp2.0</code>

To create a project that targets a framework earlier than the SDK that you're using, see [--framework](#) for [console projects](#) earlier in this article.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in *launchSettings.json*.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in *launchSettings.json*. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

reactredux

- `--exclude-launch-settings`

Excludes *launchSettings.json* from the generated template.

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Option not available in .NET Core 2.2 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>

SDK VERSION	DEFAULT VALUE
3.1	netcoreapp3.1
3.0	netcoreapp3.0
2.1	netcoreapp2.0

To create a project that targets a framework earlier than the SDK that you're using, see [--framework](#) for [console projects](#) earlier in this article.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--no-https`

Turns off HTTPS.

- `--kestrelHttpPort`

Port number to use for the HTTP endpoint in *launchSettings.json*.

- `--kestrelHttpsPort`

Port number to use for the HTTPS endpoint in *launchSettings.json*. This option is not applicable when the parameter `no-https` is used (but `no-https` is ignored when an individual or organizational authentication setting is chosen for `--auth`).

razorclasslib

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `-s|--support-pages-and-views`

Supports adding traditional Razor pages and Views in addition to components to this library. Available since .NET Core 3.0 SDK.

webapi

- `-au|--auth <AUTHENTICATION_TYPE>`

The type of authentication to use. The possible values are:

- `None` - No authentication (Default).
- `IndividualB2C` - Individual authentication with Azure AD B2C.
- `SingleOrg` - Organizational authentication for a single tenant.
- `Windows` - Windows authentication.

- `--aad-b2c-instance <INSTANCE>`

The Azure Active Directory B2C instance to connect to. Use with `IndividualB2C` authentication. The default value is `https://login.microsoftonline.com/tfp/`.

- `-minimal`

Create a project that uses the [ASP.NET Core minimal API](#).

- `-ssp|--susi-policy-id <ID>`

The sign-in and sign-up policy ID for this project. Use with `IndividualB2C` authentication.

- `--aad-instance <INSTANCE>`

The Azure Active Directory instance to connect to. Use with `SingleOrg` authentication. The default value is `https://login.microsoftonline.com/`.

- `--client-id <ID>`

The Client ID for this project. Use with `IndividualB2C` or `SingleOrg` authentication. The default value is `11111111-1111-1111-1111-111111111111`.

- `--domain <DOMAIN>`

The domain for the directory tenant. Use with `IndividualB2C` or `SingleOrg` authentication. The default value is `qualified.domain.name`.

- `--tenant-id <ID>`

The TenantId ID of the directory to connect to. Use with `SingleOrg` authentication. The default value is `22222222-2222-2222-2222-222222222222`.

- `-r|--org-read-access`

Allows this application read-access to the directory. Only applies to `SingleOrg` authentication.

- `--exclude-launch-settings`

Excludes `launchSettings.json` from the generated template.

- `--no-https`

Turns off HTTPS. `app.UseHsts` and `app.UseHttpsRedirection` aren't added to `Startup.Configure`. This option only applies if `IndividualB2C` or `SingleOrg` aren't being used for authentication.

- `-uld|--use-local-db`

Specifies LocalDB should be used instead of SQLite. Only applies to `IndividualB2C` authentication.

- `-f|--framework <FRAMEWORK>`

Specifies the [framework](#) to target. Option not available in .NET Core 2.2 SDK.

The following table lists the default values according to the SDK version number you're using:

SDK VERSION	DEFAULT VALUE
6.0	<code>net6.0</code>
5.0	<code>net5.0</code>
3.1	<code>netcoreapp3.1</code>
3.0	<code>netcoreapp3.0</code>

SDK VERSION	DEFAULT VALUE
2.1	netcoreapp2.1

To create a project that targets a framework earlier than the SDK that you're using, see [--framework](#) for [console projects](#) earlier in this article.

- `--no-restore`

Doesn't execute an implicit restore during project creation.

- `--use-program-main`

If specified, an explicit `Program` class and `Main` method will be used instead of top-level statements.

Available since .NET SDK 6.0.300. Default value: `false`.

globaljson

- `--sdk-version <VERSION_NUMBER>`

Specifies the version of the .NET SDK to use in the *global.json* file.

editorconfig

Creates an *.editorconfig* file for configuring code style preferences.

- `--empty`

Creates an empty *.editorconfig* instead of the defaults for .NET.

Custom templates for dotnet new

9/20/2022 • 10 minutes to read • [Edit Online](#)

The [.NET SDK](#) comes with many templates already installed and ready for you to use. The `dotnet new` command isn't only the way to use a template, but also how to install and uninstall templates. You can create your own custom templates for any type of project, such as an app, service, tool, or class library. You can even create a template that outputs one or more independent files, such as a configuration file.

You can install custom templates from a NuGet package on any NuGet feed, by referencing a NuGet `.nupkg` file directly, or by specifying a file system directory that contains the template. The template engine offers features that allow you to replace values, include and exclude files, and execute custom processing operations when your template is used.

The template engine is open source, and the online code repository is at [dotnettemplating](#) on GitHub. More templates, including templates from third parties, can be found using `dotnet new --search`. For more information about creating and using custom templates, see [How to create your own templates for dotnet new](#) and the [dotnettemplating GitHub repo Wiki](#).

NOTE

Template examples are available at the [dotnet/dotnet-template-samples](#) GitHub repository. However, while these examples are good resource for learning how the templates work, the repository is archived and no longer maintained. The examples may be out of date and no longer working.

To follow a walkthrough and create a template, see the [Create a custom template for dotnet new](#) tutorial.

.NET default templates

When you install the [.NET SDK](#), you receive over a dozen built-in templates for creating projects and files, including console apps, class libraries, unit test projects, ASP.NET Core apps (including [Angular](#) and [React](#) projects), and configuration files. To list the built-in templates, run the `dotnet new` command with the `-l|--list` option:

```
dotnet new --list
```

Configuration

A template is composed of the following parts:

- Source files and folders.
- A configuration file (`template.json`).

Source files and folders

The source files and folders include whatever files and folders you want the template engine to use when the `dotnet new <TEMPLATE>` command is run. The template engine is designed to use *runnable projects* as source code to produce projects. This has several benefits:

- The template engine doesn't require you to inject special tokens into your project's source code.
- The code files aren't special files or modified in any way to work with the template engine. So, the tools you normally use when working with projects also work with template content.

- You build, run, and debug your template projects just like you do for any of your other projects.
- You can quickly create a template from an existing project just by adding a `./template.config/template.json` configuration file to the project.

Files and folders stored in the template aren't limited to formal .NET project types. Source files and folders may consist of any content that you wish to create when the template is used, even if the template engine produces just one file as its output.

Files generated by the template can be modified based on logic and settings you've provided in the `template.json` configuration file. The user can override these settings by passing options to the `dotnet new <TEMPLATE>` command. A common example of custom logic is providing a name for a class or variable in the code file that's deployed by a template.

template.json

The `template.json` file is placed in a `.template.config` folder in the root directory of the template. The file provides configuration information to the template engine. The minimum configuration requires the members shown in the following table, which is sufficient to create a functional template.

MEMBER	TYPE	DESCRIPTION
<code>\$schema</code>	URI	The JSON schema for the <code>template.json</code> file. Editors that support JSON schemas enable JSON-editing features when the schema is specified. For example, Visual Studio Code requires this member to enable IntelliSense. Use a value of http://json.schemastore.org/template .
<code>author</code>	string	The author of the template.
<code>classifications</code>	array(string)	Zero or more characteristics of the template that a user might use to find the template when searching for it. The classifications also appear in the <code>Tags</code> column when it appears in a list of templates produced by using the <code>dotnet new -l</code> or <code>dotnet new --list</code> command.
<code>identity</code>	string	A unique name for this template.
<code>name</code>	string	The name for the template that users should see.
<code>shortName</code>	string	A default shorthand name for selecting the template that applies to environments where the template name is specified by the user, not selected via a GUI. For example, the short name is useful when using templates from a command prompt with CLI commands.

MEMBER	TYPE	DESCRIPTION
<code>sourceName</code>	string	The name in the source tree to replace with the name the user specifies. The template engine will look for any occurrence of the <code>sourceName</code> mentioned in the config file and replace it in file names and file contents. The value to be replaced with can be given using the <code>-n</code> or <code>--name</code> options while running a template. If no name is specified, the current directory is used.
<code>preferNameDirectory</code>	boolean	Indicates whether to create a directory for the template if name is specified but an output directory is not set (instead of creating the content directly in the current directory). The default value is false.

The full schema for the `template.json` file is found at the [JSON Schema Store](#). For more information about the `template.json` file, see the [dotnet templating wiki](#). For deeper examples and information on how to make your templates visible in Visual Studio, check out the [resources that Sayed Hashimi has created](#).

Example

For example, here is a template folder that contains two content files: `console.cs` and `readme.txt`. Take notice that there is the required folder named `.template.config` that contains the `template.json` file.

```

└── mytemplate
    ├── console.cs
    └── readme.txt
    └── .template.config
        └── template.json

```

The `template.json` file looks like the following:

```
{
  "$schema": "http://json.schemastore.org/template",
  "author": "Travis Chau",
  "classifications": [ "Common", "Console" ],
  "identity": "AdatumCorporation.ConsoleTemplate.CSharp",
  "name": "Adatum Corporation Console Application",
  "shortName": "adatumconsole"
}
```

The `mytemplate` folder is an installable template package. Once the package is installed, the `shortName` can be used with the `dotnet new` command. For example, `dotnet new adatumconsole` would output the `console.cs` and `readme.txt` files to the current folder.

Packing a template into a NuGet package (nupkg file)

A custom template is packed with the `dotnet pack` command and a `.csproj` file. Alternatively, [NuGet](#) can be used with the `nuget pack` command along with a `.nuspec` file. However, NuGet requires the .NET Framework on Windows and [Mono](#) on Linux and macOS.

The `.csproj` file is slightly different from a traditional code-project `.csproj` file. Note the following settings:

1. The `<PackageType>` setting is added and set to `Template`.
2. The `<PackageVersion>` setting is added and set to a valid [NuGet version number](#).
3. The `<PackageId>` setting is added and set to a unique identifier. This identifier is used to uninstall the template pack and is used by NuGet feeds to register your template pack.
4. Generic metadata settings should be set: `<Title>`, `<Authors>`, `<Description>`, and `<PackageTags>`.
5. The `<TargetFramework>` setting must be set, even though the binary produced by the template process isn't used. In the example below it's set to `netstandard2.0`.

A template package, in the form of a `.nupkg` NuGet package, requires that all templates be stored in the `content` folder within the package. There are a few more settings to add to a `.csproj` file to ensure that the generated `.nupkg` can be installed as a template pack:

1. The `<IncludeContentInPack>` setting is set to `true` to include any file the project sets as `content` in the NuGet package.
2. The `<IncludeBuildOutput>` setting is set to `false` to exclude all binaries generated by the compiler from the NuGet package.
3. The `<ContentTargetFolders>` setting is set to `content`. This makes sure that the files set as `content` are stored in the `content` folder in the NuGet package. This folder in the NuGet package is parsed by the dotnet template system.

An easy way to exclude all code files from being compiled by your template project is by using the `<Compile Remove="****" />` item in your project file, inside an `<ItemGroup>` element.

An easy way to structure your template pack is to put all templates in individual folders, and then each template folder inside of a `templates` folder that is located in the same directory as your `.csproj` file. This way, you can use a single project item to include all files and folders in the `templates` as `content`. Inside of an `<ItemGroup>` element, create a `<Content Include="templates****" Exclude="templates**\bin**;templates**\obj**" />` item.

Here is an example `.csproj` file that follows all of the guidelines above. It packs the `templates` child folder to the `content` package folder and excludes any code file from being compiled.

```

<Project Sdk="Microsoft.NET.Sdk">

  <PropertyGroup>
    <PackageType>Template</PackageType>
    <PackageVersion>1.0</PackageVersion>
    <PackageId>AdatumCorporation.Utility.Templates</PackageId>
    <Title>AdatumCorporation Templates</Title>
    <Authors>Me</Authors>
    <Description>Templates to use when creating an application for Adatum Corporation.</Description>
    <PackageTags>dotnet-new;templates;contoso</PackageTags>
    <TargetFramework>netstandard2.0</TargetFramework>

    <IncludeContentInPack>true</IncludeContentInPack>
    <IncludeBuildOutput>false</IncludeBuildOutput>
    <ContentTargetFolders>content</ContentTargetFolders>
  </PropertyGroup>

  <ItemGroup>
    <Content Include="templates\**\**" Exclude="templates\**\bin\**;templates\**\obj\**" />
    <Compile Remove="**\**" />
  </ItemGroup>

</Project>

```

The example below demonstrates the file and folder structure of using a `.csproj` to create a template pack. The `MyDotnetTemplates.csproj` file and `templates` folder are both located at the root of a directory named `project_folder`. The `templates` folder contains two templates, `mytemplate1` and `mytemplate2`. Each template has

content files and a `.template.config` folder with a `template.json` config file.

```
project_folder
|   MyDotnetTemplates.csproj
|
└── templates
    ├── mytemplate1
    |   ├── console.cs
    |   └── readme.txt
    |
    └── .template.config
        template.json
    └── mytemplate2
        ├── otherfile.cs
        └── .template.config
            template.json
```

NOTE

To ensure that the template package appears in `dotnet new --search` result, set the NuGet package type to `Template`.

Installing a template package

Use the `dotnet new --install` command to install a template package.

To install a template package from a NuGet package stored at nuget.org

Use the NuGet package identifier to install a template package.

```
dotnet new --install <NUGET_PACKAGE_ID>
```

To install a template package from a local nupkg file

Provide the path to a `.nupkg` NuGet package file.

```
dotnet new --install <PATH_TO_NUPKG_FILE>
```

To install a template package from a file system directory

Templates can be installed from a template folder, such as the `mytemplate1` folder from the example above. Specify the folder path of the `.template.config` folder. The path to the template directory does not need to be absolute.

```
dotnet new --install <FILE_SYSTEM_DIRECTORY>
```

Get a list of installed template packages

The `uninstall` command, without any other parameters, will list all installed template packages and included templates.

```
dotnet new --uninstall
```

That command returns something similar to the following output:

```
Template Instantiation Commands for .NET CLI

Currently installed items:
Microsoft.DotNet.Common.ItemTemplates
    Templates:
        global.json file (globaljson)
        NuGet Config (nugetconfig)
        Solution File (sln)
        Dotnet local tool manifest file (tool-manifest)
        Web Config (webconfig)
Microsoft.DotNet.Common.ProjectTemplates.3.0
    Templates:
        Class library (classlib) C#
        Class library (classlib) F#
        Class library (classlib) VB
        Console Application (console) C#
        Console Application (console) F#
        Console Application (console) VB
...
...
```

The first level of items after `Currently installed items:` are the identifiers used in uninstalling a template package. And in the example above, `Microsoft.DotNet.Common.ItemTemplates` and `Microsoft.DotNet.Common.ProjectTemplates.3.0` are listed. If the template package was installed by using a file system path, this identifier will be the folder path of the `.template.config` folder.

Uninstalling a template package

Use the `dotnet new -u|--uninstall` command to uninstall a template package.

If the package was installed by either a NuGet feed or by a `.nupkg` file directly, provide the identifier.

```
dotnet new --uninstall <NUGET_PACKAGE_ID>
```

If the package was installed by specifying a path to the `.template.config` folder, use that path to uninstall the package. You can see the absolute path of the template package in the output provided by the `dotnet new --uninstall` command. For more information, see the [Get a list of installed templates](#) section above.

```
dotnet new --uninstall <FILE_SYSTEM_DIRECTORY>
```

Create a project using a custom template

After a template is installed, use the template by executing the `dotnet new <TEMPLATE>` command as you would with any other pre-installed template. You can also specify [options](#) to the `dotnet new` command, including template-specific options you configured in the template settings. Supply the template's short name directly to the command:

```
dotnet new <TEMPLATE>
```

dotnet nuget delete

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet nuget delete` - Deletes or unlists a package from the server.

Synopsis

```
dotnet nuget delete [<PACKAGE_NAME> <PACKAGE_VERSION>] [--force-english-output]
    [--interactive] [-k|--api-key <API_KEY>] [--no-service-endpoint]
    [--non-interactive] [-s|--source <SOURCE>]
```

```
dotnet nuget delete -h|--help
```

Description

The `dotnet nuget delete` command deletes or unlists a package from the server. For [nuget.org](#), the action is to unlist the package.

Arguments

- `<PACKAGE_NAME>`

Name/ID of the package to delete.

- `<PACKAGE_VERSION>`

Version of the package to delete.

Options

- `--force-english-output`

Forces the application to run using an invariant, English-based culture.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

Available since .NET Core 3.0 SDK.

- `-k|--api-key <API_KEY>`

The API key for the server.

- `--no-service-endpoint`

Doesn't append "api/v2/package" to the source URL.

- `--non-interactive`

Doesn't prompt for user input or confirmations.

- `-s|--source <SOURCE>`

Specifies the server URL. Supported URLs for nuget.org include `https://www.nuget.org`, `https://www.nuget.org/api/v3`, and `https://www.nuget.org/api/v2/package`. For private feeds, replace the host name (for example, `%hostname%/api/v3`).

Examples

- Deletes version 1.0 of package `Microsoft.AspNetCore.Mvc`:

```
dotnet nuget delete Microsoft.AspNetCore.Mvc 1.0
```

- Deletes version 1.0 of package `Microsoft.AspNetCore.Mvc`, not prompting user for credentials or other input:

```
dotnet nuget delete Microsoft.AspNetCore.Mvc 1.0 --non-interactive
```

dotnet nuget locals

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet nuget locals` - Clears or lists local NuGet resources.

Synopsis

```
dotnet nuget locals <CACHE_LOCATION> [(-c|--clear)|(-l|--list)] [--force-english-output]
```

```
dotnet nuget locals -h|--help
```

Description

The `dotnet nuget locals` command clears or lists local NuGet resources in the http-request cache, temporary cache, or machine-wide global packages folder.

Arguments

- `CACHE_LOCATION`

The cache location to list or clear. It accepts one of the following values:

- `all` - Indicates that the specified operation is applied to all cache types: http-request cache, global packages cache, and the temporary cache.
- `http-cache` - Indicates that the specified operation is applied only to the http-request cache. The other cache locations aren't affected.
- `global-packages` - Indicates that the specified operation is applied only to the global packages cache. The other cache locations aren't affected.
- `temp` - Indicates that the specified operation is applied only to the temporary cache. The other cache locations aren't affected.

Options

- `--force-english-output`

Forces the application to run using an invariant, English-based culture.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-c|--clear`

The clear option executes a clear operation on the specified cache type. The contents of the cache directories are deleted recursively. The executing user/group must have permission to the files in the cache directories. If not, an error is displayed indicating the files/folders that weren't cleared.

- `-l|--list`

The list option is used to display the location of the specified cache type.

Examples

- Displays the paths of all the local cache directories (http-cache directory, global-packages cache directory, and temporary cache directory):

```
dotnet nuget locals all -l
```

- Displays the path for the local http-cache directory:

```
dotnet nuget locals http-cache --list
```

- Clears all files from all local cache directories (http-cache directory, global-packages cache directory, and temporary cache directory):

```
dotnet nuget locals all --clear
```

- Clears all files in local global-packages cache directory:

```
dotnet nuget locals global-packages -c
```

- Clears all files in local temporary cache directory:

```
dotnet nuget locals temp -c
```

Troubleshooting

For information on common problems and errors while using the `dotnet nuget locals` command, see [Managing the NuGet cache](#).

dotnet nuget push

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet nuget push` - Pushes a package to the server and publishes it.

Synopsis

```
dotnet nuget push [<ROOT>] [-d|--disable-buffering] [--force-english-output]
    [--interactive] [-k|--api-key <API_KEY>] [-n|--no-symbols]
    [--no-service-endpoint] [-s|--source <SOURCE>] [--skip-duplicate]
    [-sk|--symbol-api-key <API_KEY>] [-ss|--symbol-source <SOURCE>]
    [-t|--timeout <TIMEOUT>]

dotnet nuget push -h|--help
```

Description

The `dotnet nuget push` command pushes a package to the server and publishes it. The push command uses server and credential details found in the system's NuGet config file or chain of config files. For more information on config files, see [Configuring NuGet Behavior](#). NuGet's default configuration is obtained by loading `%AppData%\NuGet\NuGet.config` (Windows) or `$HOME/.nuget/NuGet/NuGet.Config` (Linux/macOS), then loading any `nuget.config` or `.nuget\NuGet.config` starting from the root of drive and ending in the current directory.

The command pushes an existing package. It doesn't create a package. To create a package, use `dotnet pack`.

Arguments

- `ROOT`

Specifies the file path to the package to be pushed.

Options

- `-d|--disable-buffering`

Disables buffering when pushing to an HTTP(S) server to reduce memory usage.

- `--force-english-output`

Forces the application to run using an invariant, English-based culture.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

Available since .NET Core 3.0 SDK.

- `-k|--api-key <API_KEY>`

The API key for the server.

- `-n|--no-symbols`

Doesn't push symbols (even if present).

- `--no-service-endpoint`

Doesn't append "api/v2/package" to the source URL.

- `-s|--source <SOURCE>`

Specifies the server URL. NuGet identifies a UNC or local folder source and simply copies the file there instead of pushing it using HTTP.

IMPORTANT

Starting with NuGet 3.4.2, this is a mandatory parameter unless the NuGet config file specifies a `DefaultPushSource` value. For more information, see [Configuring NuGet behavior](#).

- `--skip-duplicate`

When pushing multiple packages to an HTTP(S) server, treats any 409 Conflict response as a warning so that the push can continue.

- `-sk|--symbol-api-key <API_KEY>`

The API key for the symbol server.

- `-ss|--symbol-source <SOURCE>`

Specifies the symbol server URL.

- `-t|--timeout <TIMEOUT>`

Specifies the timeout for pushing to a server in seconds. Defaults to 300 seconds (5 minutes). Specifying 0 applies the default value.

Examples

- Push `foo.nupkg` to the default push source specified in the NuGet config file, using an API key:

```
dotnet nuget push foo.nupkg -k 4003d786-cc37-4004-bfdf-c4f3e8ef9b3a
```

- Push `foo.nupkg` to the official NuGet server, specifying an API key:

```
dotnet nuget push foo.nupkg -k 4003d786-cc37-4004-bfdf-c4f3e8ef9b3a -s  
https://api.nuget.org/v3/index.json
```

- Push `foo.nupkg` to the custom push source `https://customsource`, specifying an API key:

```
dotnet nuget push foo.nupkg -k 4003d786-cc37-4004-bfdf-c4f3e8ef9b3a -s https://customsource/
```

- Push *foo.nupkg* to the default push source specified in the NuGet config file:

```
dotnet nuget push foo.nupkg
```

- Push *foo.symbols.nupkg* to the default symbols source:

```
dotnet nuget push foo.symbols.nupkg
```

- Push *foo.nupkg* to the default push source specified in the NuGet config file, with a 360-second timeout:

```
dotnet nuget push foo.nupkg --timeout 360
```

- Push all *.nupkg* files in the current directory to the default push source specified in the NuGet config file:

```
dotnet nuget push "*.nupkg"
```

NOTE

If this command doesn't work, it might be due to a bug that existed in older versions of the SDK (.NET Core 2.1 SDK and earlier versions). To fix this, upgrade your SDK version or run the following command instead:

```
dotnet nuget push "**/*.nupkg"
```

NOTE

The enclosing quotes are required for shells such as bash that perform file globbing. For more information, see [NuGet/Home#4393](#).

- Push all *.nupkg* files to the default push source specified in the NuGet config file, even if a 409 Conflict response is returned by an HTTP(S) server:

```
dotnet nuget push "*.nupkg" --skip-duplicate
```

- Push all *.nupkg* files in the current directory to a local feed directory:

```
dotnet nuget push "*.nupkg" -s c:\mydir
```

- For pushing to Azure Artifacts, [see Azure Artifacts' push documentation](#).

This command doesn't store packages in a hierarchical folder structure, which is recommended to optimize performance. For more information, see [Local feeds](#).

dotnet nuget add source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget add source` - Add a NuGet source.

Synopsis

```
dotnet nuget add source <PACKAGE_SOURCE_PATH> [--name <SOURCE_NAME>] [--username <USER>]
  [--password <PASSWORD>] [--store-password-in-clear-text]
  [--valid-authentication-types <TYPES>] [--configfile <FILE>]

dotnet nuget add source -h|--help
```

Description

The `dotnet nuget add source` command adds a new package source to your NuGet configuration files.

WARNING

When adding multiple package sources, be careful not to introduce a [dependency confusion vulnerability](#).

Arguments

- `PACKAGE_SOURCE_PATH`

Path to the package source.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-n|--name <SOURCE_NAME>`

Name of the source.

- `-p|--password <PASSWORD>`

Password to be used when connecting to an authenticated source.

- `--store-password-in-clear-text`

Enables storing portable package source credentials by disabling password encryption.

- `-u|--username <USER>`

Username to be used when connecting to an authenticated source.

- `--valid-authentication-types <TYPES>`

Comma-separated list of valid authentication types for this source. Set this to `basic` if the server advertises NTLM or Negotiate and your credentials must be sent using the Basic mechanism, for instance when using a PAT with on-premises Azure DevOps Server. Other valid values include `negotiate`, `kerberos`, `ntlm`, and `digest`, but these values are unlikely to be useful.

Examples

- Add `nuget.org` as a source:

```
dotnet nuget add source https://api.nuget.org/v3/index.json -n nuget.org
```

- Add `c:\packages` as a local source:

```
dotnet nuget add source c:\packages
```

- Add a source that needs authentication:

```
dotnet nuget add source https://someServer/myTeam -n myTeam -u myUsername -p myPassword --store-password-in-clear-text
```

- Add a source that needs authentication (then go install credential provider):

```
dotnet nuget add source https://azureartifacts.microsoft.com/myTeam -n myTeam
```

dotnet nuget disable source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget disable source` - Disable a NuGet source.

Synopsis

```
dotnet nuget disable source <NAME> [--configfile <FILE>]
```

```
dotnet nuget disable source -h|--help
```

Description

The `dotnet nuget disable source` command disables an existing source in your NuGet configuration files.

Arguments

- `<NAME>`

Name of the source.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used.

If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

Examples

- Disable a source with name of `mySource`:

```
dotnet nuget disable source mySource
```

See also

- [Package source sections in NuGet.config files](#)
- [sources command \(nuget.exe\)](#)

dotnet nuget enable source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget enable source` - Enable a NuGet source.

Synopsis

```
dotnet nuget enable source <NAME> [--configfile <FILE>]
```

```
dotnet nuget enable source -h|--help
```

Description

The `dotnet nuget enable source` command enables an existing source in your NuGet configuration files.

Arguments

- `<NAME>`

Name of the source.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used.

If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

Examples

- Enable a source with name of `mySource` :

```
dotnet nuget enable source mySource
```

See also

- [Package source sections in NuGet.config files](#)
- [sources command \(nuget.exe\)](#)

dotnet nuget list source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget list source` - Lists all configured NuGet sources.

Synopsis

```
dotnet nuget list source [--format [Detailed|Short]] [--configfile <FILE>]
```

```
dotnet nuget list source -h|--help
```

Description

The `dotnet nuget list source` command lists all existing sources from your NuGet configuration files.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--format [Detailed|Short]`

The format of the list command output: `Detailed` (the default) and `Short`.

Examples

- List configured sources from the current directory:

```
dotnet nuget list source
```

See also

- [Package source sections in NuGet.config files](#)
- [sources command \(nuget.exe\)](#)

dotnet nuget remove source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget remove source` - Remove a NuGet source.

Synopsis

```
dotnet nuget remove source <NAME> [--configfile <FILE>]
```

```
dotnet nuget remove source -h|--help
```

Description

The `dotnet nuget remove source` command removes an existing source from your NuGet configuration files.

Arguments

- `<NAME>`

Name of the source.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used.

If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

Examples

- Remove a source with name of `mySource` :

```
dotnet nuget remove source mySource
```

See also

- [Package source sections in NuGet.config files](#)
- [sources command \(nuget.exe\)](#)

dotnet nuget update source

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1.200 SDK and later versions

Name

`dotnet nuget update source` - Update a NuGet source.

Synopsis

```
dotnet nuget update source <NAME> [--source <SOURCE>] [--username <USER>]  
    [--password <PASSWORD>] [--store-password-in-clear-text]  
    [--valid-authentication-types <TYPES>] [--configfile <FILE>]
```

```
dotnet nuget update source -h|--help
```

Description

The `dotnet nuget update source` command updates an existing source in your NuGet configuration files.

Arguments

- `<NAME>`

Name of the source.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-p|--password <PASSWORD>`

Password to be used when connecting to an authenticated source.

- `-s|--source <SOURCE>`

Path to the package source.

- `--store-password-in-clear-text`

Enables storing portable package source credentials by disabling password encryption.

- `-u|--username <USER>`

Username to be used when connecting to an authenticated source.

- `--valid-authentication-types <TYPES>`

Comma-separated list of valid authentication types for this source. Set this to `basic` if the server

advertises NTLM or Negotiate and your credentials must be sent using the Basic mechanism, for instance when using a PAT with on-premises Azure DevOps Server. Other valid values include `negotiate`, `kerberos`, `ntlm`, and `digest`, but these values are unlikely to be useful.

Examples

- Update a source with name of `mySource`:

```
dotnet nuget update source mySource --source c:\packages
```

See also

- [Package source sections in NuGet.config files](#)

dotnet nuget verify

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 5.0.100-rc.2.x SDK and later versions

Name

`dotnet nuget verify` - Verifies a signed NuGet package.

Synopsis

```
dotnet nuget verify [<package-path(s)>]
  [--all]
  [--certificate-fingerprint <FINGERPRINT>]
  [-v|--verbosity <LEVEL>]
  [--configfile <FILE>]

dotnet nuget verify -h|--help
```

Description

The `dotnet nuget verify` command verifies a signed NuGet package.

Arguments

- `package-path(s)`

Specifies the file path to the package(s) to be verified. Multiple position arguments can be passed in to verify multiple packages.

Options

- `--all`

Specifies that all verifications possible should be performed on the package(s). By default, only `signatures` are verified.

NOTE

This command currently supports only `signature` verification.

- `--certificate-fingerprint <FINGERPRINT>`

Verify that the signer certificate matches with one of the specified `SHA256` fingerprints. This option can be supplied multiple times to provide multiple fingerprints.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

The following table shows what is displayed for each verbosity level.

	Q[UIET]	M[INIMAL]	N[ORMAL]	D[ETAILED]	DIAG[NOSTIC]
Certificate chain Information	✗	✗	✗	✓	✓
Path to package being verified	✗	✗	✓	✓	✓
Hashing algorithm used for signature	✗	✗	✓	✓	✓
Author/Repository Certificate -> SHA1 hash	✗	✗	✓	✓	✓
Author/Repository Certificate -> Issued By	✗	✗	✓	✓	✓
Timestamp Certificate -> Issued By	✗	✗	✓	✓	✓
Timestamp Certificate -> SHA-256 hash	✗	✗	✓	✓	✓
Timestamp Certificate -> Validity period	✗	✗	✓	✓	✓
Timestamp Certificate -> SHA1 hash	✗	✗	✓	✓	✓
Timestamp Certificate -> Subject name	✗	✗	✓	✓	✓
Author/Repository Certificate -> Subject name	✗	✓	✓	✓	✓
Author/Repository Certificate -> SHA-256 hash	✗	✓	✓	✓	✓
Author/Repository Certificate -> Validity period	✗	✓	✓	✓	✓
Author/Repository Certificate -> Service index URL (If applicable)	✗	✓	✓	✓	✓

Q[UIET]	M[INIMAL]	N[ORMAL]	D[ETAILED]	DIAG[NOSTIC]
---------	-----------	----------	------------	--------------

Package name being verified	✗	✓	✓	✓	✓
Type of signature (author or repository)	✗	✓	✓	✓	✓

✗ indicates details that are **not** displayed. ✓ indicates details that are displayed.

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Verify *foo.nupkg*:

```
dotnet nuget verify foo.nupkg
```

- Verify multiple NuGet packages - *foo.nupkg* and *all .nupkg files in the directory specified*:

```
dotnet nuget verify foo.nupkg c:\mydir\*.nupkg
```

- Verify *foo.nupkg* signature matches with the specified certificate fingerprint:

```
dotnet nuget verify foo.nupkg --certificate-fingerprint  
CE40881FF5F0AD3E58965DA20A9F571EF1651A56933748E1BF1C99E537C4E039
```

- Verify *foo.nupkg* signature matches with one of the specified certificate fingerprints:

```
dotnet nuget verify foo.nupkg --certificate-fingerprint  
CE40881FF5F0AD3E58965DA20A9F571EF1651A56933748E1BF1C99E537C4E039 --certificate-fingerprint  
EC10992GG5F0AD3E58965DA20A9F571EF1651A56933748E1BF1C99E537C4E027
```

- Verify the signature of *foo.nupkg* by using settings (`packagesources` and `trustedSigners`) only from the specified *nuget.config* file:

```
dotnet nuget verify foo.nupkg --configfile ..\Settings\NuGet.config
```

dotnet nuget trust

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 5.0.300 SDK and later versions

Name

`dotnet nuget trust` - Gets or sets trusted signers to the NuGet configuration.

Synopsis

```
dotnet nuget trust [command] [Options]
```

```
dotnet nuget trust -h|--help
```

Description

The `dotnet nuget trust` command manages the trusted signers. By default, NuGet accepts all authors and repositories. These commands allow you to specify only a specific subset of signers whose signatures will be accepted, while rejecting all others. For more information, see [Common NuGet configurations](#). For details on what the `nuget.config` schema looks like, refer to the [NuGet config file reference](#).

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Commands

If no command is specified, the command will default to `list`.

`list`

Lists all the trusted signers in the configuration. This option will include all the certificates (with fingerprint and fingerprint algorithm) each signer has. If a certificate has a preceding [U], it means that certificate entry has `allowUntrustedRoot` set as true.

Synopsis:

```
dotnet nuget trust list [--configfile <PATH>] [-h|--help] [-v, --verbosity <LEVEL>]
```

Options:

- `--configfile <FILE>`

The NuGet configuration file (`nuget.config`) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

sync

Deletes the current list of certificates and replaces them with an up-to-date list from the repository.

Synopsis

```
dotnet nuget trust sync <NAME> [--configfile <PATH>] [-h|--help] [-v, --verbosity <LEVEL>]
```

Arguments

- `NAME`

The name of the existing trusted signer to sync.

Options:

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

remove

Removes any trusted signers that match the given name.

Synopsis

```
dotnet nuget trust remove <NAME> [--configfile <PATH>] [-h|--help] [-v, --verbosity <LEVEL>]
```

Arguments

- `NAME`

The name of the existing trusted signer to remove.

Options:

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`,

and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

author

Adds a trusted signer with the given name, based on the author signature of the package.

Synopsis

```
dotnet nuget trust author <NAME> <PACKAGE> [--allow-untrusted-root] [--configfile <PATH>] [-h|--help] [-v, --verbosity <LEVEL>]
```

Arguments

- `NAME`

The name of the trusted signer to add. If `NAME` already exists in the configuration, the signature is appended.

- `PACKAGE`

The given `PACKAGE` should be a local path to the signed `.nupkg` file.

Options:

- `--allow-untrusted-root`

Specifies if the certificate for the trusted signer should be allowed to chain to an untrusted root. This is not recommended.

- `--configfile <FILE>`

The NuGet configuration file (`nuget.config`) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

repository

Adds a trusted signer with the given name, based on the repository signature or countersignature of a signed package.

Synopsis

```
dotnet nuget trust repository <NAME> <PACKAGE> [--allow-untrusted-root] [--configfile <PATH>] [-h|--help] [-owners <LIST>] [-v, --verbosity <LEVEL>]
```

Arguments

- `NAME`

The name of the trusted signer to add. If `NAME` already exists in the configuration, the signature is appended.

- `PACKAGE`

The given `PACKAGE` should be a local path to the signed `.nupkg` file.

Options:

- `--allow-untrusted-root`

Specifies if the certificate for the trusted signer should be allowed to chain to an untrusted root. This is not recommended.

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--owners <LIST>`

Semicolon-separated list of trusted owners to further restrict the trust of a repository.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

`certificate`

Adds a trusted signer with the given name, based on a certificate fingerprint.

Synopsis

```
dotnet nuget trust certificate <NAME> <FINGERPRINT> [--algorithm <ALGORITHM>] [--allow-untrusted-root] [--configfile <PATH>] [-h|--help] [-v, --verbosity <LEVEL>]
```

Arguments

- `NAME`

The name of the trusted signer to add. If a trusted signer with the given name already exists, the certificate item is added to that signer. Otherwise a trusted author is created with a certificate item from the given certificate information.

- `FINGERPRINT`

The fingerprint of the certificate.

Options:

- `--algorithm <ALGORITHM>`

Specifies the hash algorithm used to calculate the certificate fingerprint. Defaults to SHA256. Values supported are SHA256, SHA384 and SHA512.

- `--allow-untrusted-root`

Specifies if the certificate for the trusted signer should be allowed to chain to an untrusted root. This is not recommended.

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

source

Adds a trusted signer based on a given package source.

Synopsis

```
dotnet nuget trust source <NAME> [--configfile <PATH>] [-h|--help] [--owners <LIST>] [--source-url] [-v, --verbosity <LEVEL>]
```

Arguments

- `<NAME>`

The name of the trusted signer to add. If only `<NAME>` is provided without `--<source-url>`, the package source from your NuGet configuration files with the same name is added to the trusted list. If `<NAME>` already exists in the configuration, the package source is appended to it.

Options:

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--owners <LIST>`

Semicolon-separated list of trusted owners to further restrict the trust of a repository.

- `--source-url`

If a `<source-url>` is provided, it must be a v3 package source URL (like `https://api.nuget.org/v3/index.json`). Other package source types are not supported.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- List trusted signers:

```
dotnet nuget trust list
```

- Trust source *NuGet* in specified *nuget.config* file:

```
dotnet nuget trust source NuGet --configfile ..\nuget.config
```

- Trust an author from signed nupkg package file *foo.nupkg*:

```
dotnet nuget trust author PackageAuthor .\foo.nupkg
```

- Trust a repository from signed nupkg package file *foo.nupkg*:

```
dotnet nuget trust repository PackageRepository .\foo.nupkg
```

- Trust a package signing certificate using its SHA256 fingerprint:

```
dotnet nuget trust certificate MyCert  
F99EC8CDCE5642B380296A19E22FA8EB3AEF1C70079541A2B3D6E4A93F5E1AFD --algorithm SHA256
```

- Trust owners *NuGet* and *Microsoft* from the repository <https://api.nuget.org/v3/index.json>:

```
dotnet nuget trust source NuGetTrust --source-url https://api.nuget.org/v3/index.json --owners  
"Nuget;Microsoft"
```

- Remove trusted signer named *NuGet* from specified *nuget.config* file:

```
dotnet nuget trust remove NuGet --configfile ..\nuget.config
```

dotnet nuget sign

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet nuget sign` - Signs all the NuGet packages matching the first argument with a certificate.

Synopsis

```
dotnet nuget sign [<package-path(s)>]
  [--certificate-path <PATH>]
  [--certificate-store-name <STORENAME>]
  [--certificate-store-location <STORELOCATION>]
  [--certificate-subject-name <SUBJECTNAME>]
  [--certificate-fingerprint <FINGERPRINT>]
  [--certificate-password <PASSWORD>]
  [--hash-algorithm <HASHALGORITHM>]
  [-o|--output <OUTPUT DIRECTORY>]
  [--overwrite]
  [--timestamp-hash-algorithm <HASHALGORITHM>]
  [--timestamper <TIMESTAMPINGSERVER>]
  [-v|--verbosity <LEVEL>]
```

```
dotnet nuget sign -h|--help
```

Description

The `dotnet nuget sign` command signs all the packages matching the first argument with a certificate. The certificate with the private key can be obtained from a file or from a certificate installed in a certificate store by providing a subject name or a SHA-1 fingerprint.

Arguments

- `package-path(s)`

Specifies the file path to the package(s) to be signed. Multiple arguments can be passed in to sign multiple packages.

Options

- `--certificate-path <PATH>`

Specifies the file path to the certificate to be used in signing the package.

NOTE

This option currently supports only `PKCS12 (PFX)` files that contain the certificate's private key.

- `--certificate-store-name <STORENAME>`

Specifies the name of the X.509 certificate store to use to search for the certificate. Defaults to "My", the X.509 certificate store for personal certificates. This option should be used when specifying the certificate via `--certificate-subject-name` or `--certificate-fingerprint` options.

- `--certificate-store-location <STORELOCATION>`

Specifies the name of the X.509 certificate store use to search for the certificate. Defaults to "CurrentUser", the X.509 certificate store used by the current user. This option should be used when specifying the certificate via `--certificate-subject-name` or `--certificate-fingerprint` options.

- `--certificate-subject-name <SUBJECTNAME>`

Specifies the subject name of the certificate used to search a local certificate store for the certificate. The search is a case-insensitive string comparison using the supplied value, which will find all certificates with the subject name containing that string, regardless of other subject values. The certificate store can be specified by `--certificate-store-name` and `--certificate-store-location` options.

NOTE

This option currently supports only a single matching certificate in the result. If there are multiple matching certificates in the result, or no matching certificate in the result, the sign command will fail.

- `--certificate-fingerprint <FINGERPRINT>`

SHA-1 fingerprint of the certificate used to search a local certificate store for the certificate.

- `--certificate-password <PASSWORD>`

Specifies the certificate password, if needed. If a certificate is password protected but no password is provided, the sign command will fail.

NOTE

The `sign` command only supports non-interactive mode. There won't be any prompt for a password at run time.

- `--hash-algorithm <HASHALGORITHM>`

Hash algorithm to be used to sign the package. Defaults to SHA256. Possible values are SHA256, SHA384, and SHA512.

- `-o|--output`

Specifies the directory where the signed package should be saved. If this option is not specified, by default the original package is overwritten by the signed package.

- `--overwrite`

Indicate that the current signature should be overwritten. By default the command will fail if the package already has a signature.

- `--timestamp-hash-algorithm <HASHALGORITHM>`

Hash algorithm to be used by the RFC 3161 timestamp server. Defaults to SHA256.

- `--timestamper <TIMESTAMPINGSERVER>`

URL to an RFC 3161 timestamping server.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Sign `foo.nupkg` with certificate `cert.pfx` (not password protected):

```
dotnet nuget sign foo.nupkg --certificate-path cert.pfx
```

- Sign `foo.nupkg` with certificate `cert.pfx` (password protected):

```
dotnet nuget sign foo.nupkg --certificate-path cert.pfx --certificate-password password
```

- Sign `foo.nupkg` with certificate (password protected) matches with the specified SHA-1 fingerprint in the default certificate store (`CurrentUser\My`):

```
dotnet nuget sign foo.nupkg --certificate-fingerprint 89967D1DD995010B6C66AE24FF8E66885E6E03A8 --certificate-password password
```

- Sign `foo.nupkg` with certificate (password protected) matches with the specified subject name "Test certificate for testing signing" in the default certificate store (`CurrentUser\My`):

```
dotnet nuget sign foo.nupkg --certificate-subject-name "Test certificate for testing signing" --certificate-password password
```

- Sign `foo.nupkg` with certificate (password protected) matches with the specified SHA-1 fingerprint in the certificate store `CurrentUser\Root`:

```
dotnet nuget sign foo.nupkg --certificate-fingerprint 89967D1DD995010B6C66AE24FF8E66885E6E03A8 --certificate-password password --certificate-store-location CurrentUser --certificate-store-name Root
```

- Sign multiple NuGet packages - `foo.nupkg` and *all .nupkg files in the directory specified* with certificate `cert.pfx` (not password protected):

```
dotnet nuget sign foo.nupkg c:\mydir\*.nupkg --certificate-path cert.pfx
```

- Sign `foo.nupkg` with certificate `cert.pfx` (password protected), and timestamp with `http://timestamp.test`:

```
dotnet nuget sign foo.nupkg --certificate-path cert.pfx --certificate-password password --timestamper http://timestamp.test
```

- Sign `foo.nupkg` with certificate `cert.pfx` (not password protected) and save the signed package under specified directory:

```
dotnet nuget sign foo.nupkg --certificate-path cert.pfx --output c:\signed\
```

- Sign *foo.nupkg* with certificate *cert.pfx* (not password protected) and overwrite the current signature if the package is already signed:

```
dotnet nuget sign foo.nupkg --certificate-path cert.pfx --overwrite
```

dotnet pack

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet pack` - Packs the code into a NuGet package.

Synopsis

```
dotnet pack [<PROJECT>|<SOLUTION>] [-c|--configuration <CONFIGURATION>]
  [--force] [--include-source] [--include-symbols] [--interactive]
  [--no-build] [--no-dependencies] [--no-restore] [--nologo]
  [-o|--output <OUTPUT_DIRECTORY>] [--runtime <RUNTIME_IDENTIFIER>]
  [-s|--serviceable] [-v|--verbosity <LEVEL>]
  [--version-suffix <VERSION_SUFFIX>]

dotnet pack -h|--help
```

Description

The `dotnet pack` command builds the project and creates NuGet packages. The result of this command is a NuGet package (that is, a `.nupkg` file).

If you want to generate a package that contains the debug symbols, you have two options available:

- `--include-symbols` - it creates the symbols package.
- `--include-source` - it creates the symbols package with a `src` folder inside containing the source files.

NuGet dependencies of the packed project are added to the `.nuspec` file, so they're properly resolved when the package is installed. If the packed project has references to other projects, the other projects are not included in the package. Currently, you must have a package per project if you have project-to-project dependencies.

By default, `dotnet pack` builds the project first. If you wish to avoid this behavior, pass the `--no-build` option.

This option is often useful in Continuous Integration (CI) build scenarios where you know the code was previously built.

NOTE

In some cases, the implicit build cannot be performed. This can occur when `GeneratePackageOnBuild` is set, to avoid a cyclic dependency between build and pack targets. The build can also fail if there is a locked file or other issue.

You can provide MSBuild properties to the `dotnet pack` command for the packing process. For more information, see [NuGet pack target properties](#) and the [MSBuild Command-Line Reference](#). The [Examples](#) section shows how to use the MSBuild `-p` switch for a couple of different scenarios.

NOTE

Web projects aren't packable.

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

This command supports the `dotnet restore` options when passed in the long form (for example, `--source`). Short form options, such as `-s`, are not supported.

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Arguments

`PROJECT | SOLUTION`

The project or solution to pack. It's either a path to a csproj, vbproj, or fsproj file, or to a solution file or directory. If not specified, the command searches the current directory for a project or solution file.

Options

- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project.

- `--force`

Forces all dependencies to be resolved even if the last restore was successful. Specifying this flag is the same as deleting the `project.assets.json` file.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--include-source`

Includes the debug symbols NuGet packages in addition to the regular NuGet packages in the output directory. The sources files are included in the `src` folder within the symbols package.

- `--include-symbols`

Includes the debug symbols NuGet packages in addition to the regular NuGet packages in the output directory.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

- `--no-build`

Doesn't build the project before packing. It also implicitly sets the `--no-restore` flag.

- `--no-dependencies`

Ignores project-to-project references and only restores the root project.

- `--no-restore`

Doesn't execute an implicit restore when running the command.

- `--nologo`

Doesn't display the startup banner or the copyright message.

- `-o|--output <OUTPUT_DIRECTORY>`

Places the built packages in the directory specified.

- `--runtime <RUNTIME_IDENTIFIER>`

Specifies the target runtime to restore packages for. For a list of Runtime Identifiers (RIDs), see the [RID catalog](#).

- `-s|--serviceable`

Sets the serviceable flag in the package. For more information, see [.NET Blog: .NET Framework 4.5.1 Supports Microsoft Security Updates for .NET NuGet Libraries](#).

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. For more information, see [LoggerVerbosity](#).

- `--version-suffix <VERSION_SUFFIX>`

Defines the value for the `VersionSuffix` MSBuild property. The effect of this property on the package version depends on the values of the `Version` and `VersionPrefix` properties, as shown in the following table:

PROPERTIES WITH VALUES	PACKAGE VERSION
None	<code>1.0.0</code>
<code>Version</code>	<code>\$(Version)</code>
<code>VersionPrefix</code> only	<code>\$(VersionPrefix)</code>
<code>VersionSuffix</code> only	<code>1.0.0-\$(VersionSuffix)</code>
<code>VersionPrefix</code> and <code>VersionSuffix</code>	<code>\$(VersionPrefix)-\$(VersionSuffix)</code>

If you want to use `--version-suffix`, specify `VersionPrefix` and not `Version` in the project file. For example, if `versionPrefix` is `0.1.2` and you pass `--version-suffix rc.1` to `dotnet pack`, the package version will be `0.1.2-rc.1`.

If `Version` has a value and you pass `--version-suffix` to `dotnet pack`, the value specified for `--version-suffix` is ignored.

Examples

- Pack the project in the current directory:

```
dotnet pack
```

- Pack the `app1` project:

```
dotnet pack ~/projects/app1/project.csproj
```

- Pack the project in the current directory and place the resulting packages into the `nupkgs` folder:

```
dotnet pack --output nupkgs
```

- Pack the project in the current directory into the `nupkgs` folder and skip the build step:

```
dotnet pack --no-build --output nupkgs
```

- With the project's version suffix configured as `<VersionSuffix>$(VersionSuffix)</VersionSuffix>` in the `.csproj` file, pack the current project and update the resulting package version with the given suffix:

```
dotnet pack --version-suffix "ci-1234"
```

- Set the package version to `2.1.0` with the `PackageVersion` MSBuild property:

```
dotnet pack -p:PackageVersion=2.1.0
```

- Pack the project for a specific [target framework](#):

```
dotnet pack -p:TargetFrameworks=net45
```

- Pack the project and use a specific runtime (Windows 10) for the restore operation:

```
dotnet pack --runtime win10-x64
```

- Pack the project using a `.nuspec` file:

```
dotnet pack ~/projects/app1/project.csproj -p:NuspecFile=~/projects/app1/project.nuspec -  
p:NuspecbasePath=~/projects/app1/nuget
```

For information about how to use `NuspecFile`, `NuspecbasePath`, and `NuspecProperties`, see the following resources:

- [Packing using a .nuspec](#)
- [Advanced extension points to create customized package](#)
- [Global properties](#)

dotnet publish

9/20/2022 • 9 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet publish` - Publishes the application and its dependencies to a folder for deployment to a hosting system.

Synopsis

```
dotnet publish [<PROJECT>|<SOLUTION>] [-a|--arch <ARCHITECTURE>]
  [-c|--configuration <CONFIGURATION>]
  [-f|--framework <FRAMEWORK>] [--force] [--interactive]
  [--manifest <PATH_TO_MANIFEST_FILE>] [--no-build] [--no-dependencies]
  [--no-restore] [--nologo] [-o|--output <OUTPUT_DIRECTORY>]
  [--os <OS>] [-r|--runtime <RUNTIME_IDENTIFIER>]
  [--sc|--self-contained [true|false]] [--no-self-contained]
  [-s|--source <SOURCE>] [-v|--verbosity <LEVEL>]
  [--version-suffix <VERSION_SUFFIX>]

dotnet publish -h|--help
```

Description

`dotnet publish` compiles the application, reads through its dependencies specified in the project file, and publishes the resulting set of files to a directory. The output includes the following assets:

- Intermediate Language (IL) code in an assembly with a *dll* extension.
- A *.deps.json* file that includes all of the dependencies of the project.
- A *.runtimeconfig.json* file that specifies the shared runtime that the application expects, as well as other configuration options for the runtime (for example, garbage collection type).
- The application's dependencies, which are copied from the NuGet cache into the output folder.

The `dotnet publish` command's output is ready for deployment to a hosting system (for example, a server, PC, Mac, laptop) for execution. It's the only officially supported way to prepare the application for deployment. Depending on the type of deployment that the project specifies, the hosting system may or may not have the .NET shared runtime installed on it. For more information, see [Publish .NET apps with the .NET CLI](#).

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

MSBuild

The `dotnet publish` command calls MSBuild, which invokes the `Publish` target. If the `IsPublishable` property is set to `false` for a particular project, the `Publish` target can't be invoked, and the `dotnet publish` command only runs the implicit `dotnet restore` on the project.

Any parameters passed to `dotnet publish` are passed to MSBuild. The `-c` and `-o` parameters map to MSBuild's `Configuration` and `PublishDir` properties, respectively.

The `dotnet publish` command accepts MSBuild options, such as `-p` for setting properties and `-l` to define a logger. For example, you can set an MSBuild property by using the format: `-p:<NAME>=<VALUE>`.

You can also set publish-related properties by referring to a `.pubxml` file. For example:

```
dotnet publish -p:PublishProfile=FolderProfile
```

The preceding example uses the `FolderProfile.pubxml` file that is found in the `<project_folder>/Properties/PublishProfiles` folder. If you specify a path and file extension when setting the `PublishProfile` property, they are ignored. MSBuild by default looks in the `Properties/PublishProfiles` folder and assumes the `pubxml` file extension. To specify the path and filename including extension, set the `PublishProfileFullPath` property instead of the `PublishProfile` property.

The following MSBuild properties change the output of `dotnet publish`.

- `PublishReadyToRun`

Compiles application assemblies as ReadyToRun (R2R) format. R2R is a form of ahead-of-time (AOT) compilation. For more information, see [ReadyToRun images](#).

To see warnings about missing dependencies that could cause runtime failures, use

```
PublishReadyToRunShowWarnings=true
```

We recommend that you specify `PublishReadyToRun` in a publish profile rather than on the command line.

- `PublishSingleFile`

Packages the app into a platform-specific single-file executable. For more information about single-file publishing, see the [single-file bundler design document](#).

We recommend that you specify this option in the project file rather than on the command line.

- `PublishTrimmed`

Trims unused libraries to reduce the deployment size of an app when publishing a self-contained executable. For more information, see [Trim self-contained deployments and executables](#). Available since .NET 6 SDK.

We recommend that you specify this option in the project file rather than on the command line.

For more information, see the following resources:

- [MSBuild command-line reference](#)
- [Visual Studio publish profiles \(.pubxml\) for ASP.NET Core app deployment](#)
- [dotnet msbuild](#)

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Arguments

- `PROJECT|SOLUTION`

The project or solution to publish.

- `PROJECT` is the path and filename of a C#, F#, or Visual Basic project file, or the path to a directory that contains a C#, F#, or Visual Basic project file. If the directory is not specified, it defaults to the current directory.
- `SOLUTION` is the path and filename of a solution file (`.sln` extension), or the path to a directory that contains a solution file. If the directory is not specified, it defaults to the current directory.

Options

- `-a|--arch <ARCHITECTURE>`

Specifies the target architecture. This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--arch x86` sets the RID to `win-x86`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6 Preview 7.

- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project.

- `-f|--framework <FRAMEWORK>`

Publishes the application for the specified [target framework](#). You must specify the target framework in the project file.

- `--force`

Forces all dependencies to be resolved even if the last restore was successful. Specifying this flag is the same as deleting the `project.assets.json` file.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

- `--manifest <PATH_TO_MANIFEST_FILE>`

Specifies one or several [target manifests](#) to use to trim the set of packages published with the app. The manifest file is part of the output of the `dotnet store` command. To specify multiple manifests, add a `--manifest` option for each manifest.

- `--no-build`

Doesn't build the project before publishing. It also implicitly sets the `--no-restore` flag.

- `--no-dependencies`

Ignores project-to-project references and only restores the root project.

- `--nologo`

Doesn't display the startup banner or the copyright message.
- `--no-restore`

Doesn't execute an implicit restore when running the command.
- `-o|--output <OUTPUT_DIRECTORY>`

Specifies the path for the output directory.

If not specified, it defaults to `[project_file_folder]/bin/[configuration]/[framework]/publish` for a framework-dependent executable and cross-platform binaries. It defaults to `[project_file_folder]/bin/[configuration]/[framework]/[runtime]/publish` for a self-contained executable.

In a web project, if the output folder is in the project folder, successive `dotnet publish` commands result in nested output folders. For example, if the project folder is `myproject`, and the publish output folder is `myproject/publish`, and you run `dotnet publish` twice, the second run puts content files such as `.config` and `.json` files in `myproject/publish/publish`. To avoid nesting publish folders, specify a publish folder that is not **directly** under the project folder, or exclude the publish folder from the project. To exclude a publish folder named `publishoutput`, add the following element to a `PropertyGroup` element in the `.csproj` file:

```
<DefaultItemExcludes>$(<DefaultItemExcludes>);publishoutput**</DefaultItemExcludes>
```

 - .NET Core 3.x SDK and later

If you specify a relative path when publishing a project, the generated output directory is relative to the current working directory, not to the project file location.

If you specify a relative path when publishing a solution, all output for all projects goes into the specified folder relative to the current working directory. To make publish output go to separate folders for each project, specify a relative path by using the msbuild `PublishDir` property instead of the `--output` option. For example, `dotnet publish -p:PublishDir=.\publish` sends publish output for each project to a `publish` folder under the folder that contains the project file.
 - .NET Core 2.x SDK

If you specify a relative path when publishing a project, the generated output directory is relative to the project file location, not to the current working directory.

If you specify a relative path when publishing a solution, each project's output goes into a separate folder relative to the project file location. If you specify an absolute path when publishing a solution, all publish output for all projects goes into the specified folder.- `--os <OS>`

Specifies the target operating system (OS). This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--os linux` sets the RID to `linux-x64`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6.
- `--sc|--self-contained [true|false]`

Publishes the .NET runtime with your application so the runtime doesn't need to be installed on the target machine. Default is `true` if a runtime identifier is specified and the project is an executable project (not a library project). For more information, see [.NET application publishing](#) and [Publish .NET apps with the](#)

.NET CLI

If this option is used without specifying `true` or `false`, the default is `true`. In that case, don't put the solution or project argument immediately after `--self-contained`, because `true` or `false` is expected in that position.

- `--no-self-contained`

Equivalent to `--self-contained false`.

- `--source <SOURCE>`

The URI of the NuGet package source to use during the restore operation.

- `-r|--runtime <RUNTIME_IDENTIFIER>`

Publishes the application for a given runtime. For a list of Runtime Identifiers (RIDs), see the [RID catalog](#). For more information, see [.NET application publishing](#) and [Publish .NET apps with the .NET CLI](#). If you use this option, use `--self-contained` or `--no-self-contained` also.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

- `--version-suffix <VERSION_SUFFIX>`

Defines the version suffix to replace the asterisk (`*`) in the version field of the project file.

Examples

- Create a [framework-dependent cross-platform binary](#) for the project in the current directory:

```
dotnet publish
```

Starting with .NET Core 3.0 SDK, this example also creates a [framework-dependent executable](#) for the current platform.

- Create a [self-contained executable](#) for the project in the current directory, for a specific runtime:

```
dotnet publish --runtime osx.10.11-x64
```

The RID must be in the project file.

- Create a [framework-dependent executable](#) for the project in the current directory, for a specific platform:

```
dotnet publish --runtime osx.10.11-x64 --self-contained false
```

The RID must be in the project file. This example applies to .NET Core 3.0 SDK and later versions.

- Publish the project in the current directory, for a specific runtime and target framework:

```
dotnet publish --framework netcoreapp3.1 --runtime osx.10.11-x64
```

- Publish the specified project file:

```
dotnet publish ~/projects/app1/app1.csproj
```

- Publish the current application but don't restore project-to-project (P2P) references, just the root project during the restore operation:

```
dotnet publish --no-dependencies
```

dotnet restore

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet restore` - Restores the dependencies and tools of a project.

Synopsis

```
dotnet restore [<ROOT>] [--configfile <FILE>] [--disable-parallel]
    [-f|--force] [--force-evaluate] [--ignore-failed-sources]
    [--interactive] [--lock-file-path <LOCK_FILE_PATH>] [--locked-mode]
    [--no-cache] [--no-dependencies] [--packages <PACKAGES_DIRECTORY>]
    [-r|--runtime <RUNTIME_IDENTIFIER>] [-s|--source <SOURCE>]
    [--use-lock-file] [-v|--verbosity <LEVEL>]

dotnet restore -h|--help
```

Description

The `dotnet restore` command uses NuGet to restore dependencies as well as project-specific tools that are specified in the project file. In most cases, you don't need to explicitly use the `dotnet restore` command, since a NuGet restore is run implicitly if necessary when you run the following commands:

- `dotnet new`
- `dotnet build`
- `dotnet build-server`
- `dotnet run`
- `dotnet test`
- `dotnet publish`
- `dotnet pack`

Sometimes, it might be inconvenient to run the implicit NuGet restore with these commands. For example, some automated systems, such as build systems, need to call `dotnet restore` explicitly to control when the restore occurs so that they can control network usage. To prevent the implicit NuGet restore, you can use the `--no-restore` flag with any of these commands to disable implicit restore.

Specify feeds

To restore the dependencies, NuGet needs the feeds where the packages are located. Feeds are usually provided via the *nuget.config* configuration file. A default configuration file is provided when the .NET SDK is installed. To specify additional feeds, do one of the following:

- Create your own *nuget.config* file in the project directory. For more information, see [Common NuGet configurations](#) and [nuget.config differences](#) later in this article.
- Use `dotnet nuget` commands such as `dotnet nuget add source`.

You can override the *nuget.config* feeds with the `-s` option.

For information about how to use authenticated feeds, see [Consuming packages from authenticated feeds](#).

Global packages folder

For dependencies, you can specify where the restored packages are placed during the restore operation using the `--packages` argument. If not specified, the default NuGet package cache is used, which is found in the `.nuget/packages` directory in the user's home directory on all operating systems. For example, `/home/user1` on Linux or `C:\Users\user1` on Windows.

Project-specific tooling

For project-specific tooling, `dotnet restore` first restores the package in which the tool is packed, and then proceeds to restore the tool's dependencies as specified in its project file.

nuget.config differences

The behavior of the `dotnet restore` command is affected by the settings in the *nuget.config* file, if present. For example, setting the `globalPackagesFolder` in *nuget.config* places the restored NuGet packages in the specified folder. This is an alternative to specifying the `--packages` option on the `dotnet restore` command. For more information, see the [nuget.config reference](#).

There are three specific settings that `dotnet restore` ignores:

- [bindingRedirects](#)

Binding redirects don't work with `<PackageReference>` elements and .NET only supports `<PackageReference>` elements for NuGet packages.

- [solution](#)

This setting is Visual Studio specific and doesn't apply to .NET. .NET doesn't use a `packages.config` file and instead uses `<PackageReference>` elements for NuGet packages.

- [trustedSigners](#)

Support for cross-platform package signature verification was added in the .NET 5.0.100 SDK.

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Arguments

- `ROOT`

Optional path to the project file to restore.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Disables restoring multiple projects in parallel.

- `--force`

Forces all dependencies to be resolved even if the last restore was successful. Specifying this flag is the same as deleting the `project.assets.json` file.

- `--force-evaluate`

Forces restore to reevaluate all dependencies even if a lock file already exists.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Only warn about failed sources if there are packages meeting the version requirement.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--lock-file-path <LOCK_FILE_PATH>`

Output location where project lock file is written. By default, this is `PROJECT_ROOT\packages\lock.json`.

- `--locked-mode`

Don't allow updating project lock file.

- `--no-cache`

Specifies to not cache HTTP requests.

- `--no-dependencies`

When restoring a project with project-to-project (P2P) references, restores the root project and not the references.

- `--packages <PACKAGES_DIRECTORY>`

Specifies the directory for restored packages.

- `-r|--runtime <RUNTIME_IDENTIFIER>`

Specifies a runtime for the package restore. This is used to restore packages for runtimes not explicitly listed in the `<RuntimeIdentifiers>` tag in the `.csproj` file. For a list of Runtime Identifiers (RIDs), see the [RID catalog](#).

- `-s|--source <SOURCE>`

Specifies the URI of the NuGet package source to use during the restore operation. This setting overrides all of the sources specified in the `nuget.config` files. Multiple sources can be provided by specifying this option multiple times.

- `--use-lock-file`

Enables project lock file to be generated and used with restore.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- Restore dependencies and tools for the project in the current directory:

```
dotnet restore
```

- Restore dependencies and tools for the `app1` project found in the given path:

```
dotnet restore ./projects/app1/app1.csproj
```

- Restore the dependencies and tools for the project in the current directory using the file path provided as the source:

```
dotnet restore -s c:\packages\mypackages
```

- Restore the dependencies and tools for the project in the current directory using the two file paths provided as sources:

```
dotnet restore -s c:\packages\mypackages -s c:\packages\myotherpackages
```

- Restore dependencies and tools for the project in the current directory showing detailed output:

```
dotnet restore --verbosity detailed
```

dotnet run

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet run` - Runs source code without any explicit compile or launch commands.

Synopsis

```
dotnet run [-a|--arch <ARCHITECTURE>] [-c|--configuration <CONFIGURATION>]
[-f|--framework <FRAMEWORK>] [--force] [--interactive]
[--launch-profile <NAME>] [--no-build]
[--no-dependencies] [--no-launch-profile] [--no-restore]
[--os <OS>] [--project <PATH>] [-r|--runtime <RUNTIME_IDENTIFIER>]
[-v|--verbosity <LEVEL>] [[--] [application arguments]]  
dotnet run -h|--help
```

Description

The `dotnet run` command provides a convenient option to run your application from the source code with one command. It's useful for fast iterative development from the command line. The command depends on the `dotnet build` command to build the code. Any requirements for the build, such as that the project must be restored first, apply to `dotnet run` as well.

NOTE

`dotnet run` doesn't respect arguments like `/property:property=value`, which are respected by `dotnet build`.

Output files are written into the default location, which is `bin/<configuration>/<target>`. For example if you have a `netcoreapp2.1` application and you run `dotnet run`, the output is placed in `bin/Debug/netcoreapp2.1`. Files are overwritten as needed. Temporary files are placed in the `obj` directory.

If the project specifies multiple frameworks, executing `dotnet run` results in an error unless the `-f|--framework <FRAMEWORK>` option is used to specify the framework.

The `dotnet run` command is used in the context of projects, not built assemblies. If you're trying to run a framework-dependent application DLL instead, you must use `dotnet` without a command. For example, to run `myapp.dll`, use:

```
dotnet myapp.dll
```

For more information on the `dotnet` driver, see the [.NET Command Line Tools \(CLI\)](#) topic.

To run the application, the `dotnet run` command resolves the dependencies of the application that are outside of the shared runtime from the NuGet cache. Because it uses cached dependencies, it's not recommended to use `dotnet run` to run applications in production. Instead, [create a deployment](#) using the `dotnet publish` command

and deploy the published output.

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

This command supports the `dotnet restore` options when passed in the long form (for example, `--source`). Short form options, such as `-s`, are not supported.

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Options

- `--`

Delimits arguments to `dotnet run` from arguments for the application being run. All arguments after this delimiter are passed to the application run.

- `-a|--arch <ARCHITECTURE>`

Specifies the target architecture. This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--arch x86` sets the RID to `win-x86`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6 Preview 7.

- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project.

- `-f|--framework <FRAMEWORK>`

Builds and runs the app using the specified [framework](#). The framework must be specified in the project file.

- `--force`

Forces all dependencies to be resolved even if the last restore was successful. Specifying this flag is the same as deleting the `project.assets.json` file.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.

- `--launch-profile <NAME>`

The name of the launch profile (if any) to use when launching the application. Launch profiles are defined in the `launchSettings.json` file and are typically called `Development`, `Staging`, and `Production`. For more information, see [Working with multiple environments](#).

- `--no-build`

Doesn't build the project before running. It also implicitly sets the `--no-restore` flag.

- `--no-dependencies`

When restoring a project with project-to-project (P2P) references, restores the root project and not the references.

- `--no-launch-profile`

Doesn't try to use `launchSettings.json` to configure the application.

- `--no-restore`

Doesn't execute an implicit restore when running the command.

- `--os <OS>`

Specifies the target operating system (OS). This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--os linux` sets the RID to `linux-x64`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6.

- `--project <PATH>`

Specifies the path of the project file to run (folder name or full path). If not specified, it defaults to the current directory.

The `-p` abbreviation for `--project` is [deprecated](#) starting in .NET 6 SDK. For a limited time starting in .NET 6 RC1 SDK, `-p` can still be used for `--project` despite the deprecation warning. If the argument provided for the option doesn't contain `=`, the command accepts `-p` as short for `--project`. Otherwise, the command assumes that `-p` is short for `--property`. This flexible use of `-p` for `--project` will be phased out in .NET 7.

- `--property:<NAME>=<VALUE>`

Sets one or more MSBuild properties. Specify multiple properties delimited by semicolons or by repeating the option:

```
--property:<NAME1>=<VALUE1>;<NAME2>=<VALUE2>
--property:<NAME1>=<VALUE1> --property:<NAME2>=<VALUE2>
```

The short form `-p` can be used for `--property`. If the argument provided for the option contains `=`, `-p` is accepted as short for `--property`. Otherwise, the command assumes that `-p` is short for `--project`.

To pass `--property` to the application rather than set an MSBuild property, provide the option after the `--` syntax separator, for example:

```
dotnet run -- --property name=value
```

- `-r|--runtime <RUNTIME_IDENTIFIER>`

Specifies the target runtime to restore packages for. For a list of Runtime Identifiers (RIDs), see the [RID catalog](#).

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- Run the project in the current directory:

```
dotnet run
```

- Run the specified project:

```
dotnet run --project ./projects/proj1/proj1.csproj
```

- Run the project in the current directory, specifying Release configuration:

```
dotnet run --property:Configuration=Release
```

- Run the project in the current directory (the `--help` argument in this example is passed to the application, since the blank `--` option is used):

```
dotnet run --configuration Release -- --help
```

- Restore dependencies and tools for the project in the current directory only showing minimal output and then run the project:

```
dotnet run --verbosity m
```

dotnet sdk check

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 and later versions

Name

`dotnet sdk check` - Lists the latest available version of the .NET SDK and .NET Runtime, for each feature band.

Synopsis

```
dotnet sdk check
```

```
dotnet sdk check -h|--help
```

Description

The `dotnet sdk check` command makes it easier to track when new versions of the SDK and Runtimes are available. Within each feature band it tells you:

- The latest available version of the .NET SDK and .NET Runtime.
- Whether your installed versions are up-to-date or out of support.

Here's an example of output from the command:

.NET SDKs:		
Version	Status	
2.1.816	Up to date.	
2.2.401	.NET 2.2 is out of support.	
3.1.410	Up to date.	
5.0.204	Up to date.	
5.0.301	Up to date.	
.NET Runtimes:		
Name	Version	Status
Microsoft.AspNetCore.All	2.1.28	Up to date.
Microsoft.AspNetCore.App	2.1.28	Up to date.
Microsoft.NETCore.App	2.1.28	Up to date.
Microsoft.AspNetCore.All	2.2.6	.NET 2.2 is out of support.
Microsoft.AspNetCore.App	2.2.6	.NET 2.2 is out of support.
Microsoft.NETCore.App	2.2.6	.NET 2.2 is out of support.
Microsoft.AspNetCore.App	3.1.16	Up to date.
Microsoft.NETCore.App	3.1.16	Up to date.
Microsoft.WindowsDesktop.App	3.1.16	Up to date.
Microsoft.AspNetCore.App	5.0.7	Up to date.
Microsoft.NETCore.App	5.0.7	Up to date.
Microsoft.WindowsDesktop.App	5.0.7	Up to date.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Show up-to-date status of installed .NET SDKs and .NET Runtimes.

```
dotnet sdk check
```

dotnet sln

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet sln` - Lists or modifies the projects in a .NET solution file.

Synopsis

```
dotnet sln [<SOLUTION_FILE>] [command]
```

```
dotnet sln [command] -h|--help
```

Description

The `dotnet sln` command provides a convenient way to list and modify projects in a solution file.

Create a solution file

To use the `dotnet sln` command, the solution file must already exist. If you need to create one, use the `dotnet new` command with the `sln` template name.

The following example creates a `.sln` file in the current folder, with the same name as the folder:

```
dotnet new sln
```

The following example creates a `.sln` file in the current folder, with the specified file name:

```
dotnet new sln --name MySolution
```

The following example creates a `.sln` file in the specified folder, with the same name as the folder:

```
dotnet new sln --output MySolution
```

Arguments

- `SOLUTION_FILE`

The solution file to use. If this argument is omitted, the command searches the current directory for one. If it finds no solution file or multiple solution files, the command fails.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Commands

list

Lists all projects in a solution file.

Synopsis

```
dotnet sln list [-h|--help]
```

Arguments

- `SOLUTION_FILE`

The solution file to use. If this argument is omitted, the command searches the current directory for one. If it finds no solution file or multiple solution files, the command fails.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

add

Adds one or more projects to the solution file.

Synopsis

```
dotnet sln [<SOLUTION_FILE>] add [--in-root] [-s|--solution-folder <PATH>] <PROJECT_PATH>
[<PROJECT_PATH>...]
dotnet sln add [-h|--help]
```

Arguments

- `SOLUTION_FILE`

The solution file to use. If it is unspecified, the command searches the current directory for one and fails if there are multiple solution files.

- `PROJECT_PATH`

The path to the project or projects to add to the solution. Unix/Linux shell [globbing pattern](#) expansions are processed correctly by the `dotnet sln` command.

If `PROJECT_PATH` includes folders that contain the project folder, that portion of the path is used to create [solution folders](#). For example, the following commands create a solution with `myapp` in solution folder `folder1/folder2`:

```
dotnet new sln
dotnet new console --output folder1/folder2/myapp
dotnet sln add folder1/folder2/myapp
```

You can override this default behavior by using the `--in-root` or the `-s|--solution-folder <PATH>` option.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--in-root`

Places the projects in the root of the solution, rather than creating a [solution folder](#). Can't be used with `-s|--solution-folder`.

- `-s|--solution-folder <PATH>`

The destination [solution folder](#) path to add the projects to. Can't be used with `--in-root`.

`remove`

Removes a project or multiple projects from the solution file.

Synopsis

```
dotnet sln [<SOLUTION_FILE>] remove <PROJECT_PATH> [<PROJECT_PATH>...]  
dotnet sln [<SOLUTION_FILE>] remove [-h|--help]
```

Arguments

- `SOLUTION_FILE`

The solution file to use. If it is unspecified, the command searches the current directory for one and fails if there are multiple solution files.

- `PROJECT_PATH`

The path to the project or projects to remove from the solution. Unix/Linux shell [globbing pattern](#) expansions are processed correctly by the `dotnet sln` command.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- List the projects in a solution:

```
dotnet sln todo.sln list
```

- Add a C# project to a solution:

```
dotnet sln add todo-app/todo-app.csproj
```

- Remove a C# project from a solution:

```
dotnet sln remove todo-app/todo-app.csproj
```

- Add multiple C# projects to the root of a solution:

```
dotnet sln todo.sln add todo-app/todo-app.csproj back-end/back-end.csproj --in-root
```

- Add multiple C# projects to a solution:

```
dotnet sln todo.sln add todo-app/todo-app.csproj back-end/back-end.csproj
```

- Remove multiple C# projects from a solution:

```
dotnet sln todo.sln remove todo-app/todo-app.csproj back-end/back-end.csproj
```

- Add multiple C# projects to a solution using a globbing pattern (Unix/Linux only):

```
dotnet sln todo.sln add **/*.csproj
```

- Add multiple C# projects to a solution using a globbing pattern (Windows PowerShell only):

```
dotnet sln todo.sln add (ls -r **/*.csproj)
```

- Remove multiple C# projects from a solution using a globbing pattern (Unix/Linux only):

```
dotnet sln todo.sln remove **/*.csproj
```

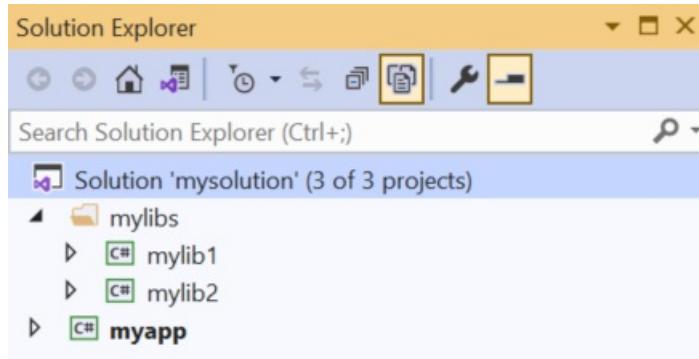

- Remove multiple C# projects from a solution using a globbing pattern (Windows PowerShell only):

```
dotnet sln todo.sln remove (ls -r **/*.csproj)
```

- Create a solution, a console app, and two class libraries. Add the projects to the solution, and use the `--solution-folder` option of `dotnet sln` to organize the class libraries into a solution folder.

```
dotnet new sln -n mysolution
dotnet new console -o myapp
dotnet new classlib -o mylib1
dotnet new classlib -o mylib2
dotnet sln mysolution.sln add myapp\myapp.csproj
dotnet sln mysolution.sln add mylib1\mylib1.csproj --solution-folder mylibs
dotnet sln mysolution.sln add mylib2\mylib2.csproj --solution-folder mylibs
```

The following screenshot shows the result in Visual Studio 2019 Solution Explorer:

dotnet store

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet store` - Stores the specified assemblies in the [runtime package store](#).

Synopsis

```
dotnet store -m|--manifest <PATH_TO_MANIFEST_FILE>
-f|--framework <FRAMEWORK_VERSION> -r|--runtime <RUNTIME_IDENTIFIER>
[--framework-version <FRAMEWORK_VERSION>] [--output <OUTPUT_DIRECTORY>]
[--skip-optimization] [--skip-symbols] [-v|--verbosity <LEVEL>]
[--working-dir <WORKING_DIRECTORY>]

dotnet store -h|--help
```

Description

`dotnet store` stores the specified assemblies in the [runtime package store](#). By default, assemblies are optimized for the target runtime and framework. For more information, see the [runtime package store](#) topic.

Required options

- `-f|--framework <FRAMEWORK>`

Specifies the [target framework](#). The target framework has to be specified in the project file.

- `-m|--manifest <PATH_TO_MANIFEST_FILE>`

The *package store manifest file* is an XML file that contains the list of packages to store. The format of the manifest file is compatible with the SDK-style project format. So, a project file that references the desired packages can be used with the `-m|--manifest` option to store assemblies in the runtime package store. To specify multiple manifest files, repeat the option and path for each file. For example:

```
--manifest packages1.csproj --manifest packages2.csproj .
```

- `-r|--runtime <RUNTIME_IDENTIFIER>`

The [runtime identifier](#) to target.

Optional options

- `--framework-version <FRAMEWORK_VERSION>`

Specifies the .NET SDK version. This option enables you to select a specific framework version beyond the framework specified by the `-f|--framework` option.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-o|--output <OUTPUT_DIRECTORY>`

Specifies the path to the runtime package store. If not specified, it defaults to the *store* subdirectory of the user profile .NET installation directory.

- `--skip-optimization`

Skips the optimization phase. For more information about optimization, see [Preparing a runtime environment](#).

- `--skip-symbols`

Skips symbol generation. Currently, you can only generate symbols on Windows and Linux.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. For more information, see [LoggerVerbosity](#).

- `-w|--working-dir <WORKING_DIRECTORY>`

The working directory used by the command. If not specified, it uses the *obj* subdirectory of the current directory.

Examples

- Store the packages specified in the *packages.csproj* project file for .NET 6.0.1:

```
dotnet store --manifest packages.csproj --framework-version 6.0.1 --framework net6.0 --runtime win-x64
```

- Store the packages specified in the *packages.csproj* without optimization:

```
dotnet store --manifest packages.csproj --skip-optimization --framework net6.0 --runtime linux-x64
```

See also

- [Runtime package store](#)

dotnet test

9/20/2022 • 11 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet test` - .NET test driver used to execute unit tests.

Synopsis

```
dotnet test [<PROJECT> | <SOLUTION> | <DIRECTORY> | <DLL> | <EXE>]
[-a|--test-adapter-path <ADAPTER_PATH>]
[--arch <ARCHITECTURE>]
[--blame]
[--blame-crash]
[--blame-crash-dump-type <DUMP_TYPE>]
[--blame-crash-collect-always]
[--blame-hang]
[--blame-hang-dump-type <DUMP_TYPE>]
[--blame-hang-timeout <TIMESPAN>]
[-c|--configuration <CONFIGURATION>]
[--collect <DATA_COLLECTOR_NAME>]
[-d|--diag <LOG_FILE>]
[-f|--framework <FRAMEWORK>]
[-e|--environment <NAME="VALUE">]
[--filter <EXPRESSION>]
[--interactive]
[-l|--logger <LOGGER>]
[--no-build]
[--nologo]
[--no-restore]
[-o|--output <OUTPUT_DIRECTORY>]
[--os <OS>]
[-r|--results-directory <RESULTS_DIR>]
[--runtime <RUNTIME_IDENTIFIER>]
[-s|--settings <SETTINGS_FILE>]
[-t|--list-tests]
[-v|--verbosity <LEVEL>]
[<args>...]
[[--] <RunSettings arguments>]

dotnet test -h|--help
```

Description

The `dotnet test` command is used to execute unit tests in a given solution. The `dotnet test` command builds the solution and runs a test host application for each test project in the solution. The test host executes tests in the given project using a test framework, for example: MSTest, NUnit, or xUnit, and reports the success or failure of each test. If all tests are successful, the test runner returns 0 as an exit code; otherwise if any test fails, it returns 1.

For multi-targeted projects, tests are run for each targeted framework. The test host and the unit test framework are packaged as NuGet packages and are restored as ordinary dependencies for the project.

Test projects specify the test runner using an ordinary `<PackageReference>` element, as seen in the following

sample project file:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>

<ItemGroup>
  <PackageReference Include="Microsoft.NET.Test.Sdk" Version="17.3.1" />
  <PackageReference Include="xunit" Version="2.4.2" />
  <PackageReference Include="xunit.runner.visualstudio" Version="2.4.5" />
</ItemGroup>

</Project>
```

Where `Microsoft.NET.Test.Sdk` is the test host, `xunit` is the test framework. And `xunit.runner.visualstudio` is a test adapter, which allows the xUnit framework to work with the test host.

Implicit restore

You don't have to run `dotnet restore` because it's run implicitly by all commands that require a restore to occur, such as `dotnet new`, `dotnet build`, `dotnet run`, `dotnet test`, `dotnet publish`, and `dotnet pack`. To disable implicit restore, use the `--no-restore` option.

The `dotnet restore` command is still useful in certain scenarios where explicitly restoring makes sense, such as [continuous integration builds in Azure DevOps Services](#) or in build systems that need to explicitly control when the restore occurs.

For information about how to manage NuGet feeds, see the [dotnet restore documentation](#).

Workload manifest downloads

When you run this command, it initiates an asynchronous background download of advertising manifests for workloads. If the download is still running when this command finishes, the download is stopped. For more information, see [Advertising manifests](#).

Arguments

- `PROJECT | SOLUTION | DIRECTORY | DLL | EXE`

- Path to the test project.
- Path to the solution.
- Path to a directory that contains a project or a solution.
- Path to a test project `.dll` file.
- Path to a test project `.exe` file.

If not specified, the effect is the same as using the `DIRECTORY` argument to specify the current directory.

Options

- `-a|--test-adapter-path <ADAPTER_PATH>`

Path to a directory to be searched for additional test adapters. Only `.dll` files with suffix `.TestAdapter.dll` are inspected. If not specified, the directory of the test `.dll` is searched.

- `--arch <ARCHITECTURE>`

Specifies the target architecture. This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying

--arch x86 sets the RID to win-x86. If you use this option, don't use the -r|--runtime option. Available since .NET 6 Preview 7.

- --blame

Runs the tests in blame mode. This option is helpful in isolating problematic tests that cause the test host to crash. When a crash is detected, it creates a sequence file in TestResults/<Guid>/<Guid>_Sequence.xml that captures the order of tests that were run before the crash.

This option does not create a memory dump and is not helpful when the test is hanging.

- --blame-crash (Available since .NET 5.0 SDK)

Runs the tests in blame mode and collects a crash dump when the test host exits unexpectedly. This option depends on the version of .NET used, the type of error, and the operating system.

For exceptions in managed code, a dump will be automatically collected on .NET 5.0 and later versions. It will generate a dump for testhost or any child process that also ran on .NET 5.0 and crashed. Crashes in native code will not generate a dump. This option works on Windows, macOS, and Linux.

Crash dumps in native code, or when using .NET Core 3.1 or earlier versions, can only be collected on Windows, by using Procdump. A directory that contains procdump.exe and procdump64.exe must be in the PATH or PROCDUMP_PATH environment variable. [Download the tools](#). Implies --blame.

To collect a crash dump from a native application running on .NET 5.0 or later, the usage of Procdump can be forced by setting the VTEST_DUMP_FORCEPROCDUMP environment variable to 1.

- --blame-crash-dump-type <DUMP_TYPE> (Available since .NET 5.0 SDK)

The type of crash dump to be collected. Supported dump types are full (default), and mini. Implies --blame-crash.

- --blame-crash-collect-always (Available since .NET 5.0 SDK)

Collects a crash dump on expected as well as unexpected test host exit.

- --blame-hang (Available since .NET 5.0 SDK)

Run the tests in blame mode and collects a hang dump when a test exceeds the given timeout.

- --blame-hang-dump-type <DUMP_TYPE> (Available since .NET 5.0 SDK)

The type of crash dump to be collected. It should be full, mini, or none. When none is specified, test host is terminated on timeout, but no dump is collected. Implies --blame-hang.

- --blame-hang-timeout <TIMESPAN> (Available since .NET 5.0 SDK)

Per-test timeout, after which a hang dump is triggered and the test host process and all of its child processes are dumped and terminated. The timeout value is specified in one of the following formats:

- 1.5h, 1.5hour, 1.5hours
- 90m, 90min, 90minute, 90minutes
- 5400s, 5400sec, 5400second, 5400seconds
- 5400000ms, 5400000mil, 5400000millisecond, 5400000milliseconds

When no unit is used (for example, 5400000), the value is assumed to be in milliseconds. When used together with data driven tests, the timeout behavior depends on the test adapter used. For xUnit, NUnit, and MSTest 2.2.4+, the timeout is renewed after every test case. For MSTest before version 2.2.4, the timeout is used for all test cases. This option is supported on Windows with netcoreapp2.1 and later, on Linux with netcoreapp3.1 and later, and on macOS with net5.0 or later. Implies --blame and

- `--blame-hang`.
- `-c|--configuration <CONFIGURATION>`

Defines the build configuration. The default for most projects is `Debug`, but you can override the build configuration settings in your project.
- `--collect <DATA_COLLECTOR_NAME>`

Enables data collector for the test run. For more information, see [Monitor and analyze test run](#).

On Windows (x86, x64 and Arm64), Linux (x64) and macOS (x64), you can collect code coverage by using the `--collect "Code Coverage"` option. For more information, see [Use code coverage](#) and [Customize code coverage analysis](#).

To collect code coverage on any platform that is supported by .NET Core, install [Coverlet](#) and use the `--collect "XPlat Code Coverage"` option.
- `-d|--diag <LOG_FILE>`

Enables diagnostic mode for the test platform and writes diagnostic messages to the specified file and to files next to it. The process that is logging the messages determines which files are created, such as `*.host_<date>.txt` for test host log, and `*.datacollector_<date>.txt` for data collector log.
- `-e|--environment <NAME="VALUE">`

Sets the value of an environment variable. Creates the variable if it does not exist, overrides if it does exist. Use of this option will force the tests to be run in an isolated process. The option can be specified multiple times to provide multiple variables.
- `-f|--framework <FRAMEWORK>`

The [target framework moniker \(TFM\)](#) of the target framework to run tests for. The target framework must also be specified in the project file.
- `--filter <EXPRESSION>`

Filters out tests in the current project using the given expression. For more information, see the [Filter option details](#) section. For more information and examples on how to use selective unit test filtering, see [Running selective unit tests](#).
- `-?|-h|--help`

Prints out a description of how to use the command.
- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication. Available since .NET Core 3.0 SDK.
- `-l|--logger <LOGGER>`

Specifies a logger for test results. Unlike MSBuild, `dotnet test` doesn't accept abbreviations: instead of `-l "console;v=d"` use `-l "console;verbosity=detailed"`. Specify the parameter multiple times to enable multiple loggers. For more information, see [Reporting test results](#), [Switches for loggers](#), and the [examples](#) later in this article.
- `--no-build`

Doesn't build the test project before running it. It also implicitly sets the `--no-restore` flag.

- `--nologo`

Run tests without displaying the Microsoft TestPlatform banner. Available since .NET Core 3.0 SDK.
- `--no-restore`

Doesn't execute an implicit restore when running the command.
- `-o|--output <OUTPUT_DIRECTORY>`

Directory in which to find the binaries to run. If not specified, the default path is `./bin/<configuration>/<framework>/`. For projects with multiple target frameworks (via the `TargetFrameworks` property), you also need to define `--framework` when you specify this option. `dotnet test` always runs tests from the output directory. You can use [AppDomain.BaseDirectory](#) to consume test assets in the output directory.
- `--os <OS>`

Specifies the target operating system (OS). This is a shorthand syntax for setting the [Runtime Identifier \(RID\)](#), where the provided value is combined with the default RID. For example, on a `win-x64` machine, specifying `--os linux` sets the RID to `linux-x64`. If you use this option, don't use the `-r|--runtime` option. Available since .NET 6.
- `-r|--results-directory <RESULTS_DIR>`

The directory where the test results are going to be placed. If the specified directory doesn't exist, it's created. The default is `TestResults` in the directory that contains the project file.
- `--runtime <RUNTIME_IDENTIFIER>`

The target runtime to test for.
- `-s|--settings <SETTINGS_FILE>`

The `.runsettings` file to use for running the tests. The `TargetPlatform` element (x86|x64) has no effect for `dotnet test`. To run tests that target x86, install the x86 version of .NET Core. The bitness of the `dotnet.exe` that is on the path is what will be used for running tests. For more information, see the following resources:

 - [Configure unit tests by using a `.runsettings` file.](#)
 - [Configure a test run](#)
- `-t|--list-tests`

List the discovered tests instead of running the tests.
- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).
- `args`

Specifies extra arguments to pass to the adapter. Use a space to separate multiple arguments.

The list of possible arguments depends upon the specified behavior:

 - When you specify a project, solution, or a directory, or if you omit this argument, the call is forwarded to `msbuild`. In that case, the available arguments can be found in [the dotnet msbuild documentation](#).
 - When you specify a `.dll` or an `.exe`, the call is forwarded to `vstest`. In that case, the available

arguments can be found in [the dotnet vstest documentation](#).

- `RunSettings` arguments

Inline `RunSettings` are passed as the last arguments on the command line after "-- " (note the space after --).

Inline `RunSettings` are specified as `[name]=[value]` pairs. A space is used to separate multiple `[name]=[value]` pairs.

Example: `dotnet test -- MSTest.DeploymentEnabled=false MSTest.MapInconclusiveToFailed=True`

For more information, see [Passing RunSettings arguments through command line](#).

Examples

- Run the tests in the project in the current directory:

```
dotnet test
```

- Run the tests in the `test1` project:

```
dotnet test ~/projects/test1/test1.csproj
```

- Run the tests using `test1.dll` assembly:

```
dotnet test ~/projects/test1/bin/debug/test1.dll
```

- Run the tests in the project in the current directory, and generate a test results file in the `trx` format:

```
dotnet test --logger trx
```

- Run the tests in the project in the current directory, and generate a code coverage file (after installing [Coverlet](#) collectors integration):

```
dotnet test --collect:"XPlat Code Coverage"
```

- Run the tests in the project in the current directory, and generate a code coverage file (Windows only):

```
dotnet test --collect "Code Coverage"
```

- Run the tests in the project in the current directory, and log with detailed verbosity to the console:

```
dotnet test --logger "console;verbosity=detailed"
```

- Run the tests in the project in the current directory, and log with the `trx` logger to `testResults.trx` in the `TestResults` folder:

```
dotnet test --logger "trx;logfilename=testResults.trx"
```

Since the log file name is specified, the same name is used for each target framework in the case of a multi-targeted project. The output for each target framework overwrites the output for preceding target frameworks. The file is created in the `TestResults` folder in the test project folder, because relative paths

are relative to that folder. The following example shows how to produce a separate file for each target framework.

- Run the tests in the project in the current directory, and log with the trx logger to files in the *TestResults* folder, with file names that are unique for each target framework:

```
dotnet test --logger:"trx;LogFilePrefix=testResults"
```

- Run the tests in the project in the current directory, and log with the html logger to *testResults.htm* in the *TestResults* folder:

```
dotnet test --logger "html;logfilename=testResults.html"
```

- Run the tests in the project in the current directory, and report tests that were in progress when the test host crashed:

```
dotnet test --blame
```

- Run the tests in the `test1` project, providing the `-bl` (binary log) argument to `msbuild`:

```
dotnet test ~/projects/test1/test1.csproj -bl
```

- Run the tests in the `test1` project, setting the MSBuild `DefineConstants` property to `DEV`:

```
dotnet test ~/projects/test1/test1.csproj -p:DefineConstants="DEV"
```

Filter option details

```
--filter <EXPRESSION>
```

`<Expression>` has the format `<property><operator><value>[|&<Expression>]`.

`<property>` is an attribute of the `Test Case`. The following are the properties supported by popular unit test frameworks:

TEST FRAMEWORK	SUPPORTED PROPERTIES
MSTest	<ul style="list-style-type: none">FullyQualifiedNameNameClassNamePriorityTestCategory
xUnit	<ul style="list-style-type: none">FullyQualifiedNameDisplayNameCategory

TEST FRAMEWORK	SUPPORTED PROPERTIES
NUnit	<ul style="list-style-type: none"> • FullyQualifiedName • Name • TestCategory • Priority

The `<operator>` describes the relationship between the property and the value:

OPERATOR	FUNCTION
<code>=</code>	Exact match
<code>!=</code>	Not exact match
<code>~</code>	Contains
<code>!~</code>	Not contains

`<value>` is a string. All the lookups are case insensitive.

An expression without an `<operator>` is automatically considered as a `contains` on `FullyQualifiedName` property (for example, `dotnet test --filter xyz` is same as `dotnet test --filter FullyQualifiedName~xyz`).

Expressions can be joined with conditional operators:

OPERATOR	FUNCTION
<code> </code>	OR
<code>&</code>	AND

You can enclose expressions in parenthesis when using conditional operators (for example, `(Name~TestMethod1) | (Name~TestMethod2)`).

For more information and examples on how to use selective unit test filtering, see [Running selective unit tests](#).

dotnet tool install

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool install` - Installs the specified .NET tool on your machine.

Synopsis

```
dotnet tool install <PACKAGE_NAME> -g|--global  
  [--add-source <SOURCE>] [--configfile <FILE>] [--disable-parallel]  
  [--framework <FRAMEWORK>] [--ignore-failed-sources] [--interactive]  
  [--no-cache] [--prerelease]  
  [--tool-manifest <PATH>] [-v|--verbosity <LEVEL>]  
  [--version <VERSION_NUMBER>]  
  
dotnet tool install <PACKAGE_NAME> --tool-path <PATH>  
  [--add-source <SOURCE>] [--configfile <FILE>] [--disable-parallel]  
  [--framework <FRAMEWORK>] [--ignore-failed-sources] [--interactive]  
  [--no-cache] [--prerelease]  
  [--tool-manifest <PATH>] [-v|--verbosity <LEVEL>]  
  [--version <VERSION_NUMBER>]  
  
dotnet tool install <PACKAGE_NAME> [--local]  
  [--add-source <SOURCE>] [--configfile <FILE>] [--disable-parallel]  
  [--framework <FRAMEWORK>] [--ignore-failed-sources] [--interactive]  
  [--no-cache] [--prerelease]  
  [--tool-manifest <PATH>] [-v|--verbosity <LEVEL>]  
  [--version <VERSION_NUMBER>]  
  
dotnet tool install -h|--help
```

Description

The `dotnet tool install` command provides a way for you to install .NET tools on your machine. To use the command, you specify one of the following installation options:

- To install a global tool in the default location, use the `--global` option.
- To install a global tool in a custom location, use the `--tool-path` option.
- To install a local tool, omit the `--global` and `--tool-path` options.

Global tools are installed in the following directories by default when you specify the `-g` or `--global` option:

OS	Path
Linux/macOS	<code>\$HOME/.dotnet/tools</code>
Windows	<code>%USERPROFILE%\.dotnet\tools</code>

Local tools are added to a `dotnet-tools.json` file in a `.config` directory under the current directory. If a manifest file doesn't exist yet, create it by running the following command:

```
dotnet new tool-manifest
```

For more information, see [Install a local tool](#).

Arguments

- `PACKAGE_NAME`

Name/ID of the NuGet package that contains the .NET tool to install.

Options

- `--add-source <SOURCE>`

Adds an additional NuGet package source to use during installation. Feeds are accessed in parallel, not sequentially in some order of precedence. If the same package and version is in multiple feeds, the fastest feed wins. For more information, see [What happens when a NuGet package is installed?](#).

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevent restoring multiple projects in parallel.

- `--framework <FRAMEWORK>`

Specifies the [target framework](#) to install the tool for. By default, the .NET SDK tries to choose the most appropriate target framework.

- `-g|--global`

Specifies that the installation is user wide. Can't be combined with the `--tool-path` option. Omitting both `--global` and `--tool-path` specifies a local tool installation.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treat package source failures as warnings.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--local`

Update the tool and the local tool manifest. Can't be combined with the `--global` option or the `--tool-path` option.

- `--no-cache`

Do not cache packages and HTTP requests.

- `--prerelease`

Include prerelease packages.

- `--tool-manifest <PATH>`

Path to the manifest file.

- `--tool-path <PATH>`

Specifies the location where to install the Global Tool. PATH can be absolute or relative. If PATH doesn't exist, the command tries to create it. Omitting both `--global` and `--tool-path` specifies a local tool installation.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. For more information, see [LoggerVerbosity](#).

- `--version <VERSION_NUMBER>`

The version of the tool to install. By default, the latest stable package version is installed. Use this option to install preview or older versions of the tool.

Examples

- `dotnet tool install -g dotnetsay`

Installs `dotnetsay` as a global tool in the default location.

- `dotnet tool install dotnetsay --tool-path c:\global-tools`

Installs `dotnetsay` as a global tool in a specific Windows directory.

- `dotnet tool install dotnetsay --tool-path ~/bin`

Installs `dotnetsay` as a global tool in a specific Linux/macOS directory.

- `dotnet tool install -g dotnetsay --version 2.0.0`

Installs version 2.0.0 of `dotnetsay` as a global tool.

- `dotnet tool install dotnetsay`

Installs `dotnetsay` as a local tool for the current directory.

dotnet tool list

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool list` - Lists all .NET tools of the specified type currently installed on your machine.

Synopsis

```
dotnet tool list -g|--global  
dotnet tool list --tool-path <PATH>  
dotnet tool list --local  
dotnet tool list  
dotnet tool list -h|--help
```

Description

The `dotnet tool list` command provides a way for you to list all .NET global, tool-path, or local tools installed on your machine. The command lists the package name, version installed, and the tool command. To use the command, you specify one of the following:

- To list global tools installed in the default location, use the `--global` option
- To list global tools installed in a custom location, use the `--tool-path` option.
- To list local tools, use the `--local` option or omit the `--global`, `--tool-path`, and `--local` options.

Options

- `-g|--global`

Lists user-wide global tools. Can't be combined with the `--tool-path` option. Omitting both `--global` and `--tool-path` lists local tools.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--local`

Lists local tools for the current directory. Can't be combined with the `--global` or `--tool-path` options. Omitting both `--global` and `--tool-path` lists local tools even if `--local` is not specified.

- `--tool-path <PATH>`

Specifies a custom location where to find global tools. PATH can be absolute or relative. Can't be combined with the `--global` option. Omitting both `--global` and `--tool-path` lists local tools.

Examples

- `dotnet tool list -g`

Lists all global tools installed user-wide on your machine (current user profile).

- `dotnet tool list --tool-path c:\global-tools`

Lists the global tools from a specific Windows directory.

- `dotnet tool list --tool-path ~/bin`

Lists the global tools from a specific Linux/macOS directory.

- `dotnet tool list` or `dotnet tool list --local`

Lists all local tools available in the current directory.

- [.NET tools](#)
- [Tutorial: Install and use a .NET global tool using the .NET CLI](#)
- [Tutorial: Install and use a .NET local tool using the .NET CLI](#)

dotnet tool restore

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool restore` - Installs the .NET local tools that are in scope for the current directory.

Synopsis

```
dotnet tool restore
  [--configfile <FILE>] [--add-source <SOURCE>]
  [--tool-manifest <PATH_TO_MANIFEST_FILE>] [--disable-parallel]
  [--ignore-failed-sources] [--no-cache] [--interactive]
  [-v|--verbosity <LEVEL>]

dotnet tool restore -h|--help
```

Description

The `dotnet tool restore` command finds the tool manifest file that is in scope for the current directory and installs the tools that are listed in it. For information about manifest files, see [Install a local tool](#) and [Invoke a local tool](#).

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--add-source <SOURCE>`

Adds an additional NuGet package source to use during installation. Feeds are accessed in parallel, not sequentially in some order of precedence. If the same package and version is in multiple feeds, the fastest feed wins. For more information, see [What happens when a NuGet package is installed?](#).

- `--tool-manifest <PATH>`

Path to the manifest file.

- `--disable-parallel`

Prevent restoring multiple projects in parallel.

- `--ignore-failed-sources`

Treat package source failures as warnings.

- `--no-cache`

Do not cache packages and http requests.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]` , `m[inimal]` , `n[ormal]` , `d[etailed]` , and `diag[nostic]` . For more information, see [LoggerVerbosity](#).

Example

- `dotnet tool restore`

Restores local tools for the current directory.

See also

- [.NET tools](#)
- [Tutorial: Install and use a .NET local tool using the .NET CLI](#)

dotnet tool run

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool run` - Invokes a local tool.

Synopsis

```
dotnet tool run <COMMAND NAME>
```

```
dotnet tool run -h|--help
```

Description

The `dotnet tool run` command searches tool manifest files that are in scope for the current directory. When it finds a reference to the specified tool, it runs the tool. For more information, see [Invoke a local tool](#).

Arguments

- `COMMAND_NAME`

The command name of the tool to run.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Example

- `dotnet tool run dotnetsay`

Runs the `dotnetsay` local tool.

See also

- [.NET tools](#)
- [Tutorial: Install and use a .NET local tool using the .NET CLI](#)

dotnet tool search

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 5 SDK and later versions

Name

`dotnet tool search` - Searches all .NET tools that are published to NuGet.

Synopsis

```
dotnet tool search [--detail] [--prerelease]
                   [--skip <NUMBER>] [--take <NUMBER>] <SEARCH TERM>

dotnet tool search -h|--help
```

Description

The `dotnet tool search` command provides a way for you to search NuGet for tools that can be used as .NET global, tool-path, or local tools. The command searches the tool names and metadata such as titles, descriptions, and tags.

The command uses the [NuGet Search API](#). It filters on `packageType=dotnettool` to select only .NET tool packages.

Options

- `--detail`

Shows detailed results from the query.

- `--prerelease`

Includes pre-release packages.

- `--skip <NUMBER>`

Specifies the number of query results to skip. Used for pagination.

- `--take <NUMBER>`

Specifies the number of query results to show. Used for pagination.

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Search NuGet.org for .NET tools that have "format" in their package name or description:

```
dotnet tool search format
```

The output looks like the following example:

Package ID	Downloads	Verified	Latest Version	Authors
dotnet-format	496746		4.1.131201	Microsoft
bsoa.generator	533		1.0.0	Microsoft

- Search NuGet.org for .NET tools that have "format" in their package name or metadata, show only the first result, and show a detailed view.

```
dotnet tool search format --take 1 --detail
```

The output looks like the following example:

```
-----  
dotnet-format  
Latest Version: 4.1.131201  
Authors: Microsoft  
Tags:  
Downloads: 496746  
Verified: False  
Description: Command line tool for formatting C# and Visual Basic code files based on .editorconfig settings.  
Versions:  
    3.0.2 Downloads: 1973  
    3.0.4 Downloads: 9064  
    3.1.37601 Downloads: 114730  
    3.2.107702 Downloads: 13423  
    3.3.111304 Downloads: 131195  
    4.0.130203 Downloads: 78610  
    4.1.131201 Downloads: 145927
```

dotnet tool uninstall

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool uninstall` - Uninstalls the specified .NET tool from your machine.

Synopsis

```
dotnet tool uninstall <PACKAGE_NAME> -g|--global  
dotnet tool uninstall <PACKAGE_NAME> --tool-path <PATH>  
dotnet tool uninstall <PACKAGE_NAME>  
dotnet tool uninstall -h|--help
```

Description

The `dotnet tool uninstall` command provides a way for you to uninstall .NET tools from your machine. To use the command, you specify one of the following options:

- To uninstall a global tool that was installed in the default location, use the `--global` option.
- To uninstall a global tool that was installed in a custom location, use the `--tool-path` option.
- To uninstall a local tool, omit the `--global` and `--tool-path` options.

Arguments

- `<PACKAGE_NAME>`

Name/ID of the NuGet package that contains the .NET tool to uninstall. You can find the package name using the `dotnet tool list` command.

Options

- `-g|--global`

Specifies that the tool to be removed is from a user-wide installation. Can't be combined with the `--tool-path` option. Omitting both `--global` and `--tool-path` specifies that the tool to be removed is a local tool.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--tool-path <PATH>`

Specifies the location where to uninstall the tool. PATH can be absolute or relative. Can't be combined with the `--global` option. Omitting both `--global` and `--tool-path` specifies that the tool to be removed is a local tool.

Examples

- `dotnet tool uninstall -g dotnetsay`

Uninstalls the `dotnetsay` global tool.

- `dotnet tool uninstall dotnetsay --tool-path c:\global-tools`

Uninstalls the `dotnetsay` global tool from a specific Windows directory.

- `dotnet tool uninstall dotnetsay --tool-path ~/bin`

Uninstalls the `dotnetsay` global tool from a specific Linux/macOS directory.

- `dotnet tool uninstall dotnetsay`

Uninstalls the `dotnetsay` local tool from the current directory.

dotnet tool update

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet tool update` - Updates the specified .NET tool on your machine.

Synopsis

```
dotnet tool update <PACKAGE_ID> -g|--global  
  [--add-source <SOURCE>] [--configfile <FILE>]  
  [--disable-parallel] [--framework <FRAMEWORK>]  
  [--ignore-failed-sources] [--interactive] [--no-cache]  
  [-v|--verbosity <LEVEL>] [--version <VERSION>]  
  
dotnet tool update <PACKAGE_ID> --tool-path <PATH>  
  [--add-source <SOURCE>] [--configfile <FILE>]  
  [--disable-parallel] [--framework <FRAMEWORK>]  
  [--ignore-failed-sources] [--interactive] [--no-cache]  
  [-v|--verbosity <LEVEL>] [--version <VERSION>]  
  
dotnet tool update <PACKAGE_ID> --local  
  [--add-source <SOURCE>] [--configfile <FILE>]  
  [--disable-parallel] [--framework <FRAMEWORK>]  
  [--ignore-failed-sources] [--interactive] [--no-cache]  
  [--tool-manifest <PATH>]  
  [-v|--verbosity <LEVEL>] [--version <VERSION>]  
  
dotnet tool update -h|--help
```

Description

The `dotnet tool update` command provides a way for you to update .NET tools on your machine to the latest stable version of the package. The command uninstalls and reinstalls a tool, effectively updating it. To use the command, you specify one of the following options:

- To update a global tool that was installed in the default location, use the `-global` option
- To update a global tool that was installed in a custom location, use the `--tool-path` option.
- To update a local tool, use the `--local` option.

Arguments

- `<PACKAGE_ID>`

Name/ID of the NuGet package that contains the .NET global tool to update. You can find the package name using the [dotnet tool list](#) command.

Options

- `--add-source <SOURCE>`

Adds an additional NuGet package source to use during installation. Feeds are accessed in parallel, not sequentially in some order of precedence. If the same package and version is in multiple feeds, the fastest feed wins. For more information, see [What happens when a NuGet package is installed?](#)

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevent restoring multiple projects in parallel.

- `--framework <FRAMEWORK>`

Specifies the [target framework](#) to update the tool for.

- `-g|--global`

Specifies that the update is for a user-wide tool. Can't be combined with the `--tool-path` option. Omitting both `--global` and `--tool-path` specifies that the tool to be updated is a local tool.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treat package source failures as warnings.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--local`

Update the tool and the local tool manifest. Can't be combined with the `--global` option or the `--tool-path` option.

- `--no-cache`

Do not cache packages and HTTP requests.

- `--tool-manifest <PATH>`

Path to the manifest file.

- `--tool-path <PATH>`

Specifies the location where the global tool is installed. PATH can be absolute or relative. Can't be combined with the `--global` option. Omitting both `--global` and `--tool-path` specifies that the tool to be updated is a local tool.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. For more information, see [LoggerVerbosity](#).

- `--version <VERSION>`

The version range of the tool package to update to. This cannot be used to downgrade versions, you must

`uninstall` newer versions first.

Examples

- `dotnet tool update -g dotnetsay`

Updates the `dotnetsay` global tool.

- `dotnet tool update dotnetsay --tool-path c:\global-tools`

Updates the `dotnetsay` global tool located in a specific Windows directory.

- `dotnet tool update dotnetsay --tool-path ~/bin`

Updates the `dotnetsay` global tool located in a specific Linux/macOS directory.

- `dotnet tool update dotnetsay`

Updates the `dotnetsay` local tool installed for the current directory.

- `dotnet tool update -g dotnetsay --version 2.0.*`

Updates the `dotnetsay` global tool to the latest patch version, with a major version of `2`, and a minor version of `0`.

- `dotnet tool update -g dotnetsay --version (2.0.*,2.1.4)`

Updates the `dotnetsay` global tool to the lowest version within the specified range `(> 2.0.0 && < 2.1.4)`, version `2.1.0` would be installed. For more information on semantic versioning ranges, see [NuGet packaging version ranges](#).

dotnet vstest

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

IMPORTANT

The `dotnet vstest` command is superseded by `dotnet test`, which can now be used to run assemblies. See [dotnet test](#).

Name

`dotnet vstest` - Runs tests from the specified assemblies.

Synopsis

```
dotnet vstest [<TEST_FILE_NAMES>] [--Blame] [--Diag <PATH_TO_LOG_FILE>]
    [--Framework <FRAMEWORK>] [--InIsolation] [-lt|--ListTests <FILE_NAME>]
    [--logger <LOGGER_URI/FRIENDLY_NAME>] [--Parallel]
    [--ParentProcessId <PROCESS_ID>] [--Platform] <PLATFORM_TYPE>
    [--Port <PORT>] [--ResultsDirectory<PATH>] [--Settings <SETTINGS_FILE>]
    [--TestAdapterPath <PATH>] [--TestCaseFilter <EXPRESSION>]
    [--Tests <TEST_NAMES>] [[--] <args>...]]]

dotnet vstest -?|--Help
```

Description

The `dotnet vstest` command runs the `vstest.console` command-line application to run automated unit tests.

Arguments

- `TEST_FILE_NAMES`

Run tests from the specified assemblies. Separate multiple test assembly names with spaces. Wildcards are supported.

Options

- `--Blame`

Runs the tests in blame mode. This option is helpful in isolating the problematic tests causing test host to crash. It creates an output file in the current directory as *Sequence.xml* that captures the order of tests execution before the crash.

- `--Diag <PATH_TO_LOG_FILE>`

Enables verbose logs for the test platform. Logs are written to the provided file.

- `--Framework <FRAMEWORK>`

Target .NET Framework version used for test execution. Examples of valid values are

.NETFramework,Version=v4.6 or .NETCoreApp,Version=v1.0. Other supported values are Framework40, Framework45, FrameworkCore10, and FrameworkUap10.

- --InIsolation

Runs the tests in an isolated process. This makes *vstest.console.exe* process less likely to be stopped on an error in the tests, but tests may run slower.

- -lt|--ListTests <FILE_NAME>

Lists all discovered tests from the given test container.

- --logger <LOGGER_URI/FRIENDLY_NAME>

Specify a logger for test results.

- To publish test results to Team Foundation Server, use the TfsPublisher logger provider:

```
/logger:TfsPublisher;
    Collection=<team project collection url>;
    BuildName=<build name>;
    TeamProject=<team project name>
    [;Platform=<Defaults to "Any CPU">]
    [;Flavor=<Defaults to "Debug">]
    [;RunTitle=<title>]
```

- To log results to a Visual Studio Test Results File (TRX), use the trx logger provider. This switch creates a file in the test results directory with given log file name. If LogFileName isn't provided, a unique file name is created to hold the test results.

```
/logger:trx [;LogFileName=<Defaults to unique file name>]
```

- --Parallel

Run tests in parallel. By default, all available cores on the machine are available for use. Specify an explicit number of cores by setting the MaxCpuCount property under the RunConfiguration node in the *runsettings* file.

- --ParentProcessId <PROCESS_ID>

Process ID of the parent process responsible for launching the current process.

- --Platform <PLATFORM_TYPE>

Target platform architecture used for test execution. Valid values are x86, x64, and ARM.

- --Port <PORT>

Specifies the port for the socket connection and receiving the event messages.

- --ResultsDirectory:<PATH>

Test results directory will be created in specified path if not exists.

- --Settings <SETTINGS_FILE>

Settings to use when running tests.

- --TestAdapterPath <PATH>

Use custom test adapters from a given path (if any) in the test run.

- `--TestCaseFilter <EXPRESSION>`

Run tests that match the given expression. `<EXPRESSION>` is of the format `<property>Operator<value>[|&<EXPRESSION>]`, where Operator is one of `=`, `!=`, or `~`. Operator `~` has 'contains' semantics and is applicable for string properties like `DisplayName`. Parentheses `()` are used to group subexpressions. For more information, see [TestCase filter](#).

- `--Tests <TEST_NAMES>`

Run tests with names that match the provided values. Separate multiple values with commas.

- `-?|--Help`

Prints out a short help for the command.

- `@<file>`

Reads response file for more options.

- `args`

Specifies extra arguments to pass to the adapter. Arguments are specified as name-value pairs of the form `<n>=<v>`, where `<n>` is the argument name and `<v>` is the argument value. Use a space to separate multiple arguments.

Examples

Run tests in `mytestproject.dll`:

```
dotnet vstest mytestproject.dll
```

Run tests in `mytestproject.dll`, exporting to custom folder with custom name:

```
dotnet vstest mytestproject.dll --logger:"trx;LogFileName=custom_file_name.trx" --
ResultsDirectory:custom/file/path
```

Run tests in `mytestproject.dll` and `myothertestproject.exe`:

```
dotnet vstest mytestproject.dll myothertestproject.exe
```

Run `TestMethod1` tests:

```
dotnet vstest /Tests:TestMethod1
```

Run `TestMethod1` and `TestMethod2` tests:

```
dotnet vstest /Tests:TestMethod1,TestMethod2
```

dotnet watch

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Name

`dotnet watch` - Restarts or [hot reloads](#) the specified application when changes in the source code are detected.

Synopsis

```
dotnet watch [--list]
[--no-hot-reload] [--non-interactive]
[--project <PROJECT>]
[-q|--quiet] [-v|--verbose]
[--version]
[--] <forwarded arguments>

dotnet watch -?|-h|--help
```

Description

The `dotnet watch` command is a file watcher. When it detects a change that is supported for [hot reload](#), it hot reloads the specified application. When it detects an unsupported change, it restarts the application. This process enables fast iterative development from the command line.

While running `dotnet watch`, you can force the app to rebuild and restart by pressing Ctrl+R in the command shell. This feature is available only while the app is running. For example, if you run `dotnet watch` on a console app that ends before you press Ctrl+R, pressing Ctrl+R has no effect. However, in that case `dotnet watch` is still watching files and will restart the app if a file is updated.

Arguments

- `forwarded arguments`

Arguments to pass to the child `dotnet` process. For example: `run` with options for [dotnet run](#) or `test` with options for [dotnet test](#). If the child command isn't specified, the default is `run` for `dotnet run`.

Options

- `--list`

Lists all discovered files without starting the watcher.

- `--no-hot-reload`

Suppress [hot reload](#) for supported apps.

- `--non-interactive`

Runs `dotnet watch` in non-interactive mode. Use this option to prevent console input from being requested. When hot reload is enabled and a [rude edit](#) is detected, dotnet watch restarts the app.

- `--project <PATH>`
Specifies the path of the project file to run (folder only or including the project file name). If not specified, it defaults to the current directory.
- `-q|--quiet`
Suppresses all output that is generated by the `dotnet watch` command except warnings and errors. The option is not passed on to child commands. For example, output from `dotnet restore` and `dotnet run` continues to be output.
- `-v|--verbose`
Shows verbose output for debugging.
- `--version`
Shows the version of `dotnet watch`.
- `--`
The **double-dash option ('--')** can be used to delimit `dotnet watch` options from arguments that will be passed to the child process. Its use is optional. When the double-dash option isn't used, `dotnet watch` considers the first unrecognized argument to be the beginning of arguments that it should pass into the child `dotnet` process.

Environment variables

`dotnet watch` uses the following environment variables:

- `DOTNET_HOTRELOAD_NAMEDPIPE_NAME`
This value is configured by `dotnet watch` when the app is to be launched, and it specifies the named pipe.
- `DOTNET_USE_POLLING_FILE_WATCHER`
When set to `1` or `true`, `dotnet watch` uses a polling file watcher instead of `System.IO.FileSystemWatcher`. Polling is required for some file systems, such as network shares, Docker mounted volumes, and other virtual file systems. The `PhysicalFileProvider` class uses `DOTNET_USE_POLLING_FILE_WATCHER` to determine whether the `PhysicalFileProvider.Watch` method will rely on the `PollingFileChangeToken`.
- `DOTNET_WATCH`
`dotnet watch` sets this variable to `1` on all child processes that it launches.
- `DOTNET_WATCH_AUTO_RELOAD_WS_HOSTNAME`
As part of `dotnet watch`, the browser refresh server mechanism reads this value to determine the WebSocket host environment. The value `127.0.0.1` is replaced by `localhost`, and the `http://` and `https://` schemes are replaced with `ws://` and `wss://` respectively.
- `DOTNET_WATCH_ITERATION`
`dotnet watch` sets this variable to `1` and increments by one each time a file is changed and the command restarts or hot reloads the application.
- `DOTNET_WATCH_SUPPRESS_BROWSER_REFRESH`
When set to `1` or `true`, `dotnet watch` won't refresh browsers when it detects file changes.

- `DOTNET_WATCH_SUPPRESS_EMOJIS`

With the .NET SDK 6.0.300 and later, `dotnet watch` emits non-ASCII characters to the console, as shown in the following example:

```
dotnet watch [ Hot reload enabled. For a list of supported edits, see https://aka.ms/dotnet/hot-reload.  
[ Press "Ctrl + R" to restart.  
dotnet watch [ Building...  
dotnet watch [ Started  
dotnet watch [ Exited  
dotnet watch [ Waiting for a file to change before restarting dotnet...]
```

On certain console hosts, these characters may appear garbled. To avoid seeing garbled characters, set this variable to `1` or `true`.

- `DOTNET_WATCH_SUPPRESS_LAUNCH_BROWSER`

When set to `1` or `true`, `dotnet watch` won't launch or refresh browsers for web apps that have `launchBrowser` configured in `launchSettings.json`.

- `DOTNET_WATCH_SUPPRESS_MSBUILD_INCREMENTALISM`

By default, `dotnet watch` optimizes the build by avoiding certain operations, such as running restore or re-evaluating the set of watched files on every file change. If this variable is set to `1` or `true`, these optimizations are disabled.

- `DOTNET_WATCH_SUPPRESS_STATIC_FILE_HANDLING`

When set to `1` or `true`, `dotnet watch` won't do special handling for static content files. `dotnet watch` sets MSBuild property `DotNetWatchContentFiles` to `false`.

Files watched by default

`dotnet watch` watches all items in the `Watch` item group in the project file. By default, this group includes all items in the `Compile` and `EmbeddedResource` groups. `dotnet watch` also scans the entire graph of project references and watches all files within those projects.

By default, the `Compile` and `EmbeddedResource` groups include all files matching the following glob patterns:

- `**/*.cs`
- `*.csproj`
- `**/*.resx`
- Content files in web apps: `wwwroot/**`

By default, `.config`, and `.json` files don't trigger a `dotnet watch` restart because the configuration system has its own mechanisms for handling configuration changes.

Files can be added to the watch list or removed from the list by editing the project file. Files can be specified individually or by using glob patterns.

Watch additional files

More files can be watched by adding items to the `Watch` group. For example, the following markup extends that group to include JavaScript files:

```
<ItemGroup>
  <Watch Include="**\*.js" Exclude="node_modules\**\*;**\*.js.map;obj\**\*;bin\**\*" />
</ItemGroup>
```

Ignore specified files

`dotnet watch` will ignore `Compile` and `EmbeddedResource` items that have the `Watch="false"` attribute, as shown in the following example:

```
<ItemGroup>
  <Compile Update="Generated.cs" Watch="false" />
  <EmbeddedResource Update="Strings.resx" Watch="false" />
</ItemGroup>
```

`dotnet watch` will ignore project references that have the `Watch="false"` attribute, as shown in the following example:

```
<ItemGroup>
  <ProjectReference Include="..\ClassLibrary1\ClassLibrary1.csproj" Watch="false" />
</ItemGroup>
```

Advanced configuration

`dotnet watch` performs a design-time build to find items to watch. When this build is run, `dotnet watch` sets the property `DotNetWatchBuild=true`. This property can be used as shown in the following example:

```
<ItemGroup Condition="'$(DotNetWatchBuild)'=='true'">
  <!-- only included in the project when dotnet-watch is running -->
</ItemGroup>
```

Hot Reload

Starting in .NET 6, `dotnet watch` includes support for *hot reload*. Hot reload is a feature that lets you apply changes to a running app without having to rebuild and restart it. The changes may be to code files or static assets, such as stylesheet files and JavaScript files. This feature streamlines the local development experience, as it gives immediate feedback when you modify your app.

For information about app types and .NET versions that support hot reload, see [Supported .NET app frameworks and scenarios](#).

Rude edits

When a file is modified, `dotnet watch` determines if the app can be hot reloaded. If it can't be hot reloaded, the change is called a *rude edit* and `dotnet watch` asks if you want to restart the app:

```
dotnet watch ↵ Unable to apply hot reload because of a rude edit.
 ↵ Do you want to restart your app - Yes (y) / No (n) / Always (a) / Never (v)?
```

- **Yes:** Restarts the app.
- **No:** Leaves the app running without the changes applied.
- **Always:** Restarts the app and doesn't prompt anymore for rude edits.
- **Never:** Leaves the app running without the changes applied and doesn't prompt anymore for rude edits.

For information about what kinds of changes are considered rude edits, see [Edit code and continue debugging](#) and [Unsupported changes to code](#).

To disable hot reload when you run `dotnet watch`, use the `--no-hot-reload` option, as shown in the following example:

```
dotnet watch --no-hot-reload
```

Examples

- Run `dotnet run` for the project in the current directory whenever source code changes:

```
dotnet watch
```

Or:

```
dotnet watch run
```

- Run `dotnet test` for the project in the current directory whenever source code changes:

```
dotnet watch test
```

- Run `dotnet run --project ./HelloWorld.csproj` whenever source code changes:

```
dotnet watch run --project ./HelloWorld.csproj
```

- Run `dotnet run -- arg0` for the project in the current directory whenever source code changes:

```
dotnet watch run -- arg0
```

Or:

```
dotnet watch -- run arg0
```

dotnet workload install

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload install` - Installs optional workloads.

Synopsis

```
dotnet workload install <WORKLOAD_ID>...
  [--configfile <FILE>] [--disable-parallel]
  [--ignore-failed-sources] [--include-previews] [--interactive]
  [--no-cache] [--skip-manifest-update]
  [--source <SOURCE>] [--temp-dir <PATH>] [-v|--verbosity <LEVEL>]

dotnet workload install -?|-h|--help
```

Description

The `dotnet workload install` command installs one or more *optional workloads*. Optional workloads can be installed on top of the .NET SDK to provide support for various application types, such as [.NET MAUI](#) and [Blazor WebAssembly AOT](#).

Use [dotnet workload search](#) to learn what workloads are available to install.

When to run elevated

For macOS and Linux SDK installations that are installed to a protected directory, the command needs to run elevated (use the `sudo` command). On Windows, the command doesn't need to run elevated even if the SDK is installed to the *Program Files* directory. For Windows, the command uses MSI installers for that location.

Results vary by SDK version

The `dotnet workload` commands operate in the context of specific SDK versions. Suppose you have both .NET 6.0.100 SDK and .NET 6.0.200 SDK installed. The `dotnet workload` commands will give different results depending on which SDK version you select. This behavior applies to major and minor version and feature band differences, not to patch version differences. For example, .NET SDK 6.0.101 and 6.0.102 give the same results, whereas 6.0.100 and 6.0.200 give different results. You can specify the SDK version by using the [`global.json` file](#) or the `--sdk-version` option of the `dotnet workload` commands.

Advertising manifests

The names and versions of the assets that a workload installation requires are maintained in *manifests*. By default, the `dotnet workload install` command downloads the latest available manifests before it installs a workload. The local copy of a manifest then provides the information needed to find and download the assets for a workload.

The `dotnet workload list` command compares the versions of installed workloads with the currently available versions. When it finds that a version newer than the installed version is available, it advertises that fact in the command output. These newer-version notifications in `dotnet workload list` are available starting in .NET 6.

To enable these notifications, the latest available versions of the manifests are downloaded and stored as

advertising manifests. These downloads happen asynchronously in the background when any of the following commands are run.

- `dotnet build`
- `dotnet pack`
- `dotnet publish`
- `dotnet restore`
- `dotnet run`
- `dotnet test`

If a command finishes before the manifest download finishes, the download is stopped. The download is tried again the next time one of these commands is run. You can set environment variables to [disable these background downloads](#) or [control their frequency](#). By default, they don't happen more than once a day.

You can prevent the `dotnet workload install` command from doing manifest downloads by using the `--skip-manifest-update` option.

The `dotnet workload update` command also downloads advertising manifests. The downloads are required to learn if an update is available, so there is no option to prevent them from running. However, you can use the `--advertising-manifests-only` option to skip workload updates and only do the manifest downloads. This option is available starting in .NET 6.

Arguments

- `WORKLOAD_ID` ...

The workload ID or multiple IDs to install. Use [dotnet workload search](#) to learn what workloads are available.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevents restoring multiple projects in parallel.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treats package source failures as warnings.

- `--include-previews`

Allows prerelease workload manifests.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--no-cache`

Prevents caching of packages and http requests.

- `--skip-manifest-update`

Skip updating the workload manifests. The workload manifests define what assets and versions need to be installed for each workload.

- `-s|--source <SOURCE>`

Specifies the URI of the NuGet package source to use. This setting overrides all of the sources specified in the *nuget.config* files. Multiple sources can be provided by specifying this option multiple times.

- `--temp-dir <PATH>`

Specify the temporary directory used to download and extract NuGet packages (must be secure).

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. If you specify `detailed` or `diagnostic` verbosity, the command displays information about the Nuget packages that it downloads.

Examples

- Install the `maui` workload:

```
dotnet workload install maui
```

- Install the `maui-android` and `maui-ios` workloads:

```
dotnet workload install maui-android maui-ios
```

dotnet workload list

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload list` - Lists installed workloads.

Synopsis

```
dotnet workload list [-v|--verbosity <LEVEL>]  
dotnet workload list [-?|-h|--help]
```

Description

The `dotnet workload list` command lists all installed workloads.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- List the installed workloads:

```
dotnet workload list
```

dotnet workload repair

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload repair` - Repairs workloads installations.

Synopsis

```
dotnet workload repair  
  [--configfile] [--disable-parallel] [--ignore-failed-sources]  
  [--interactive] [--no-cache]  
  [-s|--source <SOURCE>] [--temp-dir <PATH>]  
  [-v|--verbosity <LEVEL>]  
  
dotnet workload repair -?|-h|--help
```

Description

The `dotnet workload repair` command reinstalls all installed workloads. Workloads are made up of multiple workload packs and it's possible to get into a state where some installed successfully but others didn't. For example, a `dotnet workload install` command might not finish installing because of a dropped internet connection.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevents restoring multiple projects in parallel.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treats package source failures as warnings.

- `--include-previews`

Allows prerelease workload manifests.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--no-cache`

Prevents caching of packages and http requests.

- `-s|--source <SOURCE>`

Specifies the URI of the NuGet package source to use. This setting overrides all of the sources specified in the *nuget.config* files. Multiple sources can be provided by specifying this option multiple times.

- `--temp-dir <PATH>`

Specify the temporary directory used to download and extract NuGet packages (must be secure).

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- Repair all installed workloads:

```
dotnet workload repair
```

dotnet workload restore

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload restore` - Installs workloads needed for a project or a solution.

Synopsis

```
dotnet workload restore [<PROJECT | SOLUTION>]
  [--configfile <FILE>] [--disable-parallel]
  [--ignore-failed-sources] [--include-previews] [--interactive]
  [--no-cache] [--skip-manifest-update]
  [-s|--source <SOURCE>] [--temp-dir <PATH>] [-v|--verbosity <LEVEL>]

dotnet workload restore -?|-h|--help
```

Description

The `dotnet workload restore` command analyzes a project or solution to determine which workloads it needs, then installs any workloads that are missing.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Arguments

- `PROJECT | SOLUTION`

The project or solution file to install workloads for. If a file is not specified, the command searches the current directory for one.

Options

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevents restoring multiple projects in parallel.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treats package source failures as warnings.

- `--include-previews`

Allows prerelease workload manifests.
- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.
- `--no-cache`

Prevents caching of packages and http requests.
- `--skip-manifest-update`

Skip updating the workload manifests. The workload manifests define what assets and versions need to be installed for each workload.
- `-s|--source <SOURCE>`

Specifies the URI of the NuGet package source to use. This setting overrides all of the sources specified in the *nuget.config* files. Multiple sources can be provided by specifying this option multiple times.
- `--temp-dir <PATH>`

Specify the temporary directory used to download and extract NuGet packages (must be secure).
- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Example

- Restore workloads needed by `MyApp.csproj`:

```
dotnet workload restore MyApp.csproj
```

dotnet workload search

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload search` - Searches for optional workloads.

Synopsis

```
dotnet workload search [<SEARCH_STRING>] [-v|--verbosity <LEVEL>]
```

```
dotnet workload search -?|-h|--help
```

Description

The `dotnet workload search` command lists available workloads. You can filter the list by specifying all or part of the workload ID you're looking for.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Arguments

- `<SEARCH_STRING>`

The workload ID to search for, or part of it. For example, if you specify `maui`, the command lists all of the workload IDs that have `maui` in their workload ID.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. For more information, see [LoggerVerbosity](#).

Examples

- List all available workloads:

```
dotnet workload search
```

- List all available workloads that have "maui" in their workload ID:

```
dotnet workload search maui
```

dotnet workload uninstall

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload uninstall` - Uninstalls a specified workload.

Synopsis

```
dotnet workload uninstall <WORKLOAD_ID...>
```

```
dotnet workload uninstall -?|-h|--help
```

Description

The `dotnet workload uninstall` command uninstalls one or more workloads.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Arguments

- `WORKLOAD_ID...`

The workload ID or multiple IDs to uninstall.

Options

- `-?|-h|--help`

Prints out a description of how to use the command.

Examples

- Uninstall the `maui` workload:

```
dotnet workload uninstall maui
```

- Uninstall the `maui-android` and `maui-ios` workloads:

```
dotnet workload uninstall maui-android maui-ios
```

dotnet workload update

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6 SDK and later versions

Name

`dotnet workload update` - Updates installed workloads.

Synopsis

```
dotnet workload update
  [--advertising-manifests-only]
  [--configfile <FILE>] [--disable-parallel]
  [--from-previous-sdk] [--ignore-failed-sources]
  [--include-previews] [--interactive] [--no-cache]
  [-s|--source <SOURCE>] [--temp-dir <PATH>]
  [-v|--verbosity <LEVEL>]

dotnet workload update -?|-h|--help
```

Description

The `dotnet workload update` command updates all installed workloads to the newest available versions. It queries Nuget.org for updated workload manifests. It then updates local manifests, downloads new versions of the installed workloads, and removes all old versions of each workload.

For more information about the `dotnet workload` commands, see the [dotnet workload install](#) command.

Options

- `--advertising-manifests-only`

Downloads [advertising manifests](#) but doesn't update any workloads.

- `--configfile <FILE>`

The NuGet configuration file (*nuget.config*) to use. If specified, only the settings from this file will be used. If not specified, the hierarchy of configuration files from the current directory will be used. For more information, see [Common NuGet Configurations](#).

- `--disable-parallel`

Prevents restoring multiple projects in parallel.

- `--from-previous-sdk`

Include workloads installed with previous SDK versions in the update.

- `-?|-h|--help`

Prints out a description of how to use the command.

- `--ignore-failed-sources`

Treats package source failures as warnings.

- `--include-previews`

Allows prerelease workload manifests.

- `--interactive`

Allows the command to stop and wait for user input or action. For example, to complete authentication.

- `--no-cache`

Prevents caching of packages and http requests.

- `-s|--source <SOURCE>`

Specifies the URI of the NuGet package source to use. This setting overrides all of the sources specified in the *nuget.config* files. Multiple sources can be provided by specifying this option multiple times.

- `--temp-dir <PATH>`

Specify the temporary directory used to download and extract NuGet packages (must be secure).

- `-v|--verbosity <LEVEL>`

Sets the verbosity level of the command. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default is `minimal`. If you specify `detailed` or `diagnostic` verbosity, the command displays information about the Nuget packages that it downloads.

Examples

- Update the installed workloads:

```
dotnet workload update
```

Elevated access for dotnet commands

9/20/2022 • 4 minutes to read • [Edit Online](#)

Software development best practices guide developers to writing software that requires the least amount of privilege. However, some software, like performance monitoring tools, requires admin permission because of operating system rules. The following guidance describes supported scenarios for writing such software with .NET Core.

The following commands can be run elevated:

- `dotnet tool` commands, such as [dotnet tool install](#).
- `dotnet run --no-build`
- `dotnet-core-uninstall`

We don't recommend running other commands elevated. In particular, we don't recommend elevation with commands that use MSBuild, such as [dotnet restore](#), [dotnet build](#), and [dotnet run](#). The primary issue is permission management problems when a user transitions back and forth between root and a restricted account after issuing dotnet commands. You may find as a restricted user that you don't have access to the file built by a root user. There are ways to resolve this situation, but they're unnecessary to get into in the first place.

You can run commands as root as long as you don't transition back and forth between root and a restricted account. For example, Docker containers run as root by default, so they have this characteristic.

Global tool installation

The following instructions demonstrate the recommended way to install, run, and uninstall .NET tools that require elevated permissions to execute.

- [Windows](#)
- [Linux](#)
- [macOS](#)

Install the tool

If the folder `%ProgramFiles%\dotnet-tools` already exists, do the following to check whether the "Users" group has permission to write or modify that directory:

- Right-click the `%ProgramFiles%\dotnet-tools` folder and select **Properties**. The **Common Properties** dialog box opens.
- Select the **Security** tab. Under **Group or user names**, check whether the "Users" group has permission to write or modify the directory.
- If the "Users" group can write or modify the directory, use a different directory name when installing the tools rather than *dotnet-tools*.

To install tools, run the following command in elevated prompt. It will create the *dotnet-tools* folder during the installation.

```
dotnet tool install PACKAGEID --tool-path "%ProgramFiles%\dotnet-tools".
```

Run the global tool

Option 1 Use the full path with elevated prompt:

```
"%ProgramFiles%\dotnet-tools\TOOLCOMMAND"
```

Option 2 Add the newly created folder to `%Path%`. You only need to do this operation once.

```
setx Path "%Path%;%ProgramFiles%\dotnet-tools\"
```

And run with:

```
TOOLCOMMAND
```

Uninstall the global tool

In an elevated prompt, type the following command:

```
dotnet tool uninstall PACKAGEID --tool-path "%ProgramFiles%\dotnet-tools"
```

Local tools

Local tools are scoped per subdirectory tree, per user. When run elevated, local tools share a restricted user environment to the elevated environment. In Linux and macOS, this results in files being set with root user-only access. If the user switches back to a restricted account, the user can no longer access or write to the files. So installing tools that require elevation as local tools isn't recommended. Instead, use the `--tool-path` option and the previous guidelines for global tools.

Elevation during development

During development, you may need elevated access to test your application. This scenario is common for IoT apps, for example. We recommend that you build the application without elevation and then run it with elevation. There are a few patterns, as follows:

- Using generated executable (it provides the best startup performance):

```
dotnet build
sudo ./bin/Debug/netcoreapp3.0/APPLICATIONNAME
```

- Using the `dotnet run` command with the `--no-build` flag to avoid generating new binaries:

```
dotnet build
sudo dotnet run --no-build
```

How to enable TAB completion for the .NET CLI

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

This article describes how to configure tab completion for four shells, PowerShell, Bash, zsh, and fish. For other shells, refer to their documentation on how to configure tab completion.

Once set up, tab completion for the .NET CLI is triggered by typing a `dotnet` command in the shell, and then pressing the TAB key. The current command line is sent to the `dotnet complete` command, and the results are processed by your shell. You can test the results without enabling tab completion by sending something directly to the `dotnet complete` command. For example:

```
> dotnet complete "dotnet a"
add
clean
--diagnostics
migrate
pack
```

If that command doesn't work, make sure that .NET Core 2.0 SDK or above is installed. If it's installed, but that command still doesn't work, make sure that the `dotnet` command resolves to a version of .NET Core 2.0 SDK and above. Use the `dotnet --version` command to see what version of `dotnet` your current path is resolving to. For more information, see [Select the .NET version to use](#).

Examples

Here are some examples of what tab completion provides:

INPUT	BECOMES	BECAUSE
<code>dotnet a*</code>	<code>dotnet add</code>	<code>add</code> is the first subcommand, alphabetically.
<code>dotnet add p*</code>	<code>dotnet add --help</code>	Tab completion matches substrings and <code>--help</code> comes first alphabetically.
<code>dotnet add p**</code>	<code>dotnet add package</code>	Pressing tab a second time brings up the next suggestion.
<code>dotnet add package Microsoft*</code>	<code>dotnet add package Microsoft.ApplicationInsights.Web</code>	Results are returned alphabetically.
<code>dotnet remove reference *</code>	<code>dotnet remove reference ..\src\OmniSharp.DotNet\OmniSharp.DotNet.csproj</code>	Tab completion is project file aware.

PowerShell

To add tab completion to PowerShell for the .NET CLI, create or edit the profile stored in the variable `$PROFILE`. For more information, see [How to create your profile](#) and [Profiles and execution policy](#).

Add the following code to your profile:

```
# PowerShell parameter completion shim for the dotnet CLI
Register-ArgumentCompleter -Native -CommandName dotnet -ScriptBlock {
    param($commandName, $wordToComplete, $cursorPosition)
        dotnet complete --position $cursorPosition "$wordToComplete" | ForEach-Object {
            [System.Management.Automation.CompletionResult]::new($_, $_, 'ParameterValue', $_)
        }
}
```

bash

To add tab completion to your **bash** shell for the .NET CLI, add the following code to your `.bashrc` file:

```
# bash parameter completion for the dotnet CLI

function _dotnet_bash_complete()
{
    local cur="${COMP_WORDS[COMP_CWORD]}" IFS=$'\n'
    local candidates

    read -d '' -ra candidates < <(dotnet complete --position "${COMP_POINT}" "${COMP_LINE}" 2>/dev/null)

    read -d '' -ra COMPREPLY < <(compgen -W "${candidates[*]}:-" -- "$cur")
}

complete -f -F _dotnet_bash_complete dotnet
```

zsh

To add tab completion to your **zsh** shell for the .NET CLI, add the following code to your `.zshrc` file:

```
# zsh parameter completion for the dotnet CLI

_dotnet_zsh_complete()
{
    local completions=$(dotnet complete "$words")

    reply=( "${(ps:\n:)completions}" )
}

compctl -K _dotnet_zsh_complete dotnet
```

fish

To add tab completion to your **fish** shell for the .NET CLI, add the following code to your `config.fish` file:

```
complete -f -c dotnet -a "(dotnet complete (commandline -cp))"
```

Develop libraries with the .NET CLI

9/20/2022 • 9 minutes to read • [Edit Online](#)

This article covers how to write libraries for .NET using the .NET CLI. The CLI provides an efficient and low-level experience that works across any supported OS. You can still build libraries with Visual Studio, and if that is your preferred experience [refer to the Visual Studio guide](#).

Prerequisites

You need the [.NET SDK](#) installed on your machine.

For the sections of this document dealing with .NET Framework versions, you need the [.NET Framework](#) installed on a Windows machine.

Additionally, if you wish to support older .NET Framework targets, you need to install targeting packs or developer packs from the [.NET Framework downloads page](#). Refer to this table:

.NET FRAMEWORK VERSION	WHAT TO DOWNLOAD
4.6.1	.NET Framework 4.6.1 Targeting Pack
4.6	.NET Framework 4.6 Targeting Pack
4.5.2	.NET Framework 4.5.2 Developer Pack
4.5.1	.NET Framework 4.5.1 Developer Pack
4.5	Windows Software Development Kit for Windows 8
4.0	Windows SDK for Windows 7 and .NET Framework 4
2.0, 3.0, and 3.5	.NET Framework 3.5 SP1 Runtime (or Windows 8+ version)

How to target .NET 5+ or .NET Standard

You control your project's target framework by adding it to your project file (`.csproj` or `.fsproj`). For guidance on how to choose between targeting .NET 5+ or .NET Standard see [.NET 5+ and .NET Standard](#).

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <TargetFramework>net6.0</TargetFramework>
  </PropertyGroup>
</Project>
```

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <TargetFramework>netstandard2.0</TargetFramework>
  </PropertyGroup>
</Project>
```

If you want to target .NET Framework versions 4.0 or below, or you wish to use an API available in .NET Framework but not in .NET Standard (for example, `System.Drawing`), read the following sections and learn how to multitarget.

How to target .NET Framework

NOTE

These instructions assume you have .NET Framework installed on your machine. Refer to the [Prerequisites](#) to get dependencies installed.

Keep in mind that some of the .NET Framework versions used here are no longer supported. Refer to the [.NET Framework Support Lifecycle Policy FAQ](#) about unsupported versions.

If you want to reach the maximum number of developers and projects, use .NET Framework 4.0 as your baseline target. To target .NET Framework, begin by using the correct Target Framework Moniker (TFM) that corresponds to the .NET Framework version you wish to support.

.NET FRAMEWORK VERSION	TFM
.NET Framework 2.0	<code>net20</code>
.NET Framework 3.0	<code>net30</code>
.NET Framework 3.5	<code>net35</code>
.NET Framework 4.0	<code>net40</code>
.NET Framework 4.5	<code>net45</code>
.NET Framework 4.5.1	<code>net451</code>
.NET Framework 4.5.2	<code>net452</code>
.NET Framework 4.6	<code>net46</code>
.NET Framework 4.6.1	<code>net461</code>
.NET Framework 4.6.2	<code>net462</code>
.NET Framework 4.7	<code>net47</code>
.NET Framework 4.8	<code>net48</code>

You then insert this TFM into the `TargetFramework` section of your project file. For example, here's how you would write a library that targets .NET Framework 4.0:

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <TargetFramework>net40</TargetFramework>
  </PropertyGroup>
</Project>
```

And that's it! Although this compiled only for .NET Framework 4, you can use the library on newer versions of .NET Framework.

How to multitarget

NOTE

The following instructions assume you have the .NET Framework installed on your machine. Refer to the [Prerequisites](#) section to learn which dependencies you need to install and where to download them from.

You may need to target older versions of the .NET Framework when your project supports both the .NET Framework and .NET. In this scenario, if you want to use newer APIs and language constructs for the newer targets, use `#if` directives in your code. You also might need to add different packages and dependencies for each platform you're targeting to include the different APIs needed for each case.

For example, let's say you have a library that performs networking operations over HTTP. For .NET Standard and the .NET Framework versions 4.5 or higher, you can use the `HttpClient` class from the `System.Net.Http` namespace. However, earlier versions of the .NET Framework don't have the `HttpClient` class, so you could use the `WebClient` class from the `System.Net` namespace for those instead.

Your project file could look like this:

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
    <TargetFrameworks>netstandard2.0;net40;net45</TargetFrameworks>
</PropertyGroup>

<!-- Need to conditionally bring in references for the .NET Framework 4.0 target -->
<ItemGroup Condition="<$(TargetFramework)> == 'net40'">
    <Reference Include="System.Net" />
</ItemGroup>

<!-- Need to conditionally bring in references for the .NET Framework 4.5 target -->
<ItemGroup Condition="<$(TargetFramework)> == 'net45'">
    <Reference Include="System.Net.Http" />
    <Reference Include="System.Threading.Tasks" />
</ItemGroup>
</Project>
```

You'll notice three major changes here:

1. The `TargetFramework` node has been replaced by `TargetFrameworks`, and three TFM's are expressed inside.
2. There is an `<ItemGroup>` node for the `net40` target pulling in one .NET Framework reference.
3. There is an `<ItemGroup>` node for the `net45` target pulling in two .NET Framework references.

Preprocessor Symbols

The build system is aware of the following preprocessor symbols used in `#if` directives:

TARGET FRAMEWORKS

SYMBOLS

ADDITIONAL SYMBOLS AVAILABLE IN
.NET 5+ SDK

TARGET FRAMEWORKS	SYMBOLS	ADDITIONAL SYMBOLS AVAILABLE IN .NET 5+ SDK
.NET Framework	NETFRAMEWORK , NET48 , NET472 , NET471 , NET47 , NET462 , NET461 , NET46 , NET452 , NET451 , NET45 , NET40 , NET35 , NET20	NET48_OR_GREATER , NET472_OR_GREATER , NET471_OR_GREATER , NET47_OR_GREATER , NET462_OR_GREATER , NET461_OR_GREATER , NET46_OR_GREATER , NET452_OR_GREATER , NET451_OR_GREATER , NET45_OR_GREATER , NET40_OR_GREATER , NET35_OR_GREATER , NET20_OR_GREATER
.NET Standard	NETSTANDARD , NETSTANDARD2_1 , NETSTANDARD2_0 , NETSTANDARD1_6 , NETSTANDARD1_5 , NETSTANDARD1_4 , NETSTANDARD1_3 , NETSTANDARD1_2 , NETSTANDARD1_1 , NETSTANDARD1_0	NETSTANDARD2_1_OR_GREATER , NETSTANDARD2_0_OR_GREATER , NETSTANDARD1_6_OR_GREATER , NETSTANDARD1_5_OR_GREATER , NETSTANDARD1_4_OR_GREATER , NETSTANDARD1_3_OR_GREATER , NETSTANDARD1_2_OR_GREATER , NETSTANDARD1_1_OR_GREATER , NETSTANDARD1_0_OR_GREATER
.NET 5+ (and .NET Core)	NET , NET7_0 , NET6_0 , NET5_0 , NETCOREAPP , NETCOREAPP3_1 , NETCOREAPP3_0 , NETCOREAPP2_2 , NETCOREAPP2_1 , NETCOREAPP2_0 , NETCOREAPP1_1 , NETCOREAPP1_0	NET7_0_OR_GREATER , NET6_0_OR_GREATER , NET5_0_OR_GREATER , NETCOREAPP3_1_OR_GREATER , NETCOREAPP3_0_OR_GREATER , NETCOREAPP2_2_OR_GREATER , NETCOREAPP2_1_OR_GREATER , NETCOREAPP2_0_OR_GREATER , NETCOREAPP1_1_OR_GREATER , NETCOREAPP1_0_OR_GREATER

NOTE

- Versionless symbols are defined regardless of the version you're targeting.
- Version-specific symbols are only defined for the version you're targeting.
- The `<framework>_OR_GREATER` symbols are defined for the version you're targeting and all earlier versions. For example, if you're targeting .NET Framework 2.0, the following symbols are defined: `NET20` , `NET20_OR_GREATER` , `NET11_OR_GREATER` , and `NET10_OR_GREATER` .
- These are different from the target framework monikers (TFMs) used by the MSBuild `TargetFramework` property and NuGet.

Here is an example making use of conditional compilation per-target:

```

using System;
using System.Text.RegularExpressions;
#ifndef NET40
// This only compiles for the .NET Framework 4 targets
using System.Net;
#else
// This compiles for all other targets
using System.Net.Http;
using System.Threading.Tasks;
#endif

namespace MultitargetLib
{
    public class Library
    {
#ifndef NET40
        private readonly WebClient _client = new WebClient();
        private readonly object _locker = new object();
#else
        private readonly HttpClient _client = new HttpClient();
#endif

#ifndef NET40
        // .NET Framework 4.0 does not have async/await
        public string GetDotNetCount()
        {
            string url = "https://www.dotnetfoundation.org/";

            var uri = new Uri(url);

            string result = "";

            // Lock here to provide thread-safety.
            lock(_locker)
            {
                result = _client.DownloadString(uri);
            }

            int dotNetCount = Regex.Matches(result, ".NET").Count;

            return $"Dotnet Foundation mentions .NET {dotNetCount} times!";
        }
#else
        // .NET Framework 4.5+ can use async/await!
        public async Task<string> GetDotNetCountAsync()
        {
            string url = "https://www.dotnetfoundation.org/";

            // HttpClient is thread-safe, so no need to explicitly lock here
            var result = await _client.GetStringAsync(url);

            int dotNetCount = Regex.Matches(result, ".NET").Count;

            return $"dotnetfoundation.org mentions .NET {dotNetCount} times in its HTML!";
        }
#endif
    }
}

```

If you build this project with `dotnet build`, you'll notice three directories under the `bin/` folder:

```

net40/
net45/
netstandard2.0/

```

Each of these contains the `.dll` files for each target.

How to test libraries on .NET

It's important to be able to test across platforms. You can use either [xUnit](#) or MSTest out of the box. Both are perfectly suitable for unit testing your library on .NET. How you set up your solution with test projects will depend on the [structure of your solution](#). The following example assumes that the test and source directories live in the same top-level directory.

NOTE

This uses some [.NET CLI](#) commands. See [dotnet new](#) and [dotnet sln](#) for more information.

1. Set up your solution. You can do so with the following commands:

```
mkdir SolutionWithSrcAndTest
cd SolutionWithSrcAndTest
dotnet new sln
dotnet new classlib -o MyProject
dotnet new xunit -o MyProject.Test
dotnet sln add MyProject/MyProject.csproj
dotnet sln add MyProject.Test/MyProject.Test.csproj
```

This will create projects and link them together in a solution. Your directory for `SolutionWithSrcAndTest` should look like this:

```
/SolutionWithSrcAndTest
|__SolutionWithSrcAndTest.sln
|__MyProject/
|__MyProject.Test/
```

2. Navigate to the test project's directory and add a reference to `MyProject.Test` from `MyProject`.

```
cd MyProject.Test
dotnet add reference ../MyProject/MyProject.csproj
```

3. Restore packages and build projects:

```
dotnet restore
dotnet build
```

4. Verify that xUnit runs by executing the `dotnet test` command. If you chose to use MSTest, then the MSTest console runner should run instead.

And that's it! You can now test your library across all platforms using command-line tools. To continue testing now that you have everything set up, testing your library is very simple:

1. Make changes to your library.
2. Run tests from the command line, in your test directory, with `dotnet test` command.

Your code will be automatically rebuilt when you invoke `dotnet test` command.

How to use multiple projects

A common need for larger libraries is to place functionality in different projects.

Imagine you want to build a library that could be consumed in idiomatic C# and F#. That would mean that consumers of your library consume it in ways that are natural to C# or F#. For example, in C# you might consume the library like this:

```
using AwesomeLibrary.CSharp;

public Task DoThings(Data data)
{
    var convertResult = await AwesomeLibrary.ConvertAsync(data);
    var result = AwesomeLibrary.Process(convertResult);
    // do something with result
}
```

In F#, it might look like this:

```
open AwesomeLibrary.FSharp

let doWork data = async {
    let! result = AwesomeLibrary.AsyncConvert data // Uses an F# async function rather than C# async method
    // do something with result
}
```

Consumption scenarios like this mean that the APIs being accessed have to have a different structure for C# and F#. A common approach to accomplishing this is to factor all of the logic of a library into a core project, with C# and F# projects defining the API layers that call into that core project. The rest of the section will use the following names:

- **AwesomeLibrary.Core** - A core project that contains all logic for the library
- **AwesomeLibrary.CSharp** - A project with public APIs intended for consumption in C#
- **AwesomeLibrary.FSharp** - A project with public APIs intended for consumption in F#

You can run the following commands in your terminal to produce the same structure as this guide:

```
mkdir AwesomeLibrary && cd AwesomeLibrary
dotnet new sln
mkdir AwesomeLibrary.Core && cd AwesomeLibrary.Core && dotnet new classlib
cd ..
mkdir AwesomeLibrary.CSharp && cd AwesomeLibrary.CSharp && dotnet new classlib
cd ..
mkdir AwesomeLibrary.FSharp && cd AwesomeLibrary.FSharp && dotnet new classlib -lang "F#"
cd ..
dotnet sln add AwesomeLibrary.Core/AwesomeLibrary.Core.csproj
dotnet sln add AwesomeLibrary.CSharp/AwesomeLibrary.CSharp.csproj
dotnet sln add AwesomeLibrary.FSharp/AwesomeLibrary.FSharp.fsproj
```

This will add the three projects above and a solution file that links them together. Creating the solution file and linking projects will allow you to restore and build projects from a top level.

Project-to-project referencing

The best way to reference a project is to use the .NET CLI to add a project reference. From the **AwesomeLibrary.CSharp** and **AwesomeLibrary.FSharp** project directories, you can run the following command:

```
dotnet add reference ../AwesomeLibrary.Core/AwesomeLibrary.Core.csproj
```

The project files for both `AwesomeLibrary.CSharp` and `AwesomeLibrary.FSharp` will now reference `AwesomeLibrary.Core` as a `ProjectReference` target. You can verify this by inspecting the project files and seeing the following in them:

```
<ItemGroup>
  <ProjectReference Include="..\AwesomeLibrary.Core\AwesomeLibrary.Core.csproj" />
</ItemGroup>
```

You can add this section to each project file manually if you prefer not to use the .NET CLI.

Structuring a solution

Another important aspect of multi-project solutions is establishing a good overall project structure. You can organize code however you like, and as long as you link each project to your solution file with `dotnet sln add`, you will be able to run `dotnet restore` and `dotnet build` at the solution level.

Tutorial: Create an item template

9/20/2022 • 5 minutes to read • [Edit Online](#)

With .NET, you can create and deploy templates that generate projects, files, even resources. This tutorial is part one of a series that teaches you how to create, install, and uninstall templates for use with the `dotnet new` command.

You can view the completed template in the [.NET Samples GitHub repository](#).

In this part of the series, you'll learn how to:

- Create a class for an item template
- Create the template config folder and file
- Install a template from a file path
- Test an item template
- Uninstall an item template

Prerequisites

- [.NET 6.0 SDK](#) or a later version.
- Read the reference article [Custom templates for dotnet new](#).

The reference article explains the basics about templates and how they're put together. Some of this information will be reiterated here.

- Open a terminal and navigate to the `working\templates` folder.

Create the required folders

This series uses a "working folder" where your template source is contained and a "testing folder" used to test your templates. The working folder and testing folder should be under the same parent folder.

First, create the parent folder, the name does not matter. Then, create a subfolder named `working`. Inside of the `working` folder, create a subfolder named `templates`.

Next, create a folder under the parent folder named `test`. The folder structure should look like the following.

```
parent_folder
├── test
└── working
    └── templates
```

Create an item template

An item template is a specific type of template that contains one or more files. These types of templates are useful when you want to generate something like a config, code, or solution file. In this example, you'll create a class that adds an extension method to the string type.

In your terminal, navigate to the `working\templates` folder and create a new subfolder named `extensions`. Enter the folder.

```
working
└─templates
    └─extensions
```

Create a new file named *CommonExtensions.cs* and open it with your favorite text editor. This class will provide an extension method named `Reverse` that reverses the contents of a string. Paste in the following code and save the file:

```
using System;

namespace System
{
    public static class StringExtensions
    {
        public static string Reverse(this string value)
        {
            var tempArray = value.ToCharArray();
            Array.Reverse(tempArray);
            return new string(tempArray);
        }
    }
}
```

Now that you have the content of the template created, you need to create the template config at the root folder of the template.

Create the template config

Templates are recognized by a special folder and config file that exist at the root of your template. In this tutorial, your template folder is located at *working\templates\extensions*.

When you create a template, all files and folders in the template folder are included as part of the template except for the special config folder. This config folder is named *.template.config*.

First, create a new subfolder named *.template.config*, enter it. Then, create a new file named *template.json*. Your folder structure should look like this:

```
working
└─templates
    └─extensions
        └─.template.config
            template.json
```

Open the *template.json* with your favorite text editor and paste in the following JSON code and save it.

```
{
    "$schema": "http://json.schemastore.org/template",
    "author": "Me",
    "classifications": [ "Common", "Code" ],
    "identity": "ExampleTemplate.StringExtensions",
    "name": "Example templates: string extensions",
    "shortName": "stringext",
    "tags": {
        "language": "C#",
        "type": "item"
    }
}
```

This config file contains all the settings for your template. You can see the basic settings, such as `name` and `shortName`, but there's also a `tags/type` value that is set to `item`. This categorizes your template as an item template. There's no restriction on the type of template you create. The `item` and `project` values are common names that .NET recommends so that users can easily filter the type of template they're searching for.

The `classifications` item represents the `tags` column you see when you run `dotnet new` and get a list of templates. Users can also search based on classification tags. Don't confuse the `tags` property in the `*.json` file with the `classifications` tags list. They're two different things unfortunately named similarly. The full schema for the `template.json` file is found at the [JSON Schema Store](#). For more information about the `template.json` file, see the [dotnet templating wiki](#).

Now that you have a valid `.template.config/template.json` file, your template is ready to be installed. In your terminal, navigate to the `extensions` folder and run the following command to install the template located at the current folder:

- **On Windows:** `dotnet new --install .\`
- **On Linux or macOS:** `dotnet new --install ./`

This command outputs the list of templates installed, which should include yours.

```
The following template packages will be installed:  
<root path>\working\templates\extensions  
  
Success: <root path>\working\templates\extensions installed the following templates:  
Templates Short Name Language Tags  
----- ----- ----- -----  
-----  
Example templates: string extensions stringext [C#] Common/Code
```

Test the item template

Now that you have an item template installed, test it. Navigate to the `test`/folder and create a new console application with `dotnet new console`. This generates a working project you can easily test with the `dotnet run` command.

```
dotnet new console
```

You get output similar to the following.

```
The template "Console Application" was created successfully.  
  
Processing post-creation actions...  
Running 'dotnet restore' on C:\test\test.csproj...  
Restore completed in 54.82 ms for C:\test\test.csproj.  
  
Restore succeeded.
```

Run the project with.

```
dotnet run
```

You get the following output.

```
Hello World!
```

Next, run `dotnet new stringext` to generate the `CommonExtensions.cs` from the template.

```
dotnet new stringext
```

You get the following output.

```
The template "Example templates: string extensions" was created successfully.
```

Change the code in `Program.cs` to reverse the `"Hello World"` string with the extension method provided by the template.

```
Console.WriteLine("Hello World!".Reverse());
```

Run the program again and you'll see that the result is reversed.

```
dotnet run
```

You get the following output.

```
!dlroW olleH
```

Congratulations! You created and deployed an item template with .NET. In preparation for the next part of this tutorial series, you must uninstall the template you created. Make sure to delete all files from the `test` folder too. This will get you back to a clean state ready for the next major section of this tutorial.

Uninstall the template

In your terminal, navigate to the `extensions` folder and run the following command to uninstall the template located at the current folder:

- On Windows: `dotnet new --uninstall .\`
- On Linux or macOS: `dotnet new --uninstall ./`

This command outputs a list of the templates that were uninstalled, which should include yours.

```
Success: <root path>\working\templates\extensions was uninstalled.
```

At any time, you can use `dotnet new --uninstall` to see a list of installed template packages, including for each template package the command to uninstall it.

Next steps

In this tutorial, you created an item template. To learn how to create a project template, continue this tutorial series.

[Create a project template](#)

Tutorial: Create a project template

9/20/2022 • 5 minutes to read • [Edit Online](#)

With .NET, you can create and deploy templates that generate projects, files, even resources. This tutorial is part two of a series that teaches you how to create, install, and uninstall, templates for use with the `dotnet new` command.

You can view the completed template in the [.NET Samples GitHub repository](#).

In this part of the series you'll learn how to:

- Create the resources of a project template
- Create the template config folder and file
- Install a template from a file path
- Test an item template
- Uninstall an item template

Prerequisites

- Complete [part 1](#) of this tutorial series.
- Open a terminal and navigate to the `working\templates` folder.

Create a project template

Project templates produce ready-to-run projects that make it easy for users to start with a working set of code. .NET includes a few project templates such as a console application or a class library. In this example, you'll create a new console project that replaces the standard "Hello World" console output with one that runs asynchronously.

In your terminal, navigate to the `working\templates` folder and create a new subfolder named `consoleasync`. Enter the subfolder and run `dotnet new console` to generate the standard console application. You'll be editing the files produced by this template to create a new template.

```
working
└── templates
    └── consoleasync
        ├── consoleasync.csproj
        └── Program.cs
```

Modify Program.cs

Open up the `Program.cs` file. The standard console project doesn't asynchronously write to the console output, so let's add that. Change the code to the following and save the file:

```
await Console.Out.WriteLineAsync("Hello World with C#");
```

Build the project

Before you complete a project template, you should test it to make sure it compiles and runs correctly.

In your terminal, run the following command.

```
dotnet run
```

You get the following output.

```
Hello World with C#
```

You can delete the `obj` and `bin` folders created by using `dotnet run`. Deleting these files ensures your template only includes the files related to your template and not any files that result from a build action.

Now that you have the content of the template created, you need to create the template config at the root folder of the template.

Create the template config

Templates are recognized in .NET by a special folder and config file that exist at the root of your template. In this tutorial, your template folder is located at `working\templates\consoleasync`.

When you create a template, all files and folders in the template folder are included as part of the template except for the special config folder. This config folder is named `.template.config`.

First, create a new subfolder named `.template.config`, enter it. Then, create a new file named `template.json`. Your folder structure should look like this.

```
working
└── templates
    └── consoleasync
        └── .template.config
            template.json
```

Open the `template.json` with your favorite text editor and paste in the following json code and save it.

```
{
  "$schema": "http://json.schemastore.org/template",
  "author": "Me",
  "classifications": [ "Common", "Console" ],
  "identity": "ExampleTemplate.AsyncProject",
  "name": "Example templates: async project",
  "shortName": "consoleasync",
  "tags": {
    "language": "C#",
    "type": "project"
  }
}
```

This config file contains all of the settings for your template. You can see the basic settings such as `name` and `shortName` but also there's a `tags/type` value that's set to `project`. This designates your template as a project template. There's no restriction on the type of template you create. The `item` and `project` values are common names that .NET recommends so that users can easily filter the type of template they're searching for.

The `classifications` item represents the `tags` column you see when you run `dotnet new` and get a list of templates. Users can also search based on classification tags. Don't confuse the `tags` property in the json file with the `classifications` tags list. They're two different things unfortunately named similarly. The full schema for the `template.json` file is found at the [JSON Schema Store](#). For more information about the `template.json` file, see the [dotnet templating wiki](#).

Now that you have a valid `.template.config/template.json` file, your template is ready to be installed. Before you install the template, make sure that you delete any extra folders and files you don't want included in your template, like the `bin` or `obj` folders. In your terminal, navigate to the `consoleasync` folder and run `dotnet new --install .\` to install the template located at the current folder. If you're using a Linux or macOS operating system, use a forward slash: `dotnet new --install ./`.

```
dotnet new --install .\
```

This command outputs a list of the installed templates, which should include yours.

```
The following template packages will be installed:  
<root path>\working\templates\consoleasync  
  
Success: <root path>\working\templates\consoleasync installed the following templates:  
Templates Short Name Language Tags  
-----  
-----  
Example templates: async project consoleasync [C#] Common/Console
```

Test the project template

Now that you have a project template installed, test it.

1. Navigate to the `test` folder
2. Create a new console application with the following command which generates a working project you can easily test with the `dotnet run` command.

```
dotnet new consoleasync
```

You get the following output.

```
The template "Example templates: async project" was created successfully.
```

3. Run the project using the following command.

```
dotnet run
```

You get the following output.

```
Hello World with C#
```

Congratulations! You created and deployed a project template with .NET. In preparation for the next part of this tutorial series, you must uninstall the template you created. Make sure to delete all files from the `test` folder too. This will get you back to a clean state ready for the next major section of this tutorial.

Uninstall the template

In your terminal, navigate to the `consoleasync` folder and run the following command to uninstall the template located in the current folder:

- On Windows: `dotnet new --uninstall .\`
- On Linux or macOS: `dotnet new --uninstall ./`

This command outputs a list of the templates that were uninstalled, which should include yours.

```
Success: <root path>\working\templates\consoleasync was uninstalled.
```

At any time, you can use `dotnet new --uninstall` to see a list of installed template packages, including for each template package the command to uninstall it.

Next steps

In this tutorial, you created a project template. To learn how to package both the item and project templates into an easy-to-use file, continue this tutorial series.

[Create a template package](#)

Tutorial: Create a template package

9/20/2022 • 6 minutes to read • [Edit Online](#)

With .NET, you can create and deploy templates that generate projects, files, and even resources. This tutorial is part three of a series that teaches you how to create, install, and uninstall templates for use with the `dotnet new` command.

You can view the completed template in the [.NET Samples GitHub repository](#).

In this part of the series you'll learn how to:

- Create a *.csproj project to build a template package
- Configure the project file for packing
- Install a template package from a NuGet package file
- Uninstall a template package by package ID

Prerequisites

- Complete [part 1](#) and [part 2](#) of this tutorial series.

This tutorial uses the two templates created in the first two parts of this tutorial. You can use a different template as long as you copy the template, as a folder, into the `working\templates` folder.

- Open a terminal and navigate to the `working\` folder.

Create a template package project

A template package is one or more templates packaged into a NuGet package. When you install or uninstall a template package, all templates contained in the package are added or removed, respectively. The previous parts of this tutorial series only worked with individual templates. To share a non-packed template, you have to copy the template folder and install via that folder. Because a template package can have more than one template in it, and is a single file, sharing is easier.

Template packages are represented by a NuGet package (.nupkg) file. And, like any NuGet package, you can upload the template package to a NuGet feed. The `dotnet new --install` command supports installing template package from a NuGet package feed. Additionally, you can install a template package from a .nupkg file directly.

Normally you use a C# project file to compile code and produce a binary. However, the project can also be used to generate a template package. By changing the settings of the `.csproj`, you can prevent it from compiling any code and instead include all the assets of your templates as resources. When this project is built, it produces a template package NuGet package.

The package you'll create will include the [item template](#) and [package template](#) previously created. Because we grouped the two templates into the `working\templates` folder, we can use the `working` folder for the `.csproj` file.

In your terminal, navigate to the `working` folder. Create a new project and set the name to `templatepack` and the output folder to the current folder.

```
dotnet new console -n templatepack -o .
```

The `-n` parameter sets the `.csproj` filename to `templatepack.csproj`. The `-o` parameter creates the files in the current directory. You should see a result similar to the following output.

```
The template "Console Application" was created successfully.

Processing post-creation actions...
Running 'dotnet restore' on ./templatepack.csproj...
Restore completed in 52.38 ms for C:\working\templatepack.csproj.

Restore succeeded.
```

The new project template generates a *Program.cs* file. You can safely delete this file as it's not used by the templates.

Next, open the *templatepack.csproj* file in your favorite editor and replace the content with the following XML:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <PackageType>Template</PackageType>
  <PackageVersion>1.0</PackageVersion>
  <PackageId>AdatumCorporation.Utility.Templates</PackageId>
  <Title>AdatumCorporation Templates</Title>
  <Authors>Me</Authors>
  <Description>Templates to use when creating an application for Adatum Corporation.</Description>
  <PackageTags>dotnet-new;templates;contoso</PackageTags>

  <TargetFramework>netstandard2.0</TargetFramework>

  <IncludeContentInPack>true</IncludeContentInPack>
  <IncludeBuildOutput>false</IncludeBuildOutput>
  <ContentTargetFolders>content</ContentTargetFolders>
  <NoWarn>$(NoWarn);NU5128</NoWarn>
  <NoDefaultExcludes>true</NoDefaultExcludes>
</PropertyGroup>

<ItemGroup>
  <Content Include="templates\**\*" Exclude="templates\**\bin\**;templates\**\obj\**" />
  <Compile Remove="**\**" />
</ItemGroup>

</Project>
```

The settings under `<PropertyGroup>` in the XML snippet are broken into three groups.

The first group deals with properties required for a NuGet package. The three `<Package*>` settings have to do with the NuGet package properties to identify your package on a NuGet feed. Specifically the `<PackageId>` value is used to uninstall the template package with a single name instead of a directory path. It can also be used to install the template package from a NuGet feed. The remaining settings, such as `<Title>` and `<PackageTags>`, have to do with metadata displayed on the NuGet feed. For more information about NuGet settings, see [NuGet and MSBuild properties](#).

NOTE

To ensure that the template package appears in `dotnet new --search` results, set `<PackageType>` to `Template`.

In the second group, the `<TargetFramework>` setting ensures that MSBuild executes properly when you run the pack command to compile and pack the project.

The third group includes settings that have to do with configuring the project to include the templates in the appropriate folder in the NuGet pack when it's created:

- The `<NoWarn>` setting suppresses a warning message that doesn't apply to template package projects.
- The `<NoDefaultExcludes>` setting ensures that files and folders that start with a `.` (like `.gitignore`) are part of the template. The *default* behavior of NuGet packages is to ignore those files and folders.

`<ItemGroup>` contains two items. First, the `<Content>` item includes everything in the *templates* folder as content. It's also set to exclude any *bin* folder or *obj* folder to prevent any compiled code (if you tested and compiled your templates) from being included. Second, the `<Compile>` item excludes all code files from compiling no matter where they're located. This setting prevents the project that's used to create the template package from trying to compile the code in the *templates* folder hierarchy.

Build and install

Save the project file. Before building the template package, verify that your folder structure is correct. Any template you want to pack should be placed in the *templates* folder, in its own folder. The folder structure should look similar to the following hierarchy:

```
working
|   templatepack.csproj
└── templates
    ├── extensions
    |   └── .template.config
    |       template.json
    └── consoleasync
        └── .template.config
            template.json
```

The *templates* folder has two folders: *extensions* and *consoleasync*.

In your terminal, from the *working* folder, run the `dotnet pack` command. This command builds your project and creates a NuGet package in the *working\bin\Debug* folder, as indicated by the following output:

```
C:\working> dotnet pack

Microsoft (R) Build Engine version 16.8.0+126527ff1 for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Restore completed in 123.86 ms for C:\working\templatepack.csproj.

templatepack -> C:\working\bin\Debug\netstandard2.0\templatepack.dll
Successfully created package 'C:\working\bin\Debug\AdatumCorporation.Utility.Templates.1.0.0.nupkg'.
```

Next, install the template package with the `dotnet new --install PATH_TO_NUPKG_FILE` command.

```
C:\working> dotnet new -i C:\working\bin\Debug\AdatumCorporation.Utility.Templates.1.0.0.nupkg
The following template packages will be installed:
  C:\working\bin\Debug\AdatumCorporation.Utility.Templates.1.0.0.nupkg

Success: AdatumCorporation.Utility.Templates::1.0.0 installed the following templates:
  Templates           Short Name      Language      Tags
  -----
  Example templates: string extensions      stringext      [C#]      Common/Code
  Example templates: async project          consoleasync      [C#]      Common/Console/C#9
```

If you uploaded the NuGet package to a NuGet feed, you can use the `dotnet new --install PACKAGEID` command where `PACKAGEID` is the same as the `<PackageId>` setting from the *.csproj* file. This package ID is the same as the

NuGet package identifier.

Uninstall the template package

No matter how you installed the template package, either with the `.nupkg` file directly or by NuGet feed, removing a template package is the same. Use the `<PackageId>` of the template you want to uninstall. You can get a list of templates that are installed by running the `dotnet new --uninstall` command.

```
C:\working> dotnet new --uninstall

Template Instantiation Commands for .NET CLI

Currently installed items:
Microsoft.DotNet.Common.ProjectTemplates.2.2
  Details:
    NuGetPackageId: Microsoft.DotNet.Common.ProjectTemplates.2.2
    Version: 1.0.2-beta4
    Author: Microsoft
  Templates:
    Class library (classlib) C#
    Class library (classlib) F#
    Class library (classlib) VB
    Console Application (console) C#
    Console Application (console) F#
    Console Application (console) VB
  Uninstall Command:
    dotnet new --uninstall Microsoft.DotNet.Common.ProjectTemplates.2.2

... cut to save space ...

AdatumCorporation.Utility.Templates
  Details:
    NuGetPackageId: AdatumCorporation.Utility.Templates
    Version: 1.0.0
    Author: Me
  Templates:
    Example templates: async project (consoleasync) C#
    Example templates: string extensions (stringext) C#
  Uninstall Command:
    dotnet new --uninstall AdatumCorporation.Utility.Templates
```

Run `dotnet new --uninstall AdatumCorporation.Utility.Templates` to uninstall the template package. The command will output information about what template packages were uninstalled.

Congratulations! You've installed and uninstalled a template package.

Next steps

To learn more about templates, most of which you've already learned, see the [Custom templates for dotnet new](#) article.

- [dotnettemplating GitHub repo Wiki](#)
- [dotnet/dotnet-template-samples GitHub repo](#)
- [template.json schema at the JSON Schema Store](#)

Obsolete features in .NET 5+

9/20/2022 • 5 minutes to read • [Edit Online](#)

Starting in .NET 5, some APIs that are newly marked as obsolete make use of two new properties on [ObsoleteAttribute](#).

- The [ObsoleteAttribute.DiagnosticId](#) property tells the compiler to generate build warnings using a custom diagnostic ID. The custom ID allows for obsolescence warning to be suppressed specifically and separately from one another. In the case of the .NET 5+ obsolescences, the format for the custom diagnostic ID is `SYSLIB0XXX`.
- The [ObsoleteAttribute.UrlFormat](#) property tells the compiler to include a URL link to learn more about the obsolescence.

If you encounter build warnings or errors due to usage of an obsolete API, follow the specific guidance provided for the diagnostic ID listed in the [Reference](#) section. Warnings or errors for these obsolescences *can't* be suppressed using the [standard diagnostic ID \(CS0618\)](#) for obsolete types or members; use the custom `SYSLIB0XXX` diagnostic ID values instead. For more information, see [Suppress warnings](#).

Reference

The following table provides an index to the `SYSLIB0XXX` obsolescences in .NET 5+.

DIAGNOSTIC ID	WARNING OR ERROR	DESCRIPTION
SYSLIB0001	Warning	The UTF-7 encoding is insecure and should not be used. Consider using UTF-8 instead.
SYSLIB0002	Error	PrincipalPermissionAttribute is not honored by the runtime and must not be used.
SYSLIB0003	Warning	Code access security (CAS) is not supported or honored by the runtime.
SYSLIB0004	Warning	The constrained execution region (CER) feature is not supported.
SYSLIB0005	Warning	The global assembly cache (GAC) is not supported.
SYSLIB0006	Warning	Thread.Abort() is not supported and throws PlatformNotSupportedException .
SYSLIB0007	Warning	The default implementation of this cryptography algorithm is not supported.

DIAGNOSTIC ID	WARNING OR ERROR	DESCRIPTION
SYSLIB0008	Warning	The CreatePdbGenerator() API is not supported and throws PlatformNotSupportedException .
SYSLIB0009	Warning	The AuthenticationManager.Authenticate and AuthenticationManager.PreAuthenticate methods are not supported and throw PlatformNotSupportedException .
SYSLIB0010	Warning	Some remoting APIs are not supported and throw PlatformNotSupportedException .
SYSLIB0011	Warning	BinaryFormatter serialization is obsolete and should not be used.
SYSLIB0012	Warning	Assembly.CodeBase and Assembly.EscapedCodeBase are only included for .NET Framework compatibility. Use Assembly.Location instead.
SYSLIB0013	Warning	Uri.EscapeUriString(String) can corrupt the Uri string in some cases. Consider using Uri.EscapeDataString(String) for query string components instead.
SYSLIB0014	Warning	WebRequest , HttpWebRequest , ServicePoint , and WebClient are obsolete. Use HttpClient instead.
SYSLIB0015	Warning	DisablePrivateReflectionAttribute has no effect in .NET 6+.
SYSLIB0016	Warning	Use the Graphics.GetContextInfo overloads that accept arguments for better performance and fewer allocations.
SYSLIB0017	Warning	Strong-name signing is not supported and throws PlatformNotSupportedException .
SYSLIB0018	Warning	Reflection-only loading is not supported and throws PlatformNotSupportedException .

Diagnostic ID	Warning or Error	Description
SYSLIB0019	Warning	The System.Runtime.InteropServices.RuntimeEnvironment members SystemConfigurationFile , GetRuntimeInterfaceAsIntPtr(Guid, Guid) , and GetRuntimeInterfaceAsObject(Guid, Guid) are no longer supported and throw PlatformNotSupportedException .
SYSLIB0020	Warning	JsonSerializerOptions.IgnoreNullValues is obsolete. To ignore null values when serializing, set DefaultIgnoreCondition to JsonIgnoreCondition.WhenWritingNull .
SYSLIB0021	Warning	Derived cryptographic types are obsolete. Use the create method on the base type instead.
SYSLIB0022	Warning	The Rijndael and RijndaelManaged types are obsolete. Use Aes instead.
SYSLIB0023	Warning	RNGCryptoServiceProvider is obsolete. To generate a random number, use one of the RandomNumberGenerator static methods instead.
SYSLIB0024	Warning	Creating and unloading AppDomains is not supported and throws an exception.
SYSLIB0025	Warning	SuppressIldasmAttribute has no effect in .NET 6+.
SYSLIB0026	Warning	X509Certificate and X509Certificate2 are immutable. Use the appropriate constructor to create a new certificate.
SYSLIB0027	Warning	PublicKey.Key is obsolete. Use the appropriate method to get the public key, such as GetRSAPublicKey() .
SYSLIB0028	Warning	X509Certificate2.PrivateKey is obsolete. Use the appropriate method to get the private key, such as RSACertificateExtensions.GetRSAPrivateKey(X509Certificate2) , or use the X509Certificate2.CopyWithPrivateKey(ECDiffieHellman) method to create a new instance with a private key.
SYSLIB0029	Warning	ProduceLegacyHmacValues is obsolete. Producing legacy HMAC values is no longer supported.

DIAGNOSTIC ID	WARNING OR ERROR	DESCRIPTION
SYSLIB0030	Warning	<code>HMACSHA1</code> always uses the algorithm implementation provided by the platform. Use a constructor without the <code>useManagedSha1</code> parameter.
SYSLIB0031	Warning	<code>CryptoConfig.EncodeOID(String)</code> is obsolete. Use the ASN.1 functionality provided in <code>System.Formats.Asn1</code> .
SYSLIB0032	Warning	Recovery from corrupted process state exceptions is not supported; <code>HandleProcessCorruptedStateExceptionsAttribute</code> is ignored.
SYSLIB0033	Warning	<code>Rfc2898DeriveBytes.CryptDeriveKey(String, String, Int32, Byte[])</code> is obsolete and is not supported. Use <code>PasswordDeriveBytes.CryptDeriveKey(String, String, Int32, Byte[])</code> instead.
SYSLIB0034	Warning	<code>CmsSigner(CspParameters)</code> is obsolete. Use an alternative constructor instead.
SYSLIB0035	Warning	<code>SignerInfo.ComputeCounterSignature()</code> is obsolete. Use the overload that accepts a <code>CmsSigner</code> instead.
SYSLIB0036	Warning	<code>Regex.CompileToAssembly</code> is obsolete and not supported. Use <code>RegexGeneratorAttribute</code> with the regular expression source generator instead.
SYSLIB0037	Warning	<code>AssemblyName</code> members <code>HashAlgorithm</code> , <code>ProcessorArchitecture</code> , and <code>VersionCompatibility</code> are obsolete and not supported.
SYSLIB0038	Warning	<code>SerializationFormat.Binary</code> is obsolete and should not be used.
SYSLIB0039	Warning	TLS versions 1.0 and 1.1 have known vulnerabilities and are not recommended. Use a newer TLS version instead, or use <code>SslProtocols.None</code> to defer to OS defaults.
SYSLIB0040	Warning	<code>EncryptionPolicy.NoEncryption</code> and <code>EncryptionPolicy.AllowNoEncryption</code> significantly reduce security and should not be used in production code.

DIAGNOSTIC ID	WARNING OR ERROR	DESCRIPTION
SYSLIB0041	Warning	The default hash algorithm and iteration counts in Rfc2898DeriveBytes constructors are outdated and insecure. Use a constructor that accepts the hash algorithm and the number of iterations.
SYSLIB0042	Warning	<code>ToXmlString</code> and <code>FromXmlString</code> have no implementation for elliptic curve cryptography (ECC) types, and are obsolete. Use a standard import and export format such as <code>ExportSubjectPublicKeyInfo</code> or <code>ImportSubjectPublicKeyInfo</code> for public keys, and <code>ExportPkcs8PrivateKey</code> or <code>ImportPkcs8PrivateKey</code> for private keys.
SYSLIB0043	Warning	<code>ECDiffieHellmanPublicKey.ToByteArray()</code> and the associated constructor do not have a consistent and interoperable implementation on all platforms. Use <code>ECDiffieHellmanPublicKey.ExportSubjectPublicKeyInfo()</code> instead.
SYSLIB0047	Warning	<code>XmlSecureResolver</code> is obsolete. Use <code>XmlResolver.ThrowingResolver</code> instead when attempting to forbid XML external entity resolution.

Suppress warnings

It's recommended that you use an available workaround whenever possible. However, if you cannot change your code, you can suppress warnings through a `#pragma` directive or a `<NoWarn>` project setting. If you must use the obsolete APIs and the `SYSLIB0XXX` diagnostic does not surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.
#pragma warning disable SYSLIB0001

// Code that uses obsolete API.
//...

// Re-enable the warning.
#pragma warning restore SYSLIB0001
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
<TargetFramework>net6.0</TargetFramework>
<!-- NoWarn below suppresses SYSLIB0001 project-wide -->
<NoWarn>$(NoWarn);SYSLIB0001</NoWarn>
<!-- To suppress multiple warnings, you can use multiple NoWarn elements -->
<NoWarn>$(NoWarn);SYSLIB0002</NoWarn>
<NoWarn>$(NoWarn);SYSLIB0003</NoWarn>
<!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->
<NoWarn>$(NoWarn);SYSLIB0001;SYSLIB0002;SYSLIB0003</NoWarn>
</PropertyGroup>
</Project>
```

NOTE

Suppressing warnings in this way only disables the obsoletion warnings you specify. It doesn't disable any other warnings, including obsoletion warnings with different diagnostic IDs.

SYSLIB0001: The UTF-7 encoding is insecure

9/20/2022 • 2 minutes to read • [Edit Online](#)

The UTF-7 encoding is no longer in wide use among applications, and many specs now [forbid its use](#) in interchange. It's also occasionally [used as an attack vector](#) in applications that don't anticipate encountering UTF-7-encoded data. Microsoft warns against use of [System.Text.UTF7Encoding](#) because it doesn't provide error detection.

Consequently, the following APIs are marked obsolete, starting in .NET 5. Use of these APIs generates warning `SYSLIB0001` at compile time.

- [Encoding.UTF7](#) property
- [UTF7Encoding](#) constructors

Workarounds

- If you're using [Encoding.UTF7](#) or [UTF7Encoding](#) within your own protocol or file format:

Switch to using [Encoding.UTF8](#) or [UTF8Encoding](#). UTF-8 is an industry standard and is widely supported across languages, operating systems, and runtimes. Using UTF-8 eases future maintenance of your code and makes it more interoperable with the rest of the ecosystem.

- If you're comparing an [Encoding](#) instance against [Encoding.UTF7](#):

Instead, consider performing a check against the well-known UTF-7 code page, which is `65000`. By comparing against the code page, you avoid the warning and also handle some edge cases, such as if somebody called `new UTF7Encoding()` or subclassed the type.

```
void DoSomething(Encoding enc)
{
    // Don't perform the check this way.
    // It produces a warning and misses some edge cases.
    if (enc == Encoding.UTF7)
    {
        // Encoding is UTF-7.
    }

    // Instead, perform the check this way.
    if (enc != null && enc.CodePage == 65000)
    {
        // Encoding is UTF-7.
    }
}
```

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0001  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0001
```

To suppress all the `SYSLIB0001` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0001</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0002: PrincipalPermissionAttribute is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [PrincipalPermissionAttribute](#) constructor is obsolete and produces compile-time error `SYSLIB0002`, starting in .NET 5. You cannot instantiate this attribute or apply it to a method.

Unlike other obsolescence warnings, you can't suppress the error.

Workarounds

- If you're applying the attribute to an ASP.NET MVC action method:

Consider using ASP.NET's built-in authorization infrastructure. The following code demonstrates how to annotate a controller with an [AuthorizeAttribute](#) attribute. The ASP.NET runtime will authorize the user before performing the action.

```
using Microsoft.AspNetCore.Authorization;

namespace MySampleApp
{
    [Authorize(Roles = "Administrator")]
    public class AdministrationController : Controller
    {
        public ActionResult MyAction()
        {
            // This code won't run unless the current user
            // is in the 'Administrator' role.
        }
    }
}
```

For more information, see [Role-based authorization in ASP.NET Core](#) and [Introduction to authorization in ASP.NET Core](#).

- If you're applying the attribute to library code outside the context of a web app:

Perform the checks manually at the beginning of your method by calling the [IPrincipal.IsInRole\(String\)](#) method.

```
using System.Threading;

void DoSomething()
{
    if (Thread.CurrentPrincipal == null
        || !Thread.CurrentPrincipal.IsInRole("Administrators"))
    {
        throw new Exception("User is anonymous or isn't an admin.");
    }

    // Code that should run only when user is an administrator.
}
```

[PrincipalPermissionAttribute is obsolete as error](#)

SYSLIB0003: Code access security is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

[Code access security \(CAS\)](#) is an unsupported, legacy technology. The infrastructure to enable CAS, which exists only in .NET Framework 2.x - 4.x, is deprecated and not receiving servicing or security fixes.

As a result, most code access security (CAS)-related types in .NET are obsolete, starting in .NET 5. This includes CAS attributes, such as [SecurityPermissionAttribute](#), CAS permission objects, such as [SocketPermission](#), [EvidenceBase](#)-derived types, and other supporting APIs. Using these APIs generates warning `SYSLIB0003` at compile time.

The complete list of obsolete CAS APIs is as follows:

- [System.AppDomain.ExecuteAssembly\(String, String\[\], Byte\[\], AssemblyHashAlgorithm\)](#)
- [System.AppDomain.PermissionSet](#)
- [System.Configuration.ConfigurationPermission](#)
- [System.Configuration.ConfigurationPermissionAttribute](#)
- [System.Data.Common.DBDataPermission](#)
- [System.Data.Common.DBDataPermissionAttribute](#)
- [System.Data.Odbc.OdbcPermission](#)
- [System.Data.Odbc.OdbcPermissionAttribute](#)
- [System.Data.OleDb.OleDbPermission](#)
- [System.Data.OleDb.OleDbPermissionAttribute](#)
- [System.Data.OracleClient.OraclePermission](#)
- [System.Data.OracleClient.OraclePermissionAttribute](#)
- [System.Data.SqlClient.SqlClientPermission](#)
- [System.Data.SqlClient.SqlClientPermissionAttribute](#)
- [System.Diagnostics.EventLogPermission](#)
- [System.Diagnostics.EventLogPermissionAttribute](#)
- [System.Diagnostics.PerformanceCounterPermission](#)
- [System.Diagnostics.PerformanceCounterPermissionAttribute](#)
- [System.DirectoryServices.DirectoryServicesPermission](#)
- [System.DirectoryServices.DirectoryServicesPermissionAttribute](#)
- [System.Drawing.Printing.PrintingPermission](#)
- [System.Drawing.Printing.PrintingPermissionAttribute](#)
- [System.Net.DnsPermission](#)
- [System.Net.DnsPermissionAttribute](#)

- [System.Transactions.DistributedTransactionPermissionAttribute](#)
- [System.Web.AspNetHostingPermission](#)
- [System.Web.AspNetHostingPermissionAttribute](#)
- [System.Xaml.Permissions.XamlLoadPermission](#)

Workarounds

- If you're asserting any security permission, remove the attribute or call that asserts the permission.

```
// REMOVE the attribute below.
[SecurityPermission(SecurityAction.Assert, ControlThread = true)]
public void DoSomething()
{
}
public void DoAssert()
{
    // REMOVE the line below.
    new SecurityPermission(SecurityPermissionFlag.ControlThread).Assert();
}
```

- If you're denying or restricting (via `PermitOnly`) any permission, contact your security advisor. Because CAS attributes are not honored by the .NET 5+ runtime, your application could have a security hole if it incorrectly relies on the CAS infrastructure to restrict access to these methods.

```
// REVIEW the attribute below; could indicate security vulnerability.
[SecurityPermission(SecurityAction.Deny, ControlThread = true)]
public void DoSomething()
{
}
public void DoPermitOnly()
{
    // REVIEW the line below; could indicate security vulnerability.
    new SecurityPermission(SecurityPermissionFlag.ControlThread).PermitOnly();
}
```

- If you're demanding any permission (except `PrincipalPermission`), remove the demand. All demands will

succeed at run time.

```
// REMOVE the attribute below; it will always succeed.  
[SecurityPermission(SecurityAction.Demand, ControlThread = true)]  
public void DoSomething()  
{  
}  
public void DoDemand()  
{  
    // REMOVE the line below; it will always succeed.  
    new SecurityPermission(SecurityPermissionFlag.ControlThread).Demand();  
}
```

- If you're demanding [PrincipalPermission](#), consult the guidance for [SYSLIB0002: PrincipalPermissionAttribute is obsolete](#). That guidance applies for both [PrincipalPermission](#) and [PrincipalPermissionAttribute](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0003  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0003
```

To suppress all the `SYSLIB0003` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0003</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

- [SYSLIB0002: PrincipalPermissionAttribute is obsolete](#)

SYSLIB0004: The constrained execution region (CER) feature is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [Constrained execution regions \(CER\)](#) feature is supported only in .NET Framework. As such, various CER-related APIs are marked obsolete, starting in .NET 5. Using these APIs generates warning `SYSLIB0004` at compile time.

The following CER-related APIs are obsolete:

- [RuntimeHelpers.ExecuteCodeWithGuaranteedCleanup\(RuntimeHelpers+TryCode, RuntimeHelpers+CleanupCode, Object\)](#)
- [RuntimeHelpers.PrepareConstrainedRegions\(\)](#)
- [RuntimeHelpers.PrepareConstrainedRegionsNoOP\(\)](#)
- [RuntimeHelpers.PrepareContractedDelegate\(Delegate\)](#)
- [RuntimeHelpers.ProbeForSufficientStack\(\)](#)
- [System.Runtime.ConstrainedExecution.Cer](#)
- [System.Runtime.ConstrainedExecution.Consistency](#)
- [System.Runtime.ConstrainedExecution.PrePrepareMethodAttribute](#)
- [System.Runtime.ConstrainedExecution.ReliabilityContractAttribute](#)

However, the following CER-related APIs are *not* obsolete:

- [RuntimeHelpers.PrepareDelegate\(Delegate\)](#)
- [RuntimeHelpers.PrepareMethod](#)
- [System.Runtime.ConstrainedExecution.CriticalFinalizerObject](#)

Workarounds

- If you've applied a CER attribute to a method, remove the attribute. These attributes have no effect in .NET 5 and later versions.

```
// REMOVE the attribute below.  
[ReliabilityContract(Consistency.WillNotCorruptState, Cer.Success)]  
public void DoSomething()  
{  
}  
  
// REMOVE the attribute below.  
[PrePrepareMethod]  
public void DoSomething()  
{  
}
```

- If you are calling `RuntimeHelpers.ProbeForSufficientStack` or `RuntimeHelpers.PrepareContractedDelegate`, remove the call. These calls have no effect in .NET 5 and later versions.

```
public void DoSomething()
{
    // REMOVE the call below.
    RuntimeHelpers.ProbeForSufficientStack();

    // (Remainder of your method logic here.)
}
```

- If you are calling `RuntimeHelpers.PrepareConstrainedRegions`, remove the call. This call has no effect in .NET 5 and later versions.

```
public void DoSomething_Old()
{
    // REMOVE the call below.
    RuntimeHelpers.PrepareConstrainedRegions();
    try
    {
        // try code
    }
    finally
    {
        // cleanup code
    }
}

public void DoSomething_Corrected()
{
    // There is no call to PrepareConstrainedRegions. It's a normal try / finally block.

    try
    {
        // try code
    }
    finally
    {
        // cleanup code
    }
}
```

- If you are calling `RuntimeHelpers.ExecuteCodeWithGuaranteedCleanup`, replace the call with a standard `try/catch/finally` block.

```
// The sample below produces warning SYSLIB0004.
public void DoSomething_Old()
{
    RuntimeHelpers.ExecuteCodeWithGuaranteedCleanup(MyTryCode, MyCleanupCode, null);
}
public void MyTryCode(object state) { /* try code */ }
public void MyCleanupCode(object state, bool exceptionThrown) { /* cleanup code */ }

// The corrected sample below does not produce warning SYSLIB0004.
public void DoSomething_Corrected()
{
    try
    {
        // try code
    }
    catch (Exception ex)
    {
        // exception handling code
    }
    finally
    {
        // cleanup code
    }
}
```

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.
#pragma warning disable SYSLIB0004

// Code that uses obsolete API.
// ...

// Re-enable the warning.
#pragma warning restore SYSLIB0004
```

To suppress all the `SYSLIB0004` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
    ...
    <NoWarn>$(NoWarn);SYSLIB0004</NoWarn>
</PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

- [Constrained execution regions](#)

SYSLIB0005: The global assembly cache (GAC) is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

.NET Core and .NET 5 and later versions eliminate the concept of the global assembly cache (GAC) that was present in .NET Framework. To help steer developers away from these APIs, some GAC-related APIs are marked as obsolete, starting in .NET 5. Using these APIs generates warning `SYSLIB0005` at compile time.

The following GAC-related APIs are marked obsolete:

- [Assembly.GlobalAssemblyCache](#)

Libraries and apps should not use the [GlobalAssemblyCache](#) API to make determinations about run-time behavior, as it always returns `false` in .NET Core and .NET 5+.

Workarounds

If your application queries the [GlobalAssemblyCache](#) property, consider removing the call. If you use the [GlobalAssemblyCache](#) value to choose between an "assembly in the GAC"-flow vs. an "assembly not in the GAC"-flow at run time, reconsider whether the flow still makes sense for a .NET 5+ application.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0005  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0005
```

To suppress all the `SYSLIB0005` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0005</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [Global assembly cache](#)

SYSLIB0006: Thread.Abort is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked obsolete, starting in .NET 5. Use of these APIs generates warning `SYSLIB0006` at compile time and a [PlatformNotSupportedException](#) at run time.

- [Thread.Abort\(\)](#)
- [Thread.Abort\(Object\)](#)

When you call [Thread.Abort](#) to abort a thread other than the current thread, you don't know what code has executed or failed to execute when the [ThreadAbortException](#) is thrown. You also cannot be certain of the state of your application or any application and user state that it's responsible for preserving. For example, calling [Thread.Abort](#) may prevent the execution of static constructors or the release of managed or unmanaged resources. For this reason, [Thread.Abort](#) always throws a [PlatformNotSupportedException](#) on .NET Core and .NET 5+.

Workarounds

Use a [CancellationToken](#) to abort processing of a unit of work instead of calling [Thread.Abort](#). The following example illustrates the use of [CancellationToken](#).

```
void ProcessPendingWorkItemsNew(CancellationToken cancellationToken)
{
    if (QueryIsMoreWorkPending())
    {
        // If the CancellationToken is marked as "needs to cancel",
        // this will throw the appropriate exception.
        cancellationToken.ThrowIfCancellationRequested();

        WorkItem work = DequeueWorkItem();
        ProcessWorkItem(work);
    }
}
```

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.
#pragma warning disable SYSLIB0006

// Code that uses obsolete API.
// ...

// Re-enable the warning.
#pragma warning restore SYSLIB0006
```

To suppress all the `SYSLIB0006` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
  ...
  <NoWarn>$(NoWarn);SYSLIB0006</NoWarn>
</PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [Thread.Abort is obsolete](#)

SYSLIB0007: Default implementations of cryptography algorithms not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The cryptographic configuration system in .NET Framework doesn't allow for proper cryptographic agility and isn't present in .NET Core and .NET 5+. .NET's backward-compatibility requirements also prohibit the framework from updating certain cryptographic APIs to keep up with advances in cryptography. As a result, the following APIs are marked obsolete, starting in .NET 5. Use of these APIs generates warning `SYSLIB0007` at compile time and a `PlatformNotSupportedException` at run time.

- `System.Security.Cryptography.AsymmetricAlgorithm.Create()`
- `System.Security.Cryptography.HashAlgorithm.Create()`
- `System.Security.Cryptography.HMAC.Create()`
- `System.Security.Cryptography.KeyedHashAlgorithm.Create()`
- `System.Security.Cryptography.SymmetricAlgorithm.Create()`

Workarounds

- The recommended course of action is to replace calls to the now-obsolete APIs with calls to factory methods for specific algorithms, for example, `Aes.Create()`. This gives you full control over which algorithms are instantiated.
- If you need to maintain compatibility with existing payloads generated by .NET Framework apps that use the now-obsolete APIs, use the replacements suggested in the following table. The table provides a mapping from .NET Framework default algorithms to their .NET 5+ equivalents.

.NET FRAMEWORK	.NET CORE / .NET 5+ COMPATIBLE REPLACEMENT	REMARKS
<code>AsymmetricAlgorithm.Create()</code>	<code>RSA.Create()</code>	
<code>HashAlgorithm.Create()</code>	<code>SHA1.Create()</code>	The SHA-1 algorithm is considered broken. Consider using a stronger algorithm if possible. Consult your security advisor for further guidance.
<code>HMAC.Create()</code>	<code>HMACSHA1()</code>	The HMACSHA1 algorithm is discouraged for most modern applications. Consider using a stronger algorithm if possible. Consult your security advisor for further guidance.
<code>KeyedHashAlgorithm.Create()</code>	<code>HMACSHA1()</code>	The HMACSHA1 algorithm is discouraged for most modern applications. Consider using a stronger algorithm if possible. Consult your security advisor for further guidance.

.NET FRAMEWORK	.NET CORE / .NET 5+ COMPATIBLE REPLACEMENT	REMARKS
<code>SymmetricAlgorithm.Create()</code>	<code>Aes.Create()</code>	

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.
#pragma warning disable SYSLIB0007

// Code that uses obsolete API.
// ...

// Re-enable the warning.
#pragma warning restore SYSLIB0007
```

To suppress all the `SYSLIB0007` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
...
<NoWarn>$({NoWarn});SYSLIB0007</NoWarn>
</PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [Instantiating default implementations of cryptographic abstractions is not supported](#)

SYSLIB0008: CreatePdbGenerator is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [DebugInfoGenerator.CreatePdbGenerator\(\)](#) API is marked obsolete, starting in .NET 5. Using this API generates warning `SYSLIB0008` at compile time and throws a [PlatformNotSupportedException](#) at run time.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0008  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0008
```

To suppress all the `SYSLIB0008` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0008</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0009: The AuthenticationManager Authenticate and PreAuthenticate methods are not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked obsolete, starting in .NET 5. Use of these APIs generates warning `SYSLIB0009` at compile time and throws a `PlatformNotSupportedException` at run time.

- [AuthenticationManager.Authenticate](#)
- [AuthenticationManager.PreAuthenticate](#)

Workarounds

Implement [IAuthenticationModule](#), which has methods that were previously called by `AuthenticationManager.Authenticate`.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0009  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0009
```

To suppress all the `SYSLIB0009` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0009</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0010: Unsupported remoting APIs

9/20/2022 • 2 minutes to read • [Edit Online](#)

.NET remoting is a legacy technology, and the infrastructure exists only in .NET Framework. The following remoting-related APIs are marked as obsolete, starting in .NET 5. Using them in code generates warning `SYSLIB0010` at compile time and throws a `PlatformNotSupportedException` at run time.

- `MarshalByRefObject.GetLifetimeService()`
- `MarshalByRefObject.InitializeLifetimeService()`

Workarounds

Consider using WCF or HTTP-based REST services to communicate with objects in other applications or across machines. For more information, see [.NET Framework technologies unavailable on .NET Core](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0010  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0010
```

To suppress all the `SYSLIB0010` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0010</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0011: BinaryFormatter serialization is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

Due to [security vulnerabilities](#) in [BinaryFormatter](#), the following APIs are marked as obsolete, starting in .NET 5. Using them in code generates warning `SYSLIB0011` at compile time.

- [System.Exception.SerializeObjectState](#)
- [BinaryFormatter.Serialize](#)
- [BinaryFormatter.Deserialize](#)
- [Formatter.Serialize\(Stream, Object\)](#)
- [Formatter.Deserialize\(Stream\)](#)
- [IFormatter.Serialize\(Stream, Object\)](#)
- [IFormatter.Deserialize\(Stream\)](#)

Workarounds

Consider using [JsonSerializer](#) or [XmlSerializer](#) instead of [BinaryFormatter](#).

For more information about recommended actions, see [Resolving BinaryFormatter obsolescence and disablement errors](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0011  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0011
```

To suppress all the `SYSLIB0011` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0011</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [Resolving BinaryFormatter obsolescence and disablement errors](#)

- `BinaryFormatter` serialization methods are obsolete and prohibited in ASP.NET apps

SYSLIB0012: Assembly.CodeBase and Assembly.EscapedCodeBase are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked as obsolete, starting in .NET 5. Using them in code generates warning `SYSLIB0012` at compile time.

- [Assembly.CodeBase](#)
- [Assembly.EscapedCodeBase](#)

Workarounds

Use [Assembly.Location](#) instead.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0012  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0012
```

To suppress all the `SYSLIB0012` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0012</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0013: EscapeUriString is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [Uri.EscapeUriString\(String\)](#) API is marked as obsolete, starting in .NET 6. Using it in code generates warning `SYSLIB0013` at compile time.

`Uri.EscapeUriString(String)` can corrupt the Uri string in some cases.

For more information, see <https://github.com/dotnet/runtime/issues/31387>.

Workarounds

Use [Uri.EscapeDataString\(String\)](#) for query string components instead.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0013  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0013
```

To suppress all the `SYSLIB0013` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0013</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0014: WebRequest, HttpWebRequest, ServicePoint, WebClient are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0014` at compile time.

- [WebRequest\(\)](#)
- [System.Net.WebRequest.Create](#)
- [System.Net.WebRequest.CreateHttp](#)
- [System.Net.WebRequest.CreateDefault\(Uri\)](#)
- [HttpWebRequest\(SerializationInfo, StreamingContext\)](#)
- [System.Net.ServicePointManager.FindServicePoint](#)
- [WebClient\(\)](#)

Workarounds

Use [HttpClient](#) instead.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0014  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0014
```

To suppress all the `SYSLIB0014` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0014</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [WebRequest, WebClient, and ServicePoint are obsolete](#)

SYSLIB0015: DisablePrivateReflectionAttribute is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

Starting in .NET 6, the [System.Runtime.CompilerServices.DisablePrivateReflectionAttribute](#) type is marked as obsolete. This attribute has no effect in .NET Core 2.1 and later apps. Using it in code generates warning `SYSLIB0015` at compile time for .NET 6 and later apps.

For more information, see <https://github.com/dotnet/runtime/issues/11811>.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0015  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0015
```

To suppress all the `SYSLIB0015` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0015</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0016: GetContextInfo() is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [Graphics.GetContextInfo\(\)](#) method that takes no arguments is marked as obsolete, starting in .NET 6. Using it in code generates warning `SYSLIB0016` at compile time.

For more information, see <https://github.com/dotnet/runtime/issues/47880>.

Workarounds

For better performance and fewer allocations, use the [Graphics.GetContextInfo](#) overloads that accept arguments:

- [System.Drawing.Graphics.GetContextInfo\(PointF\)](#)
- [System.Drawing.Graphics.GetContextInfo\(PointF, Region\)](#)

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0016  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0016
```

To suppress all the `SYSLIB0016` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$({NoWarn});SYSLIB0016</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0017: Strong-name signing is not supported and throws PlatformNotSupportedException

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0017` at compile time. These APIs throw a [PlatformNotSupportedException](#) at run time.

- [AssemblyName.KeyPair](#)
- [StrongNameKeyPair](#)

For more information, see <https://github.com/dotnet/runtime/issues/50529>.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0017  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0017
```

To suppress all the `SYSLIB0017` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$({NoWarn});SYSLIB0017</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0018: Reflection-only loading is not supported and throws PlatformNotSupportedException

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following methods are marked as obsolete, starting in .NET 6. Calling them in code generates warning `SYSLIB0018` at compile time. These methods throw a [PlatformNotSupportedException](#) at run time.

- [Assembly.ReflectionOnlyLoad](#)
- [Assembly.ReflectionOnlyLoadFrom\(String\)](#)
- [Type.ReflectionOnlyGetType\(String, Boolean, Boolean\)](#)

Workarounds

Reflection-only loading is replaced by the metadata load-context in .NET Core and .NET 5+. For more information, see [How to: Inspect assembly contents using MetadataLoadContext](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0018  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0018
```

To suppress all the `SYSLIB0018` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(<NoWarn>) ; SYSLIB0018</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0019: Some RuntimeEnvironment APIs are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following APIs are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0019` at compile time.

- `RuntimeEnvironment.SystemConfigurationFile` property
- `RuntimeEnvironment.GetRuntimeInterfaceAsIntPtr(Guid, Guid)` method
- `RuntimeEnvironment.GetRuntimeInterfaceAsObject(Guid, Guid)` method

These APIs always throw a `PlatformNotSupportedException` at run time.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0019  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0019
```

To suppress all the `SYSLIB0019` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0019</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0020: IgnoreNullValues is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `JsonSerializerOptions.IgnoreNullValues` property is marked as obsolete, starting in .NET 6. Using it in code generates warning `SYSLIB0020` at compile time.

Workarounds

To ignore null values when serializing, set `DefaultIgnoreCondition` to `JsonIgnoreCondition.WhenWritingNull`. For more information, see <https://github.com/dotnet/runtime/issues/39152>.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0020  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0020
```

To suppress all the `SYSLIB0020` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0020</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0021: Derived cryptographic types are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following derived cryptographic types are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0021` at compile time.

- [System.Security.Cryptography.AesCryptoServiceProvider](#)
- [System.Security.Cryptography.AesManaged](#)
- [System.Security.Cryptography.DESCryptoServiceProvider](#)
- [System.Security.Cryptography.MD5CryptoServiceProvider](#)
- [System.Security.Cryptography.RC2CryptoServiceProvider](#)
- [System.Security.Cryptography.SHA1CryptoServiceProvider](#)
- [System.Security.Cryptography.SHA1Managed](#)
- [System.Security.Cryptography.SHA256Managed](#)
- [System.Security.Cryptography.SHA256CryptoServiceProvider](#)
- [System.Security.Cryptography.SHA384Managed](#)
- [System.Security.Cryptography.SHA384CryptoServiceProvider](#)
- [System.Security.Cryptography.SHA512Managed](#)
- [System.Security.Cryptography.SHA512CryptoServiceProvider](#)
- [System.Security.Cryptography.TripleDESCryptoServiceProvider](#)

Workarounds

Use the `Create` method on the base type instead. For example, use [TripleDES.Create](#) instead of [TripleDESCryptoServiceProvider](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0021  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0021
```

To suppress all the `SYSLIB0021` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
...
<NoWarn>$(NoWarn);SYSLIB0021</NoWarn>
</PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0022: The Rijndael and RijndaelManaged types are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [Rijndael](#) and [RijndaelManaged](#) types are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0022` at compile time.

Workarounds

Use [System.Security.Cryptography.Aes](#) instead.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0022  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0022
```

To suppress all the `SYSLIB0022` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0022</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0023: RNGCryptoServiceProvider is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

`RNGCryptoServiceProvider` is marked as obsolete, starting in .NET 6. Using it in code generates warning `SYSLIB0023` at compile time.

Workarounds

To generate a random number, use one of the `RandomNumberGenerator` methods instead, for example, `RandomNumberGenerator.GetInt32(Int32)`.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0023  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0023
```

To suppress all the `SYSLIB0023` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0023</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0024: Creating and unloading AppDomains is not supported and throws an exception

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `AppDomain.CreateDomain(String)` and `AppDomain.Unload(AppDomain)` methods are marked as obsolete, starting in .NET 6. Using them in code generates warning `SYSLIB0024` at compile time and throws an exception at run time.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0024  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0024
```

To suppress all the `SYSLIB0024` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$({NoWarn});SYSLIB0024</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0025: SuppressIldasmAttribute is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [SuppressIldasmAttribute](#) type is marked as obsolete, starting in .NET 6. Using it in code generates warning `SYSLIB0025` at compile time. [IL Disassembler \(ildasm.exe\)](#) no longer supports this attribute.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0025  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0025
```

To suppress all the `SYSLIB0025` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0025</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0026: X509Certificate and X509Certificate2 are immutable

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following mutable x509 certificate APIs are marked as obsolete, starting in .NET 6. Using these APIs in code generates warning `SYSLIB0026` at compile time.

- [X509Certificate\(\)](#)
- [X509Certificate.Import](#)
- [X509Certificate2\(\)](#)
- [X509Certificate2.Import](#)

Workarounds

Create a new instance of `X509Certificate` and `X509Certificate2` using a constructor overload that accepts the certificate as input. For example:

```
// Change this:  
cert.Import("/path/to/certificate.crt");  
  
// To this:  
cert.Dispose();  
cert = new X509Certificate2("/path/to/certificate.crt");
```

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0026  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0026
```

To suppress all the `SYSLIB0026` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0026</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0027: PublicKey.Key is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [PublicKey.Key](#) property is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0027` at compile time.

Workarounds

Use the appropriate method to get the public key, such as [GetRSAPublicKey\(\)](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0027  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0027
```

To suppress all the `SYSLIB0027` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(<NoWarn>) ; SYSLIB0027</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0028: X509Certificate2.PrivateKey is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [X509Certificate2.PrivateKey](#) property is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0028` at compile time.

Workarounds

Use the appropriate method to get the private key, such as [RSACertificateExtensions.GetRSAPrivateKey\(X509Certificate2\)](#), or use the [X509Certificate2.CopyWithPrivateKey\(ECDiffieHellman\)](#) method to create a new instance with a private key.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0028  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0028
```

To suppress all the `SYSLIB0028` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0028</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0029: ProduceLegacyHmacValues is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following properties are marked as obsolete, starting in .NET 6:

- [HMACSHA384.ProduceLegacyHmacValues](#)
- [HMACSHA512.ProduceLegacyHmacValues](#)

Using these APIs in code generates warning `SYSLIB0029` at compile time. Producing legacy HMAC values is no longer supported.

Workarounds

None.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0029  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0029
```

To suppress all the `SYSLIB0029` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0029</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0030: HMACSHA1 always uses the algorithm implementation provided by the platform

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [HMACSHA1\(Byte\[\], Boolean\)](#) constructor is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0030` at compile time.

Workarounds

Use a constructor without the `useManagedSha1` parameter.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0030  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0030
```

To suppress all the `SYSLIB0030` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0030</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0031: EncodeOID is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [CryptoConfig.EncodeOID\(String\)](#) method is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0031` at compile time and throws a [PlatformNotSupportedException](#) exception at run time.

Workarounds

Use the ASN.1 functionality provided in [System.Formats.Asn1](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0031  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0031
```

To suppress all the `SYSLIB0031` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0031</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0032: Recovery from corrupted process state exceptions is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

Recovery from corrupted process state exceptions is not supported, and the [HandleProcessCorruptedStateExceptionsAttribute](#) type is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0032` at compile time.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0032  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0032
```

To suppress all the `SYSLIB0032` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0032</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0033: Rfc2898DeriveBytes.CryptDeriveKey is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `Rfc2898DeriveBytes.CryptDeriveKey(String, String, Int32, Byte[])` method is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0033` at compile time.

Workaround

Use `PasswordDeriveBytes.CryptDeriveKey(String, String, Int32, Byte[])` instead.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0033  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0033
```

To suppress all the `SYSLIB0033` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0033</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0034: CmsSigner(CspParameters) constructor is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [CmsSigner\(CspParameters\)](#) constructor is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0034` at compile time.

Workaround

Use an alternative constructor.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0034  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0034
```

To suppress all the `SYSLIB0034` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0034</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0035: ComputeCounterSignature without specifying a CmsSigner is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [SignerInfo.ComputeCounterSignature\(\)](#) method is marked as obsolete, starting in .NET 6. Using this API in code generates warning `SYSLIB0035` at compile time.

Workaround

Use the overload that accepts a [CmsSigner](#), that is, [SignerInfo.ComputeCounterSignature\(CmsSigner\)](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0035  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0035
```

To suppress all the `SYSLIB0035` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0035</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0036: Regex.CompileToAssembly is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [Regex.CompileToAssembly](#) method is marked as obsolete, starting in .NET 7. Using this API in code generates warning `SYSLIB0036` at compile time.

In .NET 5, .NET 6, and all versions of .NET Core, [Regex.CompileToAssembly](#) throws a [PlatformNotSupportedException](#). In .NET Framework, [Regex.CompileToAssembly](#) allows a regular expression instance to be compiled into an assembly.

Workaround

Use the `RegexGeneratorAttribute` feature, which invokes a regular expression source generator. At compile time, the source generator produces an API specific to a regular expression pattern and its options.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0036  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0036
```

To suppress all the `SYSLIB0036` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0036</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0037: AssemblyName members HashAlgorithm, ProcessorArchitecture, and VersionCompatibility are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following [System.Reflection.AssemblyName](#) properties are marked as obsolete, starting in .NET 7. Using these APIs in code generates warning `SYSLIB0037` at compile time.

- [HashAlgorithm](#)
- [ProcessorArchitecture](#)
- [VersionCompatibility](#)

These properties are not a proper part of an [AssemblyName](#) instance. They don't roundtrip through [AssemblyName](#) string representation, and they are ignored by the assembly loader in .NET Core.

Workaround

Don't use these members in scenarios where it was expected for the values to be round-tripped through the string representation of the [AssemblyName](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0037  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0037
```

To suppress all the `SYSLIB0037` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$({NoWarn});SYSLIB0037</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0038: SerializationFormat.Binary is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

`SerializationFormat.Binary` is marked as obsolete, starting in .NET 7. Using this API in code generates warning `SYSLIB0038` at compile time.

Workaround

If your code uses `SerializationFormat.Binary`, switch to using `SerializationFormat.Xml` or use another method of serialization.

Otherwise, you can set the `Switch.System.Data.AllowUnsafeSerializationFormatBinary` `AppContext` switch. This switch lets you opt in to allowing the use of `SerializationFormat.Binary`, so that code can work as before. However, this switch will be removed in .NET 8. For information about setting the switch, see [AppContext for library consumers](#).

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0038  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0038
```

To suppress all the `SYSLIB0038` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(<NoWarn>) ; SYSLIB0038</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [SerializationFormat.Binary is obsolete](#)

SYSLIB0039: SslProtocols.Tls and SslProtocols.Tls11 are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

`SslProtocols.Tls` and `SslProtocols.Tls11` are marked as obsolete, starting in .NET 7. Using these enumeration fields in code generates warning `SYSLIB0039` at compile time.

Workaround

Use a higher TLS protocol version, or use `SslProtocols.None` to defer to system defaults.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0039  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0039
```

To suppress all the `SYSLIB0039` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0039</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0040: EncryptionPolicy.NoEncryption and EncryptionPolicy.AllowNoEncryption are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

[EncryptionPolicy.NoEncryption](#) and [EncryptionPolicy.AllowNoEncryption](#) are marked as obsolete, starting in .NET 7. Using these enumeration fields in code generates warning `SYSLIB0040` at compile time.

Older SSL/TLS versions permitted no encryption, and while it may be useful for debugging, it shouldn't be used in production. In addition, NULL encryption is no longer available as of TLS 1.3.

Workaround

N/A

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0040  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0040
```

To suppress all the `SYSLIB0040` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0040</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0041: Some Rfc2898DeriveBytes constructors are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following [Rfc2898DeriveBytes](#) constructors are obsolete, starting in .NET 7. Using them in code generates warning `SYSLIB0041` at compile time.

- [Rfc2898DeriveBytes\(String, Byte\[\]\)](#)
- [Rfc2898DeriveBytes\(String, Int32\)](#)
- [Rfc2898DeriveBytes\(Byte\[\], Byte\[\], Int32\)](#)
- [Rfc2898DeriveBytes\(String, Byte\[\], Int32\)](#)
- [Rfc2898DeriveBytes\(String, Int32, Int32\)](#)

These overloads default the hash algorithm or number of iterations, and the defaults are no longer considered secure. These are all of the constructors that were available in .NET 4.7.1 and earlier versions. Going forward, you should only use the newer constructors.

Workaround

Use a different constructor overload where you can explicitly specify the iteration count (the default is 1000) and hash algorithm name (the default is [HashAlgorithmName.SHA1](#)).

If you're using the default iteration count or default hash algorithm, consider moving to more secure values—that is, a larger iteration count or a newer hash algorithm.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0041  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0041
```

To suppress all the `SYSLIB0041` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$(NoWarn);SYSLIB0041</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0042: FromXmlString and ToXmlString on ECC types are obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `FromXmlString` and `ToXmlString` methods that are on elliptic curve cryptography (ECC) types are obsolete, starting in .NET 7. Using them in code generates warning `SYSLIB0042` at compile time. They were never implemented and always threw a `PlatformNotSupportedException` exception. The obsoletion affects the following methods:

- `ECDiffieHellmanCng.FromXmlString(String, ECKeyXmlFormat)`
- `ECDiffieHellmanCng.ToXmlString(ECKeyXmlFormat)`
- `ECDiffieHellmanCngPublicKey.FromXmlString(String)`
- `ECDiffieHellmanCngPublicKey.ToString()`
- `ECDiffieHellmanPublicKey.ToString()`
- `ECDsaCng.FromXmlString(String, ECKeyXmlFormat)`
- `ECDsaCng.ToString(ECKeyXmlFormat)`

Workaround

Use a standard data format for exchanging elliptic curve (EC) keys.

Instead of `ToXmlString`, use `ExportSubjectPublicKeyInfo` or `ExportPkcs8PrivateKey` depending on whether you want the public or private key.

Instead of `FromXmlString`, use `ImportSubjectPublicKeyInfo` or `ImportPkcs8PrivateKey` depending on whether you want to import a public or private key.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0042  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0042
```

To suppress all the `SYSLIB0042` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
<PropertyGroup>
...
<NoWarn>$(NoWarn);SYSLIB0042</NoWarn>
</PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0043: ECDiffieHellmanPublicKey.ToArray is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The following methods are obsolete, starting in .NET 7. Using them in code generates warning `SYSLIB0043` at compile time.

- [ECDiffieHellmanPublicKey.ToArray\(\)](#)
- [ECDiffieHellmanPublicKey\(Byte\[\]\)](#) (constructor)

The [ECDiffieHellmanPublicKey.ToArray\(\)](#) method does not have an implied file format. Also, for the built-in implementations, it throws [PlatformNotSupportedException](#) on all non-Windows operating systems. Since [ECDiffieHellmanPublicKey](#) also has a standard format export (via the [ExportSubjectPublicKeyInfo\(\)](#) method), the older member has been obsoleted.

Workaround

If you're exporting the public key value, use the [ExportSubjectPublicKeyInfo\(\)](#) method instead.

For new derived types (or existing derived types that don't currently call the [ECDiffieHellmanPublicKey\(Byte\[\]\)](#) constructor), don't call the protected [ECDiffieHellmanPublicKey\(Byte\[\]\)](#) constructor, and either override [ToArray\(\)](#) to throw an exception, or accept the default behavior of returning an empty array.

For existing derived types that already call the protected [ECDiffieHellmanPublicKey\(Byte\[\]\)](#) constructor, continue calling the constructor and suppress the `SYSLIB0043` warning.

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.  
#pragma warning disable SYSLIB0043  
  
// Code that uses obsolete API.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB0043
```

To suppress all the `SYSLIB0043` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    ...  
    <NoWarn>$({NoWarn});SYSLIB0043</NoWarn>  
  </PropertyGroup>  
</Project>
```

For more information, see [Suppress warnings](#).

SYSLIB0047: XmlSecureResolver is obsolete

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Xml.XmlSecureResolver` type is obsolete, starting in .NET 7. Using it in code generates warning `SYSLIB0047` at compile time.

Workaround

Consider using the static property `XmlResolver.ThrowingResolver` instead. This property provides an `XmlResolver` instance that forbids resolution of external XML resources.

```
using System.Xml;

XmlResolver resolver = XmlResolver.ThrowingResolver;
```

Suppress a warning

If you must use the obsolete APIs, you can suppress the warning in code or in your project file.

To suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the warning.

```
// Disable the warning.
#pragma warning disable SYSLIB0047

// Code that uses obsolete API.
// ...

// Re-enable the warning.
#pragma warning restore SYSLIB0047
```

To suppress all the `SYSLIB0047` warnings in your project, add a `<NoWarn>` property to your project file.

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    ...
    <NoWarn>$({NoWarn});SYSLIB0047</NoWarn>
  </PropertyGroup>
</Project>
```

For more information, see [Suppress warnings](#).

See also

- [XmlSecureResolver is obsolete](#)

Source-generator diagnostics in .NET 6+

9/20/2022 • 2 minutes to read • [Edit Online](#)

If your .NET 6+ project references a package that enables source generation of code, for example, a logging solution, then the analyzers that are specific to source generation will run at compile time. This article lists the compiler diagnostics related to source-generated code.

If you encounter one of these build warnings or errors, follow the specific guidance provided for the diagnostic ID listed in the [Reference](#) section. Warnings can also be suppressed using the specific `SYSLIB1XXX` diagnostic ID value. For more information, see [Suppress warnings](#).

Analyzer warnings

The diagnostic ID values reserved for source-generated code analyzer warnings are `SYSLIB1001` through `SYSLIB1999`.

Reference

The following table provides an index to the `SYSLIB1XXX` diagnostics in .NET 6 and later versions.

DIAGNOSTIC ID	DESCRIPTION
<code>SYSLIB1001</code>	Logging method names cannot start with <code>_</code>
<code>SYSLIB1002</code>	Don't include log level parameters as templates in the logging message
<code>SYSLIB1003</code>	<code>InvalidLoggingMethodNameTitle</code>
<code>SYSLIB1005</code>	Could not find a required type definition
<code>SYSLIB1006</code>	Multiple logging methods cannot use the same event ID within a class
<code>SYSLIB1007</code>	Logging methods must return <code>void</code>
<code>SYSLIB1008</code>	One of the arguments to a logging method must implement the <code>Microsoft.Extensions.Logging.ILogger</code> interface
<code>SYSLIB1009</code>	Logging methods must be <code>static</code>
<code>SYSLIB1010</code>	Logging methods must be <code>partial</code>
<code>SYSLIB1011</code>	Logging methods cannot be generic
<code>SYSLIB1012</code>	Redundant qualifier in logging message
<code>SYSLIB1013</code>	Don't include exception parameters as templates in the logging message

DIAGNOSTIC ID	DESCRIPTION
SYSLIB1014	Logging template has no corresponding method argument
SYSLIB1015	Argument is not referenced from the logging message
SYSLIB1016	Logging methods cannot have a body
SYSLIB1017	A LogLevel value must be supplied in the <code>LoggerMessage</code> attribute or as a parameter to the logging method
SYSLIB1018	Don't include logger parameters as templates in the logging message
SYSLIB1019	Couldn't find a field of type <code>Microsoft.Extensions.Logging.ILogger</code>
SYSLIB1020	Found multiple fields of type <code>Microsoft.Extensions.Logging.ILogger</code>
SYSLIB1021	Multiple message-template item names differ only by case
SYSLIB1022	Can't have malformed format strings (for example, dangling curly braces)
SYSLIB1023	Generating more than six arguments is not supported
SYSLIB1030	The <code>System.Text.Json</code> source generator did not generate serialization metadata for type
SYSLIB1031	The <code>System.Text.Json</code> source generator encountered a duplicate <code>JsonTypeInfo</code> property name
SYSLIB1032	The <code>System.Text.Json</code> source generator encountered a context class that is not partial
SYSLIB1033	The <code>System.Text.Json</code> source generator encountered a type that has multiple <code>[JsonConstructor]</code> annotations
SYSLIB1035	The <code>System.Text.Json</code> source generator encountered a type that has multiple <code>[JsonExtensionData]</code> annotations
SYSLIB1036	The <code>System.Text.Json</code> source generator encountered an invalid <code>[JsonExtensionData]</code> annotation
SYSLIB1037	The <code>System.Text.Json</code> source generator encountered a type with init-only properties for which deserialization is not supported
SYSLIB1038	The <code>System.Text.Json</code> source generator encountered a property annotated with <code>[JsonIgnore]</code> that has inaccessible accessors

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1001: Logging method names can't start with an underscore

9/20/2022 • 2 minutes to read • [Edit Online](#)

The name of a method annotated with the `LoggerMessageAttribute` starts with an underscore character. This is not allowed, as it may result in conflicting symbol names with respect to the automatically generated code.

Workarounds

Choose a different method name that doesn't start with an underscore.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1002: Don't include log level parameters as templates in the logging message

9/20/2022 • 2 minutes to read • [Edit Online](#)

The first log-level argument to a logging method is referenced as a template in the logging message. This is not necessary, since the first log level is passed down to the logging infrastructure explicitly. It doesn't need to be repeated in the logging message.

Workarounds

Remove the template that references the log-level argument from the logging message.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1003: Logging method parameter names can't start with an underscore

9/20/2022 • 2 minutes to read • [Edit Online](#)

The name of a parameter of a method annotated with the `LoggerMessageAttribute` starts with an underscore character. This is not allowed as it may result in conflicting symbol names with respect to the automatically generated code.

Workarounds

Choose a different parameter name that doesn't start with an underscore.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1005: Could not find a required type definition

9/20/2022 • 2 minutes to read • [Edit Online](#)

The code generator was unable to find a necessary reference to a well-known type.

Workarounds

This error is highly unlikely to occur. If it does occur, you can consider adding a `<PackageReference>` to your project file to include the required type definition.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1006: Multiple logging methods cannot use the same event ID

9/20/2022 • 2 minutes to read • [Edit Online](#)

Multiple methods annotated with the `LoggerMessageAttribute` are using the same event ID value. Event ID values must be unique within the scope of each assembly.

Workarounds

Review the event ID values used for all logging methods in the assembly and ensure they are unique.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1007: Logging methods must return void

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` attribute returns a value.

Workarounds

All logging methods must return void.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1008: One of the arguments to a logging method must implement the `ILogger` interface

9/20/2022 • 2 minutes to read • [Edit Online](#)

One of the parameters of a method annotated with the `LoggerMessageAttribute` must be of the type `ILogger` or a type that implements `ILogger`.

Workarounds

Ensure that a parameter of all logging methods is of type `ILogger` or of a type that implements `ILogger`.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1009: Logging methods must be static

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` is not static.

Workarounds

All logging methods must be declared as static.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1010: Logging methods must be partial

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` is not marked as partial.

Workarounds

All logging methods must be declared partial.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1011: Logging methods cannot be generic

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` contains parameters with generic types.

Workarounds

Logging methods cannot have any generically typed parameters. Use fully resolved types instead.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1012: Redundant qualifier in logging message

9/20/2022 • 2 minutes to read • [Edit Online](#)

The message string of a `LoggerMessageAttribute` attribute contains a prefix such as `INFO:` or `ERROR:`, which is redundant because each logging message has a corresponding log level.

Workarounds

Remove the prefix from the message string.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1013: Don't include exception parameters as templates in the logging message

9/20/2022 • 2 minutes to read • [Edit Online](#)

The first exception argument to a logging method is referenced as a template in the logging message. This isn't necessary, because the first exception is passed down to the logging infrastructure explicitly. It doesn't need to be repeated in the logging message.

Workarounds

Remove the template that references the exception argument from the logging message.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1014: Logging template has no corresponding method argument

9/20/2022 • 2 minutes to read • [Edit Online](#)

A template in the logging message doesn't have a matching parameter in the logging method definition.

Workarounds

Ensure that all templates in logging messages have corresponding parameters in the logging method definition.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1015: Argument is not referenced from the logging message

9/20/2022 • 2 minutes to read • [Edit Online](#)

An argument in the logging method doesn't have a corresponding template in the logging message.

Workarounds

Ensure that all arguments to the logging method have corresponding templates in the associated logging message.

SUPPRESS WARNINGS

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1016: Logging methods cannot have a body

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `LoggerMessageAttribute` attribute was applied to a method that has a method body.

Workarounds

Remove the method body.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1017: A `LogLevel` value must be supplied in the `LoggerMessage` attribute or as a parameter to the logging method

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `LoggerMessageAttribute` attribute was applied to a method without a `LogLevel` value specified. When you do this, one argument to the logging method must be of that type so that the `LogLevel` value ends up being specified explicitly when calling the logging method.

Workarounds

Either specify a `LogLevel` value in the `LoggerMessage` attribute, or make one of the arguments of the logging method a `LogLevel` value.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>

```

SYSLIB1018: Don't include logger parameters as templates in the logging message

9/20/2022 • 2 minutes to read • [Edit Online](#)

The first logger argument to a logging method is referenced as a template in the logging message. The first logger is passed down to the logging infrastructure explicitly, so it doesn't need to be repeated in the logging message.

Workarounds

Remove the template that references the logger argument from the logging message.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1019: Couldn't find a field of type `ILogger`

9/20/2022 • 2 minutes to read • [Edit Online](#)

When a logging method definition doesn't explicitly include a parameter of type `ILogger`, then the type containing the logging method must have one and only one field of type `ILogger`. The `ILogger` will be used as the target for log messages.

Workarounds

Ensure the type containing the logging method includes a field of type `ILogger` or include a parameter of type `ILogger` in the logging method signature.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1020: Found multiple fields of type `ILogger`

9/20/2022 • 2 minutes to read • [Edit Online](#)

When a logging method definition doesn't explicitly include a parameter of type `ILogger`, then the type containing the logging method must have one and only one field of type `ILogger`, which will be used as the target for log messages.

Workarounds

Ensure the type containing the logging method includes only a single field of type `ILogger`.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1021: Multiple message-template item names differ only by case

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` attribute has multiple template item names that differ only by case.

Workarounds

Make sure the message-template item names aren't repeated with different casing in the method annotated with `LoggerMessageAttribute`.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1022: Can't have malformed format strings

9/20/2022 • 2 minutes to read • [Edit Online](#)

A method annotated with the `LoggerMessageAttribute` attribute has a message template that's formatted incorrectly. For example, the template has an unmatched curly brace (`}`).

Workarounds

Makes sure curly braces are used appropriately in the message template.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1023: Generating more than six arguments is not supported

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `LoggerMessageAttribute` is limited to the number of parameters supported by `LoggerMessage.Define`, which is six.

Workarounds

Rather than using `LoggerMessageAttribute`, consider implementing a custom attribute using a struct.

SUPPRESS WARNINGS

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1030: `System.Text.Json` source generator did not generate output for type

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator did not generate output for a given type in the input object graph. This typically means that the type is not supported by `JsonSerializer`, for example multi-dimensional arrays like `int[,]`.

Workarounds

Register a [custom converter](#) for the type.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1031: `System.Text.Json` source generator encountered a duplicate type info property name

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a duplicate type info property name to be generated on the specified partial context type.

Workarounds

Specify a new type info property name for the duplicate instance using

`System.Text.Json.Serialization.JsonSerializableAttribute.TypeInfoPropertyName`.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1032: Context classes to be augmented by the `System.Text.Json` source generator must be declared as partial

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a context type included for source generation that is not partial, or whose containing type(s) is not partial.

Workarounds

Make the context type and all containing types partial.

SUPPRESS WARNINGS

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1033: `System.Text.Json` source generator encountered a type with multiple `[JsonConstructor]` annotations

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a serializable type with multiple `[JsonConstructor]` annotations.

Workarounds

Remove duplicate `[JsonConstructor]` annotations.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1035: `System.Text.Json` source generator encountered a type with multiple `[JsonExtensionData]` annotations

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a serializable type with multiple `[JsonExtensionData]` annotations.

Workarounds

Remove duplicate `[JsonExtensionData]` annotations.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1036: `System.Text.Json` source generator encountered an invalid `[JsonExtensionData]` annotation

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a property or field annotated with `[JsonExtensionData]` but whose data type does not implement `IDictionary<string, JsonElement>`, `IDictionary<string, object>`, `IDictionary<string, JsonNode>`, or `JsonNode`.

Workarounds

Ensure that the data type for any property or field that is annotated with `[JsonExtensionData]` implements `IDictionary<string, JsonElement>`, `IDictionary<string, object>`, `IDictionary<string, JsonNode>`, or `JsonNode`.

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1037: `System.Text.Json` source generator encountered a type with init-only properties which are not supported for deserialization

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a type with init-only properties, such as a record type. These properties are currently not supported by the source generator for deserialization.

Workarounds

If deserialization of init-only properties is required, use the reflection-based `JsonSerializer` implementation.

SUPPRESS WARNINGS

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1006` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- Nowarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple Nowarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

SYSLIB1038: `System.Text.Json` source generator encountered a property annotated with `[JsonInclude]` but with inaccessible accessors

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `System.Text.Json` source generator encountered a property that is annotated with `[JsonInclude]` but has accessors that are inaccessible to the source generator. The property must have `public` or `internal` accessors.

Workarounds

If serialization or deserialization of properties with accessors that are not `public` or `internal` is required, use the [reflection-based `JsonSerializer` implementation](#).

Suppress warnings

It's recommended that you use one of the workarounds when possible. However, if you cannot change your code, you can suppress the warning through a `#pragma` directive or a `<NoWarn>` project setting. If the `SYSLIB1XXX` source generator diagnostic doesn't surface as an error, you can suppress the warning in code or in your project file.

To suppress the warnings in code:

```
// Disable the warning.  
#pragma warning disable SYSLIB1006  
  
// Code that generates compiler diagnostic.  
// ...  
  
// Re-enable the warning.  
#pragma warning restore SYSLIB1006
```

To suppress the warnings in a project file:

```
<Project Sdk="Microsoft.NET.Sdk">  
  <PropertyGroup>  
    <TargetFramework>net6.0</TargetFramework>  
    <!-- NoWarn below suppresses SYSLIB1002 project-wide -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <!-- To suppress multiple warnings, you can use multiple NoWarn elements -->  
    <NoWarn>$(NoWarn);SYSLIB1002</NoWarn>  
    <NoWarn>$(NoWarn);SYSLIB1006</NoWarn>  
    <!-- Alternatively, you can suppress multiple warnings by using a semicolon-delimited list -->  
    <NoWarn>$(NoWarn);SYSLIB1002;SYSLIB1006;SYSLIB1007</NoWarn>  
  </PropertyGroup>  
</Project>
```

.NET project SDKs

9/20/2022 • 9 minutes to read • [Edit Online](#)

.NET Core and .NET 5 and later projects are associated with a software development kit (SDK). Each *project SDK* is a set of MSBuild [targets](#) and associated [tasks](#) that are responsible for compiling, packing, and publishing code. A project that references a project SDK is sometimes referred to as an *SDK-style project*.

Available SDKs

The following SDKs are available:

ID	DESCRIPTION	REPO
<code>Microsoft.NET.Sdk</code>	The .NET SDK	https://github.com/dotnet/sdk
<code>Microsoft.NET.Sdk.Web</code>	The .NET Web SDK	https://github.com/dotnet/sdk
<code>Microsoft.NET.Sdk.BlazorWebAssembly</code>	The .NET Blazor WebAssembly SDK	
<code>Microsoft.NET.Sdk.Razor</code>	The .NET Razor SDK	
<code>Microsoft.NET.Sdk.Worker</code>	The .NET Worker Service SDK	
<code>Microsoft.NET.Sdk.WindowsDesktop</code>	The .NET Desktop SDK, which includes Windows Forms (WinForms) and Windows Presentation Foundation (WPF).*	https://github.com/dotnet/winforms and https://github.com/dotnet/wpf

The .NET SDK is the base SDK for .NET. The other SDKs reference the .NET SDK, and projects that are associated with the other SDKs have all the .NET SDK properties available to them. The Web SDK, for example, depends on both the .NET SDK and the Razor SDK.

You can also author your own SDK that can be distributed via NuGet.

* Starting in .NET 5, Windows Forms and Windows Presentation Foundation (WPF) projects should specify the .NET SDK (`Microsoft.NET.Sdk`) instead of `Microsoft.NET.Sdk.WindowsDesktop`. For these projects, setting `TargetFramework` to `net5.0-windows` and `UseWPF` or `UseWindowsForms` to `true` will automatically import the Windows desktop SDK. If your project targets .NET 5 or later and specifies the `Microsoft.NET.Sdk.WindowsDesktop` SDK, you'll get build warning NETSDK1137.

Project files

.NET projects are based on the [MSBuild](#) format. Project files, which have extensions like `.csproj` for C# projects and `.fsproj` for F# projects, are in XML format. The root element of an MSBuild project file is the [Project](#) element. The `Project` element has an optional `Sdk` attribute that specifies which SDK (and version) to use. To use the .NET tools and build your code, set the `Sdk` attribute to one of the IDs in the [Available SDKs](#) table.

```
<Project Sdk="Microsoft.NET.Sdk">
  ...
</Project>
```

To specify an SDK that comes from NuGet, include the version at the end of the name, or specify the name and version in the `global.json` file.

```
<Project Sdk="MSBuild.Sdk.Extras/2.0.54">
  ...
</Project>
```

Another way to specify the SDK is with the top-level `Sdk` element:

```
<Project>
  <Sdk Name="Microsoft.NET.Sdk" />
  ...
</Project>
```

Referencing an SDK in one of these ways greatly simplifies project files for .NET. While evaluating the project, MSBuild adds implicit imports for `Sdk.props` at the top of the project file and `Sdk.targets` at the bottom.

```
<Project>
  <!-- Implicit top import -->
  <Import Project="Sdk.props" Sdk="Microsoft.NET.Sdk" />
  ...
  <!-- Implicit bottom import -->
  <Import Project="Sdk.targets" Sdk="Microsoft.NET.Sdk" />
</Project>
```

TIP

On a Windows machine, the `Sdk.props` and `Sdk.targets` files can be found in the `%ProgramFiles%\dotnet\sdk\{version}\Sdks\Microsoft.NET.Sdk\Sdk` folder.

Preprocess the project file

You can see the fully expanded project as MSBuild sees it after the SDK and its targets are included by using the `dotnet msbuild -preprocess` command. The `preprocess` switch of the `dotnet msbuild` command shows which files are imported, their sources, and their contributions to the build without actually building the project.

If the project has multiple target frameworks, focus the results of the command on only one framework by specifying it as an MSBuild property. For example:

```
dotnet msbuild -property:TargetFramework=netcoreapp2.0 -preprocess:output.xml
```

Default includes and excludes

The default includes and excludes for `Compile` items, `embedded resources`, and `None` items are defined in the SDK. Unlike non-SDK .NET Framework projects, you don't need to specify these items in your project file, because the defaults cover most common use cases. This behavior makes the project file smaller and easier to understand and edit by hand, if needed.

The following table shows which elements and which `globs` are included and excluded in the .NET SDK:

ELEMENT	INCLUDE GLOB	EXCLUDE GLOB	REMOVE GLOB
Compile	<code>**/*.cs</code> (or other language extensions)	<code>**/*.user; **/*.*proj; **/*.sln; **/*.vsscc</code>	N/A

ELEMENT	INCLUDE GLOB	EXCLUDE GLOB	REMOVE GLOB
EmbeddedResource	**/*.resx	**/*.user; **/*.proj; **/*.sln; **/*.vsscc	N/A
None	**/*	**/*.user; **/*.proj; **/*.sln; **/*.vsscc	**/*.cs; **/*.resx

NOTE

The `./bin` and `./obj` folders, which are represented by the `$(BaseOutputPath)` and `$(BaseIntermediateOutputPath)` MSBuild properties, are excluded from the globs by default. Excludes are represented by the [DefaultItemExcludes](#) property.

The .NET Desktop SDK has more includes and excludes for WPF. For more information, see [WPF default includes and excludes](#).

Build errors

If you explicitly define any of these items in your project file, you're likely to get a "NETSDK1022" build error similar to the following:

Duplicate 'Compile' items were included. The .NET SDK includes 'Compile' items from your project directory by default. You can either remove these items from your project file, or set the 'EnableDefaultCompileItems' property to 'false' if you want to explicitly include them in your project file.

Duplicate 'EmbeddedResource' items were included. The .NET SDK includes 'EmbeddedResource' items from your project directory by default. You can either remove these items from your project file, or set the 'EnableDefaultEmbeddedResourceItems' property to 'false' if you want to explicitly include them in your project file.

To resolve the errors, do one of the following:

- Remove the explicit `Compile`, `EmbeddedResource`, or `None` items that match the implicit ones listed on the previous table.
- Set the [EnableDefaultItems](#) property to `false` to disable all implicit file inclusion:

```
<PropertyGroup>
  <EnableDefaultItems>false</EnableDefaultItems>
</PropertyGroup>
```

If you want to specify files to be published with your app, you can still use the known MSBuild mechanisms for that, for example, the `Content` element.

- Selectively disable only `Compile`, `EmbeddedResource`, or `None` globs by setting the `EnableDefaultCompileItems`, `EnableDefaultEmbeddedResourceItems`, or `EnableDefaultNoneItems` property to `false`:

```
<PropertyGroup>
  <EnableDefaultCompileItems>false</EnableDefaultCompileItems>
  <EnableDefaultEmbeddedResourceItems>false</EnableDefaultEmbeddedResourceItems>
  <EnableDefaultNoneItems>false</EnableDefaultNoneItems>
</PropertyGroup>
```

If you only disable `Compile` globs, Solution Explorer in Visual Studio still shows *.cs items as part of the project, included as `None` items. To disable the implicit `None` glob, set `EnableDefaultNoneItems` to `false` too.

Implicit using directives

Starting in .NET 6, implicit `global using` directives are added to new C# projects. This means that you can use types defined in these namespaces without having to specify their fully qualified name or manually add a `using` directive. The *implicit* aspect refers to the fact that the `global using` directives are added to a generated file in the project's *obj* directory.

Implicit `global using` directives are added for projects that use one of the following SDKs:

- Microsoft.NET.Sdk
- Microsoft.NET.Sdk.Web
- Microsoft.NET.Sdk.Worker
- Microsoft.NET.Sdk.WindowsDesktop

A `global using` directive is added for each namespaces in a set of default namespaces that's based on the project's SDK. These default namespaces are shown in the following table.

SDK	DEFAULT NAMESPACES
Microsoft.NET.Sdk	<code>System</code> <code>System.Collections.Generic</code> <code>System.IO</code> <code>System.Linq</code> <code>System.Net.Http</code> <code>System.Threading</code> <code>System.Threading.Tasks</code>
Microsoft.NET.Sdk.Web	<code>System.Net.Http.Json</code> <code>Microsoft.AspNetCore.Builder</code> <code>Microsoft.AspNetCore.Hosting</code> <code>Microsoft.AspNetCore.Http</code> <code>Microsoft.AspNetCore.Routing</code> <code>Microsoft.Extensions.Configuration</code> <code>Microsoft.Extensions.DependencyInjection</code> <code>Microsoft.Extensions.Hosting</code> <code>Microsoft.Extensions.Logging</code>
Microsoft.NET.Sdk.Worker	<code>Microsoft.Extensions.Configuration</code> <code>Microsoft.Extensions.DependencyInjection</code> <code>Microsoft.Extensions.Hosting</code> <code>Microsoft.Extensions.Logging</code>
Microsoft.NET.Sdk.WindowsDesktop (Windows Forms)	Microsoft.NET.Sdk namespaces <code>System.Drawing</code> <code>System.Windows.Forms</code>
Microsoft.NET.Sdk.WindowsDesktop (WPF)	Microsoft.NET.Sdk namespaces Removed <code>System.IO</code> Removed <code>System.Net.Http</code>

If you want to disable this feature, or if you want to enable implicit `global using` directives in an existing C# project, you can do so via the [ImplicitUsings](#) MSBuild property.

You can specify additional implicit `global using` directives by adding `Using` items (or `Import` items for Visual

Basic projects) to your project file, for example:

```
<ItemGroup>
  <Using Include="System.IO.Pipes" />
</ItemGroup>
```

Implicit package references

When targeting .NET Core 1.0 - 2.2 or .NET Standard 1.0 - 2.0, the .NET SDK adds implicit references to certain *metapackages*. A metapackage is a framework-based package that consists only of dependencies on other packages. Metapackages are implicitly referenced based on the target framework(s) specified in the [TargetFramework](#) or [TargetFrameworks](#) property of your project file.

```
<PropertyGroup>
  <TargetFramework>netcoreapp2.1</TargetFramework>
</PropertyGroup>
```

```
<PropertyGroup>
  <TargetFrameworks>netcoreapp2.1;net462</TargetFrameworks>
</PropertyGroup>
```

If needed, you can disable implicit package references using the [DisableImplicitFrameworkReferences](#) property, and add explicit references to just the frameworks or packages you need.

Recommendations:

- When targeting .NET Framework, .NET Core 1.0 - 2.2, or .NET Standard 1.0 - 2.0, don't add an explicit reference to the `Microsoft.NETCore.App` or `NETStandard.Library` metapackages via a `<PackageReference>` item in your project file. For .NET Core 1.0 - 2.2 and .NET Standard 1.0 - 2.0 projects, these metapackages are implicitly referenced. For .NET Framework projects, if any version of `NETStandard.Library` is needed when using a .NET Standard-based NuGet package, NuGet automatically installs that version.
- If you need a specific version of the runtime when targeting .NET Core 1.0 - 2.2, use the `<RuntimeFrameworkVersion>` property in your project (for example, `1.0.4`) instead of referencing the metapackage. For example, you might need a specific patch version of 1.0.0 LTS runtime if you're using [self-contained deployments](#).
- If you need a specific version of the `NETStandard.Library` metapackage when targeting .NET Standard 1.0 - 2.0, you can use the `<NetStandardImplicitPackageVersion>` property and set the version you need.

Build events

In SDK-style projects, use an MSBuild target named `PreBuild` or `PostBuild` and set the `BeforeTargets` property for `PreBuild` or the `AfterTargets` property for `PostBuild`.

```
<Target Name="PreBuild" BeforeTargets="PreBuildEvent">
  <Exec Command="$(ProjectDir)PreBuildEvent.bat" $(ProjectDir)..\"/>
</Target>

<Target Name="PostBuild" AfterTargets="PostBuildEvent">
  <Exec Command="echo Output written to $(TargetDir)" />
</Target>
```

NOTE

- You can use any name for the MSBuild targets. However, the Visual Studio IDE recognizes `PreBuild` and `PostBuild` targets, so by using those names, you can edit the commands in the IDE.
- The properties `PreBuildEvent` and `PostBuildEvent` are not recommended in SDK-style projects, because macros such as `$(ProjectDir)` aren't resolved. For example, the following code is not supported:

```
<PropertyGroup>
  <PreBuildEvent>"$(ProjectDir)PreBuildEvent.bat" "$(ProjectDir)..\" "$(ProjectDir)" "$(TargetDir)"
</PreBuildEvent>
</PropertyGroup>
```

Customize the build

There are various ways to [customize a build](#). You may want to override a property by passing it as an argument to an `msbuild` or `dotnet` command. You can also add the property to the project file or to a `Directory.Build.props` file. For a list of useful properties for .NET projects, see [MSBuild reference for .NET SDK projects](#).

Custom targets

.NET projects can package custom MSBuild targets and properties for use by projects that consume the package. Use this type of extensibility when you want to:

- Extend the build process.
- Access artifacts of the build process, such as generated files.
- Inspect the configuration under which the build is invoked.

You add custom build targets or properties by placing files in the form `<package_id>.targets` or `<package_id>.props` (for example, `Contoso.Utility.UsefulStuff.targets`) in the `build` folder of the project.

The following XML is a snippet from a `.csproj` file that instructs the `dotnet pack` command what to package. The `<ItemGroup Label="dotnet pack instructions">` element places the targets files into the `build` folder inside the package. The `<Target Name="CollectRuntimeOutputs" BeforeTargets="_GetPackageFiles">` element places the assemblies and `.json` files into the `build` folder.

```
<Project Sdk="Microsoft.NET.Sdk">

  ...
  <ItemGroup Label="dotnet pack instructions">
    <Content Include="build\*.targets">
      <Pack>true</Pack>
      <PackagePath>build\</PackagePath>
    </Content>
  </ItemGroup>
  <Target Name="CollectRuntimeOutputs" BeforeTargets="_GetPackageFiles">
    <!-- Collect these items inside a target that runs after build but before packaging. -->
    <ItemGroup>
      <Content Include="$(OutputPath)\*.dll;$(OutputPath)\*.json">
        <Pack>true</Pack>
        <PackagePath>build\</PackagePath>
      </Content>
    </ItemGroup>
  </Target>
  ...
</Project>
```

To consume a custom target in your project, add a `PackageReference` element that points to the package and its

version. Unlike the tools, the custom targets package is included in the consuming project's dependency closure.

You can configure how to use the custom target. Since it's an MSBuild target, it can depend on a given target, run after another target, or be manually invoked by using the `dotnet msbuild -t:<target-name>` command. However, to provide a better user experience, you can combine per-project tools and custom targets. In this scenario, the per-project tool accepts whatever parameters are needed and translates that into the required `dotnet msbuild` invocation that executes the target. You can see a sample of this kind of synergy on the [MVP Summit 2016 Hackathon samples](#) repo in the `dotnet-packer` project.

MSBuild reference for .NET SDK projects

9/20/2022 • 35 minutes to read • [Edit Online](#)

This page is a reference for the MSBuild properties and items that you can use to configure .NET projects.

NOTE

This page is a work in progress and does not list all of the useful MSBuild properties for the .NET SDK. For a list of common MSBuild properties, see [Common MSBuild properties](#).

Framework properties

The following MSBuild properties are documented in this section:

- [TargetFramework](#)
- [TargetFrameworks](#)
- [NetStandardImplicitPackageVersion](#)

TargetFramework

The `TargetFramework` property specifies the target framework version for the app. For a list of valid target framework monikers, see [Target frameworks in SDK-style projects](#).

```
<PropertyGroup>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>
```

For more information, see [Target frameworks in SDK-style projects](#).

TargetFrameworks

Use the `TargetFrameworks` property when you want your app to target multiple platforms. For a list of valid target framework monikers, see [Target frameworks in SDK-style projects](#).

NOTE

This property is ignored if `TargetFramework` (singular) is specified.

```
<PropertyGroup>
  <TargetFrameworks>netcoreapp3.1;net462</TargetFrameworks>
</PropertyGroup>
```

For more information, see [Target frameworks in SDK-style projects](#).

NetStandardImplicitPackageVersion

NOTE

This property only applies to projects using `netstandard1.x`. It doesn't apply to projects that use `netstandard2.x`.

Use the `NetStandardImplicitPackageVersion` property when you want to specify a framework version that's lower than the metapackage version. The project file in the following example targets `netstandard1.3` but uses the

1.6.0 version of `NETStandard.Library`.

```
<PropertyGroup>
  <TargetFramework>netstandard1.3</TargetFramework>
  <NetStandardImplicitPackageVersion>1.6.0</NetStandardImplicitPackageVersion>
</PropertyGroup>
```

Assembly attribute properties

- [GenerateAssemblyInfo](#)
- [GeneratedAssemblyInfoFile](#)

GenerateAssemblyInfo

The `GenerateAssemblyInfo` property controls `AssemblyInfo` attribute generation for the project. The default value is `true`. Use `false` to disable generation of the file:

```
<PropertyGroup>
  <GenerateAssemblyInfo>false</GenerateAssemblyInfo>
</PropertyGroup>
```

The `GeneratedAssemblyInfoFile` setting controls the name of the generated file.

When the `GenerateAssemblyInfo` value is `true`, [package-related project properties](#) are transformed into assembly attributes. The following table lists the project properties that generate the attributes. It also lists the properties that you can use to disable that generation on a per-attribute basis, for example:

```
<PropertyGroup>
  <GenerateNeutralResourcesLanguageAttribute>false</GenerateNeutralResourcesLanguageAttribute>
</PropertyGroup>
```

MSBUILD PROPERTY	ASSEMBLY ATTRIBUTE	PROPERTY TO DISABLE ATTRIBUTE GENERATION
<code>Company</code>	<code>AssemblyCompanyAttribute</code>	<code>GenerateAssemblyCompanyAttribute</code>
<code>Configuration</code>	<code>AssemblyConfigurationAttribute</code>	<code>GenerateAssemblyConfigurationAttribute</code>
<code>Copyright</code>	<code>AssemblyCopyrightAttribute</code>	<code>GenerateAssemblyCopyrightAttribute</code>
<code>Description</code>	<code>AssemblyDescriptionAttribute</code>	<code>GenerateAssemblyDescriptionAttribute</code>
<code>FileVersion</code>	<code>AssemblyFileVersionAttribute</code>	<code>GenerateAssemblyFileVersionAttribute</code>
<code>InformationalVersion</code>	<code>AssemblyInformationalVersionAttribute</code>	<code>GenerateAssemblyInformationalVersionAttribute</code>
<code>Product</code>	<code>AssemblyProductAttribute</code>	<code>GenerateAssemblyProductAttribute</code>
<code>AssemblyTitle</code>	<code>AssemblyTitleAttribute</code>	<code>GenerateAssemblyTitleAttribute</code>
<code> AssemblyVersion</code>	<code>AssemblyVersionAttribute</code>	<code>GenerateAssemblyVersionAttribute</code>
<code>NeutralLanguage</code>	<code>NeutralResourcesLanguageAttribute</code>	<code>GenerateNeutralResourcesLanguageAttribute</code>

Notes about these settings:

- `AssemblyVersion` and `FileVersion` default to the value of `$(Version)` without the suffix. For example, if `$(Version)` is `1.2.3-beta.4`, then the value would be `1.2.3`.
- `InformationalVersion` defaults to the value of `$(Version)`.
- If the `$(SourceRevisionId)` property is present, it's appended to `InformationalVersion`. You can disable this behavior using `IncludeSourceRevisionInInformationalVersion`.
- `Copyright` and `Description` properties are also used for NuGet metadata.
- `Configuration`, which defaults to `Debug`, is shared with all MSBuild targets. You can set it via the `--configuration` option of `dotnet` commands, for example, `dotnet pack`.
- Some of the properties are used when creating a NuGet package. For more information, see [Package properties](#).

Migrating from .NET Framework

.NET Framework project templates create a code file with these assembly info attributes set. The file is typically located at `.\Properties\AssemblyInfo.cs` or `.\Properties\AssemblyInfo.vb`. SDK-style projects generate this file for you based on the project settings. **You can't have both**. When porting your code to .NET 5 (or .NET Core 3.1) or later, do one of the following:

- Disable the generation of the temporary code file that contains the assembly info attributes by setting `GenerateAssemblyInfo` to `false` in your project file. This enables you to keep your `AssemblyInfo` file.
- Migrate the settings in the `AssemblyInfo` file to the project file, and then delete the `AssemblyInfo` file.

GeneratedAssemblyInfoFile

The `GeneratedAssemblyInfoFile` property defines the relative or absolute path of the generated assembly info file. Defaults to a file named `[project-name].AssemblyInfo.[cs/vb]` in the `$(IntermediateOutputPath)` (usually the `obj`) directory.

```
<PropertyGroup>
  <GeneratedAssemblyInfoFile>assemblyinfo.cs</GeneratedAssemblyInfoFile>
</PropertyGroup>
```

Package properties

- [Descriptive properties](#)
- [PackRelease](#)

Descriptive properties

You can specify properties such as `PackageId`, `PackageVersion`, `PackageIcon`, `Title`, and `Description` to describe the package that gets created from your project. For information about these and other properties, see [pack target](#).

```
<PropertyGroup>
  ...
  <PackageId>ClassLibDotNetStandard</PackageId>
  <Version>1.0.0</Version>
  <Authors>John Doe</Authors>
  <Company>Contoso</Company>
</PropertyGroup>
```

PackRelease

The `PackRelease` property is similar to the `PublishRelease` property, except that it changes the default behavior of `dotnet pack`.

```
<PropertyGroup>
  <PackRelease>true</PackRelease>
</PropertyGroup>
```

NOTE

To use `PackRelease` in a project that's part of a Visual Studio solution, you must set the environment variable `DOTNET_CLI_ENABLE_PACK_RELEASE_FOR_SOLUTIONS` to `true` (or any other value). Setting this variable will increase the time required to pack solutions that have many projects.

Publish-related properties

The following MSBuild properties are documented in this section:

- [AppendRuntimeIdentifierToOutputPath](#)
- [AppendTargetFrameworkToOutputPath](#)
- [CopyLocalLockFileAssemblies](#)
- [EnablePackageValidation](#)
- [ErrorOnDuplicatePublishOutputFiles](#)
- [GenerateRuntimeConfigDevFile](#)
- [GenerateRuntimeConfigurationFiles](#)
- [GenerateSatelliteAssembliesForCore](#)
- [IsPublishable](#)
- [PreserveCompilationContext](#)
- [PreserveCompilationReferences](#)
- [ProduceReferenceAssemblyInOutDir](#)
- [PublishRelease](#)
- [RollForward](#)
- [RuntimeFrameworkVersion](#)
- [RuntimeIdentifier](#)
- [RuntimeIdentifiers](#)
- [SatelliteResourceLanguages](#)
- [UseAppHost](#)

AppendTargetFrameworkToOutputPath

The `AppendTargetFrameworkToOutputPath` property controls whether the [target framework moniker \(TFM\)](#) is appended to the output path (which is defined by [OutputPath](#)). The .NET SDK automatically appends the target framework and, if present, the runtime identifier to the output path. Setting `AppendTargetFrameworkToOutputPath` to `false` prevents the TFM from being appended to the output path. However, without the TFM in the output path, multiple build artifacts may overwrite each other.

For example, for a .NET 5 app, the output path changes from `bin\Debug\net5.0` to `bin\Debug` with the following setting:

```
<PropertyGroup>
  <AppendTargetFrameworkToOutputPath>false</AppendTargetFrameworkToOutputPath>
</PropertyGroup>
```

AppendRuntimeIdentifierToOutputPath

The `AppendRuntimeIdentifierToOutputPath` property controls whether the [runtime identifier \(RID\)](#) is appended to the output path. The .NET SDK automatically appends the target framework and, if present, the runtime identifier

to the output path. Setting `AppendRuntimeIdentifierToOutputPath` to `false` prevents the RID from being appended to the output path.

For example, for a .NET 5 app and an RID of `win10-x64`, the output path changes from `bin\Debug\net5.0\win10-x64` to `bin\Debug\net5.0` with the following setting:

```
<PropertyGroup>
  <AppendRuntimeIdentifierToOutputPath>false</AppendRuntimeIdentifierToOutputPath>
</PropertyGroup>
```

CopyLocalLockFileAssemblies

The `CopyLocalLockFileAssemblies` property is useful for plugin projects that have dependencies on other libraries. If you set this property to `true`, any NuGet package dependencies are copied to the output directory. That means you can use the output of `dotnet build` to run your plugin on any machine.

```
<PropertyGroup>
  <CopyLocalLockFileAssemblies>true</CopyLocalLockFileAssemblies>
</PropertyGroup>
```

TIP

Alternatively, you can use `dotnet publish` to publish the class library. For more information, see [dotnet publish](#).

ErrorOnDuplicatePublishOutputFiles

The `ErrorOnDuplicatePublishOutputFiles` property relates to whether the SDK generates error NETSDK1148 when MSBuild detects duplicate files in the publish output, but can't determine which files to remove. Set the `ErrorOnDuplicatePublishOutputFiles` property to `false` if you don't want the error to be generated.

```
<PropertyGroup>
  <ErrorOnDuplicatePublishOutputFiles>false</ErrorOnDuplicatePublishOutputFiles>
</PropertyGroup>
```

This property was introduced in .NET 6.

EnablePackageValidation

The `EnablePackageValidation` property enables a series of validations on the package after the `pack` task. For more information, see [package validation](#).

```
<PropertyGroup>
  <EnablePackageValidation>true</EnablePackageValidation>
</PropertyGroup>
```

This property was introduced in .NET 6.

GenerateRuntimeConfigDevFile

Starting with the .NET 6 SDK, the `[Appname].runtimesettings.dev.json` file is [no longer generated by default](#) at compile time. If you still want this file to be generated, set the `GenerateRuntimeConfigDevFile` property to `true`.

```
<PropertyGroup>
  <GenerateRuntimeConfigDevFile>true</GenerateRuntimeConfigDevFile>
</PropertyGroup>
```

GenerateRuntimeConfigurationFiles

The `GenerateRuntimeConfigurationFiles` property controls whether runtime configuration options are copied from the `runtimeconfig.template.json` file to the `[appname].runtimeconfig.json` file. For apps that require a `runtimeconfig.json` file, that is, those whose `OutputType` is `Exe`, this property defaults to `true`.

```
<PropertyGroup>
  <GenerateRuntimeConfigurationFiles>true</GenerateRuntimeConfigurationFiles>
</PropertyGroup>
```

GenerateSatelliteAssembliesForCore

The `GenerateSatelliteAssembliesForCore` property controls whether satellite assemblies are generated using `csc.exe` or [Al.exe \(Assembly Linker\)](#) in .NET Framework projects. (.NET Core and .NET 5+ projects always use `csc.exe` to generate satellite assemblies.) For .NET Framework projects, satellite assemblies are created by `al.exe`, by default. By setting the `GenerateSatelliteAssembliesForCore` property to `true`, satellite assemblies are created by `csc.exe` instead. Using `csc.exe` can be advantageous in the following situations:

- You want to use the C# compiler [deterministic](#) option.
- You're limited by the fact that `al.exe` has no support for public signing and handles [AssemblyInformationalVersionAttribute](#) poorly.

```
<PropertyGroup>
  <GenerateSatelliteAssembliesForCore>true</GenerateSatelliteAssembliesForCore>
</PropertyGroup>
```

IsPublishable

The `IsPublishable` property allows the `Publish` target to run. This property only affects processes that use `*.proj` files and the `Publish` target, such as the `dotnet publish` command. It does not affect publishing in Visual Studio, which uses the `PublishOnly` target. The default value is `true`.

This property is useful if you run `dotnet publish` on a solution file, as it allows automatic selection of projects that should be published.

```
<PropertyGroup>
  <IsPublishable>false</IsPublishable>
</PropertyGroup>
```

PreserveCompilationContext

The `PreserveCompilationContext` property allows a built or published application to compile more code at run time using the same settings that were used at build time. The assemblies referenced at build time will be copied into the `ref` subdirectory of the output directory. The names of the reference assemblies are stored in the application's `.deps.json` file along with the options passed to the compiler. You can retrieve this information using the [DependencyContext.CompileLibraries](#) and [DependencyContext.CompilationOptions](#) properties.

This functionality is mostly used internally by ASP.NET Core MVC and Razor pages to support run-time compilation of Razor files.

```
<PropertyGroup>
  <PreserveCompilationContext>true</PreserveCompilationContext>
</PropertyGroup>
```

PreserveCompilationReferences

The `PreserveCompilationReferences` property is similar to the `PreserveCompilationContext` property, except that it only copies the referenced assemblies to the publish directory, and not the `.deps.json` file.

```
<PropertyGroup>
  <PreserveCompilationReferences>true</PreserveCompilationReferences>
</PropertyGroup>
```

For more information, see [Razor SDK properties](#).

ProduceReferenceAssemblyInOutDir

In .NET 5 and earlier versions, reference assemblies are always written to the `OutDir` directory. In .NET 6 and later versions, you can use the `ProduceReferenceAssemblyInOutDir` property to control whether reference assemblies are written to the `OutDir` directory. The default value is `false`, and reference assemblies are only written to the `IntermediateOutputPath` directory. Set the value to `true` to write reference assemblies to the `OutDir` directory.

```
<PropertyGroup>
  <ProduceReferenceAssemblyInOutDir>true</ProduceReferenceAssemblyInOutDir>
</PropertyGroup>
```

For more information, see [Write reference assemblies to intermediate output](#).

PublishRelease

The `PublishRelease` property informs `dotnet publish` to use the `Release` configuration by default instead of the `Debug` configuration.

```
<PropertyGroup>
  <PublishRelease>true</PublishRelease>
</PropertyGroup>
```

NOTE

- This property does not affect the behavior of `dotnet build /t:Publish` and changes the configuration only when publishing via the .NET CLI.
- To use `PublishRelease` in a project that's part of a Visual Studio solution, you must set the environment variable `DOTNET_CLI_ENABLE_PUBLISH_RELEASE_FOR_SOLUTIONS` to `true` (or any other value). This will increase the time required to publish solutions that have many projects. When publishing a solution with this variable enabled, the executable project's `PublishRelease` value takes precedence and flows the new default configuration to any other projects in the solution. If a solution contains multiple executable or top-level projects with differing values of `PublishRelease`, the solution won't successfully publish.

RollForward

The `RollForward` property controls how the application chooses a runtime when multiple runtime versions are available. This value is output to the `.runtimeconfig.json` as the `rollForward` setting.

```
<PropertyGroup>
  <RollForward>LatestMinor</RollForward>
</PropertyGroup>
```

Set `RollForward` to one of the following values:

VALUE	DESCRIPTION
-------	-------------

VALUE	DESCRIPTION
Minor	Default if not specified. Roll-forward to the lowest higher minor version, if requested minor version is missing. If the requested minor version is present, then the <code>LatestPatch</code> policy is used.
Major	Roll-forward to the next available higher major version, and lowest minor version, if requested major version is missing. If the requested major version is present, then the <code>Minor</code> policy is used.
LatestPatch	Roll-forward to the highest patch version. This value disables minor version roll-forward.
LatestMinor	Roll-forward to highest minor version, even if requested minor version is present.
LatestMajor	Roll-forward to highest major and highest minor version, even if requested major is present.
Disable	Don't roll-forward, only bind to the specified version. This policy isn't recommended for general use since it disables the ability to roll-forward to the latest patches. This value is only recommended for testing.

For more information, see [Control roll-forward behavior](#).

RuntimeFrameworkVersion

The `RuntimeFrameworkVersion` property specifies the version of the runtime to use when publishing. Specify a runtime version:

```
<PropertyGroup>
  <RuntimeFrameworkVersion>5.0.7</RuntimeFrameworkVersion>
</PropertyGroup>
```

When publishing a framework-dependent application, this value specifies the *minimum* version required. When publishing a self-contained application, this value specifies the *exact* version required.

RuntimeIdentifier

The `RuntimeIdentifier` property lets you specify a single [runtime identifier \(RID\)](#) for the project. The RID enables publishing a self-contained deployment.

```
<PropertyGroup>
  <RuntimeIdentifier>ubuntu.16.04-x64</RuntimeIdentifier>
</PropertyGroup>
```

RuntimeIdentifiers

The `RuntimeIdentifiers` property lets you specify a semicolon-delimited list of [runtime identifiers \(IDs\)](#) for the project. Use this property if you need to publish for multiple runtimes. `RuntimeIdentifiers` is used at restore time to ensure the right assets are in the graph.

TIP

`RuntimeIdentifier` (singular) can provide faster builds when only a single runtime is required.

```
<PropertyGroup>
  <RuntimeIdentifiers>win10-x64;osx.10.11-x64;ubuntu.16.04-x64</RuntimeIdentifiers>
</PropertyGroup>
```

SatelliteResourceLanguages

The `SatelliteResourceLanguages` property lets you specify which languages you want to preserve satellite resource assemblies for during build and publish. Many NuGet packages include localized resource satellite assemblies in the main package. For projects that reference these NuGet packages that don't require localized resources, the localized assemblies can unnecessarily inflate the build and publish output size. By adding the `SatelliteResourceLanguages` property to your project file, only localized assemblies for the languages you specify will be included in the build and publish output. For example, in the following project file, only English (US) and German (Germany) resource satellite assemblies will be retained.

```
<PropertyGroup>
  <SatelliteResourceLanguages>en-US;de-DE</SatelliteResourceLanguages>
</PropertyGroup>
```

NOTE

- You must specify this property in the project that references the NuGet package with localized resource satellite assemblies.
- To specify multiple languages as an argument to `dotnet publish`, you must add *three pairs* of quotation marks around the language identifiers. For example:

```
dotnet msbuild multi.msbuildproj -p:SatelliteResourceLanguages=""de;en""
```

UseAppHost

The `UseAppHost` property controls whether or not a native executable is created for a deployment. A native executable is required for self-contained deployments.

In .NET Core 3.0 and later versions, a framework-dependent executable is created by default. Set the `UseAppHost` property to `false` to disable generation of the executable.

```
<PropertyGroup>
  <UseAppHost>false</UseAppHost>
</PropertyGroup>
```

For more information about deployment, see [.NET application deployment](#).

Trim-related properties

Numerous MSBuild properties are available to fine tune trimming, which is a feature that trims unused code from self-contained deployments. These options are discussed in detail at [Trimming options](#). The following table provides a quick reference.

PROPERTY	VALUES	DESCRIPTION
<code>PublishTrimmed</code>	<code>true</code> or <code>false</code>	Controls whether trimming is enabled during publish.
<code>TrimMode</code>	<code>full</code> or <code>partial</code>	Default is <code>full</code> . Controls the trimming granularity.

PROPERTY	VALUES	DESCRIPTION
<code>SuppressTrimAnalysisWarnings</code>	<code>true</code> or <code>false</code>	Controls whether trim analysis warnings are produced.
<code>EnableTrimAnalyzer</code>	<code>true</code> or <code>false</code>	Controls whether a subset of trim analysis warnings are produced. You can enable analysis even if <code>PublishTrimmed</code> is set to <code>false</code> .
<code>ILLinkTreatWarningsAsErrors</code>	<code>true</code> or <code>false</code>	Controls whether trim warnings are treated as errors. For example, you may want to set this property to <code>false</code> when <code>TreatWarningsAsErrors</code> is set to <code>true</code> .
<code>TrimmerSingleWarn</code>	<code>true</code> or <code>false</code>	Controls whether a single warning per assembly is shown or all warnings.
<code>TrimmerRemoveSymbols</code>	<code>true</code> or <code>false</code>	Controls whether all symbols are removed from a trimmed application.

Compilation-related properties

The following MSBuild properties are documented in this section:

- [DisableImplicitFrameworkDefines](#)
- [DocumentationFile](#)
- [EmbeddedResourceUseDependentUponConvention](#)
- [EnablePreviewFeatures](#)
- [GenerateDocumentationFile](#)
- [GenerateRequiresPreviewFeaturesAttribute](#)
- [OptimizeImplicitlyTriggeredBuild](#)

C# compiler options, such as `LangVersion` and `Nullable`, can also be specified as MSBuild properties in your project file. For more information, see [C# compiler options](#).

DisableImplicitFrameworkDefines

The `DisableImplicitFrameworkDefines` property controls whether or not the SDK generates preprocessor symbols for the target framework and platform for the .NET project. When this property is set to `false` or is unset (which is the default value) preprocessor symbols are generated for:

- Framework without version (`NETFRAMEWORK`, `NETSTANDARD`, `NET`)
- Framework with version (`NET48`, `NETSTANDARD2_0`, `NET6_0`)
- Framework with version minimum bound (`NET48_OR_GREATER`, `NETSTANDARD2_0_OR_GREATER`, `NET6_0_OR_GREATER`)

For more information on target framework monikers and these implicit preprocessor symbols, see [Target frameworks](#).

Additionally, if you specify an operating system-specific target framework in the project (for example `net6.0-android`), the following preprocessor symbols are generated:

- Platform without version (`ANDROID`, `IOS`, `WINDOWS`)
- Platform with version (`IOS15_1`)

- Platform with version minimum bound (`IOS15_1_OR_GREATER`)

For more information on operating system-specific target framework monikers, see [OS-specific TFMs](#).

Finally, if your target framework implies support for older target frameworks, preprocessor symbols for those older frameworks are emitted. For example, `net6.0` implies support for `net5.0` and so on all the way back to `.netcoreapp1.0`. So for each of these target frameworks, the *Framework with version minimum bound* symbol will be defined.

DocumentationFile

The `DocumentationFile` property lets you specify a file name for the XML file that contains the documentation for your library. For IntelliSense to function correctly with your documentation, the file name must be the same as the assembly name and must be in the same directory as the assembly. If you don't specify this property but you do set `GenerateDocumentationFile` to `true`, the name of the documentation file defaults to the name of your assembly but with an `.xml` file extension. For this reason, it's often easier to omit this property and use the `GenerateDocumentationFile` property instead.

If you specify this property but you set `GenerateDocumentationFile` to `false`, the compiler *does not* generate a documentation file. If you specify this property and omit the `GenerateDocumentationFile` property, the compiler *does* generate a documentation file.

```
<PropertyGroup>
  <DocumentationFile>path/to/file.xml</DocumentationFile>
</PropertyGroup>
```

EmbeddedResourceUseDependentUponConvention

The `EmbeddedResourceUseDependentUponConvention` property defines whether resource manifest file names are generated from type information in source files that are co-located with resource files. For example, if `Form1.resx` is in the same folder as `Form1.cs`, and `EmbeddedResourceUseDependentUponConvention` is set to `true`, the generated `.resources` file takes its name from the first type that's defined in `Form1.cs`. For example, if `MyNamespace.Form1` is the first type defined in `Form1.cs`, the generated file name is `MyNamespace.Form1.resources`.

NOTE

If `LogicalName`, `ManifestResourceName`, or `DependentUpon` metadata is specified for an `EmbeddedResource` item, the generated manifest file name for that resource file is based on that metadata instead.

By default, in a new .NET project, this property is set to `true`. If set to `false`, and no `LogicalName`, `ManifestResourceName`, or `DependentUpon` metadata is specified for the `EmbeddedResource` item in the project file, the resource manifest file name is based off the root namespace for the project and the relative file path to the `.resx` file. For more information, see [How resource manifest files are named](#).

```
<PropertyGroup>
  <EmbeddedResourceUseDependentUponConvention>true</EmbeddedResourceUseDependentUponConvention>
</PropertyGroup>
```

EnablePreviewFeatures

The `EnablePreviewFeatures` property defines whether your project depends on any APIs or assemblies that are decorated with the `RequiresPreviewFeaturesAttribute` attribute. This attribute is used to signify that an API or assembly uses features that are considered to be in *preview* for the SDK version you're using. Preview features are not supported and may be removed in a future version. To enable the use of preview features, set the property to `True`.

```
<PropertyGroup>
  <EnablePreviewFeatures>True</EnablePreviewFeatures>
</PropertyGroup>
```

When a project contains this property set to `True`, the following assembly-level attribute is added to the `AssemblyInfo.cs` file:

```
[assembly: RequiresPreviewFeatures]
```

An analyzer warns if this attribute is present on dependencies for projects where `EnablePreviewFeatures` is not set to `True`.

Library authors who intend to ship preview assemblies should set this property to `True`. If an assembly needs to ship with a mixture of preview and non-preview APIs, see the [GenerateRequiresPreviewFeaturesAttribute](#) section below.

GenerateDocumentationFile

The `GenerateDocumentationFile` property controls whether the compiler generates an XML documentation file for your library. If you set this property to `true` and you don't specify a file name via the [DocumentationFile property](#), the generated XML file is placed in the same output directory as your assembly and has the same file name (but with an `.xml` extension).

```
<PropertyGroup>
  <GenerateDocumentationFile>true</GenerateDocumentationFile>
</PropertyGroup>
```

For more information about generating documentation from code comments, see [XML documentation comments \(C#\)](#), [Document your code with XML \(Visual Basic\)](#), or [Document your code with XML \(F#\)](#).

GenerateRequiresPreviewFeaturesAttribute

The `GenerateRequiresPreviewFeaturesAttribute` property is closely related to the `EnablePreviewFeatures` property. If your library uses preview features but you don't want the entire assembly to be marked with the `RequiresPreviewFeaturesAttribute` attribute, which would require any consumers to [enable preview features](#), set this property to `False`.

```
<PropertyGroup>
  <EnablePreviewFeatures>True</EnablePreviewFeatures>
  <GenerateRequiresPreviewFeaturesAttribute>False</GenerateRequiresPreviewFeaturesAttribute>
</PropertyGroup>
```

IMPORTANT

If you set the `GenerateRequiresPreviewFeaturesAttribute` property to `False`, you must be certain to decorate all public APIs that rely on preview features with `RequiresPreviewFeaturesAttribute`.

OptimizeImplicitlyTriggeredBuild

To speed up the build time, builds that are implicitly triggered by Visual Studio skip code analysis, including nullable analysis. Visual Studio triggers an implicit build when you run tests, for example. However, implicit builds are optimized only when `TreatWarningsAsErrors` is not `true`. If you have `TreatWarningsAsErrors` set to `true` but you still want implicitly triggered builds to be optimized, you can set

`OptimizeImplicitlyTriggeredBuild` to `True`. To turn off build optimization for implicitly triggered builds, set `OptimizeImplicitlyTriggeredBuild` to `False`.

```
<PropertyGroup>
  <OptimizeImplicitlyTriggeredBuild>True</OptimizeImplicitlyTriggeredBuild>
</PropertyGroup>
```

Default item inclusion properties

The following MSBuild properties are documented in this section:

- [DefaultItemExcludesInProjectFolder](#)
- [DefaultItemExcludes](#)
- [EnableDefaultCompileItems](#)
- [EnableDefaultEmbeddedResourceItems](#)
- [EnableDefaultItems](#)
- [EnableDefaultNoneItems](#)

For more information, see [Default includes and excludes](#).

DefaultItemExcludes

Use the `DefaultItemExcludes` property to define glob patterns for files and folders that should be excluded from the include, exclude, and remove globs. By default, the `./bin` and `./obj` folders are excluded from the glob patterns.

```
<PropertyGroup>
  <DefaultItemExcludes>$({DefaultItemExcludes});**/*.*myextension</DefaultItemExcludes>
</PropertyGroup>
```

DefaultItemExcludesInProjectFolder

Use the `DefaultItemExcludesInProjectFolder` property to define glob patterns for files and folders in the project folder that should be excluded from the include, exclude, and remove globs. By default, folders that start with a period (`.`), such as `.git` and `.vs`, are excluded from the glob patterns.

This property is very similar to the `DefaultItemExcludes` property, except that it only considers files and folders in the project folder. When a glob pattern would unintentionally match items outside the project folder with a relative path, use the `DefaultItemExcludesInProjectFolder` property instead of the `DefaultItemExcludes` property.

```
<PropertyGroup>
  <DefaultItemExcludesInProjectFolder>$({DefaultItemExcludesInProjectFolder});**/myprefix/**</DefaultItemExcludesInProjectFolder>
</PropertyGroup>
```

EnableDefaultItems

The `EnableDefaultItems` property controls whether compile items, embedded resource items, and `None` items are implicitly included in the project. The default value is `true`. Set the `EnableDefaultItems` property to `false` to disable all implicit file inclusion.

```
<PropertyGroup>
  <EnableDefaultItems>false</EnableDefaultItems>
</PropertyGroup>
```

EnableDefaultCompileItems

The `EnableDefaultCompileItems` property controls whether compile items are implicitly included in the project. The default value is `true`. Set the `EnableDefaultCompileItems` property to `false` to disable implicit inclusion of

*.cs and other language-extension files.

```
<PropertyGroup>
  <EnableDefaultCompileItems>false</EnableDefaultCompileItems>
</PropertyGroup>
```

EnableDefaultEmbeddedResourceItems

The `EnableDefaultEmbeddedResourceItems` property controls whether embedded resource items are implicitly included in the project. The default value is `true`. Set the `EnableDefaultEmbeddedResourceItems` property to `false` to disable implicit inclusion of embedded resource files.

```
<PropertyGroup>
  <EnableDefaultEmbeddedResourceItems>false</EnableDefaultEmbeddedResourceItems>
</PropertyGroup>
```

EnableDefaultNoneItems

The `EnableDefaultNoneItems` property controls whether `None` items (files that have no role in the build process) are implicitly included in the project. The default value is `true`. Set the `EnableDefaultNoneItems` property to `false` to disable implicit inclusion of `None` items.

```
<PropertyGroup>
  <EnableDefaultNoneItems>false</EnableDefaultNoneItems>
</PropertyGroup>
```

Code analysis properties

The following MSBuild properties are documented in this section:

- [AnalysisLevel](#)
- [AnalysisLevel<Category>](#)
- [AnalysisMode](#)
- [AnalysisMode<Category>](#)
- [CodeAnalysisTreatWarningsAsErrors](#)
- [EnableNETAnalyzers](#)
- [EnforceCodeStyleInBuild](#)
- [_SkipUpgradeNetAnalyzersNuGetWarning](#)

AnalysisLevel

The `AnalysisLevel` property lets you specify a set of code analyzers to run according to a .NET release. Each .NET release, starting in .NET 5, has a set of code analysis rules. Of that set, the rules that are enabled by default for that release will analyze your code. For example, if you upgrade to .NET 6 but don't want the default set of code analysis rules to change, set `AnalysisLevel` to `5`.

```
<PropertyGroup>
  <AnalysisLevel>preview</AnalysisLevel>
</PropertyGroup>
```

Optionally, starting in .NET 6, you can specify a compound value for this property that also specifies how aggressively to enable rules. Compound values take the form `<version>-<mode>`, where the `<mode>` value is one of the [AnalysisMode](#) values. The following example uses the preview version of code analyzers, and enables the recommended set of rules.

```
<PropertyGroup>
  <AnalysisLevel>preview-recommended</AnalysisLevel>
</PropertyGroup>
```

NOTE

If you set `AnalysisLevel` to `5-<mode>` or `5.0-<mode>` and then install the .NET 6 SDK and recompile your project, you may see unexpected new build warnings. For more information, see [dotnet/roslyn-analyzers#5679](#).

Default value:

- If your project targets .NET 5 or later, or if you've added the `AnalysisMode` property, the default value is `latest`.
- Otherwise, this property is omitted unless you explicitly add it to the project file.

The following table shows the values you can specify.

VALUE	MEANING
<code>latest</code>	The latest code analyzers that have been released are used. This is the default.
<code>latest-<mode></code>	The latest code analyzers that have been released are used. The <code><mode></code> value determines which rules are enabled.
<code>preview</code>	The latest code analyzers are used, even if they are in preview.
<code>preview-<mode></code>	The latest code analyzers are used, even if they are in preview. The <code><mode></code> value determines which rules are enabled.
<code>6.0</code>	The set of rules that was available for the .NET 6 release is used, even if newer rules are available.
<code>6.0-<mode></code>	The set of rules that was available for the .NET 6 release is used, even if newer rules are available. The <code><mode></code> value determines which rules are enabled.
<code>6</code>	The set of rules that was available for the .NET 6 release is used, even if newer rules are available.
<code>6-<mode></code>	The set of rules that was available for the .NET 6 release is used, even if newer rules are available. The <code><mode></code> value determines which rules are enabled.
<code>5.0</code>	The set of rules that was available for the .NET 5 release is used, even if newer rules are available.
<code>5.0-<mode></code>	The set of rules that was available for the .NET 5 release is used, even if newer rules are available. The <code><mode></code> value determines which rules are enabled.
<code>5</code>	The set of rules that was available for the .NET 5 release is used, even if newer rules are available.

VALUE	MEANING
5- <code><mode></code>	The set of rules that was available for the .NET 5 release is used, even if newer rules are available. The <code><mode></code> value determines which rules are enabled.

NOTE

- In .NET 5 and earlier versions, this property only affects [code-quality \(CAXXXX\) rules](#). Starting in .NET 6, if you set `EnforceCodeStyleInBuild` to `true`, this property affects [code-style \(IDEXXXX\) rules](#) too.
- If you set a compound value for `AnalysisLevel`, you don't need to specify an `AnalysisMode`. However, if you do, `AnalysisLevel` takes precedence over `AnalysisMode`.
- This property has no effect on code analysis in projects that don't reference a [project SDK](#), for example, legacy .NET Framework projects that reference the `Microsoft.CodeAnalysis.NetAnalyzers` NuGet package.

AnalysisLevel<Category>

Introduced in .NET 6, this property is the same as [AnalysisLevel](#), except that it only applies to a specific [category of code-analysis rules](#). This property allows you to use a different version of code analyzers for a specific category, or to enable or disable rules at a different level to the other rule categories. If you omit this property for a particular category of rules, it defaults to the [AnalysisLevel](#) value. The available values are the same as those for [AnalysisLevel](#).

```
<PropertyGroup>
  <AnalysisLevelSecurity>preview</AnalysisLevelSecurity>
</PropertyGroup>
```

```
<PropertyGroup>
  <AnalysisLevelSecurity>preview-recommended</AnalysisLevelSecurity>
</PropertyGroup>
```

The following table lists the property name for each rule category.

PROPERTY NAME	RULE CATEGORY
<code><AnalysisLevelDesign></code>	Design rules
<code><AnalysisLevelDocumentation></code>	Documentation rules
<code><AnalysisLevelGlobalization></code>	Globalization rules
<code><AnalysisLevelInteroperability></code>	Portability and interoperability rules
<code><AnalysisLevelMaintainability></code>	Maintainability rules
<code><AnalysisLevelNaming></code>	Naming rules
<code><AnalysisLevelPerformance></code>	Performance rules
<code><AnalysisLevelSingleFile></code>	Single-file application rules
<code><AnalysisLevelReliability></code>	Reliability rules

PROPERTY NAME	RULE CATEGORY
<AnalysisLevelSecurity>	Security rules
<AnalysisLevelStyle>	Code-style (IDEXXX) rules
<AnalysisLevelUsage>	Usage rules

AnalysisMode

Starting with .NET 5, the .NET SDK ships with all of the "CA" code quality rules. By default, only [some rules are enabled](#) as build warnings in each .NET release. The `AnalysisMode` property lets you customize the set of rules that are enabled by default. You can either switch to a more aggressive analysis mode where you can opt out of rules individually, or a more conservative analysis mode where you can opt in to specific rules. For example, if you want to enable all rules as build warnings, set the value to `All`.

```
<PropertyGroup>
  <AnalysisMode>All</AnalysisMode>
</PropertyGroup>
```

The following table shows the available option values in .NET 5 and .NET 6. They're listed in increasing order of the number of rules they enable.

.NET 6+ VALUE	.NET 5 VALUE	MEANING
<code>None</code>	<code>AllDisabledByDefault</code>	All rules are disabled. You can selectively opt in to individual rules to enable them.
<code>Default</code>	<code>Default</code>	Default mode, where certain rules are enabled as build warnings, certain rules are enabled as Visual Studio IDE suggestions, and the remainder are disabled.
<code>Minimum</code>	N/A	More aggressive mode than the <code>Default</code> mode. Certain suggestions that are highly recommended for build enforcement are enabled as build warnings.
<code>Recommended</code>	N/A	More aggressive mode than the <code>Minimum</code> mode, where more rules are enabled as build warnings.
<code>All</code>	<code>AllEnabledByDefault</code>	All rules are enabled as build warnings. You can selectively opt out of individual rules to disable them.

NOTE

- In .NET 5, this property only affects [code-quality \(CAXXXX\) rules](#). Starting in .NET 6, if you set `EnforceCodeStyleInBuild` to `true`, this property affects [code-style \(IDEXXXX\) rules](#) too.
- If you use a compound value for `AnalysisLevel`, for example, `<AnalysisLevel>5-recommended</AnalysisLevel>`, you can omit this property entirely. However, if you specify both properties, `AnalysisLevel` takes precedence over `AnalysisMode`.
- If `AnalysisMode` is set to `AllEnabledByDefault` and `AnalysisLevel` is set to `5` or `5.0`, and then you install the .NET 6 SDK and recompile your project, you may see unexpected new build warnings. For more information, see [dotnet/roslyn-analyzers#5679](#).
- This property has no effect on code analysis in projects that don't reference a [project SDK](#), for example, legacy .NET Framework projects that reference the `Microsoft.CodeAnalysis.NetAnalyzers` NuGet package.

AnalysisMode <Category>

Introduced in .NET 6, this property is the same as [AnalysisMode](#), except that it only applies to a specific [category of code-analysis rules](#). This property allows you to enable or disable rules at a different level to the other rule categories. If you omit this property for a particular category of rules, it defaults to the [AnalysisMode](#) value. The available values are the same as those for [AnalysisMode](#).

```
<PropertyGroup>
  <AnalysisModeSecurity>All</AnalysisModeSecurity>
</PropertyGroup>
```

The following table lists the property name for each rule category.

PROPERTY NAME	RULE CATEGORY
<code><AnalysisModeDesign></code>	Design rules
<code><AnalysisModeDocumentation></code>	Documentation rules
<code><AnalysisModeGlobalization></code>	Globalization rules
<code><AnalysisModeInteroperability></code>	Portability and interoperability rules
<code><AnalysisModeMaintainability></code>	Maintainability rules
<code><AnalysisModeNaming></code>	Naming rules
<code><AnalysisModePerformance></code>	Performance rules
<code><AnalysisModeSingleFile></code>	Single-file application rules
<code><AnalysisModeReliability></code>	Reliability rules
<code><AnalysisModeSecurity></code>	Security rules
<code><AnalysisModeStyle></code>	Code-style (IDEXXXX) rules
<code><AnalysisModeUsage></code>	Usage rules

CodeAnalysisTreatWarningsAsErrors

The `CodeAnalysisTreatWarningsAsErrors` property lets you configure whether code quality analysis warnings (CAxxx) should be treated as warnings and break the build. If you use the `-warnaserror` flag when you build your projects, [.NET code quality analysis](#) warnings are also treated as errors. If you do not want code quality analysis warnings to be treated as errors, you can set the `CodeAnalysisTreatWarningsAsErrors` MSBuild property to `false` in your project file.

```
<PropertyGroup>
  <CodeAnalysisTreatWarningsAsErrors>false</CodeAnalysisTreatWarningsAsErrors>
</PropertyGroup>
```

EnableNETAnalyzers

[.NET code quality analysis](#) is enabled, by default, for projects that target .NET 5 or a later version. If you're developing using the .NET 5+ SDK, you can enable .NET code analysis for SDK-style projects that target earlier versions of .NET by setting the `EnableNETAnalyzers` property to `true`. To disable code analysis in any project, set this property to `false`.

```
<PropertyGroup>
  <EnableNETAnalyzers>true</EnableNETAnalyzers>
</PropertyGroup>
```

NOTE

This property applies specifically to the built-in analyzers in the .NET 5+ SDK. It should not be used when you install a NuGet code analysis package.

EnforceCodeStyleInBuild

[.NET code style analysis](#) is disabled, by default, on build for all .NET projects. You can enable code style analysis for .NET projects by setting the `EnforceCodeStyleInBuild` property to `true`.

```
<PropertyGroup>
  <EnforceCodeStyleInBuild>true</EnforceCodeStyleInBuild>
</PropertyGroup>
```

All code style rules that are [configured](#) to be warnings or errors will execute on build and report violations.

NOTE

If you install .NET 6 (or Visual Studio 2022, which includes .NET 6) but want to build your project using Visual Studio 2019, you might see new CS8032 warnings if you have the `EnforceCodeStyleInBuild` property set to `true`. To resolve the warnings, you can specify the version of the .NET SDK to build your project with (in this case, something like `5.0.404`) by adding a [global.json entry](#).

SkipUpgradeNetAnalyzersNuGetWarning

The `_SkipUpgradeNetAnalyzersNuGetWarning` property lets you configure whether you receive a warning if you're using code analyzers from a NuGet package that's out-of-date when compared with the code analyzers in the latest .NET SDK. The warning looks similar to:

The .NET SDK has newer analyzers with version '6.0.0' than what version '5.0.3' of 'Microsoft.CodeAnalysis.NetAnalyzers' package provides. Update or remove this package reference.

To remove this warning and continue to use the version of code analyzers in the NuGet package, set `_SkipUpgradeNetAnalyzersNuGetWarning` to `true` in your project file.

```
<PropertyGroup>
  <_SkipUpgradeNetAnalyzersNuGetWarning>true</_SkipUpgradeNetAnalyzersNuGetWarning>
</PropertyGroup>
```

Runtime configuration properties

You can configure some run-time behaviors by specifying MSBuild properties in the project file of the app. For information about other ways of configuring run-time behavior, see [Runtime configuration settings](#).

- [ConcurrentGarbageCollection](#)
- [InvariantGlobalization](#)
- [PredefinedCulturesOnly](#)
- [RetainVMGarbageCollection](#)
- [ServerGarbageCollection](#)
- [ThreadPoolMaxThreads](#)
- [ThreadPoolMinThreads](#)
- [TieredCompilation](#)
- [TieredCompilationQuickJit](#)
- [TieredCompilationQuickJitForLoops](#)

ConcurrentGarbageCollection

The `ConcurrentGarbageCollection` property configures whether [background \(concurrent\) garbage collection](#) is enabled. Set the value to `false` to disable background garbage collection. For more information, see [Background GC](#).

```
<PropertyGroup>
  <ConcurrentGarbageCollection>false</ConcurrentGarbageCollection>
</PropertyGroup>
```

InvariantGlobalization

The `InvariantGlobalization` property configures whether the app runs in [globalization-invariant mode](#), which means it doesn't have access to culture-specific data. Set the value to `true` to run in globalization-invariant mode. For more information, see [Invariant mode](#).

```
<PropertyGroup>
  <InvariantGlobalization>true</InvariantGlobalization>
</PropertyGroup>
```

PredefinedCulturesOnly

In .NET 6 and later versions, the `PredefinedCulturesOnly` property configures whether apps can create cultures other than the invariant culture when [globalization-invariant mode](#) is enabled. The default is `true`. Set the value to `false` to allow creation of any new culture in globalization-invariant mode.

```
<PropertyGroup>
  <PredefinedCulturesOnly>false</PredefinedCulturesOnly>
</PropertyGroup>
```

For more information, see [Culture creation and case mapping in globalization-invariant mode](#).

RetainVMGarbageCollection

The `RetainVMGarbageCollection` property configures the garbage collector to put deleted memory segments on a standby list for future use or release them. Setting the value to `true` tells the garbage collector to put the

segments on a standby list. For more information, see [Retain VM](#).

```
<PropertyGroup>
  <RetainVMGarbageCollection>true</RetainVMGarbageCollection>
</PropertyGroup>
```

ServerGarbageCollection

The `ServerGarbageCollection` property configures whether the application uses [workstation garbage collection](#) or [server garbage collection](#). Set the value to `true` to use server garbage collection. For more information, see [Workstation vs. server](#).

```
<PropertyGroup>
  <ServerGarbageCollection>true</ServerGarbageCollection>
</PropertyGroup>
```

ThreadPoolMaxThreads

The `ThreadPoolMaxThreads` property configures the maximum number of threads for the worker thread pool. For more information, see [Maximum threads](#).

```
<PropertyGroup>
  <ThreadPoolMaxThreads>20</ThreadPoolMaxThreads>
</PropertyGroup>
```

ThreadPoolMinThreads

The `ThreadPoolMinThreads` property configures the minimum number of threads for the worker thread pool. For more information, see [Minimum threads](#).

```
<PropertyGroup>
  <ThreadPoolMinThreads>4</ThreadPoolMinThreads>
</PropertyGroup>
```

TieredCompilation

The `TieredCompilation` property configures whether the just-in-time (JIT) compiler uses [tiered compilation](#). Set the value to `false` to disable tiered compilation. For more information, see [Tiered compilation](#).

```
<PropertyGroup>
  <TieredCompilation>false</TieredCompilation>
</PropertyGroup>
```

TieredCompilationQuickJit

The `TieredCompilationQuickJit` property configures whether the JIT compiler uses quick JIT. Set the value to `false` to disable quick JIT. For more information, see [Quick JIT](#).

```
<PropertyGroup>
  <TieredCompilationQuickJit>false</TieredCompilationQuickJit>
</PropertyGroup>
```

TieredCompilationQuickJitForLoops

The `TieredCompilationQuickJitForLoops` property configures whether the JIT compiler uses quick JIT on methods that contain loops. Set the value to `true` to enable quick JIT on methods that contain loops. For more information, see [Quick JIT for loops](#).

```
<PropertyGroup>
  <TieredCompilationQuickJitForLoops>true</TieredCompilationQuickJitForLoops>
</PropertyGroup>
```

Reference properties

The following MSBuild properties are documented in this section:

- [AssetTargetFallback](#)
- [DisableImplicitFrameworkReferences](#)
- [DisableTransitiveProjectReferences](#)
- [Restore-related properties](#)
- [ValidateExecutableReferencesMatchSelfContained](#)

AssetTargetFallback

The `AssetTargetFallback` property lets you specify additional compatible framework versions for project references and NuGet packages. For example, if you specify a package dependency using `PackageReference` but that package doesn't contain assets that are compatible with your project's `TargetFramework`, the `AssetTargetFallback` property comes into play. The compatibility of the referenced package is rechecked using each target framework that's specified in `AssetTargetFallback`. This property replaces the deprecated property `PackageTargetFallback`.

You can set the `AssetTargetFallback` property to one or more [target framework versions](#).

```
<PropertyGroup>
  <AssetTargetFallback>net461</AssetTargetFallback>
</PropertyGroup>
```

DisableImplicitFrameworkReferences

The `DisableImplicitFrameworkReferences` property controls implicit `FrameworkReference` items when targeting .NET Core 3.0 and later versions. When targeting .NET Core 2.1 or .NET Standard 2.0 and earlier versions, it controls implicit `PackageReference` items to packages in a metapackage. (A metapackage is a framework-based package that consists only of dependencies on other packages.) This property also controls implicit references such as `System` and `System.Core` when targeting .NET Framework.

Set this property to `true` to disable implicit `FrameworkReference` or `PackageReference` items. If you set this property to `true`, you can add explicit references to just the frameworks or packages you need.

```
<PropertyGroup>
  <DisableImplicitFrameworkReferences>true</DisableImplicitFrameworkReferences>
</PropertyGroup>
```

DisableTransitiveProjectReferences

The `DisableTransitiveProjectReferences` property controls implicit project references. Set this property to `true` to disable implicit `ProjectReference` items. Disabling implicit project references results in non-transitive behavior similar to the [legacy project system](#).

When this property is `true`, it has a similar effect to that of setting `PrivateAssets="All"` on all of the dependencies of the depended-upon project.

If you set this property to `true`, you can add explicit references to just the projects you need.

```
<PropertyGroup>
  <DisableTransitiveProjectReferences>true</DisableTransitiveProjectReferences>
</PropertyGroup>
```

Restore-related properties

Restoring a referenced package installs all of its direct dependencies and all the dependencies of those dependencies. You can customize package restoration by specifying properties such as `RestorePackagesPath` and `RestoreIgnoreFailedSources`. For more information about these and other properties, see [restore target](#).

```
<PropertyGroup>
  <RestoreIgnoreFailedSource>true</RestoreIgnoreFailedSource>
</PropertyGroup>
```

ValidateExecutableReferencesMatchSelfContained

The `ValidateExecutableReferencesMatchSelfContained` property can be used to disable errors related to executable project references. If .NET detects that a self-contained executable project references a framework-dependent executable project, or vice versa, it generates errors NETSDK1150 and NETSDK1151, respectively. To avoid these errors when the reference is intentional, set the `ValidateExecutableReferencesMatchSelfContained` property to `false`.

```
<PropertyGroup>
  <ValidateExecutableReferencesMatchSelfContained>false</ValidateExecutableReferencesMatchSelfContained>
</PropertyGroup>
```

WindowsSdkPackageVersion

The `WindowsSdkPackageVersion` property can be used to override the version of the [Windows SDK targeting package](#). This property was introduced in .NET 5, and replaces the use of the `FrameworkReference` item for this purpose.

```
<PropertyGroup>
  <WindowsSdkPackageVersion>10.0.19041.18</WindowsSdkPackageVersion>
</PropertyGroup>
```

NOTE

We don't recommend overriding the Windows SDK version, because the Windows SDK targeting packages are included with the .NET 5+ SDK. Instead, to reference the latest Windows SDK package, update your version of the .NET SDK. This property should only be used in rare cases such as using preview packages or needing to override the version of C#/WinRT.

Run-related properties

The following properties are used for launching an app with the `dotnet run` command:

- [RunArguments](#)
- [RunWorkingDirectory](#)

RunArguments

The `RunArguments` property defines the arguments that are passed to the app when it is run.

```
<PropertyGroup>
  <RunArguments>-mode dryrun</RunArguments>
</PropertyGroup>
```

TIP

You can specify additional arguments to be passed to the app by using the `--` option for `dotnet run`.

RunWorkingDirectory

The `RunWorkingDirectory` property defines the working directory for the application process to be started in. It can be an absolute path or a path that's relative to the project directory. If you don't specify a directory, `OutDir` is used as the working directory.

```
<PropertyGroup>
  <RunWorkingDirectory>c:\temp</RunWorkingDirectory>
</PropertyGroup>
```

Hosting-related properties

The following MSBuild properties are documented in this section:

- [EnableComHosting](#)
- [EnableDynamicLoading](#)

EnableComHosting

The `EnableComHosting` property indicates that an assembly provides a COM server. Setting the `EnableComHosting` to `true` also implies that `EnableDynamicLoading` is `true`.

```
<PropertyGroup>
  <EnableComHosting>True</EnableComHosting>
</PropertyGroup>
```

For more information, see [Expose .NET components to COM](#).

EnableDynamicLoading

The `EnableDynamicLoading` property indicates that an assembly is a dynamically loaded component. The component could be a [COM library](#) or a non-COM library that can be [used from a native host](#) or [used as a plugin](#). Setting this property to `true` has the following effects:

- A `.runtimeconfig.json` file is generated.
- `RollForward` is set to `LatestMinor`.
- NuGet references are copied locally.

```
<PropertyGroup>
  <EnableDynamicLoading>true</EnableDynamicLoading>
</PropertyGroup>
```

Generated file properties

The following properties concern code in generated files:

- [DisableImplicitNamespaceImports](#)
- [ImplicitUsings](#)

DisableImplicitNamespaceImports

The `DisableImplicitNamespaceImports` property can be used to disable implicit namespace imports in Visual Basic projects that target .NET 6 or a later version. Implicit namespaces are the default namespaces that are imported globally in a Visual Basic project. Set this property to `true` to disable implicit namespace imports.

```
<PropertyGroup>
  <DisableImplicitNamespaceImports>true</DisableImplicitNamespaceImports>
</PropertyGroup>
```

ImplicitUsings

The `ImplicitUsings` property can be used to enable and disable implicit `global using` directives in C# projects that target .NET 6 or a later version and C# 10 or a later version. When the feature is enabled, the .NET SDK adds `global using` directives for a set of default namespaces based on the type of project SDK. Set this property to `true` or `enable` to enable implicit `global using` directives. To disable implicit `global using` directives, remove the property or set it to `false` or `disable`.

```
<PropertyGroup>
  <ImplicitUsings>enable</ImplicitUsings>
</PropertyGroup>
```

NOTE

The templates for new C# projects that target .NET 6 or later have `ImplicitUsings` set to `enable` by default.

To define an explicit `global using` directive, add a [Using](#) item.

Items

MSBuild items are inputs into the build system. Items are specified according to their type, which is the element name. For example, `Compile` and `Reference` are two [common item types](#). The following additional item types are made available by the .NET SDK:

- [AssemblyMetadata](#)
- [InternalsVisibleTo](#)
- [PackageReference](#)
- [TrimmerRootAssembly](#)
- [Using](#)

You can use any of the standard [item attributes](#), for example, `Include` and `Update`, on these items. Use `Include` to add a new item, and use `Update` to modify an existing item. For example, `Update` is often used to modify an item that has implicitly been added by the .NET SDK.

AssemblyMetadata

The `AssemblyMetadata` item specifies a key-value pair `AssemblyMetadataAttribute` assembly attribute. The `Include` metadata becomes the key, and the `Value` metadata becomes the value.

```
<ItemGroup>
  <AssemblyMetadata Include="Serviceable" Value="True" />
</ItemGroup>
```

InternalsVisibleTo

The `InternalsVisibleTo` item generates an `InternalsVisibleToAttribute` assembly attribute for the specified friend assembly.

```
<ItemGroup>
  <InternalsVisibleTo Include="MyProject.Tests" />
</ItemGroup>
```

If the friend assembly is signed, you can specify an optional `Key` metadata to specify its full public key. If you don't specify `Key` metadata and a `$(PublicKey)` is available, that key is used. Otherwise, no public key is added to the attribute.

PackageReference

The `PackageReference` item defines a reference to a NuGet package.

The `Include` attribute specifies the package ID. The `Version` attribute specifies the version or version range. For information about how to specify a minimum version, maximum version, range, or exact match, see [Version ranges](#).

The project file snippet in the following example references the `System.Runtime` package.

```
<ItemGroup>
  <PackageReference Include="System.Runtime" Version="4.3.0" />
</ItemGroup>
```

You can also [control dependency assets](#) using metadata such as `PrivateAssets`.

```
<ItemGroup>
  <PackageReference Include="Contoso.Utility.UsefulStuff" Version="3.6.0">
    <PrivateAssets>all</PrivateAssets>
  </PackageReference>
</ItemGroup>
```

For more information, see [Package references in project files](#).

TrimmerRootAssembly

The `TrimmerRootAssembly` item lets you exclude an assembly from [trimming](#). Trimming is the process of removing unused parts of the runtime from a packaged application. In some cases, trimming might incorrectly remove required references.

The following XML excludes the `System.Security` assembly from trimming.

```
<ItemGroup>
  <TrimmerRootAssembly Include="System.Security" />
</ItemGroup>
```

For more information, see [Trimming options](#).

Using

The `Using` item lets you [globally include a namespace](#) across your C# project, such that you don't have to add a `using` directive for the namespace at the top of your source files. This item is similar to the `Import` item that can be used for the same purpose in Visual Basic projects. This property is available starting in .NET 6.

```
<ItemGroup>
  <Using Include="My.Awesome.Namespace" />
</ItemGroup>
```

You can also use the `Using` item to define global `using <alias>` and `using static <type>` directives.

```
<ItemGroup>
  <Using Include="My.Awesome.Namespace" Alias="Awesome" />
</ItemGroup>
```

For example:

- `<Using Include="Microsoft.AspNetCore.Http.Results" Alias="Results" />` emits
`global using Results = global::Microsoft.AspNetCore.Http.Results;`
- `<Using Include="Microsoft.AspNetCore.Http.Results" Static="True" />` emits
`global using static global::Microsoft.AspNetCore.Http.Results;`

For more information about aliased `using` directives and `using static <type>` directives, see [using directive](#).

Item metadata

In addition to the standard [MSBuild item attributes](#), the following item metadata tags are made available by the .NET SDK:

- [CopyToPublishDirectory](#)
- [LinkBase](#)

[CopyToPublishDirectory](#)

The `CopyToPublishDirectory` metadata on an MSBuild item controls when the item is copied to the publish directory. Allowable values are `PreserveNewest`, which only copies the item if it has changed, `Always`, which always copies the item, and `Never`, which never copies the item. From a performance standpoint, `PreserveNewest` is preferable because it enables an incremental build.

```
<ItemGroup>
  <None Update="appsettings.Development.json" CopyToOutputDirectory="PreserveNewest"
        CopyToPublishDirectory="PreserveNewest" />
</ItemGroup>
```

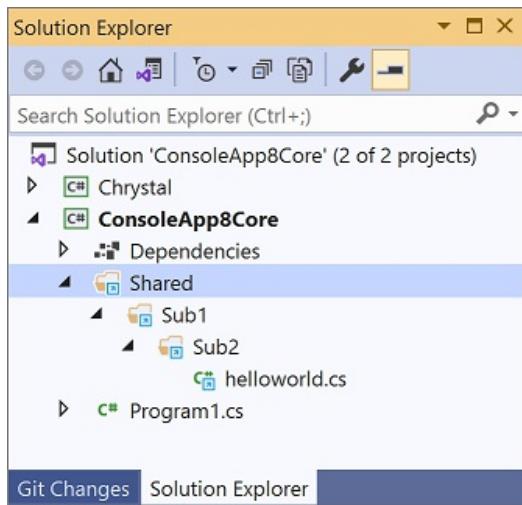

[LinkBase](#)

For an item that's outside of the project directory and its subdirectories, the publish target uses the item's [Link metadata](#) to determine where to copy the item to. `Link` also determines how items outside of the project tree are displayed in the Solution Explorer window of Visual Studio.

If `Link` is not specified for an item that's outside of the project cone, it defaults to `%({LinkBase})%({RecursiveDir})%({Filename})%({Extension})`. `LinkBase` lets you specify a sensible base folder for items outside of the project cone. The folder hierarchy under the base folder is preserved via `RecursiveDir`. If `LinkBase` is not specified, it's omitted from the `Link` path.

```
<ItemGroup>
  <Content Include="..\Extras\**\*.cs" LinkBase="Shared"/>
</ItemGroup>
```

The following image shows how a file that's included via the previous item `Include` glob displays in Solution Explorer.

MSBuild reference for .NET Desktop SDK projects

9/20/2022 • 6 minutes to read • [Edit Online](#)

This page is a reference for the MSBuild properties and items that you use to configure Windows Forms (WinForms) and Windows Presentation Foundation (WPF) projects with the .NET Desktop SDK.

NOTE

This article documents a subset of the MSBuild properties for the .NET SDK as it relates to desktop apps. For a list of common .NET SDK-specific MSBuild properties, see [MSBuild reference for .NET SDK projects](#). For a list of common MSBuild properties, see [Common MSBuild properties](#).

Enable .NET Desktop SDK

To use WinForms or WPF, configure your project file.

.NET 5 and later versions

Specify the following settings in the project file of your WinForms or WPF project:

- Target the .NET SDK `Microsoft.NET.Sdk`. For more information, see [Project files](#).
- Set `TargetFramework` to a Windows-specific target framework moniker, such as `net6.0-windows`.
- Add a UI framework property (or both, if necessary):
 - Set `UseWPF` to `true` to import and use WPF.
 - Set `UseWindowsForms` to `true` to import and use WinForms.
- (Optional) Set `OutputType` to `WinExe`. This produces an app as opposed to a library. To produce a library, omit this property.

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <OutputType>WinExe</OutputType>
  <TargetFramework>net6.0-windows</TargetFramework>

  <UseWPF>true</UseWPF>
  <!-- and/or -->
  <UseWindowsForms>true</UseWindowsForms>
</PropertyGroup>

</Project>
```

.NET Core 3.1

Specify the following settings in the project file of your WinForms or WPF project:

- Target the .NET SDK `Microsoft.NET.Sdk.WindowsDesktop`. For more information, see [Project files](#).
- Set `TargetFramework` to `netcoreapp3.1`.
- Add a UI framework property (or both, if necessary):
 - Set `UseWPF` to `true` to import and use WPF.
 - Set `UseWindowsForms` to `true` to import and use WinForms.
- (Optional) Set `OutputType` to `WinExe`. This produces an app as opposed to a library. To produce a library, omit this property.

```

<Project Sdk="Microsoft.NET.Sdk.WindowsDesktop">

  <PropertyGroup>
    <OutputType>WinExe</OutputType>
    <TargetFramework>netcoreapp3.1</TargetFramework>

    <UseWPF>true</UseWPF>
    <!-- and/or -->
    <UseWindowsForms>true</UseWindowsForms>
  </PropertyGroup>

</Project>

```

WPF default includes and excludes

SDK projects define a set of rules to implicitly include or exclude files from the project. These rules also automatically set the file's build action. This is unlike the older non-SDK .NET Framework projects, which have no default include or exclude rules. .NET Framework projects require you to explicitly declare which files to include in the project.

.NET project files include a [standard set of rules](#) for automatically processing files. WPF projects add additional rules.

The following table shows which elements and [glob](#)s are included and excluded in the .NET Desktop SDK when the `UseWPF` project property is set to `true`:

ELEMENT	INCLUDE GLOB	EXCLUDE GLOB	REMOVE GLOB
ApplicationDefinition	App.xaml or Application.xaml	N/A	N/A
Page	**/*.xaml	**/*.user; **/*.proj; **/*.sln; **/*.vsscc Any XAML defined by <i>ApplicationDefinition</i>	N/A
None	N/A	N/A	**/*.xaml

Here are the default include and exclude settings for all project types. For more information, see [Default includes and excludes](#).

ELEMENT	INCLUDE GLOB	EXCLUDE GLOB	REMOVE GLOB
Compile	**/*.cs; **/*.vb (or other language extensions)	**/*.user; **/*.proj; **/*.sln; **/*.vsscc	N/A
EmbeddedResource	**/*.resx	**/*.user; **/*.proj; **/*.sln; **/*.vsscc	N/A
None	**/*	**/*.user; **/*.proj; **/*.sln; **/*.vsscc	**/*.cs; **/*.resx

Errors related to "duplicate" items

If you explicitly added files to your project, or have XAML globs to automatically include files in your project, you might get one of the following errors:

- Duplicate 'ApplicationDefinition' items were included.
- Duplicate 'Page' items were included.

These errors are a result of the implicit `/Include` globs conflicting with your settings. To work around this problem, set either `EnableDefaultApplicationDefinition` or `EnableDefaultPageItems` to `false`. Setting these values to `false` reverts to the behavior of previous SDKs where you had to explicitly define the default globs in your project, or explicitly define the files to include in the project.

You can completely disable all implicit includes by setting the `EnableDefaultItems` property to `false`.

WPF settings

- [UseWPF](#)
- [EnableDefaultApplicationDefinition](#)
- [EnableDefaultPageItems](#)

For information about non-WPF-specific project settings, see [MSBuild reference for .NET SDK projects](#).

UseWPF

The `useWPF` property controls whether or not to include references to WPF libraries. This also alters the MSBuild pipeline to correctly process a WPF project and related files. The default value is `false`. Set the `useWPF` property to `true` to enable WPF support. You can only target the Windows platform when this property is enabled.

```
<PropertyGroup>
  <UseWPF>true</UseWPF>
</PropertyGroup>
```

When this property is set to `true`, .NET 5+ projects will automatically import the [.NET Desktop SDK](#).

.NET Core 3.1 projects need to explicitly target the [.NET Desktop SDK](#) to use this property.

EnableDefaultApplicationDefinition

The `EnableDefaultApplicationDefinition` property controls whether `ApplicationDefinition` items are implicitly included in the project. The default value is `true`. Set the `EnableDefaultApplicationDefinition` property to `false` to disable the implicit file inclusion.

```
<PropertyGroup>
  <EnableDefaultApplicationDefinition>false</EnableDefaultApplicationDefinition>
</PropertyGroup>
```

This property requires that the `EnableDefaultItems` property is set to `true`, which is the default setting.

EnableDefaultPageItems

The `EnableDefaultPageItems` property controls whether `Page` items, which are `.xaml` files, are implicitly included in the project. The default value is `true`. Set the `EnableDefaultPageItems` property to `false` to disable the implicit file inclusion.

```
<PropertyGroup>
  <EnableDefaultPageItems>false</EnableDefaultPageItems>
</PropertyGroup>
```

This property requires that the `EnableDefaultItems` property is set to `true`, which is the default

setting.

Windows Forms settings

- [ApplicationDefaultFont](#)
- [ApplicationHighDpiMode](#)
- [ApplicationUseCompatibleTextRendering](#)
- [ApplicationVisualStyles](#)
- [UseWindowsForms](#)

For information about non-WinForms-specific project properties, see [MSBuild reference for .NET SDK projects](#).

ApplicationDefaultFont

The `ApplicationDefaultFont` property specifies custom font information to be applied application-wide. It controls whether or not the source-generated `ApplicationConfiguration.Initialize()` API emits a call to the `Application.SetDefaultFont(Font)` method. The default value is an empty string, and it means the application default font is sourced from the `Control.DefaultFont` property.

A non-empty value must conform to a format equivalent to the output of the `FontConverter.ConvertTo` method invoked with the [invariant culture](#) (that is, list separator= , and decimal separator= .). The format is:

```
name, size[units[, style=style1[, style2, ...]]].
```

```
<PropertyGroup>
  <ApplicationDefaultFont>Calibri, 11pt, style=regular</ApplicationDefaultFont>
</PropertyGroup>
```

This property is supported by .NET 6 and later versions, and Visual Studio 2022 and later versions.

ApplicationHighDpiMode

The `ApplicationHighDpiMode` property specifies the application-wide default for the high DPI mode. It controls the argument of the `Application.SetHighDpiMode(HighDpiMode)` method emitted by the source-generated `ApplicationConfiguration.Initialize()` API. The default value is `SystemAware`.

```
<PropertyGroup>
  <ApplicationHighDpiMode>PerMonitorV2</ApplicationHighDpiMode>
</PropertyGroup>
```

The `ApplicationHighDpiMode` can be set to one of the `HighDpiMode` enum values:

VALUE	DESCRIPTION
<code>DpiUnaware</code>	The application window does not scale for DPI changes and always assumes a scale factor of 100%.
<code>DpiUnawareGdiScaled</code>	Similar to <code>DpiUnaware</code> , but improves the quality of GDI/GDI+ based content.
<code>PerMonitor</code>	The window checks for DPI when it's created and adjusts scale factor when the DPI changes.
<code>PerMonitorV2</code>	Similar to <code>PerMonitor</code> , but enables child window DPI change notification, improved scaling of comctl32 controls, and dialog scaling.

VALUE	DESCRIPTION
SystemAware	Default if not specified. The window queries for the DPI of the primary monitor once and uses this for the application on all monitors.

This property is supported by .NET 6 and later versions.

ApplicationUseCompatibleTextRendering

The `ApplicationUseCompatibleTextRendering` property specifies the application-wide default for the `UseCompatibleTextRendering` property defined on certain controls. It controls the argument of the `Application.SetCompatibleTextRenderingDefault(Boolean)` method emitted by the source-generated `ApplicationConfiguration.Initialize()` API. The default value is `false`.

```
<PropertyGroup>
  <ApplicationUseCompatibleTextRendering>true</ApplicationUseCompatibleTextRendering>
</PropertyGroup>
```

This property is supported by .NET 6 and later versions.

ApplicationVisualStyles

The `ApplicationVisualStyles` property specifies the application-wide default for enabling visual styles. It controls whether or not the source-generated `ApplicationConfiguration.Initialize()` API emits a call to `Application.EnableVisualStyles()`. The default value is `true`.

```
<PropertyGroup>
  <ApplicationVisualStyles>true</ApplicationVisualStyles>
</PropertyGroup>
```

This property is supported by .NET 6 and later versions.

UseWindowsForms

The `useWindowsForms` property controls whether or not your application is built to target Windows Forms. This property alters the MSBuild pipeline to correctly process a Windows Forms project and related files. The default value is `false`. Set the `useWindowsForms` property to `true` to enable Windows Forms support. You can only target the Windows platform when this setting is enabled.

```
<PropertyGroup>
  <UseWindowsForms>true</UseWindowsForms>
</PropertyGroup>
```

When this property is set to `true`, .NET 5+ projects will automatically import the [.NET Desktop SDK](#).

.NET Core 3.1 projects need to explicitly target the [.NET Desktop SDK](#) to use this property.

Shared settings

- [DisableWinExeOutputInference](#)

DisableWinExeOutputInference

Applies to .NET 5 SDK and later.

When an app has the `Exe` value set for the `outputType` property, a console window is created if the app isn't running from a console. This is generally not the desired behavior of a Windows Desktop app. With the `winExe`

value, a console window isn't created. Starting with the .NET 5 SDK, the `Exe` value is automatically transformed to `WinExe`.

The `DisableWinExeOutputInference` property reverts the behavior of treating `Exe` as `WinExe`. Set this value to `true` to restore the behavior of the `OutputType` property value of `Exe`. The default value is `false`.

```
<PropertyGroup>
  <DisableWinExeOutputInference>true</DisableWinExeOutputInference>
</PropertyGroup>
```

Target frameworks in SDK-style projects

9/20/2022 • 9 minutes to read • [Edit Online](#)

When you target a framework in an app or library, you're specifying the set of APIs that you'd like to make available to the app or library. You specify the target framework in your project file using a target framework moniker (TFM).

An app or library can target a version of [.NET Standard](#). .NET Standard versions represent standardized sets of APIs across all .NET implementations. For example, a library can target .NET Standard 1.6 and gain access to APIs that function across .NET Core and .NET Framework using the same codebase.

An app or library can also target a specific .NET implementation to gain access to implementation-specific APIs. For example, an app that targets Xamarin.iOS (for example, `xamarin.ios10`) has access to Xamarin-provided iOS API wrappers for iOS 10, or an app that targets Universal Windows Platform (UWP, `uap10.0`) has access to APIs that compile for devices that run Windows 10.

For some target frameworks, such as .NET Framework, the APIs are defined by the assemblies that the framework installs on a system and may include application framework APIs (for example, ASP.NET).

For package-based target frameworks (for example, .NET 5+, .NET Core, and .NET Standard), the APIs are defined by the NuGet packages included in the app or library.

Latest versions

The following table defines the most common target frameworks, how they're referenced, and which version of [.NET Standard](#) they implement. These target framework versions are the latest stable versions. Prerelease versions aren't shown. A target framework moniker (TFM) is a standardized token format for specifying the target framework of a .NET app or library.

TARGET FRAMEWORK	LATEST STABLE VERSION	TARGET FRAMEWORK MONIKER (TFM)	IMPLEMENTED .NET STANDARD VERSION
.NET 6	6	net6.0	2.1
.NET 5	5	net5.0	2.1
.NET Standard	2.1	netstandard2.1	N/A
.NET Core	3.1	netcoreapp3.1	2.1
.NET Framework	4.8	net48	2.0

Supported target frameworks

A target framework is typically referenced by a TFM. The following table shows the target frameworks supported by the .NET SDK and the NuGet client. Equivalents are shown within brackets. For example, `win81` is an equivalent TFM to `netcore451`.

TARGET FRAMEWORK	TFM
.NET 5+ (and .NET Core)	netcoreapp1.0 netcoreapp1.1 netcoreapp2.0 netcoreapp2.1 netcoreapp2.2 netcoreapp3.0 netcoreapp3.1 net5.0* net6.0* net7.0*
.NET Standard	netstandard1.0 netstandard1.1 netstandard1.2 netstandard1.3 netstandard1.4 netstandard1.5 netstandard1.6 netstandard2.0 netstandard2.1
.NET Framework	net11 net20 net35 net40 net403 net45 net451 net452 net46 net461 net462 net47 net471 net472 net48
Windows Store	netcore [netcore45] netcore45 [win] [win8] netcore451 [win81]
.NET Micro Framework	netmf
Silverlight	sl4 sl5
Windows Phone	wp [wp7] wp7 wp75 wp8 wp81 wpa81
Universal Windows Platform	uap [uap10.0] uap10.0 [win10] [netcore50]

* .NET 5 and later TFMs include some operating system-specific variations. For more information, see the following section, [.NET 5+ OS-specific TFMs](#).

.NET 5+ OS-specific TFMs

The `net5.0`, `net6.0`, and `net7.0` TFMs include technologies that work across different platforms. Specifying an *OS-specific TFM* makes APIs that are specific to an operating system available to your app, for example, Windows Forms or iOS bindings. OS-specific TFMs also inherit every API available to their base TFM, for example, the `net6.0` TFM.

.NET 5 introduced the `net5.0-windows` OS-specific TFM, which includes Windows-specific bindings for WinForms, WPF, and UWP APIs. .NET 6 introduces further OS-specific TFMs.

The following table shows the compatibility of the .NET 5+ TFMs.

TFM	COMPATIBLE WITH
net5.0	net1.4 (with NU1701 warning) netcoreapp1..3.1 (warning when WinForms or WPF is referenced) netstandard1..2.1
net5.0-windows	netcoreapp1..3.1 (plus everything else inherited from <code>net5.0</code>)
net6.0	(subsequent version of <code>net5.0</code>)
net6.0-android	<code>xamarin.android</code> (+everything else inherited from <code>net6.0</code>)
net6.0-ios	<code>xamarin.ios</code> (+everything else inherited from <code>net6.0</code>)
net6.0-maccatalyst	<code>xamarin.ios</code> (+everything else inherited from <code>net6.0</code>)
net6.0-macos	<code>xamarin.mac</code> (+everything else inherited from <code>net6.0</code>)
net6.0-tvos	<code>xamarin.tvos</code> (+everything else inherited from <code>net6.0</code>)
net6.0-windows	(subsequent version of <code>net5.0-windows</code>)
net7.0	(subsequent version of <code>net6.0</code>)
net7.0-android	(subsequent version of <code>net6.0-android</code>)
net7.0-ios	(subsequent version of <code>net6.0-ios</code>)
net7.0-maccatalyst	(subsequent version of <code>net6.0-maccatalyst</code>)
net7.0-macos	(subsequent version of <code>net6.0-macos</code>)
net7.0-tvos	(subsequent version of <code>net6.0-tvos</code>)
net7.0-windows	(subsequent version of <code>net6.0-windows</code>)

To make your app portable across different platforms but still have access to OS-specific APIs, you can target multiple OS-specific TFMs and add platform guards around OS-specific API calls using `#if` preprocessor directives.

Suggested targets

Use these guidelines to determine which TFM to use in your app:

- Apps that are portable to multiple platforms should target a base TFM, for example, `net6.0`. This includes most libraries but also ASP.NET Core and Entity Framework.
- Platform-specific libraries should target platform-specific flavors. For example, WinForms and WPF projects should target `net6.0-windows`.
- Cross-platform application models (Xamarin Forms, ASP.NET Core) and bridge packs (Xamarin Essentials) should at least target the base TFM, for example, `net6.0`, but might also target additional platform-specific flavors to light-up more APIs or features.

OS version in TFMs

You can also specify an optional OS version at the end of an OS-specific TFM, for example, `net6.0-ios15.0`. The version indicates which APIs are available to your app or library. It does not control the OS version that your app or library supports at run time. It's used to select the reference assemblies that your project compiles against, and to select assets from NuGet packages. Think of this version as the "platform version" or "OS API version" to disambiguate it from the run-time OS version.

When an OS-specific TFM doesn't specify the platform version explicitly, it has an implied value that can be inferred from the base TFM and platform name. For example, the default platform value for iOS in .NET 6 is `15.0`, which means that `net6.0-ios` is shorthand for the canonical `net6.0-ios15.0` TFM. The implied platform version for a newer base TFM may be higher, for example, a future `net8.0-ios` TFM could map to `net8.0-ios16.0`. The shorthand form is intended for use in project files only, and is expanded to the canonical form by the .NET SDK's MSBuild targets before being passed to other tools, such as NuGet.

The .NET SDK is designed to be able to support newly released APIs for an individual platform without a new version of the base TFM. This enables you to access platform-specific functionality without waiting for a major release of .NET. You can gain access to these newly released APIs by incrementing the platform version in the TFM. For example, if the iOS platform added iOS 15.1 APIs in a .NET 6.0.x SDK update, you could access them by using the TFM `net6.0-ios15.1`.

Support older OS versions

Although a platform-specific app or library is compiled against APIs from a specific version of that OS, you can make it compatible with earlier OS versions by adding the `SupportedOSPlatformVersion` property to your project file. The `SupportedOSPlatformVersion` property indicates the minimum OS version required to run your app or library. If you don't explicitly specify this minimum run-time OS version in the project, it defaults to the platform version from the TFM.

For your app to run correctly on an older OS version, it can't call APIs that don't exist on that version of the OS. However, you can add guards around calls to newer APIs so they are only called when running on a version of the OS that supports them. This pattern allows you to design your app or library to support running on older OS versions while taking advantage of newer OS functionality when running on newer OS versions.

The `SupportedOSPlatformVersion` value (whether explicit or default) is used by the [platform compatibility analyzer](#), which detects and warns about unguarded calls to newer APIs. It's burned into the project's compiled assembly as an `UnsupportedOSPlatformAttribute` assembly attribute, so that the platform compatibility analyzer can detect unguarded calls to that assembly's APIs from projects with a lower `SupportedOSPlatformVersion` value. On some platforms, the `SupportedOSPlatformVersion` value affects platform-specific app packaging and build processes, which is covered in the documentation for those platforms.

Here is an example excerpt of a project file that uses the `TargetFramework` and `SupportedOSPlatformVersion` MSBuild properties to specify that the app or library has access to iOS 15.0 APIs but supports running on iOS 13.0 and above:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFramework>net6.0-ios15.0</TargetFramework>
  <SupportedOSPlatformVersion>13.0</SupportedOSPlatformVersion>
</PropertyGroup>

...

</Project>
```

How to specify a target framework

Target frameworks are specified in a project file. When a single target framework is specified, use the [TargetFramework element](#). The following console app project file demonstrates how to target .NET 6:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <OutputType>Exe</OutputType>
  <TargetFramework>net6.0</TargetFramework>
</PropertyGroup>

</Project>
```

When you specify multiple target frameworks, you may conditionally reference assemblies for each target framework. In your code, you can conditionally compile against those assemblies by using preprocessor symbols with *if-then-else* logic.

The following library project targets APIs of .NET Standard (`netstandard1.4`) and .NET Framework (`net40` and `net45`). Use the plural [TargetFrameworks element](#) with multiple target frameworks. The `Condition` attributes include implementation-specific packages when the library is compiled for the two .NET Framework TFM's:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFrameworks>netstandard1.4;net40;net45</TargetFrameworks>
</PropertyGroup>

<!-- Conditionally obtain references for the .NET Framework 4.0 target -->
<ItemGroup Condition=" '$(TargetFramework)' == 'net40' ">
  <Reference Include="System.Net" />
</ItemGroup>

<!-- Conditionally obtain references for the .NET Framework 4.5 target -->
<ItemGroup Condition=" '$(TargetFramework)' == 'net45' ">
  <Reference Include="System.Net.Http" />
  <Reference Include="System.Threading.Tasks" />
</ItemGroup>

</Project>
```

Within your library or app, you write conditional code using [preprocessor directives](#) to compile for each target framework:

```

public class MyClass
{
    static void Main()
    {
#if NET40
        Console.WriteLine("Target framework: .NET Framework 4.0");
#elif NET45
        Console.WriteLine("Target framework: .NET Framework 4.5");
#else
        Console.WriteLine("Target framework: .NET Standard 1.4");
#endif
    }
}

```

The build system is aware of preprocessor symbols representing the target frameworks shown in the [Supported target framework versions](#) table when you're using SDK-style projects. When using a symbol that represents a .NET Standard, .NET Core, or .NET 5+ TFM, replace dots and hyphens with an underscore, and change lowercase letters to uppercase (for example, the symbol for `netstandard1.4` is `NETSTANDARD1_4`). You can disable generation of these symbols via the `DisableImplicitFrameworkDefines` property. For more information about this property, see [DisableImplicitFrameworkDefines](#).

The complete list of preprocessor symbols for .NET target frameworks is:

TARGET FRAMEWORKS	SYMBOLS	ADDITIONAL SYMBOLS AVAILABLE IN .NET 5+ SDK
.NET Framework	NETFRAMEWORK , NET48 , NET472 , NET471 , NET47 , NET462 , NET461 , NET46 , NET452 , NET451 , NET45 , NET40 , NET35 , NET20	NET48_OR_GREATER , NET472_OR_GREATER , NET471_OR_GREATER , NET47_OR_GREATER , NET462_OR_GREATER , NET461_OR_GREATER , NET46_OR_GREATER , NET452_OR_GREATER , NET451_OR_GREATER , NET45_OR_GREATER , NET40_OR_GREATER , NET35_OR_GREATER , NET20_OR_GREATER
.NET Standard	NETSTANDARD , NETSTANDARD2_1 , NETSTANDARD2_0 , NETSTANDARD1_6 , NETSTANDARD1_5 , NETSTANDARD1_4 , NETSTANDARD1_3 , NETSTANDARD1_2 , NETSTANDARD1_1 , NETSTANDARD1_0	NETSTANDARD2_1_OR_GREATER , NETSTANDARD2_0_OR_GREATER , NETSTANDARD1_6_OR_GREATER , NETSTANDARD1_5_OR_GREATER , NETSTANDARD1_4_OR_GREATER , NETSTANDARD1_3_OR_GREATER , NETSTANDARD1_2_OR_GREATER , NETSTANDARD1_1_OR_GREATER , NETSTANDARD1_0_OR_GREATER

TARGET FRAMEWORKS	SYMBOLS	ADDITIONAL SYMBOLS AVAILABLE IN .NET 5+ SDK
.NET 5+ (and .NET Core)	NET , NET7_0 , NET6_0 , NET5_0 , NETCOREAPP , NETCOREAPP3_1 , NETCOREAPP3_0 , NETCOREAPP2_2 , NETCOREAPP2_1 , NETCOREAPP2_0 , NETCOREAPP1_1 , NETCOREAPP1_0	NET7_0_OR_GREATER , NET6_0_OR_GREATER , NET5_0_OR_GREATER , NETCOREAPP3_1_OR_GREATER , NETCOREAPP3_0_OR_GREATER , NETCOREAPP2_2_OR_GREATER , NETCOREAPP2_1_OR_GREATER , NETCOREAPP2_0_OR_GREATER , NETCOREAPP1_1_OR_GREATER , NETCOREAPP1_0_OR_GREATER

NOTE

- Versionless symbols are defined regardless of the version you're targeting.
- Version-specific symbols are only defined for the version you're targeting.
- The `<framework>_OR_GREATER` symbols are defined for the version you're targeting and all earlier versions. For example, if you're targeting .NET Framework 2.0, the following symbols are defined: `NET20` , `NET20_OR_GREATER` , `NET11_OR_GREATER` , and `NET10_OR_GREATER` .
- These are different from the target framework monikers (TFMs) used by the MSBuild `TargetFramework` property and NuGet.

Deprecated target frameworks

The following target frameworks are deprecated. Packages that target these target frameworks should migrate to the indicated replacements.

DEPRECATED TFM	REPLACEMENT
aspnet50 aspnetcore50 dnxcore50 dnx dnx45 dnx451 dnx452	netcoreapp
dotnet dotnet50 dotnet51 dotnet52 dotnet53 dotnet54 dotnet55 dotnet56	netstandard
netcore50	uap10.0
win	netcore45
win8	netcore45
win81	netcore451

DEPRECATED TFM	REPLACEMENT
win10	uap10.0
winrt	netcore45

Manage package dependencies in .NET applications

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article explains how to add and remove package dependencies by editing the project file or by using the CLI.

The `<PackageReference>` element

The `<PackageReference>` project file element has the following structure:

```
<PackageReference Include="PACKAGE_ID" Version="PACKAGE_VERSION" />
```

The `Include` attribute specifies the ID of the package to add to the project. The `Version` attribute specifies the version to get. Versions are specified as per [NuGet version rules](#).

NOTE

If you're not familiar with project-file syntax, see the [MSBuild project reference](#) documentation for more information.

Use conditions to add a dependency that's available only in a specific target, as shown in the following example:

```
<PackageReference Include="PACKAGE_ID" Version="PACKAGE_VERSION" Condition="'$(TargetFramework)' == 'netcoreapp2.1'" />
```

The dependency in the preceding example will only be valid if the build is happening for that given target. The `$(TargetFramework)` in the condition is an MSBuild property that's being set in the project. For most common .NET applications, you don't need to do this.

Add a dependency by editing the project file

To add a dependency, add a `<PackageReference>` element inside an `<ItemGroup>` element. You can add to an existing `<ItemGroup>` or create a new one. The following example uses the default console application project that's created by `dotnet new console`:

```
<Project Sdk="Microsoft.NET.Sdk.Web">

  <PropertyGroup>
    <TargetFramework>netcoreapp3.1</TargetFramework>
  </PropertyGroup>

  <ItemGroup>
    <PackageReference Include="Microsoft.EntityFrameworkCore" Version="3.1.2" />
  </ItemGroup>

</Project>
```

Add a dependency by using the CLI

To add a dependency, run the `dotnet add package` command, as shown in the following example:

```
dotnet add package Microsoft.EntityFrameworkCore
```

Remove a dependency by editing the project file

To remove a dependency, remove its `<PackageReference>` element from the project file.

Remove a dependency by using the CLI

To remove a dependency, run the [dotnet remove package](#) command, as shown in the following example:

```
dotnet remove package Microsoft.EntityFrameworkCore
```

How to manage .NET tools

9/20/2022 • 8 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions.

A .NET tool is a special NuGet package that contains a console application. You can install a tool on your machine in the following ways:

- As a global tool.

The tool binaries are installed in a default directory that's added to the PATH environment variable. You can invoke the tool from any directory on the machine without specifying its location. One version of a tool is used for all directories on the machine.

- As a global tool in a custom location (also known as a tool-path tool).

The tool binaries are installed in a location that you specify. You can invoke the tool from the installation directory, by providing the directory with the command name, or by adding the directory to the PATH environment variable. One version of a tool is used for all directories on the machine.

- As a local tool (applies to .NET Core SDK 3.0 and later versions).

The tool binaries are installed in a default directory. You can invoke the tool from the installation directory or any of its subdirectories. Different directories can use different versions of the same tool.

The .NET CLI uses manifest files to keep track of tools that are installed as local to a directory. When the manifest file is saved in the root directory of a source code repository, a contributor can clone the repository and invoke a single .NET CLI command to install all of the tools listed in the manifest files.

IMPORTANT

.NET tools run in full trust. Don't install a .NET tool unless you trust the author.

Find a tool

Here are some ways to find tools:

- Use the [dotnet tool search](#) command to find a tool that's published to NuGet.org.
- Use the ".NET tool" package type filter to search for the [NuGet](#) website. For more information, see [Finding and choosing packages](#).
- See the source code for the tools the ASP.NET Core team created in the [Tools directory of the dotnet/aspnetcore GitHub repository](#).
- Learn about diagnostic tools at [.NET diagnostic tools](#).

Check the author and statistics

.NET tools can be powerful because they run in full trust, and global tools are added to the PATH environment variable. Don't download tools from people you don't trust.

If the tool is hosted on NuGet, you can check the author and statistics by searching for the tool.

Install a global tool

To install a tool as a global tool, use the `-g` or `--global` option of [dotnet tool install](#), as shown in the following example:

```
dotnet tool install -g dotnetsay
```

The output shows the command used to invoke the tool and the version installed, similar to the following example:

```
You can invoke the tool using the following command: dotnetsay
Tool 'dotnetsay' (version '2.1.4') was successfully installed.
```

The default location for a tool's binaries depends on the operating system:

OS	PATH
Linux/macOS	<code>\$HOME/.dotnet/tools</code>
Windows	<code>%USERPROFILE%\.dotnet\tools</code>

This location is added to the user's path when the SDK is first run. So global tools can be invoked from any directory without specifying the tool location.

Tool access is user-specific, not machine global. A global tool is only available to the user that installed the tool.

Install a global tool in a custom location

To install a tool as a global tool in a custom location, use the `--tool-path` option of [dotnet tool install](#), as shown in the following examples:

On Windows:

```
dotnet tool install dotnetsay --tool-path c:\dotnet-tools
```

On Linux or macOS:

```
dotnet tool install dotnetsay --tool-path ~/bin
```

The .NET SDK doesn't add this location automatically to the PATH environment variable. To [invoke a tool-path tool](#), you must ensure that the command is available by using one of the following methods:

- Add the installation directory to the PATH environment variable.
- Specify the full path to the tool when you invoke it.
- Invoke the tool from within the installation directory.

Install a local tool

Applies to .NET Core 3.0 SDK and later.

If you want to install a tool for local access only (for the current directory and subdirectories), you must add the tool to a tool manifest file. To create a tool manifest file, run the `dotnet new tool-manifest` command:

```
dotnet new tool-manifest
```

This command creates a manifest file named `dotnet-tools.json` under the `.config` directory. To add a local tool to the manifest file, use the `dotnet tool install` command and omit the `--global` and `--tool-path` options, as shown in the following example:

```
dotnet tool install dotnetsay
```

The command output shows in which manifest file the newly installed tool is present, similar to the following example:

```
You can invoke the tool from this directory using the following command:  
dotnet tool run dotnetsay  
Tool 'dotnetsay' (version '2.1.4') was successfully installed.  
Entry is added to the manifest file /home/name/botsay/.config/dotnet-tools.json.
```

The following example shows a manifest file with two local tools installed:

```
{  
  "version": 1,  
  "isRoot": true,  
  "tools": {  
    "botsay": {  
      "version": "1.0.0",  
      "commands": [  
        "botsay"  
      ]  
    },  
    "dotnetsay": {  
      "version": "2.1.3",  
      "commands": [  
        "dotnetsay"  
      ]  
    }  
  }  
}
```

You typically add a local tool to the root directory of the repository. After you check in the manifest file to the repository, developers who check out code from the repository get the latest manifest file. To install all of the tools listed in the manifest file, they run the `dotnet tool restore` command:

```
dotnet tool restore
```

The output indicates the restored tools:

```
Tool 'botsay' (version '1.0.0') was restored. Available commands: botsay  
Tool 'dotnetsay' (version '2.1.3') was restored. Available commands: dotnetsay  
Restore was successful.
```

Install a specific tool version

To install a pre-release version or a specific version of a tool, specify the version number by using the `--version` option, as shown in the following example:

```
dotnet tool install dotnetsay --version 2.1.3
```

To install a pre-release version of the tool without specifying the exact version number, use the `--version` option and provide a wildcard, as shown in the following example:

```
dotnet tool install --global dotnetsay --version "*-rc*"
```

Use a tool

The command that you use to invoke a tool might be different from the name of the package that you install. To display all of the tools currently installed on the machine for the current user, use the [dotnet tool list](#) command:

```
dotnet tool list
```

The output shows each tool's version and command, similar to the following example:

Package Id	Version	Commands	Manifest
botsay	1.0.0	botsay	/home/name/repository/.config/dotnet-tools.json
dotnetsay	2.1.3	dotnetsay	/home/name/repository/.config/dotnet-tools.json

As shown in the preceding example, the list shows local tools. To see global tools, use the `--global` option. To see tool-path tools, use the `--tool-path` option.

Invoke a global tool

For global tools, use the tool command by itself. For example, if the command is `dotnetsay` or `dotnet-doc`, that's what you use to invoke the global tool:

```
dotnetsay  
dotnet-doc
```

If the command begins with the prefix `dotnet-`, an alternative way to invoke the tool is to use the `dotnet` command and omit the tool command prefix. For example, if the command is `dotnet-doc`, the following command invokes the tool:

```
dotnet doc
```

However, in the following scenario you can't use the `dotnet` command to invoke a global tool:

- A global tool and a local tool have the same command prefixed by `dotnet-`.
- You want to invoke the global tool from a directory that's in scope for the local tool.

In this scenario, `dotnet doc` and `dotnet dotnet-doc` invoke the local tool. To invoke the global tool, use the command by itself:

```
dotnet-doc
```

Invoke a tool-path tool

To invoke a global tool that's installed by using the `tool-path` option, ensure that the command is available as explained [earlier in this article](#).

Invoke a local tool

To invoke a local tool, you must use the `dotnet` command from within the installation directory. You can use the

long form (`dotnet tool run <COMMAND_NAME>`) or the short form (`dotnet <COMMAND_NAME>`), as shown in the following examples:

```
dotnet tool run dotnetsay  
dotnet dotnetsay
```

If the command is prefixed by `dotnet-`, you can include or omit the prefix when you invoke the tool. For example, if the command is `dotnet-doc`, any of the following examples invokes the local tool:

```
dotnet tool run dotnet-doc  
dotnet dotnet-doc  
dotnet doc
```

Update a tool

Updating a tool involves uninstalling and reinstalling it with the latest stable version. To update a tool, use the [dotnet tool update](#) command with the same option that you used to install the tool:

```
dotnet tool update --global <packagename>  
dotnet tool update --tool-path <packagename>  
dotnet tool update <packagename>
```

For a local tool, the SDK looks in the current directory and parent directories to find the first manifest file containing the package ID. If there's no such package ID in any manifest file, the SDK adds a new entry to the closest manifest file.

Uninstall a tool

Uninstall a tool by using the [dotnet tool uninstall](#) command with the same option that you used to install the tool:

```
dotnet tool uninstall --global <packagename>  
dotnet tool uninstall --tool-path <packagename>  
dotnet tool uninstall <packagename>
```

For a local tool, the SDK looks in the current directory and parent directories to find the first manifest file containing the package ID.

Get help and troubleshoot

If a tool fails to install or run, see [Troubleshoot .NET tool usage issues](#). You can get a list of available `dotnet tool` commands and parameters by using the `--help` parameter:

```
dotnet tool --help
```

To get tool usage instructions, enter one of the following commands or see the tool's website:

```
<command> --help  
dotnet <command> --help
```

Troubleshoot .NET tool usage issues

9/20/2022 • 8 minutes to read • [Edit Online](#)

You might come across issues when trying to install or run a .NET tool, which can be a global tool or a local tool. This article describes the common root causes and some possible solutions.

Installed .NET tool fails to run

When a .NET tool fails to run, most likely you ran into one of the following issues:

- [The executable file for the tool wasn't found.](#)
- [The correct version of the .NET runtime wasn't found.](#)

Executable file not found

If the executable file isn't found, you'll see a message similar to the following:

```
Could not execute because the specified command or file was not found.  
Possible reasons for this include:  
* You misspelled a built-in dotnet command.  
* You intended to execute a .NET program, but dotnet-xyz does not exist.  
* You intended to run a global tool, but a dotnet-prefixed executable with this name could not be found on  
the PATH.
```

The name of the executable determines how you invoke the tool. The following table describes the format:

EXECUTABLE NAME FORMAT	INVOCATION FORMAT
<code>dotnet-<toolName>.exe</code>	<code>dotnet <toolName></code>
<code><toolName>.exe</code>	<code><toolName></code>

Global tools

Global tools can be installed in the default directory or in a specific location. The default directories are:

OS	PATH
Linux/macOS	<code>\$HOME/.dotnet/tools</code>
Windows	<code>%USERPROFILE%\.dotnet\tools</code>

If you're trying to run a global tool, check that the `PATH` environment variable on your machine contains the path where you installed the global tool and that the executable is in that path.

The .NET CLI tries to add the default location to the `PATH` environment variable on its first usage. However, there are some scenarios where the location might not be added to `PATH` automatically:

- If you're using Linux and you've installed the .NET SDK using `.tar.gz` files and not `apt-get` or `rpm`.
- If you're using macOS 10.15 "Catalina" or later versions.
- If you're using macOS 10.14 "Mojave" or earlier versions, and you've installed the .NET SDK using `.tar.gz` files and not `.pkg`.
- If you've installed the .NET Core 3.0 SDK and you've set the `DOTNET_ADD_GLOBAL_TOOLS_TO_PATH` environment

variable to `false`.

- If you've installed .NET Core 2.2 SDK or earlier versions, and you've set the `DOTNET_SKIP_FIRST_TIME_EXPERIENCE` environment variable to `true`.

In these scenarios or if you specified the `--tool-path` option, the `PATH` environment variable on your machine doesn't automatically contain the path where you installed the global tool. In that case, append the tool location (for example, `$HOME/.dotnet/tools`) to the `PATH` environment variable by using whatever method your shell provides for updating environment variables. For more information, see [.NET tools](#).

Local tools

If you're trying to run a local tool, verify that there's a manifest file called `dotnet-tools.json` in the current directory or any of its parent directories. This file can also live under a folder named `.config` anywhere in the project folder hierarchy, instead of the root folder. If `dotnet-tools.json` exists, open it and check for the tool you're trying to run. If the file doesn't contain an entry for `"isRoot": true`, then also check further up the file hierarchy for additional tool manifest files.

If you're trying to run a .NET tool that was installed with a specified path, you need to include that path when using the tool. An example of using a tool-path installed tool is:

```
..\<toolDirectory>\dotnet-<toolName>
```

Runtime not found

.NET tools are [framework-dependent applications](#), which means they rely on a .NET runtime installed on your machine. If the expected runtime isn't found, they follow normal .NET runtime roll-forward rules such as:

- An application rolls forward to the highest patch release of the specified major and minor version.
- If there's no matching runtime with a matching major and minor version number, the next higher minor version is used.
- Roll forward doesn't occur between preview versions of the runtime or between preview versions and release versions. So, .NET tools created using preview versions must be rebuilt and republished by the author and reinstalled.

Roll-forward won't occur by default in two common scenarios:

- Only lower versions of the runtime are available. Roll-forward only selects later versions of the runtime.
- Only higher major versions of the runtime are available. Roll-forward doesn't cross major version boundaries.

If an application can't find an appropriate runtime, it fails to run and reports an error.

You can find out which .NET runtimes are installed on your machine using one of the following commands:

```
dotnet --list-runtimes  
dotnet --info
```

If you think the tool should support the runtime version you currently have installed, you can contact the tool author and see if they can update the version number or multi-target. Once they've recompiled and republished their tool package to NuGet with an updated version number, you can update your copy. While that doesn't happen, the quickest solution for you is to install a version of the runtime that would work with the tool you're trying to run. To download a specific .NET runtime version, visit the [.NET download page](#).

If you install the .NET SDK to a non-default location, you need to set the environment variable `DOTNET_ROOT` to the directory that contains the `dotnet` executable.

.NET tool installation fails

There are a number of reasons the installation of a .NET global or local tool may fail. When the tool installation fails, you'll see a message similar to the following one:

```
Tool '{0}' failed to install. This failure may have been caused by:  
* You are attempting to install a preview release and did not use the --version option to specify the version.  
* A package by this name was found, but it was not a .NET tool.  
* The required NuGet feed cannot be accessed, perhaps because of an Internet connection problem.  
* You mistyped the name of the tool.  
  
For more reasons, including package naming enforcement, visit https://aka.ms/failure-installing-tool
```

To help diagnose these failures, NuGet messages are shown directly to the user, along with the previous message. The NuGet message may help you identify the problem.

- [Package naming enforcement](#)
- [Preview releases](#)
- [Package isn't a .NET tool](#)
- [NuGet feed can't be accessed](#)
- [Package ID incorrect](#)
- [401 \(Unauthorized\)](#)

Package naming enforcement

Microsoft has changed its guidance on the Package ID for tools, resulting in a number of tools not being found with the predicted name. The new guidance is that all Microsoft tools be prefixed with "Microsoft." This prefix is reserved and can only be used for packages signed with a Microsoft authorized certificate.

During the transition, some Microsoft tools will have the old form of the package ID, while others will have the new form:

```
dotnet tool install -g Microsoft.<toolName>  
dotnet tool install -g <toolName>
```

As package IDs are updated, you'll need to change to the new package ID to get the latest updates. Packages with the simplified tool name will be deprecated.

Preview releases

- You're attempting to install a preview release and didn't use the `--version` option to specify the version.

.NET tools that are in preview must be specified with a portion of the name to indicate that they are in preview. You don't need to include the entire preview. Assuming the version numbers are in the expected format, you can use something like the following example:

```
dotnet tool install -g --version 1.1.0-pre <toolName>
```

Package isn't a .NET tool

- A NuGet package by this name was found, but it wasn't a .NET tool.

If you try to install a NuGet package that is a regular NuGet package and not a .NET tool, you'll see an error similar to the following:

NU1212: Invalid project-package combination for <toolName>. DotnetToolReference project style can only contain references of the DotnetTool type.

NuGet feed can't be accessed

- The required NuGet feed can't be accessed, perhaps because of an Internet connection problem.

Tool installation requires access to the NuGet feed that contains the tool package. It fails if the feed isn't available. You can alter feeds with `nuget.config`, request a specific `nuget.config` file, or specify additional feeds with the `--add-source` switch. By default, NuGet throws an error for any feed that can't connect. The flag `--ignore-failed-sources` can skip these non-reachable sources.

Package ID incorrect

- You mistyped the name of the tool.

A common reason for failure is that the tool name isn't correct. This can happen because of mistyping, or because the tool has moved or been deprecated. For tools on NuGet.org, one way to ensure you have the name correct is to search for the tool at NuGet.org and copy the installation command.

401 (Unauthorized)

Most likely you've specified an alternative NuGet feed, and that feed requires authentication. There are a few different ways to solve this:

- Add the `--ignore-failed-sources` parameter to bypass the error from the private feed and use the public Microsoft feed.

If you're installing a tool from the Microsoft NuGet feed, your custom feed is returning this error before Microsoft's NuGet feed returns a result. The error terminates the request, canceling any other pending feed requests, which could be Microsoft's NuGet feed. Adding the `--ignore-failed-sources` option causes the command to treat this error as a warning and allows other feeds to process the request.

```
dotnet tool install -g --ignore-failed-sources <toolName>
```

- Force the Microsoft NuGet feed with the `--add-source` parameter.

It's possible that the global or local NuGet config file is missing the public Microsoft NuGet feed. Use a combination of the `--add-source` and `--ignore-failed-sources` parameters to avoid the erroneous feed and rely on the public Microsoft feed.

```
dotnet tool install -g --add-source 'https://api.nuget.org/v3/index.json' --ignore-failed-sources <toolName>
```

- Use a custom NuGet config, `--configfile <FILE>` parameter.

Create a local `nuget.config` file with just the public Microsoft NuGet feed, and reference it with the `--configfile` parameter:

```
dotnet tool install -g --configfile "./nuget.config" <toolName>
```

Here's an example config file:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <packageSources>
    <add key="nuget.org" value="https://api.nuget.org/v3/index.json" protocolVersion="3" />
  </packageSources>
</configuration>
```

For more information, see [nuget.config reference](#)

- Add the required credentials to the config file.

If you know the package exists in the configured feed, provide the login credentials in the NuGet config file. For more information about credentials in a nuget config file, see the [nuget.config reference's packageSourceCredentials section](#).

Tutorial: Create a .NET tool using the .NET CLI

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

This tutorial teaches you how to create and package a .NET tool. The .NET CLI lets you create a console application as a tool, which others can install and run. .NET tools are NuGet packages that are installed from the .NET CLI. For more information about tools, see [.NET tools overview](#).

The tool that you'll create is a console application that takes a message as input and displays the message along with lines of text that create the image of a robot.

This is the first in a series of three tutorials. In this tutorial, you create and package a tool. In the next two tutorials you [use the tool as a global tool](#) and [use the tool as a local tool](#). The procedures for creating a tool are the same whether you use it as a global tool or as a local tool.

Prerequisites

- [.NET SDK 6.0.100](#) or a later version.

This tutorial uses .NET SDK 6.0, but global tools are available starting in .NET Core SDK 2.1. Local tools are available starting in .NET Core SDK 3.0.

- A text editor or code editor of your choice.

Create a project

1. Open a command prompt and create a folder named *repository*.
2. Navigate to the *repository* folder and enter the following command:

```
dotnet new console -n microsoft.botsay -f net6.0
```

The command creates a new folder named *microsoft.botsay* under the *repository* folder.

NOTE

For this tutorial you create a tool that targets .NET 6.0. To target a different framework, change the `-f|--framework` option. To target multiple frameworks, change the `TargetFramework` element to a `TargetFrameworks` element in the project file, as shown in the following example:

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <OutputType>Exe</OutputType>
    <TargetFrameworks>netcoreapp3.1;net5.0;net6.0</TargetFrameworks>
  </PropertyGroup>
</Project>
```

3. Navigate to the *microsoft.botsay* folder.

```
cd microsoft.botsay
```

Add the code

1. Open the *Program.cs* file with your code editor.
2. Replace the code in *Program.cs* with the following code:

```
using System.Reflection;

namespace TeleprompterConsole;

internal class Program
{
    static void Main(string[] args)
    {
        Console.WriteLine("Hello World!");
    }
}
```

3. Replace the `Main` method with the following code to process the command-line arguments for the application.

```
static void Main(string[] args)
{
    if (args.Length == 0)
    {
        var versionString = Assembly.GetEntryAssembly()?
            .GetCustomAttribute<AssemblyInformationalVersionAttribute>()?
            .InformationalVersion
            .ToString();

        Console.WriteLine($"botsay v{versionString}");
        Console.WriteLine("-----");
        Console.WriteLine("\nUsage:");
        Console.WriteLine("  botsay <message>");
        return;
    }

    ShowBot(string.Join(' ', args));
}
```

If no arguments are passed, a short help message is displayed. Otherwise, all of the arguments are concatenated into a single string and printed by calling the `ShowBot` method that you create in the next step.

4. Add a new method named `ShowBot` that takes a string parameter. The method prints out the message and an image of a robot using lines of text.

5. Save your changes.

```
dotnet run  
dotnet run -- "Hello from the bot"  
dotnet run -- Hello from the bot
```

All arguments after the `--` delimiter are passed to your application.

Package the tool

Before you can pack and distribute the application as a tool, you need to modify the project file.

1. Open the `microsoft.botsav.csproj` file and add three new XML nodes to the end of the `<PropertyGroup>`

node:

```
<PackAsTool>true</PackAsTool>
<ToolCommandName>botsay</ToolCommandName>
<PackageOutputPath>./nupkg</PackageOutputPath>
```

`<ToolCommandName>` is an optional element that specifies the command that will invoke the tool after it's installed. If this element isn't provided, the command name for the tool is the project file name without the `.csproj` extension.

`<PackageOutputPath>` is an optional element that determines where the NuGet package will be produced. The NuGet package is what the .NET CLI uses to install your tool.

The project file now looks like the following example:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>

    <OutputType>Exe</OutputType>
    <TargetFramework>net6.0</TargetFramework>

    <PackAsTool>true</PackAsTool>
    <ToolCommandName>botsay</ToolCommandName>
    <PackageOutputPath>./nupkg</PackageOutputPath>

</PropertyGroup>

</Project>
```

2. Create a NuGet package by running the [dotnet pack](#) command:

```
dotnet pack
```

The `microsoft.botsay.1.0.0.nupkg` file is created in the folder identified by the `<PackageOutputPath>` value from the `microsoft.botsay.csproj` file, which in this example is the `./nupkg` folder.

When you want to release a tool publicly, you can upload it to <https://www.nuget.org>. Once the tool is available on NuGet, developers can install the tool by using the [dotnet tool install](#) command. For this tutorial you install the package directly from the local `nupkg` folder, so there's no need to upload the package to NuGet.

Troubleshoot

If you get an error message while following the tutorial, see [Troubleshoot .NET tool usage issues](#).

Next steps

In this tutorial, you created a console application and packaged it as a tool. To learn how to use the tool as a global tool, advance to the next tutorial.

[Install and use a global tool](#)

If you prefer, you can skip the global tools tutorial and go directly to the local tools tutorial.

[Install and use a local tool](#)

Tutorial: Install and use a .NET global tool using the .NET CLI

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

This tutorial teaches you how to install and use a global tool. You use a tool that you create in the [first tutorial of this series](#).

Prerequisites

- Complete the [first tutorial of this series](#).

Use the tool as a global tool

1. Install the tool from the package by running the `dotnet tool install` command in the `microsoft.botsay` project folder:

```
dotnet tool install --global --add-source ./nupkg microsoft.botsay
```

The `--global` parameter tells the .NET CLI to install the tool binaries in a default location that is automatically added to the PATH environment variable.

The `--add-source` parameter tells the .NET CLI to temporarily use the `./nupkg` directory as an additional source feed for NuGet packages. You gave your package a unique name to make sure that it will only be found in the `./nupkg` directory, not on the Nuget.org site.

The output shows the command used to call the tool and the version installed:

```
You can invoke the tool using the following command: botsay
Tool 'microsoft.botsay' (version '1.0.0') was successfully installed.
```

2. Invoke the tool:

```
botsay hello from the bot
```

NOTE

If this command fails, you may need to open a new terminal to refresh the PATH.

3. Remove the tool by running the `dotnet tool uninstall` command:

```
dotnet tool uninstall -g microsoft.botsay
```

Use the tool as a global tool installed in a custom location

1. Install the tool from the package.

On Windows:

```
dotnet tool install --tool-path c:\dotnet-tools --add-source ./nupkg microsoft.botsay
```

On Linux or macOS:

```
dotnet tool install --tool-path ~/bin --add-source ./nupkg microsoft.botsay
```

The `--tool-path` parameter tells the .NET CLI to install the tool binaries in the specified location. If the directory doesn't exist, it is created. This directory is not automatically added to the PATH environment variable.

The output shows the command used to call the tool and the version installed:

```
You can invoke the tool using the following command: botsay
Tool 'microsoft.botsay' (version '1.0.0') was successfully installed.
```

2. Invoke the tool:

On Windows:

```
c:\dotnet-tools\botsay hello from the bot
```

On Linux or macOS:

```
~/bin/botsay hello from the bot
```

3. Remove the tool by running the `dotnet tool uninstall` command:

On Windows:

```
dotnet tool uninstall --tool-path c:\dotnet-tools microsoft.botsay
```

On Linux or macOS:

```
dotnet tool uninstall --tool-path ~/bin microsoft.botsay
```

Troubleshoot

If you get an error message while following the tutorial, see [Troubleshoot .NET tool usage issues](#).

Next steps

In this tutorial, you installed and used a tool as a global tool. For more information about how to install and use global tools, see [Managing global tools](#). To install and use the same tool as a local tool, advance to the next tutorial.

[Install and use local tools](#)

Tutorial: Install and use a .NET local tool using the .NET CLI

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.0 SDK and later versions

This tutorial teaches you how to install and use a local tool. You use a tool that you create in the [first tutorial of this series](#).

Prerequisites

- Complete the [first tutorial of this series](#).
- Install the .NET Core 2.1 runtime.

For this tutorial you install and use a tool that targets .NET Core 2.1, so you need to have that runtime installed on your machine. To install the 2.1 runtime, go to the [.NET Core 2.1 download page](#) and find the runtime installation link in the **Run apps - Runtime** column.

Create a manifest file

To install a tool for local access only (for the current directory and subdirectories), it has to be added to a manifest file.

From the *microsoft.botsay* folder, navigate up one level to the *repository* folder:

```
cd ..
```

Create a manifest file by running the [dotnet new](#) command:

```
dotnet new tool-manifest
```

The output indicates successful creation of the file.

```
The template "Dotnet local tool manifest file" was created successfully.
```

The *.config/dotnet-tools.json* file has no tools in it yet:

```
{
  "version": 1,
  "isRoot": true,
  "tools": {}
}
```

The tools listed in a manifest file are available to the current directory and subdirectories. The current directory is the one that contains the *.config* directory with the manifest file.

When you use a CLI command that refers to a local tool, the SDK searches for a manifest file in the current directory and parent directories. If it finds a manifest file, but the file doesn't include the referenced tool, it continues the search up through parent directories. The search ends when it finds the referenced tool or it finds

a manifest file with `isRoot` set to `true`.

Install botsay as a local tool

Install the tool from the package that you created in the first tutorial:

```
dotnet tool install --add-source ./microsoft.botsay/nupkg microsoft.botsay
```

This command adds the tool to the manifest file that you created in the preceding step. The command output shows which manifest file the newly installed tool is in:

```
You can invoke the tool from this directory using the following command:  
'dotnet tool run botsay' or 'dotnet botsay'  
Tool 'microsoft.botsay' (version '1.0.0') was successfully installed.  
Entry is added to the manifest file /home/name/repository/.config/dotnet-tools.json
```

The `.config/dotnet-tools.json` file now has one tool:

```
{
  "version": 1,
  "isRoot": true,
  "tools": {
    "microsoft.botsay": {
      "version": "1.0.0",
      "commands": [
        "botsay"
      ]
    }
  }
}
```

Use the tool

Invoke the tool by running the `dotnet tool run` command from the `repository` folder:

```
dotnet tool run botsay hello from the bot
```

Restore a local tool installed by others

You typically install a local tool in the root directory of the repository. After you check in the manifest file to the repository, other developers can get the latest manifest file. To install all of the tools listed in the manifest file, they can run a single `dotnet tool restore` command.

1. Open the `.config/dotnet-tools.json` file, and replace the contents with the following JSON:

```
{  
    "version": 1,  
    "isRoot": true,  
    "tools": {  
        "microsoft.botsay": {  
            "version": "1.0.0",  
            "commands": [  
                "botsay"  
            ]  
        },  
        "dotnetsay": {  
            "version": "2.1.3",  
            "commands": [  
                "dotnetsay"  
            ]  
        }  
    }  
}
```

2. Save your changes.

Making this change is the same as getting the latest version from the repository after someone else installed the package `dotnetsay` for the project directory.

3. Run the `dotnet tool restore` command.

```
dotnet tool restore
```

The command produces output like the following example:

```
Tool 'microsoft.botsay' (version '1.0.0') was restored. Available commands: botsay  
Tool 'dotnetsay' (version '2.1.3') was restored. Available commands: dotnetsay  
Restore was successful.
```

4. Verify that the tools are available:

```
dotnet tool list
```

The output is a list of packages and commands, similar to the following example:

Package Id	Version	Commands	Manifest
microsoft.botsay	1.0.0	botsay	/home/name/repository/.config/dotnet-tools.json
dotnetsay	2.1.3	dotnetsay	/home/name/repository/.config/dotnet-tools.json

5. Test the tools:

```
dotnet tool run dotnetsay hello from dotnetsay  
dotnet tool run botsay hello from botsay
```

Update a local tool

The installed version of local tool `dotnetsay` is 2.1.3. Use the `dotnet tool update` command to update the tool to the latest version.

```
dotnet tool update dotnetsay
```

The output indicates the new version number:

```
Tool 'dotnetsay' was successfully updated from version '2.1.3' to version '2.1.7'  
(manifest file /home/name/repository/.config/dotnet-tools.json).
```

The update command finds the first manifest file that contains the package ID and updates it. If there is no such package ID in any manifest file that is in the scope of the search, the SDK adds a new entry to the closest manifest file. The search scope is up through parent directories until a manifest file with `isRoot = true` is found.

Remove local tools

Remove the installed tools by running the [dotnet tool uninstall](#) command:

```
dotnet tool uninstall microsoft.botsay
```

```
dotnet tool uninstall dotnetsay
```

Troubleshoot

If you get an error message while following the tutorial, see [Troubleshoot .NET tool usage issues](#).

For more information, see [.NET tools](#)

.NET additional tools overview

9/20/2022 • 2 minutes to read • [Edit Online](#)

This section compiles a list of tools that support and extend the .NET functionality, in addition to the .NET CLI.

.NET Uninstall Tool

The [.NET Uninstall Tool](#) (`dotnet-core-uninstall`) lets you clean up .NET SDKs and Runtimes on a system such that only the specified versions remain. A collection of options is available to specify which versions are uninstalled.

.NET diagnostic tools

[dotnet-counters](#) is a performance monitoring tool for first-level health monitoring and performance investigation.

[dotnet-dump](#) provides a way to collect and analyze Windows and Linux core dumps without a native debugger.

[dotnet-gcdump](#) provides a way to collect GC (Garbage Collector) dumps of live .NET processes.

[dotnet-monitor](#) provides a way to monitor .NET applications in production environments and to collect diagnostic artifacts (for example, dumps, traces, logs, and metrics) on-demand or using automated rules for collecting under specified conditions.

[dotnet-trace](#) collects profiling data from your app that can help in scenarios where you need to find out what causes an app to run slow.

.NET Install tool for extension authors

The [.NET Install tool for extension authors](#) is a Visual Studio Code extension that allows acquisition of the .NET runtime specifically for VS Code extension authors. This tool is intended to be leveraged in extensions that are written in .NET and require .NET to boot pieces of the extension (for example, a language server). The extension is not intended to be used directly by users to install .NET for development.

WCF Web Service Reference tool

The WCF (Windows Communication Foundation) [Web Service Reference tool](#) is a Visual Studio connected service provider that made its debut in [Visual Studio 2017 version 15.5](#). This tool retrieves metadata from a web service in the current solution, on a network location, or from a WSDL file. It generates a source file compatible with .NET, defining a WCF proxy class with methods that you can use to access the web service operations.

WCF dotnet-svcutil tool

The WCF [dotnet-svcutil tool](#) is a .NET tool that retrieves metadata from a web service on a network location or from a WSDL file. It generates a source file compatible with .NET, defining a WCF proxy class with methods that you can use to access the web service operations.

The [dotnet-svcutil](#) tool is an alternative to the [WCF Web Service Reference](#) Visual Studio connected service provider, which first shipped with Visual Studio 2017 version 15.5. The [dotnet-svcutil](#) tool, as a .NET tool, is available on Linux, macOS, and Windows.

WCF dotnet-svcutil.xmlserializer tool

On the .NET Framework, you can pre-generate a serialization assembly using the svcutil tool. The WCF [dotnet-svcutil.xmlserializer tool](#) provides similar functionality on .NET 5 (and .NET Core) and later versions. It pre-generates C# serialization code for the types in the client application that are used by the WCF Service Contract and that can be serialized by the [XmlSerializer](#). This improves the startup performance of XML serialization when serializing or deserializing objects of those types.

XML Serializer Generator

Like the [Xml Serializer Generator \(sgen.exe\)](#) for the .NET Framework, the [Microsoft.XmlSerializerGenerator NuGet package](#) is the solution for libraries that target .NET 5 (and .NET Core) and later versions. It creates an XML serialization assembly for types contained in an assembly to improve the startup performance of XML serialization when serializing or de-serializing objects of those types using [XmlSerializer](#).

Generating Self-Signed Certificates

You can use [dotnet dev-certs](#) to create self-signed certificates for development and testing scenarios.

.NET code coverage tool

You can use [dotnet-coverage](#) to collect [code coverage](#) from any .NET process.

.NET Uninstall Tool

9/20/2022 • 11 minutes to read • [Edit Online](#)

The [.NET Uninstall Tool](#) (`dotnet-core-uninstall`) lets you remove .NET SDKs and Runtimes from a system. A collection of options is available to specify which versions you want to uninstall.

The tool supports Windows and macOS. Linux is currently not supported.

On Windows, the tool can only uninstall SDKs and Runtimes that were installed using one of the following installers:

- The .NET SDK and runtime installer.
- The Visual Studio installer in versions earlier than Visual Studio 2019 version 16.3.

On macOS, the tool can only uninstall SDKs and runtimes located in the `/usr/local/share/dotnet` folder.

Because of these limitations, the tool may not be able to uninstall all of the .NET SDKs and runtimes on your machine. You can use the `dotnet --info` command to find all of the .NET SDKs and runtimes installed, including those SDKs and runtimes that this tool can't remove. The `dotnet-core-uninstall list` command displays which SDKs can be uninstalled with the tool. Versions 1.2 and later can uninstall SDKs and runtimes with version 5.0 or earlier, and previous versions of the tool can uninstall 3.1 and earlier.

Install the tool

You can download the .NET Uninstall Tool from [the tool's releases page](#) and find the source code at the [dotnet/cli-lab](#) GitHub repository.

NOTE

The tool requires elevation to uninstall .NET SDKs and runtimes. Therefore, it should be installed in a write-protected directory such as `C:\Program Files` on Windows or `/usr/local/bin` on macOS. See also [Elevated access for dotnet commands](#). For more information, see the [detailed installation instructions](#).

Run the tool

The following steps show the recommended approach for running the uninstall tool:

- [Step 1 - Display installed .NET SDKs and runtimes](#)
- [Step 2 - Do a dry run](#)
- [Step 3 - Uninstall .NET SDKs and Runtimes](#)
- [Step 4 - Delete the NuGet fallback folder \(optional\)](#)

Step 1 - Display installed .NET SDKs and runtimes

The `dotnet-core-uninstall list` command lists the installed .NET SDKs and runtimes that can be removed with this tool. Some SDKs and runtimes may be required by Visual Studio and they're displayed with a note of why it isn't recommended to uninstall them.

NOTE

The output of the `dotnet-core-uninstall list` command will not match the list of installed versions in the output of `dotnet --info` in most cases. Specifically, this tool will not display versions installed by zip files or managed by Visual Studio (any version installed with Visual Studio 2019 16.3 or later). One way to check if a version is managed by Visual Studio is to view it in `Add or Remove Programs`, where Visual Studio managed versions are marked as such in their display names.

For more information, see [list command](#) later in this article.

Step 2 - Do a dry run

The `dotnet-core-uninstall dry-run` and `dotnet-core-uninstall whatif` commands display the .NET SDKs and runtimes that will be removed based on the options provided without performing the uninstall. These commands are synonyms.

For more information, see [dry-run](#) and [whatif](#) commands later in this article.

Step 3 - Uninstall .NET SDKs and Runtimes

`dotnet-core-uninstall remove` uninstalls .NET SDKs and Runtimes that are specified by a collection of options. Versions 1.2 and later can uninstall SDKs and runtimes with version 5.0 or earlier, and previous versions of the tool can uninstall 3.1 and earlier.

Since this tool has a destructive behavior, it's **highly** recommended that you do a dry run before running the `remove` command. The dry run will show you what .NET SDKs and runtimes will be removed when you use the `remove` command. Refer to [Should I remove a version?](#) to learn which SDKs and runtimes are safe to remove.

Caution

Keep in mind the following caveats:

- This tool can uninstall versions of the .NET SDK that are required by `global.json` files on your machine. You can reinstall .NET SDKs from the [Download .NET](#) page.
- This tool can uninstall versions of the .NET Runtime that are required by framework dependent applications on your machine. You can reinstall .NET Runtimes from the [Download .NET](#) page.
- This tool can uninstall versions of the .NET SDK and runtime that Visual Studio relies on. If you break your Visual Studio installation, run "Repair" in the Visual Studio installer to get back to a working state.

By default, all commands keep the .NET SDKs and runtimes that may be required by Visual Studio or other SDKs. These SDKs and runtimes can be uninstalled by listing them explicitly as arguments or by using the `--force` option.

The tool requires elevation to uninstall .NET SDKs and runtimes. Run the tool in an Administrator command prompt on Windows and with `sudo` on macOS. The `dry-run` and `whatif` commands don't require elevation.

For more information, see [remove command](#) later in this article.

Step 4 - Delete the NuGet fallback folder (optional)

In some cases, you no longer need the `NuGetFallbackFolder` and may wish to delete it. For more information, see [Remove the NuGetFallbackFolder](#).

Uninstall the tool

- [Windows](#)
- [macOS](#)

1. Open [Add or Remove Programs](#).

2. Search for `Microsoft .NET SDK Uninstall Tool`.

3. Select **Uninstall**.

`list` command

Synopsis

```
dotnet-core-uninstall list [options]
```

Options

- [Windows](#)
- [macOS](#)

- `--aspnet-runtime`

Lists all the ASP.NET Runtimes that can be uninstalled with this tool.

- `--hosting-bundle`

Lists all the .NET hosting bundles that can be uninstalled with this tool.

- `--runtime`

Lists all .NET Runtimes that can be uninstalled with this tool.

- `--sdk`

Lists all .NET SDKs that can be uninstalled with this tool.

- `-v, --verbosity <LEVEL>`

Sets the verbosity level. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default value is `normal`.

- `--x64`

Lists all x64 .NET SDKs and runtimes that can be uninstalled with this tool.

- `--x86`

Lists all x86 .NET SDKs and runtimes that can be uninstalled with this tool.

Examples

- List all .NET SDKs and runtimes that can be removed with this tool:

```
dotnet-core-uninstall list
```

- List all x64 .NET SDKs and runtimes:

```
dotnet-core-uninstall list --x64
```

- List all x86 .NET SDKs:

```
dotnet-core-uninstall list --sdk --x86
```

`dry-run` and `whatif` commands

Synopsis

```
dotnet-core-uninstall dry-run [options] [<VERSION>...]  
dotnet-core-uninstall whatif [options] [<VERSION>...]
```

Arguments

- `VERSION`

The specified version to uninstall. You may list several versions one after the other, separated by spaces. Response files are also supported.

TIP

Response files are an alternative to placing all the versions on the command line. They're text files, typically with a `*.rsp` extension, and each version is listed on a separate line. To specify a response file for the `VERSION` argument, use the `@` character immediately followed by the response file name.

Options

- [Windows](#)
- [macOS](#)
- `--all`

Removes all .NET SDKs and runtimes.

- `--all-below <VERSION>[<VERSION>...]`

Removes only the .NET SDKs and runtimes with a version smaller than the specified version. The specified version remains installed.

- `--all-but <VERSIONS>[<VERSION>...]`

Removes all .NET SDKs and runtimes, except those versions specified.

- `--all-but-latest`

Removes .NET SDKs and runtimes, except the one highest version.

- `--all-lower-patches`

Removes .NET SDKs and runtimes superseded by higher patches. This option protects `global.json`.

- `--all-previews`

Removes .NET SDKs and runtimes marked as previews.

- `--all-previews-but-latest`

Removes .NET SDKs and runtimes marked as previews except the one highest preview.

- `--aspnet-runtime`

Removes ASP.NET Runtimes only.

- `--hosting-bundle`

Removes .NET Runtime and hosting bundles only.

- `--major-minor <MAJOR_MINOR>`

Removes .NET SDKs and runtimes that match the specified `<MAJOR_MINOR>` version.

- `--runtime`

Removes .NET Runtimes only.

- `--sdk`

Removes .NET SDKs only.

- `-v, --verbosity <LEVEL>`

Sets the verbosity level. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default value is `normal`.

- `--x64`

Must be used with `--sdk`, `--runtime`, and `--aspnet-runtime` to remove x64 SDKs or runtimes.

- `--x86`

Must be used with `--sdk`, `--runtime`, and `--aspnet-runtime` to remove x86 SDKs or runtimes.

- `--force` Forces removal of versions that might be used by Visual Studio.

Notes:

1. Exactly one of `--sdk`, `--runtime`, `--aspnet-runtime`, and `--hosting-bundle` is required.
2. `--all`, `--all-below`, `--all-but`, `--all-but-latest`, `--all-lower-patches`, `--all-previews`, `--all-previews-but-latest`, `--major-minor`, and `[<VERSION>...]` are exclusive.
3. If `--x64` or `--x86` aren't specified, then both x64 and x86 will be removed.

Examples

NOTE

By default, .NET SDKs and runtimes that may be required by Visual Studio or other SDKs are not included in `dotnet-core-uninstall dry-run` output. In the following examples, some of the specified SDKs and runtimes may not be included in the output, depending on the state of the machine. To include all SDKs and runtimes, list them explicitly as arguments or use the `--force` option.

- Dry run of removing all .NET Runtimes that have been superseded by higher patches:

```
dotnet-core-uninstall dry-run --all-lower-patches --runtime
```

- Dry run of removing all .NET SDKs below the version `2.2.301`:

```
dotnet-core-uninstall whatif --all-below 2.2.301 --sdk
```

`remove` command

Synopsis

```
dotnet-core-uninstall remove [options] [<VERSION>...]
```

Arguments

- `VERSION`

The specified version to uninstall. You may list several versions one after the other, separated by spaces. Response files are also supported.

TIP

Response files are an alternative to placing all the versions on the command line. They're text files, typically with a `*.rsp` extension, and each version is listed on a separate line. To specify a response file for the `VERSION` argument, use the `@` character immediately followed by the response file name.

Options

- [Windows](#)
- [macOS](#)

- `--all`

Removes all .NET SDKs and runtimes.

- `--all-below <VERSION>[<VERSION>...]`

Removes only the .NET SDKs and runtimes with a version smaller than the specified version. The specified version remains installed.

- `--all-but <VERSIONS>[<VERSION>...]`

Removes all .NET SDKs and runtimes, except those versions specified.

- `--all-but-latest`

Removes .NET SDKs and runtimes, except the one highest version.

- `--all-lower-patches`

Removes .NET SDKs and runtimes superseded by higher patches. This option protects `global.json`.

- `--all-previews`

Removes .NET SDKs and runtimes marked as previews.

- `--all-previews-but-latest`

Removes .NET SDKs and runtimes marked as previews except the one highest preview.

- `--aspnet-runtime`

Removes ASP.NET Runtimes only.

- `--hosting-bundle`

Removes .NET hosting bundles only.

- `--major-minor <MAJOR_MINOR>`

Removes .NET SDKs and runtimes that match the specified `major.minor` version.

- `--runtime`
Removes .NET Runtimes only.
- `--sdk`
Removes .NET SDKs only.
- `-v, --verbosity <LEVEL>`
Sets the verbosity level. Allowed values are `q[uiet]`, `m[inimal]`, `n[ormal]`, `d[etailed]`, and `diag[nostic]`. The default value is `normal`.
- `--x64`
Must be used with `--sdk`, `--runtime`, and `--aspnet-runtime` to remove x64 SDKs or runtimes.
- `--x86`
Must be used with `--sdk`, `--runtime`, and `--aspnet-runtime` to remove x86 SDKs or runtimes.
- `-y, --yes` Executes the command without requiring a yes or no confirmation.
- `--force` Forces removal of versions that might be used by Visual Studio.

Notes:

1. Exactly one of `--sdk`, `--runtime`, `--aspnet-runtime`, and `--hosting-bundle` is required.
2. `--all`, `--all-below`, `--all-but`, `--all-but-latest`, `--all-lower-patches`, `--all-previews`, `--all-previews-but-latest`, `--major-minor`, and `[<VERSION>...]` are exclusive.
3. If `--x64` or `--x86` aren't specified, then both x64 and x86 will be removed.

Examples

NOTE

By default, .NET SDKs and runtimes that may be required by Visual Studio or other SDKs are kept. In the following examples, some of the specified SDKs and runtimes may remain, depending on the state of the machine. To remove all SDKs and runtimes, list them explicitly as arguments or use the `--force` option.

- Remove all .NET Runtimes except the version `3.0.0-preview6-27804-01` without requiring Y/N confirmation:

```
dotnet-core-uninstall remove --all-but 3.0.0-preview6-27804-01 --runtime --yes
```

- Remove all .NET Core 1.1 SDKs without requiring Y/n confirmation:

```
dotnet-core-uninstall remove --sdk --major-minor 1.1 -y
```

- Remove the .NET Core 1.1.11 SDK with no console output:

```
dotnet-core-uninstall remove 1.1.11 --sdk --yes --verbosity q
```

- Remove all .NET SDKs that can safely be removed by this tool:

```
dotnet-core-uninstall remove --all --sdk
```

- Remove all .NET SDKs that can be removed by this tool, including those SDKs that may be required by Visual Studio (not recommended):

```
dotnet-core-uninstall remove --all --sdk --force
```

- Remove all .NET SDKs that are specified in the response file `versions.rsp`

```
dotnet-core-uninstall remove --sdk @versions.rsp
```

The content of `versions.rsp` is as follows:

```
2.2.300  
2.1.700
```

.NET install tool for extension authors

9/20/2022 • 2 minutes to read • [Edit Online](#)

The [.NET install tool for extension authors](#) is a Visual Studio Code extension that allows acquisition of the .NET runtime specifically for VS Code extension authors. This tool is intended to be leveraged in extensions that are written in .NET and require .NET to boot pieces of the extension (for example, a language server). The extension is not intended to be used directly by users to install .NET for development.

Getting started: extension authors

To ensure that the .NET install tool for extension authors is the right fit for your scenario, start by reviewing the [goals of this extension](#) on our GitHub page.

NOTE

This tool can be used to install the .NET runtime only, it currently does not have the capability to install the .NET SDK.

Once you have verified that the .NET install tool for extension authors fits your needs, you can take a dependency on it in your [extension manifest](#) and begin using the commands we expose with the [VS Code API](#). You can find the list of commands this extension exposes on our [GitHub](#).

Check out this [sample extension](#) to see these steps in action.

For more examples, check out these open source extensions that currently leverage this tool:

- [Azure Resource Manager \(ARM\) Tools for Visual Studio Code](#)
- [.NET Interactive Notebooks](#)

Getting started: end users

In general, the end user should not need to interact with the .NET install tool for extension authors at all. If you are having problems with the extension, check out our [troubleshooting page](#) or file an issue on our [GitHub](#).

Generate self-signed certificates with the .NET CLI

9/20/2022 • 7 minutes to read • [Edit Online](#)

There are different ways to create and use self-signed certificates for development and testing scenarios. This article covers using self-signed certificates with `dotnet dev-certs`, and other options like `PowerShell` and `OpenSSL`.

You can then validate that the certificate will load using an example such as an [ASP.NET Core app](#) hosted in a container.

Prerequisites

In the sample, you can utilize either .NET Core 3.1 or .NET 5.

For `dotnet dev-certs`, be sure to have the appropriate version of .NET installed:

- [Install .NET on Windows](#)
- [Install .NET on Linux](#)
- [Install .NET on macOS](#)

This sample requires [Docker 17.06](#) or later of the [Docker client](#).

Prepare sample app

You'll need to prepare the sample app depending on which runtime you'd like to use for testing, either [.NET Core 3.1](#) or [.NET 5](#).

For this guide, you'll use a [sample app](#) and make changes where appropriate.

.NET Core 3.1 sample app

Get the sample app.

```
git clone https://github.com/dotnet/dotnet-docker/
```

Navigate to the repository locally and open up the workspace in an editor.

NOTE

If you're looking to use dotnet publish parameters to *trim* the deployment, you should make sure that the appropriate dependencies are included for supporting SSL certificates. Update the `dotnet-docker\samples\aspnetapp\aspnetapp.csproj` to ensure that the appropriate assemblies are included in the container. For reference, check how to update the .csproj file to [support ssl certificates](#) when using trimming for self-contained deployments.

Make sure the `aspnetapp.csproj` includes the appropriate target framework:

```
<Project Sdk="Microsoft.NET.Sdk.Web">

<PropertyGroup>
  <TargetFramework>.netcoreapp3.1</TargetFramework>
  <!--Other Properties-->
</PropertyGroup>

</Project>
```

Modify the Dockerfile to make sure the runtime points to .NET Core 3.1:

```
# https://hub.docker.com/_/microsoft-dotnet-core
FROM mcr.microsoft.com/dotnet/core/sdk:3.1 AS build
WORKDIR /source

# copy csproj and restore as distinct layers
COPY *.sln .
COPY aspnetapp/*.csproj ./aspnetapp/
RUN dotnet restore

# copy everything else and build app
COPY aspnetapp/. ./aspnetapp/
WORKDIR /source/aspnetapp
RUN dotnet publish -c release -o /app --no-restore

# final stage/image
FROM mcr.microsoft.com/dotnet/core/aspnet:3.1
WORKDIR /app
COPY --from=build /app .
ENTRYPOINT ["dotnet", "aspnetapp.dll"]
```

Make sure you're pointing to the sample app.

```
cd ..\dotnet-docker\samples\aspnetapp
```

Build the container for testing locally.

```
docker build -t aspnetapp:my-sample -f Dockerfile .
```

.NET 5 sample app

For this guide, the [sample aspnetapp](#) should be checked for .NET 5.

Check sample app [Dockerfile](#) is using .NET 5.

Depending on the host OS, the ASP.NET runtime may need to be updated. For example, changing from `mcr.microsoft.com/dotnet/aspnet:5.0-nanoservercore-2009 AS runtime` to `mcr.microsoft.com/dotnet/aspnet:5.0-windowsservercore-ltsc2019 AS runtime` in the Dockerfile will help with targeting the appropriate Windows runtime.

For example, this will help with testing the certificates on Windows:

```

# https://hub.docker.com/_/microsoft-dotnet
FROM mcr.microsoft.com/dotnet/sdk:5.0 AS build
WORKDIR /source

# copy csproj and restore as distinct layers
COPY *.sln .
COPY aspnetapp/*.csproj ./aspnetapp/
RUN dotnet restore -r win-x64

# copy everything else and build app
COPY aspnetapp/. ./aspnetapp/
WORKDIR /source/aspnetapp
RUN dotnet publish -c release -o /app -r win-x64 --self-contained false --no-restore

# final stage/image
# Uses the 2009 release; 2004, 1909, and 1809 are other choices
FROM mcr.microsoft.com/dotnet/aspnet:5.0-windowsservercore-ltsc2019 AS runtime
WORKDIR /app
COPY --from=build /app ./
ENTRYPOINT ["aspnetapp"]

```

If we're testing the certificates on Linux, you can use the existing Dockerfile.

Make sure the `aspnetapp.csproj` includes the appropriate target framework:

```

<Project Sdk="Microsoft.NET.Sdk.Web">

<PropertyGroup>
  <TargetFramework>net5.0</TargetFramework>
  <!--Other Properties-->
</PropertyGroup>

</Project>

```

NOTE

If you want to use `dotnet publish` parameters to *trim* the deployment, make sure that the appropriate dependencies are included for supporting SSL certificates. Update the `dotnet-docker\samples\aspnetapp\aspnetapp.csproj` to ensure that the appropriate assemblies are included in the container. For reference, check how to update the .csproj file to [support ssl certificates](#) when using trimming for self-contained deployments.

Make sure you're pointing to the sample app.

```
cd .\dotnet-docker\samples\aspnetapp
```

Build the container for testing locally.

```
docker build -t aspnetapp:my-sample -f Dockerfile .
```

Create a self-signed certificate

You can create a self-signed certificate:

- [With dotnet dev-certs](#)
- [With PowerShell](#)

- With OpenSSL

With dotnet dev-certs

You can use `dotnet dev-certs` to work with self-signed certificates.

```
dotnet dev-certs https -ep $env:USERPROFILE\.aspnet\https\aspnetapp.pfx -p crypticpassword  
dotnet dev-certs https --trust
```

NOTE

The certificate name, in this case `aspnetapp.pfx` must match the project assembly name. `crypticpassword` is used as a stand-in for a password of your own choosing. If console returns "A valid HTTPS certificate is already present.", a trusted certificate already exists in your store. It can be exported using MMC Console.

Configure application secrets, for the certificate:

```
dotnet user-secrets -p aspnetapp\aspnetapp.csproj set "Kestrel:Certificates:Development:Password"  
"crypticpassword"
```

NOTE

Note: The password must match the password used for the certificate.

Run the container image with ASP.NET Core configured for HTTPS:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e  
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -v  
$env:APPDATA\microsoft\UserSecrets\:$env:APPDATA\microsoft\UserSecrets -v  
$env:USERPROFILE\.aspnet\https:$env:USERPROFILE\.aspnet\https -v  
mcr.microsoft.com/dotnet/samples:aspnetapp
```

Once the application starts, navigate to `https://localhost:8001` in your web browser.

Clean up

If the secrets and certificates aren't in use, be sure to clean them up.

```
dotnet user-secrets remove "Kestrel:Certificates:Development:Password" -p aspnetapp\aspnetapp.csproj  
dotnet dev-certs https --clean
```

With PowerShell

You can use PowerShell to generate self-signed certificates. The [PKI Client](#) can be used to generate a self-signed certificate.

```
$cert = New-SelfSignedCertificate -DnsName @("contoso.com", "www.contoso.com") -CertStoreLocation  
"cert:\LocalMachine\My"
```

The certificate will be generated, but for the purposes of testing, should be placed in a cert store for testing in a browser.

```
$certKeyPath = "c:\certs\contoso.com.pfx"
$password = ConvertTo-SecureString 'password' -AsPlainText -Force
$cert | Export-PfxCertificate -FilePath $certKeyPath -Password $password
$rootCert = $(Import-PfxCertificate -FilePath $certKeyPath -CertStoreLocation 'Cert:\LocalMachine\Root' -
>Password $password)
```

At this point, the certificates should be viewable from an [MMC snap-in](#).

You can run the sample container in Windows Subsystem for Linux (WSL):

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e
ASPNETCORE_Kestrel_Certificates_Default_Password="password" -e
ASPNETCORE_Kestrel_Certificates_Default_Path=https://contoso.com.pfx -v /c/certs:/https/
mcr.microsoft.com/dotnet/samples:aspnetapp
```

NOTE

Note that with the volume mount the file path could be handled differently based on host. For example, in WSL we may replace `/c/certs` with `/mnt/c/certs`.

If you're using the container built earlier for Windows, the run command would look like the following:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e
ASPNETCORE_Kestrel_Certificates_Default_Password="password" -e
ASPNETCORE_Kestrel_Certificates_Default_Path=c:\https\contoso.com.pfx -v c:\certs:C:\https aspnetapp:my-
sample
```

Once the application is up, navigate to `contoso.com:8001` in a browser.

Be sure that the host entries are updated for `contoso.com` to answer on the appropriate IP address (for example 127.0.0.1). If the certificate isn't recognized, make sure that the certificate that is loaded with the container is also trusted on the host, and that there's appropriate SAN / DNS entries for `contoso.com`.

Clean up

```
$cert | Remove-Item
Get-ChildItem $certFilePath | Remove-Item
$rootCert | Remove-item
```

With OpenSSL

You can use [OpenSSL](#) to create self-signed certificates. This example will use WSL / Ubuntu and a bash shell with `OpenSSL`.

This will generate a .crt and a .key.

```

PARENT="contoso.com"
openssl req \
-x509 \
-newkey rsa:4096 \
-sha256 \
-days 365 \
-nodes \
-keyout $PARENT.key \
-out $PARENT.crt \
-subj "/CN=${PARENT}" \
-extensions v3_ca \
-extensions v3_req \
-config <(
echo '[req]'; \
echo 'default_bits= 4096'; \
echo 'distinguished_name=req'; \
echo 'x509_extension = v3_ca'; \
echo 'req_extensions = v3_req'; \
echo '[v3_req]'; \
echo 'basicConstraints = CA:FALSE'; \
echo 'keyUsage = nonRepudiation, digitalSignature, keyEncipherment'; \
echo 'subjectAltName = @alt_names'; \
echo '[ alt_names ]'; \
echo "DNS.1 = www.${PARENT}"; \
echo "DNS.2 = ${PARENT}"; \
echo '[ v3_ca ]'; \
echo 'subjectKeyIdentifier=hash'; \
echo 'authorityKeyIdentifier=keyid:always,issuer'; \
echo 'basicConstraints = critical, CA:TRUE, pathlen:0'; \
echo 'keyUsage = critical, cRLSign, keyCertSign'; \
echo 'extendedKeyUsage = serverAuth, clientAuth')

openssl x509 -noout -text -in $PARENT.crt

```

To get a .pfx, use the following command:

```
openssl pkcs12 -export -out $PARENT.pfx -inkey $PARENT.key -in $PARENT.crt
```

NOTE

The .aspnetcore 3.1 example will use `.pfx` and a password. Starting with the `.net 5` runtime, Kestrel can also take `.crt` and PEM-encoded `.key` files.

Depending on the host os, the certificate will need to be trusted. On a Linux host, 'trusting' the certificate is different and distro dependent.

For the purposes of this guide, here's an example in Windows using PowerShell:

```
Import-Certificate -FilePath $certFilePath -CertStoreLocation 'Cert:\LocalMachine\Root'
```

For .NET Core 3.1, run the following command in WSL:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e
ASPNETCORE_Kestrel_Certificates_Default_Password="password" -e
ASPNETCORE_Kestrel_Certificates_Default_Path=/https/contoso.com.pfx -v /c/path/to/certs/:/https/
mcr.microsoft.com/dotnet/samples:aspnetapp
```

Starting with .NET 5, Kestrel can take the `.crt` and PEM-encoded `.key` files. You can run the sample with the following command for .NET 5:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e  
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e  
ASPNETCORE_Kestrel_Certificates_Default_Path=/https/contoso.com.crt -e  
ASPNETCORE_Kestrel_Certificates_Default_KeyPath=/https/contoso.com.key -v /c/path/to/certs:/https/  
mcr.microsoft.com/dotnet/samples:aspnetapp
```

NOTE

Note that in WSL, the volume mount path may change depending on the configuration.

For .NET Core 3.1 in Windows, run the following command in `Powershell`:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e  
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e  
ASPNETCORE_Kestrel_Certificates_Default_Password="password" -e  
ASPNETCORE_Kestrel_Certificates_Default_Path=c:\https\contoso.com.pfx -v c:\certs:C:\https aspnetapp:my-  
sample
```

For .NET 5 in Windows, run the following command in PowerShell:

```
docker run --rm -it -p 8000:80 -p 8001:443 -e ASPNETCORE_URLS="https://+;http://+" -e  
ASPNETCORE_HTTPS_PORT=8001 -e ASPNETCORE_ENVIRONMENT=Development -e  
ASPNETCORE_Kestrel_Certificates_Default_Path=c:\https\contoso.com.crt -e  
ASPNETCORE_Kestrel_Certificates_Default_KeyPath=c:\https\contoso.com.key -v c:\certs:C:\https  
aspnetapp:my-sample
```

Once the application is up, navigate to `contoso.com:8001` in a browser.

Be sure that the host entries are updated for `contoso.com` to answer on the appropriate IP address (for example 127.0.0.1). If the certificate isn't recognized, make sure that the certificate that is loaded with the container is also trusted on the host, and that there's appropriate SAN / DNS entries for `contoso.com`.

Clean up

Be sure to clean up the self-signed certificates once done testing.

```
Get-ChildItem $certFilePath | Remove-Item
```

Use the WCF Web Service Reference Provider Tool

9/20/2022 • 3 minutes to read • [Edit Online](#)

Over the years, many Visual Studio developers have enjoyed the productivity that the [Add Service Reference](#) tool provided when their .NET Framework projects needed to access web services.

The **WCF Web Service Reference** tool is a Visual Studio connected service extension that lets you connect your .NET 5+, .NET Core, or ASP.NET Core project to a web service. It provides an experience similar to the [Add Service Reference](#) functionality, which is for .NET Framework projects only. The **WCF Web Service Reference** tool retrieves metadata from a web service in the current solution, on a network location, or from a WSDL file, and generates a source file containing Windows Communication Foundation (WCF) client proxy code that your .NET app can use to access the web service.

IMPORTANT

You should only reference services from a trusted source. Adding references from an untrusted source may compromise security.

Prerequisites

- [Visual Studio 2017 version 15.5](#) or a later version

The screenshots in this article are from Visual Studio 2022.

How to use the extension

NOTE

The **WCF Web Service Reference** tool is applicable only to C# .NET Core and .NET Standard projects, including ASP.NET Core Web apps.

Using the **ASP.NET Core Web Application** project template as an example, this article walks you through adding a WCF service reference to the project.

1. In Solution Explorer, double-click the **Connected Services** node of the project. (For a .NET Core or .NET Standard project, this option is available when you right-click on the **Dependencies** node of the project in Solution Explorer and choose **Manage Connected Services**.)

The **Connected Services** page appears as shown in the following image:

The screenshot shows the 'Connected Services' page in Visual Studio. The left sidebar has three tabs: 'Overview', 'Connected Services' (which is selected and highlighted in blue), and 'Publish'. The main content area has two sections. The first section, 'Service Dependencies', displays the message 'There are currently no service dependencies configured.' and a link 'Add a service dependency'. The second section, 'Service References (OpenAPI, gRPC, WCF Web Service)', also displays the message 'There are currently no service references configured.' and a link 'Add a service reference'. At the top right of the main content area are four icons: a green plus sign, a circular arrow, a refresh symbol, and a more options menu.

2. On the **Connected Services** page, select **Add Service Reference**.

The **Add service reference** page opens.

3. Select **WCF Web Service**, and then choose **Next**.

This brings up the **Add new WCF Web Service service reference** wizard.

The screenshot shows the 'Add new WCF Web Service service reference' wizard. The title bar says 'Add new WCF Web Service service reference'. The main area is titled 'Specify the service to add'. It contains several sections: 'URI:' with a dropdown containing 'http://localhost:8733/Design_Time_Addresses/MyWCFService/Service1/mex'; 'Services:' showing a tree with 'Service1' expanded and 'GreetingsService' selected; 'Operations:' showing a list with 'GetData' and 'GetDataUsingDataContract' selected; 'Status:' showing 'Number of services found: 1'; 'Namespace:' with the value 'ServiceReference1'; and a footer with buttons for 'Back', 'Next', 'Finish', and 'Cancel'. The 'Discover' button is also visible near the URI input.

4. Select a service.

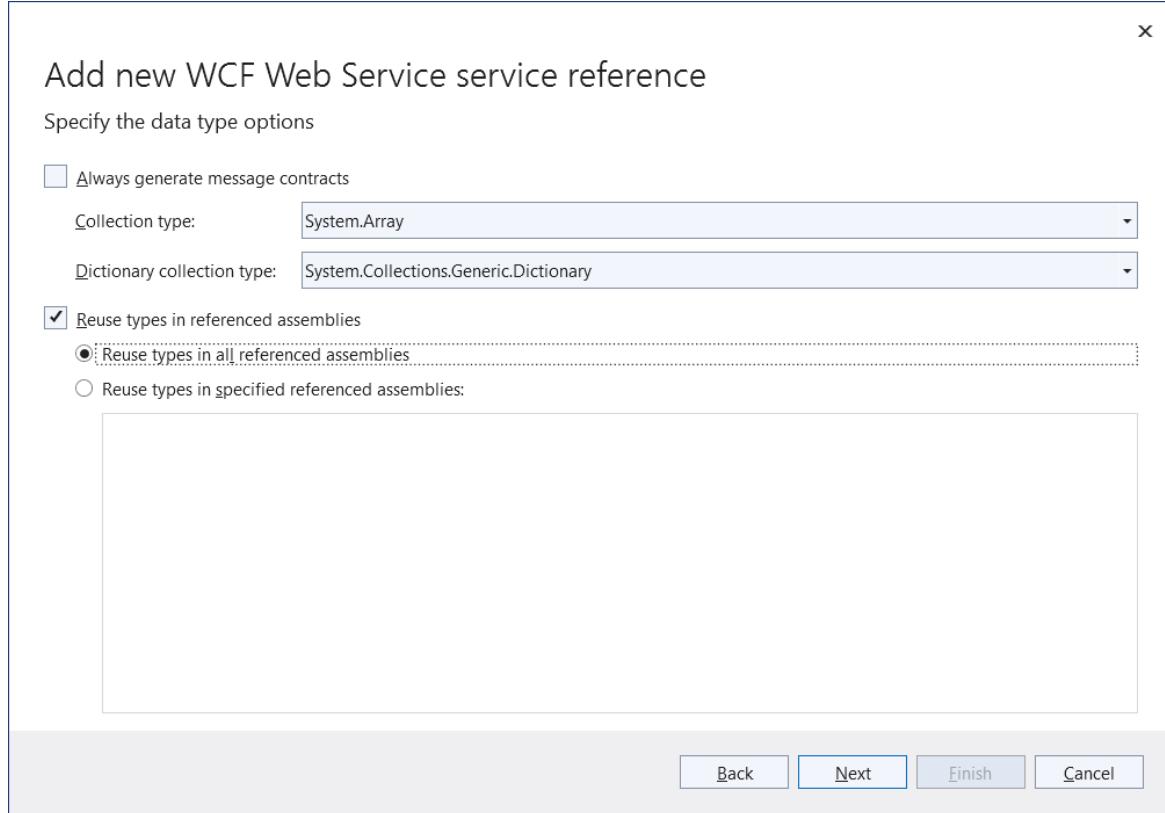

a. There are several services search options available:

- To search for services defined in the current solution, click the **Discover** button.
 - To search for services hosted at a specified address, enter a service URL in the **Address** box and click the **Go** button.
 - To select a WSDL file that contains the web service metadata information, click the **Browse** button.
- b. Select the service from the search results list in the **Services** box. If needed, enter the namespace for

the generated code in the corresponding **Namespace** text box.

c. Click the **Next** button to specify data type options or client options. Alternatively, click the **Finish** button to use the default options.

5. The **data type options** page lets refine the generated service reference configuration settings:

NOTE

The **Reuse types in referenced assemblies** check box option is useful when data types needed for service reference code generation are defined in one of your project's referenced assemblies. It's important to reuse those existing data types to avoid compile-time type clash or runtime issues.

There may be a delay while type information is loaded, depending on the number of project dependencies and other system performance factors. The **Finish** button is disabled during loading unless the **Reuse types in referenced assemblies** check box is unchecked.

6. Click **Finish** when you are done.

While displaying progress, the tool:

- Downloads metadata from the WCF service.
- Generates the service reference code in a file named *reference.cs*, and adds it to your project under the **Connected Services** node.
- Updates the project file (.csproj) with NuGet package references required to compile and run on the target platform.

Service reference configuration progress

| Importing web service metadata ...
Scaffolding service reference code ...
Number of service endpoints found: 1
Updating project ...
Done.

Successfully added service reference(s)

Automatically close when succeeded

[Back](#) [Next](#) [Close](#) [Cancel](#)

When these processes complete, you can create an instance of the generated WCF client type and invoke the service operations.

Feedback & questions

If you have any product feedback, report it at [Developer Community](#) using the [Report a problem](#) tool.

Release notes

- Refer to the [Release notes](#) for updated release information, including known issues.

WCF dotnet-svcutil tool for .NET Core

9/20/2022 • 3 minutes to read • [Edit Online](#)

The Windows Communication Foundation (WCF) **dotnet-svcutil** tool is a .NET tool that retrieves metadata from a web service on a network location or from a WSDL file, and generates a WCF class containing client proxy methods that access the web service operations.

Similar to the [Service Model Metadata - svcutil](#) tool for .NET Framework projects, the **dotnet-svcutil** is a command-line tool for generating a web service reference compatible with .NET Core and .NET Standard projects.

The **dotnet-svcutil** tool is an alternative option to the [WCF Web Service Reference](#) Visual Studio connected service provider that first shipped with Visual Studio 2017 version 15.5. The **dotnet-svcutil** tool as a .NET tool, is available cross-platform on Linux, macOS, and Windows.

IMPORTANT

You should only reference services from a trusted source. Adding references from an untrusted source may compromise security.

Prerequisites

- [dotnet-svcutil 2.x](#)
- [dotnet-svcutil 1.x](#)
- [.NET Core 2.1 SDK](#) or later versions
- Your favorite code editor

Getting started

The following example walks you through the steps required to add a web service reference to a .NET Core web project and invoke the service. You'll create a .NET Core web application named *HelloSvcutil* and add a reference to a web service that implements the following contract:

```
[ServiceContract]
public interface ISayHello
{
    [OperationContract]
    string Hello(string name);
}
```

For this example, let's assume the web service will be hosted at the following address:

`http://contoso.com/SayHello.svc`

From a Windows, macOS, or Linux command window perform the following steps:

1. Create a directory named *HelloSvcutil* for your project and make it your current directory, as in the following example:

```
mkdir HelloSvculil  
cd HelloSvculil
```

2. Create a new C# web project in that directory using the `dotnet new` command as follows:

```
dotnet new web
```

3. Install the `dotnet-svcutil` NuGet package as a CLI tool:

- `dotnet-svcutil 2.x`
- `dotnet-svcutil 1.x`

```
dotnet tool install --global dotnet-svcutil
```

4. Run the `dotnet-svcutil` command to generate the web service reference file as follows:

- `dotnet-svcutil 2.x`
- `dotnet-svcutil 1.x`

```
dotnet-svcutil http://contoso.com/SayHello.svc
```

The generated file is saved as `HelloSvculil/ServiceReference/Reference.cs`. The `dotnet-svcutil` tool also adds to the project the appropriate WCF packages required by the proxy code as package references.

Using the Service Reference

1. Restore the WCF packages using the `dotnet restore` command as follows:

```
dotnet restore
```

2. Find the name of the client class and operation you want to use. `Reference.cs` will contain a class that inherits from `System.ServiceModel.ClientBase`, with methods that can be used to call operations on the service. In this example, you want to call the `SayHello` service's `Hello` operation.

`ServiceReference.SayHelloClient` is the name of the client class, and has a method called `HelloAsync` that can be used to call the operation.

3. Open the `Startup.cs` file in your editor, and add a `using` directive for the service reference namespace at the top:

```
using ServiceReference;
```

4. Edit the `Configure` method to invoke the web service. You do this by creating an instance of the class that inherits from `ClientBase` and calling the method on the client object:

```
public void Configure(IApplicationBuilder app, IWebHostEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }

    app.Run(async (context) =>
    {
        var client = new SayHelloClient();
        var response = await client.HelloAsync();
        await context.Response.WriteAsync(response);
    });
}
```

- Run the application using the `dotnet run` command as follows:

```
dotnet run
```

- Navigate to the URL listed in the console (for example, `http://localhost:5000`) in your web browser.

You should see the following output: "Hello dotnet-svcutil!"

For a detailed description of the `dotnet-svcutil` tool parameters, invoke the tool passing the help parameter as follows:

- [dotnet-svcutil 2.x](#)
- [dotnet-svcutil 1.x](#)

```
dotnet-svcutil --help
```

Feedback & questions

If you have any questions or feedback, [open an issue on GitHub](#). You can also review any existing questions or issues at the [WCF repo on GitHub](#).

Information

- [dotnet-svcutil NuGet Package](#)

Using dotnet-svcutil.xmlserializer on .NET Core

9/20/2022 • 2 minutes to read • [Edit Online](#)

The `dotnet-svcutil.xmlserializer` NuGet package can pre-generate a serialization assembly for .NET Core projects. It pre-generates C# serialization code for the types in the client application that are used by the WCF Service Contract and that can be serialized by the XmlSerializer. This improves the startup performance of XML serialization when serializing or deserializing objects of those types.

Prerequisites

- [.NET Core 2.1 SDK](#) or later
- Your favorite code editor

You can use the command `dotnet --info` to check which versions of .NET SDK and runtime you already have installed.

Getting started

To use `dotnet-svcutil.xmlserializer` in a .NET Core console application:

1. Create a WCF Service named 'MyWCFService' using the default template 'WCF Service Application' in .NET Framework. Add `[XmlSerializerFormat]` attribute on the service method like the following:

```
[ServiceContract]
public interface IService1
{
    [XmlSerializerFormat]
    [OperationContract(Action = "http://tempuri.org/IService1/GetData", ReplyAction =
    "http://tempuri.org/IService1/GetDataResponse")]
    string GetData(int value);
}
```

2. Create a .NET Core console application as WCF client application that targets at .NET Core 2.1 or later versions. For example, create an app named 'MyWCFClient' with the following command:

```
dotnet new console --name MyWCFClient
```

To ensure your project is targeting .NET Core 2.1 or later, inspect the `<TargetFramework>` XML element in your project file:

```
<TargetFramework>netcoreapp2.1</TargetFramework>
```

3. Add a package reference to `System.ServiceModel.Http` by running the following command:

```
dotnet add package System.ServiceModel.Http
```

4. Add the WCF Client code:

```

using System.ServiceModel;

class Program
{
    static void Main(string[] args)
    {
        var myBinding = new BasicHttpBinding();
        var myEndpoint = new EndpointAddress("http://localhost:2561/Service1.svc"); //Fill your
service url here
        var myChannelFactory = new ChannelFactory<IService1>(myBinding, myEndpoint);
        IService1 client = myChannelFactory.CreateChannel();
        string s = client.GetData(1);
        ((ICommunicationObject)client).Close();
    }
}

[ServiceContract]
public interface IService1
{
    [XmlSerializerFormat]
    [OperationContract(Action = "http://tempuri.org/IService1/GetData", ReplyAction =
"http://tempuri.org/IService1/GetDataResponse")]
    string GetData(int value);
}

```

5. Add a reference to the `dotnet-svcutil.xmlserializer` package by running the following command:

```
dotnet add package dotnet-svcutil.xmlserializer
```

Running the command should add an entry to your project file similar to this:

```

<ItemGroup>
    <DotNetCliToolReference Include="dotnet-svcutil.xmlserializer" Version="1.0.0" />
</ItemGroup>

```

6. Build the application by running `dotnet build`. If everything succeeds, an assembly named `MyWCFClient.XmlSerializers.dll` is generated in the output folder. If the tool failed to generate the assembly, you'll see warnings in the build output.
7. Start the WCF service by, for example, running `http://localhost:2561/Service1.svc` in the browser. Then start the client application, and it will automatically load and use the pre-generated serializers at run time.

Using Microsoft XML Serializer Generator on .NET Core

9/20/2022 • 2 minutes to read • [Edit Online](#)

This tutorial teaches you how to use the Microsoft XML Serializer Generator in a C# .NET Core application. During the course of this tutorial, you learn:

- How to create a .NET Core app
- How to add a reference to the Microsoft.XmlSerializerGenerator package
- How to edit your `MyApp.csproj` to add dependencies
- How to add a class and an `XmlSerializer`
- How to build and run the application

Like the [Xml Serializer Generator \(sgen.exe\)](#) for the .NET Framework, the [Microsoft.XmlSerializerGenerator NuGet package](#) is the equivalent for .NET Core and .NET Standard projects. It creates an XML serialization assembly for types contained in an assembly to improve the startup performance of XML serialization when serializing or de-serializing objects of those types using [XmlSerializer](#).

Prerequisites

To complete this tutorial:

- [.NET Core 2.1 SDK](#) or later.
- Your favorite code editor.

TIP

Need to install a code editor? Try [Visual Studio!](#)

Use Microsoft XML Serializer Generator in a .NET Core console application

The following instructions show you how to use XML Serializer Generator in a .NET Core console application.

Create a .NET Core console application

Open a command prompt and create a folder named `MyApp`. Navigate to the folder you created and type the following command:

```
dotnet new console
```

Add a reference to the Microsoft.XmlSerializerGenerator package in the MyApp project

Use the `dotnet add package` command to add the reference in your project.

Type:

```
dotnet add package Microsoft.XmlSerializerGenerator -v 1.0.0
```

Verify changes to `MyApp.csproj` after adding the package

Open your code editor and let's get started! We're still working from the `MyApp` directory we built the app in.

Open `MyApp.csproj` in your text editor.

After running the `dotnet add package` command, the following lines are added to your `MyApp.csproj` project file:

```
<ItemGroup>
  <PackageReference Include="Microsoft.XmlSerializer.Generator" Version="1.0.0" />
</ItemGroup>
```

Add another `ItemGroup` section for .NET CLI Tool support

Add the following lines after the `ItemGroup` section that we inspected:

```
<ItemGroup>
  <DotNetCliToolReference Include="Microsoft.XmlSerializer.Generator" Version="1.0.0" />
</ItemGroup>
```

Add a class in the application

Open `Program.cs` in your text editor. Add the class named `MyClass` in `Program.cs`.

```
public class MyClass
{
    public int Value;
}
```

Create an `XmlSerializer` for `MyClass`

Add the following line inside `Main` to create an `XmlSerializer` for `MyClass`:

```
var serializer = new System.Xml.Serialization.XmlSerializer(typeof(MyClass));
```

Build and run the application

Still within the `MyApp` folder, run the application via `dotnet run` and it automatically loads and uses the pre-generated serializers at run time.

Type the following command in your console window:

```
dotnet run
```

NOTE

`dotnet run` calls `dotnet build` to ensure that the build targets have been built, and then calls `dotnet <assembly.dll>` to run the target application.

IMPORTANT

The commands and steps shown in this tutorial to run your application are used during development time only. Once you're ready to deploy your app, take a look at the different [deployment strategies](#) for .NET Core apps and the `dotnet publish` command.

If everything succeeds, an assembly named *MyApp.XmlSerializers.dll* is generated in the output folder.

Congratulations! You have just:

- Created a .NET Core app.
- Added a reference to the Microsoft.XmlSerializer.Generator package.
- Edited your *MyApp.csproj* to add dependencies.
- Added a class and an *XmlSerializer*.
- Built and ran the application.

Further customize XML serialization assembly (optional)

Add the following XML to your *MyApp.csproj* to further customize assembly generation:

```
<PropertyGroup>
  <SGenReferences>C:\myfolder\abc.dll;C:\myfolder\def.dll</SGenReferences>
  <SGenTypes>MyApp.MyClass;MyApp.MyClass1</SGenTypes>
  <SGenProxyTypes>false</SGenProxyTypes>
  <SGenVerbose>true</SGenVerbose>
  <SGenKeyFile>mykey.snk</SGenKeyFile>
  <SGenDelaySign>true</SGenDelaySign>
</PropertyGroup>
```

What diagnostic tools are available in .NET Core?

9/20/2022 • 4 minutes to read • [Edit Online](#)

Software doesn't always behave as you would expect, but .NET Core has tools and APIs that will help you diagnose these issues quickly and effectively.

This article helps you find the various tools you need.

Debuggers

[Debuggers](#) allow you to interact with your program. Pausing, incrementally executing, examining, and resuming gives you insight into the behavior of your code. A debugger is a good choice for diagnosing functional problems that can be easily reproduced.

Unit testing

[Unit testing](#) is a key component of continuous integration and deployment of high-quality software. Unit tests are designed to give you an early warning when you break something.

Instrumentation for observability

.NET supports industry standard instrumentation techniques using metrics, logs, and distributed traces. Instrumentation is code that is added to a software project to record what it is doing. This information can then be collected in files, databases, or in-memory and analyzed to understand how a software program is operating. This is often used in production environments to monitor for problems and diagnose them. The .NET runtime has built-in instrumentation that can be optionally enabled and APIs that allow you to add custom instrumentation specialized for your application.

Metrics

[Metrics](#) are numerical measurements recorded over time to monitor application performance and health. Metrics are often used to generate alerts when potential problems are detected. Metrics have very low performance overhead and many services configure them as always-on telemetry.

Logs

[Logging](#) is a technique where code is instrumented to produce a log, a record of interesting events that occurred while the program was running. Often a baseline set of log events are configured on by default and more extensive logging can be enabled on-demand to diagnose particular problems. Performance overhead is variable depending on how much data is being logged.

Distributed traces

[Distributed Tracing](#) is a specialized form of logging that helps you localize failures and performance issues within applications distributed across multiple machines or processes. This technique tracks requests through an application correlating together work done by different application components and separating it from other work the application may be doing for concurrent requests. It is possible to trace every request and sampling can be optionally employed to bound the performance overhead.

Dumps

A [dump](#) is a file that contains a snapshot of the process at the time of creation. These can be useful for examining the state of your application for debugging purposes.

Symbols

[Symbols](#) are a mapping between the source code and the binary produced by the compiler. These are commonly used by .NET debuggers to resolve source line numbers, local variable names, and other types of diagnostic information.

Collect diagnostics in containers

The same diagnostics tools that are used in non-containerized Linux environments can also be used to [collect diagnostics in containers](#). There are just a few usage changes needed to make sure the tools work in a Docker container.

.NET Core diagnostic global tools

dotnet-counters

[dotnet-counters](#) is a performance monitoring tool for first-level health monitoring and performance investigation. It observes performance counter values published via the [EventCounter](#) API. For example, you can quickly monitor things like the CPU usage or the rate of exceptions being thrown in your .NET Core application.

dotnet-dump

The [dotnet-dump](#) tool is a way to collect and analyze Windows and Linux core dumps without a native debugger.

dotnet-gcdump

The [dotnet-gcdump](#) tool is a way to collect GC (Garbage Collector) dumps of live .NET processes.

dotnet-monitor

The [dotnet-monitor](#) tool is a way to monitor .NET applications in production environments and to collect diagnostic artifacts (for example, dumps, traces, logs, and metrics) on-demand or using automated rules for collecting under specified conditions.

dotnet-trace

.NET Core includes what is called the [EventPipe](#) through which diagnostics data is exposed. The [dotnet-trace](#) tool allows you to consume interesting profiling data from your app that can help in scenarios where you need to root cause apps running slow.

dotnet-stack

The [dotnet-stack](#) tool allows you to quickly print the managed stacks for all threads in a running .NET process.

dotnet-symbol

[dotnet-symbol](#) downloads files (symbols, DAC/DBI, host files, etc.) needed to open a core dump or minidump. Use this tool if you need symbols and modules to debug a dump file captured on a different machine.

dotnet-sos

[dotnet-sos](#) installs the [SOS debugging extension](#) on Linux and macOS (and on Windows if you're using [Windbg/cdb](#)).

PerfCollect

[PerfCollect](#) is a bash script you can use to collect traces with [perf](#) and [LTTng](#) for a more in-depth performance analysis of .NET apps running on Linux distributions.

.NET Core diagnostics tutorials

Write your own diagnostic tool

The [diagnostics client library](#) lets you write your own custom diagnostic tool best suited for your diagnostic

scenario. Look up information in the [Microsoft.Diagnostics.NETCore.Client API reference](#).

Debug a memory leak

[Tutorial: Debug a memory leak](#) walks through finding a memory leak. The [dotnet-counters](#) tool is used to confirm the leak and the [dotnet-dump](#) tool is used to diagnose the leak.

Debug high CPU usage

[Tutorial: Debug high CPU usage](#) walks you through investigating high CPU usage. It uses the [dotnet-counters](#) tool to confirm the high CPU usage. It then walks you through using [Trace for performance analysis utility \(dotnet-trace\)](#) or Linux `perf` to collect and view CPU usage profile.

Debug deadlock

[Tutorial: Debug deadlock](#) shows you how to use the [dotnet-dump](#) tool to investigate threads and locks.

Debug ThreadPool Starvation

[Tutorial: Debug threadPool starvation](#) shows you how to use the [dotnet-counters](#) and [dotnet-stack](#) tools to investigate ThreadPool starvation.

Debug a StackOverflow

[Tutorial: Debug a StackOverflow](#) demonstrates how to debug a [StackOverflowException](#) on Linux.

Debug Linux dumps

[Debug Linux dumps](#) explains how to collect and analyze dumps on Linux.

Measure performance using EventCounters

[Tutorial: Measure performance using EventCounters in .NET](#) shows you how to use the [EventCounter API](#) to measure performance in your .NET app.

.NET Core managed debuggers

9/20/2022 • 2 minutes to read • [Edit Online](#)

Debuggers allow programs to be paused or executed step-by-step. When paused, the current state of the process can be viewed. By stepping through key sections, you gain understanding of your code and why it produces the result that it does.

Microsoft provides debuggers for managed code in **Visual Studio** and **Visual Studio Code**.

Visual Studio managed debugger

Visual Studio is an integrated development environment with the most comprehensive debugger available. Visual Studio is an excellent choice for developers working on Windows.

- [Tutorial - Debugging a .NET Core application on Windows with Visual Studio](#)
- [Debug ASP.NET Core apps in Visual Studio](#)

While Visual Studio is a Windows application, it can also be used to debug Linux apps running remotely, in WSL, or in Docker containers:

- [Remotely debug a .NET Core app on Linux](#)
- [Debug a .NET Core app in WSL2](#)
- [Debug a .NET Core app in a Docker container](#)

Visual Studio Code managed debugger

Visual Studio Code is a lightweight cross-platform code editor. It uses the same .NET Core debugger implementation as Visual Studio, but with a simplified user interface.

- [Tutorial - Debugging a .NET Core application with Visual Studio Code](#)
- [Debugging in Visual Studio Code](#)

Diagnostic port

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions

The .NET Core runtime exposes a service endpoint that allows other processes to send diagnostic commands and receive responses over an [IPC channel](#). This endpoint is called a *diagnostic port*. Commands can be sent to the diagnostic port to:

- Capture a memory dump.
- Start an [EventPipe](#) trace.
- Request the command-line used to launch the app.

The diagnostic port supports different transports depending on platform. Currently both the CoreCLR and Mono runtime implementations use Named Pipes on Windows and Unix Domain Sockets on Linux and macOS. The Mono runtime implementation on Android, iOS, and tvOS uses TCP/IP. The channel uses a [custom binary protocol](#). Most developers will never directly interact with the underlying channel and protocol, but rather will use GUI or CLI tools that communicate on their behalf. For example, the [dotnet-dump](#) and [dotnet-trace](#) tools abstract sending protocol commands to capture dumps and start traces. For developers that want to write custom tooling, the [Microsoft.Diagnostics.NETCore.Client NuGet package](#) provides a .NET API abstraction of the underlying transport and protocol.

Security considerations

The diagnostic port exposes sensitive information about a running application. If an untrusted user gains access to this channel they could observe detailed program state, including any secrets that are in memory, and arbitrarily modify the execution of the program. On the CoreCLR runtime, the default diagnostic port is configured to only be accessible by the same user account that launched the app or by an account with super-user permissions. If your security model does not trust other processes with the same user account credentials, all diagnostic ports can be disabled by setting environment variable `DOTNET_EnableDiagnostics=0`. Doing this will block your ability to use external tooling such as .NET debugging or any of the `dotnet-*` diagnostic tools.

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Default diagnostic port

On Windows, Linux, and macOS, the runtime has one diagnostic port open by default at a well-known endpoint. This is the port that the `dotnet-*` diagnostic tools are connecting to automatically when they haven't been explicitly configured to use an alternate port. The endpoint is:

- Windows - Named Pipe `\\\.\pipe\dotnet-diagnostic-{pid}`
- Linux and macOS - Unix Domain Socket `{temp}/dotnet-diagnostic-{pid}-{disambiguation_key}-socket`

`{pid}` is the process id written in decimal, `{temp}` is the `TMPDIR` environment variable or the value `/tmp` if `TMPDIR` is undefined/empty, and `{disambiguation_key}` is the process start time written in decimal. On macOS and NetBSD, the process start time is number of seconds since UNIX epoch time and on all other platforms it is

jiffies since boot time.

Suspend the runtime at startup

By default, the runtime executes managed code as soon as it starts, regardless whether any diagnostic tools have connected to the diagnostic port. Sometimes it is useful to have the runtime wait to run managed code until after a diagnostic tool is connected, to observe the initial program behavior. Setting environment variable `DOTNET_DefaultDiagnosticPortSuspend=1` causes the runtime to wait until a tool connects to the default port. If no tool is attached after several seconds, the runtime prints a warning message to the console explaining that it is still waiting for a tool to attach.

Configure additional diagnostic ports

IMPORTANT

This works for apps running .NET 5 or later only.

Both the Mono and CoreCLR runtimes can use custom configured diagnostic ports. These ports are in addition to the default port that remains available. There are a few common reasons this is useful:

- On Android, iOS and tvOS there is no default port, so configuring a port is necessary to use diagnostic tools.
- In environments with containers or firewalls, you may want to set up a predictable endpoint address that doesn't vary based on process id as the default port does. Then the custom port can be explicitly added to an allow list or proxied across some security boundary.
- For monitoring tools it is useful to have the tool listen on an endpoint, and the runtime actively attempts to connect to it. This avoids needing the monitoring tool to continuously poll for new apps starting. In environments where the default diagnostic port isn't accessible, it also avoids needing to configure the monitor with a custom endpoint for each monitored app.

In each communication channel between a diagnostic tool and the .NET runtime, one side needs to be the listener and wait for the other side to connect. The runtime can be configured to act in either role for each port. Ports can also be independently configured to suspend at startup, waiting for a diagnostic tool to issue a resume command. Ports configured to connect will repeat their connection attempts indefinitely if the remote endpoint isn't listening or if the connection is lost, but the app does not automatically suspend managed code while waiting to establish that connection. If you want the app to wait for a connection to be established, use the suspend at startup option.

Custom ports are configured using the `DOTNET_DiagnosticPorts` environment variable. This variable should be set to a semicolon delimited list of port descriptions. Each port description consists of an endpoint address and optional modifiers that control the runtime's connect or listen role and if the runtime should suspend on startup. On Windows, the endpoint address is the name of a named pipe without the `\.\pipe\` prefix. On Linux and macOS it is the full path to a Unix Domain Socket. On Android, iOS, and tvOS the address is an IP and port. For example:

1. `DOTNET_DiagnosticPorts=my_diag_port1` - (Windows) The runtime connects to the named pipe `\.\pipe\my_diag_port1`.
2. `DOTNET_DiagnosticPorts=/foo/tool1.socket;foo/tool2.socket` - (Linux and macOS) The runtime connects to both the Unix Domain Sockets `/foo/tool1.socket` and `/foo/tool2.socket`.
3. `DOTNET_DiagnosticPorts=127.0.0.1:9000` - (Android, iOS, and tvOS) The runtime connects to IP 127.0.0.1 on port 9000.
4. `DOTNET_DiagnosticPorts=/foo/tool1.socket,listen,nosuspend` - (Linux and macOS) This example has the `listen` and `nosuspend` modifiers. The runtime creates and listens to Unix Domain Socket `/foo/tool1.socket`.

instead of connecting to it. Additional diagnostic ports would normally cause the runtime to suspend at startup waiting for a resume command, but `nosuspend` causes the runtime not to wait.

The complete syntax for a port is `address[,,(listen|connect)][,(suspend|nosuspend)]`. `connect` is the default if neither `connect` or `listen` is specified. `suspend` is the default if neither `suspend` or `nosuspend` is specified.

Usage in dotnet diagnostic tools

Tools such as [dotnet-dump](#), [dotnet-counters](#), or [dotnet-trace](#) all support `collect` or `monitor` verbs which communicate to a .NET app via the diagnostic port. When these tools are using the `--processId` argument the tool automatically computes the default diagnostic port address and connects to it. When specifying the `--diagnostic-port` argument, the tool listens at the given address and you should use the `DOTNET_DiagnosticPorts` environment variable to configure your app to connect. For a complete example with `dotnet-counters`, see [Using the Diagnostic Port](#).

Use ds-router to proxy the diagnostic port

All of the `dotnet-*` diagnostic tools expect to connect to a diagnostic port that is a local Named Pipe or Unix Domain Socket. Mono often runs on isolated hardware or in emulators that need a proxy over TCP to become accessible. The [dotnet-dsrouter tool](#) can proxy a local Named Pipe or Unix Domain Socket to TCP so that the tools can be used in those environments. For more information, see [dotnet-dsrouter](#).

Dumps

9/20/2022 • 3 minutes to read • [Edit Online](#)

A dump is a file that contains a snapshot of the process at the time it was created and can be useful for examining the state of your application. Dumps can be used to debug your .NET application when it is difficult to attach a debugger to it such as production or CI environments. Using dumps allows you to capture the state of the problematic process and examine it without having to stop the application.

Collect dumps

Dumps can be collected in a variety of ways depending on which platform you are running your app on.

NOTE

Collecting a dump inside a container requires PTRACE capability, which can be added via `--cap-add=SYS_PTRACE` or `--privileged`.

NOTE

Dumps may contain sensitive information because they can contain the full memory of the running process. Handle them with any security restrictions and guidances in mind.

Collect dumps on crash

You can use environment variables to configure your application to collect a dump upon a crash. This is helpful when you want to get an understanding of why a crash happened. For example, capturing a dump when an exception is thrown helps you identify an issue by examining the state of the app when it crashed.

The following table shows the environment variables you can configure for collecting dumps on a crash.

ENVIRONMENT VARIABLE	DESCRIPTION	DEFAULT VALUE
<code>COMPlus_DbgEnableMiniDump</code> or <code>DOTNET_DbgEnableMiniDump</code>	If set to 1, enable core dump generation.	0
<code>COMPlus_DbgMiniDumpType</code> or <code>DOTNET_DbgMiniDumpType</code>	Type of dump to be collected. For more information, see the table below	2 (<code>MiniDumpWithPrivateReadWriteMemory</code>)
<code>COMPlus_DbgMiniDumpName</code> or <code>DOTNET_DbgMiniDumpName</code>	Path to a file to write the dump to.	<code>/tmp/coredump.<pid></code>
<code>COMPlus_CreateDumpDiagnostics</code> or <code>DOTNET_CreateDumpDiagnostics</code>	If set to 1, enable diagnostic logging of dump process.	0

ENVIRONMENT VARIABLE	DESCRIPTION	DEFAULT VALUE
<code>COMPlus_EnableCrashReport</code> or <code>DOTNET_EnableCrashReport</code>	(Requires .NET 6 or later) If set to 1, the runtime generates a JSON-formatted crash report that includes information about the threads and stack frames of the crashing application. The crash report name is the dump path/name with <code>.crashreport.json</code> appended.	
<code>COMPlus_CreateDumpVerboseDiagnostics</code> or <code>DOTNET_CreateDumpVerboseDiagnostics</code>	(Requires .NET 7 or later) If set to 1, enables verbose diagnostic logging of the dump process.	0
<code>COMPlus_CreateDumpLogFile</code> or <code>DOTNET_CreateDumpLogFile</code>	(Requires .NET 7 or later) The path of the file to which the diagnostic messages should be written. If unset, the diagnostic messages are written to the console of the crashing application.	

NOTE

.NET 7 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for these environment variables. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Starting in .NET 5, `DOTNET_MiniDumpName` may also include formatting template specifiers that will be filled in dynamically:

SPECIFIER	VALUE
<code>%%</code>	A single % character
<code>%p</code>	PID of dumped process
<code>%e</code>	The process executable filename
<code>%h</code>	Host name return by <code>gethostname()</code>
<code>%t</code>	Time of dump, expressed as seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC)

The following table shows all the values you can use for `DOTNET_DbgMiniDumpType`. For example, setting `DOTNET_DbgMiniDumpType` to 1 means `MiniDumpNormal` type dump will be collected on a crash.

VALUE	NAME	DESCRIPTION
1	<code>Mini</code>	A small dump containing module lists, thread lists, exception information, and all stacks.

Value	Name	Description
2	Heap	A large and relatively comprehensive dump containing module lists, thread lists, all stacks, exception information, handle information, and all memory except for mapped images.
3	Triage	Same as <code>Mini</code> , but removes personal user information, such as paths and passwords.
4	Full	The largest dump containing all memory including the module images.

Collect dumps at a specific point in time

You may want to collect a dump when the app hasn't crashed yet. For example, if you want to examine the state of an application that seems to be in a deadlock, configuring the environment variables to collect dumps on crash will not be helpful because the app is still running.

To collect dump at your own request, you can use `dotnet-dump`, which is a CLI tool for collecting and analyzing dumps. For more information on how to use it to collect dumps with `dotnet-dump`, see [Dump collection and analysis utility](#).

Analyze dumps

You can analyze dumps using the `dotnet-dump` CLI tool or with [Visual Studio](#).

NOTE

Visual Studio version 16.8 and later allows you to [open Linux dumps](#) generated on .NET Core 3.1.7 or later.

NOTE

If native debugging is necessary, the [SOS debugger extension](#) can be used with [LLDB on Linux and macOS](#). SOS is also supported with [Windbg/cdb](#) on Windows, although Visual Studio is recommended.

Debug Linux dumps

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.0 SDK and later versions

Collect dumps on Linux

The two recommended ways of collecting dumps on Linux are:

- `dotnet-dump` CLI tool
- [Environment variables](#) that collect dumps on crashes

Analyze dumps on Linux

After a dump is collected, it can be analyzed using the `dotnet-dump` tool with the `dotnet-dump analyze` command. This analysis step needs to be run on a machine that has the same architecture and Linux distro as the environment the dump was captured in. The `dotnet-dump` tool supports displaying information about .NET code, but is not useful for understanding code issues for other languages like C and C++.

Alternatively, [LLDB](#) can be used to analyze dumps on Linux, which allows analysis of both managed and native code. LLDB uses the SOS extension to debug managed code. The `dotnet-sos` CLI tool can be used to install SOS, which has [many useful commands](#) for debugging managed code. In order to analyze .NET Core dumps, LLDB and SOS require the following .NET Core binaries from the environment the dump was created in:

1. libmscordaccore.so
2. libcoreclr.so
3. dotnet (the host used to launch the app)

In most cases, these binaries can be downloaded using the `dotnet-symbol` tool. If the necessary binaries can't be downloaded with `dotnet-symbol` (for example, if a private version of .NET Core built from source was in use), it may be necessary to copy the files listed above from the environment the dump was created in. If the files aren't located next to the dump file, you can use the LLDB/SOS command `setclrpath <path>` to set the path they should be loaded from and `setsymbolserver -directory <path>` to set the path to look in for symbol files.

Once the necessary files are available, the dump can be loaded in LLDB by specifying the dotnet host as the executable to debug:

```
lldb --core <dump-file> <host-program>
```

In the above command line, `<dump-file>` is the path of the dump to analyze and `<host-program>` is the native program that started the .NET Core application. This is typically the `dotnet` binary unless the app is self-contained, in which case it is the name of the application without the dll extension.

Once LLDB starts, it may be necessary to use the `setsymbolserver` command to point at the correct symbol location (`setsymbolserver -ms` to use Microsoft's symbol server or `setsymbolserver -directory <path>` to specify a local path). Native symbols can be loaded by running `loadsymbols`. At this point, [SOS commands](#) can be used to analyze the dump.

Analyze dumps on Windows

Dumps collected from a Linux machine can also be analyzed on a Windows machine using [Visual Studio](#), [Windbg](#), or the [dotnet-dump](#) tool.

- **Visual Studio** - See the [Visual Studio dump debugging guide](#).
- **Windbg** - You can debug Linux dumps on windbg using the [same instructions](#) you would use to debug a Windows user-mode dump. Use the x64 version of windbg for dumps collected from a Linux x64 or Arm64 environment and the x86 version for dumps collected from a Linux x86 environment.
- **dotnet-dump** - View the dump using the [dotnet-dump analyze](#) command. Use the x64 version of dotnet-dump for dumps collected from a Linux x64 or Arm64 environment and the x86 version for dumps collected from a Linux x86 environment.

SOS debugging extension

9/20/2022 • 26 minutes to read • [Edit Online](#)

The SOS Debugging Extension lets you view information about code that is running inside the .NET Core runtime, both on live processes and dumps. The extension is preinstalled with [dotnet-dump](#) and [Windbg/dbg](#), and can be [downloaded](#) for use with LLDB. You can use the SOS Debugging Extension to:

- Collect information about the managed heap.
- Look for heap corruptions.
- Display internal data types used by the runtime.
- View information about all managed code running inside the runtime.

Syntax

Windows

```
![command] [options]
```

Linux and macOS

```
sos [command] [options]
```

Many of the commands have aliases or shortcuts under lldb:

```
clystack [options]
```

Commands

The following table of commands is also available under [Help](#) or [soshelp](#). Individual command help is available using `soshelp <command>`.

COMMAND	DESCRIPTION
<code>bpm [-nofuturemodule] [<module name> <method name>] [-md <MethodDesc>] -list -clear <pending breakpoint number> -clearall</code>	<p>Creates a breakpoint at the specified method in the specified module.</p> <p>If the specified module and method have not been loaded, this command waits for a notification that the module was loaded and just-in-time (JIT) compiled before creating a breakpoint.</p> <p>You can manage the list of pending breakpoints by using the <code>-list</code>, <code>-clear</code>, and <code>-clearall</code> options:</p> <p>The <code>-list</code> option generates a list of all the pending breakpoints. If a pending breakpoint has a non-zero module ID, that breakpoint is specific to a function in that particular loaded module. If the pending breakpoint has a zero module ID, that breakpoint applies to modules that have not yet been loaded.</p> <p>Use the <code>-clear</code> or <code>-clearall</code> option to remove pending breakpoints from the list.</p>

COMMAND	DESCRIPTION
<p>CLRStack [-a] [-l] [-p] [-n] [-f] [-r] [-all]</p>	<p>Provides a stack trace of managed code only.</p> <p>The -p option shows arguments to the managed function.</p> <p>The -l option shows information on local variables in a frame. The SOS Debugging Extension cannot retrieve local names, so the output for local names is in the format <i><local/ address> = <value></i>.</p> <p>The -a option is a shortcut for -l and -p combined.</p> <p>The -n option disables the display of source file names and line numbers. If the debugger has the option SYMOPT_LOAD_LINES specified, SOS will look up the symbols for every managed frame and if successful will display the corresponding source file name and line number. The -n (No line numbers) parameter can be specified to disable this behavior.</p> <p>The -f option (full mode) displays the native frames intermixing them with the managed frames and the assembly name and function offset for the managed frames. This option does not display native frames when used with <code>dotnet-dump</code>.</p> <p>The -r option dumps the registers for each stack frame.</p> <p>The -all option dumps all the managed threads' stacks.</p>
<p>COMState</p>	<p>Lists the COM apartment model for each thread and a <code>Context</code> pointer, if available. This command is only supported on Windows.</p>
<p>DumpArray [-start <i><startIndex></i>] [-length <i><length></i>] [-details] [-nofields] <i><array object address></i></p> <p>-or-</p> <p>DA [-start <i><startIndex></i>] [-length <i><length></i>] [-detail] [-nofields] <i><array object address></i></p>	<p>Examines elements of an array object.</p> <p>The -start option specifies the starting index at which to display elements.</p> <p>The -length option specifies how many elements to show.</p> <p>The -details option displays details of the element using the DumpObj and DumpVC formats.</p> <p>The -nofields option prevents arrays from displaying. This option is available only when the -detail option is specified.</p>

COMMAND	DESCRIPTION
<pre>DumpAsync (dumpasync) [-mt <MethodTable address>] [-type <partial type name>] [-waiting] [-roots]</pre>	<p>DumpAsync traverses the garbage collected heap and looks for objects representing async state machines as created when an async method's state is transferred to the heap. This command recognizes async state machines defined as <code>async void</code>, <code>async Task</code>, <code>async Task<T></code>, <code>async ValueTask</code>, and <code>async ValueTask<T></code>.</p> <p>The output includes a block of details for each async state machine object found. These details include:</p> <ul style="list-style-type: none"> - A line for the type of the async state machine object, including its MethodTable address, its object address, its size, and its type name. - A line for the state machine type name as contained in the object. - A listing of each field on the state machine. - A line for a continuation from this state machine object, if one or more has been registered. - Discovered GC roots for this async state machine object.
<pre>DumpAssembly <assembly address></pre>	<p>Displays information about an assembly.</p> <p>The DumpAssembly command lists multiple modules, if they exist.</p> <p>You can get an assembly address by using the DumpDomain command.</p>
<pre>DumpClass <EEClass address></pre>	<p>Displays information about the <code>EEClass</code> structure associated with a type.</p> <p>The DumpClass command displays static field values but does not display nonstatic field values.</p> <p>Use the DumpMT, DumpObj, Name2EE, or Token2EE command to get an <code>EEClass</code> structure address.</p>
<pre>DumpDomain [<domain address>]</pre>	<p>Enumerates each Assembly object that is loaded within the specified AppDomain object address. When called with no parameters, the DumpDomain command lists all AppDomain objects in a process. Since .NET Core only has one AppDomain, DumpDomain will only return one object.</p>

COMMAND	DESCRIPTION
<pre>DumpHeap [-stat] [-strings] [-short] [-min <size>] [-max <size>] [-thinlock] [-startAtLowerBound] [-mt <MethodTable address>] [-type <partial type name>] [start [end]]</pre>	<p>Displays information about the garbage-collected heap and collection statistics about objects.</p> <p>The DumpHeap command displays a warning if it detects excessive fragmentation in the garbage collector heap.</p> <p>The -stat option restricts the output to the statistical type summary.</p> <p>The -strings option restricts the output to a statistical string value summary.</p> <p>The -short option limits output to just the address of each object. This lets you easily pipe output from the command to another debugger command for automation.</p> <p>The -min option ignores objects that are less than the <code><size></code> parameter, specified in bytes.</p> <p>The -max option ignores objects that are larger than the <code><size></code> parameter, specified in bytes.</p> <p>The -thinlock option reports ThinLocks. For more information, see the SyncBlk command.</p> <p>The <code>-startAtLowerBound</code> option forces the heap walk to begin at the lower bound of a supplied address range. During the planning phase, the heap is often not walkable because objects are being moved. This option forces DumpHeap to begin its walk at the specified lower bound. You must supply the address of a valid object as the lower bound for this option to work. You can display memory at the address of a bad object to manually find the next method table. If the garbage collection is currently in a call to <code>memcpy</code>, you may also be able to find the address of the next object by adding the size to the start address, which is supplied as a parameter.</p> <p>The -mt option lists only those objects that correspond to the specified <code><MethodTable></code> structure.</p> <p>The -type option lists only those objects whose type name is a substring match of the specified string.</p> <p>The <code>start</code> parameter begins listing from the specified address.</p> <p>The <code>end</code> parameter stops listing at the specified address.</p>
<pre>DumpIL <Managed DynamicMethod object> <DynamicMethodDesc pointer> <MethodDesc pointer></pre>	<p>Displays the Microsoft intermediate language (MSIL) that is associated with a managed method.</p> <p>Dynamic MSIL is emitted differently than MSIL that's loaded from an assembly. Dynamic MSIL refers to objects in a managed object array rather than to metadata tokens.</p>

COMMAND	DESCRIPTION
DumpLog [-addr <addressOfStressLog>] [<Filename>]	<p>Writes the contents of an in-memory stress log to the specified file. If you do not specify a name, this command creates a file called StressLog.txt in the current directory.</p> <p>The in-memory stress log helps you diagnose stress failures without using locks or I/O. To enable the stress log, set the following registry keys under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework:</p> <p>(DWORD) StressLog = 1 (DWORD) LogFacility = 0xffffffff (DWORD) StressLogSize = 65536</p> <p>The optional <code>-addr</code> option lets you specify a stress log other than the default log.</p>
DumpMD <MethodDesc address>	<p>Displays information about a <code>MethodDesc</code> structure at the specified address.</p> <p>You can use the IP2MD command to get the <code>MethodDesc</code> structure address from a managed function.</p>
DumpMT [-MD] <MethodTable address>	<p>Displays information about a method table at the specified address. Specifying the <code>-MD</code> option displays a list of all methods defined with the object.</p> <p>Each managed object contains a method table pointer.</p>
DumpModule [-mt] <Module address>	<p>Displays information about a module at the specified address. The <code>-mt</code> option displays the types defined in a module and the types referenced by the module</p> <p>You can use the DumpDomain or DumpAssembly command to retrieve a module's address.</p>
DumpObj [-nofields] <object address> -or- DO <object address>	<p>Displays information about an object at the specified address. The DumpObj command displays the fields, the <code>EEClass</code> structure information, the method table, and the size of the object.</p> <p>You can use the DumpStackObjects command to retrieve an object's address.</p> <p>You can run the DumpObj command on fields of type <code>CLASS</code> because they are also objects.</p> <p>The <code>-nofields</code> option prevents fields of the object being displayed, it is useful for objects like String.</p>
DumpRuntimeTypes	<p>Displays the runtime type objects in the garbage collector heap and lists their associated type names and method tables.</p>

COMMAND	DESCRIPTION
DumpStack [-EE] [-n] [top <i>stack</i> [bottom <i>stack</i>]]	<p>Displays a stack trace.</p> <p>The -EE option causes the DumpStack command to display only managed functions. Use the top and bottom parameters to limit the stack frames displayed on x86 platforms.</p> <p>The -n option disables the display of source file names and line numbers. If the debugger has the option SYMOPT_LOAD_LINES specified, SOS will look up the symbols for every managed frame and if successful will display the corresponding source file name and line number. The -n (No line numbers) parameter can be specified to disable this behavior.</p>
DumpSig < <i>sigaddr</i> > < <i>moduleaddr</i> >	Displays information about a Sig structure at the specified address.
DumpSigElem < <i>sigaddr</i> > < <i>moduleaddr</i> >	Displays a single element of a signature object. In most cases, you should use DumpSig to look at individual signature objects. However, if a signature has been corrupted in some way, you can use DumpSigElem to read the valid portions of it.
DumpStackObjects [-verify] [top <i>stack</i> [bottom <i>stack</i>]] -or- DSO [-verify] [top <i>stack</i> [bottom <i>stack</i>]]	<p>Displays all managed objects found within the bounds of the current stack.</p> <p>The -verify option validates each non-static CLASS field of an object field.</p> <p>Use the DumpStackObject command with stack tracing commands such as K (windbg) or bt (lldb) along with the clrstack command to determine the values of local variables and parameters.</p>
DumpVC < <i>MethodTable address</i> > < <i>Address</i> >	<p>Displays information about the fields of a value class at the specified address.</p> <p>The MethodTable parameter allows the DumpVC command to correctly interpret fields. Value classes do not have a method table as their first field.</p>
EEHeap [-gc] [-loader]	<p>Displays information about process memory consumed by internal runtime data structures.</p> <p>The -gc and -loader options limit the output of this command to garbage collector or loader data structures.</p> <p>The information for the garbage collector lists the ranges of each segment in the managed heap. If the pointer falls within a segment range given by -gc, the pointer is an object pointer.</p>

COMMAND	DESCRIPTION
EEStack [-short] [-EE]	<p>Runs the DumpStack command on all threads in the process.</p> <p>The -EE option is passed directly to the DumpStack command. The -short parameter limits the output to the following kinds of threads:</p> <ul style="list-style-type: none"> Threads that have taken a lock. Threads that have been stalled in order to allow a garbage collection. Threads that are currently in managed code.
EHInfo [<MethodDesc address>] [<Code address>]	<p>Displays the exception handling blocks in a specified method. This command displays the code addresses and offsets for the clause block (the <code>try</code> block) and the handler block (the <code>catch</code> block).</p>
FAQ	<p>Displays frequently asked questions. Not supported in <code>dotnet-dump</code>.</p>
FinalizeQueue [-detail] [-allReady] [-short]	<p>Displays all objects registered for finalization.</p> <p>The -detail option displays extra information about any <code>SyncBlocks</code> that need to be cleaned up, and any <code>RuntimeCallableWrappers</code> (RCWs) that await cleanup. Both of these data structures are cached and cleaned up by the finalizer thread when it runs.</p> <p>The -allReady option displays all objects that are ready for finalization, regardless of whether they are already marked by the garbage collection as such, or will be marked by the next garbage collection. The objects that are in the "ready for finalization" list are finalizable objects that are no longer rooted. This option can be very expensive, because it verifies whether all the objects in the finalizable queues are still rooted.</p> <p>The -short option limits the output to the address of each object. If it is used in conjunction with -allReady, it enumerates all objects that have a finalizer that are no longer rooted. If it is used independently, it lists all objects in the finalizable and "ready for finalization" queues.</p>
FindAppDomain <Object address>	<p>Determines the application domain of an object at the specified address.</p>
FindRoots -gen <N> -gen any <object address>	<p>Causes the debugger to break in the debugger on the next collection of the specified generation. The effect is reset as soon as the break occurs. To break on the next collection, you have to reissue the command. The <code><object address></code> form of this command is used after the break caused by the -gen or -gen any has occurred. At that time, the debugger is in the right state for FindRoots to identify roots for objects from the current condemned generations. Only supported on Windows.</p>

COMMAND	DESCRIPTION
GCHandle s [-perdomain]	<p>Displays statistics about garbage collector handles in the process.</p> <p>The -perdomain option arranges the statistics by application domain.</p> <p>Use the GCHandles command to find memory leaks caused by garbage collector handle leaks. For example, a memory leak occurs when code retains a large array because a strong garbage collector handle still points to it, and the handle is discarded without freeing it.</p> <p>Only supported on Windows.</p>
GCHandleLeak s	<p>Searches memory for any references to strong and pinned garbage collector handles in the process and displays the results. If a handle is found, the GCHandleLeaks command displays the address of the reference. If a handle is not found in memory, this command displays a notification. Only supported on Windows.</p>
GCInfo <MethodDesc address> <Code address>	<p>Displays data that indicates when registers or stack locations contain managed objects. If a garbage collection occurs, the collector must know the locations of references to objects so it can update them with new object pointer values.</p>
GCRoot [-nostacks] [-all] <Object address>	<p>Displays information about references (or roots) to an object at the specified address.</p> <p>The GCRoot command examines the entire managed heap and the handle table for handles within other objects and handles on the stack. Each stack is then searched for pointers to objects, and the finalizer queue is also searched.</p> <p>This command does not determine whether a stack root is valid or is discarded. Use the clrstack and U commands to disassemble the frame that the local or argument value belongs to in order to determine if the stack root is still in use.</p> <p>The -nostacks option restricts the search to garbage collector handles and reachable objects.</p> <p>The -all option forces all roots to be displayed instead of just the unique roots.</p>
GCWhere <object address>	<p>Displays the location and size in the garbage collection heap of the argument passed in. When the argument lies in the managed heap but is not a valid object address, the size is displayed as 0 (zero).</p>
Help (soshelp) [<command>] [faq]	<p>Displays all available commands when no parameter is specified, or displays detailed help information about the specified command.</p> <p>The faq parameter displays answers to frequently asked questions.</p>

COMMAND	DESCRIPTION
HeapStat [-inclUnrooted -iu]	Displays the generation sizes for each heap and the total free space in each generation on each heap. If the -inclUnrooted option is specified, the report includes information about the managed objects from the garbage collection heap that is no longer rooted. Only supported on Windows.
HistClear	Releases any resources used by the family of Hist commands. Generally, you do not have to explicitly call HistClear , because each HistInit cleans up the previous resources.
HistInit	Initializes the SOS structures from the stress log saved in the debugger.
HistObj <obj_address>	Examines all stress log relocation records and displays the chain of garbage collection relocations that may have led to the address passed in as an argument.
HistObjFind <obj_address>	Displays all the log entries that reference an object at the specified address.
HistRoot <root>	Displays information related to both promotions and relocations of the specified root. The root value can be used to track the movement of an object through the garbage collections.
IP2MD (ip2md) <Code address>	Displays the MethodDesc structure at the specified address in code that has been JIT-compiled.
ListNearObj (lno) <obj_address>	Displays the objects preceding and following the specified address. The command looks for the address in the garbage collection heap that looks like a valid beginning of a managed object (based on a valid method table) and the object following the argument address. Only supported on Windows.
MinidumpMode [0] [1]	Prevents running unsafe commands when using a minidump. Pass 0 to disable this feature or 1 to enable this feature. By default, the MinidumpMode value is set to 0. Minidumps created with the .dump /m command or .dump command have limited CLR-specific data and allow you to run only a subset of SOS commands correctly. Some commands may fail with unexpected errors because required areas of memory are not mapped or are only partially mapped. This option protects you from running unsafe commands against minidumps. Only supported with Windbg.

COMMAND	DESCRIPTION
<p>Name2EE (<code>name2ee</code>) <module name> <type or method name></p> <p>-or-</p> <p>Name2EE <module name>!<type or method name></p>	<p>Displays the <code>MethodTable</code> structure and <code>EEClass</code> structure for the specified type or method in the specified module.</p> <p>The specified module must be loaded in the process.</p> <p>To get the proper type name, browse the module by using the Ildasm.exe (IL Disassembler). You can also pass <code>*</code> as the module name parameter to search all loaded managed modules. The <i>module name</i> parameter can also be the debugger's name for a module, such as <code>mscorlib</code> or <code>image00400000</code>.</p> <p>This command supports the Windows debugger syntax of <<code>module</code>> !<<code>type</code>>. The type must be fully qualified.</p>
<p>ObjSize [<Object address>] [-aggregate] [-stat]</p>	<p>Displays the size of the specified object. If you do not specify any parameters, the ObjSize command displays the size of all objects found on managed threads, displays all garbage collector handles in the process, and totals the size of any objects pointed to by those handles. The ObjSize command includes the size of all child objects in addition to the parent.</p> <p>The -aggregate option can be used in conjunction with the -stat argument to get a detailed view of the types that are still rooted. By using <code>!dumpheap -stat</code> and <code>!objsize -aggregate -stat</code>, you can determine which objects are no longer rooted and diagnose various memory issues.</p> <p>Only supported on Windows.</p>
<p>PrintException [-nested] [-lines] [<Exception object address>]</p> <p>-or-</p> <p>PE [-nested] [<Exception object address>]</p>	<p>Displays and formats fields of any object derived from the Exception class at the specified address. If you do not specify an address, the PrintException command displays the last exception thrown on the current thread.</p> <p>The -nested option displays details about nested exception objects.</p> <p>The -lines option displays source information, if available.</p> <p>You can use this command to format and view the <code>_stackTrace</code> field, which is a binary array.</p>
<p>ProcInfo [-env] [-time] [-mem]</p>	<p>Displays environment variables for the process, kernel CPU time, and memory usage statistics. Only supported with Windbg.</p>
<p>RCWCleanupList <RCWCleanupList address></p>	<p>Displays the list of runtime callable wrappers at the specified address that are awaiting cleanup. Only supported with Windbg.</p>
<p>SaveModule <Base address> <Filename></p>	<p>Writes an image, which is loaded in memory at the specified address, to the specified file. Only supported with Windbg.</p>

COMMAND	DESCRIPTION
SetHostRuntime [<runtime-directory>]	<p>This command sets the path to the .NET Core runtime to use to host the managed code that runs as part of SOS in the debugger (lldb). The runtime needs to be at least version 2.1.0 or greater. If there are spaces in directory, it needs to be single-quoted (').</p> <p>Normally, SOS attempts to find an installed .NET Core runtime to run its managed code automatically but this command is available if it fails. The default is to use the same runtime (libcoreclr) being debugged. Use this command if the default runtime being debugged isn't working enough to run the SOS code or if the version is less than 2.1.0.</p> <p>If you received the following error message when running a SOS command, use this command to set the path to 2.1.0 or greater .NET Core runtime.</p> <pre>(lldb) clrstack Error: Fail to initialize CoreCLR 80004005 ClrStack failed</pre> <pre>(lldb) sethostruntime /usr/share/dotnet/shared/Microsoft.NETCore.App/2.1.6</pre> <p>You can use the "dotnet --info" in a command shell to find the path of an installed .NET Core runtime.</p>
SetSymbolServer [-ms] [-disable] [-log] [-loadsymbols] [-cache <cache-path>] [-directory <search-directory>] [-sympath <windows-symbol-path>] [<symbol-server-URL>]	<p>Enables the symbol server downloading support.</p> <p>The -ms option enables downloading from the public Microsoft symbol server.</p> <p>The -disable option turns on the symbol download support.</p> <p>The -cache <cache-path> option specifies a symbol cache directory. The default is \$HOME/.dotnet/symbolcache if not specified.</p> <p>The -directory option adds a path to search for symbols. Can be more than one.</p> <p>The -sympath option adds server, cache, and directory paths in the Windows symbol path format.</p> <p>The -log option enables symbol download logging.</p> <p>The -loadsymbols option attempts to download the native .NET Core symbols for the runtime. Supported on lldb and dotnet-dump.</p>
SOSFlush	Flushes an internal SOS cache.
SOSStatus [-reset]	Displays internal SOS status or reset the internal cached state.

COMMAND	DESCRIPTION
StopOnException [-derived] [-create -create2] <Exception> <Pseudo-register number>	<p>Causes the debugger to stop when the specified exception is thrown, but to continue running when other exceptions are thrown.</p> <p>The -derived option catches the specified exception and every exception that derives from the specified exception.</p> <p>Only supported with Windbg.</p>
SyncBlk [-all <syncblk number>]	<p>Displays the specified <code>SyncBlock</code> structure or all <code>SyncBlock</code> structures. If you do not pass any arguments, the SyncBlk command displays the <code>SyncBlock</code> structure corresponding to objects that are owned by a thread.</p> <p>A <code>SyncBlock</code> structure is a container for extra information that does not need to be created for every object. It can hold COM interop data, hash codes, and locking information for thread-safe operations.</p>
ThreadPool	<p>Displays information about the managed thread pool, including the number of work requests in the queue, the number of completion port threads, and the number of timers.</p>
Threads (clrthreads) [-live] [-special]	<p>Displays all managed threads in the process.</p> <p>The Threads command displays the debugger shorthand ID, the CLR thread ID, and the operating system thread ID. Additionally, the Threads command displays a Domain column that indicates the application domain in which a thread is executing, an APT column that displays the COM apartment mode, and an Exception column that displays the last exception thrown in the thread.</p> <p>The -live option displays threads associated with a live thread.</p> <p>The -special option displays all special threads created by the CLR. Special threads include garbage collection threads (in concurrent and server garbage collection), debugger helper threads, finalizer threads, AppDomain unload threads, and thread pool timer threads.</p>
ThreadState < State value field >	<p>Displays the state of the thread. The <code>value</code> parameter is the value of the <code>state</code> field in the Threads report output.</p>
Token2EE <module name> <token>	<p>Turns the specified metadata token in the specified module into a <code>MethodTable</code> structure or <code>MethodDesc</code> structure.</p> <p>You can pass <code>*</code> for the module name parameter to find what that token maps to in every loaded managed module. You can also pass the debugger's name for a module, such as <code>mscorlib</code> or <code>image00400000</code>.</p>

COMMAND	DESCRIPTION
U [-gcinfo] [-ehinfo] [-n] <MethodDesc address> <Code address>	<p>Displays an annotated disassembly of a managed method specified either by a <code>MethodDesc</code> structure pointer for the method or by a code address within the method body. The U command displays the entire method from start to finish, with annotations that convert metadata tokens to names.</p> <p>The <code>-gcinfo</code> option causes the U command to display the <code>GCInfo</code> structure for the method.</p> <p>The <code>-ehinfo</code> option displays exception information for the method. You can also obtain this information with the EHInfo command.</p> <p>The <code>-n</code> option disables the display of source file names and line numbers. If the debugger has the option <code>SYMOPT_LOAD_LINES</code> specified, SOS looks up the symbols for every managed frame and, if successful, displays the corresponding source file name and line number. You can specify the <code>-n</code> option to disable this behavior.</p>
VerifyHeap	<p>Checks the garbage collector heap for signs of corruption and displays any errors found.</p> <p>Heap corruptions can be caused by platform invoke calls that are constructed incorrectly.</p>
VerifyObj <object address>	Checks the object that is passed as an argument for signs of corruption. Only supported on Windows.
VMMap	Traverses the virtual address space and displays the type of protection applied to each region. Only supported with Windbg.
VMStat	Provides a summary view of the virtual address space, ordered by each type of protection applied to that memory (free, reserved, committed, private, mapped, image). The TOTAL column displays the result of the AVERAGE column multiplied by the BLK COUNT column. Only supported with Windbg.

Dotnet-Dump

For a list of available SOS commands with `dotnet-dump analyze`, see [dotnet-dump](#).

Windows Debugger

You can also use the SOS Debugging Extension by loading it into the [WinDbg/dbg debugger](#) and executing commands within the Windows debugger. SOS commands can be used on live processes or dumps.

Windbg should load the SOS extension automatically whenever the process being debugged contains the .NET Core runtime (coreclr.dll or libcoreclr.so).

LLDB Debugger

For instructions on configuring SOS for LLDB, see [dotnet-sos](#). SOS commands can be used on live processes or dumps.

By default you can reach all the SOS commands by entering: `sos [command_name]`. However, the common commands have been aliased so that you don't need the `sos` prefix:

COMMAND	FUNCTION
<code>bpmd</code>	Creates a breakpoint at the specified managed method in the specified module.
<code>clrstack</code>	Provides a stack trace of managed code only.
<code>clrthreads</code>	List the managed threads that are running.
<code>clru</code>	Displays an annotated disassembly of a managed method.
<code>dso</code>	Displays all managed objects found within the bounds of the current stack.
<code>dumpasync</code>	Displays info about async state machines on the garbage-collected heap.
<code>dumpclass</code>	Displays information about the <code>EEClass</code> structure at the specified address.
<code>dumpdomain</code>	Displays information all the AppDomains and all assemblies within the specified domain.
<code>dumpheap</code>	Displays info about the garbage-collected heap and collection statistics about objects.
<code>dumpil</code>	Displays the Microsoft intermediate language (MSIL) that is associated with a managed method.
<code>dumplog</code>	Writes the contents of an in-memory stress log to the specified file.
<code>dumpmd</code>	Displays information about the <code>MethodDesc</code> structure at the specified address.
<code>dumpmodule</code>	Displays information about the module at the specified address.
<code>dumpmt</code>	Displays information about the method table at the specified address.
<code>dumpobj</code>	Displays info the object at the specified address.
<code>dumpstack</code>	Displays a native and managed stack trace.
<code>eeheap</code>	Displays info about process memory consumed by internal runtime data structures.
<code>eestack</code>	Runs <code>dumpstack</code> on all threads in the process.
<code>gcroot</code>	Displays info about references (or roots) to the object at the specified address.
<code>histclear</code>	Releases any resources used by the family of Hist commands.

COMMAND	FUNCTION
<code>histinit</code>	Initializes the SOS structures from the stress log saved in the debugger.
<code>histobj</code>	Examines all stress log relocation records and displays the chain of garbage collection relocations that may have led to the address passed in as an argument.
<code>histobjfind</code>	Displays all the log entries that reference the object at the specified address.
<code>histroot</code>	Displays information related to both promotions and relocations of the specified root.
<code>ip2md</code>	Displays the <code>MethodDesc</code> structure at the specified address in code that has been JIT-compiled.
<code>loadsymbols</code>	Load the .NET Core native module symbols.
<code>name2ee</code>	Displays the <code>MethodTable</code> and <code>EEClass</code> structures for the specified type or method in the specified module.
<code>pe</code>	Displays and formats fields of any object derived from the <code>Exception</code> class at the specified address.
<code>setclrpath</code>	Sets the path to load coreclr dac/dbi files. <code>setclrpath <path></code>
<code>sethostruntime</code>	Sets or displays the .NET Core runtime directory to use to run managed code in SOS.
<code>setsymbolserver</code>	Enables the symbol server support.
<code>setsostid</code>	Sets the current OS tid/thread index instead of using the one lldb provides. <code>setsostid <tid> <index></code>
<code>sos</code>	Various coreclr debugging commands. For more information, see 'soshelp'. <code>sos <command-name> <args></code>
<code>soshelp</code>	Displays all available commands when no parameter is specified, or displays detailed help information about the specified command: <code>soshelp <command></code>
<code>syncblk</code>	Displays the SyncBlock holder info.

Windbg/cdb example usage

COMMAND	DESCRIPTION
<code>!dumparray -start 2 -length 5 -detail 00ad28d0</code>	Displays the contents of an array at the address <code>00ad28d0</code> . The display starts from the second element and continues for five elements.

COMMAND	DESCRIPTION
<code>!dumpassembly 1ca248</code>	Displays the contents of an assembly at the address <code>1ca248</code> .
<code>!dumpheap</code>	Displays information about the garbage collector heap.
<code>!DumpLog</code>	Writes the contents of the in-memory stress log to a (default) file called <code>StressLog.txt</code> in the current directory.
<code>!dumpmd 902f40</code>	Displays the <code>MethodDesc</code> structure at the address <code>902f40</code> .
<code>!dumpmodule 1caa50</code>	Displays information about a module at the address <code>1caa50</code> .
<code>!DumpObj a79d40</code>	Displays information about an object at the address <code>a79d40</code> .
<code>!DumpVC 0090320c 00a79d9c</code>	Displays the fields of a value class at the address <code>00a79d9c</code> using the method table at the address <code>0090320c</code> .
<code>!eeheap -gc</code>	Displays the process memory used by the garbage collector.
<code>!finalizequeue</code>	Displays all objects scheduled for finalization.
<code>!findappdomain 00a79d98</code>	Determines the application domain of an object at the address <code>00a79d98</code> .
<code>!gcinfo 5b68dbb8</code>	Displays all garbage collector handles in the current process.
<code>!name2ee unittest.exe MainClass.Main</code>	Displays the <code>MethodTable</code> and <code>EEClass</code> structures for the <code>Main</code> method in the class <code>MainClass</code> in the module <code>unittest.exe</code> .
<code>!token2ee unittest.exe 02000003</code>	Displays information about the metadata token at the address <code>02000003</code> in the module <code>unittest.exe</code> .

LLDB example usage

COMMAND	DESCRIPTION
<code>sos DumpArray -start 2 -length 5 -detail 00ad28d0</code>	Displays the contents of an array at the address <code>00ad28d0</code> . The display starts from the second element and continues for five elements.
<code>sos DumpAssembly 1ca248</code>	Displays the contents of an assembly at the address <code>1ca248</code> .
<code>dumpheap</code>	Displays information about the garbage collector heap.
<code>dumplog</code>	Writes the contents of the in-memory stress log to a (default) file called <code>StressLog.txt</code> in the current directory.

COMMAND	DESCRIPTION
<code>dumpmd 902f40</code>	Displays the <code>MethodDesc</code> structure at the address <code>902f40</code> .
<code>dumpmodule 1caa50</code>	Displays information about a module at the address <code>1caa50</code> .
<code>dumpobj a79d40</code>	Displays information about an object at the address <code>a79d40</code> .
<code>sos DumpVC 0090320c 00a79d9c</code>	Displays the fields of a value class at the address <code>00a79d9c</code> using the method table at the address <code>0090320c</code> .
<code>eeheap -gc</code>	Displays the process memory used by the garbage collector.
<code>sos FindAppDomain 00a79d98</code>	Determines the application domain of an object at the address <code>00a79d98</code> .
<code>sos GCInfo 5b68dbb8</code>	Displays all garbage collector handles in the current process.
<code>name2ee unittest.exe MainClass.Main</code>	Displays the <code>MethodTable</code> and <code>EEClass</code> structures for the <code>Main</code> method in the class <code>MainClass</code> in the module <code>unittest.exe</code> .
<code>sos Token2EE unittest.exe 02000003</code>	Displays information about the metadata token at the address <code>02000003</code> in the module <code>unittest.exe</code> .
<code>clrthreads</code>	Displays the managed threads.

.NET logging and tracing

9/20/2022 • 3 minutes to read • [Edit Online](#)

Code can be instrumented to produce a log, which serves as a record of interesting events that occurred while the program was running. To understand the application's behavior, logs are reviewed. Logging and tracing both encapsulate this technique. .NET has accumulated several different logging APIs over its history and this article will help you understand what options are available.

Key distinctions in logging APIs

Structured logging

Logging APIs can either be structured or unstructured:

- Unstructured: Log entries have free-form text content that is intended to be viewed by humans.
- Structured: Log entries have a well defined schema and can be encoded in different binary and textual formats. These logs are designed to be machine translatable and queryable so that both humans and automated systems can work with them easily.

APIs that support structured logging are preferable for non-trivial usage. They offer more functionality, flexibility, and performance with little difference in usability.

Configuration

For simple use cases, you might want to use APIs that directly write messages to the console or a file. But most software projects will find it useful to configure which log events get recorded and how they are persisted. For example, when running in a local dev environment, you might want to output plain text to the console for easy readability. Then when the application is deployed to a production environment, you might switch to have the logs stored in a dedicated database or a set of rolling files. APIs with good configuration options will make these transitions easy, whereas less configurable options would require updating the instrumentation code everywhere to make changes.

Sinks

Most logging APIs allow log messages to be sent to different destinations called sinks. Some APIs have a large number of pre-made sinks, whereas others only have a few. If no pre-made sink exists, there's usually an extensibility API that will let you author a custom sink, although this requires writing a bit more code.

.NET logging APIs

`ILogger`

For most cases, whether adding logging to an existing project or creating a new project, the `ILogger` interface is a good default choice. `ILogger` supports fast structured logging, flexible configuration, and a collection of [common sinks](#). Additionally, the `ILogger` interface can also serve as a facade over many [third party logging implementations](#) that offer more functionality and extensibility.

`EventSource`

`EventSource` is an older high performance structured logging API. It was originally designed to integrate well with [Event Tracing for Windows \(ETW\)](#), but was later extended to support [EventPipe](#) cross-platform tracing and [EventListener](#) for custom sinks. In comparison to `ILogger`, `EventSource` has relatively few pre-made logging sinks and there is no built-in support to configure via separate configuration files. `EventSource` is excellent if you want tighter control over [ETW](#) or [EventPipe](#) integration, but for general purpose logging, `ILogger` is more

flexible and easier to use.

Trace

`System.Diagnostics.Trace` and `System.Diagnostics.Debug` are .NET's oldest logging APIs. These classes have flexible configuration APIs and a large ecosystem of sinks, but only support unstructured logging. On .NET Framework they can be configured via an app.config file, but in .NET Core, there's no built-in, file-based configuration mechanism. The .NET team continues to support these APIs for backward-compatibility purposes, but no new functionality will be added. These APIs are a fine choice for applications that are already using them. For newer apps that haven't already committed to a logging API, `ILogger` may offer better functionality.

Specialized logging APIs

Console

The `System.Console` class has the `Write` and `WriteLine` methods that can be used in simple logging scenarios. These APIs are very easy to get started with but the solution won't be as flexible as a general purpose logging API. Console only allows unstructured logging and there is no configuration support to select which log messages are enabled or to retarget to a different sink. Using the `ILogger` or `Trace` APIs with a console sink doesn't take much additional effort and keeps the logging configurable.

DiagnosticSource

`System.Diagnostics.DiagnosticSource` is intended for logging where the log messages will be analyzed synchronously in-process rather than serialized to any storage. This allows the source and listener to exchange arbitrary .NET objects as messages, whereas most logging APIs require the log event to be serializable. This technique can also be extremely fast, handling log events in tens of nanoseconds if the listener is implemented efficiently. Tools that use these APIs often act more like in-process profilers, though the API doesn't impose any constraint here.

EventLog

`System.Diagnostics.EventLog` is a Windows only API that writes messages to the Windows EventLog. In many cases using `ILogger` with an optional EventLog sink when running on Windows may give similar functionality without coupling the app tightly to the Windows OS.

Well-known event providers in .NET

9/20/2022 • 4 minutes to read • [Edit Online](#)

The .NET runtime and libraries write diagnostic events through a number of different event providers. Depending on your diagnostic needs, you can choose the appropriate providers to enable. This article describes some of the most commonly used event providers in the .NET runtime and libraries.

CoreCLR

"Microsoft-Windows-DotNetRuntime" provider

This provider emits various events from the .NET runtime, including GC, loader, JIT, exception, and other events. Read more about each event from this provider in [Runtime Provider Events List](#).

"Microsoft-DotNetCore-SampleProfiler" provider

This provider is a .NET runtime event provider that is used for CPU sampling for managed callstacks. When enabled, it captures a snapshot of each thread's managed callstack every 10 milliseconds. To enable this capture, you must specify an [EventLevel](#) of [Informational](#) or higher.

Framework libraries

"Microsoft-Extensions-DependencyInjection" provider

This provider logs information from [DependencyInjection](#). The following table shows events logged by the [Microsoft-Extensions-DependencyInjection](#) provider:

EVENT NAME	KEYWORD	LEVEL	DESCRIPTION
<code>CallSiteBuilt</code>		Verbose (5)	A call site has been built.
<code>ServiceResolved</code>		Verbose (5)	A service has been resolved.
<code>ExpressionTreeGenerated</code>		Verbose (5)	An expression tree has been generated.
<code>DynamicMethodBuilt</code>		Verbose (5)	A DynamicMethod has been built.
<code>ScopeDisposed</code>		Verbose (5)	A scope has been disposed.
<code>ServiceRealizationFailed</code>		Verbose (5)	A service realization has failed.
<code>ServiceProviderBuilt</code>	<code>ServiceProviderInitialized(0)</code>	Verbose (5)	A ServiceProvider has been built.
<code>ServiceProviderDescriptors</code>	<code>ServiceProviderInitialized(0)</code>	Verbose (5)	A list of ServiceDescriptor that has been used during the ServiceProvider build.

"System.Buffers.ArrayPoolEventSource" provider

This provider logs information from the [ArrayPool](#). The following table shows the events logged by

ArrayPoolEventSource :

EVENT NAME	LEVEL	DESCRIPTION
BufferRented	Verbose (5)	A buffer is successfully rented.
BufferAllocated	Informational (4)	A buffer is allocated by the pool.
BufferReturned	Verbose (5)	A buffer is returned to the pool.
BufferTrimmed	Informational (4)	A buffer is attempted to be freed due to memory pressure or inactivity.
BufferTrimPoll	Informational (4)	A check is being made to trim buffers.

"System.Net.Http" provider

This provider logs information from the HTTP stack. The following table shows the events logged by `System.Net.Http` provider:

EVENT NAME	LEVEL	DESCRIPTION
RequestStart	Informational (4)	An HTTP request has started.
RequestStop	Informational (4)	An HTTP request has finished.
RequestFailed	Error (2)	An HTTP request has failed.
ConnectionEstablished	Informational (4)	An HTTP connection has been established.
ConnectionClosed	Informational (4)	An HTTP connection has been closed.
RequestLeftQueue	Informational (4)	An HTTP request has left the request queue.
RequestHeadersStart	Informational (4)	An HTTP request for header has started.
RequestHeaderStop	Informational (4)	An HTTP request for header has finished.
RequestContentStart	Informational (4)	An HTTP request for content has started.
RequestContentStop	Informational (4)	An HTTP request for content has finished.
ResponseHeadersStart	Informational (4)	An HTTP response for header has started.
ResponseHeaderStop	Informational (4)	An HTTP response for header has finished.

EVENT NAME	LEVEL	DESCRIPTION
ResponseContentStart	Informational (4)	An HTTP response for content has started.
ResponseContentStop	Informational (4)	An HTTP response for content has finished.

"System.Net.NameResolution" provider

This provider logs information related to domain name resolution. The following table shows the events logged by `System.Net.NameResolution` :

EVENT NAME	LEVEL	DESCRIPTION
<code>ResolutionStart</code>	Informational (4)	A domain name resolution has started.
<code>ResolutionStop</code>	Informational (4)	A domain name resolution has finished.
<code>ResolutionFailed</code>	Informational (4)	A domain name resolution has failed.

"System.Net.Sockets" provider

This provider logs information from `Socket`. The following table shows the events logged by `System.Net.Sockets` provider:

EVENT NAME	LEVEL	DESCRIPTION
<code>ConnectStart</code>	Informational (4)	An attempt to start a socket connection has started.
<code>ConnectStop</code>	Informational (4)	An attempt to start a socket connection has finished.
<code>ConnectFailed</code>	Informational (4)	An attempt to start a socket connection has failed.
<code>AcceptStart</code>	Informational (4)	An attempt to accept a socket connection has started.
<code>AcceptStop</code>	Informational (4)	An attempt to accept a socket connection has finished.
<code>AcceptFailed</code>	Informational (4)	An attempt to accept a socket connection has failed.

"System.Threading.Tasks.TplEventSource" provider

This provider logs information on the [Task Parallel Library](#), such as Task scheduler events. The following table shows the events logged by `TplEventSource` :

EVENT NAME	KEYWORD	LEVEL	DESCRIPTION

Event Name	Keyword	Level	Description
<code>TaskScheduled</code>	<code>TaskTransfer (0x1)</code> <code>Tasks (0x2)</code>	Informational (4)	A Task is queued to the Task scheduler.
<code>TaskStarted</code>	<code>Tasks (0x2)</code>	Informational (4)	A Task has started executing.
<code>TaskCompleted</code>	<code>TaskStops (0x40)</code>	Informational (4)	A Task has finished executing.
<code>TaskWaitBegin</code>	<code>TaskTransfer (0x1)</code> <code>TaskWait (0x2)</code>	Informational (4)	Fired when an implicit or an explicit wait on a Task completion has started.
<code>TaskWaitEnd</code>	<code>Tasks (0x2)</code>	Verbose (5)	Fired when the wait for a Task completion returns.
<code>TaskWaitContinuationStarted</code>	<code>Tasks (0x2)</code>	Verbose (5)	Fired when the work (method) associated with a <code>TaskWaitEnd</code> is started.
<code>TaskWaitContinuationComplete</code>	<code>TaskStops (0x40)</code>	Verbose (5)	Fired when the work (method) associated with a <code>TaskWaitEnd</code> is completed.
<code>AwaitTaskContinuationSchedul</code>	<code>TaskTransfer (0x1)</code> <code>Tasks (0x2)</code>	Informational (4)	Fired when the an asynchronous continuation for a Task is scheduled.

ASP.NET Core

ASP.NET Core also provides several events to help you diagnose issues in the ASP.NET Core stack.

To learn more about the events in ASP.NET Core and how to consume them, see [Logging in .NET Core and ASP.NET Core](#).

Entity Framework core

EF Core also provides events to help you diagnose issues in EF Core.

To learn more about the events in EF Core and how to consume them, see [.NET Events in EF Core](#).

EventSource

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

[System.Diagnostics.Tracing.EventSource](#) is a fast structured logging solution built into the .NET runtime. On .NET Framework EventSource can send events to [Event Tracing for Windows \(ETW\)](#) and [System.Diagnostics.Tracing.EventListener](#). On .NET Core EventSource additionally supports [EventPipe](#), a cross-platform tracing option. Most often developers use EventSource logs for performance analysis, but EventSource can be used for any diagnostic tasks where logs are useful. The .NET runtime is already instrumented with [built-in events](#) and you can log your own custom events.

NOTE

Many technologies that integrate with EventSource use the terms 'Tracing' and 'Traces' instead of 'Logging' and 'Logs'. The meaning is the same here.

- [Getting started](#)
- [Instrumenting code to create events](#)
- [Collecting and viewing event traces](#)
- [Understanding Activity IDs](#)

Getting Started with EventSource

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

This walkthrough shows how to log a new event with [System.Diagnostics.Tracing.EventSource](#), collect events in a trace file, view the trace, and understand basic EventSource concepts.

NOTE

Many technologies that integrate with EventSource use the terms 'Tracing' and 'Traces' instead of 'Logging' and 'Logs'. The meaning is the same here.

Log an event

The goal of EventSource is to allow .NET developers to write code like this to log an event:

```
DemoEventSource.Log.AppStarted("Hello World!", 12);
```

This line of code has a logging object (`DemoEventSource.Log`), a method representing the event to log (`AppStarted`), and optionally some strongly typed event parameters (`HelloWorld!` and `12`). There are no verbosity levels, event IDs, message templates, or anything else that doesn't need to be at the call site. All of this other information about events is written by defining a new class derived from [System.Diagnostics.Tracing.EventSource](#).

Here's a complete minimal example:

```
using System.Diagnostics.Tracing;

namespace EventSourceDemo
{
    public static class Program
    {
        public static void Main(string[] args)
        {
            DemoEventSource.Log.AppStarted("Hello World!", 12);
        }
    }

    [EventSource(Name = "Demo")]
    class DemoEventSource : EventSource
    {
        public static DemoEventSource Log { get; } = new DemoEventSource();

        [Event(1)]
        public void AppStarted(string message, int favoriteNumber) => WriteEvent(1, message,
favoriteNumber);
    }
}
```

The `DemoEventSource` class declares a method for each type of event that you wish to log. In this case, a single event called 'AppStarted' is defined by the `AppStarted()` method. Each time the code invokes the `AppStarted` method another `AppStarted` event will be recorded in the trace if the event is enabled. This is some of the data

that can be captured with each event:

- Event name - A name that identifies the kind of event that was logged. The event name will be identical to the method name, 'AppStarted' in this case.
- Event ID - A numerical ID that identifies the kind of event that was logged. This serves a similar role to the name but can assist in fast automated log processing. The AppStarted event has an ID of 1, specified in the [EventAttribute](#).
- Source name - The name of the EventSource that contains the event. This is used as a namespace for events. Event names and IDs only need to be unique within the scope of their source. Here the source is named "Demo", specified in the [EventSourceAttribute](#) on the class definition. The source name is also commonly referred to as a provider name.
- Arguments - All the method argument values are serialized.
- Other information - Events can also contain timestamps, thread IDs, processor IDs, [Activity IDs](#), stack traces, and event metadata such as message templates, verbosity levels, and keywords.

For more information and best practices on creating events, see [Instrumenting code to create events](#).

Collect and view a trace file

There's no required configuration in code that describes which events should be enabled, where the logged data should be sent, or what format the data should be stored in. If you run the app now, it won't produce any trace file by default. EventSource uses the [Publish-subscribe pattern](#), which requires subscribers to indicate the events that should be enabled and to control all serialization for the subscribed events. EventSource has integrations for subscribing from [Event Tracing for Windows \(ETW\)](#) and [EventPipe](#) (.NET Core only). Custom subscribers can also be created using the [System.Diagnostics.Tracing.EventListener API](#).

This demo shows an [EventPipe](#) example for .NET Core apps. To learn about more options see [Collecting and viewing event traces](#). [EventPipe](#) is an open and cross-platform tracing technology built into the .NET Core runtime to give .NET developers trace collection tools and a portable compact trace format (*.nettrace files). [dotnet-trace](#) is a command-line tool that collects EventPipe traces.

1. Download and Install [dotnet-trace](#)
2. Build the console app above. This demo assumes the app is named EventSourceDemo.exe and it is in the current directory. At the command-line run:

```
>dotnet-trace collect --providers Demo -- EventSourceDemo.exe
```

This should show output similar to:

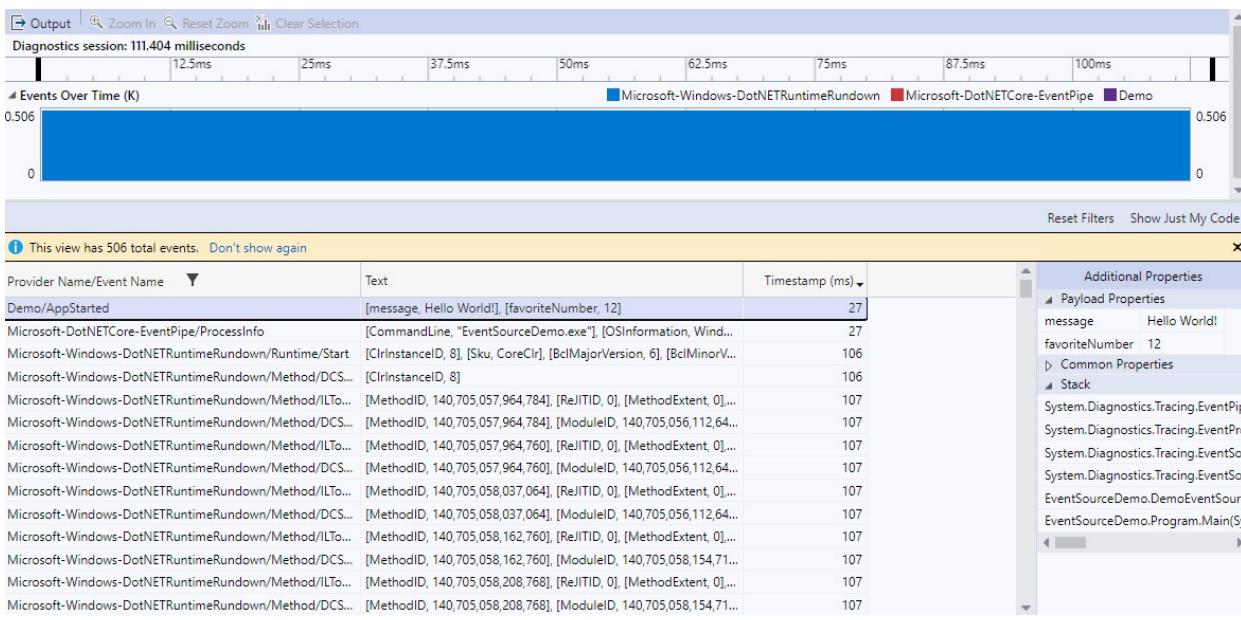

```
Provider Name          Keywords      Level      Enabled By
Demo                  0xFFFFFFFFFFFF  Verbose(5)  --providers

Launching: EventSourceDemo.exe
Process      : E:\temp\EventSourceDemo\bin\Debug\net6.0\EventSourceDemo.exe
Output File   : E:\temp\EventSourceDemo\bin\Debug\net6.0\EventSourceDemo.exe_20220303_001619.nettrace

[00:00:00:00]  Recording trace 0.00    (B)
Press <Enter> or <Ctrl+C> to exit...

Trace completed.
```

This command ran EventSourceDemo.exe with all events in the 'Demo' EventSource enabled and output the trace file `EventSourceDemo.exe_20220303_001619.nettrace`. Opening the file in Visual Studio shows the events that were logged.

In the list view, you can see the first event is the Demo/AppStarted event. The text column has the saved arguments, the timestamp column shows the event occurred 27 ms after logging started and to the right you can see the callstack. The other events are automatically enabled in every trace collected by dotnet-trace though they can be ignored and filtered from view in the UI if they're distracting. Those extra events capture some information about the process and jitted code, which allows Visual Studio to reconstruct the event stack traces.

Learning more about EventSource

- Instrumenting code to create events
- Collecting and viewing event traces

Instrument Code to Create EventSource Events

9/20/2022 • 12 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

The [Getting Started guide](#) showed you how to create a minimal EventSource and collect events in a trace file. This tutorial goes into more detail about creating events using [System.Diagnostics.Tracing.EventSource](#).

A minimal EventSource

```
[EventSource(Name = "Demo")]
class DemoEventSource : EventSource
{
    public static DemoEventSource Log { get; } = new DemoEventSource();

    [Event(1)]
    public void AppStarted(string message, int favoriteNumber) => WriteEvent(1, message, favoriteNumber);
}
```

The basic structure of a derived EventSource is always the same. In particular:

- The class inherits from [System.Diagnostics.Tracing.EventSource](#)
- For each different type of event you wish to generate, a method needs to be defined. This method should be named using the name of the event being created. If the event has additional data these should be passed using arguments. These event arguments need to be serialized so only [certain types](#) are allowed.
- Each method has a body that calls `WriteEvent` passing it an ID (a numeric value that represents the event) and the arguments of the event method. The ID needs to be unique within the EventSource. The ID is explicitly assigned using the [System.Diagnostics.Tracing.EventAttribute](#)
- EventSources are intended to be singleton instances. Thus it's convenient to define a static variable, by convention called `Log`, that represents this singleton.

Rules for defining event methods

1. Any instance, non-virtual, void returning method defined in an EventSource class is by default an event logging method.
2. Virtual or non-void-returning methods are included only if they're marked with the [System.Diagnostics.Tracing.EventAttribute](#)
3. To mark a qualifying method as non-logging you must decorate it with the [System.Diagnostics.Tracing.NonEventAttribute](#)
4. Event logging methods have event IDs associated with them. This can be done either explicitly by decorating the method with a [System.Diagnostics.Tracing.EventAttribute](#) or implicitly by the ordinal number of the method in the class. For example using implicit numbering the first method in the class has ID 1, the second has ID 2, and so on.
5. Event logging methods must call a [WriteEvent](#), [WriteEventCore](#), [WriteEventWithRelatedActivityId](#) or [WriteEventWithRelatedActivityIdCore](#) overload.
6. The event ID, whether implied or explicit, must match the first argument passed to the `WriteEvent*` API it calls.
7. The number, types and order of arguments passed to the EventSource method must align with how they're passed to the `WriteEvent*` APIs. For `WriteEvent` the arguments follow the Event ID, for

`WriteEventWithRelatedActivityId` the arguments follow the `relatedActivityId`. For the `WriteEvent*`Core methods, the arguments must be serialized manually into the `data` parameter.

8. Event names cannot contain `<` or `>` characters. While user-defined methods also cannot contain these characters, `async` methods will be rewritten by the compiler to contain them. To be sure these generated methods don't become events, mark all non-event methods on an [EventSource](#) with the [NonEventAttribute](#).

Best practices

1. Types that derive from `EventSource` usually don't have intermediate types in the hierarchy or implement interfaces. See [Advanced customizations](#) below for some exceptions where this may be useful.
2. Generally the name of the `EventSource` class is a bad public name for the `EventSource`. Public names, the names that will show up in logging configurations and log viewers, should be globally unique. Thus it's good practice to give your `EventSource` a public name using the [System.Diagnostics.Tracing.EventSourceAttribute](#). The name "Demo" used above is short and unlikely to be unique so not a good choice for production use. A common convention is to use a hierarchical name with `.` or `-` as a separator, such as "MyCompany-Samples-Demo", or the name of the Assembly or namespace for which the `EventSource` provides events. It's not recommended to include "EventSource" as part of the public name.
3. Assign Event IDs explicitly, this way seemingly benign changes to the code in the source class such as rearranging it or adding a method in the middle won't change the event ID associated with each method.
4. When authoring events that represent the start and end of a unit of work, by convention these methods are named with suffixes 'Start' and 'Stop'. For example, "RequestStart" and "RequestStop".
5. Do not specify an explicit value for `EventSourceAttribute`'s `Guid` property, unless you need it for backwards compatibility reasons. The default `Guid` value is derived from the source's name, which allows tools to accept the more human-readable name and derive the same `Guid`.
6. Call [IsEnabled\(\)](#) before performing any resource intensive work related to firing an event, such as computing an expensive event argument that won't be needed if the event is disabled.
7. Attempt to keep `EventSource` object back compatible and version them appropriately. The default version for an event is 0. The version can be changed by setting [EventAttribute.Version](#). Change the version of an event whenever you change the data that is serialized with it. Always add new serialized data to the end of the event declaration, that is, at the end of the list of method parameters. If this isn't possible, create a new event with a new ID to replace the old one.
8. When declaring events methods, specify fixed-size payload data before variably sized data.
9. Do not use strings containing null characters. When generating the manifest for ETW `EventSource` will declare all strings as null terminated, even though it is possible to have a null character in a C# String. If a string contains a null character the entire string will be written to the event payload, but any parser will treat the first null character as the end of the string. If there are payload arguments after the string, the remainder of the string will be parsed instead of the intended value.

Typical event customizations

Setting event verbosity levels

Each event has a verbosity level and event subscribers often enable all events on an `EventSource` up to a certain verbosity level. Events declare their verbosity level using the `Level` property. For example in this `EventSource` below a subscriber that requests events of level `Informational` and lower won't log the `Verbose DebugMessage` event.

```
[EventSource(Name = "MyCompany-Samples-Demo")]
class DemoEventSource : EventSource
{
    public static DemoEventSource Log { get; } = new DemoEventSource();

    [Event(1, Level = EventLevel.Informational)]
    public void AppStarted(string message, int favoriteNumber) => WriteEvent(1, message, favoriteNumber);
    [Event(2, Level = EventLevel.Verbose)]
    public void DebugMessage(string message) => WriteEvent(2, message);
}
```

If the verbosity level of an event is not specified in the `EventAttribute`, then it defaults to `Informational`.

Best practice

Use levels less than `Informational` for relatively rare warnings or errors. When in doubt, stick with the default of `Informational` and use `Verbose` for events that occur more frequently than 1000 events/sec.

Setting event keywords

Some event tracing systems support keywords as an additional filtering mechanism. Unlike verbosity that categorizes events by level of detail, keywords are intended to categorize events based on other criteria such as areas of code functionality or which would be useful for diagnosing certain problems. Keywords are named bit flags and each event can have any combination of keywords applied to it. For example the `EventSource` below defines some events that relate to request processing and other events that relate to startup. If a developer wanted to analyze the performance of startup, they might only enable logging the events marked with the `startup` keyword.

```
[EventSource(Name = "Demo")]
class DemoEventSource : EventSource
{
    public static DemoEventSource Log { get; } = new DemoEventSource();

    [Event(1, Keywords = Keywords.Startup)]
    public void AppStarted(string message, int favoriteNumber) => WriteEvent(1, message, favoriteNumber);
    [Event(2, Keywords = Keywords.Requests)]
    public void RequestStart(int requestId) => WriteEvent(2, requestId);
    [Event(3, Keywords = Keywords.Requests)]
    public void RequestStop(int requestId) => WriteEvent(3, requestId);

    public class Keywords // This is a bitvector
    {
        public const EventKeywords Startup = (EventKeywords)0x0001;
        public const EventKeywords Requests = (EventKeywords)0x0002;
    }
}
```

Keywords must be defined by using a nested class called `Keywords` and each individual keyword is defined by a member typed `public const EventKeywords`.

Best practice

Keywords are more important when distinguishing between high volume events. This allows an event consumer to raise the verbosity to a high level but manage the performance overhead and log size by only enabling narrow subsets of the events. Events that are triggered more than 1,000/sec are good candidates for a unique keyword.

Supported parameter types

`EventSource` requires that all event parameters can be serialized so it only accepts a limited set of types. These are:

- Primitives: bool, byte, sbyte, char, short, ushort, int, uint, long, ulong, float, double, IntPtr, and UIntPtr, Guid decimal, string, DateTime, DateTimeOffset, TimeSpan
- Enums
- Structures attributed with [System.Diagnostics.Tracing.EventDataAttribute](#). Only the public instance properties with serializable types will be serialized.
- Anonymous types where all public properties are serializable types
- Arrays of serializable types
- Nullable<T> where T is a serializable type
- KeyValuePair<T, U> where T and U are both serializable types
- Types that implement IEnumerable<T> for exactly one type T and where T is a serializable type

Troubleshooting

The EventSource class was designed so that it would never throw an Exception by default. This is a useful property, as logging is often treated as optional, and you usually don't want an error writing a log message to cause your application to fail. However, this makes finding any mistake in your EventSource difficult. Here are several techniques that can help troubleshoot:

1. The EventSource constructor has overloads that take [EventSourceSettings](#). Try enabling the ThrowOnEventWriteErrors flag temporarily.
2. The [EventSource.ConstructionException](#) property stores any Exception that was generated when validating the event logging methods. This can reveal various authoring errors.
3. EventSource logs errors using event ID 0, and this error event has a string describing the error.
4. When debugging, that same error string will also be logged using Debug.WriteLine() and show up in the debug output window.
5. EventSource internally throws and then catches exceptions when errors occur. To observe when these exceptions are occurring, enable first chance exceptions in a debugger, or use event tracing with the .NET runtime's [Exception events](#) enabled.

Advanced customizations

Setting OpCodes and Tasks

ETW has concepts of [Tasks and OpCodes](#) which are further mechanisms for tagging and filtering events. You can associate events with specific tasks and opcodes using the [Task](#) and [Opcode](#) properties. Here's an example:

```

[EventSource(Name = "Samples-EventSourceDemos-Customized")]
public sealed class CustomizedEventSource : EventSource
{
    static public CustomizedEventSource Log { get; } = new CustomizedEventSource();

    [Event(1, Task = Tasks.Request, Opcode=EventOpcode.Start)]
    public void RequestStart(int RequestID, string Url)
    {
        WriteEvent(1, RequestID, Url);
    }

    [Event(2, Task = Tasks.Request, Opcode=EventOpcode.Info)]
    public void RequestPhase(int RequestID, string PhaseName)
    {
        WriteEvent(2, RequestID, PhaseName);
    }

    [Event(3, Keywords = Keywords.Requests,
           Task = Tasks.Request, Opcode=EventOpcode.Stop)]
    public void RequestStop(int RequestID)
    {
        WriteEvent(3, RequestID);
    }

    public class Tasks
    {
        public const EventTask Request = (EventTask)0x1;
    }
}

```

You can implicitly create EventTask objects by declaring two event methods with subsequent event IDs that have the naming pattern <EventName>Start and <EventName>Stop. These events must be declared next to each other in the class definition and the <EventName>Start method must come first.

Self-describing (tracelogging) vs. manifest event formats

This concept only matters when subscribing to EventSource from ETW. ETW has two different ways that it can log events, manifest format and self-describing (sometimes called tracelogging) format. Manifest-based EventSource objects generate and log an XML document representing the events defined on the class upon initialization. This requires the EventSource to reflect over itself to generate the provider and event metadata. In the Self-describing format metadata for each event is transmitted inline with the event data rather than up-front. The self-describing approach supports the more flexible [Write](#) methods that can send arbitrary events without having created a pre-defined event logging method. It's also slightly faster at startup because it avoids eager reflection. However the extra metadata that's emitted with each event adds a small performance overhead, which may not be desirable when sending a high volume of events.

To use self-describing event format, construct your EventSource using the EventSource(String) constructor, the EventSource(String, EventSourceSettings) constructor, or by setting the EtwSelfDescribingEventFormat flag on EventSourceSettings.

EventSource types implementing interfaces

An EventSource type may implement an interface in order to integrate seamlessly in various advanced logging systems that use interfaces to define a common logging target. Here's an example of a possible use:

```

public interface IMyLogging
{
    void Error(int errorCode, string msg);
    void Warning(string msg);
}

[EventSource(Name = "Samples-EventSourceDemos-MyComponentLogging")]
public sealed class MyLoggingEventSource : EventSource, IMyLogging
{
    public static MyLoggingEventSource Log { get; } = new MyLoggingEventSource();

    [Event(1)]
    public void Error(int errorCode, string msg)
    { WriteEvent(1, errorCode, msg); }

    [Event(2)]
    public void Warning(string msg)
    { WriteEvent(2, msg); }
}

```

You must specify the `EventAttribute` on the interface methods, otherwise (for compatibility reasons) the method won't be treated as a logging method. Explicit interface method implementation is disallowed in order to prevent naming collisions.

EventSource class hierarchies

In most cases, you'll be able to write types that directly derive from the `EventSource` class. Sometimes however it's useful to define functionality that will be shared by multiple derived `EventSource` types, such as customized `WriteEvent` overloads (see [optimizing performance for high volume events](#) below).

Abstract base classes can be used as long as they don't define any keywords, tasks, opcodes, channels, or events. Here's an example where the `UtilBaseEventSource` class defines an optimized `WriteEvent` overload this is needed by multiple derived `EventSources` in the same component. One of these derived types is illustrated below as `OptimizedEventSource`.

```

public abstract class UtilBaseEventSource : EventSource
{
    protected UtilBaseEventSource()
        : base()
    { }
    protected UtilBaseEventSource(bool throwOnEventWriteErrors)
        : base(throwOnEventWriteErrors)
    { }

    protected unsafe void WriteEvent(int eventId, int arg1, short arg2, long arg3)
    {
        if (IsEnabled())
        {
            EventSource.EventData* descrs = stackalloc EventSource.EventData[2];
            descrs[0].DataPointer = (IntPtr)(&arg1);
            descrs[0].Size = 4;
            descrs[1].DataPointer = (IntPtr)(&arg2);
            descrs[1].Size = 2;
            descrs[2].DataPointer = (IntPtr)(&arg3);
            descrs[2].Size = 8;
            WriteEventCore(eventId, 3, descrs);
        }
    }
}

[EventSource(Name = "OptimizedEventSource")]
public sealed class OptimizedEventSource : UtilBaseEventSource
{
    public static OptimizedEventSource Log { get; } = new OptimizedEventSource();

    [Event(1, Keywords = Keywords.Kwd1, Level = EventLevel.Informational,
          Message = "LogElements called {0}/{1}/{2}.")]
    public void LogElements(int n, short sh, long l)
    {
        WriteEvent(1, n, sh, l); // Calls UtilBaseEventSource.WriteEvent
    }

    #region Keywords / Tasks /Opcodes / Channels
    public static class Keywords
    {
        public const EventKeywords Kwd1 = (EventKeywords)1;
    }
    #endregion
}

```

Optimizing performance for high volume events

The EventSource class has a number of overloads for WriteEvent, including one for variable number of arguments. When none of the other overloads match, the params method is called. Unfortunately, the params overload is relatively expensive. In particular it:

1. Allocates an array to hold the variable arguments.
2. Casts each parameter to an object, which causes allocations for value types.
3. Assigns these objects to the array.
4. Calls the function.
5. Figures out the type of each array element to determine how to serialize it.

This is probably 10 to 20 times as expensive as specialized types. This doesn't matter much for low volume cases, but for high volume events it can be important. There are two important cases for insuring that the params overload isn't used:

1. Ensure that enumerated types are cast to 'int' so that they match one of the fast overloads.

2. Create new fast WriteEvent overloads for high volume payloads.

Here's an example for adding a WriteEvent overload that takes four integer arguments

```
[NonEvent]
public unsafe void WriteEvent(int eventId, int arg1, int arg2,
                             int arg3, int arg4)
{
    EventData* descrs = stackalloc EventProvider.EventData[4];

    descrs[0].DataPointer = (IntPtr)(&arg1);
    descrs[0].Size = 4;
    descrs[1].DataPointer = (IntPtr)(&arg2);
    descrs[1].Size = 4;
    descrs[2].DataPointer = (IntPtr)(&arg3);
    descrs[2].Size = 4;
    descrs[3].DataPointer = (IntPtr)(&arg4);
    descrs[3].Size = 4;

    WriteEventCore(eventId, 4, (IntPtr)descrs);
}
```

Collect and View EventSource Traces

9/20/2022 • 7 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

The [Getting started guide](#) showed you how to create a minimal EventSource and collect events in a trace file. This tutorial shows how different tools can configure which events are collected in a trace and then view the traces.

Example app

You'll use the following sample app that generates events for this tutorial. Compile a .NET console application containing the following code:

```
using System.Diagnostics.Tracing;

namespace EventSourceDemo
{
    public static class Program
    {
        public static void Main(string[] args)
        {
            DemoEventSource.Log.AppStarted("Hello World!", 12);
            DemoEventSource.Log.DebugMessage("Got here");
            DemoEventSource.Log.DebugMessage("finishing startup");
            DemoEventSource.Log.RequestStart(3);
            DemoEventSource.Log.RequestStop(3);
        }
    }

    [EventSource(Name = "Demo")]
    class DemoEventSource : EventSource
    {
        public static DemoEventSource Log { get; } = new DemoEventSource();

        [Event(1, Keywords = Keywords.Startup)]
        public void AppStarted(string message, int favoriteNumber) => WriteEvent(1, message,
favoriteNumber);

        [Event(2, Keywords = Keywords.Requests)]
        public void RequestStart(int requestId) => WriteEvent(2, requestId);
        [Event(3, Keywords = Keywords.Requests)]
        public void RequestStop(int requestId) => WriteEvent(3, requestId);
        [Event(4, Keywords = Keywords.Startup, Level = EventLevel.Verbose)]
        public void DebugMessage(string message) => WriteEvent(4, message);

        public class Keywords
        {
            public const EventKeywords Startup = (EventKeywords)0x0001;
            public const EventKeywords Requests = (EventKeywords)0x0002;
        }
    }
}
```

Configure which events to collect

Most event collection tools use these configuration options to decide which events should be included in a trace:

- Provider names - This is a list of one or more EventSource names. Only events that are defined on EventSources in this list are eligible to be included. To collect events from the DemoEventSource class in the preceding example app, you would need to include the EventSource name "Demo" in the list of provider names.
- Event verbosity level - For each provider you can define a verbosity level and events with **verbosity** higher than that level will be excluded from the trace. If you specified that the "Demo" provider in the preceding example app should collect at the Informational verbosity level, then the DebugMessage event would be excluded because it has a higher level. Specifying **EventLevel LogAlways(0)** is a special case that indicates that events of any verbosity level should be included.
- Event keywords - For each provider you can define a set of keywords and only events tagged with at least one of the keywords will be included. In the example app above if you specified the Startup keyword then only the AppStarted and DebugMessage events would be included. If no keywords are specified this is a special case and means that events with any keyword should be included.

Conventions for describing provider configuration

Although each tool determines its own user interface for setting the trace configuration, there's a common convention many tools use when specifying the configuration as a text string. The list of providers is specified as a semi-colon delimited list, and each provider element in the list consists of name, keywords, and level separated by colons. For example, "Demo:3:5" identifies the EventSource named "Demo" with the keyword bitmask 3 (the `Startup` bit and the `Requests` bit) and `EventLevel` 5, which is `Verbose`. Many tools also let you omit the level and keywords if no level or keyword filtering is desired. For example, "Demo:5" only does level-based filtering, "Demo:3" only does keyword-based filtering, and "Demo" does no keyword or level filtering.

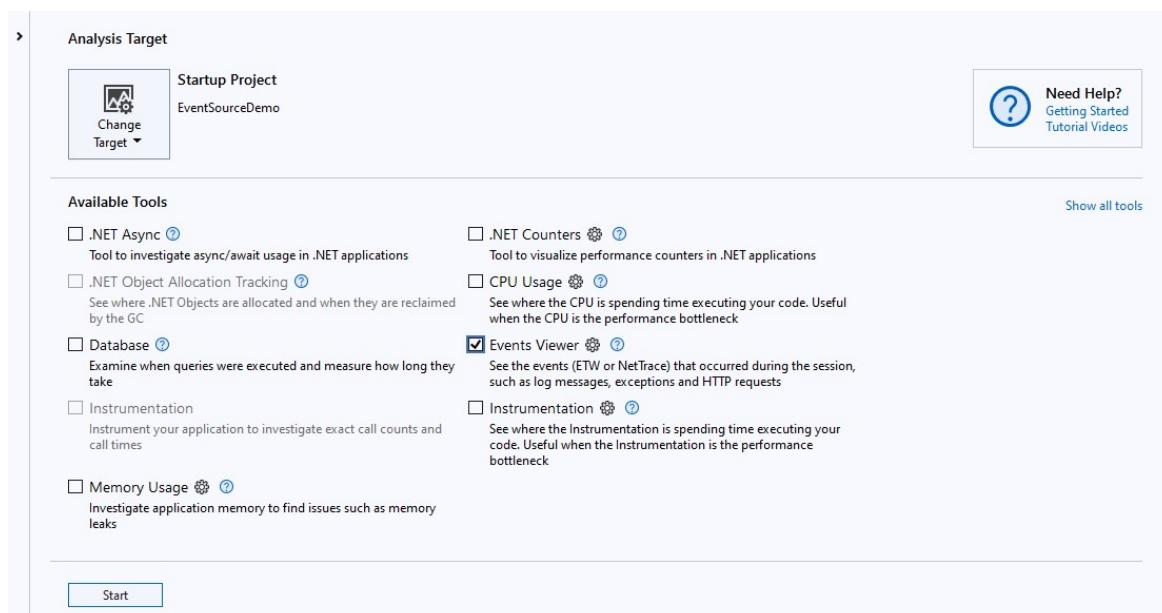

Visual Studio

The [Visual Studio profiler](#) supports both collecting and viewing traces. It also can view traces that have been collected in advance by other tools, such as [dotnet-trace](#).

Collect a trace

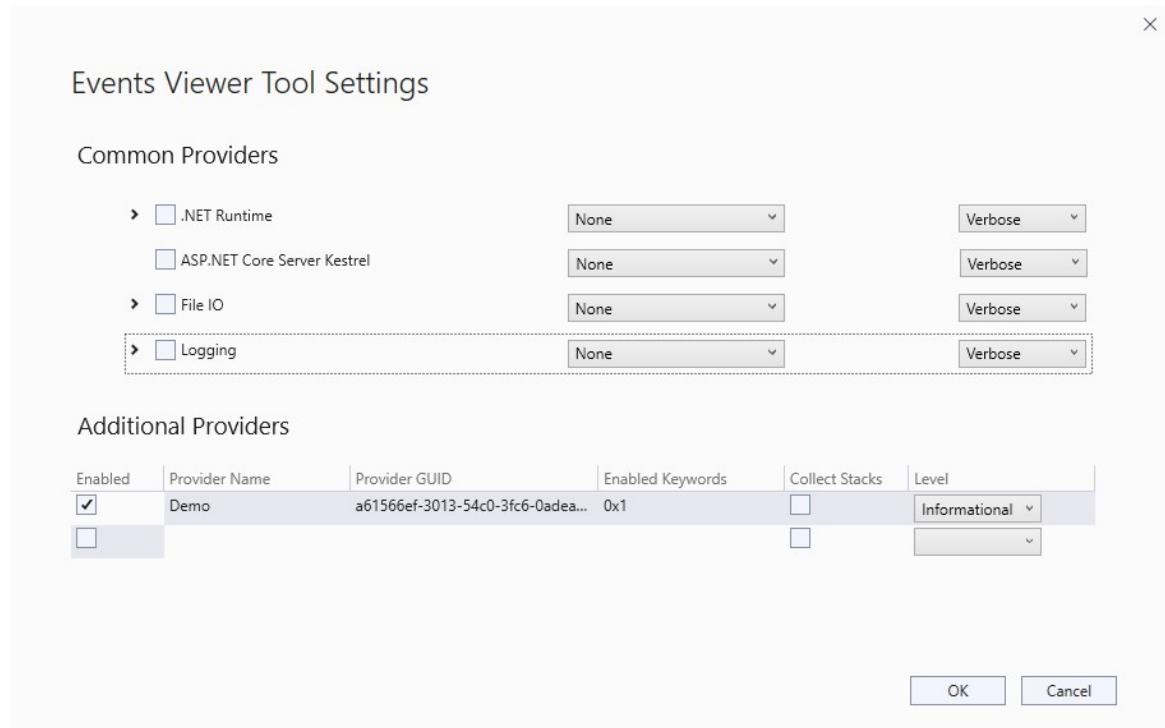

Most of Visual Studio's profiling tools use predefined sets of events that serve a particular purpose, such as analyzing CPU usage or allocations. To collect a trace with customized events, you'll use the [Events Viewer](#) tool.

- To open the Performance Profiler in Visual Studio, select Alt+F2.
- Select the **Events Viewer** check box.

- Select the small gear icon to the right of Events Viewer to open the configuration window.

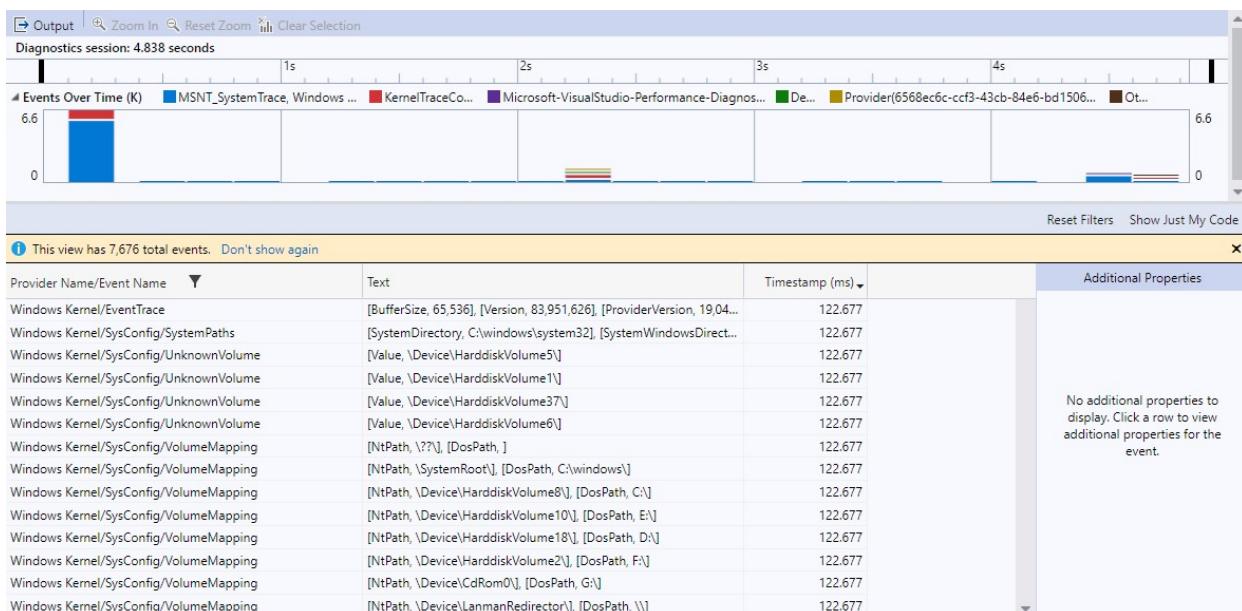

In the table below **Additional Providers**, add a row for each provider you wish to configure by clicking the **Enabled** checkbox, and then entering the provider name, keywords, and level. You don't need to enter the provider GUID; it's computed automatically.

4. Select **OK** to confirm the configuration settings.
5. Select **Start** to begin running the app and collecting logs.
6. Select **Stop Collection** or exit the app to stop collecting logs and show the collected data.

View a trace

Visual Studio can view traces it collected itself, or it can view traces collected in other tools. To view traces from other tools, use **File > Open** and select a trace file in the file picker. Visual Studio profiler supports **.etl** files (ETW's standard format), **.nettrace** files (EventPipe's standard format), and **.diagsession** files (Visual Studio's standard format). For information about working with trace files in Visual Studio, see the [Visual Studio documentation](#).

NOTE

Visual Studio collects some events automatically from ETW or EventPipe, even if they weren't explicitly configured. If you see events you don't recognize in the Provider Name or Event Name column and want to filter them out, use the filter icon to the right to select only the events you want to view.

PerfView

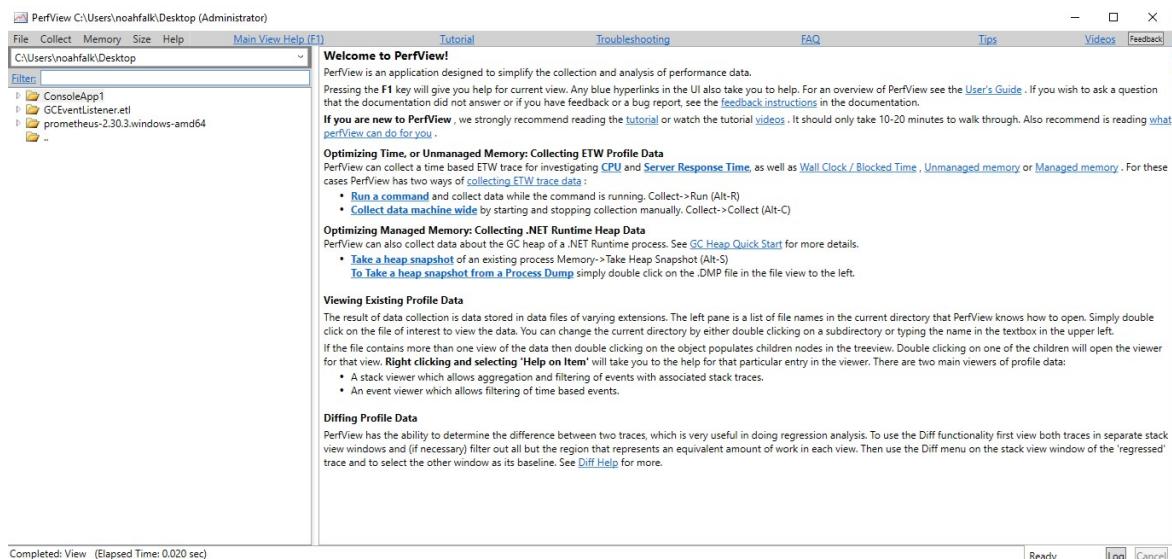

PerfView is a performance tool created by the .NET team that can collect and view ETW traces. It can also view trace files collected by other tools in various formats. In this tutorial, you'll collect an ETW trace of the [demo app](#) and then examine the collected events in PerfView's event viewer.

Collect a trace

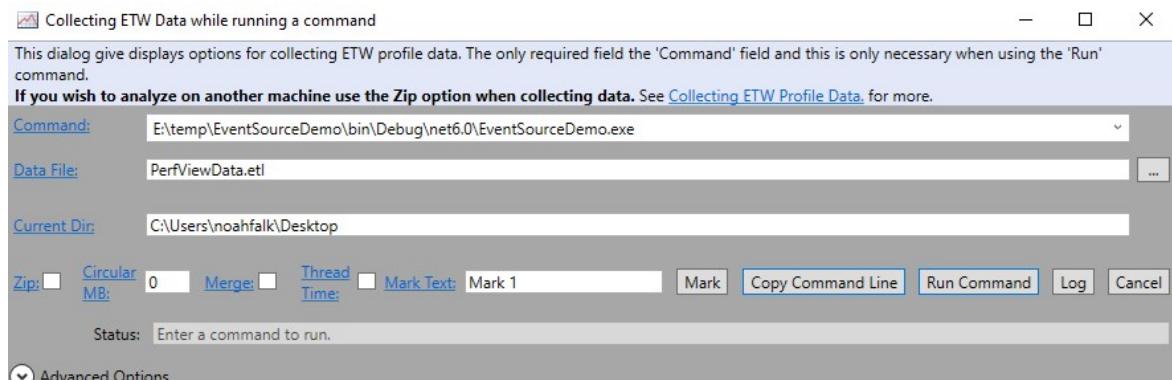

1. Download PerfView from the [releases page](#). This tutorial was done with [PerfView version 2.0.76](#), but any recent version should work.
2. Start PerfView.exe with administrator permissions.

NOTE

ETW trace collection always requires administrator permissions, however if you are only using PerfView to view a pre-existing trace, then no special permissions are needed.

3. From the **Collect** menu, select **Run**. This opens a new dialog where you'll enter the path to the [demo app](#).

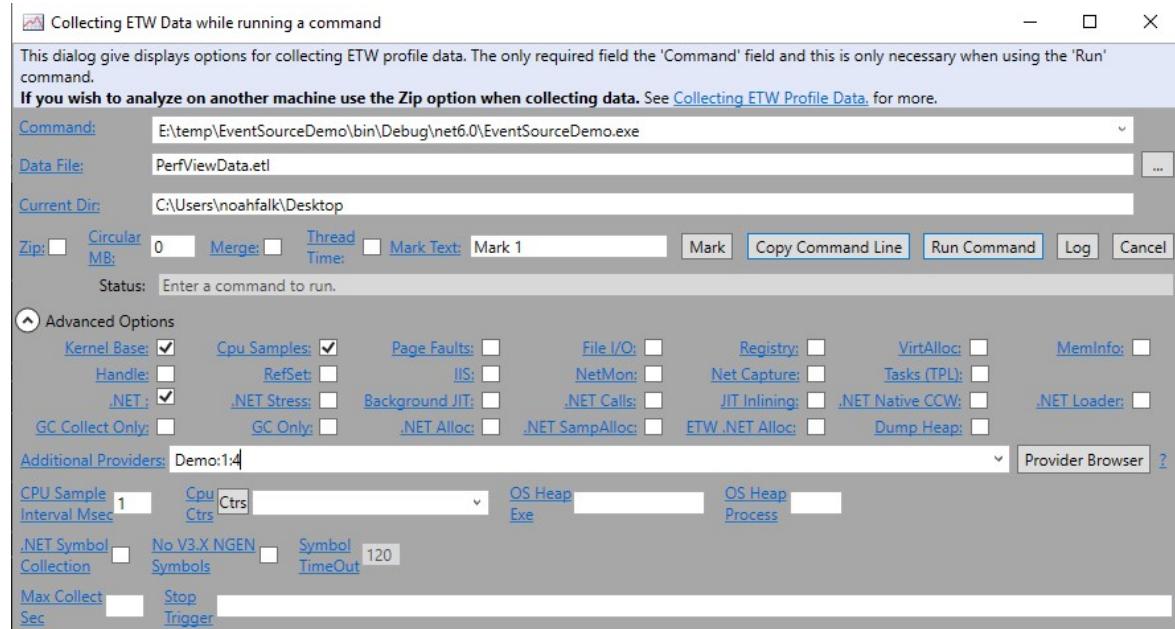

4. To configure which events get collected, expand **Advanced Options** at the bottom of the dialog. In the

Additional Providers text box, enter providers using the [conventional text format](#) described previously.

In this case, you're entering "Demo:1:4", which means keyword bit 1 ([Startup](#) events) and verbosity 4 (

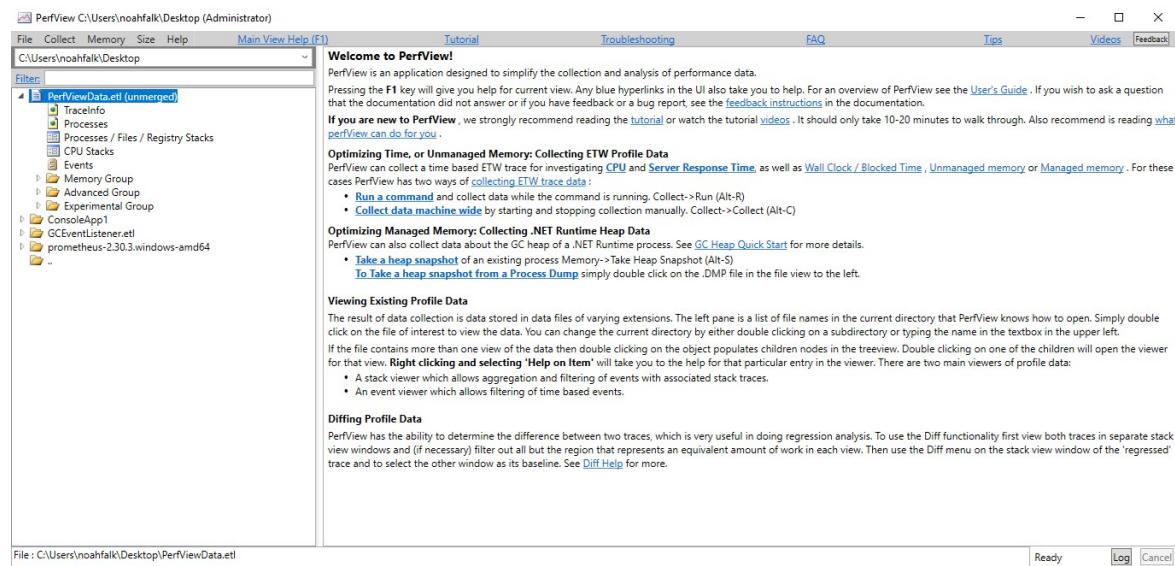

[Informational](#)).

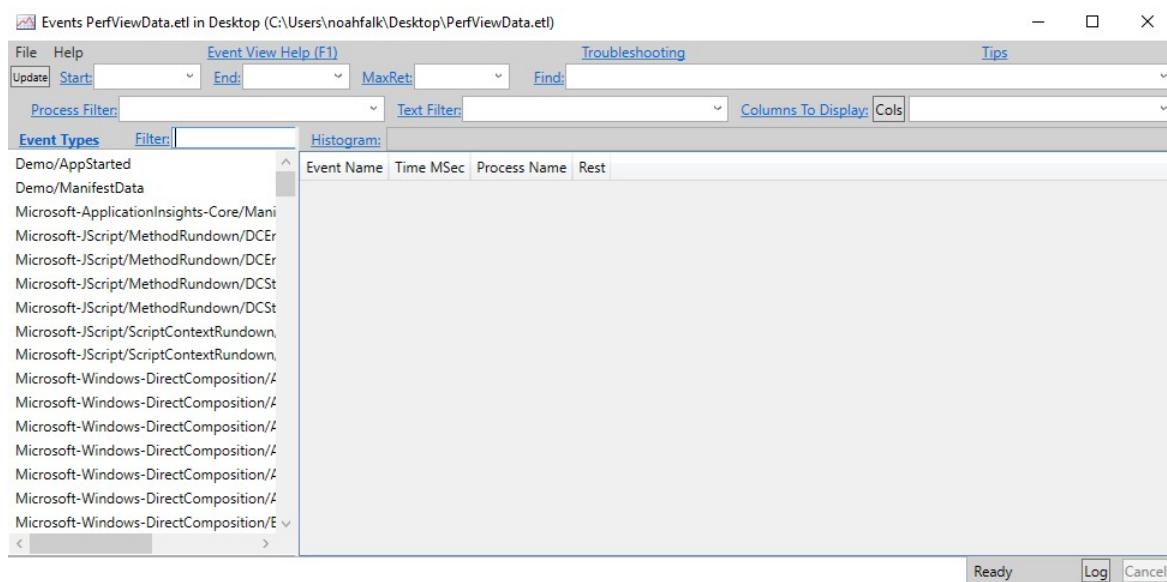

5. To launch the app and begin collecting the trace, select the **Run Command** button. When the app exits, the trace *PerfViewData.etl* is saved in the current directory.

View a trace

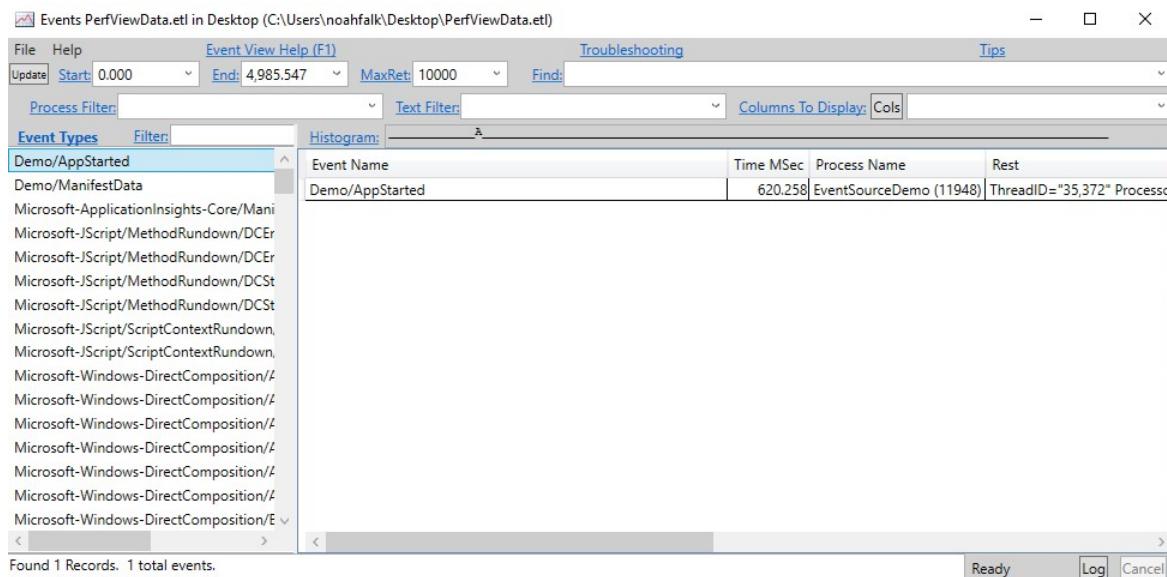

1. In the main window drop-down text box at the upper left, select the directory containing the trace file. Then double click the trace file in the tree view below.

2. To bring up the Events viewer, double click the **Events** item that appears in the tree view below the trace file.

3. All event types in the trace are shown in the list at the left. Double click an event type, such as Demo\AppStarted, to show all events of that type in the table on the right.

Learn more

To learn more about using PerfView, see the [PerfView video tutorials](#).

dotnet-trace

[dotnet-trace](#) is a cross-platform command-line tool that can collect traces from .NET Core apps using [EventPipe](#) tracing. It doesn't support viewing trace data, but the traces it collects can be viewed by other tools such as [PerfView](#) or [Visual Studio](#). dotnet-trace also supports converting its default `.nettrace` format traces into other formats, such as Chromium or [Speedscope](#).

Collect a trace

1. Download and Install [dotnet-trace](#).
2. At the command line, run the `dotnet-trace collect` command:

```
E:\temp\EventSourceDemo\bin\Debug\net6.0>dotnet-trace collect --providers Demo:1:4 --
EventSourceDemo.exe
```

This should show output similar to:

```
E:\temp\EventSourceDemo\bin\Debug\net6.0> dotnet-trace collect --providers Demo:1:4 --
EventSourceDemo.exe

Provider Name          Keywords          Level          Enabled By
Demo                  0x0000000000000001  Informational(4)  --providers

Launching: EventSourceDemo.exe
Process      : E:\temp\EventSourceDemo\bin\Debug\net6.0\EventSourceDemo.exe
Output File   :
E:\temp\EventSourceDemo\bin\Debug\net6.0\EventSourceDemo.exe_20220317_021512.nettrace

[00:00:00:00]  Recording trace 0.00    (B)
Press <Enter> or <Ctrl+C> to exit...

Trace completed.
```

dotnet-trace uses the [conventional text format](#) for describing provider configuration in the `--providers` argument. For more options on how to take traces using dotnet-trace, see the [dotnet-trace docs](#).

EventListener

[System.Diagnostics.Tracing.EventListener](#) is an .NET API that can be used from in-process to receive callbacks for events generated by an [System.Diagnostics.Tracing.EventSource](#). This API can be used to create custom logging tools or to analyze the events in memory without ever serializing them.

To use `EventListener`, declare a type that derives from `EventListener`, invoke `EnableEvents` to subscribe to the events from any `EventSource` of interest, and override the `OnEventWritten`, which will be called whenever a new event is available. It's often useful to override `OnEventSourceCreated` to discover which `EventSource` objects exist, but this isn't required. Following is an example `EventListener` implementation that prints to console when messages are received:

1. Add this code to the [demo app](#).

```
class ConsoleWriterEventListener : EventListener
{
    protected override void OnEventSourceCreated(EventSource eventSource)
    {
        if(eventSource.Name == "Demo")
        {
            EnableEvents(eventSource, EventLevel.Informational);
        }
    }

    protected override void OnEventWritten(EventWrittenEventArgs eventData)
    {
        Console.WriteLine(eventData.TimeStamp + " " + eventData.EventName);
    }
}
```

2. Modify the `Main` method to create an instance of the new listener.

```
public static void Main(string[] args)
{
    ConsoleWriterEventLister listener = new ConsoleWriterEventLister();

    DemoEventSource.Log.AppStarted("Hello World!", 12);
    DemoEventSource.Log.DebugMessage("Got here");
    DemoEventSource.Log.DebugMessage("finishing startup");
    DemoEventSource.Log.RequestStart(3);
    DemoEventSource.Log.RequestStop(3);
}
```

3. Build and run the app. Previously, it had no output, but now it writes the events to the console:

```
3/24/2022 9:23:35 AM AppStarted
3/24/2022 9:23:35 AM RequestStart
3/24/2022 9:23:35 AM RequestStop
```

EventSource Activity IDs

9/20/2022 • 7 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

This guide explains Activity IDs, an optional identifier that can be logged with each event generated using [System.Diagnostics.Tracing.EventSource](#). For an introduction, see [Getting Started with EventSource](#).

The challenge of logging concurrent work

Long ago, a typical application may have been simple and single-threaded, which makes logging straightforward. You could write each step to a log file in order and then read the log back exactly in the order it was written to understand what happened. If the app handled requests then only one request was handled at a time. All log messages for request A would be printed in order, then all the messages for B, and so on. When apps become multi-threaded that strategy no longer works because multiple requests are being handled at the same time. However if each request is assigned to a single thread that processes it entirely, you can solve the problem by recording a thread ID for each log message. For example, a multi-threaded app might log:

Thread Id	Message
-----	-----
12	BeginRequest A
12	Doing some work
190	BeginRequest B
12	uh-oh error happened
190	Doing some work

By reading the thread IDs you know that thread 12 was processing request A and thread 190 was processing request B, therefore the 'uh-oh error happened' message related to request A. However application concurrency has continued to grow ever more sophisticated. It's now common to use `async` and `await` so that a single request could be handled partially on many different threads before the work is complete. Thread IDs are no longer sufficient to correlate together all the messages produced for one request. Activity IDs solve this problem. They provide a finer grain identifier that can track individual requests, or portions of requests, regardless of if the work is spread across different threads.

NOTE

The Activity ID concept referred to here is not the same as the `System.Diagnostics.Tracing.Activity`, despite the similar naming.

Tracking work using an Activity ID

You can run the code below to see Activity tracking in action.

```
using System.Diagnostics.Tracing;

public static class Program
{
    public static async Task Main(string[] args)
    {
        ConsoleWriterEventListener listener = new ConsoleWriterEventListener();

        Task a = ProcessWorkItem("A");
    }
}
```

```

        Task b = ProcessWorkItem("B");
        await Task.WhenAll(a, b);
    }

    private static async Task ProcessWorkItem(string requestName)
    {
        DemoEventSource.Log.WorkStart(requestName);
        await HelperA();
        await HelperB();
        DemoEventSource.Log.WorkStop();
    }

    private static async Task HelperA()
    {
        DemoEventSource.Log.DebugMessage("HelperA");
        await Task.Delay(100); // pretend to do some work
    }

    private static async Task HelperB()
    {
        DemoEventSource.Log.DebugMessage("HelperB");
        await Task.Delay(100); // pretend to do some work
    }
}

[EventSource(Name ="Demo")]
class DemoEventSource : EventSource
{
    public static DemoEventSource Log = new DemoEventSource();

    [Event(1)]
    public void WorkStart(string requestName) => WriteEvent(1, requestName);
    [Event(2)]
    public void WorkStop() => WriteEvent(2);

    [Event(3)]
    public void DebugMessage(string message) => WriteEvent(3, message);
}

class ConsoleWriterEventListener : EventListener
{
    protected override void OnEventSourceCreated(EventSource eventSource)
    {
        if(eventSource.Name == "Demo")
        {
            Console.WriteLine("{0,-5} {1,-40} {2,-15} {3}", "TID", "Activity ID", "Event", "Arguments");
            EnableEvents(eventSource, EventLevel.Verbose);
        }
        else if(eventSource.Name == "System.Threading.Tasks.TplEventSource")
        {
            // Activity IDs aren't enabled by default.
            // Enabling Keyword 0x80 on the TplEventSource turns them on
            EnableEvents(eventSource, EventLevel.LogAlways, (EventKeywords)0x80);
        }
    }

    protected override void OnEventWritten(EventWrittenEventArgs eventData)
    {
        lock (this)
        {
            Console.Write("{0,-5} {1,-40} {2,-15} ", eventData.OSThreadId, eventData.ActivityId,
eventData.EventName);
            if (eventData.Payload.Count == 1)
            {
                Console.WriteLine(eventData.Payload[0]);
            }
            else
            {
                Console.WriteLine();
            }
        }
    }
}

```

```

        }
    }
}

```

When run, this code prints output:

TID	Activity ID	Event	Arguments
21256	00000011-0000-0000-0000-00006ab99d59	WorkStart	A
21256	00000011-0000-0000-0000-00006ab99d59	DebugMessage	HelperA
21256	00000012-0000-0000-0000-00006bb99d59	WorkStart	B
21256	00000012-0000-0000-0000-00006bb99d59	DebugMessage	HelperA
14728	00000011-0000-0000-0000-00006ab99d59	DebugMessage	HelperB
11348	00000012-0000-0000-0000-00006bb99d59	DebugMessage	HelperB
11348	00000012-0000-0000-0000-00006bb99d59	WorkStop	
14728	00000011-0000-0000-0000-00006ab99d59	WorkStop	

NOTE

There is a known issue where Visual Studio debugger may cause invalid Activity IDs to be generated. Either don't run this sample under the debugger or set a breakpoint at the beginning of Main and evaluate the expression 'System.Threading.Tasks.TplEventSource.Log.TasksSetActivityIds = false' in the immediate window before continuing to work around the issue.

Using the Activity IDs you can see that all of the messages for work item A have ID `00000011-...` and all the messages for work item B have ID `00000012-...`. Both work items first did some work on thread 21256, but then each of them continued their work on separate threadpool threads 11348 and 14728 so trying to track the request only with thread IDs wouldn't have worked.

EventSource has an automatic heuristic where defining an event named `_Something_Start` followed immediately by another event named `_Something_Stop` is considered the start and stop of a unit of work. Logging the start event for a new unit of work creates a new Activity ID and begins logging all events on the same thread with that Activity ID until the stop event is logged. The ID also automatically follows async control flow when using `async` and `await`. Although we recommend that you use the Start/Stop naming suffixes, you may name the events anything you like by explicitly annotating them using the `EventAttribute.Opcode` property. Set the first event to `EventOpcode.Start` and the second to `EventOpcode.Stop`.

Log requests that do parallel work

Sometimes a single request might do different parts of its work in parallel, and you want to group all the log events and the subparts. The example below simulates a request that does two database queries in parallel and then does some processing on the result of each query. You want to isolate the work for each query, but also understand which queries belong to the same request when many concurrent requests could be running. This is modeled as a tree where each top-level request is a root and then subportions of work are branches. Each node in the tree gets its own Activity ID, and the first event logged with the new child Activity ID logs an extra field called Related Activity ID to describe its parent.

Run the following code:

```

using System.Diagnostics.Tracing;

public static class Program
{
    public static async Task Main(string[] args)
    {
        ConsoleWriterEventListener listener = new ConsoleWriterEventListener();

```

```

        await ProcessWorkItem("A");
    }

    private static async Task ProcessWorkItem(string requestName)
    {
        DemoEventSource.Log.WorkStart(requestName);
        Task query1 = Query("SELECT bowls");
        Task query2 = Query("SELECT spoons");
        await Task.WhenAll(query1, query2);
        DemoEventSource.Log.WorkStop();
    }

    private static async Task Query(string query)
    {
        DemoEventSource.Log.QueryStart(query);
        await Task.Delay(100); // pretend to send a query
        DemoEventSource.Log.DebugMessage("processing query");
        await Task.Delay(100); // pretend to do some work
        DemoEventSource.Log.QueryStop();
    }
}

[EventSource(Name = "Demo")]
class DemoEventSource : EventSource
{
    public static DemoEventSource Log = new DemoEventSource();

    [Event(1)]
    public void WorkStart(string requestName) => WriteEvent(1, requestName);
    [Event(2)]
    public void WorkStop() => WriteEvent(2);
    [Event(3)]
    public void DebugMessage(string message) => WriteEvent(3, message);
    [Event(4)]
    public void QueryStart(string query) => WriteEvent(4, query);
    [Event(5)]
    public void QueryStop() => WriteEvent(5);
}

class ConsoleWriterEventListener : EventListener
{
    protected override void OnEventSourceCreated(EventSource eventSource)
    {
        if (eventSource.Name == "Demo")
        {
            Console.WriteLine("{0,-5} {1,-40} {2,-40} {3,-15} {4}", "TID", "Activity ID", "Related Activity ID", "Event", "Arguments");
            EnableEvents(eventSource, EventLevel.Verbose);
        }
        else if (eventSource.Name == "System.Threading.Tasks.TplEventSource")
        {
            // Activity IDs aren't enabled by default.
            // Enabling Keyword 0x80 on the TplEventSource turns them on
            EnableEvents(eventSource, EventLevel.LogAlways, (EventKeywords)0x80);
        }
    }

    protected override void OnEventWritten(EventWrittenEventArgs eventData)
    {
        lock (this)
        {
            Console.Write("{0,-5} {1,-40} {2, -40} {3,-15} ", eventData.OSThreadId, eventData.ActivityId,
            eventData.RelatedActivityId, eventData.EventName);
            if (eventData.Payload.Count == 1)
            {
                Console.WriteLine(eventData.Payload[0]);
            }
            else
            {
                Console.WriteLine("Multiple payload items found!");
            }
        }
    }
}

```

```
        {
            Console.WriteLine();
        }
    }
}
```

This example prints output such as:

TID	Activity ID	Related Activity ID	Event
Arguments			
34276	0000011-0000-0000-0000-000086af9d59	0000000-0000-0000-0000-000000000000	WorkStart
34276	00001011-0000-0000-0000-000086af9d59	0000011-0000-0000-0000-000086af9d59	QueryStart
SELECT bowls			
34276	00002011-0000-0000-0000-0000868f9d59	0000011-0000-0000-0000-000086af9d59	QueryStart
SELECT spoons			
32684	00002011-0000-0000-0000-0000868f9d59	0000000-0000-0000-0000-000000000000	DebugMessage
processing query			
18624	00001011-0000-0000-0000-0000869f9d59	0000000-0000-0000-0000-000000000000	DebugMessage
processing query			
18624	00002011-0000-0000-0000-0000868f9d59	0000000-0000-0000-0000-000000000000	QueryStop
32684	00001011-0000-0000-0000-0000869f9d59	0000000-0000-0000-0000-000000000000	QueryStop
32684	0000011-0000-0000-0000-000086af9d59	0000000-0000-0000-0000-000000000000	WorkStop

This example only ran one top-level request, which was assigned Activity ID `00000011-....`. Then each `QueryStart` event began a new branch of the request with Activity IDs `00001011-....` and `00002011-....` respectively. You can identify these IDs are children of the original request because both of the start events logged their parent `00000011-....` in the Related Activity ID field.

NOTE

You may have noticed the numerical values of the IDs have some clear patterns between parent and child and aren't random. Although it can assist in spotting the relationship visually in simple cases, it's best for tools not to rely on this and treat the IDs as opaque identifiers. As the nesting level grows deeper, the byte pattern will change. Using the Related Activity ID field is the best way to ensure tools work reliably regardless of nesting level.

Because requests with complex trees of subwork items will generate many different Activity IDs, these IDs are usually best parsed by tools rather than trying to reconstruct the tree by hand. [PerfView](#) is one tool that knows how to correlate events annotated with these IDs.

DiagnosticSource and DiagnosticListener

9/20/2022 • 11 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.5 and later versions

[System.Diagnostics.DiagnosticSource](#) is a module that allows code to be instrumented for production-time logging of rich data payloads for consumption within the process that was instrumented. At run time, consumers can dynamically discover data sources and subscribe to the ones of interest.

[System.Diagnostics.DiagnosticSource](#) was designed to allow in-process tools to access rich data. When using [System.Diagnostics.DiagnosticSource](#), the consumer is assumed to be within the same process and as a result, non-serializable types (for example, `HttpResponseMessage` or `HttpContext`) can be passed, giving customers plenty of data to work with.

Getting Started with DiagnosticSource

This walkthrough shows how to create a `DiagnosticSource` event and instrument code with [System.Diagnostics.DiagnosticSource](#). It then explains how to consume the event by finding interesting `DiagnosticListeners`, subscribing to their events, and decoding event data payloads. It finishes by describing *filtering*, which allows only specific events to pass through the system.

DiagnosticSource Implementation

You will work with the following code. This code is an `HttpClient` class with a `SendWebRequest` method that sends an HTTP request to the URL and receives a reply.

```
using System.Diagnostics;
MyListener TheListener = new MyListener();
TheListener.Listening();
HTTPClient Client = new HTTPClient();
Client.SendWebRequest("https://docs.microsoft.com/dotnet/core/diagnostics/");

class HTTPClient
{
    private static DiagnosticSource httpLogger = new DiagnosticListener("System.Net.Http");
    public byte[] SendWebRequest(string url)
    {
        if (httpLogger.IsEnabled("RequestStart"))
        {
            httpLogger.Write("RequestStart", new { Url = url });
        }
        //Pretend this sends an HTTP request to the url and gets back a reply.
        byte[] reply = new byte[] { };
        return reply;
    }
}
class Observer<T> : IObserver<T>
{
    public Observer(Action<T> onNext, Action onCompleted)
    {
        _onNext = onNext ?? new Action<T>(_ => { });
        _onCompleted = onCompleted ?? new Action(() => { });
    }
    public void OnCompleted() { _onCompleted(); }
    public void OnError(Exception error) { }
    public void OnNext(T value) { _onNext(value); }
    private Action<T> _onNext;
    private Action _onCompleted;
```

```

}
class MyListener
{
    IDisposable networkSubscription;
    IDisposable listenerSubscription;
    private readonly object allListeners = new();
    public void Listening()
    {
        Action<KeyValuePair<string, object>> whenHeard = delegate (KeyValuePair<string, object> data)
        {
            Console.WriteLine($"Data received: {data.Key}: {data.Value}");
        };
        Action<DiagnosticListener> onNewListener = delegate (DiagnosticListener listener)
        {
            Console.WriteLine($"New Listener discovered: {listener.Name}");
            //Subscribe to the specific DiagnosticListener of interest.
            if (listener.Name == "System.Net.Http")
            {
                //Use lock to ensure the callback code is thread safe.
                lock (allListeners)
                {
                    if (networkSubscription != null)
                    {
                        networkSubscription.Dispose();
                    }
                    IObserver<KeyValuePair<string, object>> iobserver = new Observer<KeyValuePair<string, object>>(whenHeard, null);
                    networkSubscription = listener.Subscribe(iobserver);
                }
            }
        };
        //Subscribe to discover all DiagnosticListeners
        IObserver<DiagnosticListener> observer = new Observer<DiagnosticListener>(onNewListener, null);
        //When a listener is created, invoke the onNext function which calls the delegate.
        listenerSubscription = DiagnosticListener.AllListeners.Subscribe(observer);
    }
    // Typically you leave the listenerSubscription subscription active forever.
    // However when you no longer want your callback to be called, you can
    // call listenerSubscription.Dispose() to cancel your subscription to the IObservable.
}

```

Running the provided implementation prints to the console.

```

New Listener discovered: System.Net.Http
Data received: RequestStart: { Url = https://docs.microsoft.com/dotnet/core/diagnostics/ }

```

Log an event

The `DiagnosticSource` type is an abstract base class that defines the methods needed to log events. The class that holds the implementation is `DiagnosticListener`. The first step in instrumenting code with `DiagnosticSource` is to create a `DiagnosticListener`. For example:

```
private static DiagnosticSource httpLogger = new DiagnosticListener("System.Net.Http");
```

Notice that `httpLogger` is typed as a `DiagnosticSource`. That's because this code only writes events and thus is only concerned with the `DiagnosticSource` methods that the `DiagnosticListener` implements. `DiagnosticListeners` are given names when they are created, and this name should be the name of a logical grouping of related events (typically the component). Later, this name is used to find the Listener and subscribe to any of its events. Thus the event names only need to be unique within a component.

The `DiagnosticSource` logging interface consists of two methods:

```
bool IsEnabled(string name)
void Write(string name, object value);
```

This is instrument site specific. You need to check the instrumentation site to see what types are passed into `IsEnabled`. This provides you with the information to know what to cast the payload to.

A typical call site will look like:

```
if (httpLogger.IsEnabled("RequestStart"))
{
    httpLogger.Write("RequestStart", new { Url = url });
}
```

Every event has a `string` name (for example, `RequestStart`), and exactly one `object` as a payload. If you need to send more than one item, you can do so by creating an `object` with properties to represent all its information. C#'s [anonymous type](#) feature is typically used to create a type to pass 'on the fly', and makes this scheme very convenient. At the instrumentation site, you must guard the call to `Write()` with an `.IsEnabled()` check on the same event name. Without this check, even when the instrumentation is inactive, the rules of the C# language require all the work of creating the payload `object` and calling `Write()` to be done, even though nothing is actually listening for the data. By guarding the `Write()` call, you make it efficient when the source is not enabled.

Combining everything you have:

```
class HttpClient
{
    private static DiagnosticSource httpLogger = new DiagnosticListener("System.Net.Http");
    public byte[] SendWebRequest(string url)
    {
        if (httpLogger.IsEnabled("RequestStart"))
        {
            httpLogger.Write("RequestStart", new { Url = url });
        }
        //Pretend this sends an HTTP request to the url and gets back a reply.
        byte[] reply = new byte[] { };
        return reply;
    }
}
```

Discovery of `DiagnosticListeners`

The first step in receiving events is to discover which `DiagnosticListeners` you are interested in.

`DiagnosticListener` supports a way of discovering `DiagnosticListeners` that are active in the system at run time. The API to accomplish this is the [AllListeners](#) property.

Implement an `Observer<T>` class that inherits from the `IEnumerable` interface, which is the 'callback' version of the `IEnumerable` interface. You can learn more about it at the [Reactive Extensions](#) site. An `IEnumerable` has three callbacks, `OnNext`, `OnComplete`, and `OnError`. An `IEnumerable` has a single method called `Subscribe` that gets passed one of these Observers. Once connected, the Observer gets callbacks (mostly `OnNext` callbacks) when things happen.

A typical use of the `AllListeners` static property looks like this:

```

class Observer<T> : IObserver<T>
{
    public Observer(Action<T> onNext, Action onCompleted)
    {
        _onNext = onNext ?? new Action<T>(_ => { });
        _onCompleted = onCompleted ?? new Action(() => { });
    }
    public void OnCompleted() { _onCompleted(); }
    public void OnError(Exception error) { }
    public void OnNext(T value) { _onNext(value); }
    private Action<T> _onNext;
    private Action _onCompleted;
}
class MyListener
{
    IDisposable networkSubscription;
    IDisposable listenerSubscription;
    private readonly object allListeners = new();
    public void Listening()
    {
        Action<KeyValuePair<string, object>> whenHeard = delegate (KeyValuePair<string, object> data)
        {
            Console.WriteLine($"Data received: {data.Key}: {data.Value}");
        };
        Action<DiagnosticListener> onNewListener = delegate (DiagnosticListener listener)
        {
            Console.WriteLine($"New Listener discovered: {listener.Name}");
            //Subscribe to the specific DiagnosticListener of interest.
            if (listener.Name == "System.Net.Http")
            {
                //Use lock to ensure the callback code is thread safe.
                lock (allListeners)
                {
                    if (networkSubscription != null)
                    {
                        networkSubscription.Dispose();
                    }
                    IObserver<KeyValuePair<string, object>> iobserver = new Observer<KeyValuePair<string,
object>>(whenHeard, null);
                    networkSubscription = listener.Subscribe(iobserver);
                }
            }
        };
        //Subscribe to discover all DiagnosticListeners
        IObserver<DiagnosticListener> observer = new Observer<DiagnosticListener>(onNewListener, null);
        //When a listener is created, invoke the onNext function which calls the delegate.
        listenerSubscription = DiagnosticListener.AllListeners.Subscribe(observer);
    }
    // Typically you leave the listenerSubscription subscription active forever.
    // However when you no longer want your callback to be called, you can
    // call listenerSubscription.Dispose() to cancel your subscription to the IObservable.
}

```

This code creates a callback delegate and, using the `AllListeners.Subscribe` method, requests that the delegate be called for every active `DiagnosticListener` in the system. The decision of whether or not to subscribe to the listener is made by inspecting its name. The code above is looking for the 'System.Net.Http' listener that you created previously.

Like all calls to `Subscribe()`, this one returns an `IDisposable` that represents the subscription itself. Callbacks will continue to happen as long as nothing calls `Dispose()` on this subscription object. The code example never calls `Dispose()`, so it will receive callbacks forever.

When you subscribe to `AllListeners`, you get a callback for ALL ACTIVE `DiagnosticListeners`. Thus, upon

subscribing, you get a flurry of callbacks for all existing `DiagnosticListeners`, and as new ones are created, you receive a callback for those as well. You receive a complete list of everything it's possible to subscribe to.

Subscribe to `DiagnosticListeners`

A `DiagnosticListener` implements the `IEnumerable<KeyValuePair<string, object>>` interface, so you can call `Subscribe()` on it as well. The following code shows how to fill out the previous example:

```
Disposable networkSubscription;
Disposable listenerSubscription;
private readonly object allListeners = new();
public void Listening()
{
    Action<KeyValuePair<string, object>> whenHeard = delegate (KeyValuePair<string, object> data)
    {
        Console.WriteLine($"Data received: {data.Key}: {data.Value}");
    };
    Action<DiagnosticListener> onNewListener = delegate (DiagnosticListener listener)
    {
        Console.WriteLine($"New Listener discovered: {listener.Name}");
        //Subscribe to the specific DiagnosticListener of interest.
        if (listener.Name == "System.Net.Http")
        {
            //Use lock to ensure the callback code is thread safe.
            lock (allListeners)
            {
                if (networkSubscription != null)
                {
                    networkSubscription.Dispose();
                }
                IObserver<KeyValuePair<string, object>> iobserver = new Observer<KeyValuePair<string, object>>(whenHeard, null);
                networkSubscription = listener.Subscribe(iobserver);
            }
        }
    };
    //Subscribe to discover all DiagnosticListeners
    IObserver<DiagnosticListener> observer = new Observer<DiagnosticListener>(onNewListener, null);
    //When a listener is created, invoke the onNext function which calls the delegate.
    listenerSubscription = DiagnosticListener.AllListeners.Subscribe(observer);
}
```

In this example, after finding the 'System.Net.Http' `DiagnosticListener`, an action is created that prints out the name of the listener event, and `payload.ToString()`.

NOTE

`DiagnosticListener` implements `IEnumerable<KeyValuePair<string, object>>`. This means on each callback we get a `KeyValuePair`. The key of this pair is the name of the event and the value is the payload `object`. The example simply logs this information to the console.

It's important to keep track of subscriptions to the `DiagnosticListener`. In the previous code, the `networkSubscription` variable remembers this. If you form another `creation`, you must unsubscribe the previous listener and subscribe to the new one.

The `DiagnosticSource / DiagnosticListener` code is thread safe, but the callback code also needs to be thread safe. To ensure the callback code is thread safe, locks are used. It is possible to create two `DiagnosticListeners` with the same name at the same time. To avoid race conditions, updates of shared variables are performed under the protection of a lock.

Once the previous code is run, the next time a `Write()` is done on 'System.Net.Http' `DiagnosticListener` the information will be logged to the console.

Subscriptions are independent of one another. As a result, other code can do exactly the same thing as the code example and generate two 'pipes' of the logging information.

Decode Payloads

The `KeyValuePair` that is passed to the callback has the event name and payload, but the payload is typed simply as an `object`. There are two ways of getting more specific data:

If the payload is a well known type (for example, a `string`, or an `HttpMessageRequest`), then you can simply cast the `object` to the expected type (using the `as` operator so as not to cause an exception if you are wrong) and then access the fields. This is very efficient.

Use reflection API. For example, assume the following method is present.

```
/// Define a shortcut method that fetches a field of a particular name.
static class PropertyExtensions
{
    static object GetProperty(this object _this, string propertyName)
    {
        return _this.GetType().GetTypeInfo().GetDeclaredProperty(propertyName)?.GetValue(_this);
    }
}
```

To decode the payload more fully, you could replace the `listener.Subscribe()` call with the following code.

```
networkSubscription = listener.Subscribe(delegate(KeyValuePair<string, object> evnt) {
    var eventName = evnt.Key;
    var payload = evnt.Value;
    if (eventName == "RequestStart")
    {
        var url = payload.GetProperty("Url") as string;
        var request = payload.GetProperty("Request");
        Console.WriteLine("Got RequestStart with URL {0} and Request {1}", url, request);
    }
});
```

Note that using reflection is relatively expensive. However, using reflection is the only option if the payloads were generated using anonymous types. This overhead can be reduced by making fast, specialized property fetchers using either `PropertyInfo.GetMethod.CreateDelegate()` or `xref<System.Reflection.Emit>` namespace, but that's beyond the scope of this article. (For an example of a fast, delegate-based property fetcher, see the `PropertySpec` class used in the `DiagnosticSourceEventSource`.)

Filtering

In the previous example, the code uses the `IEnumerable.Subscribe()` method to hook up the callback. This causes all events to be given to the callback. However, `DiagnosticListener` has overloads of `Subscribe()` that allow the controller to control which events are given.

The `listener.Subscribe()` call in the previous example can be replaced with the following code to demonstrate.

```

// Create the callback delegate.
Action<KeyValuePair<string, object>> callback = (KeyValuePair<string, object> evnt) =>
    Console.WriteLine("From Listener {0} Received Event {1} with payload {2}", networkListener.Name,
evnt.Key, evnt.Value.ToString());

// Turn it into an observer (using the Observer<T> Class above).
Observer<KeyValuePair<string, object>> observer = new Observer<KeyValuePair<string, object>>(callback);

// Create a predicate (asks only for one kind of event).
Predicate<string> predicate = (string eventName) => eventName == "RequestStart";

// Subscribe with a filter predicate.
IDisposable subscription = listener.Subscribe(observer, predicate);

// subscription.Dispose() to stop the callbacks.

```

This efficiently subscribes to only the 'RequestStart' events. All other events will cause the `DiagnosticSource.IsEnabled()` method to return `false` and thus be efficiently filtered out.

Context-based filtering

Some scenarios require advanced filtering based on extended context. Producers can call `DiagnosticSource.IsEnabled` overloads and supply additional event properties as shown in the following code.

```

//aRequest and anActivity are the current request and activity about to be logged.
if (httpLogger.IsEnabled("RequestStart", aRequest, anActivity))
    httpLogger.Write("RequestStart", new { Url="http://clr", Request=aRequest });

```

The next code example demonstrates that consumers can use such properties to filter events more precisely.

```

// Create a predicate (asks only for Requests for certains URIs)
Func<string, object, object, bool> predicate = (string eventName, object context, object activity) =>
{
    if (eventName == "RequestStart")
    {
        if (context is HttpRequestMessage request)
        {
            return IsUriEnabled(request.RequestUri);
        }
    }
    return false;
}

// Subscribe with a filter predicate
IDisposable subscription = listener.Subscribe(observer, predicate);

```

Producers are not aware of the filter a consumer has provided. `DiagnosticListener` will invoke the provided filter, omitting additional arguments if necessary, thus the filter should expect to receive a `null` context. If a producer calls `.IsEnabled()` with event name and context, those calls are enclosed in an overload that takes only the event name. Consumers must ensure that their filter allows events without context to pass through.

EventPipe

9/20/2022 • 4 minutes to read • [Edit Online](#)

EventPipe is a runtime component that can be used to collect tracing data, similar to ETW or LTTng. The goal of EventPipe is to allow .NET developers to easily trace their .NET applications without having to rely on platform-specific OS-native components such as ETW or LTTng.

EventPipe is the mechanism behind many of the diagnostic tools and can be used for consuming events emitted by the runtime as well as custom events written with [EventSource](#).

This article is a high-level overview of EventPipe. It describes when and how to use EventPipe, and how to configure it to best suit your needs.

EventPipe basics

EventPipe aggregates events emitted by runtime components - for example, the Just-In-Time compiler or the garbage collector - and events written from [EventSource](#) instances in the libraries and user code.

The events are then serialized in the `.nettrace` file format and can be written directly to a file or streamed through a [diagnostic port](#) for out-of-process consumption.

To learn more about the EventPipe serialization format, refer to the [EventPipe format documentation](#).

EventPipe vs. ETW/LTTng

EventPipe is part of the .NET runtime (CoreCLR) and is designed to work the same way across all the platforms .NET Core supports. This allows tracing tools based on EventPipe, such as `dotnet-counters`, `dotnet-gcdump`, and `dotnet-trace`, to work seamlessly across platforms.

However, because EventPipe is a runtime built-in component, its scope is limited to managed code and the runtime itself. EventPipe cannot be used for tracking some lower-level events, such as resolving native code stack or getting various kernel events. If you use C/C++ interop in your app or you want to trace the runtime itself (which is written in C++), or want deeper diagnostics into the behavior of the app that requires kernel events (that is, native-thread context-switching events) you should use ETW or [perf/LTTng](#).

Another major difference between EventPipe and ETW/LTTng is admin/root privilege requirement. To trace an application using ETW or LTTng you need to be an admin/root. Using EventPipe, you can trace applications as long as the tracer (for example, `dotnet-trace`) is run as the same user as the user that launched the application.

The following table is a summary of the differences between EventPipe and ETW/LTTng.

FEATURE	EVENTPIPE	ETW	LTTNG
Cross-platform	Yes	No (only on Windows)	No (only on supported Linux distros)
Require admin/root privilege	No	Yes	Yes
Can get OS/kernel events	No	Yes	Yes
Can resolve native callstacks	No	Yes	Yes

Use EventPipe to trace your .NET application

You can use EventPipe to trace your .NET application in many ways:

- Use one of the [diagnostics tools](#) that are built on top of EventPipe.
- Use [Microsoft.Diagnostics.NETCore.Client](#) library to write your own tool to configure and start EventPipe sessions.
- Use [environment variables](#) to start EventPipe.

After you've produced a `nettrace` file that contains your EventPipe events, you can view the file in [PerfView](#) or Visual Studio. On non-Windows platforms, you can convert the `nettrace` file to a `speedscope` or `Chromium` trace format by using `dotnet-trace convert` command and view it with `speedscope` or Chrome DevTools.

You can also analyze EventPipe traces programmatically with [TraceEvent](#).

Tools that use EventPipe

This is the easiest way to use EventPipe to trace your application. To learn more about how to use each of these tools, refer to each tool's documentation.

- [dotnet-counters](#) lets you monitor and collect various metrics emitted by the .NET runtime and core libraries, as well as custom metrics you can write.
- [dotnet-gcdump](#) lets you collect GC heap dumps of live processes for analyzing an application's managed heap.
- [dotnet-trace](#) lets you collect traces of applications to analyze for performance.

Trace using environment variables

The preferred mechanism for using EventPipe is to use [dotnet-trace](#) or the [Microsoft.Diagnostics.NETCore.Client](#) library.

However, you can use the following environment variables to set up an EventPipe session on an app and have it write the trace directly to a file. To stop tracing, exit the application.

- `DOTNET_EnableEventPipe` : Set this to `1` to start an EventPipe session that writes directly to a file. The default value is `0`.
- `DOTNET_EventPipeOutputPath` : The path to the output EventPipe trace file when it's configured to run via `DOTNET_EnableEventPipe`. The default value is `trace.nettrace`, which will be created in the same directory that the app is running from.

NOTE

Since .NET 6, instances of the string `{pid}` in `DOTNET_EventPipeOutputPath` are replaced with the process id of the process being traced.

- `DOTNET_EventPipeCircularMB` : A hexadecimal value that represents the size of EventPipe's internal buffer in megabytes. This configuration value is only used when EventPipe is configured to run via `DOTNET_EnableEventPipe`. The default buffer size is 1024MB which translates to this environment variable being set to `400`, since `0x400 == 1024`.

NOTE

If the target process writes events too frequently, it can overflow this buffer and some events might be dropped. If too many events are getting dropped, increase the buffer size to see if the number of dropped events reduces. If the number of dropped events does not decrease with a larger buffer size, it may be due to a slow reader preventing the target process' buffers from being flushed.

- `DOTNET_EventPipeProcNumbers` : Set this to `1` to enable capturing processor numbers in EventPipe event headers. The default value is `0`.
- `DOTNET_EventPipeConfig` : Sets up the EventPipe session configuration when starting an EventPipe session with `DOTNET_EnableEventPipe`. The syntax is as follows:

```
<provider>:<keyword>:<level>
```

You can also specify multiple providers by concatenating them with a comma:

```
<provider1>:<keyword1>:<level1>,<provider2>:<keyword2>:<level2>
```

If this environment variable is not set but EventPipe is enabled by `DOTNET_EnableEventPipe`, it will start tracing by enabling the following providers with the following keywords and levels:

- `Microsoft-Windows-DotNETRuntime:4c14fccbd:5`
- `Microsoft-Windows-DotNETRuntimePrivate:4002000b:5`
- `Microsoft-DotNETCore-SampleProfiler:0:5`

To learn more about some of the well-known providers in .NET, refer to [Well-known Event Providers](#).

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

.NET metrics

9/20/2022 • 2 minutes to read • [Edit Online](#)

Metrics are numerical measurements reported over time, most often used to monitor the health of an application and generate alerts. For example, a web service might track how many requests it receives each second, how many milliseconds it took to respond, and how many of the responses sent an error back to the user. These metrics can be reported to a monitoring system at regular intervals. If the example web service is intended to respond to requests within 400 ms and then one day the response time slows to 600 ms, the monitoring system can notify engineers that the application is not operating as expected.

Getting started

There are two parts to using metrics in a .NET app:

- **Instrumentation:** Code in .NET libraries takes measurements and associates these measurements with a metric name.
- **Collection:** A .NET app developer configures which named metrics need to be transmitted from the app for external storage and analysis. Some tools may also let engineers configure this outside the app using config files or separate UI.

.NET library developers are primarily interested in the instrumentation step. App developers or operational engineers usually focus on the collection step, leveraging the pre-existing instrumentation within libraries they are using. However, if you're an app developer and none of the existing metrics meet your needs, you can also create new metrics.

Next steps

- [Instrumentation tutorial](#) - How to create new metrics in code
- [Collection tutorial](#) - How to store and view metric data for your app
- [Built-in metrics](#) - Discover metrics that are ready for use in .NET runtime libraries
- [Compare metric APIs](#)
- [EventCounters](#) - Learn what EventCounters are, how to implement them, and how to consume them

Creating Metrics

9/20/2022 • 16 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.6.1 and later versions

.NET applications can be instrumented using the [System.Diagnostics.Metrics](#) APIs to track important metrics. Some metrics are included in standard .NET libraries, but you may want to add new custom metrics that are relevant for your applications and libraries. In this tutorial, you will add new metrics and understand what types of metrics are available.

NOTE

.NET has some older metric APIs, namely [EventCounters](#) and [System.Diagnostics.PerformanceCounter](#), that are not covered here. To learn more about these alternatives, see [Compare metric APIs](#).

Create a custom metric

Prerequisites: [.NET Core 3.1 SDK](#) or a later version

Create a new console application that references the [System.Diagnostics.DiagnosticSource NuGet package](#) version 6 or greater. Applications that target .NET 6+ include this reference by default. Then, update the code in [Program.cs](#) to match:

```
> dotnet new console  
> dotnet add package System.Diagnostics.DiagnosticSource
```

```
using System;  
using System.Diagnostics.Metrics;  
using System.Threading;  
  
class Program  
{  
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");  
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>("hats-sold");  
  
    static void Main(string[] args)  
    {  
        Console.WriteLine("Press any key to exit");  
        while(!Console.KeyAvailable)  
        {  
            // Pretend our store has a transaction each second that sells 4 hats  
            Thread.Sleep(1000);  
            s_hatsSold.Add(4);  
        }  
    }  
}
```

The [System.Diagnostics.Metrics.Meter](#) type is the entry point for a library to create a named group of instruments. Instruments record the numeric measurements that are needed to calculate metrics. Here we used [CreateCounter](#) to create a Counter instrument named "hats-sold". During each pretend transaction, the code calls [Add](#) to record the measurement of hats that were sold, 4 in this case. The "hats-sold" instrument implicitly defines some metrics that could be computed from these measurements, such as the total number of hats sold or hats sold/sec. Ultimately it is up to metric collection tools to determine which metrics to compute and how to

perform those computations, but each instrument has some default conventions that convey the developer's intent. For Counter instruments, the convention is that collection tools show the total count and/or the rate at which the count is increasing.

The generic parameter `int` on `Counter<int>` and `CreateCounter<int>(...)` defines that this counter must be able to store values up to `Int32.MaxValue`. You can use any of `byte`, `short`, `int`, `long`, `float`, `double`, or `decimal` depending on the size of data you need to store and whether fractional values are needed.

Run the app and leave it running for now. We will view the metrics next.

```
> dotnet run  
Press any key to exit
```

Best practices

- Create the Meter once, store it in a static variable or DI container, and use that instance as long as needed. Each library or library subcomponent can (and often should) create its own [Meter](#). Consider creating a new Meter rather than reusing an existing one if you anticipate app developers would appreciate being able to enable and disable the groups of metrics separately.
- The name passed to the [Meter](#) constructor has to be unique to avoid conflicts with any other Meters. Use a dotted hierarchical name that contains the assembly name and optionally a subcomponent name. If an assembly is adding instrumentation for code in a second, independent assembly, the name should be based on the assembly that defines the Meter, not the assembly whose code is being instrumented.
- The [Meter](#) constructor version parameter is optional. We recommend that you provide a version in case you release multiple versions of the library and make changes to the instruments.
- .NET doesn't enforce any naming scheme for metrics, but by convention all the .NET runtime libraries have metric names using '-' if a separator is needed. Other metric ecosystems have encouraged using '!' or '_' as the separator. Microsoft's suggestion is to use '-' in code and let the metric consumer such as OpenTelemetry or Prometheus convert to an alternate separator if needed.
- The APIs to create instruments and record measurements are thread-safe. In .NET libraries, most instance methods require synchronization when invoked on the same object from multiple threads, but that's not needed in this case.
- The Instrument APIs to record measurements ([Add](#) in this example) typically run in <10 ns when no data is being collected, or tens to hundreds of nanoseconds when measurements are being collected by a high-performance collection library or tool. This allows these APIs to be used liberally in most cases, but take care for code that is extremely performance sensitive.

View the new metric

There are many options to store and view metrics. This tutorial uses the [dotnet-counters](#) tool, which is useful for ad-hoc analysis. You can also see the [metrics collection tutorial](#) for other alternatives. If the [dotnet-counters](#) tool is not already installed, use the SDK to install it:

```
> dotnet tool update -g dotnet-counters  
You can invoke the tool using the following command: dotnet-counters  
Tool 'dotnet-counters' (version '5.0.251802') was successfully installed.
```

While the example app is still running, list the running processes in a second shell to determine the process ID:

```
> dotnet-counters ps
  10180 dotnet      C:\Program Files\dotnet\dotnet.exe
  19964 metric-instr E:\temp\metric-instr\bin\Debug\netcoreapp3.1\metric-instr.exe
```

Find the ID for the process name that matches the example app and have dotnet-counters monitor the new counter:

```
> dotnet-counters monitor -p 19964 HatCo.HatStore
Press p to pause, r to resume, q to quit.
  Status: Running

[HatCo.HatStore]
  hats-sold (Count / 1 sec)        4
```

As expected, you can see that HatCo store is steadily selling 4 hats each second.

Types of instruments

In the previous example, we've only demonstrated a [Counter<T>](#) instrument, but there are more instrument types available. Instruments differ in two ways:

- **Default metric computations** - Tools that collect and analyze the instrument measurements will compute different default metrics depending on the instrument.
- **Storage of aggregated data** - Most useful metrics need data to be aggregated from many measurements. One option is the caller provides individual measurements at arbitrary times and the collection tool manages the aggregation. Alternatively, the caller can manage the aggregate measurements and provide them on-demand in a callback.

Types of instruments currently available:

- **Counter** ([CreateCounter](#)) - This instrument tracks a value that increases over time and the caller reports the increments using [Add](#). Most tools will calculate the total and the rate of change in the total. For tools that only show one thing, the rate of change is recommended. For example, assume that the caller invokes [Add\(\)](#) once each second with successive values 1, 2, 4, 5, 4, 3. If the collection tool updates every three seconds, then the total after three seconds is $1+2+4=7$ and the total after six seconds is $1+2+4+5+4+3=19$. The rate of change is the (`current_total - previous_total`), so at three seconds the tool reports $7-0=7$, and after six seconds, it reports $19-7=12$.
- **UpDownCounter** ([CreateCounter](#)) - This instrument tracks a value that may increase or decrease over time. The caller reports the increments and decrements using [Add](#). For example, assume that the caller invokes [Add\(\)](#) once each second with successive values 1, 5, -2, 3, -1, -3. If the collection tool updates every three seconds, then the total after three seconds is $1+5-2=4$ and the total after six seconds is $1+5-2+3-1-3=3$.
- **ObservableCounter** ([CreateObservableCounter](#)) - This instrument is similar to Counter except that the caller is now responsible for maintaining the aggregated total. The caller provides a callback delegate when the ObservableCounter is created and the callback is invoked whenever tools need to observe the current total. For example, if a collection tool updates every three seconds, then the callback function will also be invoked every three seconds. Most tools will have both the total and rate of change in the total available. If only one can be shown, rate of change is recommended. If the callback returns 0 on the initial call, 7 when it is called again after three seconds, and 19 when called after six seconds, then the tool will report those values unchanged as the totals. For rate of change, the tool will show $7-0=7$ after three seconds and $19-7=12$ after six seconds.
- **ObservableUpDownCounter** ([CreateObservableUpDownCounter](#)) - This instrument is similar to

`UpDownCounter` except that the caller is now responsible for maintaining the aggregated total. The caller provides a callback delegate when the `ObservableUpDownCounter` is created and the callback is invoked whenever tools need to observe the current total. For example, if a collection tool updates every three seconds, then the callback function will also be invoked every three seconds. Whatever value is returned by the callback will be shown in the collection tool unchanged as the total.

- **ObservableGauge** ([CreateObservableGauge](#)) - This instrument allows the caller to provide a callback where the measured value is passed through directly as the metric. Each time the collection tool updates, the callback is invoked, and whatever value is returned by the callback is displayed in the tool.
- **Histogram** ([CreateHistogram](#)) - This instrument tracks the distribution of measurements. There isn't a single canonical way to describe a set of measurements, but tools are recommended to use histograms or computed percentiles. For example, assume the caller invoked `Record` to record these measurements during the collection tool's update interval: 1,5,2,3,10,9,7,4,6,8. A collection tool might report that the 50th, 90th, and 95th percentiles of these measurements are 5, 9, and 9 respectively.

Best practices when selecting an instrument type

- For counting things, or any other value that solely increases over time, use Counter or `ObservableCounter`. Choose between Counter and `ObservableCounter` depending on which is easier to add to the existing code: either an API call for each increment operation, or a callback that will read the current total from a variable the code maintains. In extremely hot code paths where performance is important and using `Add` would create more than one million calls per second per thread, using `ObservableCounter` may offer more opportunity for optimization.
- For timing things, Histogram is usually preferred. Often it's useful to understand the tail of these distributions (90th, 95th, 99th percentile) rather than averages or totals.
- Other common cases, such as cache hit rates or sizes of caches, queues, and files are usually well suited for `UpDownCounter` or `ObservableUpDownCounter`. Choose between them depending on which is easier to add to the existing code: either an API call for each increment and decrement operation or a callback that will read the current value from a variable the code maintains.

NOTE

If you're using an older version of .NET or a DiagnosticSource NuGet package that doesn't support `UpDownCounter` and `ObservableUpDownCounter` (before version 7), `observableGauge` is often a good substitute.

Example of different instrument types

Stop the example process started previously, and replace the example code in `Program.cs` with:

```

using System;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>("hats-sold");
    static Histogram<int> s_orderProcessingTimeMs = s_meter.CreateHistogram<int>("order-processing-time");
    static int s_coatsSold;
    static int s_ordersPending;

    static Random s_rand = new Random();

    static void Main(string[] args)
    {
        s_meter.CreateObservableCounter<int>("coats-sold", () => s_coatsSold);
        s_meter.CreateObservableGauge<int>("orders-pending", () => s_ordersPending);

        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has one transaction each 100ms that each sell 4 hats
            Thread.Sleep(100);
            s_hatsSold.Add(4);

            // Pretend we also sold 3 coats. For an ObservableCounter we track the value in our variable and
            // report it
            // on demand in the callback
            s_coatsSold += 3;

            // Pretend we have some queue of orders that varies over time. The callback for the "orders-
            pending" gauge will report
            // this value on-demand.
            s_ordersPending = s_rand.Next(0, 20);

            // Last we pretend that we measured how long it took to do the transaction (for example we could
            // time it with Stopwatch)
            s_orderProcessingTimeMs.Record(s_rand.Next(5, 15));
        }
    }
}

```

Run the new process and use dotnet-counters as before in a second shell to view the metrics:

```

> dotnet-counters ps
  2992 dotnet      C:\Program Files\dotnet\dotnet.exe
  20508 metric-instr E:\temp\metric-instr\bin\Debug\netcoreapp3.1\metric-instr.exe
> dotnet-counters monitor -p 20508 HatCo.HatStore
Press p to pause, r to resume, q to quit.
  Status: Running

[HatCo.HatStore]
  coats-sold (Count / 1 sec)          30
  hats-sold (Count / 1 sec)           40
  order-processing-time
    Percentile=50                   125
    Percentile=95                   146
    Percentile=99                   146
  orders-pending                   3

```

This example uses some randomly generated numbers so your values will vary a bit. You can see that `hats-sold` (the Counter) and `coats-sold` (the ObservableCounter) both show up as a rate. The ObservableGauge, `orders-pending`, appears as an absolute value. Dotnet-counters renders Histogram

instruments as three percentile statistics (50th, 95th, and 99th) but other tools may summarize the distribution differently or offer more configuration options.

Best practices

- Histograms tend to store a lot more data in memory than other metric types, however, the exact memory usage is determined by the collection tool being used. If you're defining a large number (>100) of Histogram metrics, you may need to give users guidance not to enable them all at the same time, or to configure their tools to save memory by reducing precision. Some collection tools may have hard limits on the number of concurrent Histograms they will monitor to prevent excessive memory use.
- Callbacks for all observable instruments are invoked in sequence, so any callback that takes a long time can delay or prevent all metrics from being collected. Favor quickly reading a cached value, returning no measurements, or throwing an exception over performing any potentially long-running or blocking operation.
- The [CreateObservableGauge](#) and [CreateObservableCounter](#) functions do return an instrument object, but in most cases you don't need to save it in a variable because no further interaction with the object is needed. Assigning it to a static variable as we did for the other instruments is legal but error prone, because C# static initialization is lazy and the variable is usually never referenced. Here is an example of the problem:

```
using System;
using System.Diagnostics.Metrics;

class Program
{
    // BEWARE! Static initializers only run when code in a running method refers to a static variable.
    // These statics will never be initialized because none of them were referenced in Main().
    //
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static ObservableCounter<int> s_coatsSold = s_meter.CreateObservableCounter<int>("coats-sold", () =>
s_rand.Next(1,10));
    static Random s_rand = new Random();

    static void Main(string[] args)
    {
        Console.ReadLine();
    }
}
```

Descriptions and units

Instruments can specify optional descriptions and units. These values are opaque to all metric calculations but can be shown in collection tool UI to help engineers understand how to interpret the data. Stop the example process you started previously, and replace the example code in [Program.cs](#) with:

```

using System;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>(name: "hats-sold",
                                                               unit: "Hats",
                                                               description: "The number of hats sold in our
store");

    static void Main(string[] args)
    {
        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has a transaction each 100ms that sells 4 hats
            Thread.Sleep(100);
            s_hatsSold.Add(4);
        }
    }
}

```

Run the new process and use dotnet-counters as before in a second shell to view the metrics:

```

Press p to pause, r to resume, q to quit.
Status: Running

[HatCo.HatStore]
hats-sold (Hats / 1 sec)          40

```

dotnet-counters doesn't currently use the description text in the UI, but it does show the unit when it is provided. In this case, you see "Hats" has replaced the generic term "Count" that is visible in previous descriptions.

Best practices

The unit specified in the constructor should describe the units appropriate for an individual measurement. This will sometimes differ from the units on the final metric. In this example, each measurement is a number of hats, so "Hats" is the appropriate unit to pass in the constructor. The collection tool calculated a rate and derived on its own that the appropriate unit for the calculated metric is Hats/sec.

Multi-dimensional metrics

Measurements can also be associated with key-value pairs called tags that allow data to be categorized for analysis. For example, HatCo might want to record not only the number of hats that were sold, but also which size and color they were. When analyzing the data later, HatCo engineers can break out the totals by size, color, or any combination of both.

Counter and Histogram tags can be specified in overloads of the [Add](#) and [Record](#) that take one or more `KeyValuePair` arguments. For example:

```

s_hatsSold.Add(2,
               new KeyValuePair<string, object>("Color", "Red"),
               new KeyValuePair<string, object>("Size", 12));

```

Replace the code of `Program.cs` and rerun the app and dotnet-counters as before:

```

using System;
using System.Collections.Generic;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>("hats-sold");

    static void Main(string[] args)
    {
        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has a transaction, every 100ms, that sells 2 (size 12) red hats, and 1
            (size 19) blue hat.
            Thread.Sleep(100);
            s_hatsSold.Add(2,
                new KeyValuePair<string,object>("Color", "Red"),
                new KeyValuePair<string,object>("Size", 12));
            s_hatsSold.Add(1,
                new KeyValuePair<string,object>("Color", "Blue"),
                new KeyValuePair<string,object>("Size", 19));
        }
    }
}

```

Dotnet-counters now shows a basic categorization:

```

Press p to pause, r to resume, q to quit.
Status: Running

[HatCo.HatStore]
hats-sold (Count / 1 sec)
Color=Blue,Size=19                      9
Color=Red,Size=12                        18

```

For ObservableCounter and ObservableGauge, tagged measurements can be provided in the callback passed to the constructor:

```

using System;
using System.Collections.Generic;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");

    static void Main(string[] args)
    {
        s_meter.CreateObservableGauge<int>("orders-pending", GetOrdersPending);
        Console.WriteLine("Press any key to exit");
        Console.ReadLine();
    }

    static IEnumerable<Measurement<int>> GetOrdersPending()
    {
        return new Measurement<int>[]
        {
            // pretend these measurements were read from a real queue somewhere
            new Measurement<int>(6, new KeyValuePair<string,object>("Country", "Italy")),
            new Measurement<int>(3, new KeyValuePair<string,object>("Country", "Spain")),
            new Measurement<int>(1, new KeyValuePair<string,object>("Country", "Mexico")),
        };
    }
}

```

When run with dotnet-counters as before, the result is:

```

Press p to pause, r to resume, q to quit.
Status: Running

[HatCo.HatStore]
  orders-pending
    Country=Italy           6
    Country=Mexico          1
    Country=Spain            3

```

Best practices

- Although the API allows any object to be used as the tag value, numeric types and strings are anticipated by collection tools. Other types may or may not be supported by a given collection tool.
- Beware of having very large or unbounded combinations of tag values being recorded in practice. Although the .NET API implementation can handle it, collection tools will likely allocate storage for metric data associated with each tag combination and this could become very large. For example, it's fine if HatCo has 10 different hat colors and 25 hat sizes for up to $10 \times 25 = 250$ sales totals to track. However, if HatCo added a third tag that's a CustomerID for the sale and they sell to 100 million customers worldwide, now there are now likely to be billions of different tag combinations being recorded. Most metric collection tools will either drop data to stay within technical limits or there can be large monetary costs to cover the data storage and processing. The implementation of each collection tool will determine its limits, but likely less than 1000 combinations for one instrument is safe. Anything above 1000 combinations will require the collection tool to apply filtering or be engineered to operate at high scale. Histogram implementations tend to use far more memory than other metrics, so safe limits could be 10-100 times lower. If you anticipate large number of unique tag combinations, then logs, transactional databases, or big data processing systems may be more appropriate solutions to operate at the needed scale.
- For instruments that will have very large numbers of tag combinations, prefer using a smaller storage

type to help reduce memory overhead. For example, storing the `short` for a `Counter<short>` only occupies 2 bytes per tag combination, whereas a `double` for `Counter<double>` occupies 8 bytes per tag combination.

- Collection tools are encouraged to optimize for code that specifies the same set of tag names in the same order for each call to record measurements on the same instrument. For high-performance code that needs to call [Add](#) and [Record](#) frequently, prefer using the same sequence of tag names for each call.
- The .NET API is optimized to be allocation-free for [Add](#) and [Record](#) calls with three or fewer tags specified individually. To avoid allocations with larger numbers of tags, use [TagList](#). In general, the performance overhead of these calls increases as more tags are used.

NOTE

OpenTelemetry refers to tags as 'attributes'. These are two different names for the same functionality.

Collect metrics

9/20/2022 • 11 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions ✓ .NET Framework 4.6.1 and later versions

Instrumented code can record numeric measurements, but the measurements usually need to be aggregated, transmitted, and stored to create useful metrics for monitoring. This process of aggregating, transmitting, and storing the data is called collection. In this tutorial, we will show several examples on how to collect metrics:

- Populating metrics in Grafana with OpenTelemetry and Prometheus.
- Viewing metrics in real time with the `dotnet-counters` command-line tool.
- Creating a custom collection tool using the underlying .NET [MeterListener API](#).

For more information about custom metric instrumentation and an overview of instrumentation options, see [Compare metric APIs](#).

Create an example application

Prerequisites: [.NET Core 3.1 SDK](#) or a later version

Before metrics can be collected, we need to produce some measurements. For simplicity, we will create a small app that has some trivial metric instrumentation. The .NET runtime also has [various metrics built-in](#). For more information about creating new metrics using the `System.Diagnostics.Metrics.Meter` API shown here, see [the instrumentation tutorial](#).

```
dotnet new console
dotnet add package System.Diagnostics.DiagnosticSource
```

Replace the code of `Program.cs` with:

```
using System;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>("hats-sold");

    static void Main(string[] args)
    {
        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has a transaction each second that sells 4 hats
            Thread.Sleep(1000);
            s_hatsSold.Add(4);
        }
    }
}
```

View metrics with `dotnet-counters`

`dotnet-counters` is a simple command-line tool that can view live metrics for any .NET Core application on

demand. It doesn't require any advance setup, which can make it useful for ad-hoc investigations or to verify that metric instrumentation is working correctly. It works with both [System.Diagnostics.Metrics](#) based APIs and [EventCounters](#).

If the [dotnet-counters](#) tool is not already installed, use the SDK to install it:

```
> dotnet tool update -g dotnet-counters
You can invoke the tool using the following command: dotnet-counters
Tool 'dotnet-counters' (version '5.0.251802') was successfully installed.
```

While the example app is still running, list the running processes in a second shell to determine the process ID:

```
> dotnet-counters ps
10180 dotnet      C:\Program Files\dotnet\dotnet.exe
19964 metric-instr E:\temp\metric-instr\bin\Debug\netcoreapp3.1\metric-instr.exe
```

Find the ID for the process name that matches the example app and have dotnet-counters monitor all metrics from the "HatCo.HatStore" meter. The meter name is case-sensitive.

```
> dotnet-counters monitor -p 19964 HatCo.HatStore
Press p to pause, r to resume, q to quit.
Status: Running

[HatCo.HatStore]
hats-sold (Count / 1 sec)          4
```

We can also run dotnet-counters specifying a different set of metrics to see some of the built-in instrumentation from the .NET runtime:

```
> dotnet-counters monitor -p 19964 System.Runtime
Press p to pause, r to resume, q to quit.
Status: Running

[System.Runtime]
% Time in GC since last GC (%)                      0
Allocation Rate (B / 1 sec)                          8,168
CPU Usage (%)                                       0
Exception Count (Count / 1 sec)                     0
GC Heap Size (MB)                                    2
Gen 0 GC Count (Count / 1 sec)                     0
Gen 0 Size (B)                                     2,216,256
Gen 1 GC Count (Count / 1 sec)                     0
Gen 1 Size (B)                                     423,392
Gen 2 GC Count (Count / 1 sec)                     0
Gen 2 Size (B)                                     203,248
LOH Size (B)                                       933,216
Monitor Lock Contention Count (Count / 1 sec)     0
Number of Active Timers                           1
Number of Assemblies Loaded                      39
ThreadPool Completed Work Item Count (Count / 1 sec) 0
ThreadPool Queue Length                           0
ThreadPool Thread Count                           3
Working Set (MB)                                    30
```

For more information about the tool, see the [dotnet-counters](#). To learn more about metrics that are available out of the box in .NET, see [built-in metrics](#).

View metrics in Grafana with OpenTelemetry and Prometheus

Prerequisites

- [.NET Core 3.1 SDK](#) or a later version

Overview

[OpenTelemetry](#) is a vendor-neutral open-source project supported by the [Cloud Native Computing Foundation](#) that aims to standardize generating and collecting telemetry for cloud-native software. The built-in platform metric APIs are designed to be compatible with this standard to make integration straightforward for any .NET developers that wish to use it. At the time of writing, support for OpenTelemetry metrics is relatively new, but [Azure Monitor](#) and many major APM vendors have endorsed it and have integration plans underway.

This example shows one of the integrations available now for OpenTelemetry metrics using the popular OSS [Prometheus](#) and [Grafana](#) projects. The metrics data will flow like this:

1. The .NET metric APIs collect measurements from our example application.
2. The OpenTelemetry library running inside the same process aggregates these measurements.
3. The Prometheus exporter library makes the aggregated data available via an HTTP metrics endpoint. 'Exporter' is what OpenTelemetry calls the libraries that transmit telemetry to vendor-specific backends.
4. A Prometheus server, potentially running on a different machine, polls the metrics endpoint, reads the data, and stores it in a database for long-term persistence. Prometheus refers to this as 'scraping' an endpoint.
5. The Grafana server, potentially running on a different machine, queries the data stored in Prometheus and displays it to engineers on a web-based monitoring dashboard.

Configure the example application to use OpenTelemetry's Prometheus exporter

Add a reference to the OpenTelemetry Prometheus exporter to the example application:

```
dotnet add package OpenTelemetry.Exporter.Prometheus --version 1.2.0-beta1
```

NOTE

The Prometheus exporter library includes a reference to OpenTelemetry's shared library so this command implicitly adds both libraries to the application.

NOTE

This tutorial is using a pre-release build of OpenTelemetry's Prometheus support available at the time of writing. The OpenTelemetry project maintainers might make changes prior to the official release.

Modify the code of [Program.cs](#) so that it contains the extra code to configure OpenTelemetry at the beginning of Main():

```

using System;
using System.Diagnostics.Metrics;
using System.Threading;
using OpenTelemetry;
using OpenTelemetry.Metrics;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>(name: "hats-sold",
                                                               unit: "Hats",
                                                               description: "The number of hats sold in our
store");

    static void Main(string[] args)
    {
        using MeterProvider meterProvider = Sdk.CreateMeterProviderBuilder()
            .AddMeter("HatCo.HatStore")
            .AddPrometheusExporter(opt =>
            {
                opt.StartHttpListener = true;
                opt.HttpListenerPrefixes = new string[] { $"http://localhost:9184/" };
            })
            .Build();

        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has a transaction each second that sells 4 hats
            Thread.Sleep(1000);
            s_hatsSold.Add(4);
        }
    }
}

```

`AddMeter("HatCo.HatStore")` configures OpenTelemetry to transmit all the metrics collected by the Meter our app defined. `AddPrometheusExporter(...)` configures OpenTelemetry to expose Prometheus' metrics endpoint on port 9184 and to use the HttpListener. See the [OpenTelemetry documentation](#) for more information about OpenTelemetry configuration options, in particular, alternative hosting options that are useful for ASP.NET applications.

NOTE

At the time of writing, OpenTelemetry only supports metrics emitted using the [System.Diagnostics.Metrics](#) APIs. However, support for [EventCounters](#) is planned.

Run the example app and leave it running in the background.

```

> dotnet run
Press any key to exit

```

Set up and configure Prometheus

Follow the [Prometheus first steps](#) to set up your Prometheus server and confirm it is working.

Modify the `prometheus.yml` configuration file so that Prometheus will scrape the metrics endpoint that our example app is exposing. Add this text in the `scrape_configs` section:

```

- job_name: 'OpenTelemetryTest'
scrape_interval: 1s # poll very quickly for a more responsive demo
static_configs:
  - targets: ['localhost:9184']

```

If you are starting from the default configuration, then `scrape_configs` should now look like this:

```

scrape_configs:
# The job name is added as a label `job=<job_name>` to any timeseries scraped from this config.
- job_name: "prometheus"

# metrics_path defaults to '/metrics'
# scheme defaults to 'http'.

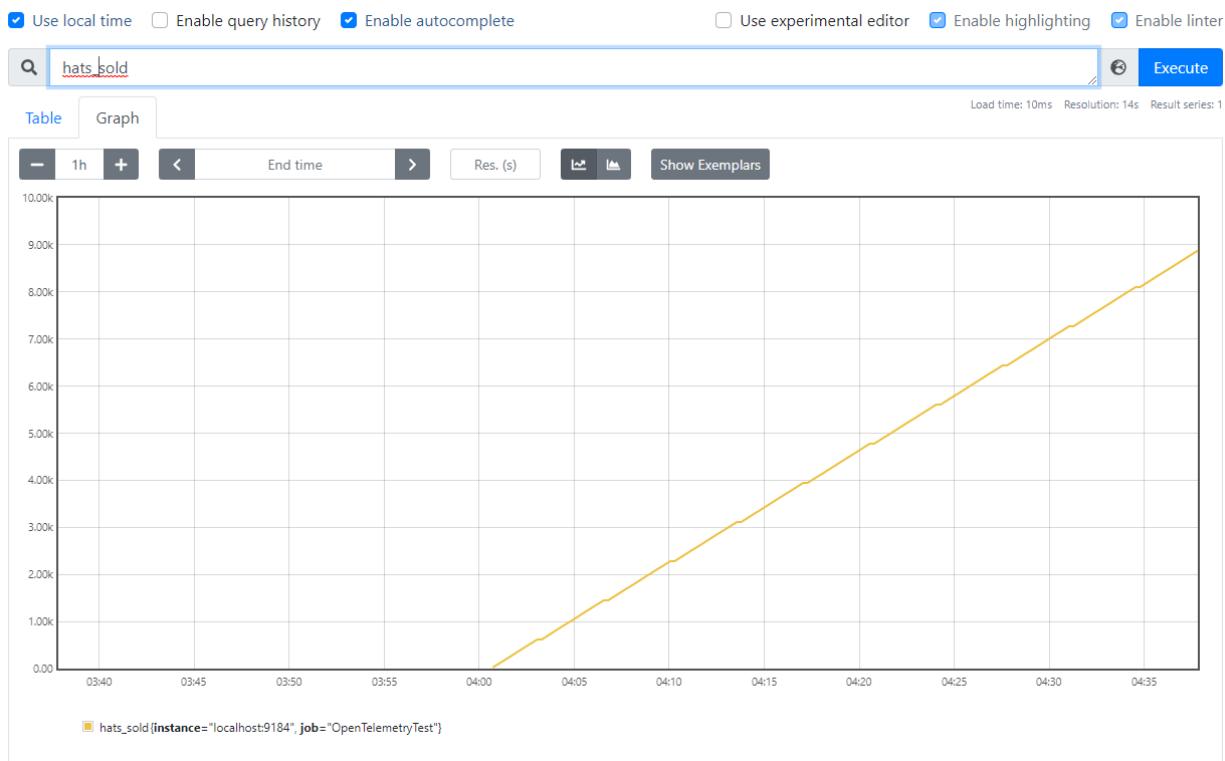

static_configs:
  - targets: ["localhost:9090"]

- job_name: 'OpenTelemetryTest'
scrape_interval: 1s # poll very quickly for a more responsive demo
static_configs:
  - targets: ['localhost:9184']

```

Reload the configuration or restart the Prometheus server, then confirm that OpenTelemetryTest is in the UP state in the **Status > Targets** page of the Prometheus web portal.

On the Graph page of the Prometheus web portal, enter `hats_sold` in the expression text box. In the graph tab, Prometheus should show the steadily increasing value of the "hats-sold" Counter that is being emitted by our example application.

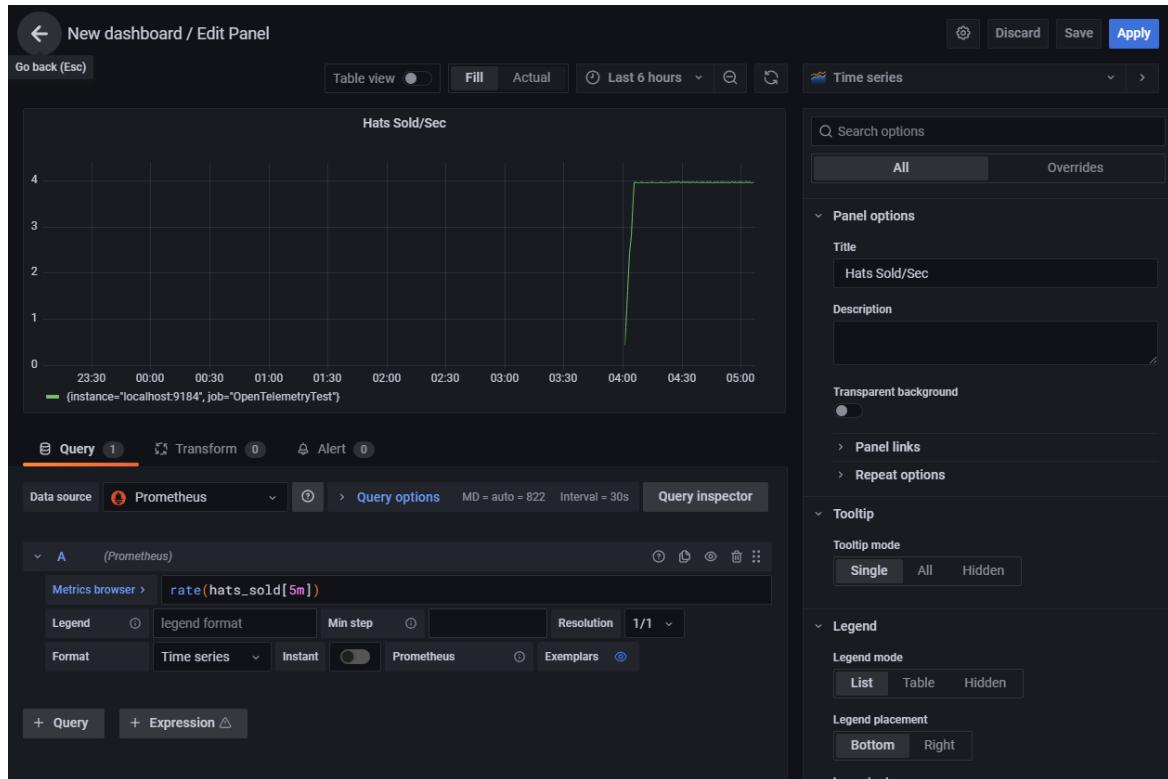

If the Prometheus server hasn't been scraping the example app for long, you may need to wait a short while for data to accumulate. You can also adjust the time range control in the upper left to "1m" (1 minute) to get a better view of very recent data.

Show metrics on a Grafana dashboard

1. Follow [the standard instructions](#) to install Grafana and connect it to a Prometheus data source.

2. Create a Grafana dashboard by clicking the + icon on the left toolbar in the Grafana web portal, then select **Dashboard**. In the dashboard editor that appears, enter 'Hats Sold/Sec' as the Title and 'rate(hats_sold[5m])' in the PromQL expression field. It should look like this:

3. Click **Apply** to save and view the simple new dashboard.

Create a custom collection tool using the .NET MeterListener API

The .NET [MeterListener](#) API allows creating custom in-process logic to observe the measurements being recorded by [System.Diagnostics.Metrics.Meter](#). For guidance creating custom logic compatible with the older EventCounters instrumentation, see [EventCounters](#).

Modify the code of `Program.cs` to use [MeterListener](#) like this:

```

using System;
using System.Collections.Generic;
using System.Diagnostics.Metrics;
using System.Threading;

class Program
{
    static Meter s_meter = new Meter("HatCo.HatStore", "1.0.0");
    static Counter<int> s_hatsSold = s_meter.CreateCounter<int>(name: "hats-sold",
                                                               unit: "Hats",
                                                               description: "The number of hats sold in our
store");

    static void Main(string[] args)
    {
        using MeterListener meterListener = new MeterListener();
        meterListener.InstrumentPublished = (instrument, listener) =>
        {
            if(instrument.Meter.Name == "HatCo.HatStore")
            {
                listener.EnableMeasurementEvents(instrument);
            }
        };
        meterListener.SetMeasurementEventCallback<int>(OnMeasurementRecorded);
        meterListener.Start();

        Console.WriteLine("Press any key to exit");
        while(!Console.KeyAvailable)
        {
            // Pretend our store has a transaction each second that sells 4 hats
            Thread.Sleep(1000);
            s_hatsSold.Add(4);
        }
    }

    static void OnMeasurementRecorded<T>(Instrument instrument, T measurement,
    ReadOnlySpan<KeyValuePair<string,object>> tags, object state)
    {
        Console.WriteLine($"{instrument.Name} recorded measurement {measurement}");
    }
}

```

When run, the application now runs our custom callback on each measurement:

```

> dotnet run
Press any key to exit
hats-sold recorded measurement 4
hats-sold recorded measurement 4
hats-sold recorded measurement 4
hats-sold recorded measurement 4
...

```

Let's break down what happens in the example above.

```
using MeterListener meterListener = new MeterListener();
```

First we created an instance of the [MeterListener](#), which we will use to receive measurements.

```
meterListener.InstrumentPublished = (instrument, listener) =>
{
    if(instrument.Meter.Name == "HatCo.HatStore")
    {
        listener.EnableMeasurementEvents(instrument);
    }
};
```

Here we configured which instruments the listener will receive measurements from. `InstrumentPublished` is a delegate that will be invoked anytime a new instrument is created within the app. Our delegate can examine the instrument, such as checking the name, the Meter, or any other public property to decide whether to subscribe. If we do want to receive measurements from this instrument, then we invoke `EnableMeasurementEvents` to indicate that. If your code has another way to obtain a reference to an instrument, it's legal to invoke `EnableMeasurementEvents()` at any time with that reference, but this is probably uncommon.

```
meterListener.SetMeasurementEventCallback<int>(OnMeasurementRecorded);
...
static void OnMeasurementRecorded<T>(Instrument instrument, T measurement,
ReadOnlySpan<KeyValuePair<string,object>> tags, object state)
{
    Console.WriteLine($"{instrument.Name} recorded measurement {measurement}");
}
```

Next we configured the delegate that is invoked when measurements are received from an instrument by calling `SetMeasurementEventCallback`. The generic parameter controls which data type of measurement will be received by the callback. For example, a `Counter<int>` generates `int` measurements whereas a `Counter<double>` generates `double` measurements. Instruments can be created with `byte`, `short`, `int`, `long`, `float`, `double`, and `decimal` types. We recommend registering a callback for every data type unless you have scenario-specific knowledge that not all data types will be needed, such as in this example. Making repeated calls to `SetMeasurementEventCallback()` with different generic arguments may appear a little unusual. The API is designed this way to allow MeterListeners to receive measurements with extremely low performance overhead, typically just a few nanoseconds.

When `MeterListener.EnableMeasurementEvents()` was called initially, there was an opportunity to provide a `state` object as one of the parameters. That object can be anything you want. If you provide a state object in that call, then it will be stored with that instrument and returned to you as the `state` parameter in the callback. This is intended both as a convenience and as a performance optimization. Often listeners need to create an object for each instrument that will store measurements in memory and have code to do calculations on those measurements. Although you could create a Dictionary that maps from the instrument to the storage object and look it up on every measurement, that would be much slower than accessing it from `state`.

```
meterListener.Start();
```

Once the `MeterListener` is configured, we need to start it to trigger callbacks to begin. The `InstrumentPublished` delegate will be invoked for every pre-existing Instrument in the process. In the future, any newly created Instrument will also trigger `InstrumentPublished` to be invoked.

```
using MeterListener meterListener = new MeterListener();
```

Once we are done listening, disposing the listener stops the flow of callbacks and releases any internal references to the listener object. The `using` keyword we used when declaring `meterListener` causes `Dispose()` to be called automatically when the variable goes out of scope. Be aware that `Dispose()` is only promising that it won't initiate new callbacks. Because callbacks occur on different threads, there may still be callbacks in

progress after the call to `Dispose()` returns. If you need a guarantee that a certain region of code in your callback isn't currently executing and will never execute again in the future, then you will need some additional thread synchronization to enforce that. `Dispose()` doesn't include the synchronization by default because it adds performance overhead in every measurement callback—and `MeterListener` is designed as a highly performance conscious API.

EventCounters in .NET

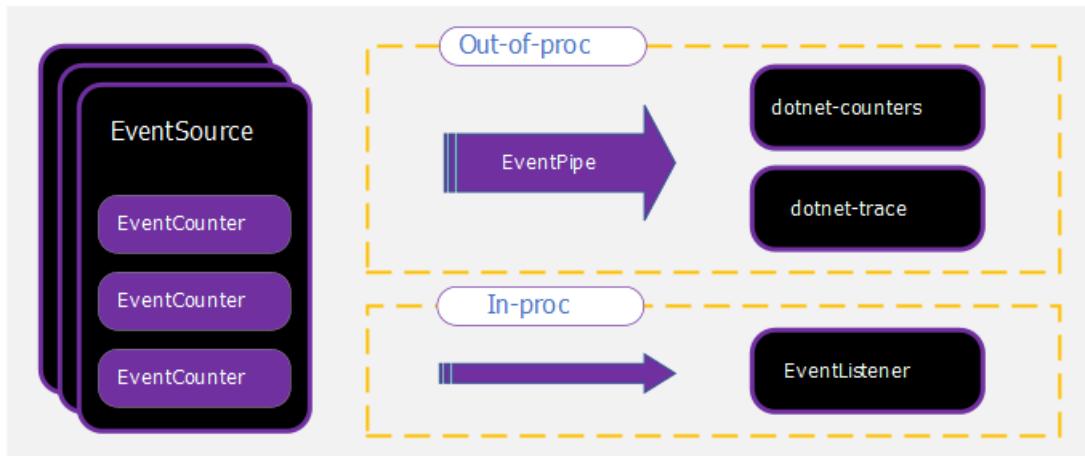

9/20/2022 • 10 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.0 SDK and later versions

EventCounters are .NET APIs used for lightweight, cross-platform, and near real-time performance metric collection. EventCounters were added as a cross-platform alternative to the "performance counters" of .NET Framework on Windows. In this article, you'll learn what EventCounters are, how to implement them, and how to consume them.

The .NET runtime and a few .NET libraries publish basic diagnostics information using EventCounters starting in .NET Core 3.0. Apart from the EventCounters that are provided by the .NET runtime, you may choose to implement your own EventCounters. EventCounters can be used to track various metrics. Learn more about them in [well-known EventCounters in .NET](#)

EventCounters live as a part of an [EventSource](#), and are automatically pushed to listener tools on a regular basis. Like all other events on an [EventSource](#), they can be consumed both in-proc and out-of-proc via [EventListener](#) and [EventPipe](#). This article focuses on the cross-platform capabilities of EventCounters, and intentionally excludes PerfView and ETW (Event Tracing for Windows) - although both can be used with EventCounters.

EventCounter API overview

There are two primary categories of EventCounters. Some counters are for "rate" values, such as total number of exceptions, total number of GCs, and total number of requests. Other counters are "snapshot" values, such as heap usage, CPU usage, and working set size. Within each of these categories of counters, there are two types of counters that vary by how they get their value. Polling counters retrieve their value via a callback, and non-polling counters have their values directly set on the counter instance.

The counters are represented by the following implementations:

- [EventCounter](#)
- [IncrementingEventCounter](#)
- [PollingCounter](#)
- [IncrementingPollingCounter](#)

An event listener specifies how long measurement intervals are. At the end of each interval a value is transmitted to the listener for each counter. The implementations of a counter determine what APIs and

calculations are used to produce the value each interval.

- The [EventCounter](#) records a set of values. The [EventCounter.WriteMetric](#) method adds a new value to the set. With each interval, a statistical summary for the set is computed, such as the min, max, and mean. The [dotnet-counters](#) tool will always display the mean value. The [EventCounter](#) is useful to describe a discrete set of operations. Common usage may include monitoring the average size in bytes of recent IO operations, or the average monetary value of a set of financial transactions.
- The [IncrementingEventCounter](#) records a running total for each time interval. The [IncrementingEventCounter.Increment](#) method adds to the total. For example, if `Increment()` is called three times during one interval with values `1`, `2`, and `5`, then the running total of `8` will be reported as the counter value for this interval. The [dotnet-counters](#) tool will display the rate as the recorded total / time. The [IncrementingEventCounter](#) is useful to measure how frequently an action is occurring, such as the number of requests processed per second.
- The [PollingCounter](#) uses a callback to determine the value that is reported. With each time interval, the user provided callback function is invoked and the return value is used as the counter value. A [PollingCounter](#) can be used to query a metric from an external source, for example getting the current free bytes on a disk. It can also be used to report custom statistics that can be computed on demand by an application. Examples include reporting the 95th percentile of recent request latencies, or the current hit or miss ratio of a cache.
- The [IncrementingPollingCounter](#) uses a callback to determine the reported increment value. With each time interval, the callback is invoked, and then the difference between the current invocation, and the last invocation is the reported value. The [dotnet-counters](#) tool will always display the difference as a rate, the reported value / time. This counter is useful when it isn't feasible to call an API on each occurrence, but it's possible to query the total number of occurrences. For example, you could report the number of bytes written to a file per second, even without a notification each time a byte is written.

Implement an EventSource

The following code implements a sample [EventSource](#) exposed as the named `"Sample.EventCounter.Minimal"` provider. This source contains an [EventCounter](#) representing request-processing time. Such a counter has a name (that is, its unique ID in the source) and a display name, both used by listener tools such as [dotnet-counter](#).

```

using System.Diagnostics.Tracing;

[EventSource(Name = "Sample.EventCounter.Minimal")]
public sealed class MinimalEventCounterSource : EventSource
{
    public static readonly MinimalEventCounterSource Log = new MinimalEventCounterSource();

    private EventCounter _requestCounter;

    private MinimalEventCounterSource() =>
        _requestCounter = new EventCounter("request-time", this)
        {
            DisplayName = "Request Processing Time",
            DisplayUnits = "ms"
        };

    public void Request(string url, long elapsedMilliseconds)
    {
        WriteEvent(1, url, elapsedMilliseconds);
        _requestCounter?.WriteMetric(elapsedMilliseconds);
    }

    protected override void Dispose(bool disposing)
    {
        _requestCounter?.Dispose();
        _requestCounter = null;

        base.Dispose(disposing);
    }
}

```

You use `dotnet-counters ps` to display a list of .NET processes that can be monitored:

```

dotnet-counters ps
 1398652 dotnet      C:\Program Files\dotnet\dotnet.exe
 1399072 dotnet      C:\Program Files\dotnet\dotnet.exe
 1399112 dotnet      C:\Program Files\dotnet\dotnet.exe
 1401880 dotnet      C:\Program Files\dotnet\dotnet.exe
 1400180 sample-counters C:\sample-counters\bin\Debug\netcoreapp3.1\sample-counters.exe

```

Pass the `EventSource` name to the `--counters` option to start monitoring your counter:

```
dotnet-counters monitor --process-id 1400180 --counters Sample.EventCounter.Minimal
```

The following example shows monitor output:

```

Press p to pause, r to resume, q to quit.
Status: Running

[Samples-EventCounterDemos-Minimal]
Request Processing Time (ms)          0.445

```

Press `q` to stop the monitoring command.

Conditional counters

When implementing an `EventSource`, the containing counters can be conditionally instantiated when the `EventSource.OnEventCommand` method is called with a `Command` value of `EventCommand.Enable`. To safely instantiate a counter instance only if it is `null`, use the [null-coalescing assignment operator](#). Additionally, custom methods can evaluate the `IsEnabled` method to determine whether or not the current event source is

enabled.

```
using System.Diagnostics.Tracing;

[EventSource(Name = "Sample.EventCounter.Conditional")]
public sealed class ConditionalEventCounterSource : EventSource
{
    public static readonly ConditionalEventCounterSource Log = new ConditionalEventCounterSource();

    private EventCounter _requestCounter;

    private ConditionalEventCounterSource() { }

    protected override void OnEventCommand(EventCommandEventEventArgs args)
    {
        if (args.Command == EventCommand.Enable)
        {
            _requestCounter ??= new EventCounter("request-time", this)
            {
                DisplayName = "Request Processing Time",
                DisplayUnits = "ms"
            };
        }
    }

    public void Request(string url, float elapsedMilliseconds)
    {
        if (IsEnabled())
        {
            _requestCounter?.WriteMetric(elapsedMilliseconds);
        }
    }

    protected override void Dispose(bool disposing)
    {
        _requestCounter?.Dispose();
        _requestCounter = null;

        base.Dispose(disposing);
    }
}
```

TIP

Conditional counters are counters that are conditionally instantiated, a micro-optimization. The runtime adopts this pattern for scenarios where counters are normally not used, to save a fraction of a millisecond.

.NET Core runtime example counters

There are many great example implementations in the .NET Core runtime. Here is the runtime implementation for the counter that tracks the working set size of the application.

```
var workingSetCounter = new PollingCounter(
    "working-set",
    this,
    () => (double)(Environment.WorkingSet / 1_000_000))
{
    DisplayName = "Working Set",
    DisplayUnits = "MB"
};
```

The [PollingCounter](#) reports the current amount of physical memory mapped to the process (working set) of the

app, since it captures a metric at a moment in time. The callback for polling a value is the provided lambda expression, which is just a call to the `System.Environment.WorkingSet` API. `DisplayName` and `DisplayUnits` are optional properties that can be set to help the consumer side of the counter to display the value more clearly. For example, `dotnet-counters` uses these properties to display the more display-friendly version of the counter names.

IMPORTANT

The `DisplayName` properties are not localized.

For the `PollingCounter`, and the `IncrementingPollingCounter`, nothing else needs to be done. They both poll the values themselves at an interval requested by the consumer.

Here is an example of a runtime counter implemented using `IncrementingPollingCounter`.

```
var monitorContentionCounter = new IncrementingPollingCounter(
    "monitor-lock-contention-count",
    this,
    () => Monitor.LockContentionCount
)
{
    DisplayName = "Monitor Lock Contention Count",
    DisplayRateTimeScale = TimeSpan.FromSeconds(1)
};
```

The `IncrementingPollingCounter` uses the `Monitor.LockContentionCount` API to report the increment of the total lock contention count. The `DisplayRateTimeScale` property is optional, but when used it can provide a hint for what time interval the counter is best displayed at. For example, the lock contention count is best displayed as *count per second*, so its `DisplayRateTimeScale` is set to one second. The display rate can be adjusted for different types of rate counters.

NOTE

The `DisplayRateTimeScale` is *not* used by `dotnet-counters`, and event listeners are not required to use it.

There are more counter implementations to use as a reference in the [.NET runtime](#) repo.

Concurrency

TIP

The EventCounters API does not guarantee thread safety. When the delegates passed to `PollingCounter` or `IncrementingPollingCounter` instances are called by multiple threads, it's your responsibility to guarantee the delegates' thread-safety.

For example, consider the following `EventSource` to keep track of requests.

```

using System;
using System.Diagnostics.Tracing;

public class RequestEventSource : EventSource
{
    public static readonly RequestEventSource Log = new RequestEventSource();

    private IncrementingPollingCounter _requestRateCounter;
    private long _requestCount = 0;

    private RequestEventSource() =>
        _requestRateCounter = new IncrementingPollingCounter("request-rate", this, () => _requestCount)
    {
        DisplayName = "Request Rate",
        DisplayRateTimeScale = TimeSpan.FromSeconds(1)
    };

    public void AddRequest() => ++_requestCount;

    protected override void Dispose(bool disposing)
    {
        _requestRateCounter?.Dispose();
        _requestRateCounter = null;

        base.Dispose(disposing);
    }
}

```

The `AddRequest()` method can be called from a request handler, and the `RequestRateCounter` polls the value at the interval specified by the consumer of the counter. However, the `AddRequest()` method can be called by multiple threads at once, putting a race condition on `_requestCount`. A thread-safe alternative way to increment the `_requestCount` is to use [Interlocked.Increment](#).

```
public void AddRequest() => Interlocked.Increment(ref _requestCount);
```

To prevent torn reads (on 32-bit architectures) of the `long`-field `_requestCount` use [Interlocked.Read](#).

```

_requestRateCounter = new IncrementingPollingCounter("request-rate", this, () => Interlocked.Read(ref
_requestCount))
{
    DisplayName = "Request Rate",
    DisplayRateTimeScale = TimeSpan.FromSeconds(1)
};

```

Consume EventCounters

There are two primary ways of consuming EventCounters: in-proc and out-of-proc. The consumption of EventCounters can be distinguished into three layers of various consuming technologies.

- Transporting events in a raw stream via ETW or EventPipe:

ETW APIs come with the Windows OS, and EventPipe is accessible as a [.NET API](#), or the diagnostic [IPC protocol](#).

- Decoding the binary event stream into events:

The [TraceEvent library](#) handles both ETW and EventPipe stream formats.

- Command-line and GUI tools:

Tools like PerfView (ETW or EventPipe), dotnet-counters (EventPipe only), and dotnet-monitor (EventPipe only).

Consume out-of-proc

Consuming EventCounters out-of-proc is a common approach. You can use [dotnet-counters](#) to consume them in a cross-platform manner via an EventPipe. The `dotnet-counters` tool is a cross-platform dotnet CLI global tool that can be used to monitor the counter values. To find out how to use `dotnet-counters` to monitor your counters, see [dotnet-counters](#), or work through the [Measure performance using EventCounters](#) tutorial.

dotnet-trace

The `dotnet-trace` tool can be used to consume the counter data through an EventPipe. Here is an example using `dotnet-trace` to collect counter data.

```
dotnet-trace collect --process-id <pid> Sample.EventCounter.Minimal:0:0:EventCounterIntervalSec=1
```

For more information on how to collect counter values over time, see the [dotnet-trace](#) documentation.

Azure Application Insights

EventCounters can be consumed by Azure Monitor, specifically Azure Application Insights. Counters can be added and removed, and you're free to specify custom counters, or well-known counters. For more information, see [Customizing counters to be collected](#).

dotnet-monitor

The `dotnet-monitor` tool makes it easier to access diagnostics from a .NET process in a remote and automated fashion. In addition to traces, it can monitor metrics, collect memory dumps, and collect GC dumps. It's distributed as both a CLI tool and a docker image. It exposes a REST API, and the collection of diagnostic artifacts occurs through REST calls.

For more information, see [dotnet-monitor](#).

Consume in-proc

You can consume the counter values via the [EventListener](#) API. An [EventListener](#) is an in-proc way of consuming any events written by all instances of an [EventSource](#) in your application. For more information on how to use the `EventListener` API, see [EventListener](#).

First, the [EventSource](#) that produces the counter value needs to be enabled. Override the `EventListener.OnEventSourceCreated` method to get a notification when an [EventSource](#) is created, and if this is the correct [EventSource](#) with your EventCounters, then you can call `EventListener.EnableEvents` on it. Here is an example override:

```
protected override void OnEventSourceCreated(EventSource source)
{
    if (!source.Name.Equals("System.Runtime"))
    {
        return;
    }

    EnableEvents(source, EventLevel.Verbose, EventKeywords.All, new Dictionary<string, string>()
    {
        ["EventCounterIntervalSec"] = "1"
    });
}
```

Sample code

Here is a sample [EventListener](#) class that prints all the counter names and values from the .NET runtime's [EventSource](#), for publishing its internal counters (`System.Runtime`) every second.

```

using System;
using System.Collections.Generic;
using System.Diagnostics.Tracing;

public class SimpleEventListener : EventListener
{
    public SimpleEventListener()
    {
    }

    protected override void OnEventSourceCreated(EventSource source)
    {
        if (!source.Name.Equals("System.Runtime"))
        {
            return;
        }

        EnableEvents(source, EventLevel.Verbose, EventKeywords.All, new Dictionary<string, string>()
        {
            ["EventCounterIntervalSec"] = "1"
        });
    }

    protected override void OnEventWritten(EventWrittenEventArgs eventData)
    {
        if (!eventData.EventName.Equals("EventCounters"))
        {
            return;
        }

        for (int i = 0; i < eventData.Payload.Count; ++ i)
        {
            if (eventData.Payload[i] is IDictionary<string, object> eventPayload)
            {
                var (counterName, counterValue) = GetRelevantMetric(eventPayload);
                Console.WriteLine($"{counterName} : {counterValue}");
            }
        }
    }

    private static (string counterName, string counterValue) GetRelevantMetric(
        IDictionary<string, object> eventPayload)
    {
        var counterName = "";
        var counterValue = "";

        if (eventPayload.TryGetValue("DisplayName", out object displayValue))
        {
            counterName = displayValue.ToString();
        }
        if (eventPayload.TryGetValue("Mean", out object value) ||
            eventPayload.TryGetValue("Increment", out value))
        {
            counterValue = value.ToString();
        }

        return (counterName, counterValue);
    }
}

```

As shown above, you *must* make sure the `"EventCounterIntervalSec"` argument is set in the `filterPayload` argument when calling `EnableEvents`. Otherwise the counters will not be able to flush out values since it doesn't know at which interval it should be getting flushed out.

Well-known EventCounters in .NET

9/20/2022 • 7 minutes to read • [Edit Online](#)

The .NET runtime and libraries implement and publish several [EventCounters](#) that can be used to identify and diagnose various performance issues. This article is a reference on the providers that can be used to monitor these counters and their descriptions.

System.Runtime counters

The following counters are published as part of .NET runtime (CoreCLR) and are maintained in the

[RuntimeEventSource.cs](#).

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
% Time in GC since last GC (<code>time-in-gc</code>)	The percent of time in GC since the last GC	.NET Core 3.1
Allocation Rate (<code>alloc-rate</code>)	The number of bytes allocated per update interval	.NET Core 3.1
CPU Usage (<code>cpu-usage</code>)	The percent of the process's CPU usage relative to all of the system CPU resources	.NET Core 3.1
Exception Count (<code>exception-count</code>)	The number of exceptions that have occurred	.NET Core 3.1
GC Heap Size (<code>gc-heap-size</code>)	The number of megabytes thought to be allocated based on GC.GetTotalMemory(Boolean)	.NET Core 3.1
Gen 0 GC Count (<code>gen-0-gc-count</code>)	The number of times GC has occurred for Gen 0 per update interval	.NET Core 3.1
Gen 0 Size (<code>gen-0-size</code>)	The number of bytes for Gen 0 GC	.NET Core 3.1
Gen 1 GC Count (<code>gen-1-gc-count</code>)	The number of times GC has occurred for Gen 1 per update interval	.NET Core 3.1
Gen 1 Size (<code>gen-1-size</code>)	The number of bytes for Gen 1 GC	.NET Core 3.1
Gen 2 GC Count (<code>gen-2-gc-count</code>)	The number of times GC has occurred for Gen 2 per update interval	.NET Core 3.1
Gen 2 Size (<code>gen-2-size</code>)	The number of bytes for Gen 2 GC	.NET Core 3.1
LOH Size (<code>loh-size</code>)	The number of bytes for the large object heap	.NET Core 3.1

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
POH Size (<code>poh-size</code>)	The number of bytes for the pinned object heap (available on .NET 5 and later versions)	.NET Core 3.1
GC Fragmentation (<code>gc-fragmentation</code>)	The GC Heap Fragmentation (available on .NET 5 and later versions)	.NET Core 3.1
Monitor Lock Contention Count (<code>monitor-lock-contention-count</code>)	The number of times there was contention when trying to take the monitor's lock, based on Monitor.LockContentionCount	.NET Core 3.1
Number of Active Timers (<code>active-timer-count</code>)	The number of Timer instances that are currently active, based on Timer.ActiveCount	.NET Core 3.1
Number of Assemblies Loaded (<code>assembly-count</code>)	The number of Assembly instances loaded into a process at a point in time	.NET Core 3.1
ThreadPool Completed Work Item Count (<code>threadpool-completed-items-count</code>)	The number of work items that have been processed so far in the ThreadPool	.NET Core 3.1
ThreadPool Queue Length (<code>threadpool-queue-length</code>)	The number of work items that are currently queued to be processed in the ThreadPool	.NET Core 3.1
ThreadPool Thread Count (<code>threadpool-thread-count</code>)	The number of thread pool threads that currently exist in the ThreadPool , based on ThreadPool.ThreadCount	.NET Core 3.1
Working Set (<code>working-set</code>)	The number of megabytes of physical memory mapped to the process context at a point in time base on Environment.WorkingSet	.NET Core 3.1
IL Bytes Jitted (<code>il-bytes-jitted</code>)	The total size of ILs that are JIT-compiled, in bytes	.NET 5
Method Jitted Count (<code>method-jitted-count</code>)	The number of methods that are JIT-compiled	.NET 5
GC Committed Bytes (<code>gc-committed</code>)	The number of bytes committed by the GC	.NET 6

Microsoft.AspNetCore.Hosting counters

The following counters are published as part of [ASP.NET Core](#) and are maintained in [HostingEventSource.cs](#).

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Current Requests (<code>current-requests</code>)	The total number of requests that have started, but not yet stopped	.NET Core 3.1

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Failed Requests (<code>failed-requests</code>)	The total number of failed requests that have occurred for the life of the app	.NET Core 3.1
Request Rate (<code>requests-per-second</code>)	The number of requests that occur per update interval	.NET Core 3.1
Total Requests (<code>total-requests</code>)	The total number of requests that have occurred for the life of the app	.NET Core 3.1

Microsoft.AspNetCore.Http.Connections counters

The following counters are published as part of [ASP.NET Core SignalR](#) and are maintained in [`HttpConnectionsEventSource.cs`](#).

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Average Connection Duration (<code>connections-duration</code>)	The average duration of a connection in milliseconds	.NET Core 3.1
Current Connections (<code>current-connections</code>)	The number of active connections that have started, but not yet stopped	.NET Core 3.1
Total Connections Started (<code>connections-started</code>)	The total number of connections that have started	.NET Core 3.1
Total Connections Stopped (<code>connections-stopped</code>)	The total number of connections that have stopped	.NET Core 3.1
Total Connections Timed Out (<code>connections-timed-out</code>)	The total number of connections that have timed out	.NET Core 3.1

Microsoft-AspNetCore-Server-Kestrel counters

The following counters are published as part of the [ASP.NET Core Kestrel web server](#) and are maintained in [`KestrelEventSource.cs`](#).

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Connection Queue Length (<code>connection-queue-length</code>)	The current length of the connection queue	.NET 5
Connection Rate (<code>connections-per-second</code>)	The number of connections per update interval to the web server	.NET 5
Current Connections (<code>current-connections</code>)	The current number of active connections to the web server	.NET 5
Current TLS Handshakes (<code>current-tls-handshakes</code>)	The current number of TLS handshakes	.NET 5

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Current Upgraded Requests (WebSockets) (<code>current-upgraded-requests</code>)	The current number of upgraded requests (WebSockets)	.NET 5
Failed TLS Handshakes (<code>failed-tls-handshakes</code>)	The total number of failed TLS handshakes	.NET 5
Request Queue Length (<code>request-queue-length</code>)	The current length of the request queue	.NET 5
TLS Handshake Rate (<code>tls-handshakes-per-second</code>)	The number of TLS handshakes per update interval	.NET 5
Total Connections (<code>total-connections</code>)	The total number of connections to the web server	.NET 5
Total TLS Handshakes (<code>total-tls-handshakes</code>)	The total number of TLS handshakes with the web server	.NET 5

System.Net.Http counters

The following counters are published by the HTTP stack.

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Requests Started (<code>requests-started</code>)	The number of requests started since the process started	.NET 5
Requests Started Rate (<code>requests-started-rate</code>)	The number of requests started per update interval	.NET 5
Requests Failed (<code>requests-failed</code>)	The number of failed requests since the process started	.NET 5
Requests Failed Rate (<code>requests-failed-rate</code>)	The number of failed requests per update interval	.NET 5
Current Requests (<code>current-requests</code>)	Current number of active HTTP requests that have started but not yet completed or failed	.NET 5
Current HTTP 1.1 Connections (<code>http11-connections-current-total</code>)	The current number of HTTP 1.1 connections that have started but not yet completed or failed	.NET 5
Current HTTP 2.0 Connections (<code>http20-connections-current-total</code>)	The current number of HTTP 2.0 connections that have started but not yet completed or failed	.NET 5
HTTP 1.1 Requests Queue Duration (<code>http11-requests-queue-duration</code>)	The average duration of the time HTTP 1.1 requests spent in the request queue	.NET 5

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
HTTP 2.0 Requests Queue Duration (<code>http20-requests-queue-duration</code>)	The average duration of the time HTTP 2.0 requests spent in the request queue	.NET 5

System.Net.NameResolution counters

The following counters track metrics related to DNS lookups.

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
DNS Lookups Requested (<code>dns-lookups-requested</code>)	The number of DNS lookups requested since the process started	.NET 5
Average DNS Lookup Duration (<code>dns-lookups-duration</code>)	The average time taken for a DNS lookup	.NET 5

System.Net.Security counters

The following counters track metrics related to the Transport Layer Security protocol.

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
TLS handshakes completed (<code>tls-handshake-rate</code>)	The number of TLS handshakes completed per update interval	.NET 5
Total TLS handshakes completed (<code>total-tls-handshakes</code>)	The total number of TLS handshakes completed since the process started	.NET 5
Current TLS handshakes (<code>current-tls-handshakes</code>)	The current number of TLS handshakes that have started but not yet completed	.NET 5
Total TLS handshakes failed (<code>failed-tls-handshakes</code>)	The total number of failed TLS handshakes since the process started	.NET 5
All TLS Sessions Active (<code>all-tls-sessions-open</code>)	The number of active TLS sessions of any version	.NET 5
TLS 1.0 Sessions Active (<code>tls10-sessions-open</code>)	The number of active TLS 1.0 sessions	.NET 5
TLS 1.1 Sessions Active (<code>tls11-sessions-open</code>)	The number of active TLS 1.1 sessions	.NET 5
TLS 1.2 Sessions Active (<code>tls12-sessions-open</code>)	The number of active TLS 1.2 sessions	.NET 5
TLS 1.3 Sessions Active (<code>tls13-sessions-open</code>)	The number of active TLS 1.3 sessions	.NET 5

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
TLS Handshake Duration (<code>all-tls-handshake-duration</code>)	The average duration of all TLS handshakes	.NET 5
TLS 1.0 Handshake Duration (<code>tls10-handshake-duration</code>)	The average duration of TLS 1.0 handshakes	.NET 5
TLS 1.1 Handshake Duration (<code>tls11-handshake-duration</code>)	The average duration of TLS 1.1 handshakes	.NET 5
TLS 1.2 Handshake Duration (<code>tls12-handshake-duration</code>)	The average duration of TLS 1.2 handshakes	.NET 5
TLS 1.3 Handshake Duration (<code>tls13-handshake-duration</code>)	The average duration of TLS 1.3 handshakes	.NET 5

System.Net.Sockets counters

The following counters track metrics related to [Socket](#).

COUNTER	DESCRIPTION	FIRST AVAILABLE IN
Outgoing Connections Established (<code>outgoing-connections-established</code>)	The total number of outgoing connections established since the process started	.NET 5
Incoming Connections Established (<code>incoming-connections-established</code>)	The total number of incoming connections established since the process started	.NET 5
Bytes Received (<code>bytes-received</code>)	The total number of bytes received since the process started	.NET 5
Bytes Sent (<code>bytes-sent</code>)	The total number of bytes sent since the process started	.NET 5
Datagrams Received (<code>datagrams-received</code>)	The total number of datagrams received since the process started	.NET 5
Datagrams Sent (<code>datagrams-sent</code>)	The total number of datagrams sent since the process started	.NET 5

Tutorial: Measure performance using EventCounters in .NET Core

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.0 SDK and later versions

In this tutorial, you'll learn how an [EventCounter](#) can be used to measure performance with a high frequency of events. You can use the [available counters](#) published by various official .NET Core packages, third-party providers, or create your own metrics for monitoring.

In this tutorial, you will:

- Implement an [EventSource](#).
- Monitor counters with [dotnet-counters](#).

Prerequisites

The tutorial uses:

- [.NET Core 3.1 SDK](#) or a later version.
- [dotnet-counters](#) to monitor event counters.
- A [sample debug target app](#) to diagnose.

Get the source

The sample application will be used as a basis for monitoring. The [sample ASP.NET Core repository](#) is available from the samples browser. You download the zip file, extract it once downloaded, and open it in your favorite IDE. Build and run the application to ensure that it works properly, then stop the application.

Implement an EventSource

For events that happen every few milliseconds, you'll want the overhead per event to be low (less than a millisecond). Otherwise, the impact on performance will be significant. Logging an event means you're going to write something to disk. If the disk is not fast enough, you will lose events. You need a solution other than logging the event itself.

When dealing with a large number of events, knowing the measure per event is not useful either. Most of the time all you need is just some statistics out of it. So you could get the statistics within the process itself and then write an event once in a while to report the statistics, that's what [EventCounter](#) will do.

Below is an example of how to implement an [System.Diagnostics.Tracing.EventSource](#). Create a new file named *MinimalEventCounterSource.cs* and use the code snippet as its source:

```

using System.Diagnostics.Tracing;

[EventSource(Name = "Sample.EventCounter.Minimal")]
public sealed class MinimalEventCounterSource : EventSource
{
    public static readonly MinimalEventCounterSource Log = new MinimalEventCounterSource();

    private EventCounter _requestCounter;

    private MinimalEventCounterSource() =>
        _requestCounter = new EventCounter("request-time", this)
    {
        DisplayName = "Request Processing Time",
        DisplayUnits = "ms"
    };

    public void Request(string url, long elapsedMilliseconds)
    {
        WriteEvent(1, url, elapsedMilliseconds);
        _requestCounter?.WriteMetric(elapsedMilliseconds);
    }

    protected override void Dispose(bool disposing)
    {
        _requestCounter?.Dispose();
        _requestCounter = null;

        base.Dispose(disposing);
    }
}

```

The `EventSource.WriteEvent` line is the `EventSource` part and is not part of `EventCounter`, it was written to show that you can log a message together with the event counter.

Add an action filter

The sample source code is an ASP.NET Core project. You can add an [action filter](#) globally that will log the total request time. Create a new file named `LogRequestTimeFilterAttribute.cs`, and use the following code:

```

using System.Diagnostics;
using Microsoft.AspNetCore.Http.Extensions;
using Microsoft.AspNetCore.Mvc.Filters;

namespace DiagnosticScenarios
{
    public class LogRequestTimeFilterAttribute : ActionFilterAttribute
    {
        readonly Stopwatch _stopwatch = new Stopwatch();

        public override void OnActionExecuting(ActionExecutingContext context) => _stopwatch.Start();

        public override void OnActionExecuted(ActionExecutedContext context)
        {
            _stopwatch.Stop();

            MinimalEventCounterSource.Log.Request(
                context.HttpContext.Request.GetDisplayUrl(), _stopwatch.ElapsedMilliseconds);
        }
    }
}

```

The action filter starts a `Stopwatch` as the request begins, and stops after it has completed, capturing the elapsed time. The total milliseconds is logged to the `MinimalEventCounterSource` singleton instance. In order for this filter

to be applied, you need to add it to the filters collection. In the `Startup.cs` file, update the `ConfigureServices` method to include this filter.

```
public void ConfigureServices(IServiceCollection services) =>
    services.AddControllers(options => options.Filters.Add<LogRequestTimeFilterAttribute>())
        .AddNewtonsoftJson();
```

Monitor event counter

With the implementation on an [EventSource](#) and the custom action filter, build and launch the application. You logged the metric to the [EventCounter](#), but unless you access the statistics from it, it is not useful. To get the statistics, you need to enable the [EventCounter](#) by creating a timer that fires as frequently as you want the events, as well as a listener to capture the events. To do that, you can use [dotnet-counters](#).

Use the `dotnet-counters ps` command to display a list of .NET processes that can be monitored.

```
dotnet-counters ps
```

Using the process identifier from the output of the `dotnet-counters ps` command, you can start monitoring the event counter with the following `dotnet-counters monitor` command:

```
dotnet-counters monitor --process-id 2196 --counters
Sample.EventCounter.Minimal,Microsoft.AspNetCore.Hosting[total-requests,requests-per-second],System.Runtime[cpu-usage]
```

While the `dotnet-counters monitor` command is running, hold F5 on the browser to start issuing continuous requests to the `https://localhost:5001/api/values` endpoint. After a few seconds stop by pressing q

```
Press p to pause, r to resume, q to quit.
Status: Running

[Microsoft.AspNetCore.Hosting]
  Request Rate / 1 sec          9
  Total Requests                134
[System.Runtime]
  CPU Usage (%)                 13
[Sample.EventCounter.Minimal]
  Request Processing Time (ms)  34.5
```

The `dotnet-counters monitor` command is great for active monitoring. However, you may want to collect these diagnostic metrics for post processing and analysis. For that, use the `dotnet-counters collect` command. The `collect` switch command is similar to the `monitor` command, but accepts a few additional parameters. You can specify the desired output file name and format. For a JSON file named `diagnostics.json` use the following command:

```
dotnet-counters collect --process-id 2196 --format json -o diagnostics.json --counters
Sample.EventCounter.Minimal,Microsoft.AspNetCore.Hosting[total-requests,requests-per-second],System.Runtime[cpu-usage]
```

Again, while the command is running, hold F5 on the browser to start issuing continuous requests to the `https://localhost:5001/api/values` endpoint. After a few seconds stop by pressing q. The `diagnostics.json` file is written. The JSON file that is written is not indented, however; for readability it is indented here.

Metric APIs comparison

9/20/2022 • 3 minutes to read • [Edit Online](#)

When adding new metric instrumentation to a .NET app or library, there are various different APIs to choose from. This article will help you understand what is available and some of the tradeoffs involved.

There are two major categories of APIs, vendor-neutral and vendor-specific. Vendor-specific APIs have the advantage that the vendor can iterate their designs quickly, add specialized features, and achieve tight integration between their instrumentation APIs and their backend systems. As an example, if you instrumented your app with metric APIs provided by [Application Insights](#), then you would expect to find well-integrated functionality and all of Application Insights' latest features when working with their analysis tools. However the library or app would also now be coupled to this vendor and changing to a different one in the future would require rewriting the instrumentation. For libraries, this coupling can be particularly problematic because the library developer might use one vendor's API and the app developer that references the library wants to work with a different vendor. To resolve this coupling issue, vendor-neutral options provide a standardized API façade and extensibility points to route data to various vendor backend systems depending on configuration. However, vendor-neutral APIs may provide fewer capabilities, and you're still constrained to pick a vendor that has integrated with the façade's extensibility mechanism.

.NET APIs

Over .NET's 20+ year history, we've iterated a few times on the design for metric APIs, all of which are supported and vendor-neutral:

PerformanceCounter

[System.Diagnostics.PerformanceCounter](#) APIs are the oldest metric APIs. They're only supported on Windows and provide a managed wrapper for Windows OS [Performance Counter](#) technology. They are available in all supported versions of .NET.

These APIs are provided primarily for compatibility; the .NET team considers this a stable area that's unlikely to receive further improvement aside from bug fixes. These APIs are not suggested for new development projects unless the project is Windows-only and you have a desire to use Windows Performance Counter tools.

For more information, see [Performance counters in .NET Framework](#).

EventCounters

The [EventCounters](#) API came next after [PerformanceCounters](#). This API aimed to provide a uniform cross-platform experience. The APIs are available by targeting .NET Core 3.1+, and a small subset is available on .NET Framework 4.7.1 and above. These APIs are fully supported and are actively used by key .NET libraries, but they have less functionality than the newer [System.Diagnostics.Metrics](#) APIs. EventCounters are able to report rates of change and averages, but do not support histograms and percentiles. There is also no support for multi-dimensional metrics. Custom tooling is possible via the [EventListener](#) API, though it is not strongly typed, only gives access to the aggregated values, and has limitations when using more than one listener simultaneously. EventCounters are supported directly by [Visual Studio](#), [Application Insights](#), [dotnet-counters](#), and [dotnet-monitor](#). For third-party tool support, check the vendor or project documentation to see if it's available.

At the time of writing, this is the cross-platform .NET runtime API that has the broadest and most stable ecosystem support. However, it will likely be overtaken soon by growing support for [System.Diagnostics.Metrics](#). The .NET team doesn't expect to make substantial new investments on this API going forward, but as with [PerformanceCounters](#), the API remains actively supported for all current and future users.

System.Diagnostics.Metrics

[System.Diagnostics.Metrics](#) APIs are the newest cross-platform APIs, and were designed in close collaboration with the [OpenTelemetry](#) project. The OpenTelemetry effort is an industry-wide collaboration across telemetry tooling vendors, programming languages, and application developers to create a broadly compatible standard for telemetry APIs. To eliminate any friction associated with adding third-party dependencies, .NET embeds the metrics API directly into the base class libraries. It's available by targeting .NET 6, or in older .NET Core and .NET Framework apps by adding a reference to the .NET [System.Diagnostics.DiagnosticsSource](#) 6.0 NuGet package. In addition to aiming at broad compatibility, this API adds support for many things that were lacking from EventCounters, such as:

- Histograms and percentiles
- Multi-dimensional metrics
- Strongly typed high-performance listener API
- Multiple simultaneous listeners
- Listener access to unaggregated measurements

Although this API was designed to work well with OpenTelemetry and its growing ecosystem of pluggable vendor integration libraries, applications also have the option to use the .NET built-in listener APIs directly. With this option, you can create custom metric tooling without taking any external library dependencies. At the time of writing, the System.Diagnostics.Metrics APIs are brand new and support is limited to [dotnet-counters](#) and [OpenTelemetry.NET](#). However, we expect support for these APIs will grow quickly given the active nature of the OpenTelemetry project.

Third-party APIs

Most application performance monitoring (APM) vendors such as [AppDynamics](#), [Application Insights](#), [DataDog](#), [DynaTrace](#), and [NewRelic](#) include metrics APIs as part of their instrumentation libraries. [Prometheus](#) and [AppMetrics](#) are also popular .NET OSS projects. To learn more about these projects, check the various project websites.

.NET distributed tracing

9/20/2022 • 2 minutes to read • [Edit Online](#)

Distributed tracing is a diagnostic technique that helps engineers localize failures and performance issues within applications, especially those that may be distributed across multiple machines or processes. This technique tracks requests through an application correlating together work done by different application components and separating it from other work the application may be doing for concurrent requests. For example, a request to a typical web service might be first received by a load balancer, then forwarded to a web server process, which then makes several queries to a database. Using distributed tracing allows engineers to distinguish if any of those steps failed, how long each step took, and potentially logging messages produced by each step as it ran.

Getting started for .NET app developers

Key .NET libraries are instrumented to produce distributed tracing information automatically. However, this information needs to be collected and stored so that it will be available for review later. Typically, app developers select a telemetry service that stores this trace information for them and then use a corresponding library to transmit the distributed tracing telemetry to their chosen service:

- [OpenTelemetry](#) is a vendor-neutral library that supports several services. For more information, see [Collect distributed traces with OpenTelemetry](#).
- [Application Insights](#) is a full-featured service provided by Microsoft. For more information, see [Collect distributed traces with Application Insights](#).
- There are many high-quality third-party application performance monitoring (APM) vendors that offer integrated .NET solutions.

For more information, see [Understand distributed tracing concepts](#) and the following guides:

- [Collect distributed traces with custom logic](#)
- [Adding custom distributed trace instrumentation](#)

For third-party telemetry collection services, follow the setup instructions provided by the vendor.

Getting started for .NET library developers

.NET libraries don't need to be concerned with how telemetry is ultimately collected, only with how it is produced. If you want consumers of your library to be able to see the work that it does detailed in a distributed trace, add distributed tracing instrumentation to support it.

For more information, see [Understand distributed tracing concepts](#) and the [Adding custom distributed trace instrumentation](#) guide.

.NET distributed tracing concepts

9/20/2022 • 5 minutes to read • [Edit Online](#)

Distributed tracing is a diagnostic technique that helps engineers localize failures and performance issues within applications, especially those that may be distributed across multiple machines or processes. See the [Distributed Tracing Overview](#) for general information about where distributed tracing is useful and example code to get started.

Traces and Activities

Each time a new request is received by an application, it can be associated with a trace. In application components written in .NET, units of work in a trace are represented by instances of [System.Diagnostics.Activity](#) and the trace as a whole forms a tree of these Activities, potentially spanning across many distinct processes. The first Activity created for a new request forms the root of the trace tree and it tracks the overall duration and success/failure handling the request. Child activities can be optionally created to subdivide the work into different steps that can be tracked individually. For example given an Activity that tracked a specific inbound HTTP request in a web server, child activities could be created to track each of the database queries that were necessary to complete the request. This allows the duration and success for each query to be recorded independently. Activities can record other information for each unit of work such as [OperationName](#), name-value pairs called [Tags](#), and [Events](#). The name identifies the type of work being performed, tags can record descriptive parameters of the work, and events are a simple logging mechanism to record timestamped diagnostic messages.

NOTE

Another common industry name for units of work in a distributed trace are 'Spans'. .NET adopted the term 'Activity' many years ago, before the name 'Span' was well established for this concept.

Activity IDs

Parent-Child relationships between Activities in the distributed trace tree are established using unique IDs. .NET's implementation of distributed tracing supports two ID schemes: the W3C standard [TraceContext](#), which is the default in .NET 5+, and an older .NET convention called 'Hierarchical' that's available for backwards compatibility. [Activity.DefaultIdFormat](#) controls which ID scheme is used. In the W3C TraceContext standard, every trace is assigned a globally unique 16-byte trace-id ([Activity.TraceId](#)), and every Activity within the trace is assigned a unique 8-byte span-id ([Activity.SpanId](#)). Each Activity records the trace-id, its own span-id, and the span-id of its parent ([Activity.ParentSpanId](#)). Because distributed traces can track work across process boundaries, parent and child Activities may not be in the same process. The combination of a trace-id and parent span-id can uniquely identify the parent Activity globally, regardless of what process it resides in.

[Activity.DefaultIdFormat](#) controls which ID format is used for starting new traces, but by default adding a new Activity to an existing trace uses whatever format the parent Activity is using. Setting [Activity.ForceDefaultIdFormat](#) to true overrides this behavior and creates all new Activities with the DefaultIdFormat, even when the parent uses a different ID format.

Start and stop Activities

Each thread in a process may have a corresponding Activity object that is tracking the work occurring on that thread, accessible via [Activity.Current](#). The current activity automatically flows along all synchronous calls on a

thread as well as following async calls that are processed on different threads. If Activity A is the current activity on a thread and code starts a new Activity B, then B becomes the new current activity on that thread. By default, activity B will also treat Activity A as its parent. When Activity B is later stopped, activity A will be restored as the current Activity on the thread. When an Activity is started, it captures the current time as the [Activity.StartTimeUtc](#). When it stops, [Activity.Duration](#) is calculated as the difference between the current time and the start time.

Coordinate across process boundaries

To track work across process boundaries, Activity parent IDs need to be transmitted across the network so that the receiving process can create Activities that refer to them. When using W3C TraceContext ID format, .NET also uses the HTTP headers recommended by [the standard](#) to transmit this information. When using the [Hierarchical](#) ID format, .NET uses a custom request-id HTTP header to transmit the ID. Unlike many other language runtimes, .NET in-box libraries such as the ASP.NET web server and System.Net.Http natively understand how to decode and encode Activity IDs on HTTP messages. The runtime also understands how to flow the ID through synchronous and asynchronous calls. This means that .NET applications that receive and emit HTTP messages participate in flowing distributed trace IDs automatically, with no special coding by the app developer or third-party library dependencies. Third-party libraries may add support for transmitting IDs over non-HTTP message protocols or supporting custom encoding conventions for HTTP.

Collect traces

Instrumented code can create [Activity](#) objects as part of a distributed trace, but the information in these objects needs to be transmitted and serialized in a centralized persistent store so that the entire trace can be usefully reviewed later. There are several telemetry collection libraries that can do this task such as [Application Insights](#), [OpenTelemetry](#), or a library provided by a third-party telemetry or APM vendor. Alternately developers can author their own custom Activity telemetry collection by using [System.Diagnostics.ActivityListener](#) or [System.Diagnostics.DiagnosticListener](#). ActivityListener supports observing any Activity regardless of whether the developer has any prior knowledge about it. This makes ActivityListener a simple and flexible general purpose solution. By contrast using DiagnosticListener is a more complex scenario that requires the instrumented code to opt in by invoking [DiagnosticSource.StartActivity](#) and the collection library needs to know the exact naming information that the instrumented code used when starting it. Using DiagnosticSource and DiagnosticListener allows the creator and listener to exchange arbitrary .NET objects and establish customized information passing conventions.

Sampling

For improved performance in high throughput applications, distributed tracing on .NET supports sampling only a subset of traces rather than recording all of them. For activities created with the recommended [ActivitySource.StartActivity](#) API, telemetry collection libraries can control sampling with the [ActivityListener.Sample](#) callback. The logging library can elect not to create the Activity at all, to create it with minimal information necessary to propagate distributing tracing IDs, or to populate it with complete diagnostic information. These choices trade-off increasing performance overhead for increasing diagnostic utility. Activities that are started using the older pattern of invoking [Activity.Activity](#) and [DiagnosticSource.StartActivity](#) may also support DiagnosticListener sampling by first calling [DiagnosticSource.IsEnabled](#). Even when capturing full diagnostic information the .NET implementation is designed to be fast - coupled with an efficient collector an Activity can be created, populated, and transmitted in about a microsecond on modern hardware. Sampling can reduce the instrumentation cost to less than 100 nanoseconds for each Activity that isn't recorded.

Next steps

For example code to get started using distributed tracing in .NET applications, see the [Distributed Tracing Instrumentation](#).

Adding distributed tracing instrumentation

9/20/2022 • 9 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 and later versions ✓ .NET Framework 4.5 and later versions

.NET applications can be instrumented using the [System.Diagnostics.Activity](#) API to produce distributed tracing telemetry. Some instrumentation is built into standard .NET libraries, but you may want to add more to make your code more easily diagnosable. In this tutorial, you will add new custom distributed tracing instrumentation. See [the collection tutorial](#) to learn more about recording the telemetry produced by this instrumentation.

Prerequisites

- [.NET Core 2.1 SDK](#) or a later version

Create initial app

First you will create a sample app that collects telemetry using OpenTelemetry, but doesn't yet have any instrumentation.

```
dotnet new console
```

Applications that target .NET 5 and later already have the necessary distributed tracing APIs included. For apps targeting older .NET versions, add the [System.Diagnostics.DiagnosticSource NuGet package](#) version 5 or greater.

```
dotnet add package System.Diagnostics.DiagnosticSource
```

Add the [OpenTelemetry](#) and [OpenTelemetry.Exporter.Console](#) NuGet packages, which will be used to collect the telemetry.

```
dotnet add package OpenTelemetry
dotnet add package OpenTelemetry.Exporter.Console
```

Replace the contents of the generated Program.cs with this example source:

```

using OpenTelemetry;
using OpenTelemetry.Resources;
using OpenTelemetry.Trace;
using System;
using System.Threading.Tasks;

namespace Sample.DistributedTracing
{
    class Program
    {
        static async Task Main(string[] args)
        {
            using var tracerProvider = Sdk.CreateTracerProviderBuilder()
                .SetResourceBuilder(ResourceBuilder.CreateDefault().AddService("MySample"))
                .AddSource("Sample.DistributedTracing")
                .AddConsoleExporter()
                .Build();

            await DoSomeWork("banana", 8);
            Console.WriteLine("Example work done");
        }

        // All the functions below simulate doing some arbitrary work
        static async Task DoSomeWork(string foo, int bar)
        {
            await StepOne();
            await StepTwo();
        }

        static async Task StepOne()
        {
            await Task.Delay(500);
        }

        static async Task StepTwo()
        {
            await Task.Delay(1000);
        }
    }
}

```

The app has no instrumentation yet so there is no trace information to display:

```

> dotnet run
Example work done

```

Best practices

Only app developers need to reference an optional third-party library for collecting the distributed trace telemetry, such as OpenTelemetry in this example. .NET library authors can exclusively rely on APIs in `System.Diagnostics.DiagnosticSource`, which is part of .NET runtime. This ensures that libraries will run in a wide range of .NET apps, regardless of the app developer's preferences about which library or vendor to use for collecting telemetry.

Add basic instrumentation

Applications and libraries add distributed tracing instrumentation using the `System.Diagnostics.ActivitySource` and `System.Diagnostics.Activity` classes.

ActivitySource

First create an instance of `ActivitySource`. `ActivitySource` provides APIs to create and start `Activity` objects. Add

the static ActivitySource variable above Main() and `using System.Diagnostics;` to the using statements.

```
using OpenTelemetry;
using OpenTelemetry.Resources;
using OpenTelemetry.Trace;
using System;
using System.Diagnostics;
using System.Threading.Tasks;

namespace Sample.DistributedTracing
{
    class Program
    {
        private static ActivitySource source = new ActivitySource("Sample.DistributedTracing", "1.0.0");

        static async Task Main(string[] args)
        {
            ...
        }
    }
}
```

Best practices

- Create the ActivitySource once, store it in a static variable and use that instance as long as needed. Each library or library subcomponent can (and often should) create its own source. Consider creating a new source rather than reusing an existing one if you anticipate app developers would appreciate being able to enable and disable the Activity telemetry in the sources independently.
- The source name passed to the constructor has to be unique to avoid the conflicts with any other sources. If there are multiple sources within the same assembly, use a hierarchical name that contains the assembly name and optionally a component name, for example, `Microsoft.AspNetCore.Hosting`. If an assembly is adding instrumentation for code in a second, independent assembly, the name should be based on the assembly that defines the ActivitySource, not the assembly whose code is being instrumented.
- The version parameter is optional. We recommend that you provide the version in case you release multiple versions of the library and make changes to the instrumented telemetry.

NOTE

OpenTelemetry uses alternate terms 'Tracer' and 'Span'. In .NET 'ActivitySource' is the implementation of Tracer and Activity is the implementation of 'Span'. .NET's Activity type long pre-dates the OpenTelemetry specification and the original .NET naming has been preserved for consistency within the .NET ecosystem and .NET application compatibility.

Activity

Use the ActivitySource object to Start and Stop Activity objects around meaningful units of work. Update DoSomeWork() with the code shown here:

```
static async Task DoSomeWork(string foo, int bar)
{
    using (Activity activity = source.StartActivity("SomeWork"))
    {
        await StepOne();
        await StepTwo();
    }
}
```

Running the app now shows the new Activity being logged:

```
> dotnet run
Activity.Id:          00-f443e487a4998c41a6fd6fe88bae644e-5b7253de08ed474f-01
Activity.DisplayName: SomeWork
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:36:51.4720202Z
Activity.Duration:    00:00:01.5025842
Resource associated with Activity:
  service.name: MySample
  service.instance.id: 067f4bb5-a5a8-4898-a288-dec569d6dbef
```

Notes

- [ActivitySource.StartActivity](#) creates and starts the activity at the same time. The listed code pattern is using the `using` block, which automatically disposes the created `Activity` object after executing the block. Disposing the `Activity` object will stop it so the code doesn't need to explicitly call [Activity.Stop\(\)](#). That simplifies the coding pattern.
- [ActivitySource.StartActivity](#) internally determines if there are any listeners recording the `Activity`. If there are no registered listeners or there are listeners that are not interested, `StartActivity()` will return `null` and avoid creating the `Activity` object. This is a performance optimization so that the code pattern can still be used in functions that are called frequently.

Optional: Populate tags

Activities support key-value data called Tags, commonly used to store any parameters of the work that may be useful for diagnostics. Update `DoSomeWork()` to include them:

```
static async Task DoSomeWork(string foo, int bar)
{
    using (Activity activity = source.StartActivity("SomeWork"))
    {
        activity?.SetTag("foo", foo);
        activity?.SetTag("bar", bar);
        await StepOne();
        await StepTwo();
    }
}
```

```
> dotnet run
Activity.Id:          00-2b56072db8cb5a4496a4fb69f46aa06-7bc4acda3b9cce4d-01
Activity.DisplayName: SomeWork
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:37:31.4949570Z
Activity.Duration:    00:00:01.5417719
Activity.TagObjects:
  foo: banana
  bar: 8
Resource associated with Activity:
  service.name: MySample
  service.instance.id: 25bbc1c3-2de5-48d9-9333-062377fea49c

Example work done
```

Best practices

- As mentioned above, `activity` returned by [ActivitySource.StartActivity](#) may be null. The null-coalescing operator `?.` in C# is a convenient short-hand to only invoke [Activity.SetTag](#) if `activity` is not null. The behavior is identical to writing:

```

if(activity != null)
{
    activity.SetTag("foo", foo);
}

```

- OpenTelemetry provides a set of recommended [conventions](#) for setting Tags on Activities that represent common types of application work.
- If you are instrumenting functions with high-performance requirements, [Activity.IsAllDataRequested](#) is a hint that indicates whether any of the code listening to Activities intends to read auxiliary information such as Tags. If no listener will read it, then there is no need for the instrumented code to spend CPU cycles populating it. For simplicity, this sample doesn't apply that optimization.

Optional: Add events

Events are timestamped messages that can attach an arbitrary stream of additional diagnostic data to Activities. Add some events to the Activity:

```

static async Task DoSomeWork(string foo, int bar)
{
    using (Activity activity = source.StartActivity("SomeWork"))
    {
        activity?.SetTag("foo", foo);
        activity?.SetTag("bar", bar);
        await StepOne();
        activity?.AddEvent(new ActivityEvent("Part way there"));
        await StepTwo();
        activity?.AddEvent(new ActivityEvent("Done now"));
    }
}

```

```

> dotnet run
Activity.Id:          00-82cf6ea92661b84d9fd881731741d04e-33fff2835a03c041-01
Activity.DisplayName: SomeWork
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:39:10.6902609Z
Activity.Duration:    00:00:01.5147582
Activity.TagObjects:
    foo: banana
    bar: 8
Activity.Events:
    Part way there [3/18/2021 10:39:11 AM +00:00]
    Done now [3/18/2021 10:39:12 AM +00:00]
Resource associated with Activity:
    service.name: MySample
    service.instance.id: ea7f0fc...-e4af5a86ce4f

Example work done

```

Best practices

- Events are stored in an in-memory list until they can be transmitted which makes this mechanism only suitable for recording a modest number of events. For a large or unbounded volume of events, it's better to use a logging API focused on this task, such as [ILogger](#). ILogger also ensures that the logging information will be available regardless whether the app developer opts to use distributed tracing. ILogger supports automatically capturing the active Activity IDs so messages logged via that API can still be correlated with the distributed trace.

Optional: Add status

OpenTelemetry allows each Activity to report a [Status](#) that represents the pass/fail result of the work. .NET does not currently have a strongly typed API for this purpose but there is an established convention using Tags:

- `otel.status_code` is the Tag name used to store `StatusCode`. Values for the StatusCode tag must be one of the strings "UNSET", "OK", or "ERROR", which correspond respectively to the enums `Unset`, `Ok`, and `Error` from `StatusCode`.
- `otel.status_description` is the Tag name used to store the optional `Description`

Update `DoSomeWork()` to set status:

```
static async Task DoSomeWork(string foo, int bar)
{
    using (Activity activity = source.StartActivity("SomeWork"))
    {
        activity?.SetTag("foo", foo);
        activity?.SetTag("bar", bar);
        await StepOne();
        activity?.AddEvent(new ActivityEvent("Part way there"));
        await StepTwo();
        activity?.AddEvent(new ActivityEvent("Done now"));

        // Pretend something went wrong
        activity?.SetTag("otel.status_code", "ERROR");
        activity?.SetTag("otel.status_description", "Use this text give more information about the
error");
    }
}
```

Optional: Add additional Activities

Activities can be nested to describe portions of a larger unit of work. This can be valuable around portions of code that might not execute quickly or to better localize failures that come from specific external dependencies. Although this sample uses an Activity in every method, that is solely because extra code has been minimized. In a larger and more realistic project, using an Activity in every method would produce extremely verbose traces, so it's not recommended.

Update `StepOne` and `StepTwo` to add more tracing around these separate steps:

```
static async Task StepOne()
{
    using (Activity activity = source.StartActivity("StepOne"))
    {
        await Task.Delay(500);
    }
}

static async Task StepTwo()
{
    using (Activity activity = source.StartActivity("StepTwo"))
    {
        await Task.Delay(1000);
    }
}
```

```

> dotnet run
Activity.Id:          00-9d5aa439e0df7e49b4abff8d2d5329a9-39cac574e8fda44b-01
Activity.ParentId:    00-9d5aa439e0df7e49b4abff8d2d5329a9-f16529d0b7c49e44-01
Activity.DisplayName: StepOne
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:40:51.4278822Z
Activity.Duration:    00:00:00.5051364
Resource associated with Activity:
  service.name: MySample
  service.instance.id: e0a8c12c-249d-4bdd-8180-8931b9b6e8d0

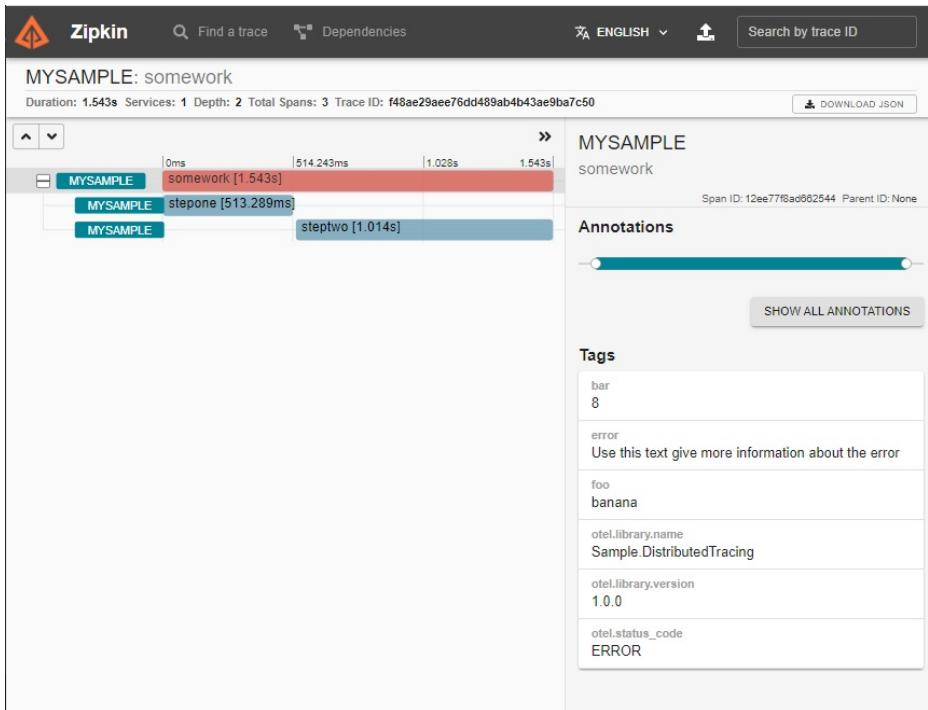

Activity.Id:          00-9d5aa439e0df7e49b4abff8d2d5329a9-4cccb6efdc59546-01
Activity.ParentId:    00-9d5aa439e0df7e49b4abff8d2d5329a9-f16529d0b7c49e44-01
Activity.DisplayName: StepTwo
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:40:51.9441095Z
Activity.Duration:    00:00:01.0052729
Resource associated with Activity:
  service.name: MySample
  service.instance.id: e0a8c12c-249d-4bdd-8180-8931b9b6e8d0

Activity.Id:          00-9d5aa439e0df7e49b4abff8d2d5329a9-f16529d0b7c49e44-01
Activity.DisplayName: SomeWork
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:40:51.4256627Z
Activity.Duration:    00:00:01.5286408
Activity.TagObjects:
  foo: banana
  bar: 8
  otel.status_code: ERROR
  otel.status_description: Use this text give more information about the error
Activity.Events:
  Part way there [3/18/2021 10:40:51 AM +00:00]
  Done now [3/18/2021 10:40:52 AM +00:00]
Resource associated with Activity:
  service.name: MySample
  service.instance.id: e0a8c12c-249d-4bdd-8180-8931b9b6e8d0

Example work done

```

Notice that both StepOne and StepTwo include a ParentId that refers to SomeWork. The console is not a great visualization of nested trees of work, but many GUI viewers such as [Zipkin](#) can show this as a Gantt chart:

Optional: ActivityKind

Activities have an [Activity.Kind](#) property, which describes the relationship between the Activity, its parent, and its children. By default, all new Activities are set to [Internal](#), which is appropriate for Activities that are an internal operation within an application with no remote parent or children. Other kinds can be set using the kind parameter on [ActivitySource.StartActivity](#). For other options, see [System.Diagnostics.ActivityKind](#).

Optional: Links

When work occurs in batch processing systems, a single Activity might represent work on behalf of many different requests simultaneously, each of which has its own trace-id. Although Activity is restricted to have a single parent, it can link to additional trace-ids using [System.Diagnostics.ActivityLink](#). Each ActivityLink is populated with an [ActivityContext](#) that stores ID information about the Activity being linked to. ActivityContext can be retrieved from in-process Activity objects using [Activity.Context](#) or it can be parsed from serialized ID information using [ActivityContext.Parse\(String, String\)](#).

```
void DoBatchWork(ActivityContext[] requestContexts)
{
    // Assume each context in requestContexts encodes the trace-id that was sent with a request
    using(Activity activity = s_source.StartActivity(name: "BigBatchOfWork",
        kind: ActivityKind.Internal,
        parentContext: null,
        links: requestContexts.Select(ctx => new
            ActivityLink(ctx)))
    {
        // do the batch of work here
    }
}
```

Unlike events and Tags that can be added on-demand, links must be added during `StartActivity()` and are immutable afterwards.

Collect a distributed trace

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 and later versions ✓ .NET Framework 4.5 and later versions

Instrumented code can create [Activity](#) objects as part of a distributed trace, but the information in these objects needs to be collected into centralized storage so that the entire trace can be reviewed later. In this tutorial, you will collect the distributed trace telemetry in different ways so that it's available to diagnose application issues when needed. See [the instrumentation tutorial](#) if you need to add new instrumentation.

Collect traces using OpenTelemetry

Prerequisites

- [.NET Core 2.1 SDK](#) or a later version

Create an example application

Before any distributed trace telemetry can be collected, we need to produce it. Often this instrumentation might be in libraries, but for simplicity, you'll create a small app that has some example instrumentation using [StartActivity](#). At this point, no collection has happened, and StartActivity() has no side-effect and returns null. See [the instrumentation tutorial](#) for more details.

```
dotnet new console
```

Applications that target .NET 5 and later already have the necessary distributed tracing APIs included. For apps targeting older .NET versions, add the [System.Diagnostics.DiagnosticSource NuGet package](#) version 5 or greater.

```
dotnet add package System.Diagnostics.DiagnosticSource
```

Replace the contents of the generated Program.cs with this example source:

```

using System;
using System.Diagnostics;
using System.Threading.Tasks;

namespace Sample.DistributedTracing
{
    class Program
    {
        static ActivitySource s_source = new ActivitySource("Sample.DistributedTracing");

        static async Task Main(string[] args)
        {
            await DoSomeWork();
            Console.WriteLine("Example work done");
        }

        static async Task DoSomeWork()
        {
            using (Activity a = s_source.StartActivity("SomeWork"))
            {
                await StepOne();
                await StepTwo();
            }
        }

        static async Task StepOne()
        {
            using (Activity a = s_source.StartActivity("StepOne"))
            {
                await Task.Delay(500);
            }
        }

        static async Task StepTwo()
        {
            using (Activity a = s_source.StartActivity("StepTwo"))
            {
                await Task.Delay(1000);
            }
        }
    }
}

```

Running the app does not collect any trace data yet:

```

> dotnet run
Example work done

```

Collect using OpenTelemetry

[OpenTelemetry](#) is a vendor-neutral open-source project supported by the [Cloud Native Computing Foundation](#) that aims to standardize generating and collecting telemetry for cloud-native software. In this example, you will collect and display distributed trace information on the console though OpenTelemetry can be reconfigured to send it elsewhere. For more information, see the [OpenTelemetry getting started guide](#).

Add the [OpenTelemetry.Exporter.Console](#) NuGet package.

```
dotnet add package OpenTelemetry.Exporter.Console
```

Update Program.cs with additional OpenTelemetry `using` directives:

```
using OpenTelemetry;
using OpenTelemetry.Resources;
using OpenTelemetry.Trace;
using System;
using System.Diagnostics;
using System.Threading.Tasks;
```

Update `Main()` to create the OpenTelemetry TracerProvider:

```
public static async Task Main()
{
    using var tracerProvider = Sdk.CreateTracerProviderBuilder()
        .SetResourceBuilder(ResourceBuilder.CreateDefault().AddService("MySample"))
        .AddSource("Sample.DistributedTracing")
        .AddConsoleExporter()
        .Build();

    await DoSomeWork();
    Console.WriteLine("Example work done");
}
```

Now the app collects distributed trace information and displays it to the console:

```
> dotnet run
Activity.Id:          00-7759221f2c5599489d455b84fa0f90f4-6081a9b8041cd840-01
Activity.ParentId:    00-7759221f2c5599489d455b84fa0f90f4-9a52f72c08a9d447-01
Activity.DisplayName: StepOne
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:46:46.8649754Z
Activity.Duration:    00:00:00.5069226
Resource associated with Activity:
  service.name: MySample
  service.instance.id: 909a4624-3b2e-40e4-a86b-4a2c8003219e

Activity.Id:          00-7759221f2c5599489d455b84fa0f90f4-d2b283db91cf774c-01
Activity.ParentId:    00-7759221f2c5599489d455b84fa0f90f4-9a52f72c08a9d447-01
Activity.DisplayName: StepTwo
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:46:47.3838737Z
Activity.Duration:    00:00:01.0142278
Resource associated with Activity:
  service.name: MySample
  service.instance.id: 909a4624-3b2e-40e4-a86b-4a2c8003219e

Activity.Id:          00-7759221f2c5599489d455b84fa0f90f4-9a52f72c08a9d447-01
Activity.DisplayName: SomeWork
Activity.Kind:        Internal
Activity.StartTime:   2021-03-18T10:46:46.8634510Z
Activity.Duration:    00:00:01.5402045
Resource associated with Activity:
  service.name: MySample
  service.instance.id: 909a4624-3b2e-40e4-a86b-4a2c8003219e

Example work done
```

Sources

In the example code, you invoked `AddSource("Sample.DistributedTracing")` so that OpenTelemetry would capture the Activities produced by the `ActivitySource` that was already present in the code:

```
static ActivitySource s_source = new ActivitySource("Sample.DistributedTracing");
```

Telemetry from any ActivitySource can be captured by calling `AddSource()` with the source's name.

Exporters

The console exporter is helpful for quick examples or local development but in a production deployment you will probably want to send traces to a centralized store. OpenTelemetry supports various destinations using different [exporters](#). For more information about configuring OpenTelemetry, see the [OpenTelemetry getting started guide](#).

Collect traces using Application Insights

Distributed tracing telemetry is automatically captured after configuring the Application Insights SDK for [ASP.NET](#) or [ASP.NET Core](#) apps, or by enabling [code-less instrumentation](#).

For more information, see the [Application Insights distributed tracing documentation](#).

NOTE

Currently, Application Insights only supports collecting specific well-known Activity instrumentation and ignores new user-added Activities. Application Insights offers [TrackDependency](#) as a vendor-specific API for adding custom distributed tracing information.

Collect traces using custom logic

Developers are free to create their own customized collection logic for Activity trace data. This example collects the telemetry using the [System.Diagnostics.ActivityListener](#) API provided by .NET and prints it to the console.

Prerequisites

- [.NET Core 2.1 SDK](#) or a later version

Create an example application

First you will create an example application that has some distributed trace instrumentation but no trace data is being collected.

```
dotnet new console
```

Applications that target .NET 5 and later already have the necessary distributed tracing APIs included. For apps targeting older .NET versions, add the [System.Diagnostics.DiagnosticSource NuGet package](#) version 5 or greater.

```
dotnet add package System.Diagnostics.DiagnosticSource
```

Replace the contents of the generated Program.cs with this example source:

```

using System;
using System.Diagnostics;
using System.Threading.Tasks;

namespace Sample.DistributedTracing
{
    class Program
    {
        static ActivitySource s_source = new ActivitySource("Sample.DistributedTracing");

        static async Task Main(string[] args)
        {
            await DoSomeWork();
            Console.WriteLine("Example work done");
        }

        static async Task DoSomeWork()
        {
            using (Activity a = s_source.StartActivity("SomeWork"))
            {
                await StepOne();
                await StepTwo();
            }
        }

        static async Task StepOne()
        {
            using (Activity a = s_source.StartActivity("StepOne"))
            {
                await Task.Delay(500);
            }
        }

        static async Task StepTwo()
        {
            using (Activity a = s_source.StartActivity("StepTwo"))
            {
                await Task.Delay(1000);
            }
        }
    }
}

```

Running the app does not collect any trace data yet:

```

> dotnet run
Example work done

```

Add code to collect the traces

Update Main() with this code:

```

static async Task Main(string[] args)
{
    Activity.DefaultIdFormat = ActivityIdFormat.W3C;
    Activity.ForceDefaultIdFormat = true;

    Console.WriteLine("      {0,-15} {1,-60} {2,-15}", "OperationName", "Id", "Duration");
    ActivitySource.AddActivityListener(new ActivityListener()
    {
        ShouldListenTo = (source) => true,
        Sample = (ref ActivityCreationOptions<ActivityContext> options) =>
ActivitySamplingResult.AllDataAndRecorded,
        ActivityStarted = activity => Console.WriteLine("Started: {0,-15} {1,-60}",
activity.OperationName, activity.Id),
        ActivityStopped = activity => Console.WriteLine("Stopped: {0,-15} {1,-60} {2,-15}",
activity.OperationName, activity.Id, activity.Duration)
    });

    await DoSomeWork();
    Console.WriteLine("Example work done");
}

```

The output now includes logging:

```

> dotnet run
      OperationName   Id                               Duration
Started: SomeWork  00-bdb5fafffc2fc1548b6ba49a31c4a0ae0-c447fb302059784f-01

Stopped: StepOne  00-bdb5fafffc2fc1548b6ba49a31c4a0ae0-a7c77a4e9a02dc4a-01  00:00:00.5093849
Started: StepTwo   00-bdb5fafffc2fc1548b6ba49a31c4a0ae0-9210ad536cae9e4e-01
Stopped: StepTwo  00-bdb5fafffc2fc1548b6ba49a31c4a0ae0-9210ad536cae9e4e-01  00:00:01.0111847
Stopped: SomeWork  00-bdb5fafffc2fc1548b6ba49a31c4a0ae0-c447fb302059784f-01  00:00:01.5236391
Example work done

```

Setting [DefaultIdFormat](#) and [ForceDefaultIdFormat](#) is optional but helps ensure the sample produces similar output on different .NET runtime versions. .NET 5 uses the W3C TraceContext ID format by default but earlier .NET versions default to using [Hierarchical](#) ID format. For more information, see [Activity IDs](#).

[System.Diagnostics.ActivityListener](#) is used to receive callbacks during the lifetime of an Activity.

- [ShouldListenTo](#) - Each Activity is associated with an [ActivitySource](#), which acts as its namespace and producer. This callback is invoked once for each [ActivitySource](#) in the process. Return true if you are interested in performing sampling or being notified about start/stop events for Activities produced by this source.
- [Sample](#) - By default [StartActivity](#) does not create an Activity object unless some [ActivityListener](#) indicates it should be sampled. Returning [AllDataAndRecorded](#) indicates that the Activity should be created, [IsAllDataRequested](#) should be set to true, and [ActivityTraceFlags](#) will have the [Recorded](#) flag set. [IsAllDataRequested](#) can be observed by the instrumented code as a hint that a listener wants to ensure that auxiliary Activity information such as Tags and Events are populated. The Recorded flag is encoded in the W3C TraceContext ID and is a hint to other processes involved in the distributed trace that this trace should be sampled.
- [ActivityStarted](#) and [ActivityStopped](#) are called when an Activity is started and stopped respectively. These callbacks provide an opportunity to record relevant information about the Activity or potentially to modify it. When an Activity has just started, much of the data may still be incomplete and it will be populated before the Activity stops.

Once an [ActivityListener](#) has been created and the callbacks are populated, calling [ActivitySource.AddActivityListener\(ActivityListener\)](#) initiates invoking the callbacks. Call [ActivityListener.Dispose\(\)](#) to stop the flow of callbacks. Be aware that in multi-threaded code, callback notifications in progress could be received while [Dispose\(\)](#) is running or even shortly after it has returned.

Symbols

9/20/2022 • 3 minutes to read • [Edit Online](#)

Symbols are useful for debugging and other diagnostic tools. The contents of symbol files vary between languages, compilers, and platforms. At a very high level symbols are a mapping between the source code and the binary produced by the compiler. These mappings are used by tools like [Visual Studio](#) and [Visual Studio Code](#) to resolve source line number information or local variable names.

The [Windows documentation on symbols](#) contain more detailed information on symbols for Windows, although many of the concepts apply to other platforms as well.

Learn about .NET's Portable PDB format

.NET Core introduces a new symbol file (PDB) format - the portable PDB. Unlike traditional PDBs which are Windows-only, portable PDBs can be created and read on all platforms.

What is a PDB?

A PDB file is an auxiliary file produced by a compiler to provide other tools, especially debuggers, information about what is in the main executable file and how it was produced. For example, a debugger reads a PDB to map foo.cs line 12 to the right executable location so that it can set a breakpoint. The Windows PDB format has been around a long time, and it evolved from other native debugging symbol formats which were even older. It started out its life as a format for native (C/C++) programs. For the first release of the .NET Framework, the Windows PDB format was extended to support .NET.

The Portable PDB format was introduced in .NET Core, and it's used by default when targeting .NET Core and .NET 5+. When targeting .NET Framework, you can enable Portable PDB symbols by specifying

`<DebugType>portable</DebugType>` in your project file. The Portable PDB format is based on ECMA-335 metadata format. For more information, see [Portable PDB v1.0: Format Specification](#). Diagnostic tools can use the [System.Reflection.Metadata](#) library to read Portable PDB files (for an example, see [System.Reflection.Metadata.Document](#)).

Use the correct PDB format for your scenario

Neither portable PDBs nor Windows PDBs are supported everywhere, so you need to consider where your project will want to be used and debugged to decide which format to use. If you have a project that you want to be able to use and debug in both formats, you can use different build configurations and build the project twice to support both types of consumer.

Support for Portable PDBs

Portable PDBs can be read on any operating systems and is the recommended symbol format for managed code, but there are a number of legacy tools and applications where they aren't supported:

- Applications targeting .NET Framework 4.7.1 or earlier: printing stack traces with mappings back to line numbers (such as in an ASP.NET error page). The name of methods is unaffected, only the source file names and line numbers are unsupported.
- Using .NET decompilers such as ildasm or .NET reflector and expecting to see source line mappings or local parameter names.
- The latest versions of [DIA](#) and tools using it for reading symbols, such as WinDBG support Portable PDBs, but older versions do not.

- There may be older versions of profilers that do not support portable PDBs.

To use portable PDBs on tools that do not support them, you can try using [Pdb2Pdb](#) which converts between Portable PDBs and Windows PDBs.

Support for Windows PDBs

Windows PDBs can only be written or read on Windows. Using Windows PDBs for managed code is obsolete and is only needed for legacy tools. It is recommended that you use portable PDBs instead of Windows PDBs as some newer compiler features that are implemented for only portable PDBs.

Diagnostics client library

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.0 SDK and later versions for target apps, .NET Standard 2.0 to use the library.

`Microsoft.Diagnostics.NETCore.Client` (also known as the Diagnostics client library) is a managed library that lets you interact with .NET Core runtime (CoreCLR) for various diagnostics related tasks, such as tracing via [EventPipe](#), requesting a dump, or attaching an `ICorProfiler`. This library is the backing library behind many diagnostics tools such as [dotnet-counters](#), [dotnet-trace](#), [dotnet-gcdump](#), [dotnet-dump](#), and [dotnet-monitor](#). Using this library, you can write your own diagnostics tools customized for your particular scenario.

You can acquire [Microsoft.Diagnostics.NETCore.Client](#) by adding a `PackageReference` to your project. The package is hosted on [NuGet.org](#).

The samples in the following sections show how to use `Microsoft.Diagnostics.NETCore.Client` library. Some of these examples also show parsing the event payloads by using [TraceEvent](#) library.

Attach to a process and print out all GC events

This snippet shows how to start an EventPipe session using the [.NET runtime provider](#) with the GC keyword at informational level. It also shows how to use the `EventPipeEventSource` class provided by the [TraceEvent library](#) to parse the incoming events and print their names to the console in real time.

```

using Microsoft.Diagnostics.NETCore.Client;
using Microsoft.Diagnostics.Tracing;
using Microsoft.Diagnostics.Tracing.EventPipe;
using Microsoft.Diagnostics.Tracing.Parsers;
using System;
using System.Collections.Generic;
using System.Diagnostics.Tracing;

public class RuntimeGCEventsPrinter
{
    public static void PrintRuntimeGCEvents(int processId)
    {
        var providers = new List<EventPipeProvider>()
        {
            new EventPipeProvider("Microsoft-Windows-DotNETRuntime",
                EventLevel.Informational, (long)ClrTraceEventParser.Keywords.GC)
        };

        var client = new DiagnosticsClient(processId);
        using (EventPipeSession session = client.StartEventPipeSession(providers, false))
        {
            var source = new EventPipeEventSource(session.EventStream);

            source.Clr.All += (TraceEvent obj) => Console.WriteLine(obj.ToString());

            try
            {
                source.Process();
            }
            catch (Exception e)
            {
                Console.WriteLine("Error encountered while processing events");
                Console.WriteLine(e.ToString());
            }
        }
    }
}

```

Write a core dump

This sample shows how to trigger the collection of a [core dump](#) using `DiagnosticsClient`.

```

using Microsoft.Diagnostics.NETCore.Client;

public partial class Dumper
{
    public static void TriggerCoreDump(int processId)
    {
        var client = new DiagnosticsClient(processId);
        client.WriteDump(DumpType.Normal, "/tmp/minidump.dmp");
    }
}

```

Trigger a core dump when CPU usage goes above a threshold

This sample shows how to monitor the `cpu-usage` counter published by the .NET runtime and request a dump when the CPU usage grows beyond a certain threshold.

```

using Microsoft.Diagnostics.NETCore.Client;
using Microsoft.Diagnostics.Tracing;
using Microsoft.Diagnostics.Tracing.EventPipe;
using Microsoft.Diagnostics.Tracing.Parsers;
using System;
using System.Collections.Generic;
using System.Diagnostics.Tracing;

public partial class Dumper
{
    public static void TriggerDumpOnCpuUsage(int processId, int threshold)
    {
        var providers = new List<EventPipeProvider>()
        {
            new EventPipeProvider(
                "System.Runtime",
                EventLevel.Informational,
                (long)ClrTraceEventParser.Keywords.None,
                new Dictionary<string, string>
                {
                    ["EventCounterIntervalSec"] = "1"
                }
            )
        };
        var client = new DiagnosticsClient(processId);
        using (var session = client.StartEventPipeSession(providers))
        {
            var source = new EventPipeEventSource(session.EventStream);
            source.Dynamic.All += (TraceEvent obj) =>
            {
                if (obj.EventName.Equals("EventCounters"))
                {
                    var payloadVal = (IDictionary<string, object>)(obj.PayloadValue(0));
                    var payloadFields = (IDictionary<string, object>)(payloadVal["Payload"]);
                    if (payloadFields["Name"].ToString().Equals("cpu-usage"))
                    {
                        double cpuUsage = Double.Parse(payloadFields["Mean"].ToString());
                        if (cpuUsage > (double)threshold)
                        {
                            client.WriteDump(DumpType.Normal, "/tmp/minidump.dmp");
                        }
                    }
                }
            };
            try
            {
                source.Process();
            }
            catch (Exception) {}
        }
    }
}

```

Trigger a CPU trace for given number of seconds

This sample shows how to trigger an EventPipe session for certain period of time with the default CLR trace keyword as well as the sample profiler. Afterward, it reads the output stream and writes the bytes out to a file. Essentially this is what `dotnet-trace` uses internally to write a trace file.

```

using Microsoft.Diagnostics.Tracing;
using Microsoft.Diagnostics.Tracing.Parsers;
using Microsoft.Diagnostics.NETCore.Client;
using System;
using System.Collections.Generic;
using System.Diagnostics;
using System.Diagnostics.Tracing;
using System.IO;
using System.Threading.Tasks;

public partial class Tracer
{
    public void TraceProcessForDuration(int processId, int duration, string traceName)
    {
        var cpuProviders = new List<EventPipeProvider>()
        {
            new EventPipeProvider("Microsoft-Windows-DotNETRuntime", EventLevel.Informational,
(Clong)ClrTraceEventParser.Keywords.Default),
            new EventPipeProvider("Microsoft-DotNETCore-SampleProfiler", EventLevel.Informational,
(Clong)ClrTraceEventParser.Keywords.None)
        };
        var client = new DiagnosticsClient(processId);
        using (var traceSession = client.StartEventPipeSession(cpuProviders))
        {
            Task copyTask = Task.Run(async () =>
            {
                using (FileStream fs = new FileStream(traceName, FileMode.Create, FileAccess.Write))
                {
                    await traceSession.EventStream.CopyToAsync(fs);
                }
            });
            Task.WhenAny(copyTask, Task.Delay(TimeSpan.FromMilliseconds(duration * 1000)));
            traceSession.Stop();
        }
    }
}

```

Print names of processes that published a diagnostics channel

This sample shows how to use `DiagnosticsClient.GetPublishedProcesses` API to print the names of the .NET processes that published a diagnostics IPC channel.

```

using Microsoft.Diagnostics.NETCore.Client;
using System;
using System.Diagnostics;
using System.Linq;

public class ProcessTracker
{
    public static void PrintProcessStatus()
    {
        var processes = DiagnosticsClient.GetPublishedProcesses()
            .Select(Process.GetProcessById)
            .Where(process => process != null);

        foreach (var process in processes)
        {
            Console.WriteLine($"{process.ProcessName}");
        }
    }
}

```

Parse events in real time

This sample shows an example where we create two tasks, one that parses the events coming in live with `EventPipeEventSource` and one that reads the console input for a user input signaling the program to end. If the target app exits before the user presses enter, the app exits gracefully. Otherwise, `inputTask` will send the Stop command to the pipe and exit gracefully.

```
using Microsoft.Diagnostics.NETCore.Client;
using Microsoft.Diagnostics.Tracing;
using Microsoft.Diagnostics.Tracing.EventPipe;
using Microsoft.Diagnostics.Tracing.Parsers;
using System;
using System.Collections.Generic;
using System.Diagnostics.Tracing;
using System.Threading.Tasks;

public partial class Tracer
{
    public static void PrintEventsLive(int processId)
    {
        var providers = new List<EventPipeProvider>()
        {
            new EventPipeProvider("Microsoft-Windows-DotNETRuntime",
                EventLevel.Informational, (long)ClrTraceEventParser.Keywords.Default)
        };
        var client = new DiagnosticsClient(processId);
        using (var session = client.StartEventPipeSession(providers, false))
        {

            Task streamTask = Task.Run(() =>
            {
                var source = new EventPipeEventSource(session.EventStream);
                source.Clr.All += (TraceEvent obj) => Console.WriteLine(obj.EventName);
                try
                {
                    source.Process();
                }
                // NOTE: This exception does not currently exist. It is something that needs to be added to
                TraceEvent.
                catch (Exception e)
                {
                    Console.WriteLine("Error encountered while processing events");
                    Console.WriteLine(e.ToString());
                }
            });
            Task inputTask = Task.Run(() =>
            {
                Console.WriteLine("Press Enter to exit");
                while (Console.ReadKey().Key != ConsoleKey.Enter)
                {
                    Task.Delay(TimeSpan.FromMilliseconds(100));
                }
                session.Stop();
            });

            Task.WaitAny(streamTask, inputTask);
        }
    }
}
```

Attach an ICorProfiler profiler

This sample shows how to attach an ICorProfiler to a process via profiler attach.

```
using System;
using Microsoft.Diagnostics.NETCore.Client;

public class Profiler
{
    public static void AttachProfiler(int processId, Guid profilerGuid, string profilerPath)
    {
        var client = new DiagnosticsClient(processId);
        client.AttachProfiler(TimeSpan.FromSeconds(10), profilerGuid, profilerPath);
    }
}
```

Microsoft.Diagnostics.NETCore.Client API

9/20/2022 • 6 minutes to read • [Edit Online](#)

This section describes the APIs of the diagnostics client library.

DiagnosticsClient class

```
public DiagnosticsClient
{
    public DiagnosticsClient(int processId);

    public EventPipeSession StartEventPipeSession(
        IEnumerable<EventPipeProvider> providers,
        bool requestRundown = true,
        int circularBufferMB = 256);

    public void WriteDump(
        DumpType dumpType,
        string dumpPath,
        bool logDumpGeneration = false);

    public async Task WriteDumpAsync(
        DumpType dumpType,
        string dumpPath,
        bool logDumpGeneration,
        CancellationToken token);

    public void AttachProfiler(
        TimeSpan attachTimeout,
        Guid profilerGuid,
        string profilerPath,
        byte[] additionalData = null);

    public void SetStartupProfiler(
        Guid profilerGuid,
        string profilerPath);

    public void ResumeRuntime();

    public void SetEnvironmentVariable(
        string name,
        string value);

    public Dictionary<string, string> GetProcessEnvironment();

    public static IEnumerable<int> GetPublishedProcesses();
}
```

Constructor

```
public DiagnosticsClient(int processId);
```

Creates a new instance of `DiagnosticsClient` for a compatible .NET process running with process ID of `processId`.

`processID` : Process ID of the target application.

StartEventPipeSession methods

```
public EventPipeSession StartEventPipeSession(
    IEnumerable<EventPipeProvider> providers,
    bool requestRundown = true,
    int circularBufferMB = 256);
```

Starts an EventPipe tracing session using the given providers and settings.

- `providers` : An `IEnumerable` of `EventPipeProvider`s to start tracing.
- `requestRundown` : A `bool` specifying whether rundown provider events from the target app's runtime should be requested.
- `circularBufferMB` : An `int` specifying the total size of circular buffer used by the target app's runtime on collecting events.

```
public EventPipeSession StartEventPipeSession(EventPipeProvider providers, bool requestRundown=true, int
circularBufferMB=256)
```

- `providers` : An `EventPipeProvider` to start tracing.
- `requestRundown` : A `bool` specifying whether rundown provider events from the target app's runtime should be requested.
- `circularBufferMB` : An `int` specifying the total size of circular buffer used by the target app's runtime on collecting events.

NOTE

Rundown events contain payloads that may be needed for post analysis, such as resolving method names of thread samples. Unless you know you do not want this, we recommend setting this to true. In large applications, this may take a while.

- `circularBufferMB` : The size of the circular buffer to be used as a buffer for writing events within the runtime.

WriteDump method

```
public void WriteDump(
    DumpType dumpType,
    string dumpPath,
    bool logDumpGeneration=false);
```

Request a dump for post-mortem debugging of the target application. The type of the dump can be specified using the `DumpType` enum.

- `dumpType` : Type of the dump to be requested.
- `dumpPath` : The path to the dump to be written out to.
- `logDumpGeneration` : If set to `true`, the target application will write out diagnostic logs during dump generation.

```
public void WriteDump(DumpType dumpType, string dumpPath, WriteDumpFlags flags)
```

Request a dump for post-mortem debugging of the target application. The type of the dump can be specified using the `DumpType` enum.

- `dumpType` : Type of the dump to be requested.
- `dumpPath` : The path to the dump to be written out to.

- `flags` : logging and crash report flags. On runtimes less than 6.0, only LoggingEnabled is supported.

```
public async Task WriteDumpAsync(DumpType dumpType, string dumpPath, bool logDumpGeneration,
CancellationToken token)
```

Request a dump for post-mortem debugging of the target application. The type of the dump can be specified using the `DumpType` enum.

- `dumpType` : Type of the dump to be requested.
- `dumpPath` : The path to the dump to be written out to.
- `logDumpGeneration` : If set to `true`, the target application will write out diagnostic logs during dump generation.
- `token` : The token to monitor for cancellation requests.

```
public async Task WriteDumpAsync(DumpType dumpType, string dumpPath, WriteDumpFlags flags, CancellationToken
token)
```

Request a dump for post-mortem debugging of the target application. The type of the dump can be specified using the `DumpType` enum.

- `dumpType` : Type of the dump to be requested.
- `dumpPath` : The path to the dump to be written out to.
- `flags` : logging and crash report flags. On runtimes less than 6.0, only LoggingEnabled is supported.
- `token` : The token to monitor for cancellation requests.

AttachProfiler method

```
public void AttachProfiler(
    TimeSpan attachTimeout,
    Guid profilerGuid,
    string profilerPath,
    byte[] additionalData=null);
```

Request to attach an ICorProfiler to the target application.

- `attachTimeout` : A `TimeSpan` after which attach will be aborted.
- `profilerGuid` : `Guid` of the ICorProfiler to be attached.
- `profilerPath` : Path to the ICorProfiler dll to be attached.
- `additionalData` : Optional additional data that can be passed to the runtime during profiler attach.

SetStartupProfiler method

```
public void SetStartupProfiler(
    Guid profilerGuid,
    string profilerPath);
```

Set a profiler as the startup profiler. It is only valid to issue this command while the runtime is paused at startup.

- `profilerGuid` : `Guid` for the profiler to be attached.
- `profilerPath` : Path to the profiler to be attached.

ResumeRuntime method

```
public void ResumeRuntime();
```

Tell the runtime to resume execution after being paused at startup.

SetEnvironmentVariable method

```
public void SetEnvironmentVariable(  
    string name,  
    string value);
```

Set an environment variable in the target process.

- `name` : The name of the environment variable to set.
- `value` : The value of the environment variable to set.

GetProcessEnvironment

```
public Dictionary<string, string> GetProcessEnvironment()
```

Gets all environment variables and their values from the target process.

GetPublishedProcesses method

```
public static IEnumerable<int> GetPublishedProcesses();
```

Get an `IEnumerable` of process IDs of all the active .NET processes that can be attached to.

EventPipeProvider class

```
public class EventPipeProvider  
{  
    public EventPipeProvider(  
        string name,  
        EventLevel eventLevel,  
        long keywords = 0,  
        IDictionary<string, string> arguments = null)  
  
    public string Name { get; }  
  
    public EventLevel EventLevel { get; }  
  
    public long Keywords { get; }  
  
    public IDictionary<string, string> Arguments { get; }  
  
    public override string ToString();  
  
    public override bool Equals(object obj);  
  
    public override int GetHashCode();  
  
    public static bool operator ==(Provider left, Provider right);  
  
    public static bool operator !=(Provider left, Provider right);  
}
```

Constructor

```
public EventPipeProvider(
    string name,
    EventLevel eventLevel,
    long keywords = 0,
    IDictionary<string, string> arguments = null)
```

Creates a new instance of `EventPipeProvider` with the given provider name, `EventLevel`, keywords, and arguments.

Name property

```
public string Name { get; }
```

Gets the name of the Provider.

EventLevel property

```
public EventLevel EventLevel { get; }
```

Gets the `EventLevel` of the given instance of `EventPipeProvider`.

Keywords property

```
public long Keywords { get; }
```

Gets a value that represents bitmask for keywords of the `EventSource`.

Arguments property

```
public IDictionary<string, string> Arguments { get; }
```

Gets an `IDictionary` of key-value pair strings representing optional arguments to be passed to `EventSource` representing the given `EventPipeProvider`.

Remarks

This class is immutable, because EventPipe does not allow a provider's configuration to be modified during an EventPipe session as of .NET Core 3.1.

EventPipeSession class

```
public class EventPipeSession : IDisposable
{
    public Stream EventStream { get; }
    public void Stop();
}
```

This class represents an ongoing EventPipe session. It is immutable and acts as a handle to an EventPipe session of the given runtime.

EventStream property

```
public Stream EventStream { get; }
```

Gets a `Stream` that can be used to read the event stream.

Stop method

```
public void Stop();
```

Stops the given `EventPipe` session.

DumpType enum

```
public enum DumpType
{
    Normal = 1,
    WithHeap = 2,
    Triage = 3,
    Full = 4
}
```

Represents the type of dump that can be requested.

- `Normal` : Include just the information necessary to capture stack traces for all existing traces for all existing threads in a process. Limited GC heap memory and information.
- `WithHeap` : Includes the GC heaps and information necessary to capture stack traces for all existing threads in a process.
- `Triage` : Include just the information necessary to capture stack traces for all existing traces for all existing threads in a process. Limited GC heap memory and information.
- `Full` : Include all accessible memory in the process. The raw memory data is included at the end, so that the initial structures can be mapped directly without the raw memory information. This option can result in a very large dump file.

Exceptions

Exceptions that are thrown from the library are of type `DiagnosticsClientException` or a derived type.

```
public class DiagnosticsClientException : Exception
```

UnsupportedCommandException

```
public class UnsupportedCommandException : DiagnosticsClientException
```

This may be thrown when the command is not supported by either the library or the target process's runtime.

UnsupportedProtocolException

```
public class UnsupportedProtocolException : DiagnosticsClientException
```

This may be thrown when the target process's runtime is not compatible with the diagnostics IPC protocol used by the library.

ServerNotAvailableException

```
public class ServerNotAvailableException : DiagnosticsClientException
```

This may be thrown when the runtime is not available for diagnostics IPC commands, such as early during runtime startup before the runtime is ready for diagnostics commands, or when the runtime is shutting down.

ServerErrorException

```
public class ServerErrorException : DiagnosticsClientException
```

This may be thrown when the runtime responds with an error to a given command.

.NET runtime events

9/20/2022 • 2 minutes to read • [Edit Online](#)

The .NET runtime (CoreCLR) emits various events that can be used to diagnose issues with your .NET application that can be consumed via various mechanisms such as [ETW](#), [LTTng](#), and [EventPipe](#).

This document serves as a reference on the events that are fired by .NET Core runtime.

For runtime events in .NET Framework, see [CLR ETW Events](#).

In this section

[Contention Events](#)

These events collect information about monitor lock contentions.

[Garbage Collection Events](#)

These events collect information pertaining to garbage collection. They help in diagnostics and debugging, including determining how many times garbage collection was performed, how much memory was freed during garbage collection, etc.

[Exception Events](#)

These runtime events capture information about exceptions that are thrown.

[Interop Events](#)

These runtime events capture information about Common Intermediate Language (CIL) stub generation.

[Loader and Binder Events](#)

These events collect information relating to loading and unloading assemblies and modules.

[Method Events](#)

These events collect information that is specific to methods. The payload of these events is required for symbol resolution. In addition, these events provide helpful information such as the number of times a method was called.

[Thread Events](#)

These events collect information about worker and I/O threads.

[Type Events](#)

These events collect information about the type system.

.NET runtime contention events

9/20/2022 • 2 minutes to read • [Edit Online](#)

These runtime events capture information about monitor lock contentions such as with `Monitor.Enter` or the C# lock keyword. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

ContentionStart_V2 event

This event is emitted at the start of a monitor lock contention.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ContentionKeyword</code> (0x4000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ContentionStart_V2</code>	81	A monitor lock contention starts.

FIELD NAME	DATA TYPE	DESCRIPTION
<code>Flags</code>	<code>win:UInt8</code>	<code>0</code> for managed; <code>1</code> for native.
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CoreCLR.
<code>LockObjectID</code>	<code>win:Pointer</code>	Address of the lock object.
<code>LockOwnerThreadID</code>	<code>win:Pointer</code>	Address of the thread that owns the lock.

ContentionStop_V1 event

This event is emitted at the end of a monitor lock contention.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ContentionKeyword</code> (0x4000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ContentionStop_V1</code>	91	A monitor lock contention ends.

FIELD NAME	DATA TYPE	DESCRIPTION
Flags	win:UInt8	0 for managed; 1 for native.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.
DurationNs	win:Double	Duration of the contention in nanoseconds.

.NET runtime exception events

9/20/2022 • 2 minutes to read • [Edit Online](#)

These runtime events capture information about exceptions that are thrown. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

ExceptionThrown_V1 event

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ExceptionKeyword</code> (0x8000)	Error (1)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ExceptionThrown_V1</code>	80	A managed exception is thrown.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>ExceptionType</code>	<code>win:UnicodeString</code>	Type of the exception; for example, <code>System.NullReferenceException</code> .
<code>ExceptionMessage</code>	<code>win:UnicodeString</code>	Actual exception message.
<code>EIPCodeThrow</code>	<code>win:Pointer</code>	Instruction pointer where exception occurred.
<code>ExceptionHR</code>	<code>win:UInt32</code>	Exception HRESULT .
<code>ExceptionFlags</code>	<code>win:UInt16</code>	 <code>0x01</code> : HasInnerException. <code>0x02</code> : IsNestedException. <code>0x04</code> : IsRethrownException. <code>0x08</code> : IsCorruptedStateException (indicates that the process state is corrupt; see Handling Corrupted State Exceptions). <code>0x10</code> : IsCLSCompliant (an exception that derives from <code>Exception</code> is CLS-compliant; otherwise, it is not CLS-compliant).
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CLR or CoreCLR.

ExceptionCatchStart event

This event is emitted when a managed exception catch handler begins.

KEYWORD FOR RAISING THE EVENT	LEVEL
ExceptionKeyword (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
ExceptionCatchStart	250	A managed exception is handled by the runtime.

FIELD NAME	DATA TYPE	DESCRIPTION
EIPCodeThrow	win:Pointer	Instruction pointer where exception occurred.
MethodID	win:Pointer	Pointer to the method descriptor on the method where exception occurred.
MethodName	win:UnicodeString	Name of the method where exception occurred.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ExceptionCatchStop event

This event is emitted when a managed exception catch handler ends.

KEYWORD FOR RAISING THE EVENT	LEVEL
ExceptionKeyword (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
ExceptionCatchStop	251	A managed exception catch handler is done.

ExceptionFinallyStart event

This event is emitted when a managed exception finally handler begins.

KEYWORD FOR RAISING THE EVENT	LEVEL
ExceptionKeyword (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ExceptionFinallyStart</code>	252	A managed exception is handled by the runtime.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>EIPCodeThrow</code>	<code>win:Pointer</code>	Instruction pointer where exception occurred.
<code>MethodID</code>	<code>win:Pointer</code>	Pointer to the method descriptor on the method where exception occurred.
<code>MethodName</code>	<code>win:UnicodeString</code>	Name of the method where exception occurred.
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CLR or CoreCLR.

ExceptionFinallyStop event

This event is emitted when a managed exception catch handler ends.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ExceptionKeyword</code> (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ExceptionFinallyStop</code>	253	A managed exception finally handler is done.

ExceptionFilterStart event

This event is emitted when a managed exception filtering begins.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ExceptionKeyword</code> (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
<code>ExceptionFilterStart</code>	254	A managed exception filtering begins.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>EIPCodeThrow</code>	<code>win:Pointer</code>	Instruction pointer where exception occurred.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:Pointer	Pointer to the method descriptor on the method where exception occurred.
MethodName	win:UnicodeString	Name of the method where exception occurred.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

ExceptionFilterStop event

This event is emitted when a managed exception filtering ends.

KEYWORD FOR RAISING THE EVENT	LEVEL
ExceptionKeyword (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
ExceptionFilteringStart	255	A managed exception filtering ends.

ExceptionThrownStop event

This event is emitted when the runtime is done handling a managed exception that was thrown.

KEYWORD FOR RAISING THE EVENT	LEVEL
ExceptionKeyword (0x8000)	Informational (4)

The following table shows event information.

EVENT	EVENT ID	RAISED WHEN
ExceptionThrownStop	256	A managed exception filtering ends.

.NET runtime garbage collection events

9/20/2022 • 11 minutes to read • [Edit Online](#)

These events collect information pertaining to garbage collection. They help in diagnostics and debugging, including determining how many times garbage collection was performed, how much memory was freed during garbage collection, etc. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

GCStart_V2 Event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>GCKeyword</code> (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
<code>GCStart_V1</code>	1	A garbage collection has started.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
<code>Count</code>	<code>win:UInt32</code>	The <i>n</i> th garbage collection.
<code>Depth</code>	<code>win:UInt32</code>	The generation that is being collected.
<code>Reason</code>	<code>win:UInt32</code>	Why the garbage collection was triggered: 0x0 - Small object heap allocation. 0x1 - Induced. 0x2 - Low memory. 0x3 - Empty. 0x4 - Large object heap allocation. 0x5 - Out of space (for small object heap). 0x6 - Out of space (for large object heap). 0x7 - Induced but not forced as blocking.

FIELD NAME	DATA TYPE	DESCRIPTION
Type	win:UInt32	<p>0x0 - Blocking garbage collection occurred outside background garbage collection.</p> <p>0x1 - Background garbage collection.</p> <p>0x2 - Blocking garbage collection occurred during background garbage collection.</p>
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

GCEnd_V1 Event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCEnd_V1	2	The garbage collection has ended.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt32	The <i>n</i> th garbage collection.
Depth	win:UInt32	The generation that was collected.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

GCHeapStats_V2 Event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	DESCRIPTION
GCHeapStats_V2	4	Shows the heap statistics at the end of each garbage collection.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
GenerationSize0	win:UInt64	The size, in bytes, of generation 0 memory.
TotalPromotedSize0	win:UInt64	The number of bytes that are promoted from generation 0 to generation 1.
GenerationSize1	win:UInt64	The size, in bytes, of generation 1 memory.
TotalPromotedSize1	win:UInt64	The number of bytes that are promoted from generation 1 to generation 2.
GenerationSize2	win:UInt64	The size, in bytes, of generation 2 memory.
TotalPromotedSize2	win:UInt64	The number of bytes that survived in generation 2 after the last collection.
GenerationSize3	win:UInt64	The size, in bytes, of the large object heap.
TotalPromotedSize3	win:UInt64	The number of bytes that survived in the large object heap after the last collection.
FinalizationPromotedSize	win:UInt64	The total size, in bytes, of the objects that are ready for finalization.
FinalizationPromotedCount	win:UInt64	The number of objects that are ready for finalization.
PinnedObjectCount	win:UInt32	The number of pinned (unmovable) objects.
SinkBlockCount	win:UInt32	The number of synchronization blocks in use.
GCHandleCount	win:UInt32	The number of garbage collection handles in use.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.
GenerationSize4	win:UInt64	The size, in bytes, of the pinned object heap.
TotalPromotedSize4	win:UInt64	The number of bytes that survived in the pinned object heap after the last collection.

GCCreateSegment_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCCreateSegment_V1	5	A new garbage collection segment has been created. In addition, when tracing is enabled on a process that is already running, this event is raised for each existing segment.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
Address	win:UInt64	The address of the segment.
Size	win:UInt64	The size of the segment.
Type	win:UInt32	0x0 - Small object heap. 0x1 - Large object heap. 0x2 - Read-only heap.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

Note that the size of segments allocated by the garbage collector is implementation-specific and is subject to change at any time, including in periodic updates. Your app should never make assumptions about or depend on a particular segment size, nor should it attempt to configure the amount of memory available for segment allocations.

GCFreeSegment_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCFreeSegment_V1	6	A garbage collection segment has been released.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
Address	win:UInt64	The address of the segment.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

GCRestartEEBegin_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCRestartEEBegin_V1	7	Resumption from common language runtime suspension has begun.

This event does not have any event data.

GCRestartEEEEnd_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCRestartEEEEnd_V1	3	Resumption from common language runtime suspension has ended.

This event does not have any event data.

GCSuspendEEEEnd_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN

EVENT	EVENT ID	RAISED WHEN
GCSuspendEEEnd_V1	8	End of suspension of the execution engine for garbage collection.

This event does not have any event data.

GCSuspendEEBegin_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCSuspendEEBegin_V1	8	Start of suspension of the execution engine for garbage collection.
FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt32	The <i>n</i> th garbage collection.
Reason	win:UInt32	Reason for EE suspension. 0x0 : Suspend for Other 0x1 : Suspend for GC. 0x2 : Suspend for AppDomain shutdown. 0x3 : Suspend for code pitching. 0x4 : Suspend for shutdown. 0x5 : Suspend for debugger. 0x6 : Suspend for GC Prep. 0x7 : Suspend for debugger sweep

GCAccumulationTick_V3 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Verbose (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCAllocationTick_V3	10	Each time approximately 100 KB is allocated.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
AllocationAmount	win:UInt32	The allocation size, in bytes. This value is accurate for allocations that are less than the length of a ULONG (4,294,967,295 bytes). If the allocation is greater, this field contains a truncated value. Use AllocationAmount64 for very large allocations.
AllocationKind	win:UInt32	<p>0x0 - Small object allocation (allocation is in small object heap).</p> <p>0x1 - Large object allocation (allocation is in large object heap).</p>
AllocationAmount64	win:UInt64	The allocation size, in bytes. This value is accurate for very large allocations.
TypeId	win:Pointer	The address of the MethodTable. When there are several types of objects that were allocated during this event, this is the address of the MethodTable that corresponds to the last object allocated (the object that caused the 100 KB threshold to be exceeded).
TypeName	win:UnicodeString	The name of the type that was allocated. When there are several types of objects that were allocated during this event, this is the type of the last object allocated (the object that caused the 100 KB threshold to be exceeded).
HeapIndex	win:UInt32	The heap where the object was allocated. This value is 0 (zero) when running with workstation garbage collection.
Address	win:Pointer	The address of the last allocated object.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

GCCreateConcurrentThread_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>GCKeyword</code> (0x1)	Informational (4)
<code>ThreadingKeyword</code> (0x10000)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
<code>GCCreateConcurrentThread_V1</code>	11	Concurrent garbage collection thread was created.

This event does not have any event data.

GCTerminateConcurrentThread_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>GCKeyword</code> (0x1)	Informational (4)
<code>ThreadingKeyword</code> (0x10000)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
<code>GCTerminateConcurrentThread_V1</code>	12	Concurrent garbage collection thread was terminated.

This event does not have any event data.

GCFinalizersBegin_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>GCKeyword</code> (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
<code>GCFinalizersBegin_V1</code>	14	The start of running finalizers.

This event does not have any event data.

GCFinalizersEnd_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCFinalizersEnd_V1	13	The end of running finalizers.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt32	The number of finalizers that were run.
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

SetGCHandle event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCHandleKeyword (0x2)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
SetGCHandle	30	A GC Handle has been set.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
HandleID	win:Pointer	The address of the allocated handle.
ObjectID	win:Pointer	The address of the object whose handle was created.

FIELD NAME	DATA TYPE	DESCRIPTION
Kind	win:UInt32	The type of GC handle that was set. 0x0 : WeakShort 0x1 : WeakLong 0x2 : Strong 0x3 : Pinned 0x4 : Variable 0x5 : RefCounted 0x6 : Dependent 0x7 : AsyncPinned 0x8 : SizedRef
Generation	win:UInt32	The generation of the object whose handle was created.
AppDomainID	win:UInt64	The AppDomain ID.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

DestroyGCHandle event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCHandleKeyword (0x2)	Informational (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
DestroyGCHandle	31	A GC Handle is destroyed.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
HandleID	win:Pointer	The address of the destroyed handle.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

PinObjectAtGCTime event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Verbose (5)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
PinObjectAtGCTime	33	An object was pinned during a GC.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
HandleID	win:Pointer	The address of the handle.
ObjectID	win:Pointer	The address of the pinned object.
ObjectSize	win:UInt64	The size of the pinned object.
TypeName	win:UnicodeString	The name of the type of the pinned object.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

GCTriggered event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Verbose (5)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCTriggered	33	A GC has been triggered.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION

FIELD NAME	DATA TYPE	DESCRIPTION
Reason	win:UInt32	<p>The reason a GC was triggered.</p> <p>0x0 : AllocSmall</p> <p>0x1 : Induced</p> <p>0x2 : LowMemory</p> <p>0x3 : Empty</p> <p>0x4 : AllocLarge</p> <p>0x5 : OutOfSpaceSmallObjectHeap</p> <p>0x6 : OutOfSpaceLargeObjectHeap</p> <p>0x7 : InducedNoForce</p> <p>0x8 : Stress</p> <p>0x9 : InducedLowMemory</p>
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

IncreaseMemoryPressure event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Information (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
IncreaseMemoryPressure	200	Memory pressure was increased.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

DecreaseMemoryPressure event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Information (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
DecreaseMemoryPressure	201	Memory pressure was decreased.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
BytesFreed	win:UInt32	Bytes freed.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

GCMarkWithType event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
GCKeyword (0x1)	Information (4)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
GCMarkWithType	202	A GC root has been marked during GC mark phase.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
HeapNum	win:UInt32	The heap number.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.
Type	win:UInt32	<p>The GC root type.</p> <ul style="list-style-type: none"> <code>0x0</code> : Stack <code>0x1</code> : Finalizer <code>0x2</code> : Handle <code>0x3</code> : Older <code>0x4</code> : SizedRef <code>0x5</code> : Overflow
Bytes	win:UInt64	The number of bytes marked.

GCJoin_V2 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>GCKeyword</code> (0x1)	Verbose (5)

The following table shows the event information:

EVENT	EVENT ID	RAISED WHEN
<code>GCJoin_V2</code>	203	A GC thread joined.

The following table shows the event data:

FIELD NAME	DATA TYPE	DESCRIPTION
<code>Heap</code>	<code>win:UInt32</code>	The heap number
<code>JoinTime</code>	<code>win:UInt32</code>	Indicates whether this event is fired at the start of a join or end of a join (0x0 for join start, 0x1 for join end)
<code>JoinType</code>	<code>win:UInt32</code>	<p>The join type.</p> <p>0x0 : Last Join</p> <p>0x1 : Join</p> <p>0x2 : Restart</p> <p>0x3 : First Reverse Join</p> <p>0x4 : Reverse Join</p>
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CoreCLR.

.NET runtime interop events

9/20/2022 • 2 minutes to read • [Edit Online](#)

These runtime events capture information about Common Intermediate Language (CIL) stub generation. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

ILStubGenerated event

KEYWORD FOR RAISING THE EVENT	LEVEL	
<code>InteropKeyword</code> (0x2000)	Informational(4)	
EVENT	EVENT ID	RAISED WHEN
<code>ILStubGenerated</code>	88	An IL Stub is generated.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>ModuleID</code>	<code>win:UInt16</code>	The module identifier.
<code>StubMethodID</code>	<code>win:UInt64</code>	The stub method identifier.
<code>StubFlags</code>	<code>win:UInt32</code>	<p>The flags for the stub:</p> <ul style="list-style-type: none"><code>0x1</code> - Reverse interop.<code>0x2</code> - COM interop.<code>0x4</code> - Stub generated by NGen.exe.<code>0x8</code> - Delegate.<code>0x10</code> - Variable argument.<code>0x20</code> - Unmanaged callee.<code>0x40</code> - Struct Marshal
<code>ManagedInteropMethodToken</code>	<code>win:UInt32</code>	The token for the managed interop method.
<code>ManagedInteropMethodNameSpace</code>	<code>win:UnicodeString</code>	The namespace and enclosing type of the managed interop method.
<code>ManagedInteropMethodName</code>	<code>win:UnicodeString</code>	The name of the managed interop method.
<code>ManagedInteropMethodSignature</code>	<code>win:UnicodeString</code>	The signature of the managed interop method.

FIELD NAME	DATA TYPE	DESCRIPTION
NativeMethodSignature	win:UnicodeString	The native method signature.
StubMethodSignature	win:UnicodeString	The stub method signature.
StubMethodILCode	win:UnicodeString	The Common Intermediate Language (CIL) code for the stub method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

.NET runtime loader and binder events

9/20/2022 • 9 minutes to read • [Edit Online](#)

These events collect information relating to loading and unloading assemblies and modules. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
<code>LoaderKeyword</code> (0x8)	<code>DomainModuleLoad_V1</code>	Informational (4)
EVENT	EVENT ID	DESCRIPTION
<code>DomainModuleLoad_V1</code>	151	Raised when a module is loaded for an application domain.

ModuleLoad_V2 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
<code>LoaderKeyword</code> (0x8)	<code>DomainModuleLoad_V1</code>	Informational (4)
EVENT	EVENT ID	DESCRIPTION
<code>ModuleLoad_V2</code>	152	Raised when a module is loaded during the lifetime of a process.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>ModuleID</code>	<code>win:UInt64</code>	Unique ID for the module.
<code>AssemblyID</code>	<code>win:UInt64</code>	ID of the assembly in which this module resides.
<code>ModuleFlags</code>	<code>win:UInt32</code>	<p>0x1: Domain neutral module.</p> <p>0x2: Module has a native image.</p> <p>0x4: Dynamic module.</p> <p>0x8: Manifest module.</p>
<code>Reserved1</code>	<code>win:UInt32</code>	Reserved field.
<code>ModuleILPath</code>	<code>win:UnicodeString</code>	Path of the Common Intermediate Language (CIL) image for the module, or dynamic module name if it is a dynamic assembly (null-terminated).

FIELD NAME	DATA TYPE	DESCRIPTION
ModuleNativePath	win:UnicodeString	Path of the module native image, if present (null-terminated).
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.
ManagedPdbSignature	win:GUID	GUID signature of the managed program database (PDB) that matches this module.
ManagedPdbAge	win:UInt32	Age number written to the managed PDB that matches this module.
ManagedPdbBuildPath	win:UnicodeString	Path to the location where the managed PDB that matches this module was built. In some cases, this may just be a file name.
NativePdbSignature	win:GUID	GUID signature of the Native Image Generator (NGen) PDB that matches this module, if applicable.
NativePdbAge	win:UInt32	Age number written to the NGen PDB that matches this module, if applicable.
NativePdbBuildPath	win:UnicodeString	Path to the location where the NGen PDB that matches this module was built, if applicable. In some cases, this may just be a file name.

ModuleUnload_V2 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)
EVENT	EVENT ID	DESCRIPTION
ModuleUnload_V2	153	Raised when a module is unloaded during the lifetime of a process.
FIELD NAME	DATA TYPE	DESCRIPTION
ModuleID	win:UInt64	Unique ID for the module.
AssemblyID	win:UInt64	ID of the assembly in which this module resides.

FIELD NAME	DATA TYPE	DESCRIPTION
ModuleFlags	win:UInt32	0x1: Domain neutral module. 0x2: Module has a native image. 0x4: Dynamic module. 0x8: Manifest module.
Reserved1	win:UInt32	Reserved field.
ModuleILPath	win:UnicodeString	Path of the Common Intermediate Language (CIL) image for the module, or dynamic module name if it is a dynamic assembly (null-terminated).
ModuleNativePath	win:UnicodeString	Path of the module native image, if present (null-terminated).
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.
ManagedPdbSignature	win:GUID	GUID signature of the managed program database (PDB) that matches this module.
ManagedPdbAge	win:UInt32	Age number written to the managed PDB that matches this module.
ManagedPdbBuildPath	win:UnicodeString	Path to the location where the managed PDB that matches this module was built. In some cases, this may just be a file name.
NativePdbSignature	win:GUID	GUID signature of the Native Image Generator (NGen) PDB that matches this module, if applicable.
NativePdbAge	win:UInt32	Age number written to the NGen PDB that matches this module, if applicable.
NativePdbBuildPath	win:UnicodeString	Path to the location where the NGen PDB that matches this module was built, if applicable. In some cases, this may just be a file name.

ModuleDCStart_V2 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)

EVENT	EVENT ID	DESCRIPTION
ModuleDCStart_V2	153	Enumerates modules during a start rundown.
FIELD NAME	DATA TYPE	DESCRIPTION
ModuleID	win:UInt64	Unique ID for the module.
AssemblyID	win:UInt64	ID of the assembly in which this module resides.
ModuleFlags	win:UInt32	<p>0x1: Domain neutral module.</p> <p>0x2: Module has a native image.</p> <p>0x4: Dynamic module.</p> <p>0x8: Manifest module.</p>
Reserved1	win:UInt32	Reserved field.
ModuleILPath	win:UnicodeString	Path of the Common Intermediate Language (CIL) image for the module, or dynamic module name if it is a dynamic assembly (null-terminated).
ModuleNativePath	win:UnicodeString	Path of the module native image, if present (null-terminated).
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.
ManagedPdbSignature	win:GUID	GUID signature of the managed program database (PDB) that matches this module.
ManagedPdbAge	win:UInt32	Age number written to the managed PDB that matches this module.
ManagedPdbBuildPath	win:UnicodeString	Path to the location where the managed PDB that matches this module was built. In some cases, this may just be a file name.
NativePdbSignature	win:GUID	GUID signature of the Native Image Generator (NGen) PDB that matches this module, if applicable.
NativePdbAge	win:UInt32	Age number written to the NGen PDB that matches this module, if applicable.
NativePdbBuildPath	win:UnicodeString	Path to the location where the NGen PDB that matches this module was built, if applicable. In some cases, this may just be a file name.

ModuleDCEnd_V2 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)
EVENT	EVENT ID	DESCRIPTION
ModuleDCEnd_V2	154	Enumerates modules during an end rundown.
FIELD NAME	DATA TYPE	DESCRIPTION
ModuleID	win:UInt64	Unique ID for the module.
AssemblyID	win:UInt64	ID of the assembly in which this module resides.
ModuleFlags	win:UInt32	<p>0x1: Domain neutral module.</p> <p>0x2: Module has a native image.</p> <p>0x4: Dynamic module.</p> <p>0x8: Manifest module.</p>
Reserved1	win:UInt32	Reserved field.
ModuleILPath	win:UnicodeString	Path of the Common Intermediate Language (CIL) image for the module, or dynamic module name if it is a dynamic assembly (null-terminated).
ModuleNativePath	win:UnicodeString	Path of the module native image, if present (null-terminated).
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.
ManagedPdbSignature	win:GUID	GUID signature of the managed program database (PDB) that matches this module.
ManagedPdbAge	win:UInt32	Age number written to the managed PDB that matches this module.
ManagedPdbBuildPath	win:UnicodeString	Path to the location where the managed PDB that matches this module was built. In some cases, this may just be a file name.
NativePdbSignature	win:GUID	GUID signature of the Native Image Generator (NGen) PDB that matches this module, if applicable.

FIELD NAME	DATA TYPE	DESCRIPTION
NativePdbAge	win:UInt32	Age number written to the NGen PDB that matches this module, if applicable.
NativePdbBuildPath	win:UnicodeString	Path to the location where the NGen PDB that matches this module was built, if applicable. In some cases, this may just be a file name.

AssemblyLoad_V1 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)
EVENT	EVENT ID	DESCRIPTION
AssemblyLoad_V1	154	Raised when an assembly is loaded.

FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyID	win:UInt64	Unique ID for the assembly.
AppDomainID	win:UInt64	ID of the domain of this assembly.
BindingID	win:UInt64	ID that uniquely identifies the assembly binding.
AssemblyFlags	win:UInt32	0x1: Domain neutral assembly. 0x2: Dynamic assembly. 0x4: Assembly has a native image. 0x8: Collectible assembly.
AssemblyName	win:UnicodeString	Fully qualified assembly name.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

AssemblyUnload_V1 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)
EVENT	EVENT ID	DESCRIPTION
FireAssemblyUnload_V1	155	Raised when an assembly is loaded.

FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyID	win:UInt64	Unique ID for the assembly.
AppDomainID	win:UInt64	ID of the domain of this assembly.
BindingID	win:UInt64	ID that uniquely identifies the assembly binding.
AssemblyFlags	win:UInt32	0x1: Domain neutral assembly. 0x2: Dynamic assembly. 0x4: Assembly has a native image. 0x8: Collectible assembly.
AssemblyName	win:UnicodeString	Fully qualified assembly name.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

AssemblyDCStart_V1 event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
LoaderKeyword (0x8)	DomainModuleLoad_V1	Informational (4)
EVENT	EVENT ID	DESCRIPTION
AssemblyDCStart_V1	155	Enumerates assemblies during a start rundown.
FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyID	win:UInt64	Unique ID for the assembly.
AppDomainID	win:UInt64	ID of the domain of this assembly.
BindingID	win:UInt64	ID that uniquely identifies the assembly binding.
AssemblyFlags	win:UInt32	0x1: Domain neutral assembly. 0x2: Dynamic assembly. 0x4: Assembly has a native image. 0x8: Collectible assembly.
AssemblyName	win:UnicodeString	Fully qualified assembly name.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

AssemblyLoadStart event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
<code>Binder</code> (0x4)	<code>AssemblyLoadStart</code>	Informational (4)
EVENT	EVENT ID	DESCRIPTION
<code>AssemblyLoadStart</code>	290	An assembly load has been requested.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>AssemblyName</code>	<code>win:UnicodeString</code>	Name of assembly name.
<code>AssemblyPath</code>	<code>win:UnicodeString</code>	Path of assembly name.
<code>RequestingAssembly</code>	<code>win:UnicodeString</code>	Name of the requesting ("parent") assembly.
<code>AssemblyLoadContext</code>	<code>win:UnicodeString</code>	Load context of the assembly.
<code>RequestingAssemblyLoadContext</code>	<code>win:UnicodeString</code>	Load context of the requesting ("parent") assembly.
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CoreCLR.

AssemblyLoadStop event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
<code>Binder</code> (0x4)	<code>AssemblyLoadStart</code>	Informational (4)
EVENT	EVENT ID	DESCRIPTION
<code>AssemblyLoadStart</code>	291	An assembly load has been requested.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>AssemblyName</code>	<code>win:UnicodeString</code>	Name of assembly name.
<code>AssemblyPath</code>	<code>win:UnicodeString</code>	Path of assembly name.
<code>RequestingAssembly</code>	<code>win:UnicodeString</code>	Name of the requesting ("parent") assembly.
<code>AssemblyLoadContext</code>	<code>win:UnicodeString</code>	Load context of the assembly.
<code>RequestingAssemblyLoadContext</code>	<code>win:UnicodeString</code>	Load context of the requesting ("parent") assembly.

FIELD NAME	DATA TYPE	DESCRIPTION
Success	win:Boolean	Whether the assembly load succeeded.
ResultAssemblyName	win:UnicodeString	The name of assembly that was loaded.
ResultAssemblyPath	win:UnicodeString	The path of the assembly that was loaded from.
Cached	win:UnicodeString	Whether the load was cached.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

ResolutionAttempted event

KEYWORD FOR RAISING THE EVENT		
Binder (0x4)		Informational (4)
EVENT	EVENT ID	DESCRIPTION
ResolutionAttempted	292	An assembly load has been requested.
FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyName	win:UnicodeString	Name of assembly name.
Stage	win:UInt16	<p>The resolution stage.</p> <p>0: Find in load.</p> <p>1: Assembly Load Context</p> <p>2: Application assemblies.</p> <p>3: Default assembly load context fallback.</p> <p>4: Resolve satellite assembly.</p> <p>5: Assembly load context resolving.</p> <p>6: AppDomain assembly resolving.</p>
AssemblyLoadContext	win:UnicodeString	Load context of the assembly.

FIELD NAME	DATA TYPE	DESCRIPTION
Result	win:UInt16	The result of resolution attempt. 0: Success 1: Assembly NotFound 2: Incompatible Version 3: Mismatched Assembly Name 4: Failure 5: Exception
ResultAssemblyName	win:UnicodeString	The name of assembly that was resolved.
ResultAssemblyPath	win:UnicodeString	The path of the assembly that was resolved from.
ErrorMessage	win:UnicodeString	Error message if there is an exception.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

AssemblyLoadContextResolvingHandlerInvoked event

KEYWORD FOR RAISING THE EVENT	LEVEL	
Binder (0x4)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
AssemblyLoadContextResolvingHandlerInvoked	293	An AssemblyLoadContext.Resolving handler has been invoked.

FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyName	win:UnicodeString	Name of assembly name.
HandlerName	win:UnicodeString	Name of the handler invoked.
AssemblyLoadContext	win:UnicodeString	Load context of the assembly.
ResultAssemblyName	win:UnicodeString	The name of assembly that was resolved.
ResultAssemblyPath	win:UnicodeString	The path of the assembly that was resolved from.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

AppDomainAssemblyResolveHandlerInvoked event

KEYWORD FOR RAISING THE EVENT	LEVEL	
Binder (0x4)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
AppDomainAssemblyResolveHandlerInvoke	294	An AppDomain.AssemblyResolve handler has been invoked.
FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyName	win:UnicodeString	Name of assembly name.
HandlerName	win:UnicodeString	Name of the handler invoked.
ResultAssemblyName	win:UnicodeString	The name of assembly that was resolved.
ResultAssemblyPath	win:UnicodeString	The path of the assembly that was resolved from.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

AssemblyLoadFromResolveHandlerInvoked event

KEYWORD FOR RAISING THE EVENT	LEVEL	
Binder (0x4)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
AssemblyLoadFromResolveHandlerInvoke	295	An Assembly.LoadFrom handler has been invoked.
FIELD NAME	DATA TYPE	DESCRIPTION
AssemblyName	win:UnicodeString	Name of assembly name.
IsTrackedLoad	win:Boolean	Whether the assembly load is tracked.
RequestingAssemblyPath	win:UnicodeString	The path of the requesting assembly.
ComputedRequestedAssemblyPath	win:UnicodeString	The path of the assembly that was requested.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

KnownPathProbed event

KEYWORD FOR RAISING THE EVENT	LEVEL	
<code>Binder</code> (0x4)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
<code>KnownPathProbed</code>	296	A known path was probed for an assembly.
FIELD NAME	DATA TYPE	DESCRIPTION
<code>FilePath</code>	<code>win:UnicodeString</code>	Path probed.
<code>Source</code>	<code>win:UInt16</code>	<p>Source of the path probed.</p> <p>0x0:Application Assemblies.</p> <p>0x1:App native image path.</p> <p>0x2:App path.</p> <p>0x3:Platform resource roots.</p> <p>0x4:Satellite Subdirectory.</p>
<code>Result</code>	<code>win:UInt32</code>	HRESULT for the probe.
<code>ClrInstanceID</code>	<code>win:UInt16</code>	Unique ID for the instance of CoreCLR.

.NET runtime method events

9/20/2022 • 11 minutes to read • [Edit Online](#)

These events collect information that is specific to methods. The payload of these events is required for symbol resolution. In addition, these events provide helpful information such as methods that are loaded and unloaded. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

All method events have a level of "Informational (4)". All method verbose events have a level of "Verbose (5)".

All method events are raised by the `JITKeyword` (0x10) keyword or the `NGenKeyword` (0x20) keyword under the runtime provider, or `JitRundownKeyword` (0x10) or `NGENRundownKeyword` (0x20) under the rundown provider.

The V2 versions of these events include the ReJITID, the V1 versions do not.

MethodLoad_V1 event

The following table shows the event information:

EVENT	EVENT ID	DESCRIPTION
<code>MethodLoad_V1</code>	141	Raised when a method is just-in-time loaded (JIT-loaded) or an NGEN image is loaded. Dynamic and generic methods do not use this version for method loads. JIT helpers never use this version.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>JITKeyword</code> (0x10) runtime provider	Informational (4)
<code>NGenKeyword</code> (0x20) runtime provider	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
<code>MethodID</code>	<code>win:UInt64</code>	Unique identifier of a method. For JIT helper methods, this is set to the start address of the method.
<code>ModuleID</code>	<code>win:UInt64</code>	Identifier of the module to which this method belongs (0 for JIT helpers).
<code>MethodStartAddress</code>	<code>win:UInt64</code>	Start address of the method.
<code>MethodSize</code>	<code>win:UInt32</code>	Size of the method.
<code>MethodToken</code>	<code>win:UInt32</code>	0 for dynamic methods and JIT helpers.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled code method (otherwise NGEN native image code). 0x8: Helper method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodLoad_V2 event

EVENT	EVENT ID	DESCRIPTION
MethodLoad_V2	141	Raised when a method is just-in-time loaded (JIT-loaded) or an NGEN image is loaded. Dynamic and generic methods do not use this version for method loads. JIT helpers never use this version.

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10) runtime provider	Informational (4)
NGenKeyword (0x20) runtime provider	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a method. For JIT helper methods, this is set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address of the method.
MethodSize	win:UInt32	Size of the method.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled code method (otherwise NGEN native image code). 0x8: Helper method.

FIELD NAME	DATA TYPE	DESCRIPTION
ReJITID	win:UInt64	ReJIT ID of the method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodUnLoad_V1 event

EVENT	EVENT ID	DESCRIPTION
MethodUnLoad_V1	142	Raised when a module is unloaded, or an application domain is destroyed. Dynamic methods never use this version for method unloads.

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10)	Informational (4)
NGenKeyword (0x20)	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a method. For JIT helper methods, this is set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address of the method.
MethodSize	win:UInt32	Size of the method.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled code method (otherwise NGEN native image code). 0x8: Helper method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodUnLoad_V2 event

EVENT	EVENT ID	DESCRIPTION
MethodUnLoad_V2	142	Raised when a module is unloaded, or an application domain is destroyed. Dynamic methods never use this version for method unloads.
KEYWORD FOR RAISING THE EVENT	LEVEL	
JITKeyword (0x10)	Informational (4)	
NGenKeyword (0x20)	Informational (4)	
FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a method. For JIT helper methods, this is set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address of the method.
MethodSize	win:UInt32	Size of the method.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled code method (otherwise NGEN native image code). 0x8: Helper method.
ReJITID	win:UInt64	ReJIT ID of the method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

R2RGetEntryPoint event

EVENT	EVENT ID	DESCRIPTION
R2RGetEntryPoint	159	Raised when an R2R entry point lookup ends.
KEYWORD FOR RAISING THE EVENT	LEVEL	
CompilationDiagnosticKeyword (0x2000000000)	Informational (4)	

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a R2R method.
MethodNamespace	win:UnicodeString	The namespace of method being looked up.
MethodName	win:UnicodeString	The name of the method being looked up.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
EntryPoint	win:UInt64	The pointer to the entry point of the R2R method
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

R2RGetEntryPointStart event

EVENT	EVENT ID	DESCRIPTION
R2RGetEntryPointStart	160	Raised when an R2R entry point lookup starts.
KEYWORD FOR RAISING THE EVENT	LEVEL	
CompilationDiagnosticKeyword (0x2000000000)	Informational (4)	
FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a R2R method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodLoadVerbose_V1 event

EVENT	EVENT ID	DESCRIPTION
MethodLoadVerbose_V1	143	Raised when a method is JIT-loaded or an NGEN image is loaded. Dynamic and generic methods always use this version for method loads. JIT helpers always use this version.
KEYWORD FOR RAISING THE EVENT	LEVEL	
JITKeyword (0x10)	Informational (4)	
NGenKeyword (0x20)	Informational (4)	

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of the method. For JIT helper methods, set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address.
MethodSize	win:UInt32	Method length.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled method (otherwise, generated by NGen.exe) 0x8: Helper method.
MethodNameSpace	win:UnicodeString	Full namespace name associated with the method.
MethodName	win:UnicodeString	Full class name associated with the method.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodLoadVerbose_V2 event

EVENT	EVENT ID	DESCRIPTION
MethodLoadVerbose_V1	143	Raised when a method is JIT-loaded or an NGEN image is loaded. Dynamic and generic methods always use this version for method loads. JIT helpers always use this version.

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10)	Informational (4)
NGenKeyword (0x20)	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of the method. For JIT helper methods, set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address.
MethodSize	win:UInt32	Method length.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled method (otherwise, generated by NGen.exe) 0x8: Helper method.
MethodNameSpace	win:UnicodeString	Full namespace name associated with the method.
MethodName	win:UnicodeString	Full class name associated with the method.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
ReJITID	win:UInt64	ReJIT ID of the method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodUnLoadVerbose_V1 event

EVENT	EVENT ID	DESCRIPTION
MethodUnLoadVerbose_V1	144	Raised when a dynamic method is destroyed, a module is unloaded, or an application domain is destroyed. Dynamic methods always use this version for method unloads.

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10)	Informational (4)
NGenKeyword (0x20)	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of the method. For JIT helper methods, set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address.
MethodSize	win:UInt32	Method length.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled method (otherwise, generated by NGen.exe) 0x8: Helper method.
MethodNameSpace	win:UnicodeString	Full namespace name associated with the method.
MethodName	win:UnicodeString	Full class name associated with the method.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodUnLoadVerbose_V2 event

EVENT	EVENT ID	DESCRIPTION
MethodUnLoadVerbose_V2	144	Raised when a dynamic method is destroyed, a module is unloaded, or an application domain is destroyed. Dynamic methods always use this version for method unloads.

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10)	Informational (4)
NGenKeyword (0x20)	Informational (4)

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of the method. For JIT helper methods, set to the start address of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs (0 for JIT helpers).
MethodStartAddress	win:UInt64	Start address.
MethodSize	win:UInt32	Method length.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodFlags	win:UInt32	0x1: Dynamic method. 0x2: Generic method. 0x4: JIT-compiled method (otherwise, generated by NGen.exe) 0x8: Helper method.
MethodNameSpace	win:UnicodeString	Full namespace name associated with the method.
MethodName	win:UnicodeString	Full class name associated with the method.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
ReJITID	win:UInt64	ReJIT ID of the method.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodJittingStarted_V1 event

The following table shows the keyword and level:

KEYWORD FOR RAISING THE EVENT	LEVEL
JITKeyword (0x10)	Verbose (5)
NGenKeyword (0x20)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodJittingStarted_V1	145	Raised when a method is being JIT-compiled.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of the method.
ModuleID	win:UInt64	Identifier of the module to which this method belongs.
MethodToken	win:UInt32	0 for dynamic methods and JIT helpers.
MethodILSize	win:UInt32	The size of the Common Intermediate Language (CIL) for the method that is being JIT-compiled.
MethodNameSpace	win:UnicodeString	Full class name associated with the method.
MethodName	win:UnicodeString	Name of the method.
MethodSignature	win:UnicodeString	Signature of the method (comma-separated list of type names).
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodJitInliningSucceeded event

KEYWORD FOR RAISING THE EVENT	LEVEL
JITTracingKeyword (0x1000)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodJitInliningSucceeded	185	Raised when a method is successfully inlined by the JIT compiler.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodBeingCompiledNamespace	win:UnicodeString	Namespace of the method being compiled.
MethodBeingCompiledName	win:UnicodeString	Name of the method being compiled.
MethodBeingCompiledNameSignature	win:UnicodeString	Signature of the method (comma-separated list of type names) being compiled.
InlinerNamespace	win:UnicodeString	The namespace of inliner ("parent") method.
InlinerName	win:UnicodeString	Name of the inliner ("parent") method.

FIELD NAME	DATA TYPE	DESCRIPTION
InlinerNameSignature	win:UnicodeString	Signature of the inliner ("parent") method (comma-separated list of type names).
InlineeNamespace	win:UnicodeString	The namespace of inlinee ("child") method.
InlineeName	win:UnicodeString	Name of the inlinee ("child") method.
InlineeNameSignature	win:UnicodeString	Signature of the inlinee ("child") method (comma-separated list of type names).
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodJitInliningFailed event

KEYWORD FOR RAISING THE EVENT	LEVEL
JITTracingKeyword (0x1000)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodJitInliningFailed	192	Raised when a method was failed to be inlined by the JIT compiler.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodBeingCompiledNamespace	win:UnicodeString	Namespace of the method being compiled.
MethodBeingCompiledName	win:UnicodeString	Name of the method being compiled.
MethodBeingCompiledNameSignature	win:UnicodeString	Signature of the method (comma-separated list of type names) being compiled.
InlineerNamespace	win:UnicodeString	The namespace of inliner ("parent") method.
InlineerName	win:UnicodeString	Name of the inliner ("parent") method.
InlineerNameSignature	win:UnicodeString	Signature of the inliner ("parent") method (comma-separated list of type names).
InlineeNamespace	win:UnicodeString	The namespace of inlinee ("child") method.
InlineeName	win:UnicodeString	Name of the inlinee ("child") method.

FIELD NAME	DATA TYPE	DESCRIPTION
InlineeNameSignature	win:UnicodeString	Signature of the inlinee ("child") method (comma-separated list of type names).
FailAlways	win:Boolean	Whether the method is marked as not inlinable.
FailReason	win:UnicodeString	Reason inlining failed.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodJitTailCallSucceeded event

KEYWORD FOR RAISING THE EVENT	LEVEL
JITTracingKeyword (0x1000)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodJitTailCallSucceeded	192	Raised by the JIT compiler when a method can be successfully tail called.
FIELD NAME	DATA TYPE	DESCRIPTION
MethodBeingCompiledNamespace	win:UnicodeString	Namespace of the method being compiled.
MethodBeingCompiledName	win:UnicodeString	Name of the method being compiled.
MethodBeingCompiledNameSignature	win:UnicodeString	Signature of the method (comma-separated list of type names) being compiled.
CallerNamespace	win:UnicodeString	Namespace of the caller method.
CallerName	win:UnicodeString	Name of the caller method.
CallerNameSignature	win:UnicodeString	Signature of the caller method (Comma-separated list of type names).
CalleeNamespace	win:UnicodeString	Namespace of the callee method.
CalleeName	win:UnicodeString	Name of the callee method.
CalleeNameSignature	win:UnicodeString	Signature of the callee method (Comma-separated list of type names).
TailPrefix	win:Boolean	Whether it is a tail prefix instruction.

FIELD NAME	DATA TYPE	DESCRIPTION
TailCallType	win:UInt32	<p>The type of tail call.</p> <p>0: Optimized tail call (epilog + jmp)</p> <p>1: Recursive tail call (method tail calls itself)</p> <p>2: Helper assisted tail call</p>
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodJitTailCallFailed event

KEYWORD FOR RAISING THE EVENT	LEVEL
JITTracingKeyword (0x1000)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodJitTailCallFailed	191	Raised by the JIT compiler when a method was failed to be tail called.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodBeingCompiledNamespace	win:UnicodeString	Namespace of the method being compiled.
MethodBeingCompiledName	win:UnicodeString	Name of the method being compiled.
MethodBeingCompiledNameSignature	win:UnicodeString	Signature of the method (comma-separated list of type names) being compiled.
CallerNamespace	win:UnicodeString	Namespace of the caller method.
CallerName	win:UnicodeString	Name of the caller method.
CallerNameSignature	win:UnicodeString	Signature of the caller method (Comma-separated list of type names).
CalleeNamespace	win:UnicodeString	Namespace of the callee method.
CalleeName	win:UnicodeString	Name of the callee method.
CalleeNameSignature	win:UnicodeString	Signature of the callee method (Comma-separated list of type names).
TailPrefix	win:Boolean	Whether it is a tail prefix instruction.
FailReason	win:UnicodeString	Reason tail call failed.

FIELD NAME	DATA TYPE	DESCRIPTION
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

MethodILToNativeMap event

KEYWORD FOR RAISING THE EVENT	LEVEL
JittedMethodILToNativeMapKeyword (0x20000)	Verbose (5)

EVENT	EVENT ID	DESCRIPTION
MethodILToNativeMap	190	Maps the IL-to-native map event for JIT-compiled methods.

FIELD NAME	DATA TYPE	DESCRIPTION
MethodID	win:UInt64	Unique identifier of a method.
ReJITID	win:UInt64	The ReJIT ID of the method.
MethodExtent	win:UInt8	The extent for the jitted method.
CountOfMapEntries	win:UInt8	Number of map entries
ILOffsets	win:UInt32	The IL offset.
NativeOffsets	win:UInt32	The native code offset.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

.NET runtime thread pool events

9/20/2022 • 8 minutes to read • [Edit Online](#)

These events collect information about worker and I/O threads in the threadpool. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

IOThreadCreate_V1 event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ThreadingKeyword</code> (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	RAISED WHEN
<code>IOThreadCreate_V1</code>	44	An I/O thread is created in the thread pool.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
<code>Count</code>	<code>win:UInt64</code>	Number of I/O threads, including the newly created thread.
<code>NumRetired</code>	<code>win:UInt64</code>	Number of retired worker threads.
<code>ClrInstanceId</code>	<code>win:UInt16</code>	Unique ID for the instance of CLR or CoreCLR.

IOThreadTerminate_V1 event

The following table shows the keyword and level

KEYWORD FOR RAISING THE EVENT	LEVEL
<code>ThreadingKeyword</code> (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	RAISED WHEN
<code>IOThreadTerminate</code>	45	An I/O thread is terminated in the thread pool.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt64	Number of I/O threads remaining in the thread pool.
NumRetired	win:UInt64	Number of retired I/O threads.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

IOThreadRetire_V1 event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	RAISED WHEN
IOThreadRetire_V1	46	An I/O thread becomes a retirement candidate.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt64	Number of I/O threads remaining in the thread pool.
NumRetired	win:UInt64	Number of retired I/O threads.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

IOThreadUnretire_V1 event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	RAISED WHEN
IOThreadUnretire_V1	47	An I/O thread is unretired because of I/O that arrives within a waiting period after the thread becomes a retirement candidate.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
Count	win:UInt64	Number of I/O threads in the thread pool, including this one.
NumRetired	win:UInt64	Number of retired I/O threads.
ClrInstanceID	Win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadStart event

KEYWORD FOR RAISING THE EVENT		
<code>ThreadingKeyword</code> (0x10000)		
EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadStart	50	A worker thread is created.
FIELD NAME	DATA TYPE	DESCRIPTION
ActiveWorkerThreadCount	win:UInt32	Number of worker threads available to process work, including those that are already processing work.
RetiredWorkerThreadCount	win:UInt32	Number of worker threads that are not available to process work, but that are being held in reserve in case more threads are needed later.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadStop event

KEYWORD FOR RAISING THE EVENT		
<code>ThreadingKeyword</code> (0x10000)		
EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadStop	51	A worker thread is stopped.
FIELD NAME	DATA TYPE	DESCRIPTION
ActiveWorkerThreadCount	win:UInt32	Number of worker threads available to process work, including those that are already processing work.

FIELD NAME	DATA TYPE	DESCRIPTION
RetiredWorkerThreadCount	win:UInt32	Number of worker threads that are not available to process work, but that are being held in reserve in case more threads are needed later.
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadWait event

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadWait	57	A worker thread starts waiting for work.

FIELD NAME	DATA TYPE	DESCRIPTION
ActiveWorkerThreadCount	win:UInt32	Number of worker threads available to process work, including those that are already processing work.
RetiredWorkerThreadCount	win:UInt32	Number of worker threads that are not available to process work, but that are being held in reserve in case more threads are needed later.
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadRetirementStart event

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadRetirementStart	52	A worker thread retires.

FIELD NAME	DATA TYPE	DESCRIPTION
ActiveWorkerThreadCount	win:UInt32	Number of worker threads available to process work, including those that are already processing work.

FIELD NAME	DATA TYPE	DESCRIPTION
RetiredWorkerThreadCount	win:UInt32	Number of worker threads that are not available to process work, but that are being held in reserve in case more threads are needed later.
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadRetirementStop event

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadRetirementStop	53	A retired worker thread becomes active again.

FIELD NAME	DATA TYPE	DESCRIPTION
ActiveWorkerThreadCount	win:UInt32	Number of worker threads available to process work, including those that are already processing work.
RetiredWorkerThreadCount	win:UInt32	Number of worker threads that are not available to process work, but that are being held in reserve in case more threads are needed later.
ClrInstanceId	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadAdjustmentSample event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadAdjustmentSample	64	Refers to the collection of information for one sample; that is, a measurement of throughput with a certain concurrency level, in an instant of time.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
Throughput	win:Double	Number of completions per unit of time.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadAdjustmentAdjustment event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadAdjustmentAdjustment	55	Records a change in control, when the thread injection (hill-climbing) algorithm determines that a change in concurrency level is in place.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
AverageThroughput	win:Double	Average throughput of a sample of measurements.
NewWorkerThreadCount	win:UInt32	New number of active worker threads.
Reason	win:UInt32	Reason for the adjustment. 0x0 - Warmup. 0x1 - Initializing. 0x2 - Random move. 0x3 - Climbing move. 0x4 - Change point. 0x5 - Stabilizing. 0x6 - Starvation. 0x7 - Thread timed out.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolWorkerThreadAdjustmentStats event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolWorkerThreadAdjustmentStats	56	Gathers data on the thread pool.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
Duration	win:Double	Amount of time, in seconds, during which these statistics were collected.
Throughput	win:Double	Average number of completions per second during this interval.
ThreadWave	win:Double	Reserved for internal use.
ThroughputWave	win:Double	Reserved for internal use.
ThroughputErrorEstimate	win:Double	Reserved for internal use.
AverageThroughputErrorEstimate	win:Double	Reserved for internal use.
ThroughputRatio	win:Double	The relative improvement in throughput caused by variations in active worker thread count during this interval.
Confidence	win:Double	A measure of the validity of the ThroughputRatio field.
NewcontrolSetting	win:Double	The number of active worker threads that serve as the baseline for future variations in active thread count.
NewThreadWaveMagnitude	win:UInt16	The magnitude of future variations in active thread count.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

ThreadPoolEnqueue event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolEnqueue	61	A work item was enqueued in the thread pool queue.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
WorkID	win:Pointer	Pointer to the work request.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadPoolDequeue event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolDequeue	62	A work item was dequeued from the thread pool queue.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
WorkID	win:Pointer	Pointer to the work request.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadPoolIOEnqueue event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolIOEnqueue	63	A thread enqueues an IO completion notification after an async IO completion occurs.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
NativeOverlapped	win:Pointer	Reserved for internal use.
Overlapped	win:Pointer	Reserved for internal use.
MultiDequeues	win:Boolean	Reserved for internal use.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadPoolIODequeue event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolIODequeue	64	A thread dequeues the IO completion notification.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
NativeOverlapped	win:Pointer	Reserved for internal use.
Overlapped	win:Pointer	Reserved for internal use.
MultiDequeues	win:Boolean	Reserved for internal use.
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadPoolIOPack event

The following table shows the keyword and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Verbose (5)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadPoolIOPack	65	ThreadPool overlapped IO pack is called.

The following table shows the event data

FIELD NAME	DATA TYPE	DESCRIPTION
NativeOverlapped	win:Pointer	Reserved for internal use.
Overlapped	win:Pointer	Reserved for internal use.
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadCreating event

The following table shows the keywords and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadCreating	70	Thread has been created.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
ID	win:Pointer	Thread ID
ClrInstanceId	win:UInt16	Unique ID for the instance of CoreCLR.

ThreadRunning event

The following table shows the keywords and level.

KEYWORD FOR RAISING THE EVENT	LEVEL
ThreadingKeyword (0x10000)	Informational (4)

The following table shows the event information.

EVENT	EVENT ID	DESCRIPTION
ThreadRunning	71	Thread has started running.

The following table shows the event data.

FIELD NAME	DATA TYPE	DESCRIPTION
ID	win:Pointer	Thread ID
ClrInstanceID	win:UInt16	Unique ID for the instance of CoreCLR.

.NET runtime type events

9/20/2022 • 2 minutes to read • [Edit Online](#)

These events collect information relating to loading types. For more information about how to use these events for diagnostic purposes, see [logging and tracing .NET applications](#)

TypeLoadStart Event

KEYWORD FOR RAISING THE EVENT	EVENT	LEVEL
TypeDiagnosticKeyword (0x8000000000)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
TypeLoadStart	73	A type load has started.
FIELD NAME	DATA TYPE	DESCRIPTION
TypeLoadStartID	win:UInt32	ID for the type load operation.
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

TypeLoadStop Event

KEYWORD FOR RAISING THE EVENT	LEVEL	
TypeDiagnosticKeyword (0x8000000000)	Informational (4)	
EVENT	EVENT ID	DESCRIPTION
TypeLoadStop	74	A type load is finished.
FIELD NAME	DATA TYPE	DESCRIPTION
TypeLoadStartID	win:UInt32	ID for the type load operation (matches the corresponding TypeLoadStart event's TypeLoadStartID).
LoadLevel	win:UInt16	Type load level.
TypeID	win:UInt64	Pointer to the type handle.
TypeName	win:UnicodeString	Name of the type.

FIELD NAME	DATA TYPE	DESCRIPTION
ClrInstanceID	win:UInt16	Unique ID for the instance of CLR or CoreCLR.

Collect diagnostics in containers

9/20/2022 • 2 minutes to read • [Edit Online](#)

The same diagnostics tools that are useful for diagnosing .NET Core issues in other scenarios also work in Docker containers. However, some of the tools require special steps to work in a container. This article covers how tools for gathering performance traces and collecting dumps can be used in Docker containers.

Using .NET CLI tools in a container

This tools apply to: ✓ .NET Core 3.1 SDK and later versions

The .NET Core global CLI diagnostic tools ([dotnet-counters](#), [dotnet-dump](#), [dotnet-gcdump](#), [dotnet-monitor](#), and [dotnet-trace](#)) are designed to work in a wide variety of environments and should all work directly in Docker containers. Because of this, these tools are the preferred method of collecting diagnostic information for .NET Core scenarios targeting .NET Core 3.1 or later in containers.

You can also install these tools without the .NET SDK by downloading the single-file variants from the links in the previous paragraph. These installs require a global install of the .NET runtime version 3.1 or later, which you can acquire following any of the prescribed methods in the [.NET installation documentation](#) or by consuming any of the official runtime containers.

Using .NET Core global CLI tools in a sidecar container

If you would like to use .NET Core global CLI diagnostic tools to diagnose processes in a different container, bear the following additional requirements in mind:

1. The containers must [share a process namespace](#) (so that tools in the sidecar container can access processes in the target container).
2. The .NET Core global CLI diagnostic tools need access to files the .NET Core runtime writes to the /tmp directory, so the /tmp directory must be shared between the target and sidecar container via a volume mount. This could be done, for example, by having the containers share a common [volume](#) or a Kubernetes [emptyDir](#) volume. If you attempt to use the diagnostic tools from a sidecar container without sharing the /tmp directory, you will get an error about the process "not running compatible .NET runtime."

Using `PerfCollect` in a container

This tool applies to: ✓ .NET Core 2.1 and later versions

The `PerfCollect` script is useful for collecting performance traces and is the recommended tool for collecting traces prior to .NET Core 3.0. If using `PerfCollect` in a container, keep the following requirements in mind:

- `PerfCollect` requires the [SYS_ADMIN capability](#) (in order to run the `perf` tool), so be sure the container is [started with that capability](#).
- `PerfCollect` requires some environment variables be set prior to the app it is profiling starting. These can be set either in a [Dockerfile](#) or when [starting the container](#). Because these variables shouldn't be set in normal production environments, it's common to just add them when starting a container that will be profiled. The two variables that `PerfCollect` requires are:
 - `DOTNET_PerfMapEnabled=1`
 - `DOTNET_EnableEventLog=1`

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Using `PerfCollect` in a sidecar container

If you would like to run `PerfCollect` in one container to profile a .NET Core process in a different container, the experience is almost the same except for these differences:

- The environment variables mentioned previously (`DOTNET_PerfMapEnabled` and `DOTNET_EnableEventLog`) must be set for the target container (not the one running `PerfCollect`).
- The container running `PerfCollect` must have the `SYS_ADMIN` capability (not the target container).
- The two containers must [share a process namespace](#).

Investigate performance counters (dotnet-counters)

9/20/2022 • 13 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-counters` version 3.0.47001 and later versions

Install

There are two ways to download and install `dotnet-counters`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-counters` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-counters
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

NOTE

To use `dotnet-counters` on an x86 app, you need a corresponding x86 version of the tool.

Synopsis

```
dotnet-counters [-h|--help] [--version] <command>
```

Description

`dotnet-counters` is a performance monitoring tool for ad-hoc health monitoring and first-level performance investigation. It can observe performance counter values that are published via the [EventCounter API](#) or the [Meter API](#). For example, you can quickly monitor things like the CPU usage or the rate of exceptions being thrown in your .NET Core application to see if there's anything suspicious before diving into more serious performance investigation using `PerfView` or `dotnet-trace`.

Options

- `--version`

Displays the version of the dotnet-counters utility.

- `-h|--help`

Shows command-line help.

Commands

COMMAND

```
dotnet-counters collect  
dotnet-counters list  
dotnet-counters monitor  
dotnet-counters ps
```

dotnet-counters collect

Periodically collect selected counter values and export them into a specified file format for post-processing.

Synopsis

```
dotnet-counters collect [-h|--help] [-p|--process-id] [-n|--name] [--diagnostic-port] [--refresh-interval]  
[--counters <COUNTERS>] [--format] [-o|--output] [-- <command>]
```

Options

- `-p|--process-id <PID>`

The ID of the process to collect counter data from.

- `-n|--name <name>`

The name of the process to collect counter data from.

- `--diagnostic-port`

The name of the diagnostic port to create. See [using diagnostic port](#) for how to use this option to start monitoring counters from app startup.

- `--refresh-interval <SECONDS>`

The number of seconds to delay between updating the displayed counters

- `--counters <COUNTERS>`

A comma-separated list of counters. Counters can be specified `[provider_name[:counter_name]]`. If the `provider_name` is used without a qualifying list of counters, then all counters from the provider are shown. To discover provider and counter names, use the [dotnet-counters list](#) command. For [EventCounters](#), `provider_name` is the name of the EventSource and for [Meters](#), `provider_name` is the name of the Meter.

- `--format <csv|json>`

The format to be exported. Currently available: csv, json.

- `-o|--output <output>`

The name of the output file.

- `-- <command>` (for target applications running .NET 5 or later only)

After the collection configuration parameters, the user can append `--` followed by a command to start a .NET application with at least a 5.0 runtime. `dotnet-counters` will launch a process with the provided command and collect the requested metrics. This is often useful to collect metrics for the application's startup path and can be used to diagnose or monitor issues that happen early before or shortly after the main entrypoint.

NOTE

Using this option monitors the first .NET 5 process that communicates back to the tool, which means if your command launches multiple .NET applications, it will only collect the first app. Therefore, it is recommended you use this option on self-contained applications, or using the `dotnet exec <app.dll>` option.

NOTE

Launching a .NET executable via `dotnet-counters` will make its input/output to be redirected and you won't be able to interact with its stdin/stdout. Exiting the tool via CTRL+C or SIGTERM will safely end both the tool and the child process. If the child process exits before the tool, the tool will exit as well and the trace should be safely viewable. If you need to use stdin/stdout, you can use the `--diagnostic-port` option. See [Using diagnostic port](#) for more information.

NOTE

On Linux and macOS, this command expects the target application and `dotnet-counters` to share the same `TMPDIR` environment variable. Otherwise, the command will time out.

NOTE

To collect metrics using `dotnet-counters`, it needs to be run as the same user as the user running target process or as root. Otherwise, the tool will fail to establish a connection with the target process.

Examples

- Collect all counters at a refresh interval of 3 seconds and generate a csv as output:

```
> dotnet-counters collect --process-id 1902 --refresh-interval 3 --format csv  
counter_list is unspecified. Monitoring all counters by default.  
Starting a counter session. Press Q to quit.
```

- Start `dotnet mvc.dll` as a child process and start collecting runtime counters and ASP.NET Core Hosting counters from startup and save it as a JSON output:

```
> dotnet-counters collect --format json --counters System.Runtime,Microsoft.AspNetCore.Hosting --  
dotnet mvc.dll  
Starting a counter session. Press Q to quit.  
File saved to counter.json
```

dotnet-counters list

Displays a list of counter names and descriptions, grouped by provider.

Synopsis

```
dotnet-counters list [-h|--help]
```

Example

```
> dotnet-counters list
Showing well-known counters only. Specific processes may support additional counters.

System.Runtime
  cpu-usage                                Amount of time the process has utilized the CPU (ms)
  working-set                               Amount of working set used by the process (MB)
  gc-heap-size                             Total heap size reported by the GC (MB)
  gen-0-gc-count                          Number of Gen 0 GCs per interval
  gen-1-gc-count                          Number of Gen 1 GCs per interval
  gen-2-gc-count                          Number of Gen 2 GCs per interval
  time-in-gc                               % time in GC since the last GC
  gen-0-size                               Gen 0 Heap Size
  gen-1-size                               Gen 1 Heap Size
  gen-2-size                               Gen 2 Heap Size
  loh-size                                 LOH Heap Size
  alloc-rate                               Allocation Rate
  assembly-count                          Number of Assemblies Loaded
  exception-count                         Number of Exceptions per interval
  threadpool-thread-count                 Number of ThreadPool Threads
  monitor-lock-contention-count          Monitor Lock Contention Count
  threadpool-queue-length                ThreadPool Work Items Queue Length
  threadpool-completed-items-count       ThreadPool Completed Work Items Count
  active-timer-count                      Active Timers Count

Microsoft.AspNetCore.Hosting
  requests-per-second                     Request rate
  total-requests                          Total number of requests
  current-requests                        Current number of requests
  failed-requests                         Failed number of requests
```

NOTE

The `Microsoft.AspNetCore.Hosting` counters are displayed when there are processes identified that support these counters, for example, when an ASP.NET Core application is running on the host machine.

dotnet-counters monitor

Displays periodically refreshing values of selected counters.

Synopsis

```
dotnet-counters monitor [-h|--help] [-p|--process-id] [-n|--name] [--diagnostic-port] [--refresh-interval]
[--counters] [-- <command>]
```

Options

- `-p|--process-id <PID>`

The ID of the process to be monitored.

- `-n|--name <name>`

The name of the process to be monitored.

- `--diagnostic-port`

The name of the diagnostic port to create. See [using diagnostic port](#) for how to use this option to start monitoring counters from app startup.

- `--refresh-interval <SECONDS>`

The number of seconds to delay between updating the displayed counters

- `--counters <COUNTERS>`

A comma-separated list of counters. Counters can be specified `[provider_name[:counter_name]]`. If the `provider_name` is used without a qualifying list of counters, then all counters from the provider are shown. To discover provider and counter names, use the [dotnet-counters list](#) command. For `EventCounters`, `provider_name` is the name of the EventSource and for `Meters`, `provider_name` is the name of the Meter.

`-- <command>` (for target applications running .NET 5 or later only)

After the collection configuration parameters, the user can append `--` followed by a command to start a .NET application with at least a 5.0 runtime. `dotnet-counters` will launch a process with the provided command and monitor the requested metrics. This is often useful to collect metrics for the application's startup path and can be used to diagnose or monitor issues that happen early before or shortly after the main entrypoint.

NOTE

Using this option monitors the first .NET 5 process that communicates back to the tool, which means if your command launches multiple .NET applications, it will only collect the first app. Therefore, it is recommended you use this option on self-contained applications, or using the `dotnet exec <app.dll>` option.

NOTE

Launching a .NET executable via `dotnet-counters` will make its input/output to be redirected and you won't be able to interact with its `stdin/stdout`. Exiting the tool via `CTRL+C` or `SIGTERM` will safely end both the tool and the child process. If the child process exits before the tool, the tool will exit as well. If you need to use `stdin/stdout`, you can use the `--diagnostic-port` option. See [Using diagnostic port](#) for more information.

NOTE

On Linux and macOS, this command expects the target application and `dotnet-counters` to share the same `TMPDIR` environment variable.

NOTE

To monitor metrics using `dotnet-counters`, it needs to be run as the same user as the user running target process or as root.

NOTE

If you see an error message similar to the following one:

```
[ERROR] System.ComponentModel.Win32Exception (299): A 32 bit processes cannot access modules of a 64 bit process.
```

, you are trying to use `dotnet-counters` that has mismatched bitness against the target process. Make sure to download the correct bitness of the tool in the [install](#) link.

Examples

- Monitor all counters from `System.Runtime` at a refresh interval of 3 seconds:

```
> dotnet-counters monitor --process-id 1902 --refresh-interval 3 --counters System.Runtime
Press p to pause, r to resume, q to quit.
Status: Running

[System.Runtime]
% Time in GC since last GC (%) 0
Allocation Rate (B / 1 sec) 5,376
CPU Usage (%) 0
Exception Count (Count / 1 sec) 0
GC Fragmentation (%) 48.467
GC Heap Size (MB) 0
Gen 0 GC Count (Count / 1 sec) 1
Gen 0 Size (B) 24
Gen 1 GC Count (Count / 1 sec) 1
Gen 1 Size (B) 24
Gen 2 GC Count (Count / 1 sec) 1
Gen 2 Size (B) 272,000
IL Bytes Jitted (B) 19,449
LOH Size (B) 19,640
Monitor Lock Contention Count (Count / 1 sec) 0
Number of Active Timers 0
Number of Assemblies Loaded 7
Number of Methods Jitted 166
POH (Pinned Object Heap) Size (B) 24
ThreadPool Completed Work Item Count (Count / 1 sec) 0
ThreadPool Queue Length 0
ThreadPool Thread Count 2
Working Set (MB) 19
```

- Monitor just CPU usage and GC heap size from `System.Runtime`:

```
> dotnet-counters monitor --process-id 1902 --counters System.Runtime[cpu-usage,gc-heap-size]
Press p to pause, r to resume, q to quit.
Status: Running

[System.Runtime]
CPU Usage (%) 24
GC Heap Size (MB) 811
```

- Monitor `EventCounter` values from user-defined `EventSource`. For more information, see [Tutorial: Measure performance using EventCounters in .NET Core](#).

```
> dotnet-counters monitor --process-id 1902 --counters Samples-EventCounterDemos-Minimal
Press p to pause, r to resume, q to quit.
request 100
```

- View all well-known counters that are available in `dotnet-counters` :

```
> dotnet-counters list

Showing well-known counters for .NET (Core) version 3.1 only. Specific processes may support
additional counters.

System.Runtime
  cpu-usage                               The percent of process' CPU usage relative to all of the
  system CPU resources [0-100]
    working-set                            Amount of working set used by the process (MB)
    gc-heap-size                           Total heap size reported by the GC (MB)
    gen-0-gc-count                         Number of Gen 0 GCs between update intervals
    gen-1-gc-count                         Number of Gen 1 GCs between update intervals
    gen-2-gc-count                         Number of Gen 2 GCs between update intervals
    time-in-gc                             % time in GC since the last GC
    gen-0-size                             Gen 0 Heap Size
    gen-1-size                             Gen 1 Heap Size
    gen-2-size                             Gen 2 Heap Size
    loh-size                                LOH Size
    alloc-rate                             Number of bytes allocated in the managed heap between update
intervals
    assembly-count                          Number of Assemblies Loaded
    exception-count                        Number of Exceptions / sec
    threadpool-thread-count                Number of ThreadPool Threads
    monitor-lock-contention-count         Number of times there were contention when trying to take the
monitor lock between update intervals
    threadpool-queue-length                ThreadPool Work Items Queue Length
    threadpool-completed-items-count      ThreadPool Completed Work Items Count
    active-timer-count                    Number of timers that are currently active

Microsoft.AspNetCore.Hosting
  requests-per-second                     Number of requests between update intervals
  total-requests                          Total number of requests
  current-requests                        Current number of requests
  failed-requests                         Failed number of requests
```

- View all well-known counters that are available in `dotnet-counters` for .NET 5 apps:

```
> dotnet-counters list --runtime-version 5.0

Showing well-known counters for .NET (Core) version 5.0 only. Specific processes may support
additional counters.

System.Runtime
  cpu-usage                               The percent of process' CPU usage relative to all of the
  system CPU resources [0-100]
    working-set                            Amount of working set used by the process (MB)
    gc-heap-size                           Total heap size reported by the GC (MB)
    gen-0-gc-count                         Number of Gen 0 GCs between update intervals
    gen-1-gc-count                         Number of Gen 1 GCs between update intervals
    gen-2-gc-count                         Number of Gen 2 GCs between update intervals
    time-in-gc                             % time in GC since the last GC
    gen-0-size                            Gen 0 Heap Size
    gen-1-size                            Gen 1 Heap Size
    gen-2-size                            Gen 2 Heap Size
    loh-size                               LOH Size
    poh-size                               POH (Pinned Object Heap) Size
    alloc-rate                            Number of bytes allocated in the managed heap between update
    intervals
    gc-fragmentation                      GC Heap Fragmentation
    assembly-count                         Number of Assemblies Loaded
    exception-count                        Number of Exceptions / sec
    threadpool-thread-count                Number of ThreadPool Threads
    monitor-lock-contention-count          Number of times there were contention when trying to take the
    monitor lock between update intervals
    threadpool-queue-length                ThreadPool Work Items Queue Length
    threadpool-completed-items-count      ThreadPool Completed Work Items Count
    active-timer-count                     Number of timers that are currently active
    il-bytes-jitted                       Total IL bytes jitted

  connection-queue-length                Length of Kestrel Connection Queue
  request-queue-length                  Length total HTTP request queue

System.Net.Http
  requests-started                        Total Requests Started
  requests-started-rate                  Number of Requests Started between update intervals
  requests-aborted                        Total Requests Aborted
  requests-aborted-rate                  Number of Requests Aborted between update intervals
  current-requests                       Current Requests
```

- Launch `my-aspnet-server.exe` and monitor the # of assemblies loaded from its startup (.NET 5 or later only):

IMPORTANT

This works for apps running .NET 5 or later only.

```
> dotnet-counters monitor --counters System.Runtime[assembly-count] -- my-aspnet-server.exe

Press p to pause, r to resume, q to quit.
Status: Running

[System.Runtime]
Number of Assemblies Loaded 24
```

- Launch `my-aspnet-server.exe` with `arg1` and `arg2` as command-line arguments and monitor its working set and GC heap size from its startup (.NET 5 or later only):

IMPORTANT

This works for apps running .NET 5 or later only.

```
> dotnet-counters monitor --counters System.Runtime[working-set,gc-heap-size] -- my-aspnet-server.exe
arg1 arg2
```

```
Press p to pause, r to resume, q to quit.
Status: Running
```

[System.Runtime]	
GC Heap Size (MB)	39
Working Set (MB)	59

dotnet-counters ps

Lists the dotnet processes that can be monitored by `dotnet-counters`. `dotnet-counters` version 6.0.320703 and later, also display the command-line arguments that each process was started with, if available.

Synopsis

```
dotnet-counters ps [-h|--help]
```

Example

Suppose you start a long-running app using the command `dotnet run --configuration Release`. In another window, you run the `dotnet-counters ps` command. The output you'll see is as follows. The command-line arguments, if any, are shown in `dotnet-counters` version 6.0.320703 and later.

```
> dotnet-counters ps

21932 dotnet      C:\Program Files\dotnet\dotnet.exe    run --configuration Release
36656 dotnet      C:\Program Files\dotnet\dotnet.exe
```

Using diagnostic port

IMPORTANT

This works for apps running .NET 5 or later only.

[Diagnostic port](#) is a runtime feature added in .NET 5 that allows you to start monitoring or collecting counters

from app startup. To do this using `dotnet-counters`, you can either use `dotnet-counters <collect|monitor> -- <command>` as described in the examples above, or use the `--diagnostic-port` option.

Using `dotnet-counters <collect|monitor> -- <command>` to launch the application as a child process is the simplest way to quickly monitor it from its startup.

However, when you want to gain a finer control over the lifetime of the app being monitored (for example, monitor the app for the first 10 minutes only and continue executing) or if you need to interact with the app using the CLI, using `--diagnostic-port` option allows you to control both the target app being monitored and `dotnet-counters`.

1. The command below makes `dotnet-counters` create a diagnostics socket named `myport.sock` and wait for a connection.

```
dotnet-counters collect --diagnostic-port myport.sock
```

Output:

```
Waiting for connection on myport.sock
Start an application with the following environment variable:
DOTNET_DiagnosticPorts=/home/user/myport.sock
```

2. In a separate console, launch the target application with the environment variable `DOTNET_DiagnosticPorts` set to the value in the `dotnet-counters` output.

```
export DOTNET_DiagnosticPorts=/home/user/myport.sock
./my-dotnet-app arg1 arg2
```

This should then enable `dotnet-counters` to start collecting counters on `my-dotnet-app`:

```
Waiting for connection on myport.sock
Start an application with the following environment variable: DOTNET_DiagnosticPorts=myport.sock
Starting a counter session. Press Q to quit.
```

IMPORTANT

Launching your app with `dotnet run` can be problematic because the dotnet CLI may spawn many child processes that are not your app and they can connect to `dotnet-counters` before your app, leaving your app to be suspended at run time. It is recommended you directly use a self-contained version of the app or use `dotnet exec` to launch the application.

dotnet-coverage code coverage utility

9/20/2022 • 9 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

Synopsis

```
dotnet-coverage [-h, --help] [--version] <command>
```

Description

The `dotnet-coverage` tool:

- Enables the collection of code coverage data of a running process on Windows (x86, x64 and Arm64), Linux (x64) and macOS (x64).
- Provides cross-platform merging of code coverage reports.

Options

- `-h|--help`

Shows command-line help.

- `--version`

Displays the version of the `dotnet-coverage` utility.

Install

To install the latest release version of the `dotnet-coverage` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-coverage
```

Commands

COMMAND

[dotnet-coverage merge](#)

[dotnet-coverage collect](#)

[dotnet-coverage connect](#)

[dotnet-coverage snapshot](#)

[dotnet-coverage shutdown](#)

dotnet-coverage merge

The `merge` command is used to merge several code coverage reports into one. This command is available on all platforms. This command supports the following code coverage report formats:

- `coverage`
- `cobertura`
- `xml`

Synopsis

```
dotnet-coverage merge  
  [--remove-input-files] [-r|--recursive]  
  [-o|--output <output>] [-f|--output-format <output-format>]  
  [-l|--log-file <log-file>] [-ll|--log-level <log-level>] [-?|-h|--help]  
  <files>
```

Arguments

- `<files>`

The input code coverage reports.

Options

- `--remove-input-files`

Removes all input coverage reports that were merged.

- `-r, --recursive`

Search for coverage reports in subdirectories.

- `-o|--output <output>`

Sets the code coverage report output file.

- `-f|--output-format <output-format>`

The output file format. Supported values: `coverage`, `xml`, and `cobertura`. Default is `coverage` (binary format that can be opened in Visual Studio).

- `-l|--log-file <log-file>`

Sets the log file path. When you provide a directory (with a path separator at the end), a new log file is generated for each process under analysis.

- `-ll|--log-level <log-level>`

Sets the log level. Supported values: `Error`, `Info`, and `Verbose`.

dotnet-coverage collect

The `collect` command is used to collect code coverage data for any .NET process and its subprocesses. For example, you can collect code coverage data for a console application or a Blazor application. This command is available on Windows (x86, x64 and Arm64), Linux (x64), and macOS (x64). The command supports only .NET modules. Native modules are not supported.

Synopsis

The `collect` command can run in two modes.

Command Mode

The `collect` command will collect code coverage for the given process executed by the `command` argument.

```
dotnet-coverage collect  
[-s|--settings <settings>] [-id|--session-id <session-id>]  
[-o|--output <output>] [-f|--output-format <output-format>]  
[-l|--log-file <log-file>] [-ll|--log-level <log-level>] [-?|-h|--help]  
<command> <args>
```

Server Mode

The `collect` command hosts a server for code coverage collection. Clients can connect to the server via `connect` command.

```
dotnet-coverage collect  
[-s|--settings <settings>] [-id|--session-id <session-id>]  
[-sv|--server-mode] [-b|--background] [-t|--timeout]  
[-o|--output <output>] [-f|--output-format <output-format>]  
[-l|--log-file <log-file>] [-ll|--log-level <log-level>] [-?|-h|--help]
```

Arguments

- `<command>`

The command for which to collect code coverage data.

- `<args>`

The command line arguments for the command.

Options

- `-s|--settings <settings>`

Sets the path to the XML code coverage settings.

- `-id|--session-id <session-id>`

Specifies the code coverage session ID. If not provided, the tool will generate a random GUID.

- `-sv|--server-mode`

Starts the collector in server mode. Clients can connect to the server with the `connect` command.

- `-b|--background`

Starts code coverage collection server in a new background process. Clients can connect to the server with the `connect` command.

- `-t|--timeout`

Timeout (in milliseconds) for interprocess communication between clients and the server.

- `-o|--output <output>`

Sets the code coverage report output file.

- `-f|--output-format <output-format>`

The output file format. Supported values: `coverage`, `xml`, and `cobertura`. Default is `coverage` (binary format that can be opened in Visual Studio).

- `-l|--log-file <log-file>`

Sets the log file path. When you provide a directory (with a path separator at the end), a new log file is generated for each process under analysis.

- `-l1|--log-level <log-level>`

Sets the log level. Supported values: `Error`, `Info`, and `Verbose`.

dotnet-coverage connect

The `connect` command is used to connect with the existing server and collects code coverage data for any .NET process and its subprocesses. For example, you can collect code coverage data for a console application or a Blazor application. This command is available on Windows (x86, x64 and Arm64), Linux (x64), and macOS (x64). The command supports only .NET modules. Native modules are not supported.

Synopsis

```
dotnet-coverage connect
[-b|--background] [-t|--timeout]
[-l1|--log-file <log-file>] [-l1|--log-level <log-level>] [-?|-h|--help]
<session>
<command> <args>
```

Arguments

- `<session>`

The session ID of the server hosted by the `collect` command.

- `<command>`

The command for which to collect code coverage data.

- `<args>`

The command line arguments for the command.

Options

- `-b|--background`

Starts the client in a new background process.

- `-t|--timeout`

Timeout (in milliseconds) for interprocess communication between the client and the server.*

```
-l1|--log-file <log-file>
```

Sets the log file path. When you provide a directory (with a path separator at the end), a new log file is generated for each process under analysis.

- `-l1|--log-level <log-level>`

Sets the log level. Supported values: `Error`, `Info`, and `Verbose`.

dotnet-coverage snapshot

Creates a coverage file for existing code coverage collection.

Synopsis

```
dotnet-coverage snapshot
[-r|--reset] [-o|--output <output>] [-t|--timeout]
[-l1|--log-file <log-file>] [-l1|--log-level <log-level>] [-?|-h|--help]
<session>
```

Arguments

- `<session>`

The session ID of the collection for which a coverage file is to be generated.

Options

- `-r|--reset <reset>`

Clears existing coverage information after a coverage file is created.

- `-o|--output <output>`

Sets the code coverage report output file. If not provided, it's generated automatically with a timestamp.

- `-t|--timeout`

Timeout (in milliseconds) for interprocess communication between the client and the server.

- `-l|--log-file <log-file>`

Sets the log file path. When you provide a directory (with a path separator at the end), a new log file is generated for each process under analysis.

- `-ll|--log-level <log-level>`

Sets the log level. Supported values: `Error`, `Info`, and `Verbose`.

dotnet-coverage shutdown

Closes existing code coverage collection.

Synopsis

```
dotnet-coverage shutdown
[-t|--timeout]
[-l|--log-file <log-file>] [-ll|--log-level <log-level>] [-?|-h|--help]
<session>
```

Arguments

- `<session>`

The session ID of the collection to be closed.

Options

- `-t|--timeout`

Timeout (in milliseconds) for interprocess communication with the server.

- `-l|--log-file <log-file>`

Sets the log file path. When you provide a directory (with a path separator at the end), a new log file is generated for each process under analysis.

- `-ll|--log-level <log-level>`

Sets the log level. Supported values: `Error`, `Info`, and `Verbose`.

Sample scenarios

Collecting code coverage

Collect code coverage data for any .NET application (such as console or Blazor) by using the following command:

```
dotnet-coverage collect dotnet run
```

In case of an application that requires a signal to terminate, you can use **Ctrl+C**, which will still let you collect code coverage data. For the argument, you can provide any command that will eventually start a .NET app. For example, it can be a PowerShell script.

Sessions

When you're running code coverage analysis on a .NET server that just waits for messages and sends responses, you need a way to stop the server to get final code coverage results. You can use **Ctrl+C** locally, but not in Azure Pipelines. For these scenarios, you can use sessions. You can specify a session ID when starting collection, and then use the `shutdown` command to stop collection and the server.

For example, assume you have a server in the `D:\serverexample\server` directory and a test project in the `D:\serverexample\tests` directory. Tests are communicating with the server through the network. You can start code coverage collection for the server as follows:

```
D:\serverexample\server> dotnet-coverage collect --session-id serverdemo "dotnet run"
```

Session ID was specified as `serverdemo`. Then you can run tests as follows:

```
D:\serverexample\tests> dotnet test
```

A code coverage file for session `serverdemo` can be generated with current coverage as follows:

```
dotnet-coverage snapshot --output after_first_test.coverage serverdemo
```

Finally, session `serverdemo` and the server can be closed as follows:

```
dotnet-coverage shutdown serverdemo
```

Following is an example of full output on the server side:

```
D:\serverexample\server> dotnet-coverage collect --session-id serverdemo "dotnet run"
SessionId: serverdemo
Waiting for a connection... Connected!
Received: Hello!
Sent: HELLO!
Waiting for a connection... Code coverage results: output.coverage.
D:\serverexample\server>
```

Server and client mode

Code coverage collection can be done in server-client mode as well. In this scenario, a code coverage collection server starts, and multiple clients can connect with the server. Code coverage is collected for all the clients collectively.

Start the code coverage server using the following command:

```
dotnet-coverage collect --session-id serverdemo --server-mode
```

In this example, the session ID was specified as `serverdemo` for the server. A client can connect to the server using this session ID using the following command:

```
dotnet-coverage connect serverdemo dotnet run
```

Finally, you can close the session `serverdemo` and the server using the following command:

```
dotnet-coverage shutdown serverdemo
```

The server process creates a collective code coverage report for all clients and exits.

Following is an example of full output on the server side:

```
D:\serverexample\server> dotnet-coverage collect --session-id serverdemo --server-mode
SessionId: serverdemo
// Server will be in idle state and wait for connect and shutdown commands
Code coverage results: output.coverage.
D:\serverexample\server>
```

Following is an example of full output on the client side:

```
D:\serverexample\server> dotnet-coverage connect serverdemo ConsoleApplication.exe World
Hello World!
D:\serverexample\server> dotnet-coverage connect serverdemo WpfApplication.exe
D:\serverexample\server> dotnet-coverage shutdown serverdemo
D:\serverexample\server>
```

You can also start both server and client in background mode. Another process starts in the background and returns control back to the user.

Following is an example of full output in background server client mode:

```
D:\serverexample\server> dotnet-coverage collect --session-id serverdemo --server-mode --background
D:\serverexample\server> dotnet-coverage connect --background serverdemo ConsoleApplication.exe World
D:\serverexample\server> dotnet-coverage connect --background serverdemo WpfApplication.exe
D:\serverexample\server> dotnet-coverage shutdown serverdemo
D:\serverexample\server>
```

Settings

You can specify a file with settings when you use the `collect` command. The settings file can be used to exclude some modules or methods from code coverage analysis. The format is the same as the data collector configuration inside a *runsettings* file. For more information, see [Customize code coverage analysis](#). Here's an example:

```
<?xml version="1.0" encoding="utf-8"?>
<Configuration>
  <CodeCoverage>
    <!--
        Additional paths to search for .pdb (symbol) files. Symbols must be found for modules to be
        instrumented.
        If .pdb files are in the same folder as the .dll or .exe files, they are automatically found.
        Otherwise, specify them here.
        Note that searching for symbols increases code coverage run time. So keep this small and local
    </CodeCoverage>
  </Configuration>
</?xml>
```

```

NOTE THAT SEARCHING FOR SYMBOLS IN RELEASE CODE COVERAGE TAKES TIME. SO KEEP THIS SMALL AND LOCAL.
-->
<SymbolSearchPaths>
    <Path>C:\Users\User\Documents\Visual Studio 2012\Projects\ProjectX\bin\Debug</Path>
    <Path>..\mybuildshare\builds\ProjectX</Path>
</SymbolSearchPaths>

<!--
About include/exclude lists:
Empty "Include" clauses imply all; empty "Exclude" clauses imply none.
Each element in the list is a regular expression (ECMAScript syntax). See /visualstudio/ide/using-regular-expressions-in-visual-studio.
An item must first match at least one entry in the include list to be included.
Included items must then not match any entries in the exclude list to remain included.
-->

<!-- Match assembly file paths: -->
<ModulePaths>
    <Include>
        <ModulePath>.*\.dll$</ModulePath>
        <ModulePath>.*\.exe$</ModulePath>
    </Include>
    <Exclude>
        <ModulePath>.*CPPUnitTestFramework.*</ModulePath>
    </Exclude>
</ModulePaths>

<!-- Match fully qualified names of functions: -->
<!-- (Use "\." to delimit namespaces in C# or Visual Basic, ":" in C++) -->
<Functions>
    <Exclude>
        <Function>^Fabrikam\\UnitTest\..*</Function>
        <Function>^std::.*</Function>
        <Function>^ATL::.*</Function>
        <Function>.*::__GetTestMethodInfo.*</Function>
        <Function>^Microsoft::VisualStudio::CppCodeCoverageFramework::.*</Function>
        <Function>^Microsoft::VisualStudio::CppUnitTestFramework::.*</Function>
    </Exclude>
</Functions>

<!-- Match attributes on any code element: -->
<Attributes>
    <Exclude>
        <!-- Don't forget "Attribute" at the end of the name -->
        <Attribute>^System\.\Diagnostics\.\DebuggerHiddenAttribute$</Attribute>
        <Attribute>^System\.\Diagnostics\.\DebuggerNonUserCodeAttribute$</Attribute>
        <Attribute>^System\.\CodeDom\.\Compiler\.\GeneratedCodeAttribute$</Attribute>
        <Attribute>^System\.\Diagnostics\.\CodeAnalysis\.\ExcludeFromCodeCoverageAttribute$</Attribute>
    </Exclude>
</Attributes>

<!-- Match the path of the source files in which each method is defined: -->
<Sources>
    <Exclude>
        <Source>.*\\atlmfc\\.*</Source>
        <Source>.*\\vctools\\.*</Source>
        <Source>.*\\public\\sdk\\.*</Source>
        <Source>.*\\microsoft sdks\\.*</Source>
        <Source>.*\\vc\\include\\.*</Source>
    </Exclude>
</Sources>

<!-- Match the company name property in the assembly: -->
<CompanyNames>
    <Exclude>
        <CompanyName>.*microsoft.*</CompanyName>
    </Exclude>
</CompanyNames>

```

```
<!-- Match the public key token of a signed assembly: -->
<PublicKeyTokens>
    <!-- Exclude Visual Studio extensions: -->
    <Exclude>
        <PublicKeyToken>^B77A5C561934E089$</PublicKeyToken>
        <PublicKeyToken>^B03F5F7F11D50A3A$</PublicKeyToken>
        <PublicKeyToken>^31BF3856AD364E35$</PublicKeyToken>
        <PublicKeyToken>^89845DCD8080CC91$</PublicKeyToken>
        <PublicKeyToken>^71E9BCE111E9429C$</PublicKeyToken>
        <PublicKeyToken>^8F50407C4E9E73B6$</PublicKeyToken>
        <PublicKeyToken>^E361AF139669C375$</PublicKeyToken>
    </Exclude>
</PublicKeyTokens>

</CodeCoverage>
</Configuration>
```

Merge code coverage reports

You can merge `a.coverage` and `b.coverage` and store the data in `merged.coverage` as follows:

```
dotnet-coverage merge -o merged.coverage a.coverage b.coverage
```

For example, if you run a command like `dotnet test --collect "Code Coverage"`, the coverage report is stored into a folder that is named a random GUID. Such folders are hard to find and merge. Using this tool, you can merge all code coverage reports for all your projects as follows:

```
dotnet-coverage merge -o merged.cobertura.xml -f cobertura -r *.coverage
```

The preceding command merges all coverage reports from the current directory and all subdirectories and stores the result into a cobertura file. In Azure Pipelines, you can use [Publish Code Coverage Results task](#) to publish a merged cobertura report.

You can use the `merge` command to convert a code coverage report to another format. For example, the following command converts a binary code coverage report into XML format.

```
dotnet-coverage merge -o output.xml -f xml input.coverage
```

Dump collection and analysis utility (dotnet-dump)

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-dump` version 3.0.47001 and later versions

NOTE

`dotnet-dump` for macOS is only supported with .NET 5 and later versions.

Install

There are two ways to download and install `dotnet-dump`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-dump` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-dump
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

NOTE

To use `dotnet-dump` on an x86 app, you need a corresponding x86 version of the tool.

Synopsis

```
dotnet-dump [-h|--help] [--version] <command>
```

Description

The `dotnet-dump` global tool is a way to collect and analyze dumps on Windows, Linux, and macOS without any native debugger involved. This tool is important on platforms like Alpine Linux where a fully working `lldb` isn't available. The `dotnet-dump` tool allows you to run SOS commands to analyze crashes and the garbage collector (GC), but it isn't a native debugger so things like displaying native stack frames aren't supported.

Options

- `--version`

Displays the version of the dotnet-dump utility.

- `-h|--help`

Shows command-line help.

Commands

COMMAND

`dotnet-dump collect`

`dotnet-dump analyze`

`dotnet-dump ps`

dotnet-dump collect

Captures a dump from a process.

Synopsis

```
dotnet-dump collect [-h|--help] [-p|--process-id] [-n|--name] [--type] [-o|--output] [--diag]
```

Options

- `-h|--help`

Shows command-line help.

- `-p|--process-id <PID>`

Specifies the process ID number to collect a dump from.

- `-n|--name <name>`

Specifies the name of the process to collect a dump from.

- `--type <Full|Heap|Mini>`

Specifies the dump type, which determines the kinds of information that are collected from the process.

There are three types:

- `Full` - The largest dump containing all memory including the module images.
- `Heap` - A large and relatively comprehensive dump containing module lists, thread lists, all stacks, exception information, handle information, and all memory except for mapped images.
- `Mini` - A small dump containing module lists, thread lists, exception information, and all stacks.

If not specified, `Full` is the default.

- `-o|--output <output_dump_path>`

The full path and file name where the collected dump should be written.

If not specified:

- Defaults to `.\dump_YYYYMMDD_HHMMSS.dmp` on Windows.
 - Defaults to `./core_YYYYMMDD_HHMMSS` on Linux and macOS.
- YYYYMMDD is Year/Month/Day and HHMMSS is Hour/Minute/Second.

- `--diag`

Enables dump collection diagnostic logging.

- `--crashreport`

Enables crash report generation.

NOTE

On Linux and macOS, this command expects the target application and `dotnet-dump` to share the same `TMPDIR` environment variable. Otherwise, the command will time out.

NOTE

To collect a dump using `dotnet-dump`, it needs to be run as the same user as the user running target process or as root. Otherwise, the tool will fail to establish a connection with the target process.

dotnet-dump analyze

Starts an interactive shell to explore a dump. The shell accepts various [SOS commands](#).

Synopsis

```
dotnet-dump analyze <dump_path> [-h|--help] [-c|--command]
```

Arguments

- `<dump_path>`

Specifies the path to the dump file to analyze.

Options

- `-c|--command <debug_command>`

Specifies the `command` to run in the shell on start.

Analyze SOS commands

COMMAND	FUNCTION
<code>soshelp</code> or <code>help</code>	Displays all available commands
<code>soshelp <command></code> or <code>help <command></code>	Displays the specified command.
<code>exit</code> or <code>quit</code>	Exits interactive mode.
<code>clrstack <arguments></code>	Provides a stack trace of managed code only.
<code>clrthreads <arguments></code>	Lists the managed threads running.

COMMAND	FUNCTION
<code>dumpasync <arguments></code>	Displays information about async state machines on the garbage-collected heap.
<code>dumpassembly <arguments></code>	Displays details about the assembly at the specified address.
<code>dumpclass <arguments></code>	Displays information about the <code>EEClass</code> structure at the specified address.
<code>dumpdelegate <arguments></code>	Displays information about the delegate at the specified address.
<code>dumpdomain <arguments></code>	Displays information all the AppDomains and all assemblies within the specified domain.
<code>dumpheap <arguments></code>	Displays info about the garbage-collected heap and collection statistics about objects.
<code>dumpil <arguments></code>	Displays the Microsoft intermediate language (MSIL) that is associated with a managed method.
<code>dumplog <arguments></code>	Writes the contents of an in-memory stress log to the specified file.
<code>dumpmd <arguments></code>	Displays information about the <code>MethodDesc</code> structure at the specified address.
<code>dumpmodule <arguments></code>	Displays information about the module at the specified address.
<code>dumpmt <arguments></code>	Displays information about the <code>MethodTable</code> at the specified address.
<code>dumpobj <arguments></code>	Displays info about the object at the specified address.
<code>dso <arguments></code> or <code>dumpstackobjects <arguments></code>	Displays all managed objects found within the bounds of the current stack.
<code>eeheap <arguments></code>	Displays info about process memory consumed by internal runtime data structures.
<code>finalizequeue <arguments></code>	Displays all objects registered for finalization.
<code>gcroot <arguments></code>	Displays info about references (or roots) to the object at the specified address.
<code>gcwhere <arguments></code>	Displays the location in the GC heap of the argument passed in.
<code>ip2md <arguments></code>	Displays the <code>MethodDesc</code> structure at the specified address in JIT code.

COMMAND	FUNCTION
<code>histclear <arguments></code>	Releases any resources used by the family of <code>hist*</code> commands.
<code>histinit <arguments></code>	Initializes the SOS structures from the stress log saved in the debugger.
<code>histobj <arguments></code>	Displays the garbage collection stress log relocations related to <code><arguments></code> .
<code>histobjfind <arguments></code>	Displays all the log entries that reference the object at the specified address.
<code>histroot <arguments></code>	Displays information related to both promotions and relocations of the specified root.
<code>lm</code> or <code>modules</code>	Displays the native modules in the process.
<code>name2ee <arguments></code>	Displays the <code>MethodTable</code> and <code>EEClass</code> structures for the <code><argument></code> .
<code>pe <arguments></code> or <code>printexception <arguments></code>	Displays any object derived from the <code>Exception</code> class for the <code><argument></code> .
<code>setsymbolserver <arguments></code>	Enables the symbol server support
<code>syncblk <arguments></code>	Displays the SyncBlock holder info.
<code>threads <threadid></code> or <code>setthread <threadid></code>	Sets or displays the current thread ID for the SOS commands.

NOTE

Additional details can be found in [SOS Debugging Extension for .NET](#).

dotnet-dump ps

Lists the dotnet processes that dumps can be collected from. `dotnet-dump` version 6.0.320703 and later versions also display the command-line arguments that each process was started with, if available.

Synopsis

```
dotnet-dump ps [-h|--help]
```

Example
