# Azure Hybrid Benefit for Windows Server

9/21/2022 • 5 minutes to read • [Edit Online](#)

For customers with Software Assurance, Azure Hybrid Benefit for Windows Server allows you to use your on-premises Windows Server licenses and run Windows virtual machines on Azure at a reduced cost. You can use Azure Hybrid Benefit for Windows Server to deploy new virtual machines with Windows OS. This article goes over the steps on how to deploy new VMs with Azure Hybrid Benefit for Windows Server and how you can update existing running VMs. For more information about Azure Hybrid Benefit for Windows Server licensing and cost savings, see the [Azure Hybrid Benefit for Windows Server licensing page](#).

Each 2-processor license or each set of 16-core licenses is entitled to two instances of up to 8 cores, or one instance of up to 16 cores. The Azure Hybrid Benefit for Standard Edition licenses can only be used once either on-premises or in Azure. Datacenter Edition benefits allow for simultaneous usage both on-premises and in Azure.

Using Azure Hybrid Benefit for Windows Server with any VMs running Windows Server OS are now supported in all regions, including VMs with additional software such as SQL Server or third-party marketplace software.

## Classic VMs

For classic VMs, only deploying new VM from on premises custom images is supported. To take advantage of the capabilities supported in this article, you must first migrate classic VMs to Resource Manager model.

### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

## Ways to use Azure Hybrid Benefit for Windows Server

There are few ways to use Windows virtual machines with the Azure Hybrid Benefit:

1. You can deploy VMs from one of the provided Windows Server images on the Azure Marketplace
2. You can upload a custom VM and deploy using a Resource Manager template or Azure PowerShell
3. You can toggle and convert existing VM between running with Azure Hybrid Benefit or pay on-demand cost for Windows Server
4. You can also apply Azure Hybrid Benefit for Windows Server on virtual machine scale set as well!

## Create a VM with Azure Hybrid Benefit for Windows Server

All Windows Server OS based images are supported for Azure Hybrid Benefit for Windows Server. You can use Azure platform support images or upload your own custom Windows Server images.

### Portal

To create a VM with Azure Hybrid Benefit for Windows Server, scroll to the bottom of the **Basics** tab during the creation process and under **Licensing** check the box to use an existing Windows Server license.

## PowerShell

```
New-AzVm ` 
    -ResourceGroupName "myResourceGroup" ` 
    -Name "myVM" ` 
    -Location "East US" ` 
    -ImageName "Win2016Datacenter" ` 
    -LicenseType "Windows_Server"
```

## CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --location eastus \
    --license-type Windows_Server
```

## Template

Within your Resource Manager templates, an additional parameter `licenseType` must be specified. You can read more about [authoring Azure Resource Manager templates](#).

```
"properties": { 
    "licenseType": "Windows_Server", 
    "hardwareProfile": { 
        "vmSize": "[variables('vmSize')]" 
    } 
}
```

# Convert an existing VM using Azure Hybrid Benefit for Windows Server

If you have an existing VM that you would like to convert to take advantage of Azure Hybrid Benefit for Windows Server, you can update your VM's license type by following the instructions below.

### NOTE

Changing the license type on the VM does not cause the system to reboot or cause a service interruption. It is simply an update to a metadata flag.

## Portal

From portal VM blade, you can update the VM to use Azure Hybrid Benefit by selecting "Configuration" option and toggle the "Azure hybrid benefit" option

## PowerShell

- Convert existing Windows Server VMs to Azure Hybrid Benefit for Windows Server

```
$vm = Get-AzVM -ResourceGroup "rg-name" -Name "vm-name"
$vm.LicenseType = "Windows_Server"
Update-AzVM -ResourceGroupName rg-name -VM $vm
```

- Convert Windows Server VMs with benefit back to pay-as-you-go

```
$vm = Get-AzVM -ResourceGroup "rg-name" -Name "vm-name"  
$vm.LicenseType = "None"  
Update-AzVM -ResourceGroupName rg-name -VM $vm
```

## CLI

- Convert existing Windows Server VMs to Azure Hybrid Benefit for Windows Server

```
az vm update --resource-group myResourceGroup --name myVM --set licenseType=Windows_Server
```

## How to verify your VM is utilizing the licensing benefit

Once you've deployed your VM through either PowerShell, Resource Manager template or portal, you can verify the setting in the following methods.

### Portal

From portal VM blade, you can view the toggle for Azure Hybrid Benefit for Windows Server by selecting "Configuration" tab.

### PowerShell

The following example shows the license type for a single VM

```
Get-AzVM -ResourceGroup "myResourceGroup" -Name "myVM"
```

Output:

```
Type : Microsoft.Compute/virtualMachines  
Location : westus  
LicenseType : Windows_Server
```

This output contrasts with the following VM deployed without Azure Hybrid Benefit for Windows Server licensing:

```
Type : Microsoft.Compute/virtualMachines  
Location : westus  
LicenseType :
```

## CLI

```
az vm get-instance-view -g MyResourceGroup -n MyVM --query "[?licenseType=='Windows_Server']" -o table
```

### NOTE

Changing the license type on the VM does not cause the system to reboot or cause a service interruption. It is a metadata licensing flag only.

## List all VMs and virtual machine scale sets with Azure Hybrid Benefit for Windows Server in a subscription

To see and count all virtual machines and virtual machine scale sets deployed with Azure Hybrid Benefit for Windows Server, you can run the following command from your subscription:

## Portal

From the Virtual Machine or Virtual machine scale sets resource blade, you can view a list of all your VM(s) and licensing type by configuring the table column to include "OS licensing benefit". The VM setting can either be in **Azure Hybrid Benefit for Windows**, **Not enabled**, or **Windows client with multi-tenant hosting** state.

## PowerShell

For virtual machines:

```
Get-AzVM | ?{$_.LicenseType -like "Windows_Server"} | select ResourceGroupName, Name, LicenseType
```

For virtual machine scale sets:

```
Get-AzVmss | Select * -ExpandProperty VirtualMachineProfile | ? LicenseType -eq 'Windows_Server' | select ResourceGroupName, Name, LicenseType
```

## CLI

For virtual machines:

```
az vm list --query "[?licenseType=='Windows_Server']" -o table
```

For virtual machine scale sets:

```
az vmss list --query "[?virtualMachineProfile.licenseType=='Windows_Server']" -o table
```

## Deploy a Virtual Machine Scale Set with Azure Hybrid Benefit for Windows Server

Within your virtual machine scale set Resource Manager templates, an additional parameter `licenseType` must be specified within your `VirtualMachineProfile` property. You can do this during create or update for your scale set through ARM template, PowerShell, Azure CLI or REST.

The following example uses ARM template with a Windows Server 2016 Datacenter image:

```
"virtualMachineProfile": {
    "storageProfile": {
        "osDisk": {
            "createOption": "FromImage"
        },
        "imageReference": {
            "publisher": "MicrosoftWindowsServer",
            "offer": "WindowsServer",
            "sku": "2016-Datacenter",
            "version": "latest"
        }
    },
    "licenseType": "Windows_Server",
    "osProfile": {
        "computerNamePrefix": "[parameters('vmssName')]",
        "adminUsername": "[parameters('adminUsername')]",
        "adminPassword": "[parameters('adminPassword')]"
    }
}
```

You can also learn more about how to [Modify a virtual machine scale set](#) for more ways to update your scale set.

# What are Azure Reservations?

9/21/2022 • 6 minutes to read • [Edit Online](#)

Azure Reservations help you save money by committing to one-year or three-year plans for multiple products. Committing allows you to get a discount on the resources you use. Reservations can significantly reduce your resource costs by up to 72% from pay-as-you-go prices. Reservations provide a billing discount and don't affect the runtime state of your resources. After you purchase a reservation, the discount automatically applies to matching resources.

You can pay for a reservation up front or monthly. The total cost of up-front and monthly reservations is the same and you don't pay any extra fees when you choose to pay monthly. Monthly payment is available for Azure reservations, not third-party products.

You can buy a reservation in the [Azure portal](#).

## Why buy a reservation?

If you have consistent resource usage that supports reservations, buying a reservation gives you the option to reduce your costs. For example, when you continuously run instances of a service without a reservation, you're charged at pay-as-you-go rates. When you buy a reservation, you immediately get the reservation discount. The resources are no longer charged at the pay-as-you-go rates.

## How reservation discount is applied

After purchase, the reservation discount automatically applies to the resource usage that matches the attributes you select when you buy the reservation. Attributes include the SKU, regions (where applicable), and scope. Reservation scope selects where the reservation savings apply.

For more information about how discount is applied, see [Reserved instance discount application](#).

For more information about how reservation scope works, see [Scope reservations](#).

## Determine what to purchase

All reservations, except Azure Databricks, are applied on an hourly basis. Consider reservation purchases based on your consistent base usage. You can determine which reservation to purchase by analyzing your usage data or by using reservation recommendations. Recommendations are available in:

- Azure Advisor (VMs only)
- Reservation purchase experience in the Azure portal
- Cost Management Power BI app
- APIs

For more information, see [Determine what reservation to purchase](#)

## Buying a reservation

You can purchase reservations from the Azure portal, APIs, PowerShell, and CLI.

Go to the [Azure portal](#) to make a purchase.

For more information, see [Buy a reservation](#).

## How is a reservation billed?

The reservation is charged to the payment method tied to the subscription. The reservation cost is deducted from your Azure Prepayment (previously called monetary commitment) balance, if available. When your Azure Prepayment balance doesn't cover the cost of the reservation, you're billed the overage. If you have a subscription from an individual plan with pay-as-you-go rates, the credit card you have on your account is billed immediately for up-front purchases. Monthly payments appear on your invoice and your credit card is charged monthly. When you're billed by invoice, you see the charges on your next invoice.

## Who can manage a reservation by default

By default, the following users can view and manage reservations:

- The person who buys a reservation and the account administrator of the billing subscription used to buy the reservation are added to the reservation order.
- Enterprise Agreement and Microsoft Customer Agreement billing administrators.

To allow other people to manage reservations, see [Manage Reservations for Azure resources](#).

## Get reservation details and utilization after purchase

If you have permission to view to the reservation, you can see it and its use in the Azure portal. You can get the data using APIs, as well.

For more information on how to see reservations in Azure portal, see [View reservations in the Azure portal](#)

## Manage reservations after purchase

After you buy an Azure reservation, you can update the scope to apply reservation to a different subscription, change who can manage the reservation, split a reservation into smaller parts, or change instance size flexibility.

For more information, see [Manage Reservations for Azure resources](#)

## Flexibility with Azure reservations

Azure Reservations provide flexibility to help meet your evolving needs. You can exchange a reservation for another reservation of the same type. You can also refund a reservation, up to \$50,000 USD in a 12 month rolling window, if you no longer need it. The maximum limit of the refund applies to all reservations in the scope of your agreement with Microsoft.

For more information, see [Self-service exchanges and refunds for Azure Reservations](#)

## Charges covered by reservation

- **Reserved Virtual Machine Instance** - A reservation only covers the virtual machine and cloud services compute costs. It doesn't cover additional software, Windows, networking, or storage charges.
- **Azure Storage reserved capacity** - A reservation covers storage capacity for standard storage accounts for Blob storage or Azure Data Lake Gen2 storage. The reservation doesn't cover bandwidth or transaction rates.
- **Azure Cosmos DB reserved capacity** - A reservation covers throughput provisioned for your resources. It doesn't cover the storage and networking charges.
- **Azure Data Factory data flows** - A reservation covers integration runtime cost for the compute type and number of cores that you buy.
- **SQL Database reserved vCore** - Covers both SQL Managed Instance and SQL Database Elastic Pool/single database. Only the compute costs are included with a reservation. The SQL license is billed

separately.

- **Azure Synapse Analytics** - A reservation covers cDWU usage. It doesn't cover storage or networking charges associated with the Azure Synapse Analytics usage.
- **Azure Databricks** - A reservation covers only the DBU usage. Other charges, such as compute, storage, and networking, are applied separately.
- **App Service stamp fee** - A reservation covers stamp usage. It doesn't apply to workers, so any other resources associated with the stamp are charged separately.
- **Azure Database for MySQL** - Only the compute costs are included with a reservation. A reservation doesn't cover software, networking, or storage charges associated with the MySQL Database server.
- **Azure Database for PostgreSQL** - Only the compute costs are included with a reservation. A reservation doesn't cover software, networking, or storage charges associated with the PostgreSQL Database servers.
- **Azure Database for MariaDB** - Only the compute costs are included with a reservation. A reservation doesn't cover software, networking, or storage charges associated with the MariaDB Database server.
- **Azure Data Explorer** - A reservation covers the markup charges. A reservation doesn't apply to compute, networking, or storage charges associated with the clusters.
- **Azure Cache for Redis** - Only the compute costs are included with a reservation. A reservation doesn't cover networking or storage charges associated with the Redis cache instances.
- **Azure Dedicated Host** - Only the compute costs are included with the Dedicated host.
- **Azure Disk Storage reservations** - A reservation only covers premium SSDs of P30 size or greater. It doesn't cover any other disk types or sizes smaller than P30.
- **Azure Backup Storage reserved capacity** - A capacity reservation lowers storage costs of backup data in a Recovery Services Vault.

Software plans:

- **SUSE Linux** - A reservation covers the software plan costs. The discounts apply only to SUSE meters and not to the virtual machine usage.
- **Red Hat Plans** - A reservation covers the software plan costs. The discounts apply only to RedHat meters and not to the virtual machine usage.
- **Azure VMware Solution by CloudSimple** - A reservation covers the VMware CloudSimple Nodes. Additional software costs still apply.
- **Azure Red Hat OpenShift** - A reservation applies to the OpenShift costs, not to Azure infrastructure costs.

For Windows virtual machines and SQL Database, the reservation discount doesn't apply to the software costs. You can cover the licensing costs with [Azure Hybrid Benefit](#).

# Save costs with Azure Reserved VM Instances

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

When you commit to an Azure reserved VM instance you can save money. The reservation discount is applied automatically to the number of running virtual machines that match the reservation scope and attributes. You don't need to assign a reservation to a virtual machine to get the discounts. A reserved instance purchase covers only the compute part of your VM usage. For Windows VMs, the usage meter is split into two separate meters. There's a compute meter, which is same as the Linux meter, and a Windows IP meter. The charges that you see when you make the purchase are only for the compute costs. Charges don't include Windows software costs. For more information about software costs, see [Software costs not included with Azure Reserved VM Instances](#).

## Determine the right VM size before you buy

Before you buy a reservation, you should determine the size of the VM that you need. The following sections will help you determine the right VM size.

### Use reservation recommendations

You can use reservation recommendations to help determine the reservations you should purchase.

- Purchase recommendations and recommended quantities are shown when you purchase a VM reserved instance in the Azure portal.
- Azure Advisor provides purchase recommendations for individual subscriptions.
- You can use the APIs to get purchase recommendations for both shared scope and single subscription scope. For more information, see [Reserved instance purchase recommendation APIs for enterprise customers](#).
- For Enterprise Agreement (EA) and Microsoft Customer Agreement (MCA) customers, purchase recommendations for shared and single subscription scopes are available with the [Azure Consumption Insights Power BI content pack](#).

### Services that get VM reservation discounts

Your VM reservations can apply to VM usage emitted from multiple services - not just for your VM deployments. Resources that get reservation discounts change depending on the instance size flexibility setting.

#### Instance size flexibility setting

The instance size flexibility setting determines which services get the reserved instance discounts.

Whether the setting is on or off, reservation discounts automatically apply to any matching VM usage when the *ConsumedService* is `Microsoft.Compute`. So, check your usage data for the *ConsumedService* value. Some examples include:

- Virtual machines
- Virtual machine scale sets
- Container service
- Azure Batch deployments (in user subscriptions mode)
- Azure Kubernetes Service (AKS)
- Service Fabric

When the setting is on, reservation discounts automatically apply to matching VM usage when the *ConsumedService* is any of the following items:

- Microsoft.Compute
- Microsoft.ClassicCompute
- Microsoft.Batch
- Microsoft.MachineLearningServices
- Microsoft.Kusto

Check the *ConsumedService* value in your usage data to determine if the usage is eligible for reservation discounts.

For more information about instance size flexibility, see [Virtual machine size flexibility with Reserved VM Instances](#).

### Analyze your usage information

Analyze your usage information to help determine which reservations you should purchase. Usage data is available in the usage file and APIs. Use them together to determine which reservation to purchase. Check for VM instances that have high usage on daily basis to determine the quantity of reservations to purchase. Avoid the `Meter` subcategory and `Product` fields in usage data. They don't distinguish between VM sizes that use premium storage. If you use these fields to determine the VM size for reservation purchase, you may buy the wrong size. Then you won't get the reservation discount you expect. Instead, refer to the `AdditionalInfo` field in your usage file or usage API to determine the correct VM size.

Your usage file shows your charges by billing period and daily usage. For information about downloading your usage file, see [View and download your Azure usage and charges](#). Then, by using the usage file information, you can [determine what reservation to purchase](#).

### Purchase restriction considerations

Reserved VM Instances are available for most VM sizes with some exceptions. Reservation discounts don't apply for the following VMs:

- **VM series** - A-series, Av2-series, or G-series.
- **Preview or Promo VMs** - Any VM-series or size that is in preview or uses promotional meter.
- **Clouds** - Reservations aren't available for purchase in Germany or China regions.
- **Insufficient quota** - A reservation that is scoped to a single subscription must have vCPU quota available in the subscription for the new RI. For example, if the target subscription has a quota limit of 10 vCPUs for D-Series, then you can't buy a reservation for 11 Standard\_D1 instances. The quota check for reservations includes the VMs already deployed in the subscription. For example, if the subscription has a quota of 10 vCPUs for D-Series and has two standard\_D1 instances deployed, then you can buy a reservation for 10 standard\_D1 instances in this subscription. You can [create quote increase request](#) to resolve this issue.
- **Capacity restrictions** - In rare circumstances, Azure limits the purchase of new reservations for subset of VM sizes, because of low capacity in a region.

## Buy a Reserved VM Instance

You can buy a reserved VM instance in the [Azure portal](#). Pay for the reservation [up front or with monthly payments](#). These requirements apply to buying a reserved VM instance:

- You must be in an Owner role for at least one EA subscription or a subscription with a pay-as-you-go rate.
- For EA subscriptions, the **Add Reserved Instances** option must be enabled in the [EA portal](#). Or, if that setting is disabled, you must be an EA Admin for the subscription.
- For the Cloud Solution Provider (CSP) program, only the admin agents or sales agents can buy reservations.

To buy an instance:

1. Sign in to the [Azure portal](#).
2. Select **All services > Reservations**.
3. Select **Add** to purchase a new reservation and then click **Virtual machine**.
4. Enter required fields. Running VM instances that match the attributes you select qualify to get the reservation discount. The actual number of your VM instances that get the discount depend on the scope and quantity selected.

If you have an EA agreement, you can use the **Add more option** to quickly add additional instances. The option isn't available for other subscription types.

FIELD	DESCRIPTION
Subscription	The subscription used to pay for the reservation. The payment method on the subscription is charged the costs for the reservation. The subscription type must be an enterprise agreement (offer numbers: MS-AZR-0017P or MS-AZR-0148P) or Microsoft Customer Agreement or an individual subscription with pay-as-you-go rates (offer numbers: MS-AZR-0003P or MS-AZR-0023P). The charges are deducted from the Azure Prepayment (previously called monetary commitment) balance, if available, or charged as overage. For a subscription with pay-as-you-go rates, the charges are billed to the credit card or invoice payment method on the subscription.
Scope	The reservation's scope can cover one subscription or multiple subscriptions (shared scope). If you select: <ul style="list-style-type: none"><li>• <b>Single resource group scope</b> — Applies the reservation discount to the matching resources in the selected resource group only.</li><li>• <b>Single subscription scope</b> — Applies the reservation discount to the matching resources in the selected subscription.</li><li>• <b>Shared scope</b> — Applies the reservation discount to matching resources in eligible subscriptions that are in the billing context. For EA customers, the billing context is the enrollment. For individual subscriptions with pay-as-you-go rates, the billing scope is all eligible subscriptions created by the account administrator.</li><li>• <b>Management group</b> - Applies the reservation discount to the matching resource in the list of subscriptions that are a part of both the management group and billing scope.</li></ul>
Region	The Azure region that's covered by the reservation.
VM Size	The size of the VM instances.

FIELD	DESCRIPTION
Optimize for	VM instance size flexibility is selected by default. Click <b>Advanced settings</b> to change the instance size flexibility value to apply the reservation discount to other VMs in the same <a href="#">VM size group</a> . Capacity priority prioritizes data center capacity for your deployments. It offers additional confidence in your ability to launch the VM instances when you need them. Capacity priority is only available when the reservation scope is single subscription.
Term	One year or three years. There's also a 5-year term available only for HBv2 VMs.
Quantity	The number of instances being purchased within the reservation. The quantity is the number of running VM instances that can get the billing discount. For example, if you are running 10 Standard_D2 VMs in the East US, then you would specify quantity as 10 to maximize the benefit for all running VMs.

## Usage data and reservation utilization

Your usage data has an effective price of zero for the usage that gets a reservation discount. You can see which VM instance received the reservation discount for each reservation.

For more information about how reservation discounts appear in usage data, see [Understand Azure reservation usage for your Enterprise enrollment](#) if you are an EA customer. If you have an individual subscription, see [Understand Azure reservation usage for your Pay-As-You-Go subscription](#).

## Change a reservation after purchase

You can make the following types of changes to a reservation after purchase:

- Update reservation scope
- Instance size flexibility (if applicable)
- Ownership

You can also split a reservation into smaller chunks and merge already split reservations. None of the changes cause a new commercial transaction or change the end date of the reservation.

You can't make the following types of changes after purchase, directly:

- An existing reservation's region
- SKU
- Quantity
- Duration

However, you can *exchange* a reservation if you want to make changes.

## Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations with certain limitations. For more information, see [Self-service exchanges and refunds for Azure Reservations](#).

## Need help? Contact us.

If you have questions or need help, [create a support request](#).

# Save costs with Azure Dedicated Host reservations

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

When you commit to a reserved instance of Azure Dedicated Hosts, you can save money. The reservation discount is applied automatically to the number of running dedicated hosts that match the reservation scope and attributes. You don't need to assign a reservation to a dedicated host to get the discounts. A reserved instance purchase covers only the compute part of your usage and does include software licensing costs. See the [Overview of Azure Dedicated Hosts for virtual machines](#).

## Determine the right dedicated host SKU before you buy

Before you buy a reservation, you should determine which dedicated host you need. A SKU is defined for a dedicated host representing the VM series and type.

Start by going over the supported sizes for [Windows virtual machine](#) or [Linux](#) to identify the VM series.

Next, check whether it is supported on Azure Dedicated Hosts. [Azure Dedicated Hosts pricing](#) page has the complete list of dedicated hosts SKUs, their CPU information, and various pricing options (including reserved instances).

You may find several SKUs supporting your selected VM series (with different Types). Identify the best SKU by comparing the capacity of the host (number of vCPUs). Note that you will be able to apply your reservation to multiple dedicated hosts SKUs supporting the same VM series (for example DSv3\_Type1 and DSv3\_Type2) but not across different VM series (like DSv3 and ESv3).

## Purchase restriction considerations

Reserved instances are available for most dedicated host sizes, with some exceptions.

Reservation discounts don't apply for the following:

- **Clouds** - Reservations aren't available for purchase in Germany or China regions.
- **Insufficient quota** - A reservation that is scoped to a single subscription must have vCPU quota available in the subscription for the new reserved instance. For example, if the target subscription has a quota limit of 10 vCPUs for DSv3-Series, then you can't buy a reservation dedicated hosts supporting this series. The quota check for reservations includes the VMs and dedicated hosts already deployed in the subscription. You can [create quota increase request](#) to resolve this issue.
- **Capacity restrictions** - In rare circumstances, Azure limits the purchase of new reservations for subset of dedicated host SKUs, because of low capacity in a region.

## Buy a reservation

You can buy a reserved instance of an Azure Dedicated Host instance in the [Azure portal](#).

Pay for the reservation [up front or with monthly payments](#). These requirements apply to buying a reserved Dedicated Host instance:

- You must be in an Owner role for at least one EA subscription or a subscription with a pay-as-you-go rate.

- For EA subscriptions, the **Add Reserved Instances** option must be enabled in the [EA portal](#). Or, if that setting is disabled, you must be an EA Admin for the subscription.
- For the Cloud Solution Provider (CSP) program, only the admin agents or sales agents can buy reservations.

To buy an instance:

- Sign in to the [Azure portal](#).
- Select **All services > Reservations**.
- Select **Add** to purchase a new reservation and then click **Dedicated Hosts**.
- Enter required fields. Running Dedicated Hosts instances that match the attributes you select qualify to get the reservation discount. The actual number of your Dedicated Host instances that get the discount depend on the scope and quantity selected.

If you have an EA agreement, you can use the **Add more option** to quickly add additional instances. The option isn't available for other subscription types.

FIELD	DESCRIPTION
Subscription	The subscription used to pay for the reservation. The payment method on the subscription is charged the costs for the reservation. The subscription type must be an enterprise agreement (offer numbers: MS-AZR-0017P or MS-AZR-0148P) or Microsoft Customer Agreement or an individual subscription with pay-as-you-go rates (offer numbers: MS-AZR-0003P or MS-AZR-0023P). The charges are deducted from the Azure Prepayment (previously called monetary commitment) balance, if available, or charged as overage. For a subscription with pay-as-you-go rates, the charges are billed to the credit card or invoice payment method on the subscription.
Scope	The reservation's scope can cover one subscription or multiple subscriptions (shared scope). If you select:
Region	The Azure region that's covered by the reservation.
Dedicated Host Size	The size of the Dedicated Host instances.
Term	One year or three years.
Quantity	The number of instances being purchased within the reservation. The quantity is the number of running Dedicated Host instances that can get the billing discount.

- Single resource group scope** — Applies the reservation discount to the matching resources in the selected resource group only.
- Single subscription scope** — Applies the reservation discount to the matching resources in the selected subscription.
- Shared scope** — Applies the reservation discount to matching resources in eligible subscriptions that are in the billing context. For EA customers, the billing context is the enrollment. For individual subscriptions with pay-as-you-go rates, the billing scope is all eligible subscriptions created by the account administrator.

- **Management group** — Applies the reservation discount to the matching resource in the list of subscriptions that are a part of both the management group and billing scope.

## Usage data and reservation utilization

Your usage data has an effective price of zero for the usage that gets a reservation discount. You can see which VM instance received the reservation discount for each reservation.

For more information about how reservation discounts appear in usage data, see [Understand Azure reservation usage for your Enterprise enrollment](#) if you are an EA customer. If you have an individual subscription, see [Understand Azure reservation usage for your Pay-As-You-Go subscription](#).

## Change a reservation after purchase

You can make the following types of changes to a reservation after purchase:

- Update reservation scope
- Instance size flexibility (if applicable)
- Ownership

You can also split a reservation into smaller chunks and merge already split reservations. None of the changes cause a new commercial transaction or change the end date of the reservation.

You can't make the following types of changes after purchase, directly:

- An existing reservation's region
- SKU
- Quantity
- Duration

However, you can *exchange* a reservation if you want to make changes.

## Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations with certain limitations. For more information, see [Self-service exchanges and refunds for Azure Reservations](#).

## Need help? Contact us.

If you have questions or need help, [create a support request](#).

# Virtual machine size flexibility with Reserved VM Instances

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

When you buy a Reserved VM Instance, you can choose to optimize for instance size flexibility or capacity priority. For more information about setting or changing the optimize setting for reserved VM instances, see [Change the optimize setting for reserved VM instances](#).

With a reserved virtual machine instance that's optimized for instance size flexibility, the reservation you buy can apply to the virtual machines (VMs) sizes in the same instance size flexibility group. For example, if you buy a reservation for a VM size that's listed in the DSv2 Series, like Standard\_DS3\_v2, the reservation discount can apply to the other sizes that are listed in that same instance size flexibility group:

- Standard\_DS1\_v2
- Standard\_DS2\_v2
- Standard\_DS3\_v2
- Standard\_DS4\_v2

But that reservation discount doesn't apply to VMs sizes that are listed in different instance size flexibility groups, like SKUs in DSv2 Series High Memory: Standard\_DS11\_v2, Standard\_DS12\_v2, and so on.

Within the instance size flexibility group, the number of VMs the reservation discount applies to depends on the VM size you pick when you buy a reservation. It also depends on the sizes of the VMs that you have running. The ratio column compares the relative footprint for each VM size in that instance size flexibility group. Use the ratio value to calculate how the reservation discount applies to the VMs you have running.

## Examples

The following examples use the sizes and ratios in the DSv2-series table.

You buy a reserved VM instance with the size Standard\_DS4\_v2 where the ratio or relative footprint compared to the other sizes in that series is 8.

- Scenario 1: Run eight Standard\_DS1\_v2 sized VMs with a ratio of 1. Your reservation discount applies to all eight of those VMs.
- Scenario 2: Run two Standard\_DS2\_v2 sized VMs with a ratio of 2 each. Also run a Standard\_DS3\_v2 sized VM with a ratio of 4. The total footprint is  $2+2+4=8$ . So your reservation discount applies to all three of those VMs.
- Scenario 3: Run one Standard\_DS5\_v2 with a ratio of 16. Your reservation discount applies to half that VM's compute cost.
- Scenario 4: Run one Standard\_DS5\_v2 with a ratio of 16 and purchase an additional Standard\_DS4\_v2 reservation with a ratio of 8. Both reservations combine and apply the discount to entire VM.

The following sections show what sizes are in the same size series group when you buy a reserved VM instance optimized for instance size flexibility.

## Instance size flexibility ratio for VMs

CSV below has the instance size flexibility groups, ArmSkuName and the ratios.

## Instance size flexibility ratios

Azure keeps link and schema updated so that you can use the file programmatically.

## View VM size recommendations

Azure shows VM size recommendations in the purchase experience. To view the smallest size recommendations, select **Group by smallest size**.

### Select the product you want to purchase

X

Reserved VM Instances (RIs) provide a significant discount over pay-as-you-go VM prices by allowing you to pre-purchase the base costs of your VM usage for a period of 1 or 3 years. Reserved instance discount will automatically apply to matching VMs; you don't need to re-deploy resources to get reservation discount. The reservation applies only to hardware usage. Windows is charged separately. [Learn More](#)

# On-demand Capacity Reservation

9/21/2022 • 12 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale set ✓ Flexible scale sets

On-demand Capacity Reservation enables you to reserve Compute capacity in an Azure region or an Availability Zone for any duration of time. Unlike [Reserved Instances](#), you do not have to sign up for a 1-year or a 3-year term commitment. Create and delete reservations at any time and have full control over how you want to manage your reservations.

Once the Capacity Reservation is created, the capacity is available immediately and is exclusively reserved for your use until the reservation is deleted.

Capacity Reservation has some basic properties that are always defined at the time of creation:

- **VM size**- Each reservation is for one VM size. For example, `Standard_D2s_v3`.
- **Location**- Each reservation is for one location (region). If that location has availability zones, then the reservation can also specify one of the zones.
- **Quantity**- Each reservation has a quantity of instances to be reserved.

To create a Capacity Reservation, these parameters are passed to Azure as a capacity request. If the subscription lacks the required quota or Azure does not have capacity available that meets the specification, the reservation will fail to deploy. To avoid deployment failure, request more quota or try a different VM size, location, or zone combination.

Once Azure accepts a reservation request, it is available to be consumed by VMs of matching configurations. To consume Capacity Reservation, the VM will have to specify the reservation as one of its properties. Otherwise, the Capacity Reservation will remain unused. One benefit of this design is that you can target only critical workloads to reservations and other non-critical workloads can run without reserved capacity.

## Benefits of Capacity Reservation

- Once deployed, capacity is reserved for your use and always available within the scope of applicable SLAs
- Can be deployed and deleted at any time with no term commitment
- Can be combined automatically with Reserved Instances to use term commitment discounts

## SLA for Capacity Reservation

Please read the Service Level Agreement details in the [SLA for Capacity Reservation](#).

Any claim against the SLA requires calculating the Minutes Not Available for the reserved capacity. Here is an example of how to calculate Minutes Not Available.

- A On Demand Capacity Reservation has a total Capacity of 5 Reserved Units. The On Demand Capacity Reservation starts in the Unused Capacity state with 0 Virtual Machines Allocated.
- A Supported Deployment of quantity 5 is allocated to the On Demand Capacity Reservation. 3 Virtual Machines succeed and 2 fail with a Virtual Machine capacity error. Result: 2 Reserved Units begin to accumulate Minutes Not Available.
- No action is taken for 20 minutes. Result: two Reserved Units each accumulate 15 Minutes Not Available.
- At 20 minutes, a Supported Deployment of quantity 2 is attempted. One Virtual Machine succeeds, the other Virtual Machine fails with a Virtual Machine capacity error. Result: One Reserved Unit stays at 15

accumulated Minutes Not Available. Another Reserved Unit resumes accumulating Minutes Not Available.

- Four additional Supported Deployments of quantity 1 are made at 10 minute intervals. On the fourth attempt (60 minutes after the first capacity error), the Virtual Machine is deployed. Result: The last Reserved Unit adds 40 minutes of Minutes Not Available (4 attempts x 10 minutes between attempts) for a total of 55 Minutes Not Available.

From this example accumulation of Minutes Not Available, here is the calculation of Service Credit.

- One Reserved Unit accumulated 15 minutes of Downtime. The Percentage Uptime is 99.97%. This Reserved Unit does not qualify for Service Credit.
- Another Reserved Unit accumulated 55 minutes of Downtime. The Percentage Uptime is 99.87. This Reserved Unit qualifies for Service Credit of 10%.

## Limitations and restrictions

- Creating capacity reservations requires quota in the same manner as creating virtual machines.
- Creating capacity reservation is currently limited to certain VM Series and Sizes. The Compute Resource SKUs list advertises the set of supported VM Sizes.
- The following VM Series support creation of capacity reservations:
  - Av2
  - B
  - D series, v2 and newer; AMD and Intel
  - E series, all versions; AMD and Intel
  - F series, all versions
  - Lsv3 (Intel) and Lasv3 (AMD)
  - At VM deployment, Fault Domain (FD) count of up to 3 may be set as desired using Virtual Machine Scale Sets. A deployment with more than 3 FDs will fail to deploy against a Capacity Reservation.
- Support for additional VM Series isn't currently available:
  - Ls and Lsv2 series
  - M series, any version
  - NC-series, v3 and newer
  - NV-series, v2 and newer
  - ND-series
  - Hb-series
  - Hc-series
- The following deployment types are supported:
  - Single VM
  - Virtual Machine Scale Sets with Uniform Orchestration
  - Virtual Machine Scale Sets with Flexible Orchestration (preview)
- The following deployment types are not supported:
  - Spot VMs
  - Azure Dedicated Host Nodes or VMs deployed to Dedicated Hosts
  - Availability Sets
- Other deployment constraints are not supported. For example:
  - Proximity Placement Group
  - Update domains
  - Virtual Machine Scale Sets with single placement group set 'true'
  - UltraSSD storage
  - VMs resuming from hibernation

- VMs requiring vnet encryption
- Only the subscription that created the reservation can use it.
- Reservations are only available to paid Azure customers. Sponsored accounts such as Free Trial and Azure for Students are not eligible to use this feature.

## Pricing and billing

Capacity Reservations are priced at the same rate as the underlying VM size. For example, if you create a reservation for ten D2s\_v3 VMs then you will start getting billed for ten D2s\_v3 VMs, even if the reservation is not being used.

If you then deploy a D2s\_v3 VM and specify reservation property, the Capacity Reservation gets used. Once in use, you will only pay for the VM and nothing extra for the Capacity Reservation. Let's say you deploy six D2s\_v3 VMs against the previously mentioned Capacity Reservation. You will see a bill for six D2s\_v3 VMs and four unused Capacity Reservation, both charged at the same rate as a D2s\_v3 VM.

Both used and unused Capacity Reservation are eligible for Reserved Instances term commitment discounts. In the previous example, if you have Reserved Instances for two D2s\_v3 VMs in the same Azure region, the billing for two resources (either VM or unused Capacity Reservation) will be zeroed out. The remaining eight D2s\_v3 will be billed normally. The term commitment discounts could be applied on either the VM or the unused Capacity Reservation.

## Difference between On-demand Capacity Reservation and Reserved Instances

DIFFERENCES	ON-DEMAND CAPACITY RESERVATION	RESERVED INSTANCES
Term	No term commitment required. Can be created and deleted as per the customer requirement	Fixed term commitment of either one-year or three-years
Billing discount	Charged at pay-as-you-go rates for the underlying VM size*	Significant cost savings over pay-as-you-go rates
Capacity SLA	Provides capacity guarantee in the specified location (region or availability zone)	Does not provide a capacity guarantee. Customers can choose "capacity priority" to gain better access, but that option does not carry an SLA
Region vs Availability Zones	Can be deployed per region or per availability zone	Only available at regional level

\*Eligible for Reserved Instances discount if purchased separately

## Work with Capacity Reservation

Capacity Reservation is created for a specific VM size in an Azure region or an Availability Zone. All reservations are created and managed as part of a Capacity Reservation Group.

The group specifies the Azure location:

- The group sets the region in which all reservations will be created. For example, East US, North Europe, or Southeast Asia.
- The group sets the eligible zones. For example, AZ1, AZ2, AZ3 in any combination.
- If no zones are specified, Azure will select the placement for the group somewhere in the region. Each

reservation will specify the region and may not set a zone.

Each reservation in a group is for one VM size. If eligible zones were selected for the group, the reservation must be for one of the supported zones.

A group can have only one reservation per VM size per zone, or just one reservation per VM size if no zones are selected.

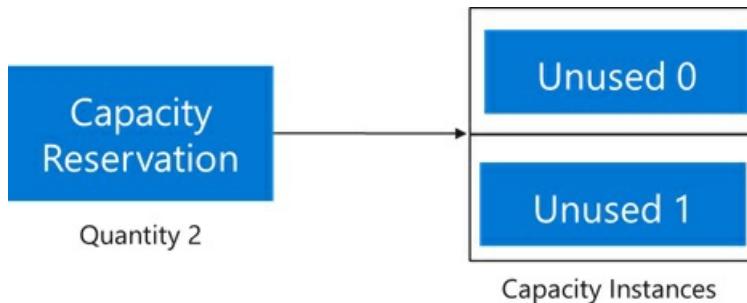

To consume Capacity Reservation, specify Capacity Reservation Group as one of the VM properties. If the group doesn't have a reservation matching the size and location, Azure will return an error message.

The quantity reserved for reservation can be adjusted after initial deployment by changing the capacity property. Other changes to Capacity Reservation, such as VM size or location, are not permitted. The recommended approach is to create a new reservation, migrate any existing VMs, and then delete the old reservation if no longer needed.

Capacity Reservation doesn't create limits on the number of VM deployments. Azure supports allocating as many VMs as desired against the reservation. As the reservation itself requires quota, the quota checks are omitted for VM deployment up to the reserved quantity. Allocating VMs beyond the reserved quantity is called overallocating the reservation. Overallocating VMs is not covered by the SLA and the VMs will be subject to quota checks and Azure fulfilling the extra capacity. Once deployed, these extra VM instances can cause the quantity of VMs allocated against the reservation to exceed the reserved quantity. To learn more, go to [Overallocating Capacity Reservation](#).

## Capacity Reservation lifecycle

When a reservation is created, Azure sets aside the requested number of capacity instances in the specified location:

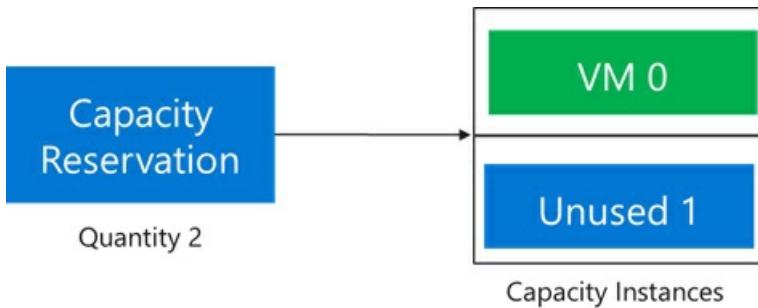

Track the state of the overall reservation through the following properties:

- `capacity` = Total quantity of instances reserved by the customer.
- `virtualMachinesAllocated` = List of VMs allocated against the Capacity Reservation and count towards consuming the capacity. These VMs are either *Running*, *Stopped (Allocated)*, or in a transitional state such as *Starting* or *Stopping*. This list doesn't include the VMs that are in deallocated state, referred to as *Stopped (deallocated)*.
- `virtualMachinesAssociated` = List of VMs associated with the Capacity Reservation. This list has all the VMs that have been configured to use the reservation, including the ones that are in deallocated state.

The previous example will start with `capacity` as 2 and length of `virtualMachinesAllocated` and `virtualMachinesAssociated` as 0.

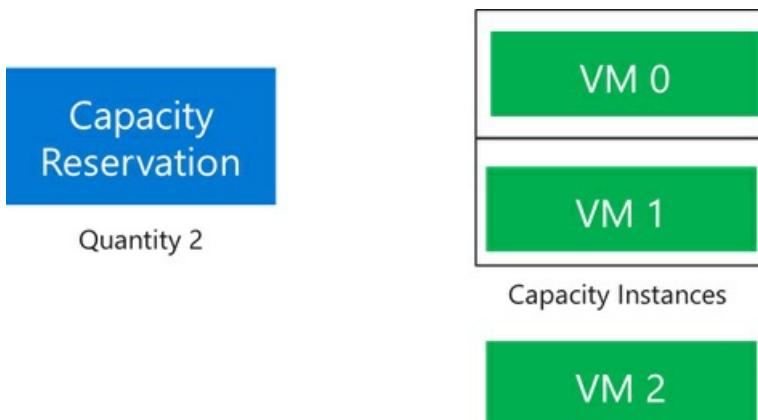

When a VM is then allocated against the Capacity Reservation, it will logically consume one of the reserved capacity instances:

The status of the Capacity Reservation will now show `capacity` as 2 and length of `virtualMachinesAllocated` and `virtualMachinesAssociated` as 1.

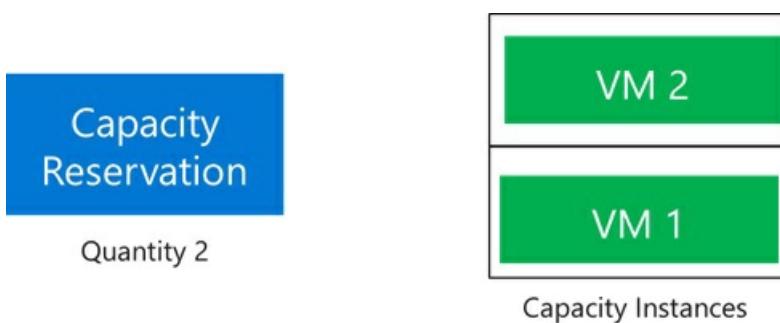

Allocations against the Capacity Reservation will succeed as long as the VMs have matching properties and there is at least one empty capacity instance.

Using our example, when a third VM is allocated against the Capacity Reservation, the reservation enters the [overallocated](#) state. This third VM will require unused quota and extra capacity fulfillment from Azure. Once the third VM is allocated, the Capacity Reservation now looks like this:

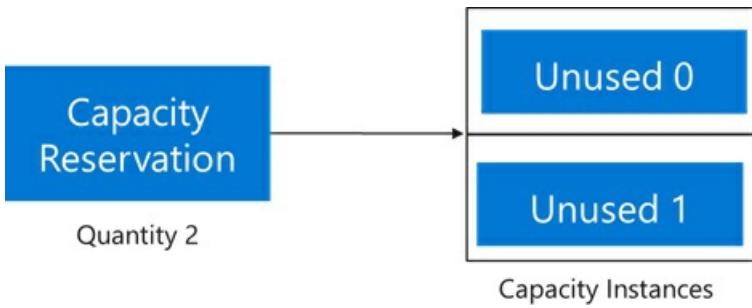

The `capacity` is 2 and the length of `virtualMachinesAllocated` and `virtualMachinesAssociated` is 3.

Now suppose the application scales down to the minimum of two VMs. Since VM 0 needs an update, it is chosen for deallocation. The reservation automatically shifts to this state:

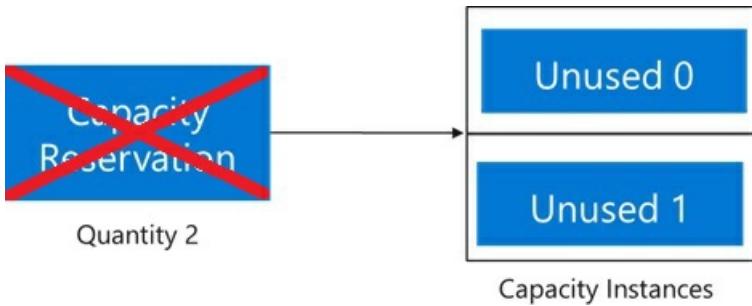

The `capacity` and the length of `virtualMachinesAllocated` are both 2. However, the length for `virtualMachinesAssociated` is still 3 as VM 0, though deallocated, is still associated with the Capacity Reservation. To prevent quota overrun, the deallocated VM 0 still counts against the quota allocated to the reservation. As long as you have enough unused quota, you can deploy new VMs to the Capacity Reservation and receive the SLA from any unused reserved capacity. Or you can delete VM 0 to remove its use of quota.

The Capacity Reservation will exist until explicitly deleted. To delete a Capacity Reservation, the first step is to dissociate all the VMs in the `virtualMachinesAssociated` property. Once disassociation is complete, the Capacity Reservation should look like this:

The status of the Capacity Reservation will now show `capacity` as 2 and length of `virtualMachinesAssociated` and `virtualMachinesAllocated` as 0. From this state, the Capacity Reservation can be deleted. Once deleted, you will not pay for the reservation anymore.

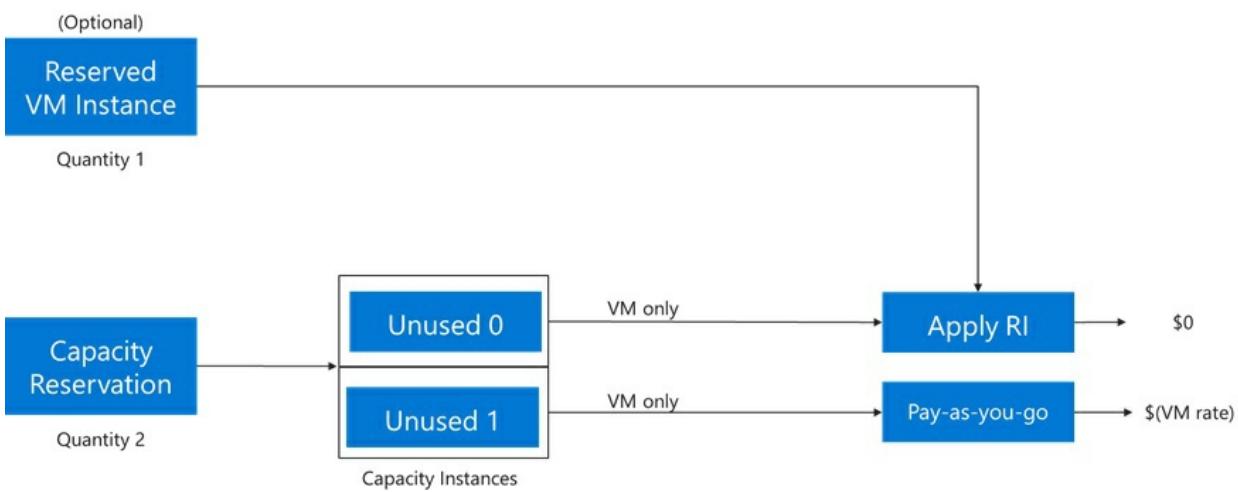

## Usage and billing

When a Capacity Reservation is empty, VM usage will be reported for the corresponding VM size and the location. [VM Reserved Instances](#) can cover some or all of the Capacity Reservation usage even when VMs are not deployed.

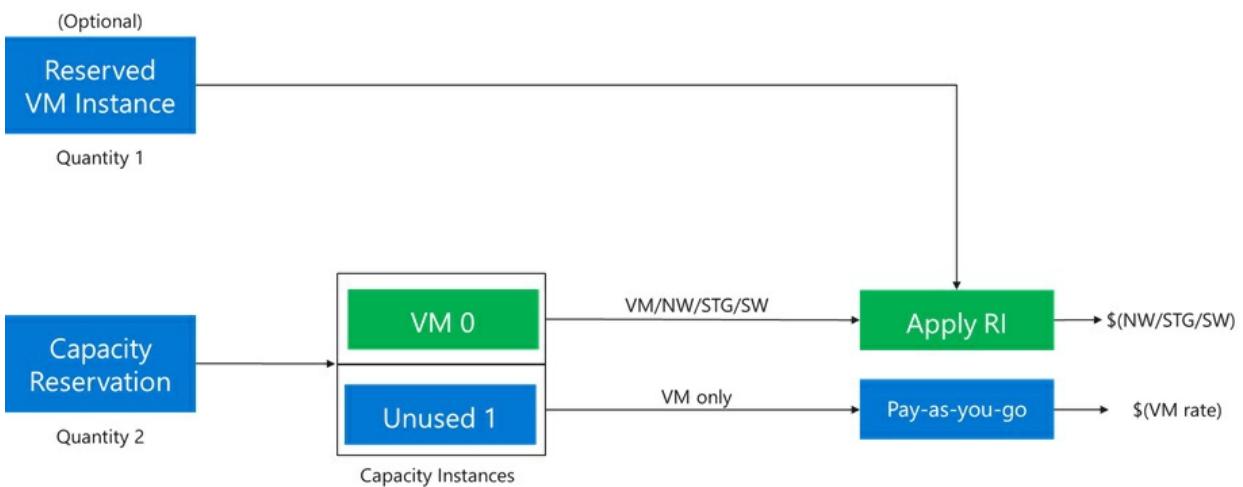

### Example

For example, let's say a Capacity Reservation with quantity reserved 2 has been created. The subscription has access to one matching Reserved VM Instance of the same size. The result is two usage streams for the Capacity Reservation, one of which is covered by the Reserved Instance:

In the previous image, a Reserved VM Instance discount is applied to one of the unused instances and the cost for that instance will be zeroed out. For the other instance, PAYG rate will be charged for the VM size reserved.

When a VM is allocated against the Capacity Reservation, the other VM components such as disks, network, extensions, and any other requested components must also be allocated. In this state, the VM usage will reflect one allocated VM and one unused capacity instance. The Reserved VM Instance will zero out the cost of either the VM or the unused capacity instance. The other charges for disks, networking, and other components associated with the allocated VM will also appear on the bill.

In the previous image, the VM Reserved Instance discount is applied to VM 0, which will only be charged for other components such as disk and networking. The other unused instance is being charged at PAYG rate for the VM size reserved.

## Frequently asked questions

- **What's the price of on-demand Capacity Reservation?**

The price of your on-demand Capacity Reservation is same as the price of underlying VM size associated with the reservation. When using Capacity Reservation, you will be charged for the VM size you selected at pay-as-you-go rates, whether the VM has been provisioned or not. Visit the [Windows](#) and [Linux](#) VM pricing pages for more details.

- **Will I get charged twice, for the cost of on-demand Capacity Reservation and for the actual VM when I finally provision it?**

No, you will only get charged once for on-demand Capacity Reservation.

- **Can I apply Reserved Virtual Machine Instance (RI) to on-demand Capacity Reservation to lower my costs?**

Yes, you can apply existing or future RIs to on-demand capacity reservations and receive RI discounts. Available RIs are applied automatically to Capacity Reservation the same way they are applied to VMs.

- **What is the difference between Reserved Virtual Machine Instance (RI) and on-demand Capacity Reservation?**

Both RIs and on-demand capacity reservations are applicable to Azure VMs. However, RIs provide discounted reservation rates for your VMs compared to pay-as-you-go rates as a result of a 1-year or 3-year term commitment. Conversely, on-demand capacity reservations do not require a commitment. You can create or cancel a Capacity Reservation at any time. However, no discounts are applied, and you will incur charges at pay-as-you-go rates after your Capacity Reservation has been successfully provisioned. Unlike RIs, which prioritize capacity but do not guarantee it, when you purchase an on-demand Capacity Reservation, Azure sets aside compute capacity for your VM and provides an SLA guarantee.

- **Which scenarios would benefit the most from on-demand capacity reservations?**

Typical scenarios include business continuity, disaster recovery, and scale-out of mission-critical applications.

# Create a Capacity Reservation

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale set ✓ Flexible scale sets

Capacity Reservation is always created as part of a Capacity Reservation group. The first step is to create a group if a suitable one doesn't exist already, then create reservations. Once successfully created, reservations are immediately available for use with virtual machines. The capacity is reserved for your use as long as the reservation is not deleted.

A well-formed request for Capacity Reservation group should always succeed as it does not reserve any capacity. It just acts as a container for reservations. However, a request for Capacity Reservation could fail if you do not have the required quota for the VM series or if Azure doesn't have enough capacity to fulfill the request. Either request more quota or try a different VM size, location, or zone combination.

A Capacity Reservation creation succeeds or fails in its entirety. For a request to reserve 10 instances, success is returned only if all 10 could be allocated. Otherwise, the Capacity Reservation creation will fail.

## Considerations

The Capacity Reservation must meet the following rules:

- The location parameter must match the location property for the parent Capacity Reservation group. A mismatch will result in an error.
- The VM size must be available in the target region. Otherwise, the reservation creation will fail.
- The subscription must have available quota equal to or more than the quantity of VMs being reserved for the VM series and for the region overall. If needed, [request more quota](#).
  - As needed to satisfy existing quota limits, single VMs can be done in stages. Create a capacity reservation with a smaller quantity and reallocate that quantity of virtual machines. This will free up quota to increase the quantity reserved and add more virtual machines. Alternatively, if the subscription uses different VM sizes in the same series, reserve and redeploy VMs for the first size. Then add a reservation to the group for another size and redeploy the VMs for the new size to the reservation group. Repeat until complete.
  - For Scale Sets, available quota will be required unless the Scale Set or its VM instances are deleted, capacity is reserved, and the Scale Set instances are added using reserved capacity. If the Scale Set is updated using blue green deployment, then reserve the capacity and deploy the new Scale Set to the reserved capacity at the next update.
- Each Capacity Reservation group can have exactly one reservation for a given VM size. For example, only one Capacity Reservation can be created for the VM size `Standard_D2s_v3`. Attempt to create a second reservation for `Standard_D2s_v3` in the same Capacity Reservation group will result in an error. However, another reservation can be created in the same group for other VM sizes, such as `Standard_D4s_v3`, `Standard_D8s_v3`, and so on.
- For a Capacity Reservation group that supports zones, each reservation type is defined by the combination of **VM size** and **zone**. For example, one Capacity Reservation for `Standard_D2s_v3` in `Zone 1`, another Capacity Reservation for `Standard_D2s_v3` in `Zone 2`, and a third Capacity Reservation for `Standard_D2s_v3` in `Zone 3` is supported.

## Create a Capacity Reservation

- [API](#)

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [ARM template](#)

## 1. Create a Capacity Reservation group

To create a Capacity Reservation group, construct the following PUT request on *Microsoft.Compute* provider:

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}&api-version=2021-04-01
```

In the request body, include the following parameter:

```
{
  "location": "eastus"
}
```

This group is created to contain reservations for the US East location.

The group in the following example will only support regional reservations, because zones were not specified at the time of creation. To create a zonal group, pass an extra parameter *zones* in the request body:

```
{
  "location": "eastus",
  "zones": ["1", "2", "3"]
}
```

## 2. Create a Capacity Reservation

To create a reservation, construct the following PUT request on *Microsoft.Compute* provider:

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}&api-version=2021-04-01
```

In the request body, include the following parameters:

```
{
  "location": "eastus",
  "sku": {
    "name": "Standard_D2s_v3",
    "capacity": 5
  },
  "tags": {
    "environment": "testing"
  }
}
```

The above request creates a reservation in the East US location for 5 quantities of the D2s\_v3 VM size.

## Check on your Capacity Reservation

Once successfully created, the Capacity Reservation is immediately available for use with VMs.

- [API](#)
- [CLI](#)
- [PowerShell](#)
- [Portal](#)

```
GET
```

```
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}?api-version=2021-04-01
```

```
{
  "name": "<CapacityReservationName>",
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{CapacityReservationName}",
  "type": "Microsoft.Compute/capacityReservationGroups/capacityReservations",
  "location": "eastus",
  "tags": {
    "environment": "testing"
  },
  "sku": {
    "name": "Standard_D2s_v3",
    "capacity": 5
  },
  "properties": {
    "reservationId": "<reservationId>",
    "provisioningTime": "<provisioningTime>",
    "provisioningState": "Updating"
  }
}
```

## Next steps

[Learn how to modify your Capacity Reservation](#)

# Overallocating Capacity Reservation

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale set ✓ Flexible scale sets

Azure permits association of extra VMs beyond the reserved count of a Capacity Reservation to facilitate burst and other scale-out scenarios, without the overhead of managing around the limits of reserved capacity. The only difference is that the count of VMs beyond the quantity reserved does not receive the capacity availability SLA benefit. As long as Azure has available capacity that meets the virtual machine requirements, the extra allocations will succeed.

The Instance View of a Capacity Reservation group provides a snapshot of usage for each member Capacity Reservation. You can use the Instance View to see how overallocation works.

This article assumes you have created a Capacity Reservation group (`myCapacityReservationGroup`), a member Capacity Reservation (`myCapacityReservation`), and a virtual machine (`myVM1`) that is associated to the group. Go to [Create a Capacity Reservation](#) and [Associate a VM to a Capacity Reservation](#) for more details.

## Instance View for Capacity Reservation group

The Instance View for a Capacity Reservation group will look like this:

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/myCapacityReservationGroup?$expand=instanceview&api-version=2021-04-01
```

```
{
  "name": "myCapacityReservationGroup",
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/myCapacityReservationGroup",
  "type": "Microsoft.Compute/capacityReservationGroups",
  "location": "eastus",
  "properties": {
    "capacityReservations": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/MYCAPACITYRESERVATIONGROUP/capacityReservations/MYCAPACITYRESERVATION"
      }
    ],
    "virtualMachinesAssociated": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
      }
    ],
    "instanceView": {
      "capacityReservations": [
        {
          "name": "myCapacityReservation",
          "utilizationInfo": {
            "virtualMachinesAllocated": [
              {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
              }
            ]
          },
          "statuses": [
            {
              "code": "ProvisioningState/succeeded",
              "level": "Info",
              "displayStatus": "Provisioningsucceeded",
              "time": "<time>"
            }
          ]
        }
      ]
    }
  }
}
```

Let's say we create another virtual machine named *myVM2* and associate it with the above Capacity Reservation group.

The Instance View for the Capacity Reservation group will now look like this:

```
{
  "name": "myCapacityReservationGroup",
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/myCapacityReservationGroup",
  "type": "Microsoft.Compute/capacityReservationGroups",
  "location": "eastus",
  "properties": {
    "capacityReservations": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/MYCAPACITYRESERVATIONGROUP/capacityReservations/MYCAPACITYRESERVATION"
      }
    ],
    "virtualMachinesAssociated": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
      },
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM2"
      }
    ],
    "instanceView": {
      "capacityReservations": [
        {
          "name": "myCapacityReservation",
          "utilizationInfo": {
            "virtualMachinesAllocated": [
              {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM1"
              },
              {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/myVM2"
              }
            ]
          }
        },
        {
          "statuses": [
            {
              "code": "ProvisioningState/succeeded",
              "level": "Info",
              "displayStatus": "Provisioningsucceeded",
              "time": "<time>"
            }
          ]
        }
      ]
    }
  }
}
```

Notice that the length of `virtualMachinesAllocated` (2) is greater than `capacity` (1). This valid state is referred to as *overallocated*.

#### **IMPORTANT**

Azure will not stop allocations just because a Capacity Reservation is fully consumed. Auto-scale rules, temporary scale-out, and related requirements will work beyond the quantity of reserved capacity as long as Azure has available capacity and other constraints such as available quota are met.

## States and considerations

There are three valid states for a given Capacity Reservations:

STATE	STATUS	CONSIDERATIONS
Reserved capacity available	Length of <code>virtualMachinesAllocated &lt; capacity</code>	Is all the reserved capacity needed? Optionally reduce the capacity to reduce costs.
Reservation consumed	Length of <code>virtualMachinesAllocated == capacity</code>	Additional VMs will not receive the capacity SLA unless some existing VMs are deallocated. Optionally try to increase the capacity so extra planned VMs will receive an SLA.
Reservation overallocated	Length of <code>virtualMachinesAllocated &gt; capacity</code>	Additional VMs will not receive the capacity SLA. Also, the quantity of VMs (Length of <code>virtualMachinesAllocated - capacity</code> ) will not receive a capacity SLA if deallocated. Optionally increase the capacity to add capacity SLA to more of the existing VMs.

## Next steps

[Learn how to remove VMs from a Capacity Reservation](#)

# Modify a Capacity Reservation (preview)

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Uniform scale set ✓ Flexible scale sets

After creating a Capacity Reservation group and Capacity Reservation, you may want to modify your reservations. This article explains how to do the following actions using API, Azure portal, and PowerShell.

- Update the number of instances reserved in a Capacity Reservation
- Resize VMs associated with a Capacity Reservation group
- Delete the Capacity Reservation group and Capacity Reservation

## Update the number of instances reserved

Update the number of virtual machine instances reserved in a Capacity Reservation.

### IMPORTANT

In rare cases when Azure cannot fulfill the request to increase the quantity reserved for existing Capacity Reservations, it is possible that a reservation goes into a *Failed* state and becomes unavailable until the [quantity is restored to the original amount](#).

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)

PATCH

```
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}?api-version=2021-04-01
```

In the request body, update the `capacity` property to the new count that you want to reserve:

```
{  
  "sku":  
  {  
    "capacity": 5  
  }  
}
```

Note that the `capacity` property is set to 5 now in this example.

## Resize VMs associated with a Capacity Reservation group

You must do one of the following options if the VM being resized is currently attached to a Capacity Reservation group and that group doesn't have a reservation for the target size:

- Create a new reservation for that size
- Remove the virtual machine from the reservation group before resizing.

Check if the target size is part of the reservation group:

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)

1. Get the names of all Capacity Reservations within the group.

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}?api-version=2021-04-01
```

```
{  
  "name": "<CapacityReservationGroupName>",  
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}",  
  "type": "Microsoft.Compute/capacityReservationGroups",  
  "location": "eastUS",  
  "zones": [  
    "1"  
  ],  
  "properties": {  
    "capacityReservations": [  
      {  
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName1}"  
      },  
      {  
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName2}"  
      }  
    ]  
  }  
}
```

2. Find out the VM size reserved for each reservation. The following example is for

`capacityReservationName1`, but you can repeat this step for other reservations.

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName1}?api-version=2021-04-01
```

```
{  
  "name": "capacityReservationName1",  
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/  
capacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationNam  
e1}",  
  "type": "Microsoft.Compute/capacityReservationGroups/capacityReservations",  
  "location": "eastUS",  
  "sku": {  
    "name": "Standard_D2s_v3",  
    "capacity": 3  
  },  
  "zones": [  
    "1"  
  ],  
  "properties": {  
    "reservationId": "<reservationId>",  
    "provisioningTime": "<provisioningTime>",  
    "provisioningState": "Succeeded"  
  }  
}
```

3. Consider the following scenarios:

- If the target VM size is not part of the group, [create a new Capacity Reservation](#) for the target VM
- If the target VM size already exists in the group, [resize the virtual machine](#)

## Delete a Capacity Reservation group and Capacity Reservation

Azure allows a group to be deleted when all the member Capacity Reservations have been deleted and no VMs are associated to the group.

To delete a Capacity Reservation, first find out all of the virtual machines that are associated to it. The list of virtual machines is available under `virtualMachinesAssociated` property.

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)

First, find all virtual machines associated with the Capacity Reservation group and dissociate them.

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}?\$expand=instanceView&api-version=2021-04-01
```

```
{
  "name": "<capacityReservationGroupName>",
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}",
  "type": "Microsoft.Compute/capacityReservationGroups",
  "location": "eastus",
  "properties": {
    "capacityReservations": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}/capacityReservations/{capacityReservationName}"
      }
    ],
    "virtualMachinesAssociated": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName1}"
      },
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName2}"
      }
    ],
    "instanceView": {
      "capacityReservations": [
        {
          "name": "{capacityReservationName}",
          "utilizationInfo": {
            "virtualMachinesAllocated": [
              {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName1}"
              }
            ]
          }
        },
        "statuses": [
          {
            "code": "ProvisioningState/succeeded",
            "level": "Info",
            "displayStatus": "Provisioningsucceeded",
            "time": "<time>"
          }
        ]
      }
    }
  }
}
```

From the above response, find the names of all virtual machines under the `virtualMachinesAssociated` property and remove them from the Capacity Reservation group using the steps in [Remove a VM association to a Capacity Reservation](#).

Once all the virtual machines are removed from the Capacity Reservation group, delete the member Capacity Reservation(s):

```
DELETE
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{capacityReservationName}?api-version=2021-04-01
```

Lastly, delete the parent Capacity Reservation group.

DELETE

<https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}?api-version=2021-04-01>

## Restore instance quantity

A well-formed request for reducing the quantity reserved should always succeed no matter the number of VMs associated with the reservation. However, increasing the quantity reserved may require more quota and for Azure to fulfill the additional capacity request. In a rare scenario in which Azure can't fulfill the request to increase the quantity reserved for existing reservations, it is possible that the reservation goes into a *Failed* state and becomes unavailable until the quantity reserved is restored to the original amount.

### NOTE

If a reservation is in a *Failed* state, all the VMs that are associated with the reservation will continue to work as normal.

For example, let's say `myCapacityReservation` has a quantity reserved 5. You request 5 extra instances, making the total quantity reserved equal 10. However, because of a constrained capacity situation in the region, Azure can't fulfill the additional 5 quantity requested. In this case, `myCapacityReservation` will fail to meet its intended state of 10 quantity reserved and will go into a *Failed* state.

To resolve this failure, take the following steps to locate the old quantity reserved value:

1. Go to [Application Change Analysis](#) in the Azure portal
2. Select the applicable **Subscription**, **Resource group**, and **Time range** in the filters
  - You can only go back up to 14 days in the past in the **Time range** filter
3. Search for the name of the Capacity Reservation
4. Look for the change in `sku.capacity` property for that reservation
  - The old quantity reserved will be the value under the **Old Value** column

Update `myCapacityReservation` to the old quantity reserved. Once updated, the reservation will be available immediately for use with your virtual machines.

## Next steps

[Learn how to remove VMs from a Capacity Reservation](#)

# Associate a VM to a Capacity Reservation group

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows Virtual Machines ✓ Linux Virtual Machines

Capacity reservation groups can be used with new or existing virtual machines. To learn more about Capacity Reservations, see the [overview article](#).

## Associate a new VM

To associate a new VM to the Capacity Reservation group, the group must be explicitly referenced as a property of the virtual machine. This reference protects the matching reservation in the group for applications and workloads intended to use it.

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [ARM template](#)

To add the `capacityReservationGroup` property to a VM, construct the following PUT request to the *Microsoft.Compute* provider:

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

```
{  
  "location": "eastus",  
  "properties": {  
    "hardwareProfile": {  
      "vmSize": "Standard_D2s_v3"  
    },  
    ...  
    "CapacityReservation":{  
      "capacityReservationGroup":{  
  
        "id": "subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}"  
      }  
      "storageProfile": {  
        ...  
      },  
      "osProfile": {  
        ...  
      },  
      "networkProfile": {  
        ...  
      }  
    }  
  }  
}
```

## Associate an existing VM

For the initial release of Capacity Reservation, a virtual machine must be allocated to a capacity reservation.

- If not already complete, follow guidance to create a capacity reservation group and capacity reservation. Or increment the quantity of an existing capacity reservation so there's unused reserved capacity.
  - Deallocate the VM.
  - Update the capacity reservation group property on the VM.
  - Restart the VM.
- 
- [API](#)
  - [Portal](#)
  - [CLI](#)
  - [PowerShell](#)

1. Deallocate the VM.

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}/deallocate?api-version=2021-04-01
```

2. Add the `capacityReservationGroup` property to the VM. Construct the following PUT request to *Microsoft.Compute* provider:

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

```
{  
    "location": "eastus",  
    "properties": {  
        "capacityReservation": {  
            "capacityReservationGroup": {  
                "id":  
                    "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}"  
            }  
        }  
    }  
}
```

## View VM association with Instance View

Once the `capacityReservationGroup` property is set, an association now exists between the VM and the group. Azure automatically finds the matching Capacity Reservation in the group and consumes a reserved slot. The Capacity Reservation's *Instance View* will reflect the new VM in the `virtualMachinesAllocated` property:

- [API](#)
- [CLI](#)
- [PowerShell](#)
- [Portal](#)

GET

[https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{capacityReservationGroupName}?\\$expand=instanceView&api-version=2021-04-01](https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{capacityReservationGroupName}?$expand=instanceView&api-version=2021-04-01)

```
{  
  "name": "{CapacityReservationGroupName}",  
  
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}",  
  "type": "Microsoft.Compute/capacityReservationGroups",  
  "location": "eastus",  
  "properties": {  
    "capacityReservations": [  
      {  
  
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/ {CapacityReservationGroupName}/capacityReservations/{CapacityReservationName}"  
      }  
    ],  
    "virtualMachinesAssociated": [  
      {  
  
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{myVM}"  
      }  
    ],  
    "instanceView": {  
      "capacityReservations": [  
        {  
          "name": "{CapacityReservationName}",  
          "utilizationInfo": {  
            "virtualMachinesAllocated": [  
              {  
  
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{myVM}"  
              }  
            ]  
          },  
          "statuses": [  
            {  
              "code": "ProvisioningState/succeeded",  
              "level": "Info",  
              "displayStatus": "Provisioning succeeded",  
              "time": "2021-05-25T15:12:10.4165243+00:00"  
            }  
          ]  
        }  
      ]  
    }  
  }  
}
```

## Next steps

[Remove a VMs association to a Capacity Reservation group](#)

# Remove a VM association from a Capacity Reservation group

9/21/2022 • 3 minutes to read • [Edit Online](#)

This article walks you through the steps of removing a VM association to a Capacity Reservation group. To learn more about capacity reservations, see the [overview article](#).

Because both the VM and the underlying Capacity Reservation logically occupy capacity, Azure imposes some constraints on this process to avoid ambiguous allocation states and unexpected errors.

There are two ways to change an association:

- Option 1: Deallocate the virtual machine, change the Capacity Reservation group property, and optionally restart the virtual machine
- Option 2: Update the reserved quantity to zero and then change the Capacity Reservation group property

## Deallocate the VM

The first option is to deallocate the VM, change the Capacity Reservation group property, and optionally restart the VM.

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)

### 1. Deallocate the VM

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{virtualMachineName}/deallocate?api-version=2021-04-01
```

### 2. Update the VM to remove association with the Capacity Reservation group

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{virtualMachineName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to null to remove the VM association to the group:

```
{  
  "location": "eastus",  
  "properties": {  
    "capacityReservation": {  
      "capacityReservationGroup": {  
        "id": null  
      }  
    }  
  }  
}
```

## Update the reserved quantity to zero

The second option involves updating the reserved quantity to zero and then changing the Capacity Reservation group property.

This option works well when the virtual machine can't be deallocated and when a reservation is no longer needed. For example, you may create a Capacity Reservation to temporarily assure capacity during a large-scale deployment. Once completed, the reservation is no longer needed.

- [API](#)
- [Portal](#)
- [CLI](#)
- [PowerShell](#)

### 1. Update the reserved quantity to zero

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/CapacityReservations/{CapacityReservationName}?api-version=2021-04-01
```

In the request body, include the following parameters:

```
{  
  "sku":  
  {  
    "capacity": 0  
  }  
}
```

Note that `capacity` property is set to 0.

### 2. Update the VM to remove the association with the Capacity Reservation group

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{VirtualMachineName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to null to remove the association:

```
{  
  "location": "eastus",  
  "properties": {  
    "capacityReservation": {  
      "capacityReservationGroup": {  
        "id": null  
      }  
    }  
  }  
}
```

## Next steps

[Learn how to associate a scale set to a Capacity Reservation group](#)

# Associate a virtual machine scale set with flexible orchestration to a Capacity Reservation group

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Flexible scale sets

Virtual Machine Scale Sets have two modes:

- **Uniform Orchestration Mode:** In this mode, virtual machine scale sets use a VM profile or a template to scale up to the desired capacity. While there is some ability to manage or customize individual VM instances, Uniform uses identical VM instances. These instances are exposed through the virtual machine scale sets VM APIs and are not compatible with the standard Azure IaaS VM API commands. Since the scale set performs all the actual VM operations, reservations are associated with the virtual machine scale set directly. Once the scale set is associated with the reservation, all the subsequent VM allocations will be done against the reservation.
- **Flexible Orchestration Mode:** In this mode, you get more flexibility managing the individual virtual machine scale set VM instances as they can use the standard Azure IaaS VM APIs instead of using the scale set interface. To use reservations with flexible orchestration mode, define both the virtual machine scale set property and the capacity reservation property on each virtual machine.

To learn more about these modes, go to [Virtual Machine Scale Sets Orchestration Modes](#).

This content applies to the flexible orchestration mode. For uniform orchestration mode, go to [Associate a virtual machine scale set with uniform orchestration to a Capacity Reservation group](#)

## IMPORTANT

Capacity Reservations with virtual machine set using flexible orchestration is currently in public preview. This preview version is provided without a service-level agreement, and we don't recommend it for production workloads. Certain features might not be supported or might have constrained capabilities. For more information, see [Supplemental Terms of Use for Microsoft Azure Previews](#). During the preview, always attach reserved capacity during creation of new scale sets using flexible orchestration mode. There are known issues attaching capacity reservations to existing scale sets using flexible orchestration. Microsoft will update this page as more options become enabled during preview.

## Associate a new virtual machine scale set to a Capacity Reservation group

**Option 1: Add to Virtual Machine profile** - If the Scale Set with flexible orchestration includes a VM profile, add the Capacity Reservation group property to the profile during Scale Set creation. Follow the same process used for a Scale Set using uniform orchestration. For sample code, see [Associate a virtual machine scale set with uniform orchestration to a Capacity Reservation group](#).

**Option 2: Add to the first Virtual Machine deployed** - If the Scale Set omits a VM profile, then you must add the Capacity Reservation group to the first Virtual Machine deployed using the Scale Set. Follow the same process used to associate a VM. For sample code, see [Associate a virtual machine to a Capacity Reservation group](#).

## Next steps

[Learn how to remove a scale set association from a Capacity Reservation](#)

# Associate a virtual machine scale set with uniform orchestration to a Capacity Reservation group

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Uniform scale set

Virtual Machine Scale Sets have two modes:

- **Uniform Orchestration Mode:** In this mode, virtual machine scale sets use a VM profile or a template to scale up to the desired capacity. While there is some ability to manage or customize individual VM instances, Uniform uses identical VM instances. These instances are exposed through the virtual machine scale sets VM APIs and are not compatible with the standard Azure IaaS VM API commands. Since the scale set performs all the actual VM operations, reservations are associated with the virtual machine scale set directly. Once the scale set is associated with the reservation, all the subsequent VM allocations will be done against the reservation.
- **Flexible Orchestration Mode:** In this mode, you get more flexibility managing the individual virtual machine scale set VM instances as they can use the standard Azure IaaS VM APIs instead of using the scale set interface. To use reservations with flexible orchestration mode, define both the virtual machine scale set property and the capacity reservation property on each virtual machine.

To learn more about these modes, go to [Virtual Machine Scale Sets Orchestration Modes](#).

This content applies to the uniform orchestration mode. For flexible orchestration mode, go to [Associate a virtual machine scale set with flexible orchestration to a Capacity Reservation group](#)

## Limitations of scale sets in Uniform Orchestration

- For Virtual Machine Scale Sets in Uniform orchestration to be compatible with Capacity Reservation, the `singlePlacementGroup` property must be set to *False*.
- The **Static Fixed Spreading** availability option for multi-zone Uniform scale sets is not supported with Capacity Reservation. This option requires use of 5 Fault Domains while the reservations only support up to 3 Fault Domains for general purpose sizes. The recommended approach is to use the **Max Spreading** option that spreads VMs across as many FDs as possible within each zone. If needed, configure a custom Fault Domain configuration of 3 or less.

There are some other restrictions while using Capacity Reservation. For the complete list, refer the [Capacity Reservations overview](#).

## Associate a new virtual machine scale set to a Capacity Reservation group

- [API](#)
- [CLI](#)
- [PowerShell](#)
- [ARM template](#)

To associate a new Uniform virtual machine scale set to a Capacity Reservation group, construct the following PUT request to the *Microsoft.Compute* provider:

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMscaleSetName}?api-version=2021-04-01
```

Add the `capacityReservationGroup` property in the `virtualMachineProfile` property:

```
{  
    "name": "<VMscaleSetName>",  
    "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMscaleSetName}",  
    "type": "Microsoft.Compute/virtualMachineScaleSets",  
    "location": "eastus",  
    "sku": {  
        "name": "Standard_D2s_v3",  
        "tier": "Standard",  
        "capacity": 3  
    },  
    "properties": {  
        "virtualMachineProfile": {  
            "capacityReservation": {  
                "capacityReservationGroup": {  
  
                    "id": "subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroup/{CapacityReservationGroupName}"  
                }  
            },  
            "osProfile": {  
                ...  
            },  
            "storageProfile": {  
                ...  
            },  
            "networkProfile": {  
                ...,  
                "extensionProfile": {  
                    ...  
                }  
            }  
        }  
    }  
}
```

## Associate an existing virtual machine scale set to Capacity Reservation group

To add an existing Capacity Reservation Group to an existing Uniform Scale Set:

- Stop the Scale Set to deallocate the VM instances
- Update the Scale Set to use a matching Capacity Reservation Group
- Start the Scale Set

This process ensures the placement for the Capacity Reservations and Scale Set in the region are compatible.

### Important notes on Upgrade Policies

- **Automatic Upgrade** – In this mode, the scale set VM instances are automatically associated with the Capacity Reservation group without any further action from you. When the scale set VMs are reallocated, they start consuming the reserved capacity.
- **Rolling Upgrade** – In this mode, scale set VM instances are associated with the Capacity Reservation group without any further action from you. However, they are updated in batches with an optional pause time between them. When the scale set VMs are reallocated, they start consuming the reserved capacity.
- **Manual Upgrade** – In this mode, nothing happens to the scale set VM instances when the virtual machine

scale set is attached to a Capacity Reservation group. You will need to update to each scale set VM by upgrading it with the latest Scale Set model.

- [API](#)
- [CLI](#)
- [PowerShell](#)

#### 1. Deallocate the virtual machine scale set.

```
POST  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSScaleSetName}/deallocate?api-version=2021-04-01
```

#### 2. Add the `capacityReservationGroup` property to the scale set model. Construct the following PUT request to *Microsoft.Compute* provider:

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSScaleSetName}?api-version=2021-04-01
```

In the request body, include the `capacityReservationGroup` property:

```
"location": "eastus",  
"properties": {  
    "virtualMachineProfile": {  
        "capacityReservation": {  
            "capacityReservationGroup": {  
                "id":  
                    "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{capacityReservationGroupName}"  
            }  
        }  
    }  
}
```

## View virtual machine scale set association with Instance View

Once the Uniform virtual machine scale set is associated with the Capacity Reservation group, all the subsequent VM allocations will happen against the Capacity Reservation. Azure automatically finds the matching Capacity Reservation in the group and consumes a reserved slot.

- [API](#)
- [CLI](#)
- [PowerShell](#)
- [Portal](#)

The Capacity Reservation group *Instance View* will reflect the new scale set VMs under the `virtualMachinesAssociated` & `virtualMachinesAllocated` properties:

```
GET  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}?$expand=instanceview&api-version=2021-04-01
```

```
{
  "name": "<CapacityReservationGroupName>",
  "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}",
  "type": "Microsoft.Compute/capacityReservationGroups",
  "location": "eastus"
},
  "properties": {
    "capacityReservations": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/capacityReservationGroups/{CapacityReservationGroupName}/capacityReservations/{CapacityReservationName}"
      }
    ],
    "virtualMachinesAssociated": [
      {
        "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSScaleSetName}/virtualMachines/{VirtualMachineId}"
      }
    ],
    "instanceView": {
      "capacityReservations": [
        {
          "name": "<CapacityReservationName>",
          "utilizationInfo": {
            "virtualMachinesAllocated": [
              {
                "id": "/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSScaleSetName}/virtualMachines/{VirtualMachineId}"
              }
            ]
          },
          "statuses": [
            {
              "code": "ProvisioningState/succeeded",
              "level": "Info",
              "displayStatus": "Provisioningsucceeded",
              "time": "2021-05-25T15:12:10.4165243+00:00"
            }
          ]
        }
      ]
    }
  }
}
```

## Region and Availability Zones considerations

Virtual machine scale sets can be created regionally or in one or more Availability Zones to protect them from data-center-level failure. Learn more about multi-zonal virtual machine scale sets, refer to [Virtual Machine Scale Sets that use Availability Zones](#).

### IMPORTANT

The location (Region and Availability Zones) of the virtual machine scale set and the Capacity Reservation group must match for the association to succeed. For a regional scale set, the region must match between the scale set and the Capacity Reservation group. For a zonal scale set, both the regions and the zones must match between the scale set and the Capacity Reservation group.

When a scale set is spread across multiple zones, it always attempts to deploy evenly across the included Availability Zones. Because of that even deployment, a Capacity Reservation group should always have the same

quantity of reserved VMs in each zone. As an illustration of why this is important, consider the following example.

In this example, each zone has a different quantity reserved. Let's say that the virtual machine scale set scales out to 75 instances. Since scale set will always attempt to deploy evenly across zones, the VM distribution should look like this:

ZONE	QUANTITY RESERVED	NO. OF SCALE SET VMS IN EACH ZONE	UNUSED QUANTITY RESERVED	OVERALLOCATED
1	40	25	15	0
2	20	25	0	5
3	15	25	0	10

In this case, the scale set is incurring extra cost for 15 unused instances in Zone 1. The scale-out is also relying on 5 VMs in Zone 2 and 10 VMs in Zone 3 that are not protected by Capacity Reservation. If each zone had 25 capacity instances reserved, then all 75 VMs would be protected by Capacity Reservation and the deployment would not incur any extra cost for unused instances.

Since the reservations can be overallocated, the scale set can continue to scale normally beyond the limits of the reservation. The only difference is that the VMs allocated above the quantity reserved are not covered by Capacity Reservation SLA. To learn more, go to [Overallocating Capacity Reservation](#).

## Next steps

[Learn how to remove a scale set association from a Capacity Reservation](#)

# Remove a virtual machine scale set association from a Capacity Reservation group

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Uniform scale set ✓ Flexible scale sets

This article walks you through removing a virtual machine scale set association from a Capacity Reservation group. To learn more about capacity reservations, see the [overview article](#).

Because both the VM and the underlying Capacity Reservation logically occupy capacity, Azure imposes some constraints on this process to avoid ambiguous allocation states and unexpected errors.

There are two ways to change an association:

- Option 1: Deallocate the Virtual machine scale set, change the Capacity Reservation group property at the scale set level, and then update the underlying VMs
- Option 2: Update the reserved quantity to zero and then change the Capacity Reservation group property

## Deallocate the Virtual machine scale set

The first option is to deallocate the virtual machine scale set, change the Capacity Reservation group property at the scale set level, and then update the underlying VMs.

Go to [upgrade policies](#) for more information about automatic, rolling, and manual upgrades.

- [API](#)
- [CLI](#)
- [PowerShell](#)

### 1. Deallocate the virtual machine scale set

```
POST  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMScaleSetName}/deallocate?api-version=2021-04-01
```

### 2. Update the virtual machine scale set to remove association with the Capacity Reservation group

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMScaleSetName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to null to remove the virtual machine scale set association to the group:

```
{  
  "location": "eastus",  
  "properties": {  
    "virtualMachineProfile": {  
      "capacityReservation": {  
        "capacityReservationGroup": {  
          "id": null  
        }  
      }  
    }  
  }  
}
```

## Update the reserved quantity to zero

The second option involves updating the reserved quantity to zero and then changing the Capacity Reservation group property.

This option works well when the scale set cannot be deallocated and when a reservation is no longer needed. For example, you may create a Capacity Reservation to temporarily assure capacity during a large-scale deployment. Once completed, the reservation is no longer needed.

Go to [upgrade policies](#) for more information about automatic, rolling, and manual upgrades.

- [API](#)
- [CLI](#)
- [PowerShell](#)

### 1. Update the reserved quantity to zero

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/CapacityReservationGroups/{CapacityReservationGroupName}/CapacityReservations/{CapacityReservationName}?api-version=2021-04-01
```

In the request body, include the following parameters:

```
{  
  "sku":  
  {  
    "capacity": 0  
  }  
}
```

Note that `capacity` property is set to 0.

### 2. Update the virtual machine scale set to remove the association with the Capacity Reservation group

```
PUT  
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSScaleSetName}/update?api-version=2021-04-01
```

In the request body, set the `capacityReservationGroup` property to null to remove the association:

```
{  
  "location": "eastus",  
  "properties": {  
    "virtualMachineProfile": {  
      "capacityReservation": {  
        "capacityReservationGroup": {  
          "id": null  
        }  
      }  
    }  
  }  
}
```

## Upgrade policies

- **Automatic Upgrade** – In this mode, the scale set VM instances are automatically dissociated from the Capacity Reservation group without any further action from you.
- **Rolling Upgrade** – In this mode, the scale set VM instances are dissociated from the Capacity Reservation group without any further action from you. However, they are updated in batches with an optional pause time between them.
- **Manual Upgrade** – In this mode, nothing happens to the scale set VM instances when the virtual machine scale set is updated. You will need to individually remove each scale set VM by [upgrading it with the latest Scale Set model](#).

## Next steps

[Learn about overallocating a Capacity Reservation](#)

# Create a complete Linux virtual machine with the Azure CLI

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

To quickly create a virtual machine (VM) in Azure, you can use a single Azure CLI command that uses default values to create any required supporting resources. Resources such as a virtual network, public IP address, and network security group rules are automatically created. For more control of your environment in production use, you may create these resources ahead of time and then add your VMs to them. This article guides you through how to create a VM and each of the supporting resources one by one.

Make sure that you have installed the latest [Azure CLI](#) and logged to an Azure account in with [az login](#).

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

## Create resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine and supporting virtual network resources. Create the resource group with [az group create](#). The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name myResourceGroup --location eastus
```

By default, the output of Azure CLI commands is in JSON (JavaScript Object Notation). To change the default output to a list or table, for example, use [az config set core.output=table](#). You can also add `--output` to any command for a one time change in output format. The following example shows the JSON output from the `az group create` command:

```
{
  "id": "/subscriptions/guid/resourceGroups/myResourceGroup",
  "location": "eastus",
  "name": "myResourceGroup",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null
}
```

## Create a virtual network and subnet

Next you create a virtual network in Azure and a subnet in to which you can create your VMs. Use [az network vnet create](#) to create a virtual network named *myVnet* with the *192.168.0.0/16* address prefix. You also add a subnet named *mySubnet* with the address prefix of *192.168.1.0/24*:

```
az network vnet create \
--resource-group myResourceGroup \
--name myVnet \
--address-prefix 192.168.0.0/16 \
--subnet-name mySubnet \
--subnet-prefix 192.168.1.0/24
```

The output shows the subnet is logically created inside the virtual network:

```
{
  "addressSpace": {
    "addressPrefixes": [
      "192.168.0.0/16"
    ]
  },
  "dhcpOptions": {
    "dnsServers": []
  },
  "etag": "W/\"e95496fc-f417-426e-a4d8-c9e4d27fc2ee\"",
  "id": "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Network/virtualNetworks/myVnet",
  "location": "eastus",
  "name": "myVnet",
  "provisioningState": "Succeeded",
  "resourceGroup": "myResourceGroup",
  "resourceGuid": "ed62fd03-e9de-430b-84df-8a3b87cacdbb",
  "subnets": [
    {
      "addressPrefix": "192.168.1.0/24",
      "etag": "W/\"e95496fc-f417-426e-a4d8-c9e4d27fc2ee\"",
      "id": "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Network/virtualNetworks/myVnet/subnets/mySubnet",
      "ipConfigurations": null,
      "name": "mySubnet",
      "networkSecurityGroup": null,
      "provisioningState": "Succeeded",
      "resourceGroup": "myResourceGroup",
      "resourceNavigationLinks": null,
      "routeTable": null
    }
  ],
  "tags": {},
  "type": "Microsoft.Network/virtualNetworks",
  "virtualNetworkPeerings": null
}
```

## Create a public IP address

Now let's create a public IP address with [az network public-ip create](#). This public IP address enables you to connect to your VMs from the Internet. Because the default address is dynamic, create a named DNS entry with the `--domain-name-label` parameter. The following example creates a public IP named *myPublicIP* with the DNS name of *mypublicdns*. Because the DNS name must be unique, provide your own unique DNS name:

```
az network public-ip create \
--resource-group myResourceGroup \
--name myPublicIP \
--dns-name mypublicdns
```

Output:

```
{  
  "publicIp": {  
    "dnsSettings": {  
      "domainNameLabel": "mypublicdns",  
      "fqdn": "mypublicdns.eastus.cloudapp.azure.com",  
      "reverseFqdn": null  
    },  
    "etag": "W/\"2632aa72-3d2d-4529-b38e-b622b4202925\"",  
    "id":  
      "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Network/publicIPAddresses/myPublicIP"  
    ,  
    "idleTimeoutInMinutes": 4,  
    "ipAddress": null,  
    "ipConfiguration": null,  
    "location": "eastus",  
    "name": "myPublicIP",  
    "provisioningState": "Succeeded",  
    "publicIpAddressVersion": "IPv4",  
    "publicIpAllocationMethod": "Dynamic",  
    "resourceGroup": "myResourceGroup",  
    "resourceGuid": "4c65de38-71f5-4684-be10-75e605b3e41f",  
    "tags": null,  
    "type": "Microsoft.Network/publicIPAddresses"  
  },  
}  
}
```

## Create a network security group

To control the flow of traffic in and out of your VMs, you apply a network security group to a virtual NIC or subnet. The following example uses [az network nsg create](#) to create a network security group named *myNetworkSecurityGroup*:

```
az network nsg create \  
  --resource-group myResourceGroup \  
  --name myNetworkSecurityGroup
```

You define rules that allow or deny specific traffic. To allow inbound connections on port 22 (to enable SSH access), create an inbound rule with [az network nsg rule create](#). The following example creates a rule named *myNetworkSecurityGroupRuleSSH*:

```
az network nsg rule create \  
  --resource-group myResourceGroup \  
  --nsg-name myNetworkSecurityGroup \  
  --name myNetworkSecurityGroupRuleSSH \  
  --protocol tcp \  
  --priority 1000 \  
  --destination-port-range 22 \  
  --access allow
```

To allow inbound connections on port 80 (for web traffic), add another network security group rule. The following example creates a rule named *myNetworkSecurityGroupRuleHTTP*:

```
az network nsg rule create \
--resource-group myResourceGroup \
--nsg-name myNetworkSecurityGroup \
--name myNetworkSecurityGroupRuleWeb \
--protocol tcp \
--priority 1001 \
--destination-port-range 80 \
--access allow
```

Examine the network security group and rules with [az network nsg show](#):

```
az network nsg show --resource-group myResourceGroup --name myNetworkSecurityGroup
```

Output:

```
{
  "defaultSecurityRules": [
    {
      "access": "Allow",
      "description": "Allow inbound traffic from all VMs in VNET",
      "destinationAddressPrefix": "VirtualNetwork",
      "destinationPortRange": "*",
      "direction": "Inbound",
      "etag": "W/\"3371b313-ea9f-4687-a336-a8ebdfd80523\"",
      "id": "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Network/networkSecurityGroups/myNetworkSecurityGroup/defaultSecurityRules/AllowVnetInBound",
      "name": "AllowVnetInBound",
      "priority": 65000,
      "protocol": "*",
      "provisioningState": "Succeeded",
      "resourceGroup": "myResourceGroup",
      "sourceAddressPrefix": "VirtualNetwork",
      "sourcePortRange": "*"
    },
    {

## Create a virtual NIC

Virtual network interface cards (NICs) are programmatically available because you can apply rules to their use. Depending on the [VM size](#), you can attach multiple virtual NICs to a VM. In the following [az network nic create](#) command, you create a NIC named *myNic* and associate it with your network security group. The public IP address *myPublicIP* is also associated with the virtual NIC.

```

az network nic create \
    --resource-group myResourceGroup \
    --name myNic \
    --vnet-name myVnet \
    --subnet mySubnet \
    --public-ip-address myPublicIP \
    --network-security-group myNetworkSecurityGroup

```

Output:

```
{
  "NewNIC": {
    "dnsSettings": {
      "appliedDnsServers": [],
      "dnsServers": [],
      "internalDnsNameLabel": null,
      "internalDomainNameSuffix": "brqlt10lvoxedgkeuomc4pm5tb.bx.internal.cloudapp.net",

}
}
```

## Create an availability set

Availability sets help spread your VMs across fault domains and update domains. Even though you only create one VM right now, it's best practice to use availability sets to make it easier to expand in the future.

Fault domains define a grouping of virtual machines that share a common power source and network switch. By default, the virtual machines that are configured within your availability set are separated across up to three fault domains. A hardware issue in one of these fault domains does not affect every VM that is running your app.

Update domains indicate groups of virtual machines and underlying physical hardware that can be rebooted at the same time. During planned maintenance, the order in which update domains are rebooted might not be sequential, but only one update domain is rebooted at a time.

Azure automatically distributes VMs across the fault and update domains when placing them in an availability set. For more information, see [managing the availability of VMs](#).

Create an availability set for your VM with [az vm availability-set create](#). The following example creates an availability set named *myAvailabilitySet*.

```
az vm availability-set create \
--resource-group myResourceGroup \
--name myAvailabilitySet
```

The output notes fault domains and update domains:

```
{  
  "id":  
    "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Compute/availabilitySets/myAvailabilitySet",  
  "location": "eastus",  
  "managed": null,  
  "name": "myAvailabilitySet",  
  "platformFaultDomainCount": 2,  
  "platformUpdateDomainCount": 5,  
  "resourceGroup": "myResourceGroup",  
  "sku": {  
    "capacity": null,  
    "managed": true,  
    "tier": null  
  },  
  "statuses": null,  
  "tags": {},  
  "type": "Microsoft.Compute/availabilitySets",  
  "virtualMachines": []  
}
```

## Create a VM

You've created the network resources to support Internet-accessible VMs. Now create a VM and secure it with an SSH key. In this example, let's create an Ubuntu VM based on the most recent LTS. You can find additional images with [az vm image list](#), as described in [finding Azure VM images](#).

Specify an SSH key to use for authentication. If you do not have an SSH public key pair, you can [create them](#) or use the `--generate-ssh-keys` parameter to create them for you. If you already have a key pair, this parameter uses existing keys in `~/.ssh`.

Create the VM by bringing all the resources and information together with the [az vm create](#) command. The following example creates a VM named *myVM*.

```
az vm create \  
  --resource-group myResourceGroup \  
  --name myVM \  
  --location eastus \  
  --availability-set myAvailabilitySet \  

```

SSH to your VM with the DNS entry you provided when you created the public IP address. This `fqdn` is shown in the output as you create your VM:

```
{  
  "fqdns": "mypublicdns.eastus.cloudapp.azure.com",  
  "id":  
    "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",  
  "location": "eastus",  
  "macAddress": "00-0D-3A-13-71-C8",  
  "powerState": "VM running",  
  "privateIpAddress": "192.168.1.5",  
  "publicIpAddress": "13.90.94.252",  
  "resourceGroup": "myResourceGroup"  
}
```

```
ssh azureuser@mypublicdns.eastus.cloudapp.azure.com
```

Output:

```
The authenticity of host 'mypublicdns.eastus.cloudapp.azure.com (13.90.94.252)' can't be established.  
ECDSA key fingerprint is SHA256:SyLlNP80Um6XRTvWiFaNz+H+1jcrKB1IiNgCDDJRj6A.  
Are you sure you want to continue connecting (yes/no)? yes  
Warning: Permanently added 'mypublicdns.eastus.cloudapp.azure.com,13.90.94.252' (ECDSA) to the list of known  
hosts.  
Welcome to Ubuntu 16.04.3 LTS (GNU/Linux 4.11.0-1016-azure x86_64)  
  
* Documentation: https://help.ubuntu.com  
* Management: https://landscape.canonical.com  
* Support: https://ubuntu.com/advantage  
  
Get cloud support with Ubuntu Advantage Cloud Guest:  
https://www.ubuntu.com/business/services/cloud  
  
0 packages can be updated.  
0 updates are security updates.  
  
The programs included with the Ubuntu system are free software;  
the exact distribution terms for each program are described in the  
individual files in /usr/share/doc/*/*copyright.  
  
Ubuntu comes with ABSOLUTELY NO WARRANTY, to the extent permitted by  
applicable law.  
  
To run a command as administrator (user "root"), use "sudo <command>".  
See "man sudo_root" for details.  
  
azureuser@myVM:~$
```

You can install NGINX and see the traffic flow to the VM. Install NGINX as follows:

```
sudo apt-get install -y nginx
```

To see the default NGINX site in action, open your web browser and enter your FQDN:

## Export as a template

What if you now want to create an additional development environment with the same parameters, or a production environment that matches it? Resource Manager uses JSON templates that define all the parameters for your environment. You build out entire environments by referencing this JSON template. You can [build JSON](#)

[templates manually](#) or export an existing environment to create the JSON template for you. Use [az group export](#) to export your resource group as follows:

```
az group export --name myResourceGroup > myResourceGroup.json
```

This command creates the `myResourceGroup.json` file in your current working directory. When you create an environment from this template, you are prompted for all the resource names. You can populate these names in your template file by adding the `--include-parameter-default-value` parameter to the `az group export` command. Edit your JSON template to specify the resource names, or [create a parameters.json file](#) that specifies the resource names.

To create an environment from your template, use [az deployment group create](#) as follows:

```
az deployment group create \
--resource-group myNewResourceGroup \
--template-file myResourceGroup.json
```

You might want to read [more about how to deploy from templates](#). Learn about how to incrementally update environments, use the parameters file, and access templates from a single storage location.

## Next steps

Now you're ready to begin working with multiple networking components and VMs. You can use this sample environment to build out your application by using the core components introduced here.

# How to create a Linux virtual machine with Azure Resource Manager templates

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Learn how to create a Linux virtual machine (VM) by using an Azure Resource Manager template and the Azure CLI from the Azure Cloud shell. To create a Windows virtual machine, see [Create a Windows virtual machine from a Resource Manager template](#).

An alternative is to deploy the template from the Azure portal. To open the template in the portal, select the **Deploy to Azure** button.

## Templates overview

Azure Resource Manager templates are JSON files that define the infrastructure and configuration of your Azure solution. By using a template, you can repeatedly deploy your solution throughout its lifecycle and have confidence your resources are deployed in a consistent state. To learn more about the format of the template and how you construct it, see [Quickstart: Create and deploy Azure Resource Manager templates by using the Azure portal](#). To view the JSON syntax for resources types, see [Define resources in Azure Resource Manager templates](#).

## Create a virtual machine

Creating an Azure virtual machine usually includes two steps:

1. Create a resource group. An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine.
2. Create a virtual machine.

The following example creates a VM from an [Azure Quickstart template](#). This template creates an Azure Generation 2 VM by default. See [Support for generation 2 VMs on Azure](#) to learn more about Azure Generation 2 VMs. Only SSH authentication is allowed for this deployment. When prompted, provide the value of your own SSH public key, such as the contents of `~/.ssh/id_rsa.pub`. If you need to create an SSH key pair, see [How to create and use an SSH key pair for Linux VMs in Azure](#). Here is a copy of the template:

```
{  
    "$schema": "https://schema.management.azure.com/schemas/2019-04-01/deploymentTemplate.json#",  
    "contentVersion": "1.0.0.0",

                "version": "latest"
            },
            "osDisk": {
                "createOption": "fromImage"
            }
        },
        "networkProfile": {
            "networkInterfaces": [
                {
                    "id": "[resourceId('Microsoft.Network/networkInterfaces', variables('networkInterfaceName'))]"
                }
            ]
        }
    }
}
]
}

```

To run the CLI script, Select **Try it** to open the Azure Cloud shell. To paste the script, right-click the shell, and then select **Paste**:

```

echo "Enter the Resource Group name:" &&
read resourceGroupName &&
echo "Enter the location (i.e. centralus):" &&
read location &&
echo "Enter the project name (used for generating resource names):" &&
read projectName &&
echo "Enter the administrator username:" &&
read username &&
echo "Enter the SSH public key:" &&
read key &&
az group create --name $resourceGroupName --location "$location" &&
az deployment group create --resource-group $resourceGroupName --template-uri
https://raw.githubusercontent.com/azure/azure-quickstart-templates/master/quickstarts/microsoft.compute/vm-
sshkey/azuredeploy.json --parameters projectName=$projectName adminUsername=$username adminPublicKey="$key"
&&
az vm show --resource-group $resourceGroupName --name "$projectName-vm" --show-details --query publicIps --
output tsv

```

The last Azure CLI command shows the public IP address of the newly created VM. You need the public IP address to connect to the virtual machine. See the next section of this article.

In the previous example, you specified a template stored in GitHub. You can also download or create a template and specify the local path with the `--template-file` parameter.

Here are some additional resources:

- To learn how to develop Resource Manager templates, see [Azure Resource Manager documentation](#).
- To see the Azure virtual machine schemas, see [Azure template reference](#).
- To see more virtual machine template samples, see [Azure Quickstart templates](#).

## Connect to virtual machine

You can then SSH to your VM as normal. Provide your own public IP address from the preceding command:

```
ssh <adminUsername>@<ipAddress>
```

## Next steps

In this example, you created a basic Linux VM. For more Resource Manager templates that include application frameworks or create more complex environments, browse the [Azure Quickstart templates](#).

To learn more about creating templates, view the JSON syntax and properties for the resources types you deployed:

- [Microsoft.Network/networkSecurityGroups](#)
- [Microsoft.Network/publicIPAddresses](#)
- [Microsoft.Network/virtualNetworks](#)
- [Microsoft.Network/networkInterfaces](#)
- [Microsoft.Compute/virtualMachines](#)

# Create a Linux virtual machine that uses SSH authentication with the REST API

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

A Linux virtual machine (VM) in Azure consists of various resources such as disks and network interfaces and defines parameters such as location, size and operating system image and authentication settings.

You can create a Linux VM via the Azure portal, Azure CLI 2.0, many Azure SDKs, Azure Resource Manager templates and many third-party tools such as Ansible or Terraform. All these tools ultimately use the REST API to create the Linux VM.

This article shows you how to use the REST API to create a Linux VM running Ubuntu 18.04-LTS with managed disks and SSH authentication.

## Before you start

Before you create and submit the request, you will need:

- The `{subscription-id}` for your subscription
  - If you have multiple subscriptions, see [Working with multiple subscriptions](#)
- A `{resourceGroupName}` you've created ahead of time
- A [virtual network interface](#) in the same resource group
- An SSH key pair (you can [generate a new one](#) if you don't have one)

## Request basics

To create or update a virtual machine, use the following *PUT* operation:

```
PUT https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmName}?api-version=2017-12-01
```

In addition to the `{subscription-id}` and `{resourceGroupName}` parameters, you'll need to specify the `{vmName}` (`api-version` is optional, but this article was tested with `api-version=2017-12-01`)

The following headers are required:

REQUEST HEADER	DESCRIPTION
<code>Content-Type:</code>	Required. Set to <code>application/json</code> .
<code>Authorization:</code>	Required. Set to a valid <code>Bearer</code> <a href="#">access token</a> .

For general information about working with REST API requests, see [Components of a REST API request/response](#).

## Create the request body

The following common definitions are used to build a request body:

NAME	REQUIRED	TYPE	DESCRIPTION
location	True	string	Resource location.
name		string	Name for the virtual machine.
properties.hardwareProfile		HardwareProfile	Specifies the hardware settings for the virtual machine.
properties.storageProfile		StorageProfile	Specifies the storage settings for the virtual machine disks.
properties.osProfile		OSProfile	Specifies the operating system settings for the virtual machine.
properties.networkProfile		NetworkProfile	Specifies the network interfaces of the virtual machine.

An example request body is below. Make sure you specify the VM name in the `{computerName}` and `{name}` parameters, the name of the network interface you've created under `networkInterfaces`, your username in `adminUsername` and `path`, and the `public` portion of your SSH keypair (located in, for example, `~/.ssh/id_rsa.pub`) in `keyData`. Other parameters you might want to modify include `location` and `vmSize`.

```
{
  "location": "eastus",
  "name": "{vmName}",
  "properties": {
    "hardwareProfile": {
      "vmSize": "Standard_DS1_v2"
    },
    "storageProfile": {
      "imageReference": {
        "sku": "18.04-LTS",
        "publisher": "Canonical",
        "version": "latest",
        "offer": "UbuntuServer"
      },
      "osDisk": {
        "caching": "ReadWrite",
        "managedDisk": {
          "storageAccountType": "Premium_LRS"
        },
        "name": "myVMosdisk",
        "createOption": "FromImage"
      }
    },
    "osProfile": {
      "adminUsername": "{your-username}",
      "computerName": "{vmName}",
      "linuxConfiguration": {
        "ssh": {
          "publicKeys": [
            {
              "path": "/home/{your-username}/.ssh/authorized_keys",
              "keyData": "ssh-rsa AAAAB3NzaC1{snip}mf69/J1"
            }
          ]
        },
        "disablePasswordAuthentication": true
      }
    },
    "networkProfile": {
      "networkInterfaces": [
        {
          "id": "/subscriptions/{subscription-
id}/resourceGroups/{resourceGroupName}/providers/Microsoft.Network/networkInterfaces/{existing-nic-name}",
          "properties": {
            "primary": true
          }
        }
      ]
    }
  }
}
```

For a complete list of the available definitions in the request body, see [Virtual machines create or update request body definitions](#).

## Sending the request

You may use the client of your preference for sending this HTTP request. You may also use an [in-browser tool](#) by clicking the **Try it** button.

### Responses

There are two successful responses for the operation to create or update a virtual machine:

NAME	TYPE	DESCRIPTION
200 OK	<a href="#">VirtualMachine</a>	OK
201 Created	<a href="#">VirtualMachine</a>	Created

A condensed `201 Created` response from the previous example request body that creates a VM shows a `vmId` has been assigned and the `provisioningState` is `Creating`.

```
{
  "vmId": "e0de9b84-a506-4b95-9623-00a425d05c90",
  "provisioningState": "Creating"
}
```

For more information about REST API responses, see [Process the response message](#).

## Next steps

For more information on the Azure REST APIs or other management tools such as Azure CLI or Azure PowerShell, see the following:

- [Azure Compute provider REST API](#)
- [Get started with Azure REST API](#)
- [Azure CLI](#)
- [Azure PowerShell module](#)

# Tutorial: Install a LAMP stack on an Azure Linux VM

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

This article walks you through how to deploy an Apache web server, MySQL, and PHP (the LAMP stack) on an Ubuntu VM in Azure. To see the LAMP server in action, you can optionally install and configure a WordPress site. In this tutorial you learn how to:

- Create an Ubuntu VM
- Open port 80 for web traffic
- Install Apache, MySQL, and PHP
- Verify installation and configuration
- Install WordPress

This setup is for quick tests or proof of concept. For more on the LAMP stack, including recommendations for a production environment, see the [Ubuntu documentation](#).

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create a resource group

Create a resource group with the [az group create](#) command. An Azure resource group is a logical container into which Azure resources are deployed and managed.

The following example creates a resource group named *myResourceGroup* in the *eastus* location.

```
az group create --name myResourceGroup --location eastus
```

## Create a virtual machine

Create a VM with the [az vm create](#) command.

The following example creates a VM named *myVM* and creates SSH keys if they do not already exist in a default key location. To use a specific set of keys, use the `--ssh-key-value` option. The command also sets *azureuser* as an administrator user name. You use this name later to connect to the VM.

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image UbuntuLTS \
--admin-username azureuser \
--generate-ssh-keys
```

When the VM has been created, the Azure CLI shows information similar to the following example. Take note of the `publicIpAddress`. This address is used to access the VM in later steps.

```
{  
  "fqdns": "",  
  "id": "/subscriptions/<subscription  
ID>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",  
  "location": "eastus",  
  "macAddress": "00-0D-3A-23-9A-49",  
  "powerState": "VM running",  
  "privateIpAddress": "10.0.0.4",  
  "publicIpAddress": "40.68.254.142",  
  "resourceGroup": "myResourceGroup"  
}
```

## Open port 80 for web traffic

By default, only SSH connections are allowed into Linux VMs deployed in Azure. Because this VM is going to be a web server, you need to open port 80 from the internet. Use the [az vm open-port](#) command to open the desired port.

```
az vm open-port --port 80 --resource-group myResourceGroup --name myVM
```

For more information about opening ports to your VM, see [Open ports](#).

## SSH into your VM

If you don't already know the public IP address of your VM, run the [az network public-ip list](#) command. You need this IP address for several later steps.

```
az network public-ip list --resource-group myResourceGroup --query []. ipAddress
```

Use the following command to create an SSH session with the virtual machine. Substitute the correct public IP address of your virtual machine. In this example, the IP address is *40.68.254.142*. *azureuser* is the administrator user name set when you created the VM.

```
ssh azureuser@40.68.254.142
```

## Install Apache, MySQL, and PHP

Run the following command to update Ubuntu package sources and install Apache, MySQL, and PHP. Note the caret (^) at the end of the command, which is part of the `lamp-server^` package name.

```
sudo apt update && sudo apt install lamp-server^
```

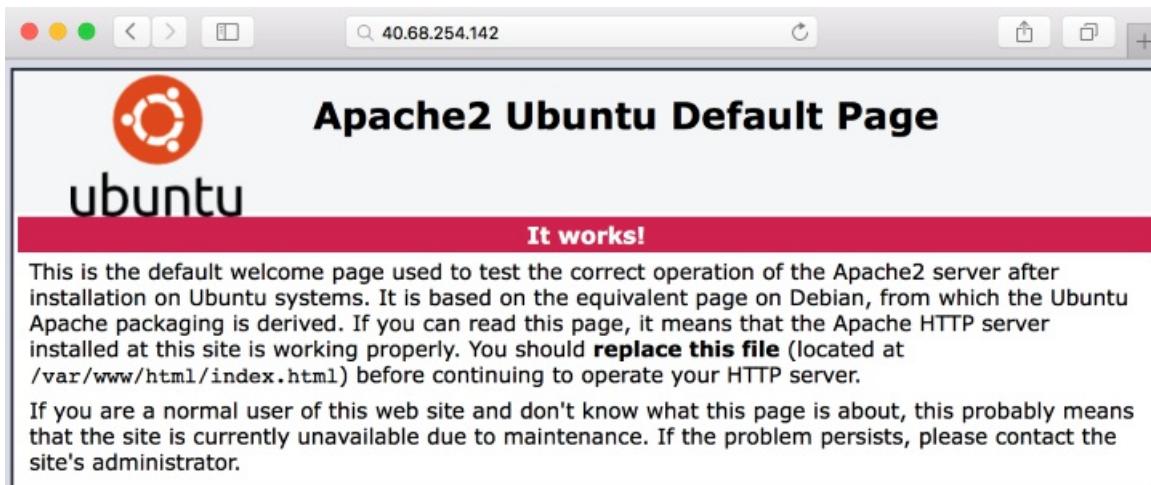

You are prompted to install the packages and other dependencies. This process installs the minimum required PHP extensions needed to use PHP with MySQL.

## Verify Apache

Check the version of Apache with the following command:

```
apache2 -v
```

With Apache installed, and port 80 open to your VM, the web server can now be accessed from the internet. To view the Apache2 Ubuntu Default Page, open a web browser, and enter the public IP address of the VM. Use the public IP address you used to SSH to the VM:

## Verify and secure MySQL

Check the version of MySQL with the following command (note the capital `v` parameter):

```
mysql -v
```

To help secure the installation of MySQL, including setting a root password, run the `mysql_secure_installation` script.

```
sudo mysql_secure_installation
```

You can optionally set up the Validate Password Plugin (recommended). Then, set a password for the MySQL root user, and configure the remaining security settings for your environment. We recommend that you answer "Y" (yes) to all questions.

If you want to try MySQL features (create a MySQL database, add users, or change configuration settings), login to MySQL. This step is not required to complete this tutorial.

```
sudo mysql -u root -p
```

When done, exit the mysql prompt by typing `\q`.

## Verify PHP

Check the version of PHP with the following command:

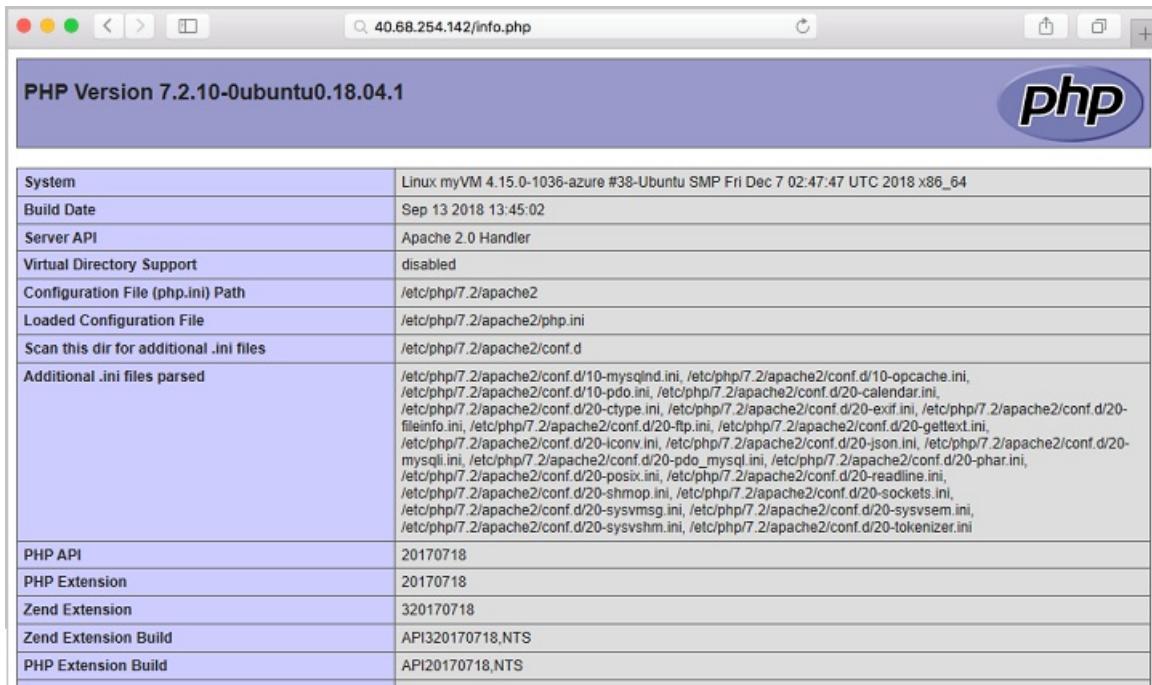

```
php -v
```

If you want to test further, create a quick PHP info page to view in a browser. The following command creates the PHP info page:

```
sudo sh -c 'echo "<?php phpinfo(); ?>" > /var/www/html/info.php'
```

Now you can check the PHP info page you created. Open a browser and go to

`http://yourPublicIPAddress/info.php`. Substitute the public IP address of your VM. It should look similar to this image.

A screenshot of a web browser window displaying PHP version information. The title bar shows the URL `40.68.254.142/info.php`. The page header includes the text "PHP Version 7.2.10-0ubuntu0.18.04.1" and the PHP logo. Below this is a table containing various PHP configuration details:

System	Linux myVM 4.15.0-1036-azure #38-Ubuntu SMP Fri Dec 7 02:47:47 UTC 2018 x86_64
Build Date	Sep 13 2018 13:45:02

PHP Extension Build	API20170718,NTS

## Install WordPress

If you want to try your stack, install a sample app. As an example, the following steps install the open source [WordPress](#) platform to create websites and blogs. Other workloads to try include [Drupal](#) and [Moodle](#).

This WordPress setup is only for proof of concept. To install the latest WordPress in production with recommended security settings, see the [WordPress documentation](#).

### Install the WordPress package

Run the following command:

```
sudo apt install wordpress
```

### Configure WordPress

Configure WordPress to use MySQL and PHP.

In a working directory, create a text file `wordpress.sql` to configure the MySQL database for WordPress:

```
sudo sensible-editor wordpress.sql
```

Add the following commands, substituting a database password of your choice for `yourPassword` (leave other values unchanged). If you previously set up a MySQL security policy to validate password strength, make sure the password meets the strength requirements. Save the file.

```
CREATE DATABASE wordpress;
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,ALTER
ON wordpress.*
TO wordpress@localhost
IDENTIFIED BY 'yourPassword';
```

Run the following command to create the database:

```
cat wordpress.sql | sudo mysql --defaults-extra-file=/etc/mysql/debian.cnf
```

Because the file `wordpress.sql` contains database credentials, delete it after use:

```
sudo rm wordpress.sql
```

To configure PHP, run the following command to open a text editor of your choice and create the file

```
/etc/wordpress/config-localhost.php :
```

```
sudo sensible-editor /etc/wordpress/config-localhost.php
```

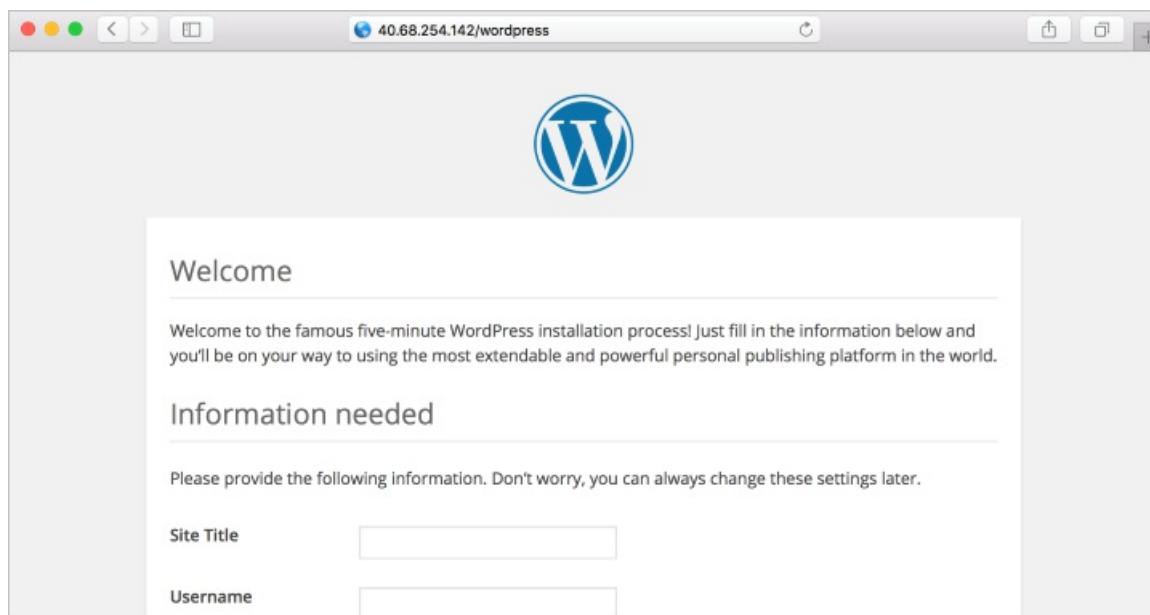

Copy the following lines to the file, substituting your WordPress database password for `yourPassword` (leave other values unchanged). Then save the file.

```
<?php
define('DB_NAME', 'wordpress');
define('DB_USER', 'wordpress');
define('DB_PASSWORD', 'yourPassword');
define('DB_HOST', 'localhost');
define('WP_CONTENT_DIR', '/usr/share/wordpress/wp-content');
?>
```

Move the WordPress installation to the web server document root:

```
sudo ln -s /usr/share/wordpress /var/www/html/wordpress
sudo mv /etc/wordpress/config-localhost.php /etc/wordpress/config-default.php
```

Now you can complete the WordPress setup and publish on the platform. Open a browser and go to `http://yourPublicIPAddress/wordpress`. Substitute the public IP address of your VM. It should look similar to this image.

## Next steps

In this tutorial, you deployed a LAMP server in Azure. You learned how to:

- Create an Ubuntu VM
- Open port 80 for web traffic
- Install Apache, MySQL, and PHP
- Verify installation and configuration
- Install WordPress on the LAMP server

Advance to the next tutorial to learn how to secure web servers with TLS/SSL certificates.

[Secure web server with TLS](#)

# Configure the rolling deployment strategy for Azure Linux virtual machines

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Azure Pipelines provides a fully featured set of CI/CD automation tools for deployments to virtual machines. This article will show you how to set up a classic release pipeline that uses the rolling strategy to deploy your web applications to Linux virtual machines.

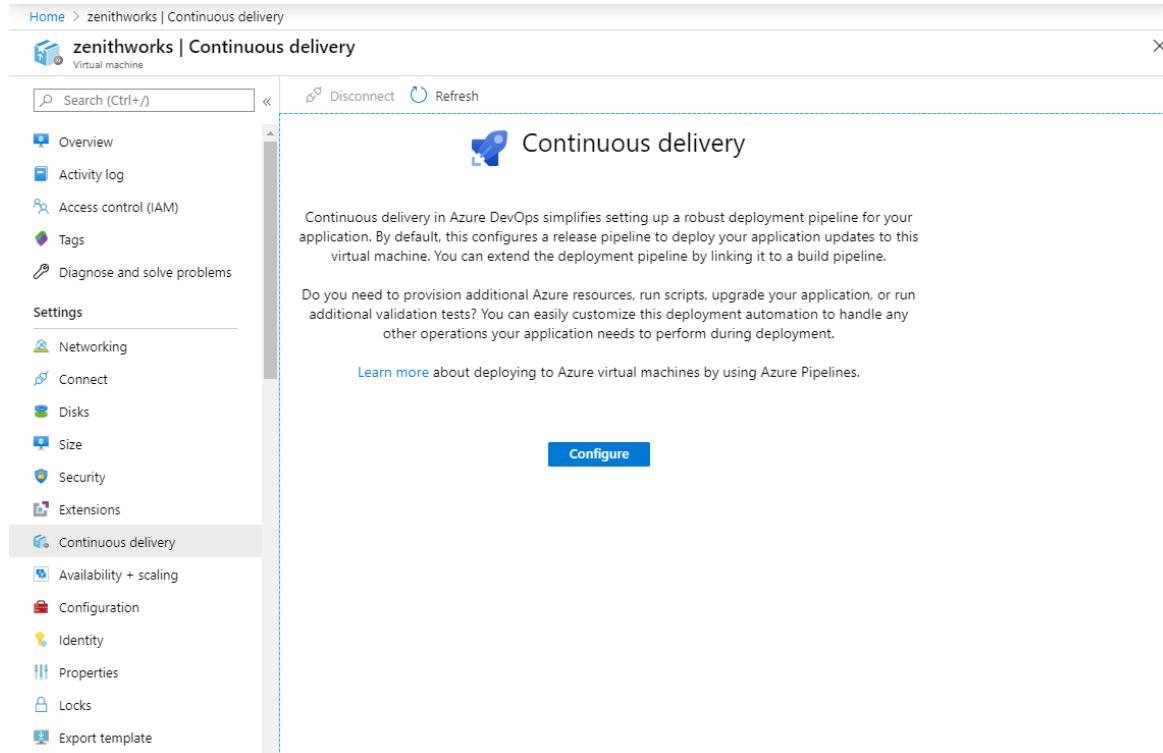

## Rolling deployments

In each iteration, a rolling deployment replaces instances of an application's previous version. It replaces them with instances of the new version on a fixed set of machines (rolling set). The following walk-through shows how to configure a rolling update to virtual machines.

Using **Continuous-delivery**, you can configure rolling updates to your virtual machines within the Azure portal.

[!IMPORTANT] Virtual Machine's Continuous delivery setting will be retired on March 31, 2023. [Learn more](#)

1. Sign in to [Azure portal](#) and navigate to a virtual machine.
2. Select **Continuous delivery**, and then select **Configure**.

3. Select your **Azure DevOps Organization** and your **Project** from the dropdown menu or **Create** a new one.
4. Select your **Deployment group** from the dropdown menu or **Create** a new one.
5. Select your **Build pipeline**.

6. Select **Deployment strategy**, and then select **Rolling**.

The screenshot shows the Azure portal interface for configuring a continuous delivery pipeline. On the left, a sidebar lists various settings like Overview, Activity log, and Tags. The 'Continuous delivery' section is selected. The main pane displays the 'Continuous delivery' configuration dialog. It includes fields for 'Azure DevOps Organization' (set to 'Use existing' and 'amja'), 'Project' (set to 'zenithworks'), 'Deployment group' (set to 'Use existing'), 'Deployment group name' (set to 'production-dg'), 'Build pipeline' (set to 'zw-core-Cl'), and 'Deployment strategy' (set to 'Rolling'). A dropdown menu also lists 'Canary' and 'Blue-Green' strategies. At the bottom right of the dialog is an 'OK' button.

7. Optionally, you can tag each machine with its role such as *web* or *db*. These tags help you target only VMs that have a specific role.

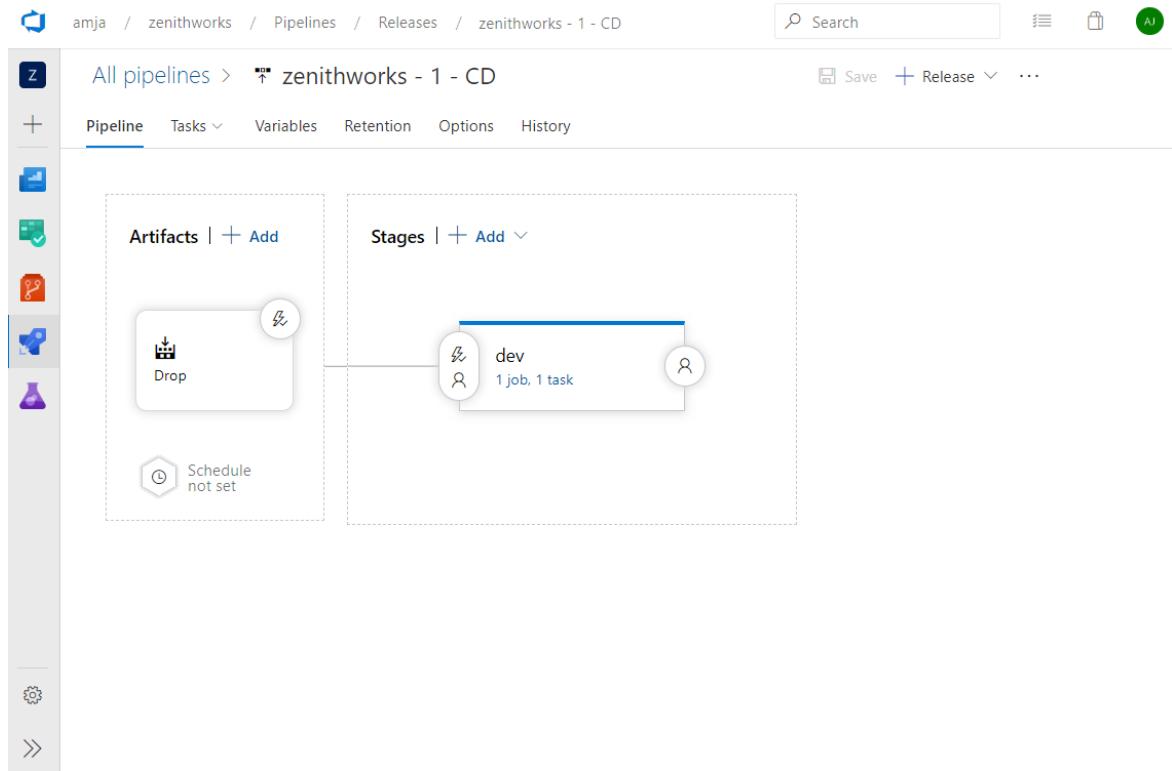

8. Select **OK** to configure the continuous delivery pipeline.

9. After completion, your continuous delivery pipeline should look similar to the following.

The screenshot shows the Azure portal interface after the continuous delivery pipeline has been configured. The sidebar and main pane are identical to the previous screenshot, but the main pane now displays the 'Deployment history' section. It shows a single deployment entry from 4/3/2020: 'zenithworks - 1 - CD > Release-1 / dev' was deployed at 7:29:43 PM on 4/3/2020, took 00:00:03, and was successful (indicated by a green checkmark). The deployment was triggered from branch 'master'.

10. If you want to configure multiple VMs, repeat steps 2 through 4 for the other VMs. If you use the same deployment group that already has a configured pipeline, the new VMs will just be added to the deployment group and no new pipelines will be created.

11. Select the link to navigate to your pipeline, and then select **Edit** to modify the pipeline definition.

12. Select the tasks in the **dev** stage to navigate to the pipeline tasks, and then select **Deploy**.

The screenshot shows the Azure Pipelines interface with the 'Tasks' tab selected. On the left, there's a sidebar with icons for Artifacts, Stages, Variables, Retention, Options, and History. The main content area shows a list of tasks under the 'dev' stage. One task, 'Deploy', is highlighted. To the right, the 'Deploy' task's configuration is shown. It has a 'Display name' of 'Deploy', a 'Deployment targets' section with a 'Deployment group' of 'production-dg', and a 'Targets to deploy to in parallel' section where 'One target at a time' is selected. There's also a 'Timeout' field set to '0'.

13. You can specify the number of target machines to deploy to in parallel in each iteration. If you want to deploy to multiple machines, you can specify the number of machines as a percentage by using the slider.
14. The **Execute Deploy Script** task will execute the deployment script located in the root folder of the published artifacts.

[← Artifacts](#)[Published](#)

Name	Size
>  buildbinaries	17 B
✓  deployscripts	17 B
□ deploy.sh	17 B

## Resources

- [Deploy to Azure virtual machine scale set](#)

## Related articles

- [Configure the canary deployment strategy](#)
- [Configure the blue-green deployment strategy](#)

## Retirement

Continuous delivery setting of Virtual Machines will be retired on March 31, 2023. Please switch to directly using Azure DevOps to create customized pipelines for deployment to Azure VMs. Release pipeline [Stage Templates](#) and [Deployments Groups](#) Azure DevOps' features provide similar experiences.

### Migration Steps

There is no migration required as VM CD experience does not store any information itself, it just helps users with their Day 0 getting started experience on Azure and Azure DevOps. Users will still be able to perform all operations from Azure DevOps after retirement. You won't be able to create and view pipelines from the Azure portal anymore.

### FAQ

Where can I set up my CD pipeline after this experience is deprecated?

You won't be able to view or create Azure DevOps pipelines from an Azure portal Virtual Machine blade after retirement. You still can go to Azure DevOps portal and view or update pipelines.

Will I lose my earlier configured pipelines?

No. Your pipelines will still be available in Azure DevOps.

How can I configure different deployment strategies?

The current experience uses [deployment groups](#) to create deployment strategies. You can use deployment groups or release pipeline [Stage Templates](#) to build your pipeline with templates.

# Configure the canary deployment strategy for Azure Linux Virtual Machines

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

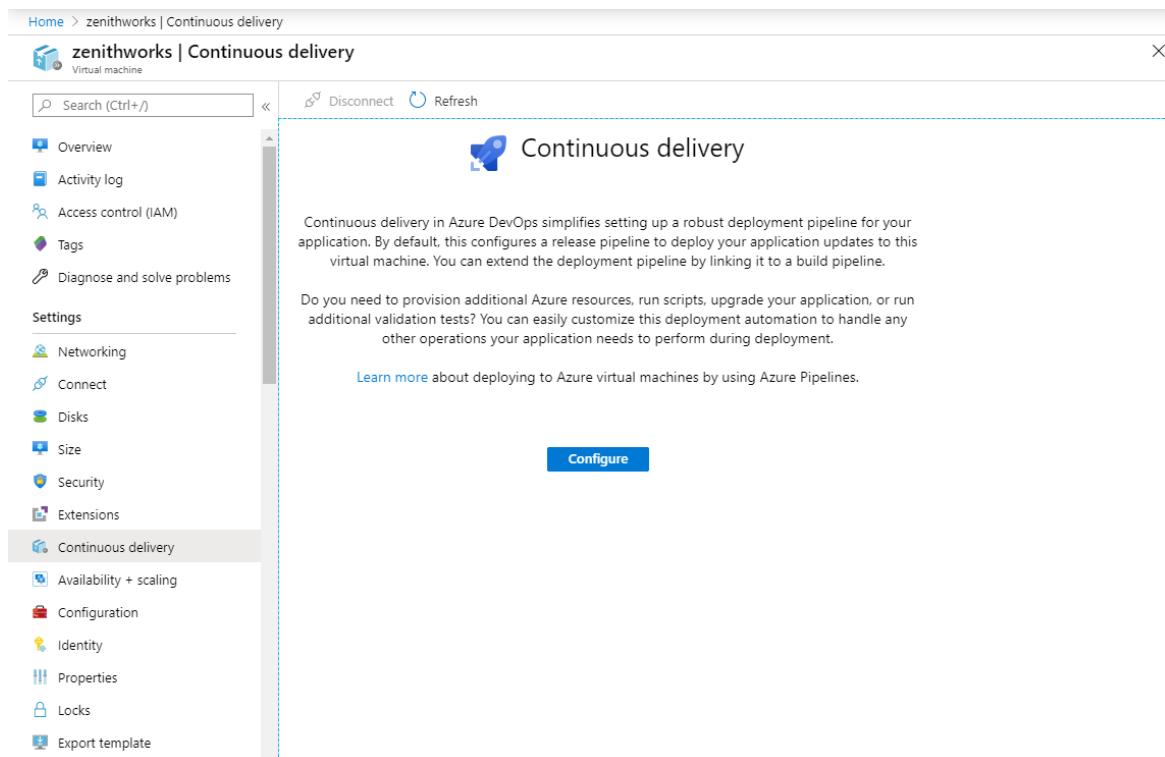

Azure Pipelines provides a fully featured set of CI/CD automation tools for deployments to virtual machines. This article will show you how to set up a classic release pipeline that uses the canary strategy to deploy web applications to Linux virtual machines.

## Canary deployments

A canary deployment reduces risk by slowly rolling out changes to a small subset of users. As you gain confidence in the new version, you can release it to more servers in your infrastructure and route more users to it.

Using the **Continuous-delivery** feature, you can use the canary strategy to deploy your application from Azure portal.

1. Sign in to [Azure portal](#) and navigate to a virtual machine.
2. Select **Continuous delivery**, and then select **Configure**.

3. In the configuration panel, select **Use existing** and select your organization/project or select **Create** and create new ones.
4. Select your **Deployment group name** from the dropdown menu or create a new one.
5. Select your **Build pipeline** from the dropdown menu.
6. Select **Deployment strategy**, and then select **Canary**.

The screenshot shows the 'Continuous delivery' configuration dialog box. In the top right corner, there is a close button (X) and a help icon (i). The title bar says 'Continuous delivery' and 'Configure a deployment pipeline'. The main area contains the following fields:

- Azure DevOps Organization \***: A dropdown menu showing 'amja'.
- Project**: A dropdown menu showing 'zenithworks'.
- Deployment group**: A dropdown menu with 'Create' and 'Use existing' options; 'Use existing' is selected.
- Deployment group name \***: A dropdown menu showing 'production-dg'.
- Build pipeline**: A dropdown menu showing 'zw-core-CI'.
- Deployment strategy \***: A dropdown menu with 'Rolling' (selected), 'Canary', and 'Blue-Green' options.

At the bottom right of the dialog box is a blue 'OK' button.

7. Add a "canary" tag to the VMs that will be used in the canary deployment.

The screenshot shows the same 'Continuous delivery' configuration dialog box as the previous one, but with a 'canary' tag added. In the bottom right corner of the dialog box, there is a 'Tags' section containing a single tag labeled 'canary'. The rest of the configuration fields are identical to the first screenshot.

8. Select OK to configure the classic release pipeline to deploy to your virtual machine.

The screenshot shows the Azure DevOps Pipelines interface. On the left, there's a sidebar with various project management and development tools like Boards, Repos, Pipelines, and Test Plans. The main area displays a release pipeline named "zenithworks - 1 - CD". The pipeline structure is shown in two columns: "Artifacts" and "Stages". The "Artifacts" column contains a single item, "Drop". The "Stages" column contains one stage named "dev", which is described as having "3 jobs, 3 tasks". Below the stage, a note says "Schedule not set".

9. Navigate to your release pipeline and then select **Edit** to view the pipeline configuration. In this example, the *dev* stage is composed of three jobs:
  - a. Deploy Canary: the application is deployed to VMs with a "canary" tag.
  - b. Wait for manual resumption: the pipeline pauses and waits for manual intervention. Before resuming the pipeline, ensure that at least one VM is tagged "prod". In the next phase, the app will be deployed only to "prod" VMs.
  - c. Deploy Prod: the application is deployed to VMs with a "prod" tag.

The screenshot shows the "Tasks" tab for the "dev" stage of the "zenithworks - 1 - CD" pipeline. The tasks listed are:

- Deploy Canary
- Execute Deploy Script
- Wait for Manual resumption
- Manual Intervention
- Deploy Prod
- Execute Deploy Script

For the "Deploy Canary" task, the configuration details on the right are:

- Deployment group \***: production-dg
- Required tags**: canary
- Targets to deploy to in parallel**:
  - Multiple
  - One target at a time
- Maximum number of targets in parallel**: 100% targets (0)
- Timeout \***: 0
- Job cancel timeout \***: 1
- Artifact download**: Specify at the time of release

# Configure the blue-green deployment strategy for Azure Linux virtual machines

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

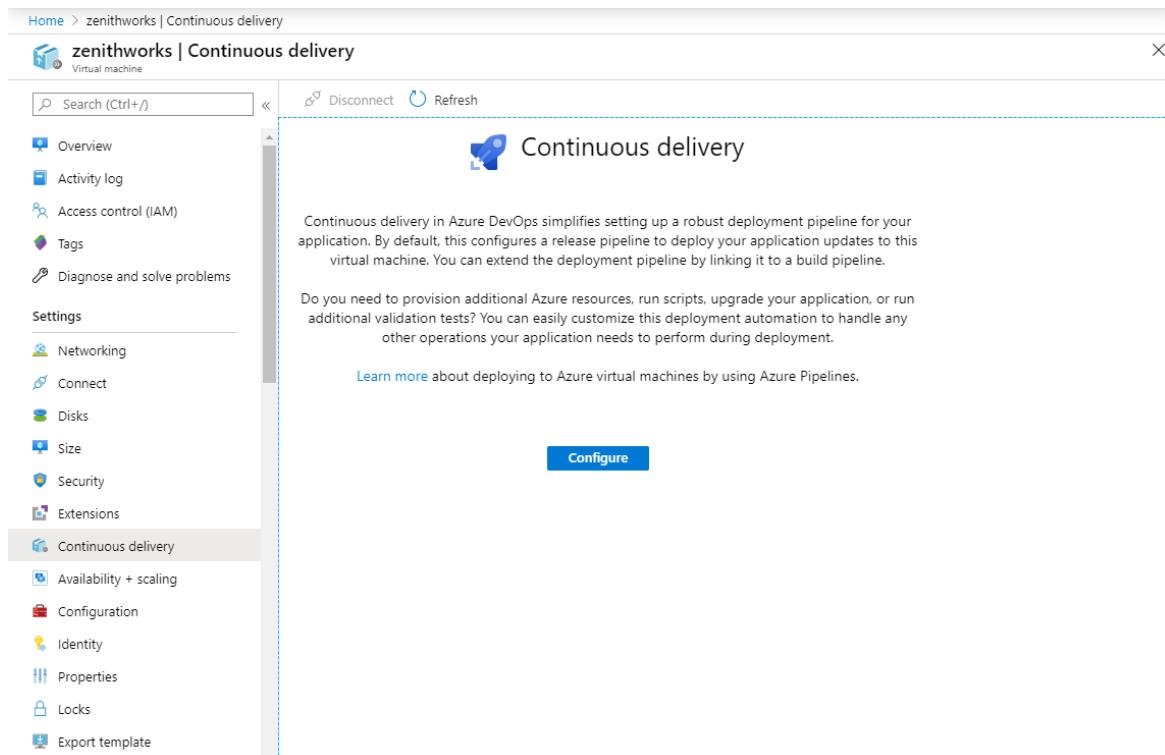

Azure Pipelines provides a fully featured set of CI/CD automation tools for deployments to virtual machines. This article will show you how to set up a classic release pipeline that uses the blue-green strategy to deploy to Linux virtual machines. Azure also supports other strategies like [rolling](#) and [canary](#) deployments.

## Blue-green deployments

A blue-green deployment is a deployment strategy where you create two separate and identical environments but only one is live at any time. This strategy is used to increase availability and reduce downtime by switching between the blue/green environments. The blue environment is usually set to run the current version of the application while the green environment is set to host the updated version. When all updates are completed, traffic is directed to the green environment and blue environment is set to idle.

Using the [Continuous-delivery](#) feature, you can use the blue-green deployment strategy to deploy to your virtual machines from Azure portal.

1. Sign in to [Azure portal](#) and navigate to a virtual machine.
2. Select [Continuous delivery](#), and then select [Configure](#).

3. In the configuration panel, select **Use existing** and select your organization/project or select **Create** and create new ones.
4. Select your **Deployment group name** from the dropdown menu or create a new one.
5. Select your **Build pipeline** from the dropdown menu.

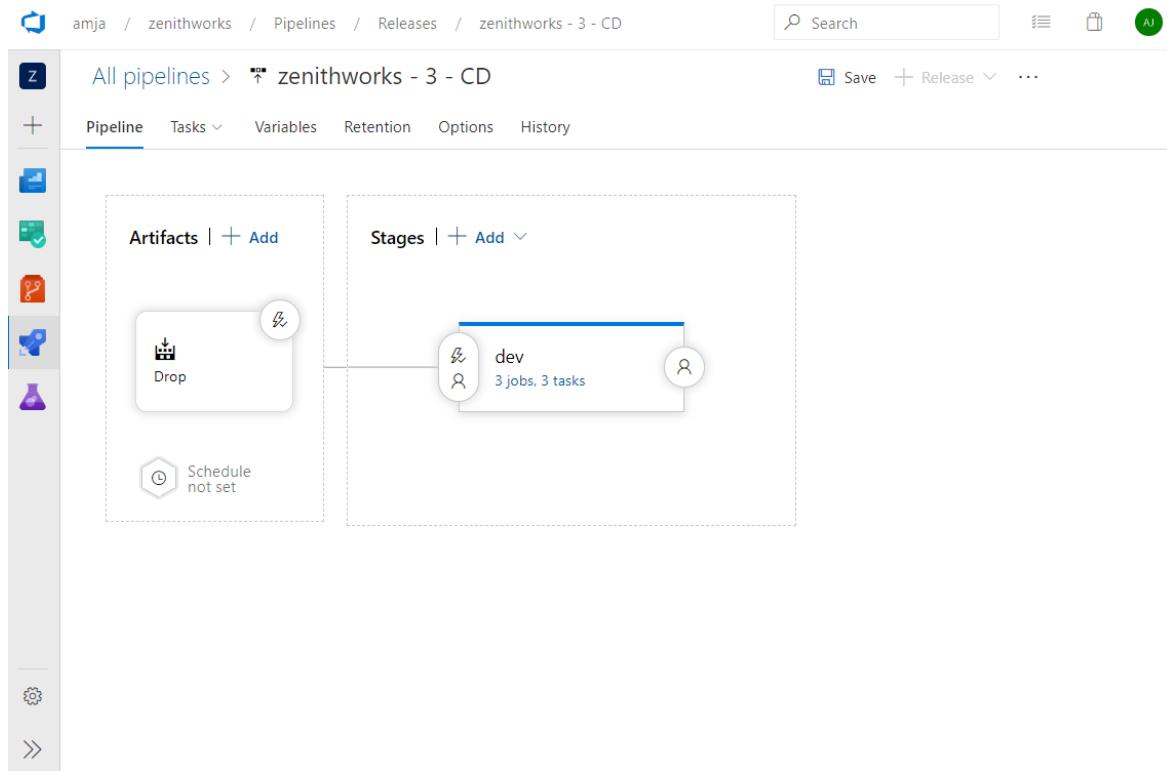

6. Select the Deployment strategy dropdown menu, and then select **Blue-Green**.

The screenshot shows the Azure portal interface for configuring continuous delivery. On the left, there's a sidebar with various settings like Overview, Activity log, and Tags. The main area is titled 'Continuous delivery' and contains instructions about setting up a release pipeline. A prominent 'Configure' button is at the bottom. To the right, a detailed configuration dialog is open. It asks for the Azure DevOps Organization (set to 'amja' and 'Use existing'). The 'Project' is set to 'zenithworks'. Under 'Deployment group', 'Use existing' is selected. The 'Deployment group name' is 'production-dg'. The 'Build pipeline' is 'zw-core-CI'. In the 'Deployment strategy' section, 'Blue-Green' is selected from a dropdown menu. At the bottom right of the dialog is a blue 'OK' button.

7. Add a "blue" or "green" tag to VMs that are used for blue-green deployments. If a VM is for a standby role, tag it as "green". Otherwise, tag it as "blue".

This screenshot is similar to the previous one but includes a 'Tags' section at the bottom of the configuration dialog. This section contains a single tag labeled 'green'. The rest of the dialog is identical to the first screenshot, showing the 'Deployment strategy' dropdown with 'Blue-Green' selected.

8. Select **OK** to configure the classic release pipeline to deploy to your virtual machine.

9. Navigate to your release pipeline and then select **Edit** to view the pipeline configuration. In this example, the *dev* stage is composed of three jobs:
  - a. Deploy Green: the app is deployed to a standby VM tagged "green".
  - b. Wait for manual resumption: the pipeline pauses and waits for manual intervention.
  - c. Swap Blue-Green: this job swaps the "blue" and "green" tags in the VMs. This ensures that VMs with older application versions are now tagged as "green". During the next pipeline run, applications will be deployed to these VMs.

The screenshot shows the detailed configuration of the 'dev' stage in the Azure DevOps Pipeline. The stage contains the following tasks:

- Deployment group job**: Deployment name is 'Deploy Green'.
- Deployment targets**: Deployment group is 'production-dg'.
- Required tags**: Tag is 'green'.
- Targets to deploy in parallel**: Multiple targets are selected.
- Maximum number of targets in parallel**: Set to 100%.
- Timeout**: Set to 10 minutes.

# Deploy your app to Linux virtual machines in Azure using Azure DevOps Services and Azure Pipelines

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

Continuous integration (CI) and continuous deployment (CD) form a pipeline by which you can build, release, and deploy your code after every code commit. This document contains the steps associated with setting up a CI/CD pipeline for doing multi-machine deployments using Azure Pipelines.

Azure Pipelines provides a complete, fully featured set of CI/CD automation tools for deployments to Virtual machines, both on-prem or on any cloud.

In this tutorial, you will set up a YAML based CI/CD pipeline to deploy your app to an Azure Pipelines [Environment](#) with Linux Virtual machines as resources, each of which serve as web servers to run the app.

You learn how to:

- Get a sample app.
- Create a YAML based Azure Pipelines CI pipeline for building the sample app.
- Create an Azure Pipelines Environment for the Azure virtual machines
- Create an Azure Pipelines CD pipeline.
- Execute manual and CI-triggered deployments.

## Before you begin

- Sign in to your Azure DevOps Services organization (<https://dev.azure.com/>). You can get a free [Azure DevOps Services organization](#).

### NOTE

For more information, see [Connect to Azure DevOps Services](#).

- You need a Linux virtual machine for a deployment target. For more information, see [Create and manage Linux VMs with the Azure CLI](#).
- Open inbound port 80 for your virtual machine. For more information, see [Create network security groups using the Azure portal](#).

## Get your sample app code

If you already have an app in GitHub that you want to deploy, you can try creating a pipeline for that code.

However, if you are a new user, then you might get a better start by using our sample code. In that case, fork this repo in GitHub:

- [Java](#)
- [JavaScript](#)

<https://github.com/spring-projects/spring-petclinic>

#### NOTE

Petclinic is a [Java Spring Boot](#) application built using [Maven](#).

## Prerequisites for the Linux VM

Sample apps mentioned above have been tested on Ubuntu 16.04, and we recommend you use the same version of Linux VM for this quickstart. Follow the additional steps described below based on the runtime stack used for the app.

- [Java](#)
- [JavaScript](#)
- For deploying Java Spring Boot and Spring Cloud based apps, create a Linux VM in Azure using [this template](#), which provides a fully supported OpenJDK-based runtime.
- For deploying Java servlets on Tomcat server, create a Linux VM with Java 8 using [this Azure template](#) and [configure Tomcat 9.x as a service](#).
- For deploying Java EE based app, use an Azure template to create a [Linux VM + Java + WebSphere 9.x](#) or a [Linux VM + Java + WebLogic 12.x](#) or a [Linux VM + Java](#) + WildFly/JBoss 14

## Create an Azure Pipelines environment with Azure virtual machines

Virtual machines can be added as resources within [environments](#) and can be targeted for multi-machine deployments. Deployment history views within environment provide traceability from VM to the pipeline and then to the commit.

You can create an environment in the “[Environments](#)” hub within the “[Pipelines](#)” section.

1. Sign in to your Azure DevOps organization and navigate to your project.
2. In your project, navigate to the [Pipelines](#) page. Then choose [Environments](#) and click [Create Environment](#). Specify a **Name** (required) for the environment and a **Description**.
3. Choose **Virtual Machines** as a **Resource** to be added to the environment and click **Next**.
4. Choose Operating System (Windows/Linux), and **copy PS registration script**.
5. Now run the copied script from an administrator PowerShell command prompt on each of the target VMs to be registered with this Environment.

#### NOTE

- Personal Access Token of the logged in user is pre-inserted in the script which expires on the same day making the copied script unusable thereon.
- If your VM already has any agent running on it, provide a unique name for “agent” to register with environment.

6. Once the VM is registered, it will start appearing as an environment resource under “resources” tab of the environment.

## New environment

X

### Virtual machine resource

#### Provider

Generic provider

#### Operating system

Windows

#### Registration script

1. Run `$ErrorActionPreference="Stop"` in administrative powershell

7. For adding more VMs, you can view and copy the script again by clicking on "Add resource" and choosing "Virtual Machines" as resource. This script would remain same for all the VMs to be added to this environment.
8. Each machine interacts with Azure Pipelines to coordinate deployment of your app.

The screenshot shows the 'Resources' tab for the 'VMenv' environment. There is one item listed:

Name	Latest job
USHAN-PC	Never deployed

9. You can add tags to the VM as part of the interactive PowerShell registration script (or) you can also add/remove the same from the resource view by clicking on the triple dots at the end of each VM resource in the resources view.

The tags you assign allow you to limit deployment to specific virtual machines when the environment is used in a Deployment job. Tags are each limited to 256 characters, but there is no limit to the number of tags you can use.

The screenshot shows the 'Resources' tab for the 'VMenv' environment. A modal window titled 'Manage tags for USHAN-PC' is open, displaying the tag 'web'. The modal has 'Cancel' and 'Save' buttons.

## Define your CI build pipeline

You'll need a continuous integration (CI) build pipeline that publishes your web application, as well as a deployment script that can be run locally on the Ubuntu server. Set up a CI build pipeline based on the runtime you want to use.

1. Sign in to your Azure DevOps organization and navigate to your project.
2. In your project, navigate to the **Pipelines** page. Then choose the action to create a new pipeline.
3. Walk through the steps of the wizard by first selecting **GitHub** as the location of your source code.
4. You might be redirected to GitHub to sign in. If so, enter your GitHub credentials.
5. When the list of repositories appears, select your desired sample app repository.
6. Azure Pipelines will analyze your repository and recommend a suitable pipeline template.
  - [Java](#)
  - [JavaScript](#)

Select the **starter** template and copy the below YAML snippet that builds your Java project and runs tests with Apache Maven:

```
jobs:  
- job: Build  
  displayName: Build Maven Project  
  steps:  
  - task: Maven@3  
    displayName: 'Maven Package'  
    inputs:  
      mavenPomFile: 'pom.xml'  
  - task: CopyFiles@2  
    displayName: 'Copy Files to artifact staging directory'  
    inputs:  
      SourceFolder: '$(System.DefaultWorkingDirectory)'  
      Contents: '**/target/*.{war|jar}'  
      TargetFolder: '$(Build.ArtifactStagingDirectory)'  
  - upload: '$(Build.ArtifactStagingDirectory)'  
    artifact: drop
```

For more guidance, follow the steps mentioned in [Build your Java app with Maven](#).

## Define CD steps to deploy to the Linux VM

1. Change the YAML file for the above pipeline to include a [deployment job](#) by referencing the environment and the VM resources which you have earlier using the YAML syntax below:

```
jobs:  
- deployment: VMDeploy  
  displayName: web  
  environment:  
    name: <environment name>  
    resourceType: VirtualMachine  
    tags: web
```

2. You can select specific sets of virtual machines from the environment to receive the deployment by specifying the **tags** that you have defined for each virtual machine in the environment. [Here](#) is the complete YAML schema for Deployment job.

3. You can specify either `runOnce` or `rolling` as deployment strategy.

`runOnce` is the simplest deployment strategy wherein all the life cycle hooks, namely `preDeploy`, `deploy`, `routeTraffic`, and `postRouteTraffic`, are executed once. Then, either `on: success` or `on: failure` is executed.

Below is the example YAML snippet for `runOnce`:

```
jobs:
- deployment: VMDeploy
  displayName: web
  pool:
    vmImage: 'Ubuntu-latest'
  environment:
    name: <environment name>
    resourceType: VirtualMachine
  strategy:
    runOnce:
      deploy:
        steps:
          - script: echo my first deployment
```

4. Below is an example of the YAML snippet that you can use to define a rolling strategy for Virtual machines updates upto 5 targets in each iteration. `maxParallel` will determine the number of targets that can be deployed to, in parallel. The selection accounts for absolute number or percentage of targets that must remain available at any time excluding the targets that are being deployed to. It is also used to determine the success and failure conditions during deployment.

```

jobs:
- deployment: VMDeploy
  displayName: web
  environment:
    name: <environment name>
    resourceType: VirtualMachine
  strategy:
    rolling:
      maxParallel: 5 #for percentages, mention as x%
      preDeploy:
        steps:
          - download: current
            artifact: drop
          - script: echo initialize, cleanup, backup, install certs
    deploy:
      steps:
        - task: Bash@3
          inputs:
            targetType: 'inline'
            script: |
              # Modify deployment script based on the app type
              echo "Starting deployment script run"
              sudo java -jar '$(Pipeline.Workspace)/drop/**/target/*.jar'
  routeTraffic:
    steps:
      - script: echo routing traffic
  postRouteTraffic:
    steps:
      - script: echo health check post-route traffic
  on:
    failure:
      steps:
        - script: echo Restore from backup! This is on failure
    success:
      steps:
        - script: echo Notify! This is on success

```

With each run of this job, deployment history is recorded against the <environment name> environment that you have created and registered the VMs.

## Run your pipeline and get traceability views in environment

Deployments view of the environment provides complete traceability of commits and work items, and a cross-pipeline deployment history per environment/resource.

## Next steps

- You can proceed to [customize the pipeline](#) you just created.
- To learn what else you can do in YAML pipelines, see [YAML schema reference](#).
- To learn about how to deploy a LAMP (Linux, Apache, MySQL, and PHP) stack, advance to the next tutorial.

[Deploy LAMP stack](#)

# Tutorial: Use TLS/SSL certificates to secure a web server

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

To secure web servers, a Transport Layer Security (TLS), previously known as Secure Sockets Layer (SSL), certificate can be used to encrypt web traffic. These TLS/SSL certificates can be stored in Azure Key Vault, and allow secure deployments of certificates to Linux virtual machines (VMs) in Azure. In this tutorial you learn how to:

- Create an Azure Key Vault
- Generate or upload a certificate to the Key Vault
- Create a VM and install the NGINX web server
- Inject the certificate into the VM and configure NGINX with a TLS binding

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Overview

Azure Key Vault safeguards cryptographic keys and secrets, such as certificates or passwords. Key Vault helps streamline the certificate management process and enables you to maintain control of keys that access those certificates. You can create a self-signed certificate inside Key Vault, or upload an existing, trusted certificate that you already own.

Rather than using a custom VM image that includes certificates baked-in, you inject certificates into a running VM. This process ensures that the most up-to-date certificates are installed on a web server during deployment. If you renew or replace a certificate, you don't also have to create a new custom VM image. The latest certificates are automatically injected as you create additional VMs. During the whole process, the certificates never leave the Azure platform or are exposed in a script, command-line history, or template.

## Create an Azure Key Vault

Before you can create a Key Vault and certificates, create a resource group with [az group create](#). The following example creates a resource group named *myResourceGroupSecureWeb* in the *eastus* location:

```
az group create --name myResourceGroupSecureWeb --location eastus
```

Next, create a Key Vault with [az keyvault create](#) and enable it for use when you deploy a VM. Each Key Vault requires a unique name, and should be all lowercase. Replace *<mykeyvault>* in the following example with your own unique Key Vault name:

```
keyvault_name=<mykeyvault>
az keyvault create \
--resource-group myResourceGroupSecureWeb \
--name $keyvault_name \
--enabled-for-deployment
```

## Generate a certificate and store in Key Vault

For production use, you should import a valid certificate signed by trusted provider with [az keyvault certificate import](#). For this tutorial, the following example shows how you can generate a self-signed certificate with [az keyvault certificate create](#) that uses the default certificate policy:

```
az keyvault certificate create \
--vault-name $keyvault_name \
--name mycert \
--policy "$(az keyvault certificate get-default-policy)"
```

### Prepare a certificate for use with a VM

To use the certificate during the VM create process, obtain the ID of your certificate with [az keyvault secret list-versions](#). Convert the certificate with [az vm secret format](#). The following example assigns the output of these commands to variables for ease of use in the next steps:

```
secret=$(az keyvault secret list-versions \
--vault-name $keyvault_name \
--name mycert \
--query "[?attributes.enabled].id" --output tsv)
vm_secret=$(az vm secret format --secrets "$secret" -g myResourceGroupSecureWeb --keyvault $keyvault_name)
```

### Create a cloud-init config to secure NGINX

[Cloud-init](#) is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. As cloud-init runs during the initial boot process, there are no additional steps or required agents to apply your configuration.

When you create a VM, certificates and keys are stored in the protected `/var/lib/waagent/` directory. To automate adding the certificate to the VM and configuring the web server, use cloud-init. In this example, you install and configure the NGINX web server. You can use the same process to install and configure Apache.

Create a file named `cloud-init-web-server.txt` and paste the following configuration:

```

#cloud-config
package_upgrade: true
packages:
- nginx
write_files:
- owner: www-data:www-data
- path: /etc/nginx/sites-available/default
content: |
  server {
    listen 443 ssl;
    ssl_certificate /etc/nginx/ssl/mycert.cert;
    ssl_certificate_key /etc/nginx/ssl/mycert.prv;
  }
runcmd:
- secretsname=$(find /var/lib/waagent/ -name "*.prv" | cut -c -57)
- mkdir /etc/nginx/ssl
- cp $secretsname.crt /etc/nginx/ssl/mycert.cert
- cp $secretsname.prv /etc/nginx/ssl/mycert.prv
- service nginx restart

```

## Create a secure VM

Now create a VM with [az vm create](#). The certificate data is injected from Key Vault with the `--secrets` parameter. You pass in the cloud-init config with the `--custom-data` parameter:

```

az vm create \
--resource-group myResourceGroupSecureWeb \
--name myVM \
--image UbuntuLTS \
--admin-username azureuser \
--generate-ssh-keys \
--custom-data cloud-init-web-server.txt \
--secrets "$vm_secret"

```

It takes a few minutes for the VM to be created, the packages to install, and the app to start. When the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access your site in a web browser.

To allow secure web traffic to reach your VM, open port 443 from the Internet with [az vm open-port](#):

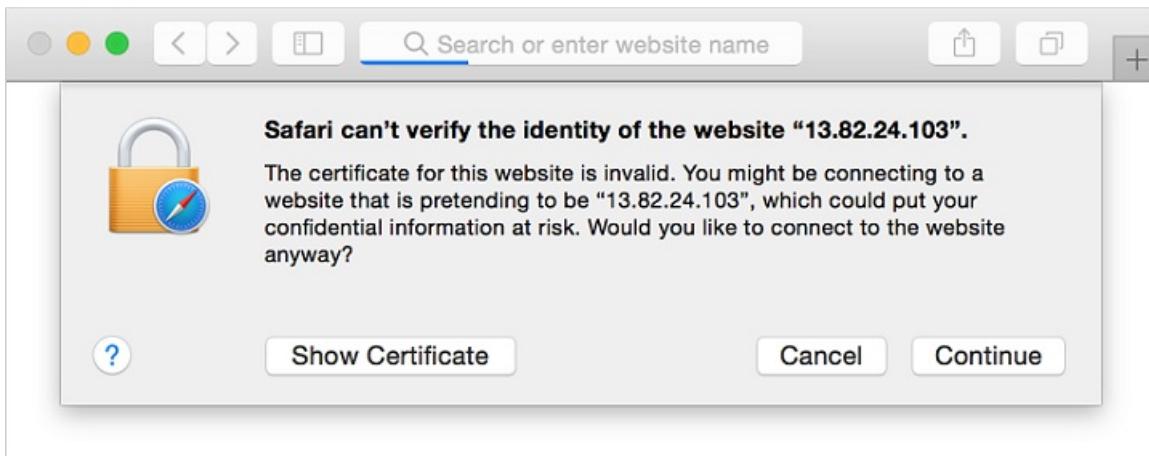

```

az vm open-port \
--resource-group myResourceGroupSecureWeb \
--name myVM \
--port 443

```

## Test the secure web app

Now you can open a web browser and enter `https://<publicIpAddress>` in the address bar. Provide your own public IP address from the VM create process. Accept the security warning if you used a self-signed certificate:

Your secured NGINX site is then displayed as in the following example:

## Next steps

In this tutorial, you secured an NGINX web server with a TLS/SSL certificate stored in Azure Key Vault. You learned how to:

- Create an Azure Key Vault
- Generate or upload a certificate to the Key Vault
- Create a VM and install the NGINX web server
- Inject the certificate into the VM and configure NGINX with a TLS binding

Follow this link to see pre-built virtual machine script samples.

[Linux virtual machine script samples](#)

# Create a VM from a VHD by using the Azure portal

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

There are several ways to create a virtual machine (VM) in Azure:

- If you already have a virtual hard disk (VHD) to use or you want to copy the VHD from an existing VM to use, you can create a new VM by *attaching* the VHD to the new VM as an OS disk.
- You can create a new VM from the VHD of a VM that has been deleted. For example, if you have an Azure VM that isn't working correctly, you can delete the VM and use its VHD to create a new VM. You can either reuse the same VHD or create a copy of the VHD by creating a snapshot and then creating a new managed disk from the snapshot. Although creating a snapshot takes a few more steps, it preserves the original VHD and provides you with a fallback.
- Take a classic VM and use the VHD to create a new VM that uses the Resource Manager deployment model and managed disks. For the best results, **Stop** the classic VM in the Azure portal before creating the snapshot.
- You can create an Azure VM from an on-premises VHD by uploading the on-premises VHD and attaching it to a new VM. You use PowerShell or another tool to upload the VHD to a storage account, and then you create a managed disk from the VHD. For more information, see [Upload a specialized VHD](#).

## IMPORTANT

When you use a specialized disk to create a new VM, the new VM retains the computer name of the original VM. Other computer-specific information (e.g. CMID) is also kept and, in some cases, this duplicate information could cause issues. When copying a VM, be aware of what types of computer-specific information your applications rely on. Thus, don't use a specialized disk if you want to create multiple VMs. Instead, for larger deployments, [create an image](#) and then [use that image to create multiple VMs](#).

We recommend that you limit the number of concurrent deployments to 20 VMs from a single snapshot or VHD.

## Copy a disk

Create a snapshot and then create a disk from the snapshot. This strategy allows you to keep the original VHD as a fallback:

1. From the [Azure portal](#), on the left menu, select **All services**.
2. In the **All services** search box, enter **disks** and then select **Disk** to display the list of available disks.
3. Select the disk that you would like to use. The **Disk** page for that disk appears.
4. From the menu at the top, select **Create snapshot**.
5. Choose a **Resource group** for the snapshot. You can use either an existing resource group or create a new one.
6. Enter a **Name** for the snapshot.
7. For **Snapshot type**, choose either **Full** or **Incremental**.
8. For **Storage type**, choose **Standard HDD**, **Premium SSD**, or **Zone-redundant storage**.
9. When you're done, select **Create** to create the snapshot.

10. After the snapshot has been created, select **Create a resource** in the left menu.
11. In the search box, enter **managed disk** and then select **Managed Disks** from the list.
12. On the **Managed Disks** page, select **Create**.
13. Choose a **Resource group** for the disk. You can use either an existing resource group or create a new one.  
This selection will also be used as the resource group where you create the VM from the disk.
14. Enter a **Name** for the disk.
15. In **Source type**, ensure **Snapshot** is selected.
16. In the **Source snapshot** drop-down, select the snapshot you want to use.
17. For **Size**, choose either **Standard (HDD)** or **Premium (SSD)** storage.
18. Make any other adjustments as needed and then select **Create** to create the disk.

## Create a VM from a disk

After you have the managed disk VHD that you want to use, you can create the VM in the portal:

1. From the [Azure portal](#), on the left menu, select **All services**.
2. In the **All services** search box, enter **disks** and then select **Disks** to display the list of available disks.
3. Select the disk that you would like to use. The **Disk** page for that disk opens.
4. In the **Overview** page, ensure that **DISK STATE** is listed as **Unattached**. If it isn't, you might need to either detach the disk from the VM or delete the VM to free up the disk.
5. In the menu at the top of the page, select **Create VM**.
6. On the **Basics** page for the new VM, enter a **Virtual machine name** and either select an existing **Resource group** or create a new one.
7. For **Size**, select **Change size** to access the **Size** page.
8. Select a VM size row and then choose **Select**.
9. On the **Disks** page, you may notice that the "OS Disk Type" cannot be changed. This preselected value is configured at the point of Snapshot or VHD creation and will carry over to the new VM. If you need to modify disk type take a new snapshot from an existing VM or disk.
10. On the **Networking** page, you can either let the portal create all new resources or you can select an existing **Virtual network** and **Network security group**. The portal always creates a new network interface and public IP address for the new VM.
11. On the **Management** page, make any changes to the monitoring options.
12. On the **Guest config** page, add any extensions as needed.
13. When you're done, select **Review + create**.
14. If the VM configuration passes validation, select **Create** to start the deployment.

## Next steps

You can also use PowerShell to [upload a VHD to Azure and create a specialized VM](#).

# Create a Windows VM from a specialized disk by using PowerShell

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Create a new VM by attaching a specialized managed disk as the OS disk. A specialized disk is a copy of a virtual hard disk (VHD) from an existing VM that contains the user accounts, applications, and other state data from your original VM.

You have several options:

- [Use an existing managed disk](#). This option is useful if you have a VM that isn't working correctly. You can delete the VM and then reuse the managed disk to create a new VM.
- [Upload a VHD](#)
- [Copy an existing Azure VM by using snapshots](#)

You can also use the Azure portal to [create a new VM from a specialized VHD](#).

This article shows you how to use managed disks. If you have a legacy deployment that requires using a storage account, see [Create a VM from a specialized VHD in a storage account](#).

## IMPORTANT

When you use a specialized disk to create a new VM, the new VM retains the computer name of the original VM.

Other computer-specific information (e.g. CMID) is also kept and, in some cases, this duplicate information could cause issues.

When copying a VM, be aware of what types of computer-specific information your applications rely on.

Thus, don't use a specialized disk if you want to create multiple VMs. Instead, for larger deployments, [create an image](#) and then [use that image to create multiple VMs](#).

We recommend that you limit the number of concurrent deployments to 20 VMs from a single VHD or snapshot.

## Option 1: Use an existing disk

If you had a VM that you deleted and you want to reuse the OS disk to create a new VM, use [Get-AzDisk](#).

```
$resourceGroupName = 'myResourceGroup'  
$osDiskName = 'myOsDisk'  
$osDisk = Get-AzDisk `  
-ResourceGroupName $resourceGroupName `  
-DiskName $osDiskName
```

You can now attach this disk as the OS disk to a [new VM](#).

## Option 2: Upload a specialized VHD

You can upload the VHD from a specialized VM created with an on-premises virtualization tool, like Hyper-V, or a VM exported from another cloud.

### Prepare the VM

Use the VHD as-is to create a new VM.

- [Prepare a Windows VHD to upload to Azure](#). Do not generalize the VM by using Sysprep.
- Remove any guest virtualization tools and agents that are installed on the VM (such as VMware tools).
- Make sure the VM is configured to get the IP address and DNS settings from DHCP. This ensures that the server obtains an IP address within the virtual network when it starts up.

## Upload the VHD

You can now upload a VHD straight into a managed disk. For instructions, see [Upload a VHD to Azure using Azure PowerShell](#).

## Option 3: Copy an existing Azure VM

You can create a copy of a VM that uses managed disks by taking a snapshot of the VM, and then by using that snapshot to create a new managed disk and a new VM.

If you want to copy an existing VM to another region, you might want to use azcopy to [create a copy of a disk in another region](#).

### Take a snapshot of the OS disk

You can take a snapshot of an entire VM (including all disks) or of just a single disk. The following steps show you how to take a snapshot of just the OS disk of your VM with the [New-AzSnapshot cmdlet](#).

First, set some parameters.

```
$resourceGroupName = 'myResourceGroup'  
$vmName = 'myVM'  
$location = 'westus'  
$snapshotName = 'mySnapshot'
```

Get the VM object.

```
$vm = Get-AzVM -Name $vmName `  
-ResourceGroupName $resourceGroupName
```

Get the OS disk name.

```
$disk = Get-AzDisk -ResourceGroupName $resourceGroupName `  
-DiskName $vm.StorageProfile.OsDisk.Name
```

Create the snapshot configuration.

```
$snapshotConfig = New-AzSnapshotConfig `  
-SourceUri $disk.Id `  
-OsType Windows `  
-CreateOption Copy `  
-Location $location
```

Take the snapshot.

```
$snapShot = New-AzSnapshot `  
-Snapshot $snapshotConfig `  
-SnapshotName $snapshotName `  
-ResourceGroupName $resourceGroupName
```

To use this snapshot to create a VM that needs to be high-performing, add the parameter `-AccountType Premium_LRS` to the `New-AzSnapshotConfig` command. This parameter creates the snapshot so that it's stored as a Premium Managed Disk. Premium Managed Disks are more expensive than Standard, so be sure you'll need Premium before using this parameter.

### Create a new disk from the snapshot

Create a managed disk from the snapshot by using [New-AzDisk](#). This example uses *myOSDisk* for the disk name.

Create a new resource group for the new VM.

```
$destinationResourceGroup = 'myDestinationResourceGroup'  
New-AzResourceGroup -Location $location  
-Name $destinationResourceGroup
```

Set the OS disk name.

```
$osDiskName = 'myOsDisk'
```

Create the managed disk.

```
$osDisk = New-AzDisk -DiskName $osDiskName -Disk `  
    (New-AzDiskConfig -Location $location -CreateOption Copy `  
        -SourceResourceId $snapshot.Id) `  
    -ResourceGroupName $destinationResourceGroup
```

## Create the new VM

Create networking and other VM resources to be used by the new VM.

### Create the subnet and virtual network

Create the [virtual network](#) and subnet for the VM.

1. Create the subnet. This example creates a subnet named *mySubNet*, in the resource group *myDestinationResourceGroup*, and sets the subnet address prefix to *10.0.0.0/24*.

```
$subnetName = 'mySubNet'  
$singleSubnet = New-AzVirtualNetworkSubnetConfig `  
    -Name $subnetName `  
    -AddressPrefix 10.0.0.0/24
```

2. Create the virtual network. This example sets the virtual network name to *myVnetName*, the location to *West US*, and the address prefix for the virtual network to *10.0.0.0/16*.

```
$vnetName = "myVnetName"  
$vnet = New-AzVirtualNetwork `  
    -Name $vnetName -ResourceGroupName $destinationResourceGroup `  
    -Location $location `  
    -AddressPrefix 10.0.0.0/16 `  
    -Subnet $singleSubnet
```

### Create the network security group and an RDP rule

To be able to sign in to your VM with remote desktop protocol (RDP), you'll need to have a security rule that allows RDP access on port 3389. In our example, the VHD for the new VM was created from an existing

specialized VM, so you can use an account that existed on the source virtual machine for RDP. This example denies RDP traffic, to be more secure. You can change `-Access` to `Allow` if you want to allow RDP access.

This example sets the network security group (NSG) name to *myNsg* and the RDP rule name to *myRdpRule*.

```
$nsgName = "myNsg"

$rdpRule = New-AzNetworkSecurityRuleConfig -Name myRdpRule -Description "Deny RDP" ` 
    -Access Deny -Protocol Tcp -Direction Inbound -Priority 110 ` 
    -SourceAddressPrefix Internet -SourcePortRange * ` 
    -DestinationAddressPrefix * -DestinationPortRange 3389
$nsg = New-AzNetworkSecurityGroup ` 
    -ResourceGroupName $destinationResourceGroup ` 
    -Location $location ` 
    -Name $nsgName -SecurityRules $rdpRule
```

For more information about endpoints and NSG rules, see [Opening ports to a VM in Azure by using PowerShell](#).

### Create a public IP address and NIC

To enable communication with the virtual machine in the virtual network, you'll need a [public IP address](#) and a network interface.

1. Create the public IP. In this example, the public IP address name is set to *myIP*.

```
$ipName = "myIP"
$pip = New-AzPublicIpAddress ` 
    -Name $ipName -ResourceGroupName $destinationResourceGroup ` 
    -Location $location ` 
    -AllocationMethod Dynamic
```

2. Create the NIC. In this example, the NIC name is set to *myNicName*.

```
$nicName = "myNicName"
$nic = New-AzNetworkInterface -Name $nicName ` 
    -ResourceGroupName $destinationResourceGroup ` 
    -Location $location -SubnetId $vnet.Subnets[0].Id ` 
    -PublicIpAddressId $pip.Id ` 
    -NetworkSecurityGroupId $nsg.Id
```

### Set the VM name and size

This example sets the VM name to *myVM* and the VM size to *Standard\_A2*.

```
$vmName = "myVM"
$vmConfig = New-AzVMConfig -VMName $vmName -VMSize "Standard_A2"
```

### Add the NIC

```
$vm = Add-AzVMNetworkInterface -VM $vmConfig -Id $nic.Id
```

### Add the OS disk

Add the OS disk to the configuration by using [Set-AzVMOSDisk](#). This example sets the size of the disk to *128 GB* and attaches the managed disk as a *Windows* OS disk.

```
$vm = Set-AzVMOSDisk -VM $vm -ManagedDiskId $osDisk.Id -StorageAccountType Standard_LRS `  
-DiskSizeInGB 128 -CreateOption Attach -Windows
```

## Complete the VM

Create the VM by using [New-AzVM](#) with the configurations that we just created.

```
New-AzVM -ResourceGroupName $destinationResourceGroup -Location $location -VM $vm
```

If this command is successful, you'll see output like this:

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase  
-----  
True      OK    OK
```

## Verify that the VM was created

You should see the newly created VM either in the [Azure portal](#) under **Browse > Virtual machines**, or by using the following PowerShell commands.

```
$vmList = Get-AzVM -ResourceGroupName $destinationResourceGroup  
$vmList.Name
```

## Next steps

Sign in to your new virtual machine. For more information, see [How to connect and log on to an Azure virtual machine running Windows](#).

# Create a Windows virtual machine from a Resource Manager template

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Learn how to create a Windows virtual machine by using an Azure Resource Manager template and Azure PowerShell from the Azure Cloud shell. The template used in this article deploys a single virtual machine running Windows Server in a new virtual network with a single subnet. For creating a Linux virtual machine, see [How to create a Linux virtual machine with Azure Resource Manager templates](#).

An alternative is to deploy the template from the Azure portal. To open the template in the portal, select the **Deploy to Azure** button.

## Create a virtual machine

Creating an Azure virtual machine usually includes two steps:

- Create a resource group. An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine.
- Create a virtual machine.

The following example creates an [Azure Generation 2 VM](#) by default from an [Azure Quickstart template](#). Here is a copy of the template:

```

}

```

To run the PowerShell script, Select **Try it** to open the Azure Cloud shell. To paste the script, right-click the shell, and then select **Paste**:

```

$resourceGroupName = Read-Host -Prompt "Enter the Resource Group name"
.setLocation = Read-Host -Prompt "Enter the location (i.e. centralus)"
$adminUsername = Read-Host -Prompt "Enter the administrator username"
$adminPassword = Read-Host -Prompt "Enter the administrator password" -AsSecureString
$dnsLabelPrefix = Read-Host -Prompt "Enter an unique DNS name for the public IP"

New-AzResourceGroup -Name $resourceGroupName -Location "$location"
New-AzResourceGroupDeployment ` 
    -ResourceGroupName $resourceGroupName ` 
    -TemplateUri "https://raw.githubusercontent.com/Azure/azure-quickstart-` 
templates/master/quickstarts/microsoft.compute/vm-simple-windows/azuredeploy.json" ` 
    -adminUsername $adminUsername ` 
    -adminPassword $adminPassword ` 
    -dnsLabelPrefix $dnsLabelPrefix

(Get-AzVm -ResourceGroupName $resourceGroupName).name

```

If you choose to install and use the PowerShell locally instead of from the Azure Cloud shell, this tutorial requires the Azure PowerShell module. Run `Get-Module -ListAvailable Az` to find the version. If you need to upgrade, see [Install Azure PowerShell module](#). If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

In the previous example, you specified a template stored in GitHub. You can also download or create a template and specify the local path with the `--template-file` parameter.

Here are some additional resources:

- To learn how to develop Resource Manager templates, see [Azure Resource Manager documentation](#).
- To see the Azure virtual machine schemas, see [Azure template reference](#).
- To see more virtual machine template samples, see [Azure Quickstart templates](#).

## Connect to the virtual machine

The last PowerShell command from the previous script shows the virtual machine name. To connect to the virtual machine, see [How to connect and sign on to an Azure virtual machine running Windows](#).

## Next Steps

- If there were issues with the deployment, you might take a look at [Troubleshoot common Azure deployment errors with Azure Resource Manager](#).
- Learn how to create and manage a virtual machine in [Create and manage Windows VMs with the Azure PowerShell module](#).

To learn more about creating templates, view the JSON syntax and properties for the resources types you deployed:

- [Microsoft.Network/virtualNetworks](#)
- [Microsoft.Network/networkInterfaces](#)
- [Microsoft.Compute/virtualMachines](#)

# Tutorial: Secure a web server on a Windows virtual machine in Azure with TLS/SSL certificates stored in Key Vault

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

## NOTE

Currently this doc only works for Generalized images. If attempting this tutorial using a Specialized disk you will receive an error.

To secure web servers, a Transport Layer Security (TLS), previously known as Secure Sockets Layer (SSL), certificate can be used to encrypt web traffic. These TLS/SSL certificates can be stored in Azure Key Vault, and allow secure deployments of certificates to Windows virtual machines (VMs) in Azure. In this tutorial you learn how to:

- Create an Azure Key Vault
- Generate or upload a certificate to the Key Vault
- Create a VM and install the IIS web server
- Inject the certificate into the VM and configure IIS with a TLS binding

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Overview

Azure Key Vault safeguards cryptographic keys and secrets, such certificates or passwords. Key Vault helps streamline the certificate management process and enables you to maintain control of keys that access those certificates. You can create a self-signed certificate inside Key Vault, or upload an existing, trusted certificate that you already own.

Rather than using a custom VM image that includes certificates baked-in, you inject certificates into a running VM. This process ensures that the most up-to-date certificates are installed on a web server during deployment. If you renew or replace a certificate, you don't also have to create a new custom VM image. The latest certificates are automatically injected as you create additional VMs. During the whole process, the certificates never leave the Azure platform or are exposed in a script, command-line history, or template.

## Create an Azure Key Vault

Before you can create a Key Vault and certificates, create a resource group with [New-AzResourceGroup](#). The following example creates a resource group named *myResourceGroupSecureWeb* in the *East US* location:

```
$resourceGroup = "myResourceGroupSecureWeb"
$location = "East US"
New-AzResourceGroup -ResourceGroupName $resourceGroup -Location $location
```

Next, create a Key Vault with [New-AzKeyVault](#). Each Key Vault requires a unique name, and should be all lower case. Replace `mykeyvault` in the following example with your own unique Key Vault name:

```
$keyvaultName="mykeyvault"
New-AzKeyVault -VaultName $keyvaultName ` 
    -ResourceGroup $resourceGroup ` 
    -Location $location ` 
    -EnabledForDeployment
```

## Generate a certificate and store in Key Vault

For production use, you should import a valid certificate signed by trusted provider with [Import-AzKeyVaultCertificate](#). For this tutorial, the following example shows how you can generate a self-signed certificate with [Add-AzKeyVaultCertificate](#) that uses the default certificate policy from [New-AzKeyVaultCertificatePolicy](#).

```
$policy = New-AzKeyVaultCertificatePolicy ` 
    -SubjectName "CN=www.contoso.com" ` 
    -SecretContentType "application/x-pkcs12" ` 
    -IssuerName Self ` 
    -ValidityInMonths 12

Add-AzKeyVaultCertificate ` 
    -VaultName $keyvaultName ` 
    -Name "mycert" ` 
    -CertificatePolicy $policy
```

## Create a virtual machine

Set an administrator username and password for the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Now you can create the VM with [New-AzVM](#). The following example creates a VM named *myVM* in the *EastUS* location. If they do not already exist, the supporting network resources are created. To allow secure web traffic, the cmdlet also opens port 443.

```

# Create a VM
New-AzVm `-
    -ResourceGroupName $resourceGroup `-
    -Name "myVM" `-
    -Location $location `-
    -VirtualNetworkName "myVnet" `-
    -SubnetName "mySubnet" `-
    -SecurityGroupName "myNetworkSecurityGroup" `-
    -PublicIpAddressName "myPublicIpAddress" `-
    -Credential $cred `-
    -OpenPorts 443

# Use the Custom Script Extension to install IIS
Set-AzVMExtension -ResourceGroupName $resourceGroup `-
    -ExtensionName "IIS" `-
    -VMName "myVM" `-
    -Location $location `-
    -Publisher "Microsoft.Compute" `-
    -ExtensionType "CustomScriptExtension" `-
    -TypeHandlerVersion 1.8 `-
    -SettingString '{"commandToExecute":"powershell Add-WindowsFeature Web-Server -IncludeManagementTools"}'

```

It takes a few minutes for the VM to be created. The last step uses the Azure Custom Script Extension to install the IIS web server with [Set-AzVmExtension](#).

## Add a certificate to VM from Key Vault

To add the certificate from Key Vault to a VM, obtain the ID of your certificate with [Get-AzKeyVaultSecret](#). Add the certificate to the VM with [Add-AzVMSecret](#):

```

$certURL=(Get-AzKeyVaultSecret -VaultName $keyvaultName -Name "mycert").id

$vml=Get-AzVM -ResourceGroupName $resourceGroup -Name "myVM"
$vaultId=(Get-AzKeyVault -ResourceGroupName $resourceGroup -VaultName $keyVaultName).ResourceId
$vm = Add-AzVMSecret -VM $vm -SourceVaultId $vaultId -CertificateStore "My" -CertificateUrl $certURL

Update-AzVM -ResourceGroupName $resourceGroup -VM $vm

```

## Configure IIS to use the certificate

Use the Custom Script Extension again with [Set-AzVMExtension](#) to update the IIS configuration. This update applies the certificate injected from Key Vault to IIS and configures the web binding:

```

$publicSettings = '{
    "fileUris": ["https://raw.githubusercontent.com/Azure-Samples/compute-automation-
configurations/master/secure-iis.ps1"],
    "commandToExecute": "powershell -ExecutionPolicy Unrestricted -File secure-iis.ps1"
}'

Set-AzVMExtension -ResourceGroupName $resourceGroup `-
    -ExtensionName "IIS" `-
    -VMName "myVM" `-
    -Location $location `-
    -Publisher "Microsoft.Compute" `-
    -ExtensionType "CustomScriptExtension" `-
    -TypeHandlerVersion 1.8 `-
    -SettingString $publicSettings

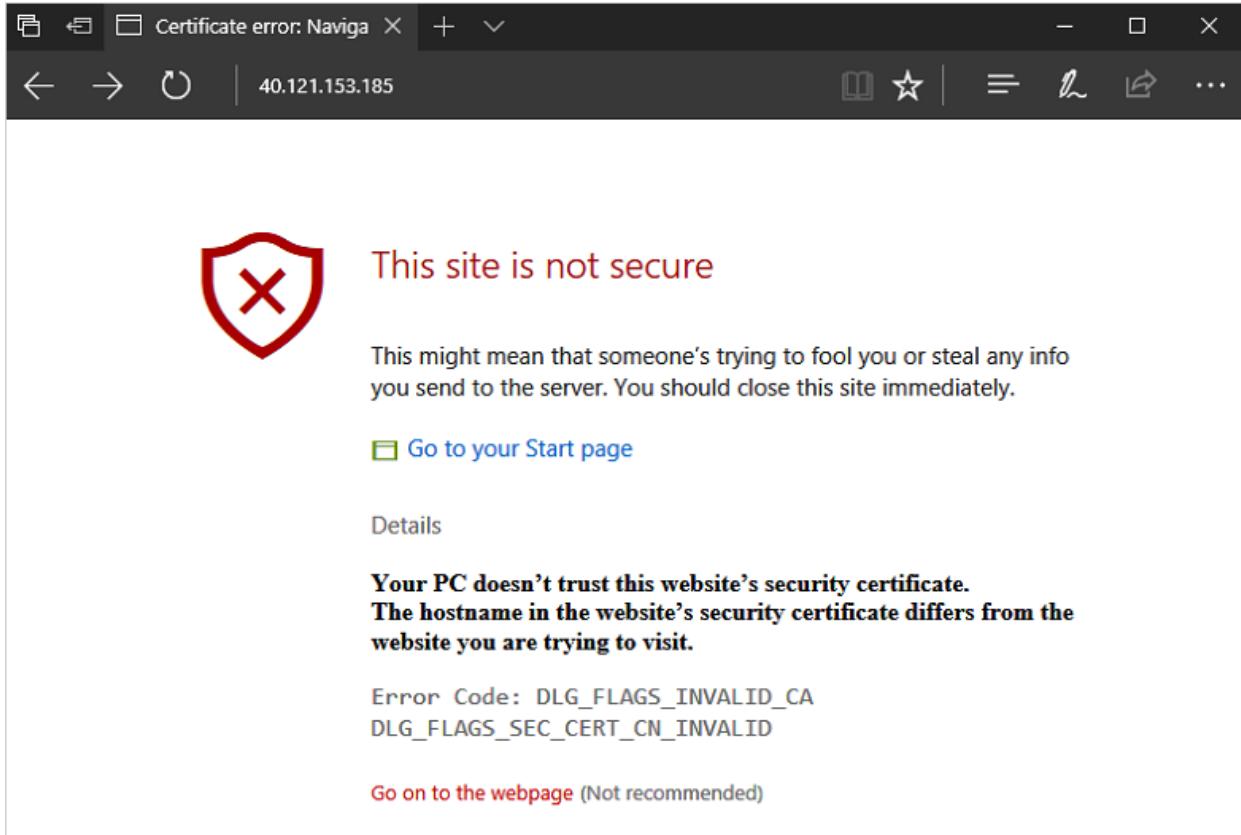

```

## Test the secure web app

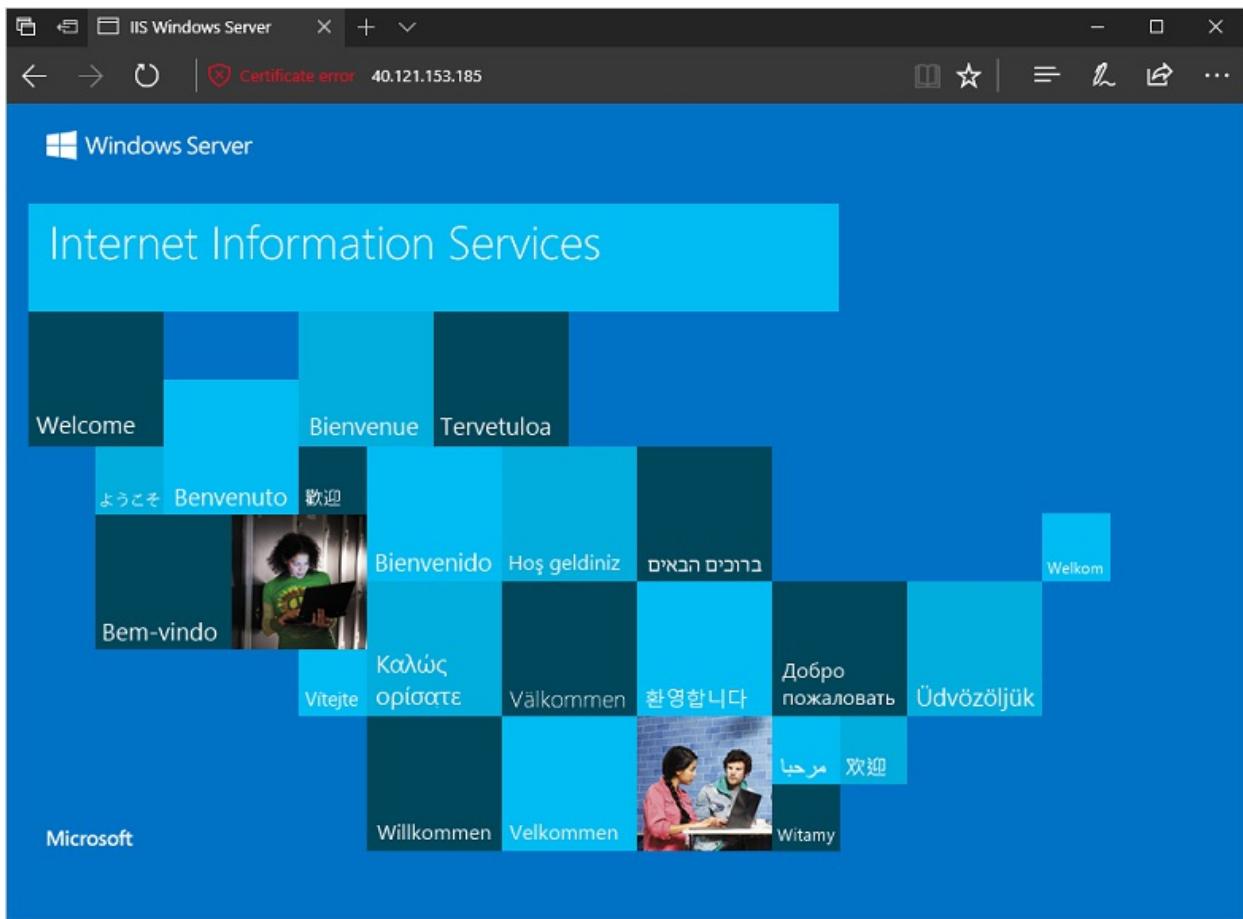

Obtain the public IP address of your VM with `Get-AzPublicIPAddress`. The following example obtains the IP address for `myPublicIP` created earlier:

```
Get-AzPublicIPAddress -ResourceGroupName $resourceGroup -Name "myPublicIPAddress" | select "IpAddress"
```

Now you can open a web browser and enter `https://<myPublicIP>` in the address bar. To accept the security warning if you used a self-signed certificate, select **Details** and then **Go on to the webpage**:

Your secured IIS website is then displayed as in the following example:

## Next steps

In this tutorial, you secured an IIS web server with a TLS/SSL certificate stored in Azure Key Vault. You learned how to:

- Create an Azure Key Vault
- Generate or upload a certificate to the Key Vault
- Create a VM and install the IIS web server
- Inject the certificate into the VM and configure IIS with a TLS binding

Follow this link to see pre-built virtual machine script samples.

[Windows virtual machine script samples](#)

# Delete a VM and attached resources

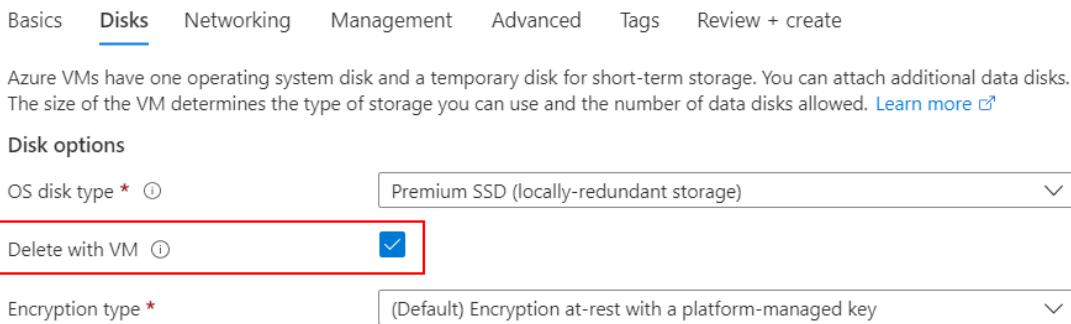

9/21/2022 • 8 minutes to read • [Edit Online](#)

Depending on how you delete a VM, it may only delete the VM resource, not the networking and disk resources. You can change the default settings for what other resources are deleted when you delete a VM.

## Set delete options when creating a VM

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

1. Open the [portal](#).
2. Select + **Create a resource**.
3. On the **Create a resource** page, under **Virtual machines**, select **Create**.
4. Make your choices on the **Basics**, then select **Next : Disks >**. The **Disks** tab will open.
5. Under **Disk options**, by default the OS disk is set to **Delete with VM**. If you don't want to delete the OS disk, clear the checkbox. If you're using an existing OS disk, the default is to detach the OS disk when the VM is deleted.

6. Under **Data disks**, you can either attach an existing data disk or create a new disk and attach it to the VM.
  - If you choose **Create and attach a new disk**, the **Create a new disk** page will open and you can select whether to delete the disk when you delete the VM.

## Create a new disk

Create a new disk to store applications and data on your VM. Disk pricing varies based on factors including disk size, storage type, and number of transactions. [Learn more](#)

Name *	<input type="text" value="deletetest_DataDisk_0"/>
Source type * ⓘ	<input type="text" value="None (empty disk)"/>
Size * ⓘ	<p>1024 GiB Premium SSD LRS <a href="#">Change size</a></p>
Encryption type *	<input type="text" value="(Default) Encryption at-rest with a platform-managed key"/>
Enable shared disk	<input type="radio"/> Yes <input checked="" type="radio"/> No
<input checked="" type="checkbox"/> Delete disk with VM <input type="checkbox"/>	

- If you choose to **Attach an existing disk**, you'll be able to choose the disk, LUN, and whether you want to delete the data disk when you delete the VM.

LUN	Name	Size (GiB)	Disk type	Host caching	Delete with VM ⓘ
0	No existing disk... ⏺			Read-only ⏺	<input type="checkbox"/>

[Create and attach a new disk](#) [Attach an existing disk](#)

- When you're done adding your disk information, select **Next : Networking**. The **Networking** tab will open.
- Towards the bottom of the page, select **Delete public IP and NIC when VM is deleted**.
- When you're done making selections, select **Review + create**. The **Review + create** page will open.
- You can verify which resources you have chosen to delete when you delete the VM.
- When you're satisfied with your selections, and validation passes, select **Create** to deploy the VM.

## Update the delete behavior on an existing VM

You can change the behavior when you delete a VM. The following example updates the VM to delete the NIC, OS disk, and data disk when the VM is deleted.

- [CLI](#)
- [REST](#)

The following example sets the delete option to `detach` so you can reuse the disk.

```
az resource update --resource-group myResourceGroup --name myVM --resource-type virtualMachines --namespace Microsoft.Compute --set properties.storageProfile.osDisk.deleteOption=detach
```

## Force Delete for VMs

Force delete allows you to forcefully delete your virtual machine, reducing delete latency and immediately freeing up attached resources. For VMs that do not require graceful shutdown, Force Delete will delete the VM as fast as possible while relieving the logical resources from the VM, bypassing the graceful shutdown and some of the cleanup operations. Force Delete will not immediately free the MAC address associated with a VM, as this is a physical resource that may take up to 10 min to free. If you need to immediately re-use the MAC address on a new VM, Force Delete is not recommended. Force delete should only be used when you are not intending to re-use virtual hard disks. You can use force delete through Portal, CLI, PowerShell, and REST API.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

When you go to delete an existing VM, you will find an option to apply force delete in the delete pane.

1. Open the [portal](#).
2. Navigate to your virtual machine.
3. On the **Overview** page, select **Delete**.
4. In the **Delete virtual machine** pane, select the checkbox for **Apply force delete**.
5. Select **Ok**.

## Force Delete for virtual machine scale sets

Force delete allows you to forcefully delete your **Uniform** virtual machine scale sets, reducing delete latency and immediately freeing up attached resources. Force Delete will not immediately free the MAC address associated with a VM, as this is a physical resource that may take up to 10 min to free. If you need to immediately re-use the MAC address on a new VM, Force Delete is not recommended. Force delete should only be used when you are not intending to re-use virtual hard disks. You can use force delete through Portal, CLI, PowerShell, and REST API.

- [Portal](#)
- [CLI](#)
- [PowerShell](#)
- [REST](#)

When you go to delete an existing virtual machine scale set, you will find an option to apply force delete in the delete pane.

1. Open the [portal](#).
2. Navigate to your virtual machine scale set.
3. On the **Overview** page, select **Delete**.
4. In the **Delete virtual machine scale set** pane, select the checkbox for **Apply force delete**.
5. Select **Ok**.

## FAQ

### **Q: Does this feature work with shared disks?**

A: For shared disks, you can't set the 'deleteOption' property to 'Delete'. You can leave it blank or set it to 'Detach'

### **Q: Which Azure resources support this feature?**

A: This feature is supported on all managed disk types used as OS disks and Data disks, NICs, and Public IPs

**Q: Can I use this feature on disks and NICs that aren't associated with a VM?**

A: No, this feature is only available on disks and NICs associated with a VM.

**Q: How does this feature work with Flexible virtual machine scale sets?**

A: For Flexible virtual machine scale sets the disks, NICs, and PublicIPs have `deleteOption` set to `Delete` by default so these resources are automatically cleaned up when the VMs are deleted.

For data disks that were explicitly created and attached to the VMs, you can modify this property to 'Detach' instead of 'Delete' if you want the disks to persist after the VM is deleted.

**Q: Do Spot VMs support this feature?**

A: Yes, you can use this feature for Spot VMs just the way you would for on-demand VMs.

**Q: How do I persist the disks, NIC, and Public IPs associated with a VM?**

A: By default, disks, NICs, and Public IPs associated with a VM are persisted when the VM is deleted. If you configure these resources to be automatically deleted, you can update the settings so that the resources remain after the VM is deleted. To keep these resources, set the `deleteOption` property to `Detach`.

## Next steps

To learn more about basic VM management, see [Tutorial: Create and Manage Linux VMs with the Azure CLI](#).

# Connect to a Linux VM

9/21/2022 • 7 minutes to read • [Edit Online](#)

In Azure there are multiple ways to connect to a Linux virtual machine. The most common practice for connecting to a Linux VM is using the Secure Shell Protocol (SSH). This is done via any standard SSH client commonly found in Linux and Windows. You can also use [Azure Cloud Shell](#) from any browser.

This document describes how to connect, via SSH, to a VM that has a public IP. If you need to connect to a VM without a public IP, see [Azure Bastion Service](#).

## Prerequisites

- You need an SSH key pair. If you don't already have one, Azure will create a key pair during the deployment process. If you need help with creating one manually, see [Create and use an SSH public-private key pair for Linux VMs in Azure](#).
- You need an existing Network Security Group (NSG). Most VMs will have an NSG by default, but if you don't already have one you can create one and attach it manually. For more information, see [Create, change, or delete a network security group](#).
- To connect to a Linux VM, you need the appropriate port open. Typically this will be port 22. The following instructions assume port 22 but the process is the same for other port numbers. You can validate an appropriate port is open for SSH using the troubleshooter or by checking manually in your VM settings.

To check if port 22 is open:

1. On the page for the VM, select **Networking** from the left menu.
2. On the **Networking** page, check to see if there is a rule which allows TCP on port 22 from the IP address of the computer you are using to connect to the VM. If the rule exists, you can move to the next section.

The screenshot shows the Azure portal interface for a Linux VM named "LinuxVM". The left sidebar shows options like Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, Settings, Networking (which is selected), Connect, and Disks. The main content area is titled "LinuxVM | Networking" and shows the "Virtual machine" blade. At the top, there are buttons for Attach network interface, Detach network interface, and Feedback. Below that, tabs for Inbound port rules, Outbound port rules, Application security groups, and Load balancing are visible. Under the Inbound port rules tab, it says "Network security group LinuxVM-nsg (attached to network interface: linuxvm395) Impacts 0 subnets, 1 network interfaces". There is a button labeled "Add inbound port rule". A table lists the current rules:

Priority	Name	Port	Protocol	Source
300	SSH	22	TCP	Any
65000	AllowVnetInBound	Any	Any	VirtualN
65001	AllowAzureLoadBala...	Any	Any	AzureLo
65500	DenyAllInBound	Any	Any	Any

3. If there isn't a rule, add one by selecting **Add inbound port rule**.
4. For **Service**, select **SSH** from the dropdown.

**Add inbound security rule**

Source ①

Any

Source port ranges \* ①

\*

Destination ①

Any

Service ①

SSH

Destination port ranges ①

22

Protocol

Any

UDP

ICMP

Action

Allow

Deny

Priority \* ①

100

Name \*

SSH

Description

Add Cancel

5. Edit Priority and Source if necessary

6. For Name, type *SSH*.

7. When you're done, select Add.

8. You should now have an SSH rule in the table of inbound port rules.

- Your VM must have a public IP address. To check if your VM has a public IP address, select **Overview** from the left menu and look at the **Networking** section. If you see an IP address next to **Public IP address**, then your VM has a public IP

If your VM does not have a public IP Address, it will look like this:

Networking	
Public IP address	-
Public IP address (IPv6)	-
Private IP address	10.1.0.4
Private IP address (IPv6)	-
Virtual network/subnet	myResourceGroup-vnet/default
DNS name	-

To learn more about adding a public IP address to an existing VM, see [Associate a public IP address to a virtual machine](#)

- Verify your VM is running. On the Overview tab, in the **Essentials** section, verify the status of the VM is **Running**. To start the VM, select **Start** at the top of the page.

## ^ Essentials

Resource group ([move](#))

LINUXVM

Status

Running

## Connect to the VM

Once the above prerequisites are met, you are ready to connect to your VM. Open your SSH client of choice. The SSH client command is typically included in Linux, macOS, and Windows. If you are using Windows 7 or older, where Win32 OpenSSH is not included by default, consider installing [WSL](#) or using [Azure Cloud Shell](#) from the browser.

### NOTE

The following examples assume the SSH key is in the key.pem format. If you used CLI or Azure PowerShell to download your keys, they may be in the id\_rsa format.

- [WSL, macOS, or native Linux client](#)
- [Windows command line \(cmd.exe, PowerShell etc.\)](#)

### SSH with a new key pair

- Ensure your public and private keys are in the correct directory. The directory is usually `~/.ssh`.

If you generated keys manually or generated them with the CLI, then the keys are probably already there. However, if you downloaded them in pem format from the Azure portal, you may need to move them to the right location. This can be done with the following syntax:

```
mv PRIVATE_KEY_SOURCE PRIVATE_KEY_DESTINATION
```

For example, if the key is in the `Downloads` folder, and `myKey.pem` is the name of your SSH key, type:

```
mv /Downloads/myKey.pem ~/.ssh
```

### NOTE

If you're using WSL, local files are found in the `/mnt/c/` directory. Accordingly, the path to the downloads folder and SSH key would be `/mnt/c/Users/{USERNAME}/Downloads/myKey.pem`

- Ensure you have read-only access to the private key by running

```
chmod 400 ~/.ssh/myKey.pem
```

- Run the SSH command with the following syntax: `ssh -i PATH_TO_PRIVATE_KEY USERNAME@EXTERNAL_IP`

For example, if your `azureuser` is the username you created and `20.51.230.13` is the public IP address of your VM, type:

```
ssh -i ~/.ssh/myKey.pem azureuser@20.51.230.13
```

#### 4. Validate the returned fingerprint.

If you have never connected to this VM before, you'll be asked to verify the hosts fingerprint. It's tempting to simply accept the fingerprint presented, but that exposes you to a potential person in the middle attack. You should always validate the hosts fingerprint. You only need to do this the first time you connect from a client. To get the host fingerprint via the portal, use the Run Command feature to execute the command:

```
ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
```

#### 5. Success! You should now be connected to your VM. If you're unable to connect, see [Troubleshoot SSH connections](#).

### SSH With existing public key

1. Run the following command in your SSH client. In this example, *20.51.230.13* is the public IP Address of your VM and *azureuser* is the username you created when you created the VM.

```
ssh azureuser@20.51.230.13
```

#### 2. Validate the returned fingerprint.

If you have never connected to this VM before you will be asked to verify the hosts fingerprint. It is tempting to simply accept the fingerprint presented, however, this exposes you to a possible person in the middle attack. You should always validate the hosts fingerprint. You only need to do this on the first time you connect from a client. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command:

```
ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
```

#### 3. Success! You should now be connected to your VM. If you're unable to connect, see our troubleshooting guide [Troubleshoot SSH connections](#).

### Password authentication

#### WARNING

This type of authentication method is not as secure and is not recommended.

1. Run the following command in your SSH client. In this example, *20.51.230.13* is the public IP Address of your VM and *azureuser* is the username you created when you created the VM.

```
ssh azureuser@20.51.230.13
```

If you forgot your password or username see [Reset Access to an Azure VM](#)

#### 2. Validate the returned fingerprint.

If you have never connected to this VM before you will be asked to verify the hosts fingerprint. It is tempting to simply accept the fingerprint presented, however, this exposes you to a possible person in the middle attack. You should always validate the hosts fingerprint. You only need to do this on the first time

you connect from a client. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command:

```
ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}'
```

3. Success! You should now be connected to your VM. If you're unable to connect using the correct method above, see [Troubleshoot SSH connections](#).

## Next steps

Learn how to transfer files to an existing VM, see [Use SCP to move files to and from a VM](#).

# Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

With a secure shell (SSH) key pair, you can create a Linux virtual machine that uses SSH keys for authentication. This article shows you how to create and use an SSH RSA public-private key file pair for SSH client connections.

If you want quick commands rather than a more in-depth explanation of SSH keys, see [How to create an SSH public-private key pair for Linux VMs in Azure](#).

To create SSH keys and use them to connect to a Linux VM from a **Windows** computer, see [How to use SSH keys with Windows on Azure](#). You can also use the [Azure portal](#) to create and manage SSH keys for creating VMs in the portal.

## Overview of SSH and keys

SSH is an encrypted connection protocol that provides secure sign-ins over unsecured connections. Although SSH provides an encrypted connection, using passwords with SSH connections still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

- The *public key* is placed on your VM.
- The *private key* remains on your local system. Protect this private key. Do not share it.

When you use an SSH client to connect to your VM (which has the public key), the remote VM tests the client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single public-private key pair to access multiple Azure VMs and services. You do not need a separate pair of keys for each VM or service you wish to access.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

## Supported SSH key formats

Azure currently supports SSH protocol 2 (SSH-2) RSA public-private key pairs with a minimum length of 2048 bits. Other key formats such as ED25519 and ECDSA are not supported.

## SSH keys use and benefits

When you create an Azure VM by specifying the public key, Azure copies the public key (in the `.pub` format) to the `~/.ssh/authorized_keys` folder on the VM. SSH keys in `~/.ssh/authorized_keys` ensure that connecting clients present the corresponding private key during an SSH connection. In an Azure Linux VM that uses SSH keys for authentication, Azure disables the SSH server's password authentication system and only allows for SSH key authentication. By creating an Azure Linux VM with SSH keys, you can help secure the VM deployment and save yourself the typical post-deployment configuration step of disabling passwords in the `sshd_config` file.

If you do not wish to use SSH keys, you can set up your Linux VM to use password authentication. If your VM is

not exposed to the Internet, using passwords may be sufficient. However, you still need to manage your passwords for each Linux VM and maintain healthy password policies and practices, such as minimum password length and regular system updates.

## Generate keys with ssh-keygen

To create the keys, a preferred command is `ssh-keygen`, which is available with OpenSSH utilities in the Azure Cloud Shell, a macOS or Linux host, and Windows (10 & 11). `ssh-keygen` asks a series of questions and then writes a private key and a matching public key.

SSH keys are by default kept in the `~/.ssh` directory. If you do not have a `~/.ssh` directory, the `ssh-keygen` command creates it for you with the correct permissions. An SSH key is created as a resource and stored in Azure for later use.

### NOTE

You can also create keys with the [Azure CLI](#) with the `az sshkey create` command, as described in [Generate and store SSH keys](#).

### Basic example

The following `ssh-keygen` command generates 4096-bit SSH RSA public and private key files by default in the `~/.ssh` directory. If an existing SSH key pair is found in the current location, those files are overwritten.

```
ssh-keygen -m PEM -t rsa -b 4096
```

### Detailed example

The following example shows additional command options to create an SSH RSA key pair. If an SSH key pair exists in the current location, those files are overwritten.

```
ssh-keygen \
-m PEM \
-t rsa \
-b 4096 \
-C "azureuser@myserver" \
-f ~/.ssh/mykeys/myprivatekey \
-N mypassphrase
```

### Command explained

`ssh-keygen` = the program used to create the keys

`-m PEM` = format the key as PEM

`-t rsa` = type of key to create, in this case in the RSA format

`-b 4096` = the number of bits in the key, in this case 4096

`-C "azureuser@myserver"` = a comment appended to the end of the public key file to easily identify it. Normally an email address is used as the comment, but use whatever works best for your infrastructure.

`-f ~/.ssh/mykeys/myprivatekey` = the filename of the private key file, if you choose not to use the default name. A corresponding public key file appended with `.pub` is generated in the same directory. The directory must exist.

`-N mypassphrase` = an additional passphrase used to access the private key file.

## Example of ssh-keygen

```
ssh-keygen -t rsa -m PEM -b 4096 -C "azureuser@myserver"
Generating public/private rsa key pair.
Enter file in which to save the key (/home/azureuser/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/azureuser/.ssh/id_rsa.
Your public key has been saved in /home/azureuser/.ssh/id_rsa.pub.
The key fingerprint is:
SHA256:vFfHHrpSGQD/oNdvNiX0sG9Vh+wR0lZBktNZw9AUjA azureuser@myserver
The key's randomart image is:

|       . .... .|
|       .. . . |
|       .. . |
+---[SHA256]-----+
```

### Saved key files

Enter file in which to save the key (/home/azureuser/.ssh/id\_rsa): `~/.ssh/id_rsa`

The key pair name for this article. Having a key pair named `id_rsa` is the default; some tools might expect the `id_rsa` private key file name, so having one is a good idea. The directory `~/ssh/` is the default location for SSH key pairs and the SSH config file. If not specified with a full path, `ssh-keygen` creates the keys in the current working directory, not the default `~/ssh`.

### List of the `~/ssh` directory

To view existing files in the `~/ssh` directory, run the following command. If no files are found in the directory or the directory itself is missing, make sure that all previous commands were successfully run. You may require root access to modify files in this directory on certain Linux distributions.

```
ls -al ~/ssh
-rw----- 1 azureuser staff 1675 Aug 25 18:04 id_rsa
-rw-r--r-- 1 azureuser staff 410 Aug 25 18:04 id_rsa.pub
```

### Key passphrase

Enter passphrase (empty for no passphrase):

It is *strongly* recommended to add a passphrase to your private key. Without a passphrase to protect the key file, anyone with the file can use it to sign in to any server that has the corresponding public key. Adding a passphrase offers more protection in case someone is able to gain access to your private key file, giving you time to change the keys.

## Generate keys automatically during deployment

If you use the [Azure CLI](#) to create your VM, you can optionally generate both public and private SSH key files by running the `az vm create` command with the `--generate-ssh-keys` option. The keys are stored in the `~/ssh` directory. Note that this command option does not overwrite keys if they already exist in that location, such as with some pre-configured Compute Gallery images.

## Provide SSH public key when deploying a VM

To create a Linux VM that uses SSH keys for authentication, provide your SSH public key when creating the VM using the Azure portal, CLI, Resource Manager templates, or other methods. When using the portal, you enter the public key itself. If you use the [Azure CLI](#) to create your VM with an existing public key, specify the value or location of this public key by running the `az vm create` command with the `--ssh-key-value` option.

If you're not familiar with the format of an SSH public key, you can see your public key by running `cat` as follows, replacing `~/.ssh/id_rsa.pub` with your own public key file location:

```
cat ~/.ssh/id_rsa.pub
```

Output is similar to the following (redacted example below):

```
ssh-rsa  
XXXXXXXXXc2EAAAADAXABAAABAXC5Am7+fGZ+5zXBGgXS6GUvmsXCLGc7tX7/rViXk3+eShZzaXnt75gUmT1I2f75zFn2h1AIDGKWF4g12K  
WcZxy81TniUOTjUsVlwPymXUXxESL/UfJKfbdstBhT0dy5EG9rYWA0K43SJmwPhH28BpoLfXXXXXG+/ilsXXXXXgRLiJ2W19MzXHp8z3Lxw  
7r9wx3HaV1P4XiFv9U4h6cp8RMI1MP1nNesFl0BpG4pV2bJRBTXNxY416F8WZ3C4ku8Xx0o8mxaTpVZ3T1841altnMTZCcPkXuMrBjYSJ  
bA8npoXAXNwiivyo3X2KMXXXXdXXXXXXXXXXXX/ azureuser@myserver
```

If you copy and paste the contents of the public key file into the Azure portal or a Resource Manager template, make sure you don't copy any additional whitespace or introduce additional line breaks. For example, if you use macOS, you can pipe the public key file (by default, `~/.ssh/id_rsa.pub`) to `pbcopy` to copy the contents (there are other Linux programs that do the same thing, such as `xclip`).

If you prefer to use a public key that is in a multiline format, you can generate an RFC4716 formatted key in a 'pem' container from the public key you previously created.

To create a RFC4716 formatted key from an existing SSH public key:

```
ssh-keygen \  
-f ~/.ssh/id_rsa.pub \  
-e \  
-m RFC4716 > ~/.ssh/id_ssh2.pem
```

## SSH to your VM with an SSH client

With the public key deployed on your Azure VM, and the private key on your local system, SSH to your VM using the IP address or DNS name of your VM. Replace `azureuser` and `myvm.westus.cloudapp.azure.com` in the following command with the administrator user name and the fully qualified domain name (or IP address):

```
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you provided a passphrase when you created your key pair, enter the passphrase when prompted during the sign-in process. (The server is added to your `~/.ssh/known_hosts` folder, and you won't be asked to connect again until the public key on your Azure VM changes or the server name is removed from `~/.ssh/known_hosts`.)

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM. For more information about the just-in-time policy, see [Manage virtual machine access using the just in time policy](#).

## Use ssh-agent to store your private key passphrase

To avoid typing your private key file passphrase with every SSH sign-in, you can use `ssh-agent` to cache your private key file passphrase on your local system. If you are using a Mac, the macOS Keychain securely stores the

private key passphrase when you invoke `ssh-agent`.

Verify and use `ssh-agent` and `ssh-add` to inform the SSH system about the key files so that you do not need to use the passphrase interactively.

```
eval "$(ssh-agent -s)"
```

Now add the private key to `ssh-agent` using the command `ssh-add`.

```
ssh-add ~/.ssh/id_rsa
```

The private key passphrase is now stored in `ssh-agent`.

## Use `ssh-copy-id` to copy the key to an existing VM

If you have already created a VM, you can add a new SSH public key to your Linux VM using `ssh-copy-id`.

```
ssh-copy-id -i ~/.ssh/id_rsa.pub azureuser@myserver
```

## Create and configure an SSH config file

You can create and configure an SSH config file (`~/.ssh/config`) to speed up log-ins and to optimize your SSH client behavior.

The following example shows a simple configuration that you can use to quickly sign in as a user to a specific VM using the default SSH private key.

Create the file.

```
touch ~/.ssh/config
```

Edit the file to add the new SSH configuration

```
vim ~/.ssh/config
```

Add configuration settings appropriate for your host VM. In this example, the VM name (Host) is *myvm*, the account name (User) is *azureuser* and the IP Address or FQDN (Hostname) is 192.168.0.255.

```
# Azure Keys
Host myvm
  Hostname 192.168.0.255
  User azureuser
# ./Azure Keys
```

You can add configurations for additional hosts to enable each to use its own dedicated key pair. See [SSH config file](#) for more advanced configuration options.

Now that you have an SSH key pair and a configured SSH config file, you are able to remotely access your Linux VM quickly and securely. When you run the following command, SSH locates and loads any settings from the `Host myvm` block in the SSH config file.

```
ssh myvm
```

The first time you sign in to a server using an SSH key, the command prompts you for the passphrase for that key file.

## Next steps

Next up is to create Azure Linux VMs using the new SSH public key. Azure VMs that are created with an SSH public key as the sign-in are better secured than VMs created with the default sign-in method, passwords.

- [Create a Linux virtual machine with the Azure portal](#)
- [Create a Linux virtual machine with the Azure CLI](#)
- [Create a Linux VM using an Azure template](#)

# Generate and store SSH keys in the Azure portal

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

If you frequently use the portal to deploy Linux VMs, you can make using SSH keys simpler by creating them directly in the portal, or uploading them from your computer.

You can create a SSH keys when you first create a VM, and reuse them for other VMs. Or, you can create SSH keys separately, so that you have a set of keys stored in Azure to fit your organizations needs.

If you have existing keys and you want to simplify using them in the portal, you can upload them and store them in Azure for reuse.

For more detailed information about creating and using SSH keys with Linux VMs, see [Use SSH keys to connect to Linux VMs](#).

## Generate new keys

1. Open the [Azure portal](#).
2. At the top of the page, type *SSH* to search. Under **Marketplace**, select **SSH keys**.
3. On the **SSH Key** page, select **Create**.

[Home](#) > [SSH Key](#) >

### Create an SSH key

[Basics](#)   [Tags](#)   [Review + create](#)

Creating an SSH key resource allows you to manage and use public keys stored in Azure with Linux virtual machines.

4. In **Resource group** select **Create new** to create a new resource group to store your keys. Type a name

for your resource group and select **OK**.

5. In **Region** select a region to store your keys. You can use the keys in any region, this is just the region where they will be stored.
6. Type a name for your key in **Key pair name**.
7. In **SSH public key source**, select **Generate public key source**.
8. When you are done, select **Review + create**.
9. After it passes validation, select **Create**.
10. You will then get a pop-up window to, select **Download private key and create resource**. This will download the SSH key as a .pem file.

## Generate new key pair

**i** An SSH key pair contains both a public key and a private key. **Azure doesn't store the private key**. After the SSH key resource is created, you won't be able to download the private key again. [Learn more](#)

**Download private key and create resource**

[Return to create an SSH key resource](#)

11. Once the .pem file is downloaded, you might want to move it somewhere on your computer where it is easy to point to from your SSH client.

## Connect to the VM

On your local computer, open a PowerShell prompt and type:

```
ssh -i <path to the .pem file> username@<ipaddress of the VM>
```

For example, type: `ssh -i /Downloads/mySSHKey.pem azureuser@123.45.67.890`

## Upload an SSH key

You can also upload a public SSH key to store in Azure. For information about how to create an SSH key pair, see [Use SSH keys to connect to Linux VMs](#).

1. Open the [Azure portal](#).
2. At the top of the page, type *SSH* to search. Under \**Marketplace*, select **SSH keys**.
3. On the **SSH Key** page, select **Create**.

4. In **Resource group** select **Create new** to create a new resource group to store your keys. Type a name for your resource group and select **OK**.
5. In **Region** select a region to store your keys. You can use the keys in any region, this is just the region where they will be stored.
6. Type a name for your key in **Key pair name**.
7. In **SSH public key source**, select **Upload existing public key**.
8. Paste the full contents of the public key into **Upload key** and then select **Review + create**.
9. After validation completes, select **Create**.

Once the key has been uploaded, you can choose to use it when you create a VM.

## List keys

SSH keys created in the portal are stored as resources, so you can filter your resources view to see all of them.

1. In the portal, select **All resource**.
2. In the filters, select **Type**, unselect the **Select all** option to clear the list.
3. Type **SSH** in the filter and select **SSH key**.

## Get the public key

If you need your public key, you can easily copy it from the portal page for the key. Just list your keys (using the process in the last section) then select a key from the list. The page for your key will open and you can click the **Copy to clipboard** icon next to the key to copy it.

## Next steps

To learn more about using SSH keys with Azure VMs, see [Use SSH keys to connect to Linux VMs](#).

# Generate and store SSH keys with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can create SSH keys before creating a VM, and store them in Azure. Each newly created SSH key is also stored locally.

If you have existing SSH keys, you can upload and store them in Azure for reuse.

For a more detailed overview of SSH, see [Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure](#).

For more detailed information about creating and using SSH keys with Linux VMs, see [Use SSH keys to connect to Linux VMs](#).

## Generate new keys

1. After you sign in, use the [az sshkey create](#) command to create the new SSH key:

```
az sshkey create --name "mySSHKey" --resource-group "myResourceGroup"
```

2. The resulting output lists the new key files' paths:

```
Private key is saved to "/home/user/.ssh/7777777777_9999999".
Public key is saved to "/home/user/.ssh/7777777777_9999999.pub".
```

3. Change the permissions for the private key file for privacy:

```
chmod 600 /home/user/.ssh/7777777777_9999999
```

## Connect to the VM

On your local computer, open a Bash prompt:

```
ssh -i <path to the private key file> username@<ipaddress of the VM>
```

For example, enter: `ssh -i /home/user/.ssh/mySSHKey azureuser@123.45.67.890`

## Upload an SSH key

You can upload a public SSH key to store in Azure.

Use the [az sshkey create](#) command to upload an SSH public key by specifying its file:

```
az sshkey create --name "mySSHKey" --public-key "@/home/user/.ssh/7777777777_9999999.pub" --resource-group "myResourceGroup"
```

## List keys

Use the [az sshkey list](#) command to list all public SSH keys, optionally specifying a resource group:

```
az sshkey list --resource-group "myResourceGroup"
```

## Get the public key

Use the [az sshkey show](#) command to show the values of a public SSH key:

```
az sshkey show --name "mySSHKey" --resource-group "myResourceGroup"
```

## Next steps

To learn more about using SSH keys with Azure VMs, see [Use SSH keys to connect to Linux VMs](#).

# Quick steps: Create and use an SSH public-private key pair for Linux VMs in Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

With a secure shell (SSH) key pair, you can create virtual machines (VMs) in Azure that use SSH keys for authentication. This article shows you how to quickly generate and use an SSH public-private key file pair for Linux VMs. You can complete these steps with the Azure Cloud Shell, a macOS, or a Linux host.

For help with troubleshooting issues with SSH, see [Troubleshoot SSH connections to an Azure Linux VM that fails, errors out, or is refused](#).

## NOTE

VMs created using SSH keys are by default configured with passwords disabled, which greatly increases the difficulty of brute-force guessing attacks.

For more background and examples, see [Detailed steps to create SSH key pairs](#).

For additional ways to generate and use SSH keys on a Windows computer, see [How to use SSH keys with Windows on Azure](#).

## Supported SSH key formats

Azure currently supports SSH protocol 2 (SSH-2) RSA public-private key pairs with a minimum length of 2048 bits. Other key formats such as ED25519 and ECDSA are not supported.

## Create an SSH key pair

Use the `ssh-keygen` command to generate SSH public and private key files. By default, these files are created in the `~/.ssh` directory. You can specify a different location, and an optional password (*passphrase*) to access the private key file. If an SSH key pair with the same name exists in the given location, those files are overwritten.

The following command creates an SSH key pair using RSA encryption and a bit length of 4096:

```
ssh-keygen -m PEM -t rsa -b 4096
```

## NOTE

You can also create key pairs with the [Azure CLI](#) with the `az sshkey create` command, as described in [Generate and store SSH keys](#).

If you use the [Azure CLI](#) to create your VM with the `az vm create` command, you can optionally generate SSH public and private key files using the `--generate-ssh-keys` option. The key files are stored in the `~/.ssh` directory unless specified otherwise with the `--ssh-dest-key-path` option. If an ssh key pair already exists and the `--generate-ssh-keys` option is used, a new key pair will not be generated but instead the existing key pair will be used. In the following command, replace *VMname* and *RGname* with your own values:

```
az vm create --name VMname --resource-group RGname --image UbuntuLTS --generate-ssh-keys
```

## Provide an SSH public key when deploying a VM

To create a Linux VM that uses SSH keys for authentication, specify your SSH public key when creating the VM using the Azure portal, Azure CLI, Azure Resource Manager templates, or other methods:

- [Create a Linux virtual machine with the Azure portal](#)
- [Create a Linux virtual machine with the Azure CLI](#)
- [Create a Linux VM using an Azure template](#)

If you're not familiar with the format of an SSH public key, you can display your public key with the following

`cat` command, replacing `~/.ssh/id_rsa.pub` with the path and filename of your own public key file if needed:

```
cat ~/.ssh/id_rsa.pub
```

A typical public key value looks like this example:

```
ssh-rsa
AAAAB3NzaC1yc2EAAQABADQABAAQACQ1/KanayNr+Q7ogR5mKnGpKWRBQU7F3JjhN7utdf7Z2iUFykaYx+MInSnT3XdnBRS8KhC0IP8ptbng
IaNOWd6zM8hB6UrcRT1Tpwk/SuGMw1Vb40x1EFphBkVEUgBolOoANIEXriAMv1DMZsgvnMFiQ12tD/u14cxy1WNEMAftey/vX3Fgp2vEq4zH
XE1iY/sFZLJUJzcRUI0MOFHXAuCjg/qyqqbIuTDFyfg8k0JTtyGFEMQhbXKcuP2yGx1uw0ice62LRzr8w0mszftXyMik1PnshRXbmE2xgINY
g5xo/ra3mq2imwtOKJpfdtFoMiKhJmSNHBSk7vFTeYgg0v2cQ2+vL381cIFX40h+QCzvNF/Ax0DV1QtVtSqfQxRVG79Zqio5p12gHFkt1fV
7recBvVIhyx2L1YUkrq4DHzkxNY5c90GSHX5le9Ys03F1J5ip18f6gPq4xFmo6dVoJodZm9N0YMKCkZ4k1qJDE5sJBk2ujDPmQqeMjJX3Fn
DXYYB182ZCGQzXfz1PDC29cWvgDZEXNHuYr0LmJTmYtLZ4WkdUhLLlt5XsdoKwqlWpbegyYtGzeZNrt00dN6ybOPJqmYFd2qRtb4sYPniGJ
DOGhx4VodXAjT09omhQJpE6w1ZbRWdVkc55R2d/CSPHJscEiuudb+1SG2uA/oik/WQ== username@domainname
```

If you copy and paste the contents of the public key file to use in the Azure portal or a Resource Manager template, make sure you don't copy any trailing whitespace. To copy a public key in macOS, you can pipe the public key file to `pbcopy`. Similarly in Linux, you can pipe the public key file to programs such as `xclip`.

The public key that you place on your Linux VM in Azure is by default stored in `~/.ssh/id_rsa.pub`, unless you specified a different location when you created the key pair. To use the [Azure CLI 2.0](#) to create your VM with an existing public key, specify the value and optionally the location of this public key using the [az vm create](#) command with the `--ssh-key-values` option. In the following command, replace *myVM*, *myResourceGroup*, *UbuntuLTS*, *azureuser*, and *mysshkey.pub* with your own values:

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image UbuntuLTS \
--admin-username azureuser \
--ssh-key-values mysshkey.pub
```

If you want to use multiple SSH keys with your VM, you can enter them in a space-separated list, like this

`--ssh-key-values sshkey-desktop.pub sshkey-laptop.pub`.

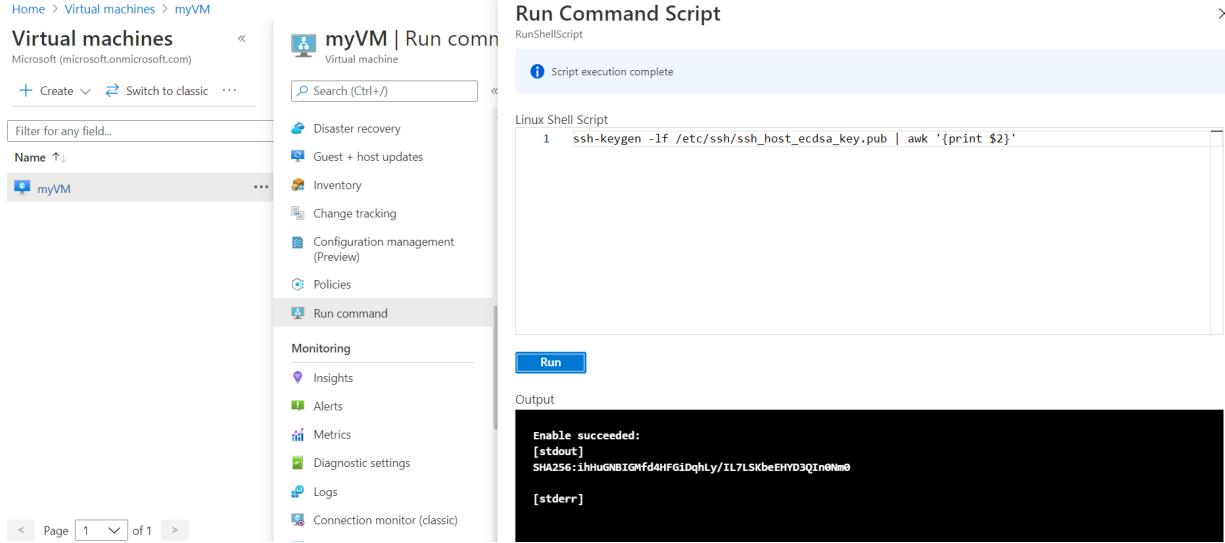

## SSH into your VM

With the public key deployed on your Azure VM, and the private key on your local system, SSH into your VM using the IP address or DNS name of your VM. In the following command, replace *azureuser* and *myvm.westus.cloudapp.azure.com* with the administrator user name and the fully qualified domain name (or IP address):

```
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you're connecting to this VM for the first time, you'll be asked to verify the host's fingerprint. It's tempting to simply accept the fingerprint that's presented, but that approach exposes you to a possible person-in-the-middle attack. You should always validate the host's fingerprint. You need to do this only the first time you connect from a client. To obtain the host fingerprint via the portal, use the Run Command feature to execute the command

```
ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}' .
```

To run the command using CLI, use [az vm run-command invoke](#).

If you specified a passphrase when you created your key pair, enter that passphrase when prompted during the sign-in process. The VM is added to your `~/.ssh/known_hosts` file, and you won't be asked to connect again until either the public key on your Azure VM changes or the server name is removed from `~/.ssh/known_hosts`.

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM. For more information about the just-in-time policy, see [Manage virtual machine access using the just in time policy](#).

## Next steps

- For more information on working with SSH key pairs, see [Detailed steps to create and manage SSH key pairs](#).
- If you have difficulties with SSH connections to Azure VMs, see [Troubleshoot SSH connections to an Azure Linux VM](#).

# How to use SSH keys with Windows on Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article is for Windows users who want to [create](#) and use *secure shell* (SSH) keys to [connect](#) to Linux virtual machines (VMs) in Azure. You can also [generate and store SSH keys in the Azure portal](#) to use when creating VMs in the portal.

To use SSH keys from a Linux or macOS client, see the [quick steps](#). For a more detailed overview of SSH, see [Detailed steps: Create and manage SSH keys for authentication to a Linux VM in Azure](#).

## Overview of SSH and keys

SSH is an encrypted connection protocol that allows secure sign-ins over unsecured connections. SSH is the default connection protocol for Linux VMs hosted in Azure. Although SSH itself provides an encrypted connection, using passwords with SSH still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

The public-private key pair is like the lock on your front door. The lock is exposed to the **public**, anyone with the right key can open the door. The key is **private**, and only given to people you trust because it can be used to unlock the door.

- The *public key* is placed on your Linux VM when you create the VM.
- The *private key* remains on your local system. Protect this private key. Do not share it.

When you connect to your Linux VM, the VM tests the SSH client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single key pair to access multiple Azure VMs and services. You do not need a separate pair of keys for each VM.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

## Supported SSH key formats

Azure currently supports SSH protocol 2 (SSH-2) RSA public-private key pairs with a minimum length of 2048 bits. Other key formats such as ED25519 and ECDSA are not supported.

## SSH clients

Recent versions of Windows 10 include [OpenSSH client commands](#) to create and use SSH keys and make SSH connections from PowerShell or a command prompt.

You can also use Bash in the [Azure Cloud Shell](#) to connect to your VM. You can use Cloud Shell in a [web browser](#), from the [Azure portal](#), or as a terminal in Visual Studio Code using the [Azure Account extension](#).

You can also install the [Windows Subsystem for Linux](#) to connect to your VM over SSH and use other native Linux tools within a Bash shell.

## Create an SSH key pair

The easiest way to create and manage your SSH keys is to [use the portal to create and store them for reuse](#).

You can also create key pairs with the [Azure CLI](#) with the `az sshkey create` command, as described in [Generate and store SSH keys](#).

To create an SSH key pair on your local computer using the `ssh-keygen` command from PowerShell or a command prompt, type the following:

```
ssh-keygen -m PEM -t rsa -b 2048
```

Enter a filename, or use the default shown in parenthesis (for example `C:\Users\username/.ssh/id_rsa`). Enter a passphrase for the file, or leave the passphrase blank if you do not want to use a passphrase.

## Create a VM using your key

To create a Linux VM that uses SSH keys for authentication, provide your SSH public key when creating the VM.

Using the Azure CLI, you specify the path and filename for the public key using `az vm create` and the `--ssh-key-value` parameter.

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image UbuntuLTS \
  --admin-username azureuser \
  --ssh-key-value ~/.ssh/id_rsa.pub
```

With PowerShell, use `New-AzVM` and add the SSH key to the VM configuration using```. For an example, see [Quickstart: Create a Linux virtual machine in Azure with PowerShell](#).

If you do a lot of deployments using the portal, you might want to upload your public key to Azure, where it can be easily selected when creating a VM from the portal. For more information, see [Upload an SSH key](#).

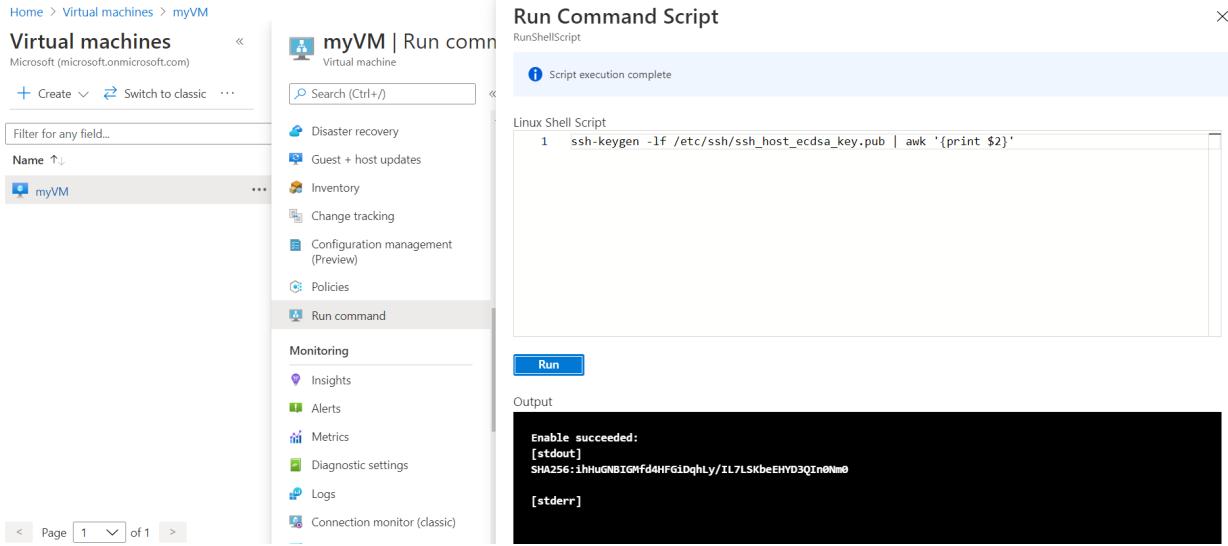

## Connect to your VM

With the public key deployed on your Azure VM, and the private key on your local system, SSH to your VM using the IP address or DNS name of your VM. Replace `azureuser` and `10.111.12.123` in the following command with the administrator user name, the IP address (or fully qualified domain name), and the path to your private key:

```
ssh -i ~/.ssh/id_rsa azureuser@10.111.12.123
```

If you have never connected to this VM before you will be asked to verify the hosts fingerprint. It is tempting to simply accept the fingerprint presented, however, this exposes you to a possible person in the middle attack. You should always validate the hosts fingerprint. You only need to do this on the first time you connect from a client. To obtain the host fingerprint via the portal use the Run Command with the following:

```
ssh-keygen -lf /etc/ssh/ssh_host_ecdsa_key.pub | awk '{print $2}' .
```

To run the command using CLI, use the `az vm run-command invoke` command.

If you configured a passphrase when you created your key pair, enter the passphrase when prompted.

If the VM is using the just-in-time access policy, you need to request access before you can connect to the VM.

For more information about the just-in-time policy, see [Manage virtual machine access using the just in time policy](#).

## Next steps

- For information about SSH keys in the Azure portal to use when creating VMs, see [Generate and store SSH keys in the Azure portal](#).
- For information about SSH keys in the Azure CLI to use when creating VMs, see [Generate and store SSH keys with the Azure CLI](#).
- For detailed steps, options, and advanced examples of working with SSH keys, see [Detailed steps to create SSH key pairs](#).
- You can also use PowerShell in Azure Cloud Shell to generate SSH keys and make SSH connections to Linux VMs. See the [PowerShell quickstart](#).
- If you have difficulty using SSH to connect to your Linux VMs, see [Troubleshoot SSH connections to an Azure Linux VM](#).

# Install and configure xrdp to use Remote Desktop with Ubuntu

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Linux virtual machines (VMs) in Azure are usually managed from the command line using a secure shell (SSH) connection. When new to Linux, or for quick troubleshooting scenarios, the use of remote desktop may be easier. This article details how to install and configure a desktop environment ([xfce](#)) and remote desktop ([xrdp](#)) for your Linux VM running Ubuntu.

The article was written and tested using an Ubuntu 18.04 VM.

## Prerequisites

This article requires an existing Ubuntu 18.04 LTS VM in Azure. If you need to create a VM, use one of the following methods:

- The [Azure CLI](#)
- The [Azure portal](#)

## Install a desktop environment on your Linux VM

Most Linux VMs in Azure do not have a desktop environment installed by default. Linux VMs are commonly managed using SSH connections rather than a desktop environment. There are various desktop environments in Linux that you can choose. Depending on your choice of desktop environment, it may consume one to 2 GB of disk space, and take 5 to 10 minutes to install and configure all the required packages.

The following example installs the lightweight [xfce4](#) desktop environment on an Ubuntu 18.04 LTS VM.

Commands for other distributions vary slightly (use `yum` to install on Red Hat Enterprise Linux and configure appropriate `selinux` rules, or use `zypper` to install on SUSE, for example).

First, SSH to your VM. The following example connects to the VM named `myvm.westus.cloudapp.azure.com` with the username of `azureuser`. Use your own values:

```
ssh azureuser@myvm.westus.cloudapp.azure.com
```

If you are using Windows and need more information on using SSH, see [How to use SSH keys with Windows](#).

Next, install xfce using `apt` as follows:

```
sudo apt-get update
sudo DEBIAN_FRONTEND=noninteractive apt-get -y install xfce4
sudo apt install xfce4-session
```

## Install and configure a remote desktop server

Now that you have a desktop environment installed, configure a remote desktop service to listen for incoming connections. [xrdp](#) is an open source Remote Desktop Protocol (RDP) server that is available on most Linux distributions, and works well with xfce. Install xrdp on your Ubuntu VM as follows:

```
sudo apt-get -y install xrdp  
sudo systemctl enable xrdp
```

On Ubuntu 20, you'll need to give certificate access to an xrdp user:

```
sudo adduser xrdp ssl-cert
```

Tell xrdp what desktop environment to use when you start your session. Configure xrdp to use xfce as your desktop environment as follows:

```
echo xfce4-session >~/.xsession
```

Restart the xrdp service for the changes to take effect as follows:

```
sudo service xrdp restart
```

## Set a local user account password

If you created a password for your user account when you created your VM, skip this step. If you only use SSH key authentication and do not have a local account password set, specify a password before you use xrdp to log in to your VM. xrdp cannot accept SSH keys for authentication. The following example specifies a password for the user account *azureuser*.

```
sudo passwd azureuser
```

### NOTE

Specifying a password does not update your SSHD configuration to permit password logins if it currently does not. From a security perspective, you may wish to connect to your VM with an SSH tunnel using key-based authentication and then connect to xrdp. If so, skip the following step on creating a network security group rule to allow remote desktop traffic.

## Create a Network Security Group rule for Remote Desktop traffic

To allow Remote Desktop traffic to reach your Linux VM, a network security group rule needs to be created that allows TCP on port 3389 to reach your VM. For more information about network security group rules, see [What is a network security group?](#) You can also [use the Azure portal to create a network security group rule](#).

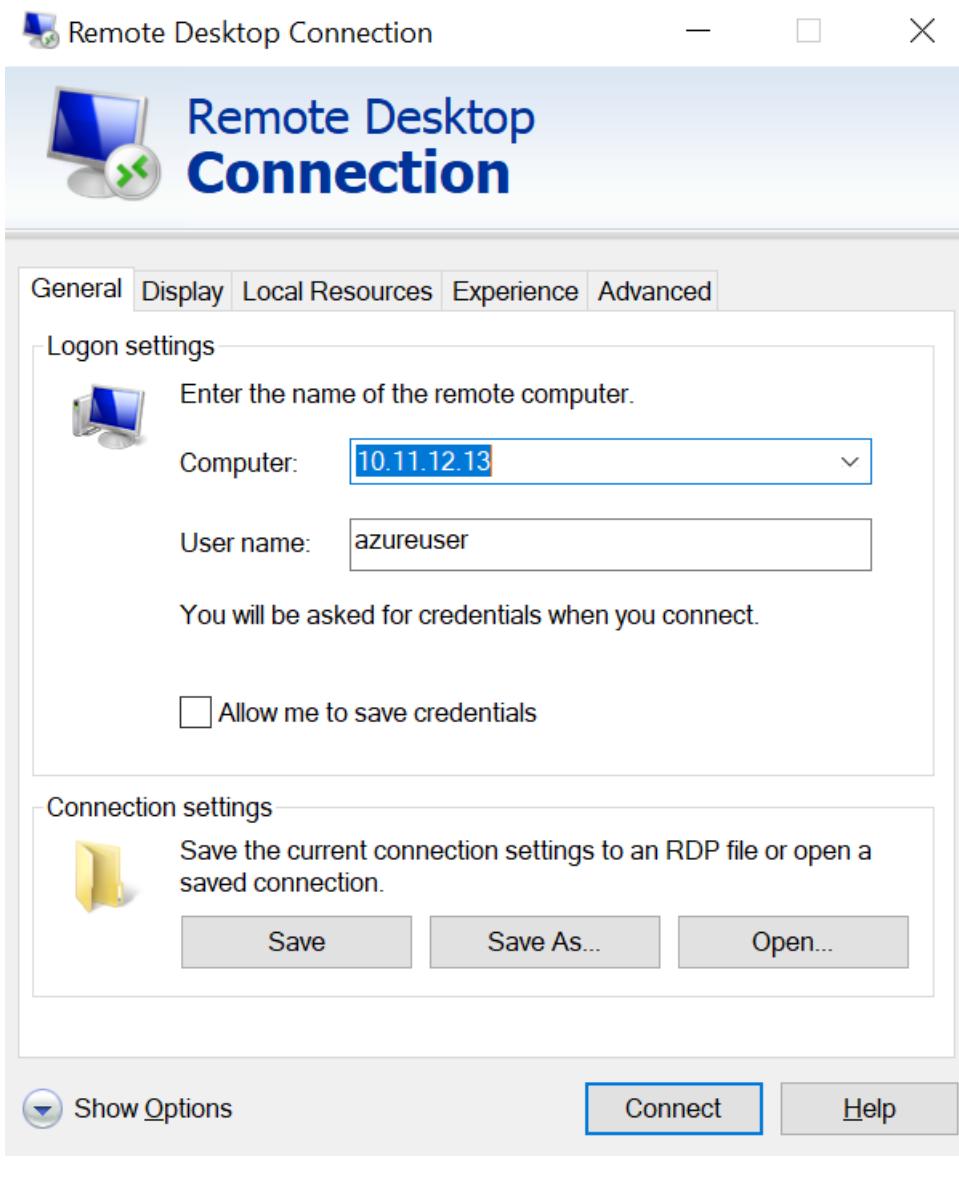

- [Azure CLI](#)
- [Azure PowerShell](#)

The following example creates a network security group rule with `az vm open-port` on port 3389. From the Azure CLI, not the SSH session to your VM, open the following network security group rule:

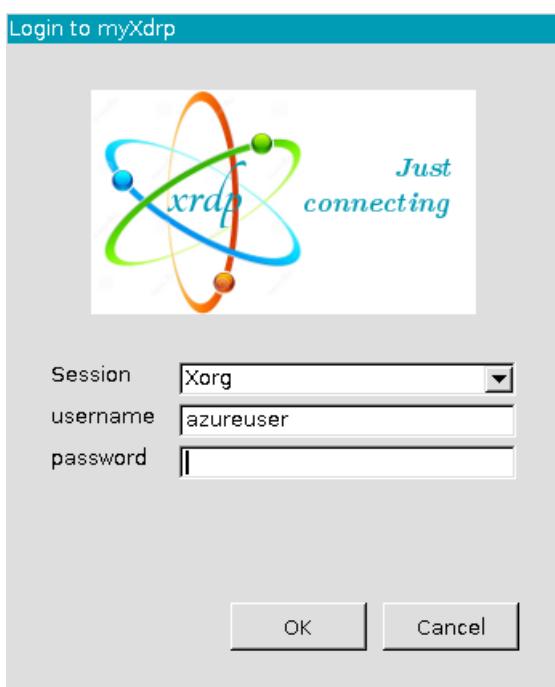

```
az vm open-port --resource-group myResourceGroup --name myVM --port 3389
```

## Connect your Linux VM with a Remote Desktop client

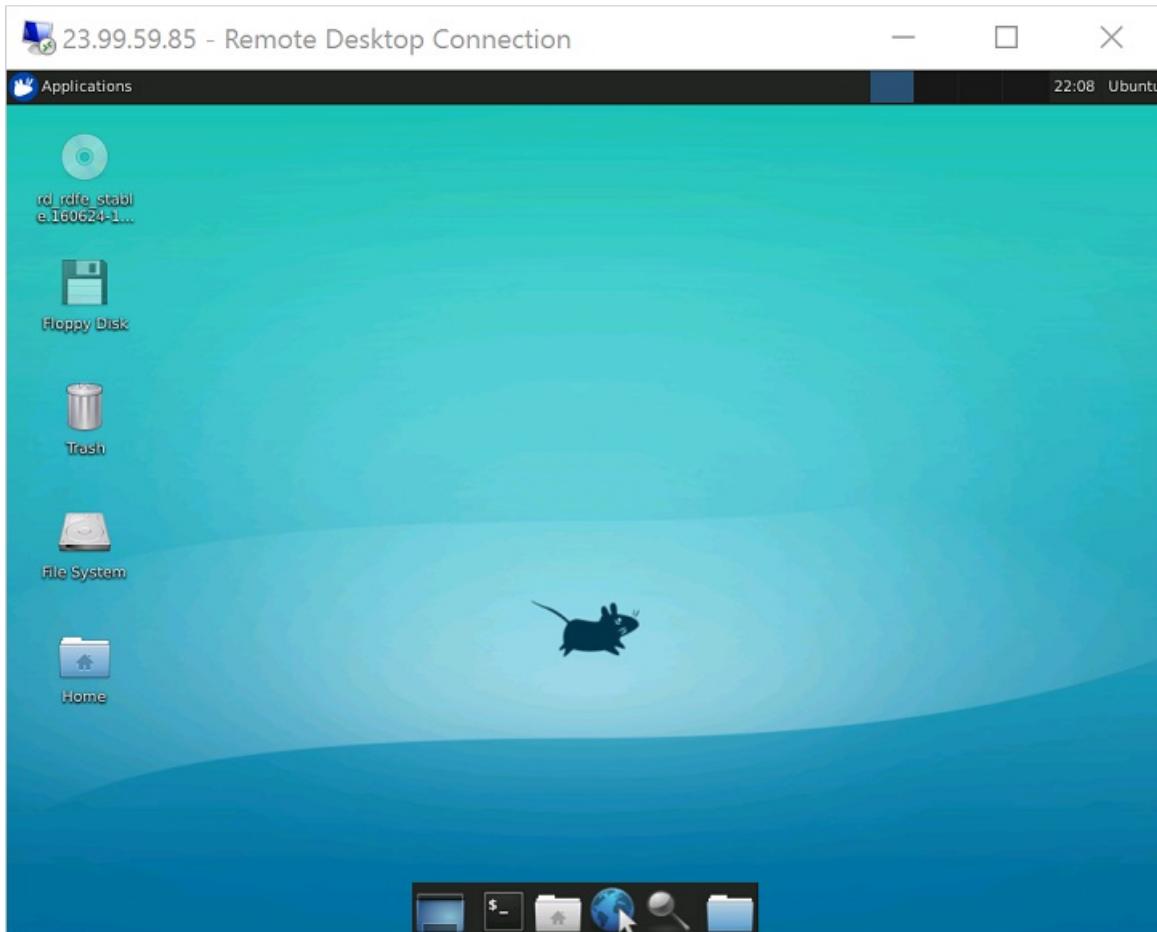

Open your local remote desktop client and connect to the IP address or DNS name of your Linux VM.

Enter the username and password for the user account on your VM as follows:

After authenticating, the xfce desktop environment will load and look similar to the following example:

If your local RDP client uses network level authentication (NLA), you may need to disable that connection setting. XRDП does not currently support NLA. You can also look at alternative RDP solutions that do support NLA, such as [FreeRDP](#).

## Troubleshoot

If you cannot connect to your Linux VM using a Remote Desktop client, use `netstat` on your Linux VM to verify that your VM is listening for RDP connections as follows:

```
sudo netstat -plnt | grep rdp
```

The following example shows the VM listening on TCP port 3389 as expected:

```
tcp      0      0      127.0.0.1:3350      0.0.0.0:*      LISTEN      53192/xrdp-sesman
tcp      0      0      0.0.0.0:3389      0.0.0.0:*      LISTEN      53188/xrdp
```

If the `xrdp-sesman` service is not listening, on an Ubuntu VM restart the service as follows:

```
sudo service xrdp restart
```

Review logs in `/var/log` on your Ubuntu VM for indications as to why the service may not be responding. You can also monitor the syslog during a remote desktop connection attempt to view any errors:

```
tail -f /var/log/syslog
```

Other Linux distributions such as Red Hat Enterprise Linux and SUSE may have different ways to restart services and alternate log file locations to review.

If you do not receive any response in your remote desktop client and do not see any events in the system log, this behavior indicates that remote desktop traffic cannot reach the VM. Review your network security group rules to ensure that you have a rule to permit TCP on port 3389. For more information, see [Troubleshoot application connectivity issues](#).

## Next steps

For more information about creating and using SSH keys with Linux VMs, see [Create SSH keys for Linux VMs in Azure](#).

For information on using SSH from Windows, see [How to use SSH keys with Windows](#).

# How to connect using Remote Desktop and sign on to an Azure virtual machine running Windows

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

You can create a remote desktop connection to a virtual machine (VM) running Windows in Azure.

To connect to a Windows VM from a Mac, you will need to install an RDP client for Mac such as [Microsoft Remote Desktop](#).

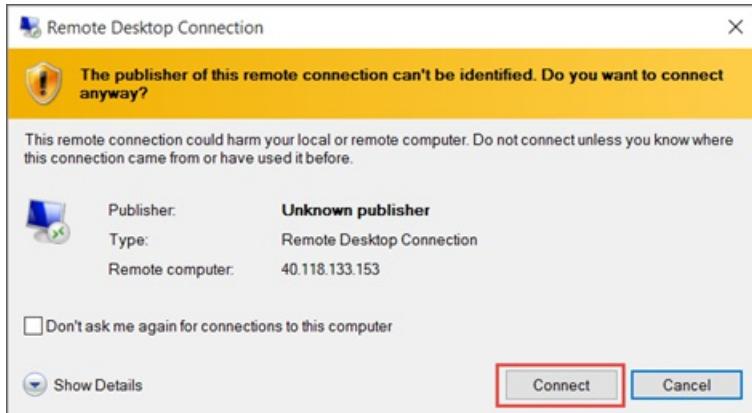

## Prerequisites

- In order to connect to a Windows Virtual Machine via RDP you need TCP connectivity to the machine on the port where Remote Desktop service is listening (3389 by default). You can validate an appropriate port is open for RDP using the troubleshooter or by checking manually in your VM settings. To check if the TCP port is open (assuming default):
  1. On the page for the VM, select **Networking** from the left menu.
  2. On the **Networking** page, check to see if there is a rule which allows TCP on port 3389 from the IP address of the computer you are using to connect to the VM. If the rule exists, you can move to the next section.
  3. If there isn't a rule, add one by selecting **Add Inbound port rule**.
  4. From the **Service** dropdown select **RDP**.
  5. Edit **Priority** and **Source** if necessary
  6. For **Name**, type *Port\_3389*
  7. When finished, select **Add**
  8. You should now have an RDP rule in the table of inbound port rules.
- Your VM must have a public IP address. To check if your VM has a public IP address, select **Overview** from the left menu and look at the **Networking** section. If you see an IP address next to **Public IP address**, then your VM has a public IP. To learn more about adding a public IP address to an existing VM, see [Associate a public IP address to a virtual machine](#)
- Verify your VM is running. On the Overview tab, in the essentials section, verify the status of the VM is **Running**. To start the VM, select **Start** at the top of the page.

## Connect to the virtual machine

1. Go to the [Azure portal](#) to connect to a VM. Search for and select **Virtual machines**.
2. Select the virtual machine from the list.
3. At the beginning of the virtual machine page, select **Connect**.
4. On the **Connect to virtual machine** page, select **RDP**, and then select the appropriate **IP address** and **Port number**. In most cases, the default IP address and port should be used. Select **Download RDP File**. If the VM has a just-in-time policy set, you first need to select the **Request access** button to request access before you can download the RDP file. For more information about the just-in-time policy, see [Manage virtual machine access using the just in time policy](#).
5. Open the downloaded RDP file and select **Connect** when prompted. You will get a warning that the

.rdp file is from an unknown publisher. This is expected. In the Remote Desktop Connection window, select **Connect** to continue.

6. In the Windows Security window, select **More choices** and then **Use a different account**. Enter the credentials for an account on the virtual machine and then select **OK**.

**Local account:** This is usually the local account user name and password that you specified when you created the virtual machine. In this case, the domain is the name of the virtual machine and it is entered as *vmname\username*.

**Domain joined VM:** If the VM belongs to a domain, enter the user name in the format *Domain\Username*. The account also needs to either be in the Administrators group or have been granted remote access privileges to the VM.

**Domain controller:** If the VM is a domain controller, enter the user name and password of a domain administrator account for that domain.

7. Select **Yes** to verify the identity of the virtual machine and finish logging on.

#### TIP

If the **Connect** button in the portal is grayed-out and you are not connected to Azure via an [Express Route](#) or [Site-to-Site VPN](#) connection, you will need to create and assign your VM a public IP address before you can use RDP. For more information, see [Public IP addresses in Azure](#).

## Connect to the virtual machine using PowerShell

If you are using PowerShell and have the Azure PowerShell module installed you may also connect using the `Get-AzRemoteDesktopFile` cmdlet, as shown below.

This example will immediately launch the RDP connection, taking you through similar prompts as above.

```
Get-AzRemoteDesktopFile -ResourceGroupName "RgName" -Name "VmName" -Launch
```

You may also save the RDP file for future use.

```
Get-AzRemoteDesktopFile -ResourceGroupName "RgName" -Name "VmName" -LocalPath "C:\Path\to\folder"
```

## Next steps

If you have difficulty connecting, see [Troubleshoot Remote Desktop connections](#).

# How to connect using Secure Shell (SSH) and sign on to an Azure virtual machine running Windows

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

The [Win32 OpenSSH](#) project makes remote connectivity using Secure Shell ubiquitous by providing native support in Windows. The capability is provided in Windows Server version 2019 and later, and can be added to older versions of Windows using a virtual machine (VM) extension.

The examples below use variables. You can set variables in your environment as follows.

SHELL	EXAMPLE
Bash/ZSH	myResourceGroup='resGroup10'
PowerShell	\$myResourceGroup='resGroup10'

## Enable SSH

First, you will need to enable SSH in your Windows machine.

### Windows Server 2019 and newer

Following the Windows Server documentation page [Get started with OpenSSH](#), run the command

```
Add-WindowsCapability -Online -Name OpenSSH.Server~~~~0.0.1.0
```

to enable the built-in capability, start the service, and open the Windows Firewall port.

You can use the Azure RunCommand extension to complete this task.

- [Azure CLI](#)
- [Azure PowerShell](#)
- [ARM template](#)
- [Bicep](#)

```
az vm run-command invoke -g $myResourceGroup -n $myVM --command-id RunPowerShellScript --scripts "Add-WindowsCapability -Online -Name OpenSSH.Server~~~~0.0.1.0"
```

### Windows Server 2016 and older

- Deploy the SSH extension for Windows. The extension provides an automated installation of the Win32 OpenSSH solution, similar to enabling the capability in newer versions of Windows. Use the following examples to deploy the extension.
- [Azure CLI](#)
  - [Azure PowerShell](#)
  - [ARM template](#)
  - [Bicep](#)

```
az vm extension set --resource-group $myResourceGroup --vm-name $myVM --name WindowsOpenSSH --publisher Microsoft.Azure.OpenSSH --version 3.0
```

## Open TCP port

Ensure the appropriate port (by default, TCP 22) is open to allow connectivity to the VM.

- [Azure CLI](#)
- [Azure PowerShell](#)
- [ARM template](#)
- [Bicep](#)

```
az network nsg rule create -g $myResourceGroup --nsg-name $myNSG -n allow-SSH --priority 1000 --source-address-prefixes 208.130.28.4/32 --destination-port-ranges 22 --protocol TCP
```

- Your VM must have a public IP address. To check if your VM has a public IP address, select **Overview** from the left menu and look at the **Networking** section. If you see an IP address next to **Public IP address**, then your VM has a public IP. To learn more about adding a public IP address to an existing VM, see [Associate a public IP address to a virtual machine](#)
- Verify your VM is running. On the Overview tab, in the essentials section, verify the status of the VM is Running. To start the VM, select **Start** at the top of the page.

## Authentication

You can authenticate to Windows machines using either username and password or SSH keys. Azure does not support provisioning public keys to Windows machines automatically, however you can copy the key using the RunCommand extension.

## Overview of SSH and keys

SSH is an encrypted connection protocol that provides secure sign-ins over unsecured connections. Although SSH provides an encrypted connection, using passwords with SSH connections still leaves the VM vulnerable to brute-force attacks. We recommend connecting to a VM over SSH using a public-private key pair, also known as *SSH keys*.

- The *public key* is placed on your VM.
- The *private key* remains on your local system. Protect this private key. Do not share it.

When you use an SSH client to connect to your VM (which has the public key), the remote VM tests the client to make sure it has the correct private key. If the client has the private key, it's granted access to the VM.

Depending on your organization's security policies, you can reuse a single public-private key pair to access multiple Azure VMs and services. You do not need a separate pair of keys for each VM or service you wish to access.

Your public key can be shared with anyone, but only you (or your local security infrastructure) should have access to your private key.

## Supported SSH key formats

Azure currently supports SSH protocol 2 (SSH-2) RSA public-private key pairs with a minimum length of 2048

bits. Other key formats such as ED25519 and ECDSA are not supported.

### Copy a public key using the RunCommand extension.

The RunCommand extension provides an easy solution to copying a public key into Windows machines and making sure the file has correct permissions.

- [Azure CLI](#)
- [Azure PowerShell](#)
- [ARM template](#)
- [Bicep](#)

```
az vm run-command invoke -g $myResourceGroup -n $myVM --command-id RunPowerShellScript --scripts  
"MYPUBLICKEY | Add-Content 'C:\ProgramData\ssh\administratorsAuthorized_keys';icacls.exe  
'C:\ProgramData\ssh\administratorsAuthorized_keys' /inheritance:r /grant 'Administrators:F' /grant  
'SYSTEM:F'"
```

## Connect using Az CLI

Connect to Windows machines using [Az SSH](#) commands.

```
az ssh vm -g $myResourceGroup -n $myVM --local-user $myUsername
```

It is also possible to create a network tunnel for specific TCP ports through the SSH connection. A good use case for this is Remote Desktop which defaults to port 3389.

```
az ssh vm -g $myResourceGroup -n $myVM --local-user $myUsername -- -L 3389:localhost:3389
```

### Connect from Azure portal

1. Go to the [Azure portal](#) to connect to a VM. Search for and select **Virtual machines**.
2. Select the virtual machine from the list.
3. Select **Connect** from the left menu.
4. Select the **SSH** tab. If the VM has a just-in-time policy set, you first need to select the **Request access** button to request access before you can download the RDP file. For more information about the just-in-time policy, see [Manage virtual machine access using the just in time policy](#).

## Next steps

Learn how to transfer files to an existing VM, see [Use SCP to move files to and from a VM](#).

# Setting up WinRM access for Virtual Machines in Azure Resource Manager

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Here are the steps you need to take to set up a VM with WinRM connectivity

1. Create a Key Vault
2. Create a self-signed certificate
3. Upload your self-signed certificate to Key Vault
4. Get the URL for your self-signed certificate in the Key Vault
5. Reference your self-signed certificates URL while creating a VM

## Step 1: Create a Key Vault

You can use the below command to create the Key Vault

```
New-AzKeyVault -VaultName "<vault-name>" -ResourceGroupName "<rg-name>" -Location "<vault-location>" -EnabledForDeployment -EnabledForTemplateDeployment
```

## Step 2: Create a self-signed certificate

You can create a self-signed certificate using this PowerShell script

```
$certificateName = "somename"

$thumbprint = (New-SelfSignedCertificate -DnsName $certificateName -CertStoreLocation Cert:\CurrentUser\My -KeySpec KeyExchange).Thumbprint

$cert = (Get-ChildItem -Path cert:\CurrentUser\My\$thumbprint)

$password = Read-Host -Prompt "Please enter the certificate password." -AsSecureString

Export-PfxCertificate -Cert $cert -FilePath ".\$certificateName.pfx" -Password $password
```

## Step 3: Upload your self-signed certificate to the Key Vault

Before uploading the certificate to the Key Vault created in step 1, it needs to be converted into a format the Microsoft.Compute resource provider will understand. The below PowerShell script will allow you to do that

```

$fileName = "<Path to the .pfx file>"
$fileContentBytes = Get-Content $fileName -Encoding Byte
$fileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
[System.Collections.HashTable]$TableForJSON = @{
    "data"      = $fileContentEncoded;
    "dataType" = "pfx";
    "password" = "<password>";
}
[System.String]$jsonObject = $TableForJSON | ConvertTo-Json
$encoding = [System.Text.Encoding]::UTF8
$jsonEncoded = [System.Convert]::ToBase64String($encoding.GetBytes($jsonObject))
$secret = ConvertTo-SecureString -String $jsonEncoded -AsPlainText -Force
Set-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret name>" -SecretValue $secret

```

## Step 4: Get the URL for your self-signed certificate in the Key Vault

The Microsoft.Compute resource provider needs a URL to the secret inside the Key Vault while provisioning the VM. This enables the Microsoft.Compute resource provider to download the secret and create the equivalent certificate on the VM.

### **NOTE**

The URL of the secret needs to include the version as well. An example URL looks like below

<https://contosovault.vault.azure.net:443/secrets/contososecret/01h9db0df2cd4300a20ence585a6s7ve>

### **Templates**

You can get the link to the URL in the template using the below code

```

"certificateUrl": "[reference(resourceId(resourceGroup().name, 'Microsoft.KeyVault/vaults/secrets', '<vault-name>', '<secret-name>'), '2015-06-01').secretUriWithVersion]"

```

### **PowerShell**

You can get this URL using the below PowerShell command

```
$secretURL = (Get-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret name>").Id
```

## Step 5: Reference your self-signed certificates URL while creating a VM

### **Azure Resource Manager Templates**

While creating a VM through templates, the certificate gets referenced in the secrets section and the winRM section as below:

```

"osProfile": {
    ...
    "secrets": [
        {
            "sourceVault": {
                "id": "<resource id of the Key Vault containing the secret>"
            },
            "vaultCertificates": [
                {
                    "certificateUrl": "<URL for the certificate you got in Step 4>",
                    "certificateStore": "<Name of the certificate store on the VM>"
                }
            ]
        }
    ],
    "windowsConfiguration": {
        ...
        "winRM": {
            "listeners": [
                {
                    "protocol": "http"
                },
                {
                    "protocol": "https",
                    "certificateUrl": "<URL for the certificate you got in Step 4>"
                }
            ]
        },
        ...
    }
},

```

A sample template for the above can be found here at [vm-winrm-keyvault-windows](#)

Source code for this template can be found on [GitHub](#)

#### PowerShell

```

$vm = New-AzVMConfig -VMName "<VM name>" -VMSize "<VM Size>"
$credential = Get-Credential
$secretURL = (Get-AzKeyVaultSecret -VaultName "<vault name>" -Name "<secret name>").Id
$vm = Set-AzVMOperatingSystem -VM $vm -Windows -ComputerName "<Computer Name>" -Credential $credential -
WinRMHttp -WinRMHttps -ProvisionVMAgent -WinRMCertificateUrl $secretURL
$sourceVaultId = (Get-AzKeyVault -ResourceGroupName "<Resource Group name>" -VaultName "<Vault
Name>").ResourceId
$CertificateStore = "My"
$vm = Add-AzVMSecret -VM $vm -SourceVaultId $sourceVaultId -CertificateStore $CertificateStore -
CertificateUrl $secretURL

```

## Step 6: Connecting to the VM

Before you can connect to the VM, you'll need to make sure your machine is configured for WinRM remote management. Start PowerShell as an administrator and execute the below command to make sure you're set up.

```
Enable-PSRemoting -Force
```

#### NOTE

You might need to make sure the WinRM service is running if the above does not work. You can do that using

```
Get-Service WinRM
```

Once the setup is done, you can connect to the VM using the below command

```
Enter-PSSession -ConnectionUri https://<public-ip-dns-of-the-vm>:5986 -Credential $cred -SessionOption (New-PSSessionOption -SkipCACheck -SkipCNCheck -SkipRevocationCheck) -Authentication Negotiate
```

# Time sync for Linux VMs in Azure

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets ✓ Uniform scale sets

Time sync is important for security and event correlation. Sometimes it is used for distributed transactions implementation. Time accuracy between multiple computer systems is achieved through synchronization. Synchronization can be affected by multiple things, including reboots and network traffic between the time source and the computer fetching the time.

Azure is backed by infrastructure running Windows Server 2016. Windows Server 2016 has improved algorithms used to correct time and condition the local clock to synchronize with UTC. The Windows Server 2016 Accurate Time feature greatly improved how the VMCTimeSync service that governs VMs with the host for accurate time. Improvements include more accurate initial time on VM start or VM restore and interrupt latency correction.

## NOTE

For a quick overview of Windows Time service, take a look at this [high-level overview video](#).

For more information, see [Accurate time for Windows Server 2016](#).

## Overview

Accuracy for a computer clock is gauged on how close the computer clock is to the Coordinated Universal Time (UTC) time standard. UTC is defined by a multinational sample of precise atomic clocks that can only be off by one second in 300 years. But, reading UTC directly requires specialized hardware. Instead, time servers are synced to UTC and are accessed from other computers to provide scalability and robustness. Every computer has time synchronization service running that knows what time servers to use and periodically checks if computer clock needs to be corrected and adjusts time if needed.

Azure hosts are synchronized to internal Microsoft time servers that take their time from Microsoft-owned Stratum 1 devices, with GPS antennas. Virtual machines in Azure can either depend on their host to pass the accurate time (*host time*) on to the VM or the VM can directly get time from a time server, or a combination of both.

On stand-alone hardware, the Linux OS only reads the host hardware clock on boot. After that, the clock is maintained using the interrupt timer in the Linux kernel. In this configuration, the clock will drift over time. In newer Linux distributions on Azure, VMs can use the VMCTimeSync provider, included in the Linux integration services (LIS), to query for clock updates from the host more frequently.

Virtual machine interactions with the host can also affect the clock. During [memory preserving maintenance](#), VMs are paused for up to 30 seconds. For example, before maintenance begins the VM clock shows 10:00:00 AM and lasts 28 seconds. After the VM resumes, the clock on the VM would still show 10:00:00 AM, which would be 28 seconds off. To correct for this, the VMCTimeSync service monitors what is happening on the host and updates the time-of-day clock in Linux VMs to compensate.

Without time synchronization working, the clock on the VM would accumulate errors. When there is only one VM, the effect might not be significant unless the workload requires highly accurate timekeeping. But in most cases, we have multiple, interconnected VMs that use time to track transactions and the time needs to be consistent throughout the entire deployment. When time between VMs is different, you could see the following

effects:

- Authentication will fail. Security protocols like Kerberos or certificate-dependent technology rely on time being consistent across the systems.
- It's very hard to figure out what has happened in a system if logs (or other data) don't agree on time. The same event would look like it occurred at different times, making correlation difficult.
- If clock is off, the billing could be calculated incorrectly.

## Configuration options

Time sync requires that a time sync service be running in the Linux VM, plus a source of accurate time information against which to synchronize. Typically ntpd or chronyd is used as the time sync service, though there are other open source time sync services that can be used as well. The source of accurate time information can be the Azure host or an external time service that is accessed over the public internet. By itself, the VMICTimeSync service does not provide ongoing time sync between the Azure host and a Linux VM except after pauses for host maintenance as described above.

Historically, most Azure Marketplace images with Linux have been configured in one of two ways:

- No time sync service is running by default
- ntpd is running as the time sync service, and synchronizing against an external NTP time source that is accessed over the network. For example, Ubuntu 18.04 LTS Marketplace images use [ntp.ubuntu.com](http://ntp.ubuntu.com).

To confirm ntpd is synchronizing correctly, run the `ntpq -p` command.

Some Azure Marketplace images with Linux are being changed to use chronyd as the time sync service, and chronyd is configured to synchronize against the Azure host rather than an external NTP time source. The Azure host time is usually the best time source to synchronize against, as it is maintained very accurately and reliably, and is accessible without the variable network delays inherent in accessing an external NTP time source over the public internet.

The VMICTimeSync is used in parallel and provides two functions:

- Immediately updates the Linux VM time-of-day clock after a host maintenance event
- Instantiates an IEEE 1588 Precision Time Protocol (PTP) hardware clock source as a /dev/ptp device that provides the accurate time-of-day from the Azure host. Chronyd can be configured to synchronize against this time source (which is the default configuration in the newest Linux images). Linux distributions with kernel version 4.11 or later (or version 3.10.0-693 or later for RHEL/CentOS 7) support the /dev/ptp device. For earlier kernel versions that do not support /dev/ptp for Azure host time, only synchronization against an external time source is possible.

Of course, the default configuration can be changed. An older image that is configured to use ntpd and an external time source can be changed to use chronyd and the /dev/ptp device for Azure host time. Similarly, an image using Azure host time via a /dev/ptp device can be configured to use an external NTP time source if required by your application or workload.

## Tools and resources

There are some basic commands for checking your time synchronization configuration. Documentation for Linux distribution will have more details on the best way to configure time synchronization for that distribution.

### Integration services

Check to see if the integration service (hv\_utils) is loaded.

```
lsmod | grep hv_utils
```

You should see something similar to this:

```
hv_utils           24418  0
hv_vmbus          397185  7

## Check for PTP Clock Source

With newer versions of Linux, a Precision Time Protocol (PTP) clock source corresponding to the Azure host is available as part of the VMICTimeSync provider. On older versions of Red Hat Enterprise Linux or CentOS 7.x the [Linux Integration Services](#) can be downloaded and used to install the updated driver. When the PTP clock source is available, the Linux device will be of the form /dev/ptpx.

See which PTP clock sources are available.

```
ls /sys/class/ptp
```

In this example, the value returned is *ptp0*, so we use that to check the clock name. To verify the device, check the clock name.

```
cat /sys/class/ptp/ptp0/clock_name
```

This should return `hyperv`, meaning the Azure host.

In Linux VMs with Accelerated Networking enabled, you may see multiple PTP devices listed because the Mellanox mlx5 driver also creates a /dev/ptp device. Because the initialization order can be different each time Linux boots, the PTP device corresponding to the Azure host might be `/dev/ptp0` or it might be `/dev/ptp1`, which makes it difficult to configure `chronyd` with the correct clock source. To solve this problem, the most recent Linux images have a `udev` rule that creates the symlink `/dev/ptp_hyperv` to whichever `/dev/ptp` entry corresponds to the Azure host. Chrony should be configured to use this symlink instead of `/dev/ptp0` or `/dev/ptp1`.

## chrony

On Ubuntu 19.10 and later versions, Red Hat Enterprise Linux, and CentOS 8.x, `chrony` is configured to use a PTP source clock. Instead of chrony, older Linux releases use the Network Time Protocol daemon (`ntpd`), which doesn't support PTP sources. To enable PTP in those releases, chrony must be manually installed and configured (in `chrony.conf`) by using the following statement:

```
refclock PHC /dev/ptp_hyperv poll 3 dpoll -2 offset 0 stratum 2
```

If the `/dev/ptp_hyperv` symlink is available, use it instead of `/dev/ptp0` to avoid any confusion with the `/dev/ptp` device created by the Mellanox mlx5 driver.

Stratum information isn't automatically conveyed from the Azure host to the Linux guest. The preceding configuration line specifies that the Azure host time source is to be treated as Stratum 2, which in turn causes the Linux guest to report itself as Stratum 3. You can change the stratum setting in the configuration line if you want the Linux guest to report itself differently.

By default, `chronyd` accelerates or slows the system clock to fix any time drift. If the drift becomes too big, `chrony` fails to fix the drift. To overcome this, the `makestep` parameter in `/etc/chrony.conf` can be changed to

force a time sync if the drift exceeds the threshold specified.

```
makestep 1.0 -1
```

Here, chrony will force a time update if the drift is greater than 1 second. To apply the changes restart the chronyd service:

```
sudo systemctl restart chronyd
```

For more information about Ubuntu and NTP, see [Time Synchronization](#).

For more information about Red Hat and NTP, see [Configure NTP](#).

For more information about chrony, see [Using chrony](#).

## systemd

On SUSE and Ubuntu releases before 19.10, time sync is configured using [systemd](#). For more information about Ubuntu, see [Time Synchronization](#). For more information about SUSE, see Section 4.5.8 in [SUSE Linux Enterprise Server 12 SP3 Release Notes](#).

## Next steps

For more information, see [Accurate time for Windows Server 2016](#).

# Time sync for Windows VMs in Azure

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Time sync is important for security and event correlation. Sometimes it is used for distributed transactions implementation. Time accuracy between multiple computer systems is achieved through synchronization. Synchronization can be affected by multiple things, including reboots and network traffic between the time source and the computer fetching the time.

Azure is now backed by infrastructure running Windows Server 2016. Windows Server 2016 has improved algorithms used to correct time and condition the local clock to synchronize with UTC. Windows Server 2016 also improved the VMCTimeSync service that governs how VMs sync with the host for accurate time. Improvements include more accurate initial time on VM start or VM restore and interrupt latency correction for samples provided to Windows Time (W32time).

## NOTE

For a quick overview of Windows Time service, take a look at this [high-level overview video](#).

For more information, see [Accurate time for Windows Server 2016](#).

## Overview

Accuracy for a computer clock is gauged on how close the computer clock is to the Coordinated Universal Time (UTC) time standard. UTC is defined by a multinational sample of precise atomic clocks that can only be off by one second in 300 years. But, reading UTC directly requires specialized hardware. Instead, time servers are synced to UTC and are accessed from other computers to provide scalability and robustness. Every computer has time synchronization service running that knows what time servers to use and periodically checks if computer clock needs to be corrected and adjusts time if needed.

Azure hosts are synchronized to internal Microsoft time servers that take their time from Microsoft-owned Stratum 1 devices, with GPS antennas. Virtual machines in Azure can either depend on their host to pass the accurate time (*host time*) on to the VM or the VM can directly get time from a time server, or a combination of both.

Virtual machine interactions with the host can also affect the clock. During [memory preserving maintenance](#), VMs are paused for up to 30 seconds. For example, before maintenance begins the VM clock shows 10:00:00 AM and lasts 28 seconds. After the VM resumes, the clock on the VM would still show 10:00:00 AM, which would be 28 seconds off. To correct for this, the VMCTimeSync service monitors what is happening on the host and prompts for changes to happen on the VMs to compensate.

The VMCTimeSync service operates in either sample or sync mode and will only influence the clock forward. In sample mode, which requires W32time to be running, the VMCTimeSync service polls the host every 5 seconds and provides time samples to W32time. Approximately every 30 seconds, the W32time service takes the latest time sample and uses it to influence the guest's clock. Sync mode activates if a guest has been resumed or if a guest's clock drifts more than 5 seconds behind the host's clock. In cases where the W32time service is properly running, the latter case should never happen.

Without time synchronization working, the clock on the VM would accumulate errors. When there is only one VM, the effect might not be significant unless the workload requires highly accurate timekeeping. But in most

cases, we have multiple, interconnected VMs that use time to track transactions and the time needs to be consistent throughout the entire deployment. When time between VMs is different, you could see the following effects:

- Authentication will fail. Security protocols like Kerberos or certificate-dependent technology rely on time being consistent across the systems.
- It's very hard to figure out what has happened in a system if logs (or other data) don't agree on time. The same event would look like it occurred at different times, making correlation difficult.
- If clock is off, the billing could be calculated incorrectly.

The best results for Windows deployments are achieved by using Windows Server 2016 as the guest operating system, which ensures you can use the latest improvements in time synchronization.

## Configuration options

There are three options for configuring time sync for your Windows VMs hosted in Azure:

- Host time and time.windows.com. This is the default configuration used in Azure Marketplace images.
- Host-only.
- Use another, external time server with or without using host time. For this option follow the [Configure Azure Windows VMs with External NTP Source](#) guide.

### Use the default

By default Windows OS VM images are configured for w32time to sync from two sources:

- The NtpClient provider, which gets information from time.windows.com.
- The VMICTimeSync service, used to communicate the host time to the VMs and make corrections after the VM is paused for maintenance. Azure hosts use Microsoft-owned Stratum 1 devices to keep accurate time.

w32time would prefer the time provider in the following order of priority: stratum level, root delay, root dispersion, time offset. In most cases, w32time on an Azure VM would prefer host time due to evaluation it would do to compare both time sources.

For domain joined machines the domain itself establishes time sync hierarchy, but the forest root still needs to take time from somewhere and the following considerations would still hold true.

### Host-only

Because time.windows.com is a public NTP server, syncing time with it requires sending traffic over the internet, varying packet delays can negatively affect quality of the time sync. Removing time.windows.com by switching to host-only sync can sometimes improve your time sync results.

Switching to host-only time sync makes sense if you experience time sync issues using the default configuration. Try out the host-only sync to see if that would improve the time sync on VM.

### External time server

If you have specific time sync requirements, there is also an option of using external time servers. External time servers can provide specific time, which can be useful for test scenarios, ensuring time uniformity with machines hosted in non-Microsoft datacenters, or handling leap seconds in a special way.

You can combine external servers with the VMICTimeSync service and VMICTimeProvider to provide results similar to the default configuration.

## Check your configuration

Check if the NtpClient time provider is configured to use explicit NTP servers (NTP) or domain time sync (NT5DS).

```
w32tm /dumpreg /subkey:Parameters | findstr /i "type"
```

If the VM is using NTP, you will see the following output:

Value Name	Value Type	Value Data
Type	REG_SZ	NTP

To see what time server the NtpClient time provider is using, at an elevated command prompt type:

```
w32tm /dumpreg /subkey:Parameters | findstr /i "ntpserver"
```

If the VM is using the default, the output will look like this:

NtpServer	REG_SZ	time.windows.com,0x8
-----------	--------	----------------------

To see what time provider is being used currently.

```
w32tm /query /source
```

Here is the output you could see and what it would mean:

- **time.windows.com** - in the default configuration, w32time would get time from time.windows.com. The time sync quality depends on internet connectivity to it and is affected by packet delays. This is the usual output you would get on a physical machine.
- **VM IC Time Synchronization Provider** - the VM is syncing time from the host. This is the usual output you would get on a virtual machine running on Azure.
- *Your domain server* - the current machine is in a domain and the domain defines the time sync hierarchy.
- *Some other server* - w32time was explicitly configured to get the time from that another server. Time sync quality depends on this time server quality.
- **Local CMOS Clock** - clock is unsynchronized. You can get this output if w32time hasn't had enough time to start after a reboot or when all the configured time sources are not available.

## Opt in for host-only time sync

Azure is constantly working on improving time sync on hosts and can guarantee that all the time sync infrastructure is collocated in Microsoft-owned datacenters. If you have time sync issues with the default setup that prefers to use time.windows.com as the primary time source, you can use the following commands to opt in to host-only time sync.

Mark the VMIC provider as enabled.

```
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\TimeProviders\VMICTimeProvider /v Enabled /t REG_DWORD /d 1 /f
```

Mark the NTPClient provider as disabled.

```
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\TimeProviders\NtpClient /v Enabled /t REG_DWORD /d 0 /f
```

Restart the w32time Service.

```
net stop w32time && net start w32time
```

## Windows Server 2012 and R2 VMs

Windows Server 2012 and Windows Server 2012 R2 have different default settings for time sync. The w32time by default is configured in a way that prefers low overhead of the service over precise time.

If you want to move your Windows Server 2012 and 2012 R2 deployments to use the newer defaults that prefer precise time, you can apply the following settings.

Update the w32time poll and update intervals to match Windows Server 2016 settings.

```
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config /v MinPollInterval /t REG_DWORD /d 6 /f  
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config /v MaxPollInterval /t REG_DWORD /d 10 /f  
reg add HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\Config /v UpdateInterval /t REG_DWORD /d 100 /f  
w32tm /config /update
```

For `w32time` to be able to use the new poll intervals the NtpServers need to be marked as using them. If servers are annotated with the `0x1` bitflag mask, that would override this mechanism and `w32time` would use `SpecialPollInterval` instead. Make sure that specified NTP servers are either using the `0x8` flag or no flag at all:

Check what flags are being used for the NTP servers.

```
w32tm /dumpreg /subkey:Parameters | findstr /i "ntpserver"
```

## Next steps

Below are links to more details about the time sync:

# Configure Active Directory Windows Virtual Machines in Azure with External NTP Source

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows Virtual Machines

Use this guide to learn how to setup time synchronization for your Azure Windows Virtual Machines that belong to an Active Directory Domain with an external NTP source.

## Time Sync for Active Directory Windows Virtual Machines in Azure with External NTP Source

Time synchronization in Active Directory should be managed by only allowing the PDC to access an external time source or NTP Server. All other Domain Controllers would then sync time against the PDC. If your PDC is an Azure Virtual Machine follow these steps:

### NOTE

Due to Azure Security configurations, the following settings must be applied on the PDC using the **Local Group Policy Editor**.

To check current time source in your **PDC**, from an elevated command prompt run `w32tm /query /source` and note the output for later comparison.

1. From *Start* run `gpedit.msc`
2. Navigate to the *Global Configuration Settings* policy under *Computer Configuration -> Administrative Templates -> System -> Windows Time Service*.
3. Set it to *Enabled* and configure the *AnnounceFlags* parameter to 5.
4. Navigate to *Computer Settings -> Administrative Templates -> System -> Windows Time Service -> Time Providers*.
5. Double click the *Configure Windows NTP Client* policy and set it to *Enabled*, configure the parameter *NTPServer* to point to an IP address of a time server followed by `,0x9` for example: `131.107.13.100,0x9` and configure *Type* to NTP. For all the other parameters you can use the default values, or use custom ones according to your corporate needs.

### IMPORTANT

You must mark the VMIC provider as *Disabled* in the Local Registry. Remember that serious problems might occur if you modify the registry incorrectly. Therefore, make sure that you follow these steps carefully. For added protection, back up the registry before you modify it. Then, you can restore the registry if a problem occurs. For how to back up and restore the Windows Registry follow the steps below.

## Back up the registry manually

- Select Start, type `regedit.exe` in the search box, and then press Enter. If you are prompted for an administrator password or for confirmation, type the password or provide confirmation.
- In Registry Editor, locate and click the registry key or subkey that you want to back up.

- Select File -> Export.
- In the Export Registry File dialog box, select the location to which you want to save the backup copy, and then type a name for the backup file in the File name field.
- Select Save.

## Restore a manual backup

- Select Start, type regedit.exe, and then press Enter. If you are prompted for an administrator password or for confirmation, type the password or provide confirmation.
- In Registry Editor, click File -> Import.
- In the Import Registry File dialog box, select the location to which you saved the backup copy, select the backup file, and then click Open.

To mark the VMIC provider as *Disabled* from *Start* type *regedit.exe* -> In the *Registry Editor* navigate to *HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Services\w32time\TimeProviders* -> On key *VMICTimeProvider* set the value to 0

### NOTE

It can take up to 15 minutes for these changes to reflect in the system.

From an elevated command prompt rerun *w32tm /query /source* and compare the output to the one you noted at the beginning of the configuration. Now it will be set to the NTP Server you chose.

## GPO for Clients

Configure the following Group Policy Object to enable your clients to synchronize time with any Domain Controller in your Domain:

To check current time source in your client, from an elevated command prompt run *w32tm /query /source* and note the output for later comparison.

1. From a Domain Controller go to *Start* run *gpmc.msc*
2. Browse to the Forest and Domain where you want to create the GPO.
3. Create a new GPO, for example *Clients Time Sync*, in the container *Group Policy Objects*.
4. Right-click on the newly created GPO and Edit.
5. In the *Group Policy Management Editor* navigate to the *Configure Windows NTP Client* policy under *Computer Configuration -> Administrative Templates -> System -> Windows Time Service -> Time Providers*
6. Set it to *Enabled*, configure the parameter *NTPServer* to point to a Domain Controller in your Domain followed by *,0x8* for example: *DC1.contoso.com,0x8* and configure *Type* to NT5DS. For all the other parameters you can use the default values, or use custom ones according to your corporate needs.
7. Link the GPO to the Organizational Unit where your clients are located.

### IMPORTANT

In the the parameter *NTPServer* you can specify a list with all the Domain Controllers in your domain, like this:

*DC1.contoso.com,0x8 DC2.contoso.com,0x8 DC3.contoso.com,0x8*

From an elevated command prompt rerun *w32tm /query /source* and compare the output to the one you noted at the beginning of the configuration. Now it will be set to the Domain Controller that satisfied the client's authentication request.

## Next steps

Below are links to more details about the time sync:

# Run scripts in your VM by using Run Command

9/21/2022 • 2 minutes to read • [Edit Online](#)

Run Command uses the virtual machine (VM) agent to run scripts within an Azure Windows or Linux VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state. Scripts can be embedded in the properties or referenced to a pre published gallery script.

The original set of commands are action orientated. The updated set of commands, currently in Public Preview, are management orientated and enable you to run multiple scripts and has less restrictions. This article will explain the difference between the two sets of run commands and help you decide which set is the right one to use in your scenario.

## IMPORTANT

**Managed Run Command** is currently in public preview. This preview version is provided without a service-level agreement, and we don't recommend it for production workloads. Certain features might not be supported or might have constrained capabilities. For more information, see [Supplemental Terms of Use for Microsoft Azure Previews](#).

## When to use action or managed commands

The original set of commands are action orientated. You should consider using this set of commands for situations where you need to run:

- A small script to get a content from a VM
- A script to configure a VM (set registry keys, change configuration)
- A one time script for diagnostics

See [Action Run Commands for Linux](#) and [Action Run Commands for Windows](#) for available action commands and instructions on how to apply them.

The updated set of commands, currently in Public Preview, are management orientated. Consider using managed run commands if your needs align to the following examples:

- Script needs to run as part of VM deployment
- Recurrent script execution is needed
- Multiple scripts needs to execute sequentially
- Bootstrap a VM by running installation scripts
- Publish custom script to be shared and reused

See [Managed Run Command for Linux](#) and [Managed Run Command for Windows](#) to learn how to use them.

## Compare feature support

FEATURE SUPPORT	ACTION RUNCOMMAND	MANAGED RUNCOMMAND
ARM template	No, it's a POST action	Yes, it's a resource type
Long running	90 min limit	Customer specified timeout

FEATURE SUPPORT	ACTION RUNCOMMAND	MANAGED RUNCOMMAND
Execution account	System account / root	Customer specified user
Multiple run commands	Only one active	Multiple in parallel or sequenced
Large output	Limited to 4k (in status blob)	Uploaded to customer append blob
Progress tracking	Reports only final status	Reports progress and last 4k output during execution
Async execution	Goal state/provisioning waits for script to complete	Customer specified async flag if provisioning waits for the script
Virtual machine scale set support	Only on VM instance	Support virtual machine scale set model and scale out
SAS generation	No blob support	Automated, CRP generates SAS for customer blobs and manages them
Gallery (custom commands)	Only built-in commandIds	Customer can publish scripts and share them

## Next steps

Get started with [Managed Run Command for Linux](#) or [Managed Run Command for Windows](#).

# Run scripts in your Linux VM by using action Run Commands

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The Run Command feature uses the virtual machine (VM) agent to run shell scripts within an Azure Linux VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

## Benefits

You can access your virtual machines in multiple ways. Run Command can run scripts on your virtual machines remotely by using the VM agent. You use Run Command through the Azure portal, [REST API](#), or [Azure CLI](#) for Linux VMs.

This capability is useful in all scenarios where you want to run a script within a virtual machine. It's one of the only ways to troubleshoot and remediate a virtual machine that doesn't have the RDP or SSH port open because of network or administrative user configuration.

## Restrictions

The following restrictions apply when you're using Run Command:

- Output is limited to the last 4,096 bytes.
- The minimum time to run a script is about 20 seconds.
- Scripts run by default as an elevated user on Linux.
- You can run one script at a time.
- Scripts that prompt for information (interactive mode) are not supported.
- You can't cancel a running script.
- The maximum time a script can run is 90 minutes. After that, the script will time out.
- Outbound connectivity from the VM is required to return the results of the script.

### NOTE

To function correctly, Run Command requires connectivity (port 443) to Azure public IP addresses. If the extension doesn't have access to these endpoints, the scripts might run successfully but not return the results. If you're blocking traffic on the virtual machine, you can use [service tags](#) to allow traffic to Azure public IP addresses by using the `AzureCloud` tag.

## Available commands

This table shows the list of commands available for Linux VMs. You can use the `RunShellScript` command to run any custom script that you want. When you're using the Azure CLI or PowerShell to run a command, the value that you provide for the `--command-id` or `-CommandId` parameter must be one of the following listed values. When you specify a value that is not an available command, you receive this error:

The entity was not found in this Azure location

NAME	DESCRIPTION
RunShellScript	Runs a Linux shell script.
ifconfig	Gets the configuration of all network interfaces.

## Azure CLI

The following example uses the [az vm run-command](#) command to run a shell script on an Azure Linux VM.

```
az vm run-command invoke -g myResourceGroup -n myVm --command-id RunShellScript --scripts "apt-get update && apt-get install -y nginx"
```

### NOTE

To run commands as a different user, enter `sudo -u` to specify a user account.

## Azure portal

Go to a VM in the [Azure portal](#) and select **Run command** in the left menu, under **Operations**. You see a list of the available commands to run on the VM.

NAME	DESCRIPTION
RunShellScript	Executes a Linux shell script
ifconfig	List network configuration

Choose a command to run. Some of the commands might have optional or required input parameters. For those commands, the parameters are presented as text fields for you to provide the input values. For each command, you can view the script that's being run by expanding **View script**. **RunShellScript** is different from the other commands, because it allows you to provide your own custom script.

### NOTE

The built-in commands are not editable.

After you choose the command, select **Run** to run the script. After the script finishes, it returns the output and any errors in the output window. The following screenshot shows an example output from running the **ifconfig** command.

Run Command Script  
ifconfig

**Script execution complete**

**Details**  
Get the configuration of all network interfaces.

View script

**Parameters**

**ARGUMENTS** Default will be used

**Run**

**Output**

```
Enable succeeded:
[stdout]
eth0      Link encap:Ethernet  HWaddr 00:0d:3a:12:81:d1
          inet  addr:10.0.0.7   Bcast:10.0.0.255  Mask:255.255.255.0
          inet6 addr: fe80::20d:3aff:fe12:81d1/64 Scope:Link
                  UP BROADCAST RUNNING MULTICAST  MTU:1500 Metric:1
                  RX packets:2134524 errors:0 dropped:0 overruns:0 frame:0
                  TX packets:1438287 errors:0 dropped:0 overruns:0 carrier:0
                  collisions:0 txqueuelen:1000
                  RX bytes:2208675468 (2.2 GB)  TX bytes:400069292 (400.0 MB)

lo        Link encap:Local Loopback
          inet  addr:127.0.0.1   Mask:255.0.0.0
          inet6 addr: ::1/128 Scope:Host
                  UP LOOPBACK RUNNING  MTU:65536 Metric:1
                  RX packets:160 errors:0 dropped:0 overruns:0 frame:0
                  TX packets:160 errors:0 dropped:0 overruns:0 carrier:0
                  collisions:0 txqueuelen:1000
                  RX bytes:11840 (11.8 KB)  TX bytes:11840 (11.8 KB)

[stderr]
```

## PowerShell

The following example uses the [Invoke-AzVMRunCommand](#) cmdlet to run a PowerShell script on an Azure VM. The cmdlet expects the script referenced in the `-ScriptPath` parameter to be local to where the cmdlet is being run.

```
Invoke-AzVMRunCommand -ResourceGroupName '<myResourceGroup>' -Name '<myVMName>' -CommandId 'RunShellScript' -ScriptPath '<pathToScript>' -Parameter @{"arg1" = "var1";"arg2" = "var2"}
```

## Limiting access to Run Command

Listing the run commands or showing the details of a command requires the

`Microsoft.Compute/locations/runCommands/read` permission. The built-in [Reader](#) role and higher levels have this permission.

Running a command requires the `Microsoft.Compute/virtualMachines/runCommand/action` permission. The [Virtual Machine Contributor](#) role and higher levels have this permission.

You can use one of the [built-in roles](#) or create a [custom role](#) to use Run Command.

## Next steps

To learn about other ways to run scripts and commands remotely in your VM, see [Run scripts in your Linux VM](#).

# Run scripts in your Windows VM by using action Run Commands

9/21/2022 • 4 minutes to read • [Edit Online](#)

The Run Command feature uses the virtual machine (VM) agent to run PowerShell scripts within an Azure Windows VM. You can use these scripts for general machine or application management. They can help you to quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

## Benefits

You can access your virtual machines in multiple ways. Run Command can run scripts on your virtual machines remotely by using the VM agent. You use Run Command through the Azure portal, [REST API](#), or [PowerShell](#) for Windows VMs.

This capability is useful in all scenarios where you want to run a script within a virtual machine. It's one of the only ways to troubleshoot and remediate a virtual machine that doesn't have the RDP or SSH port open because of improper network or administrative user configuration.

## Restrictions

The following restrictions apply when you're using Run Command:

- Output is limited to the last 4,096 bytes.
- The minimum time to run a script is about 20 seconds.
- Scripts run as System on Windows.
- One script at a time can run.
- Scripts that prompt for information (interactive mode) are not supported.
- You can't cancel a running script.
- The maximum time a script can run is 90 minutes. After that, it will time out.
- Outbound connectivity from the VM is required to return the results of the script.
- It is not recommended to run a script that will cause a stop or update of the VM Agent. This can let the extension in a Transitioning state, leading to a timeout.

### NOTE

To function correctly, Run Command requires connectivity (port 443) to Azure public IP addresses. If the extension doesn't have access to these endpoints, the scripts might run successfully but not return the results. If you're blocking traffic on the virtual machine, you can use [service tags](#) to allow traffic to Azure public IP addresses by using the `AzureCloud` tag.

The Run Command feature doesn't work if the VM agent status is NOT READY. Check the agent status in the VM's properties in the Azure portal.

## Available commands

This table shows the list of commands available for Windows VMs. You can use the `RunPowerShellScript` command to run any custom script that you want. When you're using the Azure CLI or PowerShell to run a command, the value that you provide for the `--command-id` or `-CommandId` parameter must be one of the following listed values. When you specify a value that is not an available command, you receive this error:

The entity was not found in this Azure location

NAME	DESCRIPTION
RunPowerShellScript	Runs a PowerShell script
DisableNLA	Disable Network Level Authentication
DisableWindowsUpdate	Disable Windows Update Automatic Updates
EnableAdminAccount	Checks if the local administrator account is disabled, and if so enables it.
EnableEMS	EnableS EMS
EnableRemotePS	Configures the machine to enable remote PowerShell.
EnableWindowsUpdate	Enable Windows Update Automatic Updates
IPConfig	Shows detailed information for the IP address, subnet mask, and default gateway for each adapter bound to TCP/IP.
RDPSetting	Checks registry settings and domain policy settings. Suggests policy actions if the machine is part of a domain or modifies the settings to default values.
ResetRDPCert	Removes the TLS/SSL certificate tied to the RDP listener and restores the RDP listener security to default. Use this script if you see any issues with the certificate.
SetRDPPort	Sets the default or user-specified port number for Remote Desktop connections. Enables firewall rules for inbound access to the port.

## Azure CLI

The following example uses the [az vm run-command](#) command to run a shell script on an Azure Windows VM.

```
# script.ps1
# param(
#     [string]$arg1,
#     [string]$arg2
# )
# Write-Host This is a sample script with parameters $arg1 and $arg2

az vm run-command invoke --command-id RunPowerShellScript --name win-vm -g my-resource-group \
--scripts @script.ps1 --parameters "arg1=somefoo" "arg2=somebar"
```

## Azure portal

Go to a VM in the [Azure portal](#) and select **Run command** from the left menu, under **Operations**. You see a list of the available commands to run on the VM.

 WindowsVM1 - Run command

Virtual machine

Search (Ctrl+ /)

- Disaster recovery
- Update management
- Inventory
- Change tracking
- Run command

Monitoring

- Alerts
- Metrics
- Diagnostics settings
- Advisor recommendations

Run Command uses the VM agent to let you run a script inside this virtual machine. This can be helpful for troubleshooting and recovery, and for general machine and application maintenance. Select a command below to see details.

NAME	DESCRIPTION
RunPowerShellScript	Executes a PowerShell script
EnableAdminAccount	Enable administrator account
EnableRemotePS	Enable remote PowerShell
IPConfig	List IP configuration
RDPSettings	Verify RDP Listener Settings
ResetRDPCert	Restore RDP Authentication mode to defaults
SetRDPPort	Set Remote Desktop port

Learn more  
Run Command  
Provide feedback

Choose a command to run. Some of the commands might have optional or required input parameters. For those commands, the parameters are presented as text fields for you to provide the input values. For each command, you can view the script that's being run by expanding **View script**. **RunPowerShellScript** is different from the other commands, because it allows you to provide your own custom script.

**NOTE**

The built-in commands are not editable.

After you choose the command, select **Run** to run the script. After the script finishes, it returns the output and any errors in the output window. The following screenshot shows an example output from running the **RDPSettings** command.

Run Command Script

RDPSettings

 Script execution complete

Details  
Checks registry settings and domain policy settings. Suggests policy actions if machine is part of a domain or modifies the settings to default values.

```

## PowerShell

The following example uses the [Invoke-AzVMRunCommand](#) cmdlet to run a PowerShell script on an Azure VM. The cmdlet expects the script referenced in the `-ScriptPath` parameter to be local to where the cmdlet is being run.

```
Invoke-AzVMRunCommand -ResourceGroupName '<myResourceGroup>' -Name '<myVMName>' -CommandId  
'RunPowerShellScript' -ScriptPath '<pathToScript>' -Parameter @{"arg1" = "var1";"arg2" = "var2"}
```

### NOTE

Parameter values can be string type only and the script is responsible for converting them to other types if needed.

## Limiting access to Run Command

Listing the run commands or showing the details of a command requires the

[Microsoft.Compute/locations/runCommands/read](#) permission on Subscription Level. The built-in [Reader](#) role and higher levels have this permission.

Running a command requires the [Microsoft.Compute/virtualMachines/runCommand/action](#) permission. The [Virtual Machine Contributor](#) role and higher levels have this permission.

You can use one of the [built-in roles](#) or create a [custom role](#) to use Run Command.

## Next steps

To learn about other ways to run scripts and commands remotely in your VM, see [Run scripts in your Windows VM](#).

# Preview: Run scripts in your Linux VM by using managed Run Commands

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

## IMPORTANT

Managed Run Command is currently in public preview. This preview version is provided without a service-level agreement, and we don't recommend it for production workloads. Certain features might not be supported or might have constrained capabilities. For more information, see [Supplemental Terms of Use for Microsoft Azure Previews](#).

The Run Command feature uses the virtual machine (VM) agent to run scripts within an Azure Linux VM. You can use these scripts for general machine or application management. They can help you quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

The *updated* managed Run Command uses the same VM agent channel to execute scripts and provides the following enhancements over the [original action oriented Run Command](#):

- Support for updated Run Command through ARM deployment template
- Parallel execution of multiple scripts
- Sequential execution of scripts
- RunCommand script can be canceled
- User specified script timeout
- Support for long running (hours/days) scripts
- Passing secrets (parameters, passwords) in a secure manner

## Register for preview

You must register your subscription in order to use managed Run Command during public preview. Go to [set up preview features in Azure subscription](#) for registration instructions and use the feature name `RunCommandPreview`.

## Azure CLI

The following examples use `az vm run-command` to run shell script on an Azure Linux VM.

### Execute a script with the VM

This command will deliver the script to the VM, execute it, and return the captured output.

```
az vm run-command create --name "myRunCommand" --vm-name "myVM" --resource-group "myRG" --script "echo Hello World!"
```

### List all deployed RunCommand resources on a VM

This command will return a full list of previously deployed Run Commands along with their properties.

```
az vm run-command list --vm-name "myVM" --resource-group "myRG"
```

## Get execution status and results

This command will retrieve current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

```
az vm run-command show --name "myRunCommand" --vm-name "myVM" --resource-group "myRG" --expand instanceView
```

## Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution will be terminated.

```
az vm run-command delete --name "myRunCommand" --vm-name "myVM" --resource-group "myRG"
```

# PowerShell

## Execute a script with the VM

This command will deliver the script to the VM, execute it, and return the captured output.

```
Set-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -Location "EastUS" -RunCommandName "RunCommandName" -SourceScript "echo Hello World!"
```

## Execute a script on the VM using SourceScriptUri parameter

`OutputBlobUri` and `ErrorBlobUri` are optional parameters.

```
Set-AzVMRunCommand -ResourceGroupName -VMName -RunCommandName -SourceScriptUri "< SAS URI of a storage blob with read access or public URI>" -OutputBlobUri "< SAS URI of a storage append blob with read, add, create, write access>" -ErrorBlobUri "< SAS URI of a storage append blob with read, add, create, write access>"
```

## List all deployed RunCommand resources on a VM

This command will return a full list of previously deployed Run Commands along with their properties.

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM"
```

## Get execution status and results

This command will retrieve current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName "RunCommandName" -Expand instanceView
```

## Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution will be terminated.

```
Remove-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName "RunCommandName"
```

# REST API

To deploy a new Run Command, execute a PUT on the VM directly and specify a unique name for the Run

Command instance.

```
GET  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachines/<vmName>/runcommands?api-version=2019-12-01
```

```
{  
  "location": "<location>",  
  "properties": {  
    "source": {  
      "script": "Write-Host Hello World!",  
      "scriptUri": "<SAS URI of a storage blob with read access or public URI>",  
      "commandId": "<Id>"  
    },  
    "parameters": [  
      {  
        "name": "param1",  
        "value": "value1"  
      },  
      {  
        "name": "param2",  
        "value": "value2"  
      }  
    ],  
    "protectedParameters": [  
      {  
        "name": "secret1",  
        "value": "value1"  
      },  
      {  
        "name": "secret2",  
        "value": "value2"  
      }  
    ],  
    "runAsUser": "userName",  
    "runAsPassword": "userPassword",  
    "timeoutInSeconds": 3600,  
    "outputBlobUri": "< SAS URI of a storage append blob with read, add, create, write access>",  
    "errorBlobUri": "< SAS URI of a storage append blob with read, add, create, write access >"  
  }  
}
```

## Notes

- You can provide an inline script, a script URI, or a built-in script [command ID](#) as the input source. Script URI is either storage blob SAS URI with read access or public URI.
- Only one type of source input is supported for one command execution.
- Run Command supports writing output and error to Storage blobs using outputBlobUri and errorBlobUri parameters, which can be used to store large script outputs. Use SAS URI of a storage append blob with read, add, create, write access. The blob should be of type AppendBlob. Writing the script output or error blob would fail otherwise. The blob will be overwritten if it already exists. It will be created if it does not exist.

## List running instances of Run Command on a VM

```
GET  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachines/<vmName>/runcommands?api-version=2019-12-01
```

## Get output details for a specific Run Command deployment

```
GET  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands/<runCommandName>?$expand=instanceView&api-version=2019-12-01
```

## Cancel a specific Run Command deployment

To cancel a running deployment, you can PUT or PATCH on the running instance of Run Command and specify a blank script in the request body. This will cancel the ongoing execution.

You can also delete the instance of Run Command.

```
DELETE  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands/<runCommandName>?api-version=2019-12-01
```

## Deploy scripts in an ordered sequence

To deploy scripts sequentially, use a deployment template, specifying a `dependsOn` relationship between sequential scripts.

```
{  
    "type": "Microsoft.Compute/virtualMachines/runCommands",  
    "name": "secondRunCommand",  
    "apiVersion": "2019-12-01",  
    "location": "[parameters('location')]",  
    "dependsOn": <full resourceId of the previous other Run Command>,  
    "properties": {  
        "source": {  
            "script": "echoHelloWorld!"  
        },  
        "timeoutInSeconds": 60  
    }  
}
```

## Execute multiple Run Commands sequentially

By default, if you deploy multiple RunCommand resources using deployment template, they will be executed simultaneously on the VM. If you have a dependency on the scripts and a preferred order of execution, you can use the `dependsOn` property to make them run sequentially.

In this example, `secondRunCommand` will execute after `firstRunCommand`.

```
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "resources": [
        {
            "type": "Microsoft.Compute/virtualMachines/runCommands",
            "name": "[concat(parameters('vmName'), '/firstRunCommand')]",
            "apiVersion": "2019-12-01",
            "location": "[parameters('location')]",
            "dependsOn": [
                "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
            ],
            "properties": {
                "source": {
                    "script": "echo First: Hello World!"
                },
                "parameters": [
                    {
                        "name": "param1",
                        "value": "value1"
                    },
                    {
                        "name": "param2",
                        "value": "value2"
                    }
                ],
                "timeoutInSeconds": 20
            }
        },
        {
            "type": "Microsoft.Compute/virtualMachines/runCommands",
            "name": "[concat(parameters('vmName'), '/secondRunCommand')]",
            "apiVersion": "2019-12-01",
            "location": "[parameters('location')]",
            "dependsOn": [
                "[concat('Microsoft.Compute/virtualMachines/',
parameters('vmName'), 'runcommands/firstRunCommand')]"
            ],
            "properties": {
                "source": {
                    "scriptUri": "http://github.com/myscript.ps1"
                },
                "timeoutInSeconds": 60
            }
        }
    ]
}
```

# Preview: Run scripts in your Windows VM by using managed Run Commands

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

## IMPORTANT

Managed Run Command is currently in public preview. This preview version is provided without a service-level agreement, and we don't recommend it for production workloads. Certain features might not be supported or might have constrained capabilities. For more information, see [Supplemental Terms of Use for Microsoft Azure Previews](#).

The Run Command feature uses the virtual machine (VM) agent to scripts within an Azure Windows VM. You can use these scripts for general machine or application management. They can help you quickly diagnose and remediate VM access and network issues and get the VM back to a good state.

The *updated* managed Run Command uses the same VM agent channel to execute scripts and provides the following enhancements over the [original action orientated Run Command](#):

- Support for updated Run Command through ARM deployment template
- Parallel execution of multiple scripts
- Sequential execution of scripts
- RunCommand script can be canceled
- User specified script timeout
- Support for long running (hours/days) scripts
- Passing secrets (parameters, passwords) in a secure manner

## Register for preview

You must register your subscription in order to use managed Run Command during public preview. Go to [set up preview features in Azure subscription](#) for registration instructions and use the feature name `RunCommandPreview`

## Azure CLI

The following examples use `az vm run-command` to run shell script on an Azure Windows VM.

### Execute a script with the VM

This command will deliver the script to the VM, execute it, and return the captured output.

```
az vm run-command create --name "myRunCommand" --vm-name "myVM" --resource-group "myRG" --script "Write-Host Hello World!"
```

### List all deployed RunCommand resources on a VM

This command will return a full list of previously deployed Run Commands along with their properties.

```
az vm run-command list --vm-name "myVM" --resource-group "myRG"
```

## Get execution status and results

This command will retrieve current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

```
az vm run-command show --name "myRunCommand" --vm-name "myVM" --resource-group "myRG" --expand instanceView
```

## Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution will be terminated.

```
az vm run-command delete --name "myRunCommand" --vm-name "myVM" --resource-group "myRG"
```

# PowerShell

## Execute a script with the VM

This command will deliver the script to the VM, execute it, and return the captured output.

```
Set-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -Location "EastUS" -RunCommandName "RunCommandName" -SourceScript "echo Hello World!"
```

## Execute a script on the VM using SourceScriptUri parameter

`OutputBlobUri` and `ErrorBlobUri` are optional parameters.

```
Set-AzVMRunCommand -ResourceGroupName -VMName -RunCommandName -SourceScriptUri "< SAS URI of a storage blob with read access or public URI>" -OutputBlobUri "< SAS URI of a storage append blob with read, add, create, write access>" -ErrorBlobUri "< SAS URI of a storage append blob with read, add, create, write access>"
```

## List all deployed RunCommand resources on a VM

This command will return a full list of previously deployed Run Commands along with their properties.

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM"
```

## Get execution status and results

This command will retrieve current execution progress, including latest output, start/end time, exit code, and terminal state of the execution.

```
Get-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName "RunCommandName" -Status
```

## Delete RunCommand resource from the VM

Remove the RunCommand resource previously deployed on the VM. If the script execution is still in progress, execution will be terminated.

```
Remove-AzVMRunCommand -ResourceGroupName "myRG" -VMName "myVM" -RunCommandName "RunCommandName"
```

# REST API

To deploy a new Run Command, execute a PUT on the VM directly and specify a unique name for the Run

Command instance.

```
PUT  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands/<runCommandName>?api-version=2019-12-01
```

```
{  
    "location": "<location>",  
    "properties": {  
        "source": {  
            "script": "Write-Host Hello World!",  
            "scriptUri": "<SAS URI of a storage blob with read access or public URI>",  
            "commandId": "<Id>"  
        },  
        "parameters": [  
            {  
                "name": "param1",  
                "value": "value1"  
            },  
            {  
                "name": "param2",  
                "value": "value2"  
            }  
        ],  
        "protectedParameters": [  
            {  
                "name": "secret1",  
                "value": "value1"  
            },  
            {  
                "name": "secret2",  
                "value": "value2"  
            }  
        ],  
        "runAsUser": "userName",  
        "runAsPassword": "userPassword",  
        "timeoutInSeconds": 3600,  
        "outputBlobUri": "< SAS URI of a storage append blob with read, add, create, write access>",  
        "errorBlobUri": "< SAS URI of a storage append blob with read, add, create, write access >"  
    }  
}
```

## Notes

- You can provide an inline script, a script URI, or a built-in script [command ID](#) as the input source. Script URI is either storage blob SAS URI with read access or public URI.
- Only one type of source input is supported for one command execution.
- Run Command supports writing output and error to Storage blobs using outputBlobUri and errorBlobUri parameters, which can be used to store large script outputs. Use SAS URI of a storage append blob with read, add, create, write access. The blob should be of type AppendBlob. Writing the script output or error blob would fail otherwise. The blob will be overwritten if it already exists. It will be created if it does not exist.

## List running instances of Run Command on a VM

```
GET  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands?api-version=2019-12-01
```

## Get output details for a specific Run Command deployment

```
GET  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands/<runCommandName>?$expand=instanceView&api-version=2019-12-01
```

## Cancel a specific Run Command deployment

To cancel a running deployment, you can PUT or PATCH on the running instance of Run Command and specify a blank script in the request body. This will cancel the ongoing execution.

You can also delete the instance of Run Command.

```
DELETE  
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/virtualMachin  
es/<vmName>/runcommands/<runCommandName>?api-version=2019-12-01
```

## Deploy scripts in an ordered sequence

To deploy scripts sequentially, use a deployment template, specifying a `dependsOn` relationship between sequential scripts.

```
{  
    "type": "Microsoft.Compute/virtualMachines/runCommands",  
    "name": "secondRunCommand",  
    "apiVersion": "2019-12-01",  
    "location": "[parameters('location')]",  
    "dependsOn": <full resourceId of the previous other Run Command>,  
    "properties": {  
        "source": {  
            "script": "Write-HostHelloWorld!"  
        },  
        "timeoutInSeconds": 60  
    }  
}
```

## Execute multiple Run Commands sequentially

By default, if you deploy multiple RunCommand resources using deployment template, they will be executed simultaneously on the VM. If you have a dependency on the scripts and a preferred order of execution, you can use the `dependsOn` property to make them run sequentially.

In this example, `secondRunCommand` will execute after `firstRunCommand`.

```
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "resources": [
        {
            "type": "Microsoft.Compute/virtualMachines/runCommands",
            "name": "[concat(parameters('vmName'), '/firstRunCommand')]",
            "apiVersion": "2019-12-01",
            "location": "[parameters('location')]",
            "dependsOn": [
                "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
            ],
            "properties": {
                "source": {
                    "script": "Write-Host First: Hello World!"
                },
                "parameters": [
                    {
                        "name": "param1",
                        "value": "value1"
                    },
                    {
                        "name": "param2",
                        "value": "value2"
                    }
                ],
                "timeoutInSeconds": 20
            }
        },
        {
            "type": "Microsoft.Compute/virtualMachines/runCommands",
            "name": "[concat(parameters('vmName'), '/secondRunCommand')]",
            "apiVersion": "2019-12-01",
            "location": "[parameters('location')]",
            "dependsOn": [
                "[concat('Microsoft.Compute/virtualMachines/',
parameters('vmName'), 'runcommands/firstRunCommand')]"
            ],
            "properties": {
                "source": {
                    "scriptUri": "http://github.com/myscript.ps1"
                },
                "timeoutInSeconds": 60
            }
        }
    ]
}
```

## Next steps

To learn about other ways to run scripts and commands remotely in your VM, see [Run scripts in your Windows VM](#).

# Azure virtual machine extensions and features

9/21/2022 • 2 minutes to read • [Edit Online](#)

Extensions are small applications that provide post-deployment configuration and automation on Azure VMs. The Azure platform hosts many extensions covering VM configuration, monitoring, security, and utility applications. Publishers take an application, wrap it into an extension, and simplify the installation. All you need to do is provide mandatory parameters.

## How can I find what extensions are available?

You can view available extensions by selecting a VM, the selecting **Extensions** in the left menu. To pull a full list of extensions, see [Discovering VM Extensions for Linux](#) and [Discovering VM Extensions for Windows](#).

## How can I install an extension?

Azure VM extensions can be managed using the Azure CLI, PowerShell, Resource Manager templates, and the Azure portal. To try an extension, go to the Azure portal, select the Custom Script Extension, then pass in a command or script to run the extension.

For more information, see [Windows Custom Script Extension](#) and [Linux Custom Script Extension](#).

## How do I manage extension application lifecycle?

You do not need to connect to a VM directly to install or delete an extension. The Azure extension lifecycle is managed outside of the VM and integrated into the Azure platform.

## Anything else I should be thinking about for extensions?

Some individual VM extension applications may have their own environmental prerequisites, such as access to an endpoint. Each extension has an article that explains any pre-requisites, including which operating systems are supported.

## Troubleshoot extensions

If you are looking for general troubleshooting steps for Windows VM extensions, please refer to [Troubleshooting Azure Windows VM extension failures](#).

Otherwise, specific troubleshooting information for each extension can be found in the **Troubleshoot and support** section in the overview for the extension. Here is a list of the troubleshooting information available:

# Virtual machine extensions and features for Linux

9/21/2022 • 13 minutes to read • [Edit Online](#)

Azure virtual machine (VM) extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs. For example, if a virtual machine requires software installation, antivirus protection, or the ability to run a script inside it, you can use a VM extension.

You can run Azure VM extensions by using the Azure CLI, PowerShell, Azure Resource Manager templates (ARM templates), and the Azure portal. You can bundle extensions with a new VM deployment or run them against any existing system.

This article provides an overview of Azure VM extensions, prerequisites for using them, and guidance on how to detect, manage, and remove them. This article provides generalized information because many VM extensions are available. Each has a potentially unique configuration and its own documentation.

## Use cases and samples

Each Azure VM extension has a specific use case. Examples include:

- Apply PowerShell desired state configurations (DSCs) to a VM by using the [DSC extension for Linux](#).
- Configure monitoring of a VM by using the [Microsoft Monitoring Agent VM extension](#).
- Configure monitoring of your Azure infrastructure by using the [Chef](#) or [Datadog](#) extension.

In addition to process-specific extensions, a Custom Script extension is available for both Windows and Linux virtual machines. The [Custom Script extension for Linux](#) allows any Bash script to be run on a VM. Custom scripts are useful for designing Azure deployments that require configuration beyond what native Azure tooling can provide.

## Prerequisites

### Azure Linux Agent

To handle the extension on the VM, you need the [Azure Linux Agent](#) installed. Some individual extensions have prerequisites, such as access to resources or dependencies.

The Azure Linux Agent manages interactions between an Azure VM and the Azure fabric controller. The agent is responsible for many functional aspects of deploying and managing Azure VMs, including running VM extensions.

The Azure Linux Agent is preinstalled on Azure Marketplace images. It can also be installed manually on supported operating systems.

The agent runs on multiple operating systems. However, the extensions framework has a [limit for the operating systems that extensions use](#). Some extensions are not supported across all operating systems and might emit error code 51 ("Unsupported OS"). Check the individual extension documentation for supportability.

### Network access

Extension packages are downloaded from the Azure Storage extension repository. Extension status uploads are posted to Azure Storage.

If you use a [supported version of the Azure Linux Agent](#), you don't need to allow access to Azure Storage in the VM region. You can use the agent to redirect the communication to the Azure fabric controller for agent communications. If you're on an unsupported version of the agent, you need to allow outbound access to Azure

Storage in that region from the VM.

#### IMPORTANT

If you've blocked access to the private IP address 168.63.129.16 by using the guest firewall, extensions fail even if you're using a supported version of the agent or you've configured outbound access.

Agents can only be used to download extension packages and reporting status. For example, if an extension installation needs to download a script from GitHub (Custom Script extension) or needs access to Azure Storage (Azure Backup), then you need to open additional firewall or network security group (NSG) ports. Different extensions have different requirements, because they're applications in their own right. For extensions that require access to Azure Storage, you can allow access by using Azure NSG [service tags](#).

To redirect agent traffic requests, the Azure Linux Agent has proxy server support. However, this proxy server support does not apply extensions. You must configure each individual extension to work with a proxy.

## Discover VM extensions

- [Azure CLI](#)
- [Azure PowerShell](#)

Many VM extensions are available for use with Azure VMs. To see a complete list, use [az vm extension image list](#). The following example lists all available extensions in the *westus* location:

```
az vm extension image list --location westus --output table
```

## Run VM extensions

Azure VM extensions run on existing VMs. That's useful when you need to make configuration changes or recover connectivity on an already deployed VM. VM extensions can also be bundled with ARM template deployments. By using extensions with ARM templates, you can deploy and configure Azure VMs without post-deployment intervention.

You can use the following methods to run an extension against an existing VM.

### Azure CLI

You can run Azure VM extensions against an existing VM by using the [az vm extension set](#) command. The following example runs the Custom Script extension against a VM named *myVM* in a resource group named *myResourceGroup*. Replace the example resource group name, VM name, and script to run (<https://raw.githubusercontent.com/me/project/hello.sh>) with your own information.

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name customScript \
--publisher Microsoft.Azure.Extensions \
--settings '{"fileUris": ["https://raw.githubusercontent.com/me/project/hello.sh"], "commandToExecute": \
"./hello.sh"}'
```

When the extension runs correctly, the output is similar to the following example:

```
info: Executing command vm extension set
+ Looking up the VM "myVM"
+ Installing extension "CustomScript", VM: "myVM"
info: vm extension set command OK
```

## Azure PowerShell

You can run Azure VM extensions against an existing VM by using the [Set-AzVMExtension](#) command. The following example runs the Custom Script extension against a VM named *myVM* in a resource group named *myResourceGroup*. Replace the example resource group name, VM name, and script to run (<https://raw.githubusercontent.com/me/project/hello.sh>) with your own information.

```
$Params = @{
    ResourceGroupName = 'myResourceGroup'
    VMName           = 'myVM'
    Name              = 'CustomScript'
    Publisher         = 'Microsoft.Azure.Extensions'
    ExtensionType     = 'CustomScript'
    TypeHandlerVersion = '2.1'
    Settings          = @{'fileUris' = @('https://raw.githubusercontent.com/me/project/hello.sh');
    commandToExecute = './hello.sh'}
}
Set-AzVMExtension @Params
```

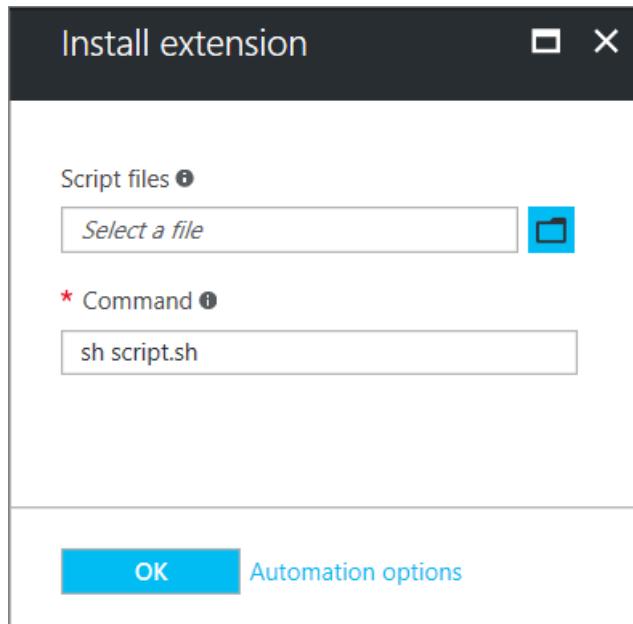

When the extension runs correctly, the output is similar to the following example:

RequestId	IsSuccess	StatusCode	StatusCode	ReasonPhrase
	True	OK	OK	

## Azure portal

You can apply VM extensions to an existing VM through the Azure portal. Select the VM in the portal, select **Extensions**, and then select **Add**. Choose the extension that you want from the list of available extensions, and follow the instructions in the wizard.

The following image shows the installation of the Custom Script extension for Linux from the Azure portal:

## Azure Resource Manager templates

You can add VM extensions to an ARM template and run them with the deployment of the template. When you deploy an extension with a template, you can create fully configured Azure deployments.

For example, the following JSON is taken from a [full ARM template](#) that deploys a set of load-balanced VMs and an Azure SQL database, and then installs a .NET Core application on each VM. The VM extension takes care of the software installation.

```
{  
    "apiVersion": "2015-06-15",  
    "type": "extensions",  
    "name": "config-app",  
    "location": "[resourceGroup().location]",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"  
    ],  
    "tags": {  
        "displayName": "config-app"  
    },  
    "properties": {  
        "publisher": "Microsoft.Azure.Extensions",  
        "type": "CustomScript",  
        "typeHandlerVersion": "2.1",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "fileUris": [  
                "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-  
linux/scripts/config-music.sh"  
            ]  
        },  
        "protectedSettings": {  
            "commandToExecute": "[concat('sudo sh config-music.sh ',variables('musicStoreSqlName'), ' ',  
parameters('adminUsername'), ' ', parameters('sqlAdminPassword'))]"  
        }  
    }  
}
```

For more information on creating ARM templates, see [Virtual machines in an Azure Resource Manager template](#).

## Help secure VM extension data

When you run a VM extension, it might be necessary to include sensitive information such as credentials, storage account names, and access keys. Many VM extensions include a protected configuration that encrypts data and only decrypts it inside the target VM. Each extension has a specific protected configuration schema, and each is detailed in extension-specific documentation.

The following example shows an instance of the Custom Script extension for Linux. The command to run includes a set of credentials. In this example, the command to run is not encrypted.

```
{
  "apiVersion": "2015-06-15",
  "type": "extensions",
  "name": "config-app",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-
linux/scripts/config-music.sh"
      ],
      "commandToExecute": "[concat('sudo sh config-music.sh ',variables('musicStoreSqlName'), ' ',parameters('adminUsername'), ' ', parameters('sqlAdminPassword'))]"
    }
  }
}
```

Moving the `commandToExecute` property to the `protected` configuration helps secure the execution string, as shown in the following example:

```
{
  "apiVersion": "2015-06-15",
  "type": "extensions",
  "name": "config-app",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-
linux/scripts/config-music.sh"
      ]
    },
    "protectedSettings": {
      "commandToExecute": "[concat('sudo sh config-music.sh ',variables('musicStoreSqlName'), ' ',parameters('adminUsername'), ' ', parameters('sqlAdminPassword'))]"
    }
  }
}
```

## How agents and extensions are updated

Agents and extensions share the same automatic update mechanism.

When an update is available and automatic updates are enabled, the update is installed on the VM only after

there's a change to an extension or after other VM model changes, such as:

- Data disks
- Extensions
- Extension Tags
- Boot diagnostics container
- Guest OS secrets
- VM size
- Network profile

Publishers make updates available to regions at various times, so it's possible that you can have VMs in different regions on different versions.

#### NOTE

Some updates might require additional firewall rules. See [Network access](#).

#### Agent updates

The Linux VM Agent contains *Provisioning Agent code* and *extension-handling code* in one package. They can't be separated.

You can disable the Provisioning Agent when you want to [provision on Azure by using cloud-init](#).

Supported versions of the agents can use automatic updates. The only code that can be updated is the extension-handling code, not the Provisioning Agent code. The Provisioning Agent code is run-once code.

The extension-handling code is responsible for:

- Communicating with the Azure fabric.
- Handling the VM extension operations, such as installations, reporting status, updating the individual extensions, and removing extensions. Updates contain security fixes, bug fixes, and enhancements to the extension-handling code.

When the agent is installed, a parent daemon is created. This parent then spawns a child process that's used to handle extensions. If an update is available for the agent, it's downloaded. The parent stops the child process, upgrades it, and then restarts it. If there's a problem with the update, the parent process rolls back to the previous child version.

The parent process can't be automatically updated. The parent can be updated only by a distribution package update.

To check what version you're running, check `waagent` as follows:

```
waagent --version
```

The output is similar to the following example:

```
WALinuxAgent-2.2.45 running on ubuntu 18.04
Python: 3.6.9
Goal state agent: 2.7.1.0
```

In the preceding example output, the parent (or package deployed version) is `WALinuxAgent-2.2.45`. The `Goal state agent` value is the auto-update version.

We highly recommend that you always enable automatic update for the agent: `AutoUpdate.Enabled=y`. If you

don't enable automatic update, you'll need to keep manually updating the agent, and you won't get bug and security fixes.

#### Extension updates

When an extension update is available and automatic updates are enabled, after a [change to the VM model](#) occurs, the Azure Linux Agent downloads and upgrades the extension.

Automatic extension updates are either *minor* or *hotfix*. You can opt in or opt out of minor updates when you provision the extension. The following example shows how to automatically upgrade minor versions in an ARM template by using `"autoUpgradeMinorVersion": true,`:

```
"publisher": "Microsoft.Azure.Extensions",
"type": "CustomScript",
"typeHandlerVersion": "2.1",
"autoUpgradeMinorVersion": true,
"settings": {
    "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-
linux/scripts/config-music.sh"
    ]
},
```

To get the latest minor-release bug fixes, we highly recommend that you always select automatic update in your extension deployments. You can't opt out of hotfix updates that carry security or key bug fixes.

If you disable automatic updates or you need to upgrade a major version, use [az vm extension set](#) or [Set-AzVMExtension](#) and specify the target version.

#### How to identify extension updates

##### Identify if the extension is set with autoUpgradeMinorVersion on a VM

- [Azure CLI](#)
- [Azure PowerShell](#)

You can see from the VM model if the extension was provisioned with `autoUpgradeMinorVersion`. To check, use [az vm show](#) and provide the resource group and VM name as follows:

```
az vm show --resource-group myResourceGroup --name myVM
```

The following example output shows that `autoUpgradeMinorVersion` is set to `true`:

```
"resources": [
    {
        "autoUpgradeMinorVersion": true,
        "forceUpdateTag": null,
        "id": "/subscriptions/guid/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM/extensi-
ons/customScript",
```

##### Identify when an autoUpgradeMinorVersion event occurred

To see when an update to the extension occurred, review the agent logs on the VM at `/var/log/waagent.log`.

In the following example, the VM had `Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025` installed. A hotfix was available to `Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027`.

```
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Expected handler state: enabled
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Decide which version to use
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Use version: 2.3.9027
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Current handler state is: NotInstalled
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Download extension package
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Unpack extension package
INFO Event: name=Microsoft.OSTCExtensions.LinuxDiagnostic, op=Download, message=Download succeeded
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Initialize extension directory
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Update settings file: 0.settings
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025] Disable extension.
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9025] Launch command:diagnostic.py -disable
...
INFO Event: name=Microsoft.OSTCExtensions.LinuxDiagnostic, op=Disable, message=Launch command succeeded:
diagnostic.py -disable
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Update extension.
INFO [Microsoft.OSTCExtensions.LinuxDiagnostic-2.3.9027] Launch command:diagnostic.py -update
2017/08/14 20:21:57 LinuxAzureDiagnostic started to handle.
```

## Agent permissions

To perform its tasks, the agent needs to run as *root*.

## Troubleshoot VM extensions

Each VM extension might have specific troubleshooting steps. For example, when you use the Custom Script extension, you can find script execution details locally on the VM where the extension was run.

The following troubleshooting actions apply to all VM extensions:

- To check the Azure Linux Agent log, look at the activity when your extension was being provisioned in */var/log/waagent.log*.
- Check the extension logs for more details in */var/log/azure/<extensionName>*.
- Check troubleshooting sections in extension-specific documentation for error codes, known issues, and other extension-specific information.
- Look at the system logs. Check for other operations that might have interfered with the extension, such as a long-running installation of another application that required exclusive access to the package manager.

### Common reasons for extension failures

- Extensions have 20 minutes to run. (Exceptions are Custom Script, Chef, and DSC, which have 90 minutes.) If your deployment exceeds this time, it's marked as a timeout. The cause of this can be low-resource VMs, or other VM configurations or startup tasks are consuming large amounts of resources while the extension is trying to provision.
- Minimum prerequisites aren't met. Some extensions have dependencies on VM SKUs, such as HPC images. Extensions might have certain networking access requirements, such as communicating with Azure Storage or public services. Other examples might be access to package repositories, running out of disk space, or security restrictions.
- Package manager access is exclusive. In some cases, a long-running VM configuration and extension installation might conflict because they both need exclusive access to the package manager.

### View extension status

- [Azure CLI](#)
- [Azure PowerShell](#)

After a VM extension has been run against a VM, use [az vm get-instance-view](#) to return extension status as follows:

```
az vm get-instance-view \
--resource-group myResourceGroup \
--name myVM \
--query "instanceView.extensions"
```

The output is similar to the following example:

```
{
  "name": "customScript",
  "statuses": [
    {
      "code": "ProvisioningState/failed/0",
      "displayStatus": "Provisioning failed",
      "level": "Error",
      "message": "Enable failed: failed to execute command: command terminated with exit
status=127\n[stdout]\n\n[stderr]\n/bin/sh: 1: ech: not found\n",
      "time": null
    }
  ],
  "substatuses": null,
  "type": "Microsoft.Azure.Extensions.CustomScript",
  "typeHandlerVersion": "2.1.6"
}
```

You can also find extension execution status in the Azure portal. Select the VM, select **Extensions**, and then select the desired extension.

### Rerun a VM extension

There might be cases in which a VM extension needs to be rerun. You can rerun an extension by removing it, and then rerunning the extension with an execution method of your choice.

- [Azure CLI](#)
- [Azure PowerShell](#)

To remove an extension, use [az vm extension delete](#) as follows:

```
az vm extension delete \
--resource-group myResourceGroup \
--vm-name myVM \
--name customScript
```

You can also remove an extension in the Azure portal:

1. Select a VM.
2. Select **Extensions**.
3. Select the extension.
4. Select **Uninstall**.

## Common VM extension reference

EXTENSION NAME	DESCRIPTION
<a href="#">Custom Script extension for Linux</a>	Run scripts against an Azure virtual machine.

EXTENSION NAME	DESCRIPTION
<a href="#">VMAccess extension</a>	Regain access to an Azure virtual machine. You can also use it to <a href="#">manage users and credentials</a> .
<a href="#">Azure Diagnostics extension</a>	Manage Azure Diagnostics.

## Next steps

For more information about VM extensions, see [Azure virtual machine extensions and features](#).

# Understanding and using the Azure Linux Agent

9/21/2022 • 8 minutes to read • [Edit Online](#)

The Microsoft Azure Linux Agent (waagent) manages Linux & FreeBSD provisioning, and VM interaction with the Azure Fabric Controller. In addition to the Linux Agent providing provisioning functionality, Azure also provides the option of using cloud-init for some Linux OSes. The Linux Agent provides the following functionality for Linux and FreeBSD IaaS deployments:

## NOTE

For more information, see the [README](#).

- **Image Provisioning**

- Creation of a user account
- Configuring SSH authentication types
- Deployment of SSH public keys and key pairs
- Setting the host name
- Publishing the host name to the platform DNS
- Reporting SSH host key fingerprint to the platform
- Resource Disk Management
- Formatting and mounting the resource disk
- Configuring swap space

- **Networking**

- Manages routes to improve compatibility with platform DHCP servers
- Ensures the stability of the network interface name

- **Kernel**

- Configures virtual NUMA (disable for kernel < 2.6.37)
- Consumes Hyper-V entropy for /dev/random
- Configures SCSI timeouts for the root device (which could be remote)

- **Diagnostics**

- Console redirection to the serial port

- **SCVMM Deployments**

- Detects and bootstraps the VMM agent for Linux when running in a System Center Virtual Machine Manager 2012 R2 environment

- **VM Extension**

- Inject component authored by Microsoft and Partners into Linux VM (IaaS) to enable software and configuration automation
- VM Extension reference implementation on <https://github.com/Azure/azure-linux-extensions>

## Communication

The information flow from the platform to the agent occurs via two channels:

- A boot-time attached DVD for IaaS deployments. This DVD includes an OVF-compliant configuration file that includes all provisioning information other than the actual SSH keypairs.
- A TCP endpoint exposing a REST API used to obtain deployment and topology configuration.

## Requirements

The following systems have been tested and are known to work with the Azure Linux Agent:

### NOTE

This list may differ from the official list of [supported distros](#).

- CoreOS
- CentOS 6.3+
- Red Hat Enterprise Linux 6.7+
- Debian 7.0+
- Ubuntu 12.04+
- openSUSE 12.3+
- SLES 11 SP3+
- Oracle Linux 6.4+

Other Supported Systems:

- FreeBSD 10+ (Azure Linux Agent v2.0.10+)

The Linux agent depends on some system packages in order to function properly:

- Python 2.6+
- OpenSSL 1.0+
- OpenSSH 5.3+
- Filesystem utilities: sfdisk, fdisk, mkfs, parted
- Password tools: chpasswd, sudo
- Text processing tools: sed, grep
- Network tools: ip-route
- Kernel support for mounting UDF filesystems.

Ensure your VM has access to IP address 168.63.129.16. For more information, see [What is IP address 168.63.129.16](#).

## Installation

Installation using an RPM or a DEB package from your distribution's package repository is the preferred method of installing and upgrading the Azure Linux Agent. All the [endorsed distribution providers](#) integrate the Azure Linux agent package into their images and repositories.

Refer to the documentation in the [Azure Linux Agent repo on GitHub](#) for advanced installation options, such as installing from source or to custom locations or prefixes.

## Command-Line Options

### Flags

- verbose: Increase verbosity of specified command
- force: Skip interactive confirmation for some commands

## Commands

- help: Lists the supported commands and flags.
- deprovision: Attempt to clean the system and make it suitable for reprovisioning. The following operation deletes:
  - All SSH host keys (if Provisioning.RegenerateSshHostKeyPair is 'y' in the configuration file)
  - Nameserver configuration in `/etc/resolv.conf`
  - Root password from `/etc/shadow` (if Provisioning.DeleteRootPassword is 'y' in the configuration file)
  - Cached DHCP client leases
  - Resets host name to localhost.localdomain

### WARNING

Deprovisioning does not guarantee that the image is cleared of all sensitive information and suitable for redistribution.

- deprovision+user: Performs everything in -deprovision (above) and also deletes the last provisioned user account (obtained from `/var/lib/waagent`) and associated data. This parameter is when de-provisioning an image that was previously provisioning on Azure so it may be captured and reused.
- version: Displays the version of waagent
- serialconsole: Configures GRUB to mark ttyS0 (the first serial port) as the boot console. This ensures that kernel bootup logs are sent to the serial port and made available for debugging.
- daemon: Run waagent as a daemon to manage interaction with the platform. This argument is specified to waagent in the waagent init script.
- start: Run waagent as a background process

## Configuration

A configuration file (`/etc/waagent.conf`) controls the actions of waagent. The following shows a sample configuration file:

```
Provisioning.Enabled=y
Provisioning.DeleteRootPassword=n
Provisioning.RegenerateSshHostKeyPair=y
Provisioning.SshHostKeyPairType=rsa
Provisioning.MonitorHostName=y
Provisioning.DecodeCustomData=n
Provisioning.ExecuteCustomData=n
Provisioning.AllowResetSysUser=n
Provisioning.PasswordCryptId=6
Provisioning.PasswordCryptSaltLength=10
ResourceDisk.Format=y
ResourceDisk.Filesystem=ext4
ResourceDisk.MountPoint=/mnt/resource
ResourceDisk.MountOptions=None
ResourceDisk.EnableSwap=n
ResourceDisk.SwapSizeMB=0
LBProbeResponder=y
Logs.Verbose=n
OS.RootDeviceScsiTimeout=300
OS.OpensslPath=None
HttpProxy.Host=None
HttpProxy.Port=None
AutoUpdate.Enabled=y
```

The following various configuration options are described. Configuration options are of three types; Boolean,

String, or Integer. The Boolean configuration options can be specified as "y" or "n". The special keyword "None" may be used for some string type configuration entries as the following details:

#### Provisioning.Enabled:

Type: Boolean  
Default: y

This allows the user to enable or disable the provisioning functionality in the agent. Valid values are "y" or "n". If provisioning is disabled, SSH host and user keys in the image are preserved and any configuration specified in the Azure provisioning API is ignored.

#### NOTE

The `Provisioning.Enabled` parameter defaults to "n" on Ubuntu Cloud Images that use cloud-init for provisioning.

#### Provisioning.DeleteRootPassword:

Type: Boolean  
Default: n

If set, the root password in the /etc/shadow file is erased during the provisioning process.

#### Provisioning.RegenerateSshHostKeyPair:

Type: Boolean  
Default: y

If set, all SSH host key pairs (ecdsa, dsa, and rsa) are deleted during the provisioning process from `/etc/ssh/`. And a single fresh key pair is generated.

The encryption type for the fresh key pair is configurable by the `Provisioning.SshHostKeyPairType` entry. Some distributions re-create SSH key pairs for any missing encryption types when the SSH daemon is restarted (for example, upon a reboot).

#### Provisioning.SshHostKeyPairType:

Type: String  
Default: rsa

This can be set to an encryption algorithm type that is supported by the SSH daemon on the virtual machine. The typically supported values are "rsa", "dsa" and "ecdsa". "putty.exe" on Windows does not support "ecdsa". So, if you intend to use putty.exe on Windows to connect to a Linux deployment, use "rsa" or "dsa".

#### Provisioning.MonitorHostName:

Type: Boolean  
Default: y

If set, waagent monitors the Linux virtual machine for hostname changes (as returned by the "hostname" command) and automatically update the networking configuration in the image to reflect the change. In order to push the name change to the DNS servers, networking is restarted in the virtual machine. This results in brief loss of Internet connectivity.

## **Provisioning.DecodeCustomData**

Type: Boolean  
Default: n

If set, waagent decodes CustomData from Base64.

## **Provisioning.ExecuteCustomData**

Type: Boolean  
Default: n

If set, waagent executes CustomData after provisioning.

## **Provisioning.AllowResetSysUser**

Type: Boolean  
Default: n

This option allows the password for the sys user to be reset; default is disabled.

## **Provisioning.PasswordCryptId**

Type: String  
Default: 6

Algorithm used by crypt when generating password hash.

- 1 - MD5
- 2a - Blowfish
- 5 - SHA-256
- 6 - SHA-512

## **Provisioning.PasswordCryptSaltLength**

Type: String  
Default: 10

Length of random salt used when generating password hash.

## **ResourceDisk.Format:**

Type: Boolean  
Default: y

If set, the resource disk provided by the platform is formatted and mounted by waagent if the filesystem type requested by the user in "ResourceDisk.Filesystem" is anything other than "ntfs". A single partition of type Linux (83) is made available on the disk. This partition is not formatted if it can be successfully mounted.

## **ResourceDisk.Filesystem:**

Type: String  
Default: ext4

This specifies the filesystem type for the resource disk. Supported values vary by Linux distribution. If the string is X, then mkfs.X should be present on the Linux image. SLES 11 images should typically use 'ext3'. FreeBSD images should use 'ufs2' here.

#### **ResourceDisk.MountPoint:**

```
Type: String  
Default: /mnt/resource
```

This specifies the path at which the resource disk is mounted. The resource disk is a *temporary* disk, and might be emptied when the VM is deprovisioned.

#### **ResourceDisk.MountOptions**

```
Type: String  
Default: None
```

Specifies disk mount options to be passed to the mount -o command. This is a comma-separated list of values, ex. 'nodev,nosuid'. See mount(8) for details.

#### **ResourceDisk.EnableSwap:**

```
Type: Boolean  
Default: n
```

If set, a swap file (/swapfile) is created on the resource disk and added to the system swap space.

#### **ResourceDisk.SwapSizeMB:**

```
Type: Integer  
Default: 0
```

The size of the swap file in megabytes.

#### **Logs.Verbose:**

```
Type: Boolean  
Default: n
```

If set, log verbosity is boosted. Waagent logs to `/var/log/waagent.log` and utilizes the system logrotate functionality to rotate logs.

#### **OS.EnableRDMA**

```
Type: Boolean  
Default: n
```

If set, the agent attempts to install and then load an RDMA kernel driver that matches the version of the firmware on the underlying hardware.

#### **OS.RootDeviceScsiTimeout:**

Type: Integer  
Default: 300

This setting configures the SCSI timeout in seconds on the OS disk and data drives. If not set, the system defaults are used.

#### OS.OpensslPath:

Type: String  
Default: None

This setting can be used to specify an alternate path for the openssl binary to use for cryptographic operations.

#### HttpProxy.Host, HttpProxy.Port

Type: String  
Default: None

If set, the agent uses this proxy server to access the internet.

#### AutoUpdate.Enabled

Type: Boolean  
Default: y

Enable or disable auto-update for goal state processing; default is enabled.

## Linux Guest Agent Automatic Logs Collection

As of version 2.7+, The azure linux guest agent has a feature to automatically collect some logs and upload them. This feature currently requires systemd, and utilizes a new systemd slice called `azure-walinuxagent-logcollector.slice` to manage resources while performing the collection. The log collector's goal is facilitate offline analysis, and therefore produces a ZIP file of some diagnostics logs before uploading them to the VM's Host. The ZIP file can then be retrieved by Engineering Teams and Support professionals to investigate issues at the behest of the VM owner. More technical information on the files collected by the guest agent can be found in the [azurelinuxagent/common/logcollector\\_manifests.py](#) file in the [agent's GitHub repository](#).

This can be disabled by editing `/etc/waagent.conf` updating `Logs.Collect` to `n`

## Ubuntu Cloud Images

Ubuntu Cloud Images utilize [cloud-init](#) to perform many configuration tasks that would otherwise be managed by the Azure Linux Agent. The following differences apply:

- **Provisioning.Enabled** defaults to "n" on Ubuntu Cloud Images that use cloud-init to perform provisioning tasks.
- The following configuration parameters have no effect on Ubuntu Cloud Images that use cloud-init to manage the resource disk and swap space:
  - **ResourceDisk.Format**
  - **ResourceDisk.Filesystem**
  - **ResourceDisk.MountPoint**
  - **ResourceDisk.EnableSwap**

- **ResourceDisk.SwapSizeMB**
- For more information, see the following resources to configure the resource disk mount point and swap space on Ubuntu Cloud Images during provisioning:
  - [Ubuntu Wiki: Configure Swap Partitions](#)
  - [Injecting Custom Data into an Azure Virtual Machine](#)

# Virtual machine extensions and features for Windows

9/21/2022 • 12 minutes to read • [Edit Online](#)

Azure virtual machine (VM) extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs. For example, if a virtual machine requires software installation, antivirus protection, or the ability to run a script inside it, you can use a VM extension.

You can run Azure VM extensions by using the Azure CLI, PowerShell, Azure Resource Manager templates (ARM templates), and the Azure portal. You can bundle extensions with a new VM deployment or run them against any existing system.

This article provides an overview of Azure VM extensions, prerequisites for using them, and guidance on how to detect, manage, and remove them. This article provides generalized information because many VM extensions are available. Each has a potentially unique configuration and its own documentation.

## Use cases and samples

Each Azure VM extension has a specific use case. Examples include:

- Apply PowerShell desired state configurations (DSCs) to a VM by using the [DSC extension for Windows](#).
- Configure monitoring of a VM by using the [Log Analytics Agent VM extension](#).
- Configure an Azure VM by using [Chef](#).
- Configure monitoring of your Azure infrastructure by using the [Datadog extension](#).

In addition to process-specific extensions, a Custom Script extension is available for both Windows and Linux virtual machines. The [Custom Script extension for Windows](#) allows any PowerShell script to be run on a VM.

Custom scripts are useful for designing Azure deployments that require configuration beyond what native Azure tooling can provide.

## Prerequisites

### Azure VM Agent

To handle the extension on the VM, you need the [Azure VM Agent for Windows](#) (also called the Windows Guest Agent) installed. Some individual extensions have prerequisites, such as access to resources or dependencies.

The Azure VM Agent manages interactions between an Azure VM and the Azure fabric controller. The agent is responsible for many functional aspects of deploying and managing Azure VMs, including running VM extensions.

The Azure VM Agent is preinstalled on Azure Marketplace images. It can also be installed manually on supported operating systems.

The agent runs on multiple operating systems. However, the extensions framework has a [limit for the operating systems that extensions use](#). Some extensions are not supported across all operating systems and might emit error code 51 ("Unsupported OS"). Check the individual extension documentation for supportability.

### Network access

Extension packages are downloaded from the Azure Storage extension repository. Extension status uploads are posted to Azure Storage.

If you use a [supported version of the Azure VM Agent](#), you don't need to allow access to Azure Storage in the VM region. You can use the agent to redirect the communication to the Azure fabric controller for agent communications (HostGAPPlugin feature through the privileged channel on private IP [168.63.129.16](#)). If you're on an unsupported version of the agent, you need to allow outbound access to Azure Storage in that region from the VM.

#### IMPORTANT

If you've blocked access to 168.63.129.16 by using the guest firewall or by using a proxy, extensions fail even if you're using a supported version of the agent or you've configured outbound access. Ports 80, 443, and 32526 are required.

Agents can only be used to download extension packages and reporting status. For example, if an extension installation needs to download a script from GitHub (Custom Script extension) or needs access to Azure Storage (Azure Backup), then you need to open additional firewall or network security group (NSG) ports. Different extensions have different requirements, because they're applications in their own right. For extensions that require access to Azure Storage or Azure Active Directory, you can allow access by using Azure NSG [service tags](#).

The Azure VM Agent does not have proxy server support for you to redirect agent traffic requests through. That means the Azure VM Agent will rely on your custom proxy (if you have one) to access resources on the internet or on the host through IP 168.63.129.16.

## Discover VM extensions

Many VM extensions are available for use with Azure VMs. To see a complete list, use [Get-AzVMExtensionImage](#). The following example lists all available extensions in the *WestUS* location:

```
Get-AzVmImagePublisher -Location "WestUS" |  
Get-AzVMExtensionImageType |  
Get-AzVMExtensionImage | Select Type, Version
```

## Run VM extensions

Azure VM extensions run on existing VMs. That's useful when you need to make configuration changes or recover connectivity on an already deployed VM. VM extensions can also be bundled with ARM template deployments. By using extensions with ARM templates, you can deploy and configure Azure VMs without post-deployment intervention.

You can use the following methods to run an extension against an existing VM.

#### PowerShell

Several PowerShell commands exist for running individual extensions. To see a list, use [Get-Command](#) and filter on *Extension*:

```
Get-Command Set-Az*Extension* -Module Az.Compute
```

This command provides output similar to the following:

CommandType	Name	Version	Source
Cmdlet	Set-AzVMAccessExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMAccessExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMAEMExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMBackupExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMBinfoExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMChefExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMCustomScriptExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMDiagnosticsExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMDiskEncryptionExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMDscExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMEExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVMSqlServerExtension	4.5.0	Az.Compute
Cmdlet	Set-AzVmssDiskEncryptionExtension	4.5.0	Az.Compute

The following example uses the [Custom Script extension](#) to download a script from a GitHub repository onto the target virtual machine and then run the script:

```
Set-AzVMCustomScriptExtension -ResourceGroupName "myResourceGroup" ` 
    -VMName "myVM" -Name "myCustomScript" ` 
    -FileUri "https://raw.githubusercontent.com/neilpeterson/nepeters-azure-templates/master/windows-custom-` 
    -script-simple/support-scripts/Create-File.ps1" ` 
    -Run "Create-File.ps1" -Location "West US"
```

The following example uses the [VMAccess extension](#) to reset the administrative password of a Windows VM to a temporary password. After you run this code, you should reset the password at first login.

```
$cred=Get-Credential

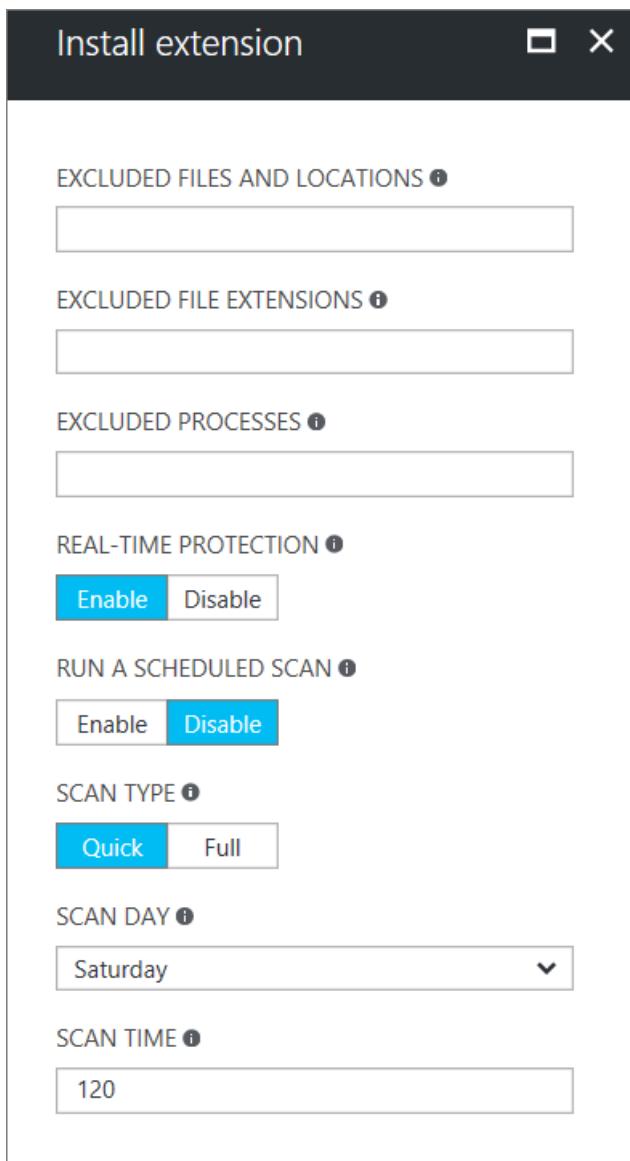

Set-AzVMAccessExtension -ResourceGroupName "myResourceGroup" -VMName "myVM" -Name "myVMAccess" ` 
    -Location WestUS -UserName $cred.GetNetworkCredential().Username ` 
    -Password $cred.GetNetworkCredential().Password -typeHandlerVersion "2.0"
```

You can use the [Set-AzVMEExtension](#) command to start any VM extension.

## Azure portal

You can apply VM extensions to an existing VM through the Azure portal. Select the VM in the portal, select **Extensions**, and then select **Add**. Choose the extension that you want from the list of available extensions, and follow the instructions in the wizard.

The following example shows the installation of the Microsoft Antimalware extension from the Azure portal:

### Azure Resource Manager templates

You can add VM extensions to an ARM template and run them with the deployment of the template. When you deploy an extension with a template, you can create fully configured Azure deployments.

For example, the following JSON is taken from a [full ARM template](#) that deploys a set of load-balanced VMs and an Azure SQL database, and then installs a .NET Core application on each VM. The VM extension takes care of the software installation.

```
{
  "apiVersion": "2015-06-15",
  "type": "extensions",
  "name": "config-app",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'),copyindex())]",
    "[variables('musicstoresqlName')]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
      ]
    },
    "protectedSettings": {
      "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password ',parameters('adminPassword'),' -sqlserver ',variables('musicstoresqlName'),'.database.windows.net')]"
    }
  }
}
```

For more information on creating ARM templates, see [Virtual machines in an Azure Resource Manager template](#).

## Help secure VM extension data

When you run a VM extension, it might be necessary to include sensitive information such as credentials, storage account names, and access keys. Many VM extensions include a protected configuration that encrypts data and only decrypts it inside the target VM. Each extension has a specific protected configuration schema, and each is detailed in extension-specific documentation.

The following example shows an instance of the Custom Script extension for Windows. The command to run includes a set of credentials. In this example, the command to run is not encrypted.

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'),copyIndex())]",
        "[variables('musicstoresqlName')]"
    ],
    "tags": {
        "displayName": "config-app"
    },
    "properties": {
        "publisher": "Microsoft.Compute",
        "type": "CustomScriptExtension",
        "typeHandlerVersion": "1.9",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "fileUris": [
                "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
            ],
            "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password ',parameters('adminPassword'),' -sqlserver ',variables('musicstoresqlName'),'.database.windows.net')]"
        }
    }
}
```

Moving the `commandToExecute` property to the `protected` configuration helps secure the execution string, as shown in the following example:

```
{
    "apiVersion": "2015-06-15",
    "type": "extensions",
    "name": "config-app",
    "location": "[resourceGroup().location]",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'),copyIndex())]",
        "[variables('musicstoresqlName')]"
    ],
    "tags": {
        "displayName": "config-app"
    },
    "properties": {
        "publisher": "Microsoft.Compute",
        "type": "CustomScriptExtension",
        "typeHandlerVersion": "1.9",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "fileUris": [
                "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"
            ]
        },
        "protectedSettings": {
            "commandToExecute": "[concat('powershell -ExecutionPolicy Unrestricted -File configure-music-app.ps1 -user ',parameters('adminUsername'),' -password ',parameters('adminPassword'),' -sqlserver ',variables('musicstoresqlName'),'.database.windows.net')]"
        }
    }
}
```

On an Azure infrastructure as a service (IaaS) VM that uses extensions, in the certificates console, you might see

certificates that have the subject **Windows Azure CRP Certificate Generator**. On a classic RedDog Front End (RDDE) VM, these certificates have the subject name **Windows Azure Service Management for Extensions**.

These certificates secure the communication between the VM and its host during the transfer of protected settings (password and other credentials) that extensions use. The certificates are built by the Azure fabric controller and passed to the Azure VM Agent. If you stop and start the VM every day, the fabric controller might create a new certificate. The certificate is stored in the computer's personal certificate store. These certificates can be deleted. The Azure VM Agent re-creates certificates if needed.

## How agents and extensions are updated

Agents and extensions share the same automatic update mechanism.

When an update is available and automatic updates are enabled, the update is installed on the VM only after there's a change to an extension or after other VM model changes, such as:

- Data disks
- Extensions
- Extension Tags
- Boot diagnostics container
- Guest OS secrets
- VM size
- Network profile

Publishers make updates available to regions at various times, so it's possible that you can have VMs in different regions on different versions.

### NOTE

Some updates might require additional firewall rules. See [Network access](#).

## Listing extensions deployed to a VM

```
$vm = Get-AzVM -ResourceGroupName "myResourceGroup" -VMName "myVM"  
$vm.Extensions | select Publisher, VirtualMachineExtensionType, TypeHandlerVersion
```

Publisher	VirtualMachineExtensionType	TypeHandlerVersion
-----	-----	-----
Microsoft.Compute	CustomScriptExtension	1.9

## Agent updates

The Azure VM Agent contains only *extension-handling code*. The *Windows provisioning code* is separate. You can uninstall the Azure VM Agent. You can't disable the automatic update of the Azure VM Agent.

The extension-handling code is responsible for:

- Communicating with the Azure fabric.
- Handling the VM extension operations, such as installations, reporting status, updating the individual extensions, and removing extensions. Updates contain security fixes, bug fixes, and enhancements to the extension-handling code.

To check what version you're running, see [Detect the VM Agent](#).

## Extension updates

When an extension update is available and automatic updates are enabled, after a [change to the VM model](#) occurs, the Azure VM Agent downloads and upgrades the extension.

Automatic extension updates are either *minor* or *hotfix*. You can opt in or opt out of minor updates when you provision the extension. The following example shows how to automatically upgrade minor versions in an ARM template by using `"autoUpgradeMinorVersion": true,`:

```
"properties": {  
    "publisher": "Microsoft.Compute",  
    "type": "CustomScriptExtension",  
    "typeHandlerVersion": "1.9",  
    "autoUpgradeMinorVersion": true,  
    "settings": {  
        "fileUris": [  
            "https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1"  
        ]  
    },  
},
```

To get the latest minor-release bug fixes, we highly recommend that you always select automatic update in your extension deployments. You can't opt out of hotfix updates that carry security or key bug fixes.

If you disable automatic updates or you need to upgrade a major version, use [Set-AzVMEExtension](#) and specify the target version.

## How to identify extension updates

### Identify if the extension is set with `autoUpgradeMinorVersion` on a VM

You can see from the VM model if the extension was provisioned with `autoUpgradeMinorVersion`. To check, use [Get-AzVm](#) and provide the resource group and VM name as follows:

```
$vm = Get-AzVm -ResourceGroupName "myResourceGroup" -VMName "myVM"  
$vm.Extensions
```

The following example output shows that `autoUpgradeMinorVersion` is set to `true`:

```
ForceUpdateTag :  
Publisher : Microsoft.Compute  
VirtualMachineExtensionType : CustomScriptExtension  
TypeHandlerVersion : 1.9  
AutoUpgradeMinorVersion : True
```

### Identify when an `autoUpgradeMinorVersion` event occurred

To see when an update to the extension occurred, review the agent logs on the VM at `C:\WindowsAzure\Logs\WaAppAgent.log`.

In the following example, the VM had `Microsoft.Compute.CustomScriptExtension` version `1.8` installed. A hotfix was available to version `1.9`.

```
[INFO] Getting plugin locations for plugin 'Microsoft.Compute.CustomScriptExtension'. Current Version:  
'1.8', Requested Version: '1.9'  
[INFO] Auto-Upgrade mode. Highest public version for plugin 'Microsoft.Compute.CustomScriptExtension' with  
requested version: '1.9', is: '1.9'
```

## Agent permissions

To perform its tasks, the agent needs to run as *Local System*.

## Troubleshoot VM extensions

Each VM extension might have specific troubleshooting steps. For example, when you use the Custom Script extension, you can find script execution details locally on the VM where the extension was run.

The following troubleshooting actions apply to all VM extensions:

- To check the Azure VM Agent Log, look at the activity when your extension was being provisioned in *C:\WindowsAzure\Logs\WaAppAgent.log*.
- Check the extension logs for more details in *C:\WindowsAzure\Logs\Plugins<extensionName>*.
- Check troubleshooting sections in extension-specific documentation for error codes, known issues, and other extension-specific information.
- Look at the system logs. Check for other operations that might have interfered with the extension, such as a long-running installation of another application that required exclusive access to the package manager.
- In a VM, if there is an existing extension with a failed provisioning state, any other new extension fails to install.

### Common reasons for extension failures

- Extensions have 20 minutes to run. (Exceptions are Custom Script, Chef, and DSC, which have 90 minutes.) If your deployment exceeds this time, it's marked as a timeout. The cause of this can be low-resource VMs, or other VM configurations or startup tasks are consuming large amounts of resources while the extension is trying to provision.
- Minimum prerequisites aren't met. Some extensions have dependencies on VM SKUs, such as HPC images. Extensions might have certain networking access requirements, such as communicating with Azure Storage or public services. Other examples might be access to package repositories, running out of disk space, or security restrictions.
- Package manager access is exclusive. In some cases, a long-running VM configuration and extension installation might conflict because they both need exclusive access to the package manager.

### View extension status

After a VM extension has been run against a VM, use [Get-AzVM](#) to return extension status. `Substatuses[0]` shows that the extension provisioning succeeded, meaning that it successfully deployed to the VM. But `Substatuses[1]` shows that the execution of the extension inside the VM failed.

```
Get-AzVM -ResourceGroupName "myResourceGroup" -VMName "myVM" -Status
```

The output is similar to the following example:

```

Extensions[0]      :
  Name          : CustomScriptExtension
  Type          : Microsoft.Compute.CustomScriptExtension
  TypeHandlerVersion : 1.9
  Substatuses[0]   :
    Code        : ComponentStatus/StdOut/succeeded
    Level       : Info
    DisplayStatus: Provisioning succeeded
    Message     : Windows PowerShell \nCopyright (C) Microsoft Corporation. All rights reserved.\n
  Substatuses[1]   :
    Code        : ComponentStatus/StdErr/succeeded
    Level       : Info
    DisplayStatus: Provisioning succeeded
    Message     : The argument 'cseTest%20Scriptparam1.ps1' to the -File parameter does not exist.
Provide the path to an existing '.ps1' file as an argument to the
-File parameter.
  Statuses[0]     :
    Code          : ProvisioningState/failed/-196608
    Level         : Error
    DisplayStatus : Provisioning failed
    Message       : Finished executing command

```

You can also find extension execution status in the Azure portal. Select the VM, select **Extensions**, and then select the desired extension.

### Rerun a VM extension

There might be cases in which a VM extension needs to be rerun. You can rerun an extension by removing it, and then rerunning the extension with an execution method of your choice. To remove an extension, use [Remove-AzVMExtension](#) as follows:

```
Remove-AzVMExtension -ResourceGroupName "myResourceGroup" -VMName "myVM" -Name "myExtensionName"
```

You can also remove an extension in the Azure portal:

1. Select a VM.
2. Select **Extensions**.
3. Select the extension.
4. Select **Uninstall**.

## Common VM extension reference

EXTENSION NAME	DESCRIPTION
<a href="#">Custom Script extension for Windows</a>	Run scripts against an Azure virtual machine.
<a href="#">DSC extension for Windows</a>	Apply PowerShell desired state configurations to a virtual machine.
<a href="#">Azure Diagnostics extension</a>	Manage Azure Diagnostics.
<a href="#">VMAccess extension</a>	Manage users and credentials.

## Next steps

For more information about VM extensions, see [Azure virtual machine extensions and features](#).

# Azure Virtual Machine Agent overview

9/21/2022 • 5 minutes to read • [Edit Online](#)

The Microsoft Azure Virtual Machine Agent (VM Agent) is a secure, lightweight process that manages virtual machine (VM) interaction with the Azure Fabric Controller. The VM Agent has a primary role in enabling and executing Azure virtual machine extensions. VM Extensions enable post-deployment configuration of VM, such as installing and configuring software. VM extensions also enable recovery features such as resetting the administrative password of a VM. Without the Azure VM Agent, VM extensions cannot be run.

This article details installation and detection of the Azure Virtual Machine Agent.

## Install the VM Agent

### Azure Marketplace image

The Azure VM Agent is installed by default on any Windows VM deployed from an Azure Marketplace image. When you deploy an Azure Marketplace image from the portal, PowerShell, Command Line Interface, or an Azure Resource Manager template, the Azure VM Agent is also installed.

The Windows Guest Agent Package is broken into two parts:

- Provisioning Agent (PA)
- Windows Guest Agent (WinGA)

To boot a VM you must have the PA installed on the VM, however the WinGA does not need to be installed. At VM deploy time, you can select not to install the WinGA. The following example shows how to select the *provisionVmAgent* option with an Azure Resource Manager template:

```
{
  "resources": [
    {
      "name": "[parameters('virtualMachineName')]",
      "type": "Microsoft.Compute/virtualMachines",
      "apiVersion": "2016-04-30-preview",
      "location": "[parameters('location')]",
      "dependsOn": "[[concat('Microsoft.Network/networkInterfaces/', parameters('networkInterfaceName'))]]",
      "properties": {
        "osProfile": {
          "computerName": "[parameters('virtualMachineName')]",
          "adminUsername": "[parameters('adminUsername')]",
          "adminPassword": "[parameters('adminPassword')]",
          "windowsConfiguration": {
            "provisionVmAgent": "false"
          }
        }
      }
    }
  ]
}
```

If you do not have the Agents installed, you cannot use some Azure services, such as Azure Backup or Azure Security. These services require an extension to be installed. If you have deployed a VM without the WinGA, you can install the latest version of the agent later.

### Manual installation

The Windows VM agent can be manually installed with a Windows installer package. Manual installation may be necessary when you create a custom VM image that is deployed to Azure. To manually install the Windows VM

Agent, [download the VM Agent installer](#) and select the latest release. You can also search a specific version in the [GitHub Windows IaaS VM Agent releases](#). The VM Agent is supported on Windows Server 2008 (64 bit) and later.

#### NOTE

It is important to update the AllowExtensionOperations option after manually installing the VMAgent on a VM that was deployed from image without ProvisionVMAgent enable.

```
$vm.OSProfile.AllowExtensionOperations = $true  
$vm | Update-AzVM
```

## Prerequisites

- The Windows VM Agent needs at least Windows Server 2008 SP2 (64-bit) to run, with the .NET Framework 4.0. See [Minimum version support for virtual machine agents in Azure](#).
- Ensure your VM has access to IP address 168.63.129.16. For more information, see [What is IP address 168.63.129.16](#).
- Ensure that DHCP is enabled inside the guest VM. This is required to get the host or fabric address from DHCP for the IaaS VM Agent and extensions to work. If you need a static private IP, you should configure it through the Azure portal or PowerShell, and make sure the DHCP option inside the VM is enabled. [Learn more](#) about setting up a static IP address with PowerShell.
- Running the VM Agent in a "Nested Virtualization" VM might lead to unpredictable behavior, hence it's not supported in that Dev/Test scenario.

## Detect the VM Agent

### PowerShell

The Azure Resource Manager PowerShell module can be used to retrieve information about Azure VMs. To see information about a VM, such as the provisioning state for the Azure VM Agent, use [Get-AzVM](#):

```
Get-AzVM
```

The following condensed example output shows the *ProvisionVMAgent* property nested inside `OSProfile`. This property can be used to determine if the VM agent has been deployed to the VM:

```
OSProfile :  
  ComputerName : myVM  
  AdminUsername : myUserName  
  WindowsConfiguration :  
    ProvisionVMAgent : True  
    EnableAutomaticUpdates : True
```

The following script can be used to return a concise list of VM names (running Windows OS) and the state of the VM Agent:

```

$vms = Get-AzVM

foreach ($vm in $vms) {
    $agent = $vm | Select -ExpandProperty OSProfile | Select -ExpandProperty WindowsConfiguration | Select
    ProvisionVMAgent
    Write-Host $vm.Name $agent.ProvisionVMAgent
}

```

The following script can be used to return a concise list of VM names (running Linux OS) and the state of the VM Agent:

```

$vms = Get-AzVM

foreach ($vm in $vms) {
    $agent = $vm | Select -ExpandProperty OSProfile | Select -ExpandProperty LinuxConfiguration | Select
    ProvisionVMAgent
    Write-Host $vm.Name $agent.ProvisionVMAgent
}

```

## Manual Detection

When logged in to a Windows VM, Task Manager can be used to examine running processes. To check for the Azure VM Agent, open Task Manager, click the *Details* tab, and look for a process name `WindowsAzureGuestAgent.exe`. The presence of this process indicates that the VM agent is installed.

## Upgrade the VM Agent

The Azure VM Agent for Windows is automatically upgraded on images deployed from the Azure Marketplace. The new versions are stored in Azure Storage, so please ensure you don't have firewalls blocking access. As new VMs are deployed to Azure, they receive the latest VM agent at VM provision time. If you have installed the agent manually or are deploying custom VM images you will need to manually update to include the new VM agent at image creation time.

## Windows Guest Agent Automatic Logs Collection

Windows Guest Agent has a feature to automatically collect some logs. This feature is controlled by the `CollectGuestLogs.exe` process. It exists for both PaaS Cloud Services and IaaS Virtual Machines and its goal is to quickly & automatically collect some diagnostics logs from a VM - so they can be used for offline analysis. The collected logs are Event Logs, OS Logs, Azure Logs and some registry keys. It produces a ZIP file that is transferred to the VM's Host. This ZIP file can then be looked at by Engineering Teams and Support professionals to investigate issues on request of the customer owning the VM.

## Guest Agent and OSProfile certificates

The Azure VM Agent is responsible for installing the certificates referenced in the `OSProfile` of a VM or Virtual Machine Scale Set. If you manually remove these certificates from the certificates MMC console inside the guest VM, it is expected that the guest agent will add them back. To permanently remove a certificate, you will have to remove it from the `OSProfile`, and then remove it from within the guest operating system.

For a Virtual Machine, use the [Remove-AzVMSecret](#) to remove certificates from the `OSProfile`.

For more information on Virtual Machine Scale Set certificates, see [Virtual Machine Scale Sets - How do I remove deprecated certificates?](#)

## Next steps

For more information about VM extensions, see [Azure virtual machine extensions and features overview](#).

# Azure Backup for SQL Server running in Azure VM

9/21/2022 • 2 minutes to read • [Edit Online](#)

Azure Backup, amongst other offerings, provides support for backing up workloads such as SQL Server running in Azure VMs. Since the SQL application is running within an Azure VM, the backup service needs permission to access the application and fetch the necessary details. To do that, Azure Backup installs the **AzureBackupWindowsWorkload** extension on the VM, in which the SQL Server is running, during the registration process triggered by the user.

## Prerequisites

For the list of supported scenarios, refer to the [supportability matrix](#) supported by Azure Backup.

## Network connectivity

Azure Backup supports NSG Tags, deploying a proxy server or listed IP ranges; for details on each of the methods, refer this [article](#).

## Extension schema

The extension schema and property values are the configuration values (runtime settings) that service is passing to CRP API. These config values are used during registration and upgrade. **AzureBackupWindowsWorkload** extension also uses this schema. The schema is pre-set; a new parameter can be added in the objectStr field

```
"runtimeSettings": [{"handlerSettings": {"protectedSettingsCertThumbprint": "", "protectedSettings": {"objectStr": "", "logsBlobUri": "", "statusBlobUri": ""}}, "publicSettings": {"locale": "en-us", "taskId": "1c0ae461-9d3b-418c-a505-bb31dfe2095d", "objectStr": "", "commandStartTimeUTCTicks": "636295005824665976", "vmType": "vmType"}}], "objectStr": ""}]}
```

The following JSON shows the schema for the WorkloadBackup extension.

```
{
  "type": "extensions",
  "name": "WorkloadBackup",
  "location": "<myLocation>",
  "properties": {
    "publisher": "Microsoft.RecoveryServices",
    "type": "AzureBackupWindowsWorkload",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "locale": "<location>",
      "taskId": "<TaskId used by Azure Backup service to communicate with extension>",

      "objectStr": "<The configuration passed by Azure Backup service to extension>",

      "commandStartTimeUTCTicks": "<Scheduled start time of registration or upgrade task>",
      "vmType": "<Type of VM where registration got triggered Eg. Compute or ClassicCompute>"
    },
    "protectedSettings": {
      "objectStr": "<The sensitive configuration passed by Azure Backup service to extension>",
      "logsBlobUri": "<blob uri where logs of command execution by extension are written to>",
      "statusBlobUri": "<blob uri where status of the command executed by extension is written>"
    }
  }
}
```

## Property values

## Template deployment

We recommended adding AzureBackupWindowsWorkload extension to a virtual machine by enabling SQL Server backup on the virtual machine. This can be achieved through the [Resource Manager template](#) designed for automating backup on a SQL Server VM.

## PowerShell deployment

You need to register the Azure VM that contains the SQL application with a Recovery services vault. During registration, AzureBackupWindowsWorkload extension gets installed on the VM. Use [Register-AzRecoveryServicesBackupContainerPS](#) cmdlet to register the VM.

```
$myVM = Get-AzVM -ResourceGroupName <VMRG Name> -Name <VMName>
Register-AzRecoveryServicesBackupContainer -ResourceId $myVM.ID -BackupManagementType AzureWorkload -WorkloadType MSSQL -VaultId $targetVault.ID -Force
```

The command will return a **backup container** of this resource and the status will be **registered**.

## Next steps

- [Learn More](#) about Azure SQL Server VM backup troubleshooting guidelines
- [Common questions](#) about backing up SQL Server databases that run on Azure virtual machines (VMs) and that use the Azure Backup service.

# Azure Disk Encryption for Linux (Microsoft.Azure.Security.AzureDiskEncryptionForLinux)

9/21/2022 • 3 minutes to read • [Edit Online](#)

## Overview

Azure Disk Encryption leverages the dm-crypt subsystem in Linux to provide full disk encryption on [select Azure Linux distributions](#). This solution is integrated with Azure Key Vault to manage disk encryption keys and secrets.

## Prerequisites

For a full list of prerequisites, see [Azure Disk Encryption for Linux VMs](#), specifically the following sections:

- [Supported VMs and operating systems](#)
- [Additional VM requirements](#)
- [Networking requirements](#)
- [Encryption key storage requirements](#)

## Extension Schema

There are two versions of extension schema for Azure Disk Encryption (ADE):

- v1.1 - A newer recommended schema that does not use Azure Active Directory (Azure AD) properties.
- v0.1 - An older schema that requires Azure Active Directory (Azure AD) properties.

To select a target schema, the `typeHandlerVersion` property must be set equal to version of schema you want to use.

### Schema v1.1: No Azure AD (recommended)

The v1.1 schema is recommended and does not require Azure Active Directory (Azure AD) properties.

#### NOTE

The `DiskFormatQuery` parameter is deprecated. Its functionality has been replaced by the `EncryptFormatAll` option instead, which is the recommended way to format data disks at time of encryption.

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "DiskFormatQuery": "[diskFormatQuery]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyVaultURL": "[keyVaultURL]",
      "KeyVaultResourceId": "[KeyVaultResourceId]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KekVaultResourceId": "[KekVaultResourceId]",
      "SequenceVersion": "sequenceVersion",
      "VolumeType": "[volumeType]"
    }
  }
}
```

## Schema v0.1: with Azure AD

The 0.1 schema requires `AADClientID` and either `AADClientSecret` or `AADClientCertificate`.

Using `AADClientSecret`:

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientSecret": "[aadClientSecret]",
      "Passphrase": "[passphrase]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "0.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "DiskFormatQuery": "[diskFormatQuery]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KeyVaultURL": "[keyVaultURL]",
      "SequenceVersion": "sequenceVersion",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Using `AADClientCertificate`:

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientCertificate": "[aadClientCertificate]",
      "Passphrase": "[passphrase]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "0.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "DiskFormatQuery": "[diskFormatQuery]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KeyVaultURL": "[keyVaultURL]",
      "SequenceVersion": "sequenceVersion",
      "VolumeType": "[volumeType]"
    }
  }
}
```

## Property values

Note: All property values are case sensitive.

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2019-07-01	date
publisher	Microsoft.Azure.Security	string
type	AzureDiskEncryptionForLinux	string

## Template deployment

For an example of template deployment based on schema v1.1, see the Azure Quickstart Template [encrypt-running-linux-vm-without-aad](#).

For an example of template deployment based on schema v0.1, see the Azure Quickstart Template [encrypt-running-linux-vm](#).

### WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM.
- When encrypting Linux OS volumes, the VM should be considered unavailable. We strongly recommend to avoid SSH logins while the encryption is in progress to avoid issues blocking any open files that will need to be accessed during the encryption process. To check progress, use the `Get-AzVMDiskEncryptionStatus` PowerShell cmdlet or the `vm encryption show` CLI command. This process can be expected to take a few hours for a 30GB OS volume, plus additional time for encrypting data volumes. Data volume encryption time will be proportional to the size and quantity of the data volumes; the `encrypt format all` option is faster than in-place encryption, but will result in the loss of all data on the disks.
- Disabling encryption on Linux VMs is only supported for data volumes. It is not supported on data or OS volumes if the OS volume has been encrypted.

### NOTE

Also if `VolumeType` parameter is set to All, data disks will be encrypted only if they are properly mounted.

## Troubleshoot and support

### Troubleshoot

For troubleshooting, refer to the [Azure Disk Encryption troubleshooting guide](#).

### Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#).

Alternatively, you can file an Azure support incident. Go to [Azure support](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure Support FAQ](#).

## Next steps

- For more information about VM extensions, see [Virtual machine extensions and features for Linux](#).
- For more information about Azure Disk Encryption for Linux, see [Linux virtual machines](#).

# Azure Disk Encryption for Windows (Microsoft.Azure.Security.AzureDiskEncryption)

9/21/2022 • 2 minutes to read • [Edit Online](#)

## Overview

Azure Disk Encryption uses BitLocker to provide full disk encryption on Azure virtual machines running Windows. This solution is integrated with Azure Key Vault to manage disk encryption keys and secrets in your key vault subscription.

## Prerequisites

For a full list of prerequisites, see [Azure Disk Encryption for Windows VMs](#), specifically the following sections:

- [Supported VMs and operating systems](#)
- [Networking requirements](#)
- [Group Policy requirements](#)

## Extension Schema

There are two versions of extension schema for Azure Disk Encryption (ADE):

- v2.2 - A newer recommended schema that does not use Azure Active Directory (Azure AD) properties.
- v1.1 - An older schema that requires Azure Active Directory (Azure AD) properties.

To select a target schema, the `typeHandlerVersion` property must be set equal to version of schema you want to use.

### Schema v2.2: No Azure AD (recommended)

The v2.2 schema is recommended for all new VMs and does not require Azure Active Directory properties.

```
{  
    "type": "extensions",  
    "name": "[name]",  
    "apiVersion": "2019-07-01",  
    "location": "[location]",  
    "properties": {  
        "publisher": "Microsoft.Azure.Security",  
        "type": "AzureDiskEncryption",  
        "typeHandlerVersion": "2.2",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "EncryptionOperation": "[encryptionOperation]",  
            "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",  
            "KeyVaultURL": "[keyVaultURL]",  
            "KeyVaultResourceId": "[keyVaultResourceID]",  
            "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",  
            "KekVaultResourceId": "[kekVaultResourceID]",  
            "SequenceVersion": "sequenceVersion]",  
            "VolumeType": "[volumeType]"  
        }  
    }  
}
```

## Schema v1.1: with Azure AD

The 1.1 schema requires `aadClientID` and either `aadClientSecret` or `AADClientCertificate` and is not recommended for new VMs.

Using `aadClientSecret`:

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientSecret": "[aadClientSecret]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryption",
    "typeHandlerVersion": "1.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyVaultURL": "[keyVaultURL]",
      "KeyVaultResourceId": "[keyVaultResourceID]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KekVaultResourceId": "[kekVaultResourceID]",
      "SequenceVersion": "sequenceVersion",
      "VolumeType": "[volumeType]"
    }
  }
}
```

Using `AADClientCertificate`:

```
{
  "type": "extensions",
  "name": "[name]",
  "apiVersion": "2019-07-01",
  "location": "[location]",
  "properties": {
    "protectedSettings": {
      "AADClientCertificate": "[aadClientCertificate]"
    },
    "publisher": "Microsoft.Azure.Security",
    "type": "AzureDiskEncryption",
    "typeHandlerVersion": "1.1",
    "settings": {
      "AADClientID": "[aadClientID]",
      "EncryptionOperation": "[encryptionOperation]",
      "KeyEncryptionAlgorithm": "[keyEncryptionAlgorithm]",
      "KeyVaultURL": "[keyVaultURL]",
      "KeyVaultResourceId": "[keyVaultResourceID]",
      "KeyEncryptionKeyURL": "[keyEncryptionKeyURL]",
      "KekVaultResourceId": "[kekVaultResourceID]",
      "SequenceVersion": "sequenceVersion",
      "VolumeType": "[volumeType]"
    }
  }
}
```

## Property values

Note: All values are case sensitive.

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2019-07-01	date
publisher	Microsoft.Azure.Security	string
type	AzureDiskEncryption	string
typeHandlerVersion	2.2, 1.1	string
(1.1 schema) AADClientID	xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx	guid
(1.1 schema) AADClientSecret	password	string
(1.1 schema) AADClientCertificate	thumbprint	string
EncryptionOperation	EnableEncryption	string
(optional - default RSA-OAEP ) KeyEncryptionAlgorithm	'RSA-OAEP', 'RSA-OAEP-256', 'RSA1_5'	string
KeyVaultURL	url	string
KeyVaultResourceId	url	string
(optional) KeyEncryptionKeyURL	url	string
(optional) KekVaultResourceId	url	string
(optional) SequenceVersion	uniqueidentifier	string
VolumeType	OS, Data, All	string

## Template deployment

For an example of template deployment based on schema v2.2, see Azure Quickstart Template [encrypt-running-windows-vm-without-aad](#).

For an example of template deployment based on schema v1.1, see Azure Quickstart Template [encrypt-running-windows-vm](#).

### NOTE

Also if `VolumeType` parameter is set to All, data disks will be encrypted only if they are properly formatted.

## Troubleshoot and support

### Troubleshoot

For troubleshooting, refer to the [Azure Disk Encryption troubleshooting guide](#).

### Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and](#)

[Stack Overflow forums](#).

Alternatively, you can file an Azure support incident. Go to [Azure support](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure Support FAQ](#).

## Next steps

- For more information about extensions, see [Virtual machine extensions and features for Windows](#).
- For more information about Azure Disk Encryption for Windows, see [Windows virtual machines](#).

# Key Vault virtual machine extension for Linux

9/21/2022 • 8 minutes to read • [Edit Online](#)

The Key Vault VM extension provides automatic refresh of certificates stored in an Azure key vault. Specifically, the extension monitors a list of observed certificates stored in key vaults. The extension retrieves and installs the corresponding certificates after detecting a change. The Key Vault VM extension is published and supported by Microsoft, currently on Linux VMs. This document details the supported platforms, configurations, and deployment options for the Key Vault VM extension for Linux.

## Operating system

The Key Vault VM extension supports these Linux distributions:

- Ubuntu-1804
- Suse-15
- [CBL-Mariner](#)

### NOTE

To get extended security features, prepare to upgrade Ubuntu-1604 and Debian-9 systems as these versions are reaching their end of designated support period.

### NOTE

The Key Vault VM Extension downloads the certificates in the default location or to the location provided by "certStoreLocation" property in the VM Extension settings. The KeyVault VM Extension updates the folder permission to 700 (drwx-----) allowing read, write and execute permission to the owner of the folder only

## Supported certificate content types

- PKCS #12
- PEM

## Prerequisites

- Key Vault instance with certificate. See [Create a Key Vault](#)
- VM/VMSS must have assigned [managed identity](#)
- The Key Vault Access Policy must be set with secrets `get` and `list` permission for VM/VMSS managed identity to retrieve a secret's portion of certificate. See [How to Authenticate to Key Vault](#) and [Assign a Key Vault access policy](#).
- VMSS should have the following identity setting:  

```
"identity": { "type": "UserAssigned", "userAssignedIdentities": { "[parameters('userAssignedIdentityResourceId')]: {} } }
```
- AKV extension should have this setting:  

```
"authenticationSettings": { "msiEndpoint": "[parameters('userAssignedIdentityEndpoint')]", "msiClientId": "[reference(parameters('userAssignedIdentityResourceId'), variables('msiApiVersion')).clientId]" }
```

## Key Vault VM extension version

- Ubuntu-18.04 and SUSE-15 users can chose to upgrade their key vault vm extension version to `v2.0` to avail full certificate chain download feature. Issuer certificates (intermediate and root) will be appended to the leaf certificate in the PEM file.
- If you prefer to upgrade to `v2.0`, you would need to delete `v1.0` first, then install `v2.0`.

```
az vm extension delete --name KeyVaultForLinux --resource-group ${resourceGroup} --vm-name ${vmName}
az vm extension set -n "KeyVaultForLinux" --publisher Microsoft.Azure.KeyVault --resource-group
"${resourceGroup}" --vm-name "${vmName}" -settings .\akvvm.json --version 2.0
```

The flag `--version 2.0` is optional because the latest version will be installed by default.

- If the VM has certificates downloaded by v1.0, deleting the v1.0 AKVVM extension will NOT delete the downloaded certificates. After installing v2.0, the existing certificates will NOT be modified. You would need to delete the certificate files or roll-over the certificate to get the PEM file with full-chain on the VM.

## Extension schema

The following JSON shows the schema for the Key Vault VM extension. The extension does not require protected settings - all its settings are considered information without security impact. The extension requires a list of monitored secrets, polling frequency, and the destination certificate store. Specifically:

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "KVVMExtensionForLinux",
  "apiVersion": "2019-07-01",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.KeyVault",
    "type": "KeyVaultForLinux",
    "typeHandlerVersion": "2.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "secretsManagementSettings": {
        "pollingIntervalInS": <polling interval in seconds, e.g. "3600">,
        "certificateStoreName": <It is ignored on Linux>,
        "linkOnRenewal": <Not available on Linux e.g.: false>,
        "certificateStoreLocation": <disk path where certificate is stored, default:
"/var/lib/waagent/Microsoft.Azure.KeyVault">,
        "requireInitialSync": <initial synchronization of certificates e..g: true>,
        "observedCertificates": <list of KeyVault URIs representing monitored certificates, e.g.:
["https://myvault.vault.azure.net/secrets/mycertificate",
"https://myvault.vault.azure.net/secrets/mycertificate2"]>
      },
      "authenticationSettings": {
        "msiEndpoint": <Optional MSI endpoint e.g.: "http://169.254.169.254/metadata/identity">,
        "msiClientId": <Optional MSI identity e.g.: "c7373ae5-91c2-4165-8ab6-7381d6e75619">
      }
    }
  }
}
```

**NOTE**

Your observed certificates URLs should be of the form <https://myVaultName.vault.azure.net/secrets/myCertName>.

This is because the `/secrets` path returns the full certificate, including the private key, while the `/certificates` path does not. More information about certificates can be found here: [Key Vault Certificates](#)

**IMPORTANT**

The 'authenticationSettings' property is required for VMs with **user assigned identities**. Set `msiClientId` to the identity that will authenticate to Key Vault.

Also required for **Azure Arc-enabled VMs**. Set `msiEndpoint` to <http://localhost:40342/metadata/identity>.

**Property values**

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2019-07-01	date
publisher	Microsoft.Azure.KeyVault	string
type	KeyVaultForLinux	string
typeHandlerVersion	2.0	int
pollingIntervalInS	3600	string
certificateStoreName	It is ignored on Linux	string
linkOnRenewal	false	boolean
certificateStoreLocation	/var/lib/waagent/Microsoft.Azure.KeyVault	string
requireInitialSync	true	boolean
observedCertificates	<code>["https://myvault.vault.azure.net/secrets/mycertificate", "https://myvault.vault.azure.net/secrets/mycertificate2"]</code>	string array
msiEndpoint	<a href="http://169.254.169.254/metadata/identity">http://169.254.169.254/metadata/identity</a>	string
msiClientId	c7373ae5-91c2-4165-8ab6-7381d6e75619	string

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment refresh of certificates. The extension can be deployed to individual VMs or virtual machine scale sets. The schema and configuration are common to both template types.

The JSON configuration for a virtual machine extension must be nested inside the virtual machine resource fragment of the template, specifically `"resources": []` object for the virtual machine template and for a virtual machine scale set under `"virtualMachineProfile": "extensionProfile": {"extensions" :[]}` object.

#### NOTE

The VM extension would require system or user managed identity to be assigned to authenticate to Key vault. See [How to authenticate to Key Vault and assign a Key Vault access policy](#).

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "KeyVaultForLinux",
  "apiVersion": "2019-07-01",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.KeyVault",
    "type": "KeyVaultForLinux",
    "typeHandlerVersion": "2.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "secretsManagementSettings": {
        "pollingIntervalInS": <polling interval in seconds, e.g. "3600">,
        "certificateStoreName": <ignored on linux>,
        "certificateStoreLocation": <disk path where certificate is stored, default: "/var/lib/waagent/Microsoft.Azure.KeyVault">,
        "observedCertificates": <list of KeyVault URIs representing monitored certificates, e.g.: "https://myvault.vault.azure.net/secrets/mycertificate"
      }
    }
  }
}
```

#### Extension Dependency Ordering

The Key Vault VM extension supports extension ordering if configured. By default the extension reports that it has successfully started as soon as it has started polling. However, it can be configured to wait until it has successfully downloaded the complete list of certificates before reporting a successful start. If other extensions depend on having the full set of certificates installed before they start, then enabling this setting will allow those extensions to declare a dependency on the Key Vault extension. This will prevent those extensions from starting until all certificates they depend on have been installed. The extension will retry the initial download indefinitely and remain in a `Transitioning` state.

To turn on extension dependency, set the following:

```
"secretsManagementSettings": {
  "requireInitialSync": true,
  ...
}
```

[Note] Using this feature is not compatible with an ARM template that creates a system assigned identity and updates a Key Vault access policy with that identity. Doing so will result in a deadlock as the vault access policy cannot be updated until all extensions have started. You should instead use a *single user assigned MSI identity* and pre-ACL your vaults with that identity before deploying.

# Azure PowerShell deployment

## WARNING

PowerShell clients often add `\` to `"` in the settings.json which will cause akvvm\_service fails with error:

```
[CertificateManagementConfiguration] Failed to parse the configuration settings with:not an object.
```

The Azure PowerShell can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

```
# Build settings
$settings = '{"secretsManagementSettings":'
{ "pollingIntervalInS": "' + <pollingInterval> +
'", "certificateStoreName": "' + <certStoreName> +
'", "certificateStoreLocation": "' + <certStoreLoc> +
'", "observedCertificates": ["' + <observedCert1> + '", "' + <observedCert2> + '"] } }'
$extName = "KeyVaultForLinux"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForLinux"

# Start the deployment
Set-AzVmExtension -TypeHandlerVersion "2.0" -ResourceGroupName <ResourceGroupName> -Location
<Location> -VMName <VMName> -Name $extName -Publisher $extPublisher -Type $extType -SettingString
$settings
```

- To deploy the extension on a virtual machine scale set:

```
# Build settings
$settings = '{"secretsManagementSettings":'
{ "pollingIntervalInS": "' + <pollingInterval> +
'", "certificateStoreName": "' + <certStoreName> +
'", "certificateStoreLocation": "' + <certStoreLoc> +
'", "observedCertificates": ["' + <observedCert1> + '", "' + <observedCert2> + '"] } }'
$extName = "KeyVaultForLinux"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForLinux"

# Add Extension to VMSS
$vmss = Get-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName>
Add-AzVmssExtension -VirtualMachineScaleSet $vmss -Name $extName -Publisher $extPublisher -Type
$extType -TypeHandlerVersion "2.0" -Setting $settings

# Start the deployment
Update-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName> -
VirtualMachineScaleSet $vmss
```

# Azure CLI deployment

The Azure CLI can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

```
# Start the deployment
az vm extension set -n "KeyVaultForLinux" ` 
--publisher Microsoft.Azure.KeyVault ` 
-g "<resourcegroup>" ` 
--vm-name "<vmName>" ` 
--version 2.0 ` 
--settings '{\"secretsManagementSettings\": { \"pollingIntervalInS\": \"<pollingInterval>\", 
\"certificateStoreName\": \"<certStoreName>\", \"certificateStoreLocation\": \"<certStoreLoc>\", 
\"observedCertificates\": [\" <observedCert1> \", \" <observedCert2> \"] }}'
```

- To deploy the extension on a virtual machine scale set:

```
# Start the deployment
az vmss extension set -n "KeyVaultForLinux" ` 
--publisher Microsoft.Azure.KeyVault ` 
-g "<resourcegroup>" ` 
--vmss-name "<vmssName>" ` 
--version 2.0 ` 
--settings '{\"secretsManagementSettings\": { \"pollingIntervalInS\": \"<pollingInterval>\", 
\"certificateStoreName\": \"<certStoreName>\", \"certificateStoreLocation\": \"<certStoreLoc>\", 
\"observedCertificates\": [\" <observedCert1> \", \" <observedCert2> \"] }}'
```

Please be aware of the following restrictions/requirements:

- Key Vault restrictions:
  - It must exist at the time of the deployment
  - The Key Vault Access Policy must be set for VM/VMSS Identity using a Managed Identity. See [How to Authenticate to Key Vault](#) and [Assign a Key Vault access policy](#).

## Troubleshoot and Support

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure PowerShell. To see the deployment state of extensions for a given VM, run the following command using the Azure PowerShell.

### Azure PowerShell

```
Get-AzVMExtension -VMName <vmName> -ResourceGroupName <resource group name>
```

### Azure CLI

```
az vm get-instance-view --resource-group <resource group name> --name <vmName> --query 
"instanceView.extensions"
```

The Azure CLI can run in several shell environments, but with slight format variations. If you have unexpected results with Azure CLI commands, see [How to use the Azure CLI successfully](#).

### Logs and configuration

The Key Vault VM extension logs only exist locally on the VM and are most informative when it comes to troubleshooting.

LOCATION	DESCRIPTION
/var/log/waagent.log	Shows when an update to the extension occurred.

LOCATION	DESCRIPTION
/var/log/azure/Microsoft.Azure.KeyVault.KeyVaultForLinux/*	Examine the Key Vault VM Extension service logs to determine the status of the akvvm_service service and certificate download. The download location of PEM files are also found in these files with an entry called certificate file name. If certificateStoreLocation is not specified, it will default to /var/lib/waagent/Microsoft.Azure.KeyVault.Store/
/var/lib/waagent/Microsoft.Azure.KeyVault.KeyVaultForLinux-<most recent version>/config/*	The configuration and binaries for Key Vault VM Extension service.

## Using Symlink

Symbolic links or Symlinks are advanced shortcuts. To avoid monitoring the folder and to get the latest certificate automatically, you can use this symlink `([VaultName].[CertificateName])` to get the latest version of certificate on Linux.

## Frequently Asked Questions

- Is there a limit on the number of observedCertificates you can setup? No, Key Vault VM Extension doesn't have limit on the number of observedCertificates.

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Key Vault virtual machine extension for Windows

9/21/2022 • 8 minutes to read • [Edit Online](#)

The Key Vault VM extension provides automatic refresh of certificates stored in an Azure key vault. Specifically, the extension monitors a list of observed certificates stored in key vaults, and, upon detecting a change, retrieves, and installs the corresponding certificates. This document details the supported platforms, configurations, and deployment options for the Key Vault VM extension for Windows.

## Operating system

The Key Vault VM extension supports below versions of Windows:

- Windows Server 2019
- Windows Server 2016
- Windows Server 2012

The Key Vault VM extension is also supported on custom local VM that is uploaded and converted into a specialized image for use in Azure using Windows Server 2019 core install.

### NOTE

The Key Vault VM extension downloads all the certificates in the windows certificate store or to the location provided by "certificateStoreLocation" property in the VM extension settings. Currently, the KV VM extension grants access to the private key of the certificate only to the local system admin account. Additionally, it is currently not possible to define certificate store location per certificate. The VM extension team is working on a solution to close this feature gap.

## Supported certificate content types

- PKCS #12
- PEM

## Prerequisites

- Key Vault instance with certificate. See [Create a Key Vault](#)
- VM must have assigned [managed identity](#)
- The Key Vault Access Policy must be set with secrets `get` and `list` permission for VM/VMSS managed identity to retrieve a secret's portion of certificate. See [How to Authenticate to Key Vault](#) and [Assign a Key Vault access policy](#).
- Virtual Machine Scale Sets should have the following identity setting:

```
"identity": {  
    "type": "UserAssigned",  
    "userAssignedIdentities": {  
        "[parameters('userAssignedIdentityResourceId'))": {}  
    }  
}
```

- AKV extension should have this setting:

```

"authenticationSettings": {
    "msiEndpoint": "[parameters('userAssignedIdentityEndpoint')]",
    "msiClientId": "[reference(parameters('userAssignedIdentityResourceId'), variables('msiApiVersion')).clientId]"
}

```

## Extension schema

The following JSON shows the schema for the Key Vault VM extension. The extension does not require protected settings - all its settings are considered public information. The extension requires a list of monitored certificates, polling frequency, and the destination certificate store. Specifically:

```

{
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "name": "KVVMExtensionForWindows",
    "apiVersion": "2019-07-01",
    "location": "<location>",
    "dependsOn": [
        "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"
    ],
    "properties": {
        "publisher": "Microsoft.Azure.KeyVault",
        "type": "KeyVaultForWindows",
        "typeHandlerVersion": "1.0",
        "autoUpgradeMinorVersion": true,
        "settings": {
            "secretsManagementSettings": {
                "pollingIntervalInS": <string specifying polling interval in seconds, e.g: "3600">,
                "certificateStoreName": <certificate store name, e.g.: "MY">,
                "linkOnRenewal": <Only Windows. This feature ensures s-channel binding when certificate renews, without necessitating a re-deployment. e.g.: false>,
                "certificateStoreLocation": <certificate store location, currently it works locally only e.g.: "LocalMachine">,
                "requireInitialSync": <initial synchronization of certificates e.g: true>,
                "observedCertificates": <list of KeyVault URIs representing monitored certificates, e.g.: "https://myvault.vault.azure.net/secrets/mycertificate"
            },
            "authenticationSettings": {
                "msiEndpoint": <Optional MSI endpoint e.g.: "http://169.254.169.254/metadata/identity">,
                "msiClientId": <Optional MSI identity e.g.: "c7373ae5-91c2-4165-8ab6-7381d6e75619">
            }
        }
    }
}

```

### NOTE

Your observed certificates URLs should be of the form `https://myVaultName.vault.azure.net/secrets/myCertName`.

This is because the `/secrets` path returns the full certificate, including the private key, while the `/certificates` path does not. More information about certificates can be found here: [Key Vault Certificates](#)

### IMPORTANT

The 'authenticationSettings' property is required only for VMs with user assigned identities. It specifies identity to use for authentication to Key Vault.

**IMPORTANT**

If you specify the 'msiClientId', then the 'msiEndpoint' property is **required**. Usually the value should be set to  
<http://169.254.169.254/metadata/identity/oauth2/token>.

**Property values**

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2019-07-01	date
publisher	Microsoft.Azure.KeyVault	string
type	KeyVaultForWindows	string
typeHandlerVersion	1.0	int
pollingIntervalInS	3600	string
certificateStoreName	MY	string
linkOnRenewal	false	boolean
certificateStoreLocation	LocalMachine or CurrentUser (case sensitive)	string
requireInitialSync	true	boolean
observedCertificates	["https://myvault.vault.azure.net/secrets/mycertificate", "https://myvault.vault.azure.net/secrets/mycertificate2"]	string array
msiEndpoint	<a href="http://169.254.169.254/metadata/identity">http://169.254.169.254/metadata/identity</a>	string
msiClientId	c7373ae5-91c2-4165-8ab6-7381d6e75619	string

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment refresh of certificates. The extension can be deployed to individual VMs or virtual machine scale sets. The schema and configuration are common to both template types.

The JSON configuration for a virtual machine extension must be nested inside the virtual machine resource fragment of the template, specifically `"resources": []` object for the virtual machine template and in case of virtual machine scale set under `"virtualMachineProfile": "extensionProfile": {"extensions": []}` object.

#### NOTE

The VM extension would require system or user managed identity to be assigned to authenticate to Key vault. See [How to authenticate to Key Vault and assign a Key Vault access policy](#).

```
{  
    "type": "Microsoft.Compute/virtualMachines/extensions",  
    "name": "KeyVaultForWindows",  
    "apiVersion": "2019-07-01",  
    "location": "<location>",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', <vmName>)]"  
    ],  
    "properties": {  
        "publisher": "Microsoft.Azure.KeyVault",  
        "type": "KeyVaultForWindows",  
        "typeHandlerVersion": "1.0",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "secretsManagementSettings": {  
                "pollingIntervalInS": <string specifying polling interval in seconds, e.g: "3600">,  
                "certificateStoreName": <certificate store name, e.g.: "MY">,  
                "certificateStoreLocation": <certificate store location, currently it works locally only e.g.:  
                "LocalMachine">,  
                "observedCertificates": <list of KeyVault URIs representing monitored certificates, e.g.:  
                ["https://myvault.vault.azure.net/secrets/mycertificate",  
                "https://myvault.vault.azure.net/secrets/mycertificate2"]>  
            }  
        }  
    }  
}
```

#### Extension Dependency Ordering

The Key Vault VM extension supports extension ordering if configured. By default the extension reports that it has successfully started as soon as it has started polling. However, it can be configured to wait until it has successfully downloaded the complete list of certificates before reporting a successful start. If other extensions depend on having the full set of certificates installed before they start, then enabling this setting will allow those extensions to declare a dependency on the Key Vault extension. This will prevent those extensions from starting until all certificates they depend on have been installed. The extension will retry the initial download indefinitely and remain in a `Transitioning` state.

To turn this on set the following:

```
"secretsManagementSettings": {  
    "requireInitialSync": true,  
    ...  
}
```

#### NOTE

Using this feature is not compatible with an ARM template that creates a system assigned identity and updates a Key Vault access policy with that identity. Doing so will result in a deadlock as the vault access policy cannot be updated until all extensions have started. You should instead use a *single user assigned MSI identity* and pre-ACL your vaults with that identity before deploying.

## Azure PowerShell deployment

## WARNING

PowerShell clients often add \ to " in the settings.json, which causes akvvm\_service to fail with the error

[CertificateManagementConfiguration] Failed to parse the configuration settings with: not an object. The extra \ and " characters will be visible in the portal, in Extensions under Settings. To avoid this, initialize \$settings as a PowerShell HashTable :

```
$settings = @{
    "secretsManagementSettings" = @{
        "pollingIntervalInS"      = "<pollingInterval>";
        "certificateStoreName"   = "<certStoreName>";
        "certificateStoreLocation" = "<certStoreLoc>";
        "observedCertificates"   = @("<observedCert1>", "<observedCert2>") } }
```

The Azure PowerShell can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

```
# Build settings
$settings = '{"secretsManagementSettings":'
{ "pollingIntervalInS": "' + <pollingInterval> +
'', "certificateStoreName": "' + <certStoreName> +
'', "certificateStoreLocation": "' + <certStoreLoc> +
'', "observedCertificates": ["' + <observedCert1> + '", "' + <observedCert2> + '"] } }'
$extName = "KeyVaultForWindows"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForWindows"

# Start the deployment
Set-AzVmExtension -TypeHandlerVersion "1.0" -ResourceGroupName <ResourceGroupName> -Location
<Location> -VMName <VMName> -Name $extName -Publisher $extPublisher -Type $extType -SettingString
$settings
```

- To deploy the extension on a virtual machine scale set:

```
# Build settings
$settings = '{"secretsManagementSettings":'
{ "pollingIntervalInS": "' + <pollingInterval> +
'', "certificateStoreName": "' + <certStoreName> +
'', "certificateStoreLocation": "' + <certStoreLoc> +
'', "observedCertificates": ["' + <observedCert1> + '", "' + <observedCert2> + '"] } }'
$extName = "KeyVaultForWindows"
$extPublisher = "Microsoft.Azure.KeyVault"
$extType = "KeyVaultForWindows"

# Add Extension to VMSS
$vmss = Get-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName>
Add-AzVmssExtension -VirtualMachineScaleSet $vmss -Name $extName -Publisher $extPublisher -Type
$extType -TypeHandlerVersion "1.0" -Setting $settings

# Start the deployment
Update-AzVmss -ResourceGroupName <ResourceGroupName> -VMScaleSetName <VmssName> -
VirtualMachineScaleSet $vmss
```

# Azure CLI deployment

The Azure CLI can be used to deploy the Key Vault VM extension to an existing virtual machine or virtual machine scale set.

- To deploy the extension on a VM:

```
# Start the deployment
az vm extension set --name "KeyVaultForWindows" ` 
--publisher Microsoft.Azure.KeyVault ` 
--resource-group "<resourcegroup>" ` 
--vm-name "<vmName>" ` 
--settings '{\"secretsManagementSettings\": { \"pollingIntervalInS\": \"<pollingInterval>\", 
\"certificateStoreName\": \"<certStoreName>\", \"certificateStoreLocation\": \"<certStoreLoc>\", 
\"observedCertificates\": [\" <observedCert1> \", \" <observedCert2> \"] }}'
```

- To deploy the extension on a virtual machine scale set :

```
# Start the deployment
az vmss extension set --name "KeyVaultForWindows" ` 
--publisher Microsoft.Azure.KeyVault ` 
--resource-group "<resourcegroup>" ` 
--vmss-name "<vmName>" ` 
--settings '{\"secretsManagementSettings\": { \"pollingIntervalInS\": \"<pollingInterval>\", 
\"certificateStoreName\": \"<certStoreName>\", \"certificateStoreLocation\": \"<certStoreLoc>\", 
\"observedCertificates\": [\" <observedCert1> \", \" <observedCert2> \"] }}'
```

Please be aware of the following restrictions/requirements:

- Key Vault restrictions:
  - It must exist at the time of the deployment
  - The Key Vault Access Policy must be set for VM/VMSS Identity using a Managed Identity. See [How to Authenticate to Key Vault](#) and [Assign a Key Vault access policy](#).

## Troubleshoot and support

### Frequently Asked Questions

- Is there a limit on the number of observedCertificates you can setup? No, Key Vault VM Extension doesn't have limit on the number of observedCertificates.

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure PowerShell. To see the deployment state of extensions for a given VM, run the following command using the Azure PowerShell.

### Azure PowerShell

```
Get-AzVMExtension -VMName <vmName> -ResourceGroupName <resource group name>
```

### Azure CLI

```
az vm get-instance-view --resource-group <resource group name> --name <vmName> --query 
"instanceView.extensions"
```

### Logs and configuration

The Key Vault VM extension logs only exist locally on the VM and are most informative when it comes to troubleshooting

LOCATION	DESCRIPTION
C:\WindowsAzure\Logs\WaAppAgent.log	Shows when an update to the extension occurred.
C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows\<most recent version>\	Shows the status of certificate download. The download location will always be the Windows computer's MY store (certlm.msc).
C:\Packages\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows\<most recent version>\RuntimeSettings\	The Key Vault VM Extension service logs show the status of the akvvm_service service.
C:\Packages\Plugins\Microsoft.Azure.KeyVault.KeyVaultForWindows\<most recent version>\Status\	The configuration and binaries for Key Vault VM Extension service.

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Overview of the guest configuration extension

9/21/2022 • 4 minutes to read • [Edit Online](#)

The Guest Configuration extension is a component of Azure Policy that performs audit and configuration operations inside virtual machines. Policies such as security baseline definitions for [Linux](#) and [Windows](#) can't check settings inside machines until the extension is installed.

## Prerequisites

For the machine to authenticate to the Guest Configuration service, the machine must have a [System-Assigned Managed Identity](#). The identity requirement on a virtual machine is met if the following property is set.

```
"identity": {  
    "type": "SystemAssigned"  
}
```

### Operating Systems

Support for the Guest Configuration extension is the same as operating system support [documented for the end to end solution](#).

### Internet connectivity

The agent installed by the Guest Configuration extension must be able to reach content packages listed by Guest Configuration assignments, and report status to the Guest Configuration service. The machine can connect using outbound HTTPS over TCP port 443, or if a connection is provided through private networking. To learn more about private networking, see the following articles:

- [Guest Configuration, communicate over private link in Azure](#)
- [Use private endpoints for Azure Storage](#)

## How can I install the extension?

The instance name of the extension must be set to "AzurePolicyforWindows" or "AzurePolicyforLinux", because the policies referenced above require these specific strings.

By default, all deployments update to the latest version. The value of property *autoUpgradeMinorVersion* defaults to "true" unless it is otherwise specified. You do not need to worry about updating your code when new versions of the extension are released.

## Automatic upgrade

The guest configuration extension supports property `enableAutomaticUpgrade`. When this property is set to `true`, Azure will automatically upgrade to the latest version of the extension as future releases become available. For more information, see the page [Automatic Extension Upgrade for VMs and Scale Sets in Azure](#)

### Azure Policy

To deploy the latest version of the extension at scale including identity requirements, [assign](#) the Azure Policy:

[Deploy prerequisites to enable Guest Configuration policies on virtual machines](#).

### Azure CLI

To deploy the extension for Linux:

```
az vm extension set --publisher Microsoft.GuestConfiguration --name ConfigurationforLinux --extension-instance-name AzurePolicyforLinux --resource-group myResourceGroup --vm-name myVM --enable-auto-upgrade true
```

To deploy the extension for Windows:

```
az vm extension set --publisher Microsoft.GuestConfiguration --name ConfigurationforWindows --extension-instance-name AzurePolicyforWindows --resource-group myResourceGroup --vm-name myVM --enable-auto-upgrade true
```

## PowerShell

To deploy the extension for Linux:

```
Set-AzVMExtension -Publisher 'Microsoft.GuestConfiguration' -Type 'ConfigurationforLinux' -Name 'AzurePolicyforLinux' -TypeHandlerVersion 1.0 -ResourceGroupName 'myResourceGroup' -Location 'myLocation' -VMName 'myVM' -EnableAutomaticUpgrade $true
```

To deploy the extension for Windows:

```
Set-AzVMExtension -Publisher 'Microsoft.GuestConfiguration' -Type 'ConfigurationforWindows' -Name 'AzurePolicyforWindows' -TypeHandlerVersion 1.0 -ResourceGroupName 'myResourceGroup' -Location 'myLocation' -VMName 'myVM' -EnableAutomaticUpgrade $true
```

## Resource Manager template

To deploy the extension for Linux:

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(parameters('VMName'), '/AzurePolicyforLinux')]",
  "apiVersion": "2020-12-01",
  "location": "[parameters('location')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', parameters('VMName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.GuestConfiguration",
    "type": "ConfigurationforLinux",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "enableAutomaticUpgrade": true,
    "settings": {},
    "protectedSettings": {}
  }
}
```

To deploy the extension for Windows:

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(parameters('VMName'), '/AzurePolicyforWindows')]",
  "apiVersion": "2020-12-01",
  "location": "[parameters('location')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', parameters('VMName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.GuestConfiguration",
    "type": "ConfigurationforWindows",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "enableAutomaticUpgrade": true,
    "settings": {},
    "protectedSettings": {}
  }
}
```

## Bicep

To deploy the extension for Linux:

```
resource virtualMachine 'Microsoft.Compute/virtualMachines@2021-03-01' existing = {
  name: 'VMName'
}
resource windowsVMGuestConfigExtension 'Microsoft.Compute/virtualMachines/extensions@2020-12-01' = {
  parent: virtualMachine
  name: 'AzurePolicyforLinux'
  location: resourceGroup().location
  properties: {
    publisher: 'Microsoft.GuestConfiguration'
    type: 'ConfigurationforLinux'
    typeHandlerVersion: '1.0'
    autoUpgradeMinorVersion: true
    enableAutomaticUpgrade: true
    settings: {}
    protectedSettings: {}
  }
}
```

To deploy the extension for Windows:

```
resource virtualMachine 'Microsoft.Compute/virtualMachines@2021-03-01' existing = {
  name: 'VMName'
}
resource windowsVMGuestConfigExtension 'Microsoft.Compute/virtualMachines/extensions@2020-12-01' = {
  parent: virtualMachine
  name: 'AzurePolicyforWindows'
  location: resourceGroup().location
  properties: {
    publisher: 'Microsoft.GuestConfiguration'
    type: 'ConfigurationforWindows'
    typeHandlerVersion: '1.0'
    autoUpgradeMinorVersion: true
    enableAutomaticUpgrade: true
    settings: {}
    protectedSettings: {}
  }
}
```

## Terraform

To deploy the extension for Linux:

```
resource "azurerm_virtual_machine_extension" "gc" {
    name          = "AzurePolicyforLinux"
    virtual_machine_id = "myVMID"
    publisher     = "Microsoft.GuestConfiguration"
    type          = "ConfigurationforLinux"
    type_handler_version = "1.0"
    auto_upgrade_minor_version = "true"
}
```

To deploy the extension for Windows:

```
resource "azurerm_virtual_machine_extension" "gc" {
    name          = "AzurePolicyforWindows"
    virtual_machine_id = "myVMID"
    publisher     = "Microsoft.GuestConfiguration"
    type          = "ConfigurationforWindows"
    type_handler_version = "1.0"
    auto_upgrade_minor_version = "true"
}
```

## Settings

There's no need to include any settings or protected-settings properties on the extension. All such information is retrieved by the agent from [Guest Configuration assignment](#) resources. For example, the [ConfigurationUri](#), [Mode](#), and [ConfigurationSetting](#) properties are each managed per-configuration rather than on the VM extension.

## Guest Configuration resource provider error codes

See below for a list of the possible error messages when enabling the extension

ERROR CODE	DESCRIPTION
NoComplianceReport	VM has not reported the compliance data.
GCExtensionMissing	Guest Configuration extension is missing.
ManagedIdentityMissing	Managed identity is missing.
UserIdentityMissing	User assigned identity is missing.
GCExtensionManagedIdentityMissing	Guest Configuration extension and managed identity is missing.
GCExtensionUserIdentityMissing	Guest Configuration extension and user identity is missing.
GCExtensionIdentityMissing	Guest Configuration extension, managed identity and user identity are missing.

## Next steps

- For more information about Azure Policy's guest configuration, see [Understand Azure Policy's Guest Configuration](#)

- For more information about how the Linux Agent and extensions work, see [Azure VM extensions and features for Linux](#).
- For more information about how the Windows Guest Agent and extensions work, see [Azure VM extensions and features for Windows](#).
- To install the Windows Guest Agent, see [Azure Windows Virtual Machine Agent Overview](#).
- To install the Linux Agent, see [Azure Linux Virtual Machine Agent Overview](#).

# Use the Azure Custom Script Extension Version 2 with Linux virtual machines

9/21/2022 • 13 minutes to read • [Edit Online](#)

The Custom Script Extension Version 2 downloads and runs scripts on Azure virtual machines (VMs). This extension is useful for post-deployment configuration, software installation, or any other configuration or management task. You can download scripts from Azure Storage or another accessible internet location, or you can provide them to the extension runtime.

The Custom Script Extension integrates with Azure Resource Manager templates. You can also run it by using the Azure CLI, PowerShell, or the Azure Virtual Machines REST API.

This article details how to use the Custom Script Extension from the Azure CLI, and how to run the extension by using an Azure Resource Manager template. This article also provides troubleshooting steps for Linux systems.

There are two Linux Custom Script Extensions:

- Version 1: Microsoft.OSTCExtensions.CustomScriptForLinux
- Version 2: Microsoft.Azure.Extensions.CustomScript

Please switch new and existing deployments to use Version 2. The new version is a drop-in replacement. The migration is as easy as changing the name and version. You don't need to change your extension configuration.

## Prerequisites

### Operating system

The Custom Script Extension for Linux will run on supported operating systems. For more information, see [Endorsed Linux distributions on Azure](#).

### Script location

You can set the extension to use your Azure Blob Storage credentials so that it can access Azure Blob Storage. The script location can be anywhere, as long as the VM can route to that endpoint (for example, GitHub or an internal file server).

### Internet connectivity

If you need to download a script externally, such as from GitHub or Azure Storage, then you need to open additional firewall or network security group (NSG) ports. For example, if your script is located in Azure Storage, you can allow access by using Azure NSG [service tags for Storage](#).

If your script is on a local server, you might still need to open additional firewall or NSG ports.

### Tips and tricks

- The highest failure rate for this extension is due to syntax errors in the script. Test that the script runs without errors. Put additional logging into the script to make it easier to find failures.
- Write scripts that are idempotent, so running them more than once accidentally won't cause system changes.
- Ensure that the scripts don't require user input when they run.
- The script is allowed 90 minutes to run. Anything longer will result in a failed provision of the extension.
- Don't put reboots inside the script. This action will cause problems with other extensions that are being installed, and the extension won't continue after the reboot.
- If you have a script that will cause a reboot before installing applications and running scripts, schedule the reboot by using a Cron job or by using tools such as DSC, Chef, or Puppet extensions.
- Don't run a script that will cause a stop or update of the VM agent. It might leave the extension in a transitioning state and lead to a timeout.

- The extension will run a script only once. If you want to run a script on every startup, you can use a [cloud-init image](#) and use a [Scripts Per Boot](#) module. Alternatively, you can use the script to create a [systemd](#) service unit.
- You can have only one version of an extension applied to the VM. To run a second custom script, you can update the existing extension with a new configuration. Alternatively, you can remove the custom script extension and reapply it with the updated script.
- If you want to schedule when a script will run, use the extension to create a Cron job.
- When the script is running, you'll only see a "transitioning" extension status from the Azure portal or CLI. If you want more frequent status updates for a running script, you'll need to create your own solution.
- The Custom Script Extension doesn't natively support proxy servers. However, you can use a file transfer tool that supports proxy servers within your script, such as [Curl](#).
- Be aware of non-default directory locations that your scripts or commands might rely on. Have logic to handle this situation.

## Extension schema

The Custom Script Extension configuration specifies things like script location and the command to be run. You can store this information in configuration files, specify it on the command line, or specify it in an Azure Resource Manager template.

You can store sensitive data in a protected configuration, which is encrypted and only decrypted on the target virtual machine. The protected configuration is useful when the execution command includes secrets such as a password. Here's an example:

```
{
  "name": "config-app",
  "type": "Extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2019-03-01",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "skipDOS2Unix":false,
      "timestamp":123456789
    },
    "protectedSettings": {
      "commandToExecute": "<command-to-execute>",
      "script": "<base64-script-to-execute>",
      "storageAccountName": "<storage-account-name>",
      "storageAccountKey": "<storage-account-key>",
      "fileUris": ["https://.."],
      "managedIdentity" : "<managed-identity-identifier>"
    }
  }
}
```

### NOTE

The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

## Property values

NAME	VALUE OR EXAMPLE	DATA TYPE
apiVersion	2019-03-01	date
publisher	Microsoft.Azure.Extensions	string
type	CustomScript	string
typeHandlerVersion	2.1	int
fileUris	https://github.com/MyProject/Archive/myPythonScript.py	
commandToExecute	python MyPythonScript.py \<my-param>	string
script	IyEvYmluL3NoCmVjaG8gIlVwZGF0aW5nIHBhY2tld2VzIC4uLiIKYXB0IHVwZGF0ZQphcHQgdXBncmFkZSAte	
skipDos2Unix	false	Boolean
timestamp	123456789	32-bit integer
storageAccountName	examplestorageacct	string
storageAccountKey	TmJK/1N3AbAZ3q/+h0Xoi/173z0qsaxXDhq99\$UpXQp2DQIBuv2Tifp60cE/OaHsJZmQZ7teQfczQj8h	
managedIdentity	{ } or { "clientId": "31b403aa-c364-4240-a7ff-d85fb6cd7232" } or { "objectId": "12dd289c-0583-46e5-b9b4-115d5c19ef4b" }	JSON object

## Property value details

PROPERTY	OPTIONAL OR REQUIRED	DETAILS
apiVersion	Not applicable	You can find the most up-to-date API version by using <a href="#">Resource Explorer</a> or by using the command <code>az provider list -o json</code> in the Azure CLI.
fileUris	Optional	URLs for files to be downloaded.
commandToExecute	Required if <code>script</code> isn't set	The entry point script to run. Use this property instead of <code>script</code> if your command contains secrets such as passwords.
script	Required if <code>commandToExecute</code> isn't set	A Base64-encoded (and optionally gzip'ed) script run by <code>/bin/sh</code> .
skipDos2Unix	Optional	Set this value to <code>false</code> if you want to skip dos2unix conversion of script-based file URLs or scripts.

PROPERTY	OPTIONAL OR REQUIRED	DETAILS
<code>timestamp</code>	Optional	Change this value only to trigger a rerun of the script. Any integer value is acceptable, as long as it's different from the previous value.
<code>storageAccountName</code>	Optional	The name of storage account. If you specify storage credentials, all <code>fileUris</code> values must be URLs for Azure blobs.
<code>storageAccountKey</code>	Optional	The access key of the storage account.
<code>managedIdentity</code>	Optional	The <a href="#">managed identity</a> for downloading files:  <code>clientId</code> (optional, string): The client ID of the managed identity.  <code>objectId</code> (optional, string): The object ID of the managed identity.

You can set the following values in either public or protected settings. The extension will reject any configuration where these values are set in both public and protected settings.

- `commandToExecute`
- `script`
- `fileUris`

Using public settings might be useful for debugging, but we strongly recommend that you use protected settings.

Public settings are sent in clear text to the VM where the script will be run. Protected settings are encrypted through a key known only to Azure and the VM. The settings are saved to the VM as they were sent. That is, if the settings were encrypted, they're saved encrypted on the VM. The certificate that's used to decrypt the encrypted values is stored on the VM. The certificate is also used to decrypt settings (if necessary) at runtime.

#### Property: `skipDos2Unix`

The default value is `false`, which means dos2unix conversion *is* executed.

The previous version of the Custom Script Extension, Microsoft.OSTCExtensions.CustomScriptForLinux, would automatically convert DOS files to UNIX files by translating `\r\n` to `\n`. This translation still exists and is on by default. This conversion is applied to all files downloaded from `fileUris` or the script setting based on either of the following criteria:

- The extension is `.sh`, `.txt`, `.py`, or `.pl`. The script setting will always match this criterion because it's assumed to be a script run with `/bin/sh`. The script setting is saved as `script.sh` on the VM.
- The file starts with `#!`.

You can skip the dos2unix conversion by setting `skipDos2Unix` to `true`:

```
{
  "fileUris": ["<url>"],
  "commandToExecute": "<command-to-execute>",
  "skipDos2Unix": true
}
```

#### Property: `script`

The Custom Script Extension supports execution of a user-defined script. The script settings combine `commandToExecute` and `fileUris` into a single setting. Instead of having to set up a file for download from Azure

Storage or a GitHub gist, you can simply encode the script as a setting. You can use the script to replace `commandToExecute` and `fileUris`.

Here are some requirements:

- The script *must* be Base64 encoded.
- The script can *optionally* be gzip'ed.
- You can use the script setting in public or protected settings.
- The maximum size of the script parameter's data is 256 KB. If the script exceeds this size, it won't be run.

For example, the following script is saved to the file `/script.sh`:

```
#!/bin/sh
echo "Updating packages ..."
apt update
apt upgrade -y
```

You would construct the correct Custom Script Extension script setting by taking the output of the following command:

```
cat script.sh | base64 -w0
```

```
{
  "script": "IyEvYmluL3NoCmVjaG8gIlVwZGF0aW5nIHBhY2thZ2VzIC4uLiIKYXB0IHVwZGF0ZQphcHQgdXBncmFkZSAteQo="
}
```

In most cases, the script can optionally be gzip'ed to further reduce size. The Custom Script Extension automatically detects the use of gzip compression.

```
cat script | gzip -9 | base64 -w 0
```

The Custom Script Extension uses the following algorithm to run a script:

1. Assert that the length of the script's value does not exceed 256 KB.
2. Base64 decode the script's value.
3. Try to gunzip the Base64-decoded value.
4. Write the decoded (and optionally decompressed) value to disk (`/var/lib/waagent/custom-script/#/script.sh`).
5. Run the script by using `/bin/sh -c /var/lib/waagent/custom-script/#/script.sh`.

#### Property: managedIdentity

##### NOTE

This property *must* be specified in protected settings only.

The Custom Script Extension (version 2.1 and later) supports [managed identities](#) for downloading files from URLs provided in the `fileUris` setting. It allows the Custom Script Extension to access Azure Storage private blobs or containers without the user having to pass secrets like shared access signature (SAS) tokens or storage account keys.

To use this feature, the user must add a [system-assigned](#) or [user-assigned](#) identity to the VM or virtual machine scale set where the Custom Script Extension is expected to run. The user must then [grant the managed identity access to the Azure Storage container or blob](#).

To use the system-assigned identity on the target VM or virtual machine scale set, set `managedIdentity` to an empty JSON object.

Example:

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],  
    "commandToExecute": "sh script1.sh",  
    "managedIdentity" : {}  
}
```

To use the user-assigned identity on the target VM or virtual machine scale set, configure `managedIdentity` with the client ID or the object ID of the managed identity.

Examples:

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],  
    "commandToExecute": "sh script1.sh",  
    "managedIdentity" : { "clientId": "31b403aa-c364-4240-a7ff-d85fb6cd7232" }  
}
```

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.sh"],  
    "commandToExecute": "sh script1.sh",  
    "managedIdentity" : { "objectId": "12dd289c-0583-46e5-b9b4-115d5c19ef4b" }  
}
```

**NOTE**

The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

## Template deployment

You can deploy Azure VM extensions by using Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Custom Script Extension during the template's deployment. You can find a sample template that includes the Custom Script Extension on [GitHub](#).

```
{
  "name": "config-app",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2019-03-01",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', concat(variables('vmName'),copyindex()))]"
  ],
  "tags": {
    "displayName": "config-app"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Extensions",
    "type": "CustomScript",
    "typeHandlerVersion": "2.1",
    "autoUpgradeMinorVersion": true,
    "settings": {
    },
    "protectedSettings": {
      "commandToExecute": "sh hello.sh <param2>",
      "fileUris": ["https://github.com/MyProject/Archive/hello.sh"]
    }
  }
}
```

#### NOTE

These property names are case-sensitive. To avoid deployment problems, use the names as shown here.

## Azure CLI

When you're using the Azure CLI to run the Custom Script Extension, create a configuration file or files. At a minimum, you must have `commandToExecute`.

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM --name customScript \
--publisher Microsoft.Azure.Extensions \
--protected-settings ./script-config.json
```

Optionally, you can specify the settings in the command as a JSON-formatted string. This allows the configuration to be specified during execution and without a separate configuration file.

```
az vm extension set \
--resource-group exttest \
--vm-name exttest \
--name customScript \
--publisher Microsoft.Azure.Extensions \
--protected-settings '{"fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"], "commandToExecute": "./config-music.sh"}'
```

#### Example: Public configuration with script file

```
{
  "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"],
  "commandToExecute": "./config-music.sh"
}
```

Azure CLI command:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM --name customScript \
--publisher Microsoft.Azure.Extensions \
--settings ./script-config.json
```

#### Example: Public configuration with no script file

```
{
  "commandToExecute": "apt-get -y update && apt-get install -y apache2"
}
```

Azure CLI command:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM --name customScript \
--publisher Microsoft.Azure.Extensions \
--settings ./script-config.json
```

#### Example: Public and protected configuration files

You use a public configuration file to specify the script file's URI. You use a protected configuration file to specify the command to be run.

Public configuration file:

```
{
  "fileUris": ["https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-linux/scripts/config-music.sh"]
}
```

Protected configuration file:

```
{
  "commandToExecute": "./config-music.sh <param1>"
}
```

Azure CLI command:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name customScript \
--publisher Microsoft.Azure.Extensions \
--settings ./script-config.json \
--protected-settings ./protected-config.json
```

## Virtual machine scale sets

If you deploy the Custom Script Extension from the Azure portal, you don't have control over the expiration of the SAS token for accessing the script in your storage account. The result is that the initial deployment works, but when the storage account's SAS token expires, any subsequent scaling operation fails because the Custom Script Extension can no longer access the storage account.

We recommend that you use [PowerShell](#), the [Azure CLI](#), or an [Azure Resource Manager template](#) when you deploy the Custom Script Extension on a virtual machine scale set. This way, you can choose to use a managed identity or have direct control of the expiration of the SAS token for accessing the script in your storage account for as long as you need.

## Troubleshooting

When the Custom Script Extension runs, the script is created or downloaded into a directory that's similar to the following example. The command output is also saved into this directory in `stdout` and `stderr` files.

```
/var/lib/waagent/custom-script/download/0/
```

To troubleshoot, first check the Linux Agent Log and ensure that the extension ran:

```
/var/log/waagent.log
```

Look for the extension execution. It will look something like:

```
2018/04/26 17:47:22.110231 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] [Enable] current handler state is: notinstalled
2018/04/26 17:47:22.306407 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Download, message=Download succeeded, duration=167
2018/04/26 17:47:22.339958 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Initialize extension directory
2018/04/26 17:47:22.368293 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Update settings file: 0.settings
2018/04/26 17:47:22.394482 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Install extension [bin/custom-script-shim install]
2018/04/26 17:47:23.432774 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Install, message=Launch command succeeded: bin/custom-script-shim install, duration=1007
2018/04/26 17:47:23.476151 INFO [Microsoft.Azure.Extensions.customScript-2.0.6] Enable extension [bin/custom-script-shim enable]
2018/04/26 17:47:24.516444 INFO Event: name=Microsoft.Azure.Extensions.customScript, op=Enable, message=Launch command succeeded: bin/custom-sc
```

In the preceding output:

- `Enable` is when the command starts running.
- `Download` relates to the downloading of the Custom Script Extension package from Azure, not the script files specified in `fileUris`.

The Azure Script Extension produces a log, which you can find here:

```
/var/log/azure/custom-script/handler.log
```

Look for the individual execution. It will look something like:

```
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=start

time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event="executed command" output=/var/lib/waagent/custom-script/download/0
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=enabled
time=2018-04-26T17:47:23Z version=v2.0.6/git@1008306-clean operation=enable seq=0 event=end
```

Here you can see:

- The `enable` command that starts this log.
- The settings passed to the extension.
- The extension downloading the file and the result of that.
- The command being run and the result.

You can also retrieve the execution state of the Custom Script Extension, including the actual arguments passed as `commandToExecute`, by using the Azure CLI:

```
az vm extension list -g myResourceGroup --vm-name myVM
```

The output looks like the following text:

```
[  
  {  
    "autoUpgradeMinorVersion": true,  
    "forceUpdateTag": null,  
    "id":  
      "/subscriptions/subscriptionid/resourceGroups/rgname/providers/Microsoft.Compute/virtualMachines/vmname/extensions/customscript",  
    "resourceGroup": "rgname",  
    "settings": {  
      "commandToExecute": "sh script.sh > ",  
      "fileUris": [  
        "https://catalogartifact.azureedge.net/publicartifacts/scripts/script.sh",  
        "https://catalogartifact.azureedge.net/publicartifacts/scripts/script.sh"  
      ]  
    },  
    "tags": null,

```

#### Azure CLI syntax issues

The Azure CLI can run in several shell environments, but with slight format variations. If you have unexpected results with Azure CLI commands, see [How to use the Azure CLI successfully](#).

## Next steps

To see the code, current issues, and versions, go to the [custom-script-extension-linux repo on GitHub](#).

# Custom Script Extension for Windows

9/21/2022 • 12 minutes to read • [Edit Online](#)

The Custom Script Extension downloads and runs scripts on Azure virtual machines (VMs). This extension is useful for post-deployment configuration, software installation, or any other configuration or management task. You can download scripts from Azure Storage or GitHub, or provide them to the Azure portal at extension runtime.

The Custom Script Extension integrates with Azure Resource Manager templates. You can also run it by using the Azure CLI, PowerShell, the Azure portal, or the Azure Virtual Machines REST API.

This article details how to use the Custom Script Extension by using the Azure PowerShell module and Azure Resource Manager templates. It also provides troubleshooting steps for Windows systems.

## Prerequisites

### NOTE

Don't use the Custom Script Extension to run `Update-AzVM` with the same VM as its parameter, because it will wait for itself.

### Operating system

The Custom Script Extension for Windows will run on these supported operating systems:

- Windows Server 2008 R2
- Windows Server 2012
- Windows Server 2012 R2
- Windows 10
- Windows Server 2016
- Windows Server 2016 Core
- Windows Server 2019
- Windows Server 2019 Core
- Windows Server 2022
- Windows Server 2022 Core
- Windows 11

### Script location

You can set the extension to use your Azure Blob Storage credentials so that it can access Azure Blob Storage. The script location can be anywhere, as long as the VM can route to that endpoint (for example, GitHub or an internal file server).

### Internet connectivity

If you need to download a script externally, such as from GitHub or Azure Storage, then you need to open additional firewall or network security group (NSG) ports. For example, if your script is located in Azure Storage, you can allow access by using Azure NSG [service tags for Storage](#).

The Custom Script Extension does not have any way to bypass certificate validation. So if you're downloading from a secured location with, for example, a self-signed certificate, you might get errors like "The remote certificate is invalid according to the validation procedure." Make sure that the certificate is correctly installed in the *Trusted Root Certification Authorities* store on the VM.

If your script is on a local server, you might still need to open additional firewall or NSG ports.

### Tips and tricks

- The highest failure rate for this extension is due to syntax errors in the script. Test that the script runs without errors. Put additional logging into the script to make it easier to find failures.
- Write scripts that are idempotent, so running them more than once accidentally won't cause system changes.
- Ensure that the scripts don't require user input when they run.
- The script is allowed 90 minutes to run. Anything longer will result in a failed provision of the extension.
- Don't put reboots inside the script. This action will cause problems with other extensions that are being installed, and the extension won't continue after the reboot.
- If you have a script that will cause a reboot before installing applications and running scripts, schedule the reboot by using a Windows Scheduled Task or by using tools such as DSC, Chef, or Puppet extensions.
- Don't run a script that will cause a stop or update of the VM agent. It might leave the extension in a transitioning state and lead to a timeout.
- The extension will run a script only once. If you want to run a script on every startup, use the extension to create a Windows Scheduled Task.
- If you want to schedule when a script will run, use the extension to create a Windows Scheduled Task.
- When the script is running, you'll only see a "transitioning" extension status from the Azure portal or CLI. If you want more frequent status updates for a running script, you'll need to create your own solution.
- The Custom Script Extension doesn't natively support proxy servers. However, you can use a file transfer tool

that supports proxy servers within your script, such as *Invoke-WebRequest*.

- Be aware of non-default directory locations that your scripts or commands might rely on. Have logic to handle this situation.
- The Custom Script Extension runs under the LocalSystem account.
- If you plan to use the `storageAccountName` and `storageAccountKey` properties, these properties must be collocated in `protectedSettings`.

## Extension schema

The Custom Script Extension configuration specifies things like script location and the command to be run. You can store this configuration in configuration files, specify it on the command line, or specify it in an Azure Resource Manager template.

You can store sensitive data in a protected configuration, which is encrypted and only decrypted inside the virtual machine. The protected configuration is useful when the execution command includes secrets such as a password or a shared access signature (SAS) file reference. Here's an example:

```
{  
    "apiVersion": "2018-06-01",  
    "type": "Microsoft.Compute/virtualMachines/extensions",  
    "name": "virtualMachineName/config-app",  
    "location": "[resourceGroup().location]",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'),copyindex())]",  
        "[variables('musicstoresqlName')]"  
    ],  
    "tags": {  
        "displayName": "config-app"  
    },  
    "properties": {  
        "publisher": "Microsoft.Compute",  
        "type": "CustomScriptExtension",  
        "typeHandlerVersion": "1.10",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "timestamp": 123456789  
        },  
        "protectedSettings": {  
            "commandToExecute": "myExecutionCommand",  
            "storageAccountName": "myStorageAccountName",  
            "storageAccountKey": "myStorageAccountKey",  
            "managedIdentity": {},  
            "fileUris": [  
                "script location"  
            ]  
        }  
    }  
}
```

### NOTE

The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

Only one version of an extension can be installed on a VM at a point in time. Specifying a custom script twice in the same Azure Resource Manager template for the same VM will fail.

You can use this schema inside the VM resource or as a standalone resource. The name of the resource has to be in the format `virtualMachineName/extensionName`, if this extension is used as a standalone resource in the Azure Resource Manager template.

### Property values

NAME	VALUE OR EXAMPLE	DATA TYPE
<code>apiVersion</code>	2015-06-15	date
<code>publisher</code>	Microsoft.Compute	string
<code>type</code>	CustomScriptExtension	string
<code>typeHandlerVersion</code>	1.10	int
<code>fileUris</code>	<a href="https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1">https://raw.githubusercontent.com/Microsoft/dotnet-core-sample-templates/master/dotnet-core-music-windows/scripts/configure-music-app.ps1</a>	
<code>timestamp</code>	123456789	32-bit integer
<code>commandToExecute</code>	powershell -ExecutionPolicy Unrestricted -File configure-music-app.ps1	string

NAME	VALUE OR EXAMPLE	DATA TYPE
<code>storageAccountName</code>	<code>examplestorageacct</code>	string
<code>storageAccountKey</code>	<code>TmJK/1N3AbAZ3q/+hOxoi/173zOqsaxXDhqa9t8singsUpXQp2DQIBuv2Tifp60cE/OaHsJZmQZ7teQfczQj8hg==</code>	
<code>managedIdentity</code>	<p>{ } or  { "clientId": "31b403aa-c364-4240-a7ff-d85fb6cd7232" }</p> <p>Or</p> <p>{ "objectId": "12dd289c-0583-46e5-b9b4-115d5c19ef4b" }</p>	JSON object

#### NOTE

These property names are case-sensitive. To avoid deployment problems, use the names as shown here.

#### Property value details

PROPERTY	OPTIONAL OR REQUIRED	DETAILS
<code>fileUris</code>	Optional	URLs for files to be downloaded. If URLs are sensitive (for example, they contain keys), this field should be specified in <code>protectedSettings</code> .
<code>commandToExecute</code>	Required	The entry point script to run. Use this property if your command contains secrets such as passwords or if your file URLs are sensitive.
<code>timestamp</code>	Optional	Change this value only to trigger a rerun of the script. Any integer value is acceptable, as long as it's different from the previous value.
<code>storageAccountName</code>	Optional	The name of storage account. If you specify storage credentials, all <code>fileUris</code> values must be URLs for Azure blobs.
<code>storageAccountKey</code>	Optional	The access key of the storage account.
<code>managedIdentity</code>	Optional	<p>The <a href="#">managed identity</a> for downloading files:</p> <p><code>clientId</code> (optional, string): The client ID of the managed identity.</p> <p><code>objectId</code> (optional, string): The object ID of the managed identity.</p>

You can set the following values in either public or protected settings. The extension will reject any configuration where these values are set in both public and protected settings.

- `commandToExecute`
- `fileUris`

Using public settings might be useful for debugging, but we recommend that you use protected settings.

Public settings are sent in clear text to the VM where the script will be run. Protected settings are encrypted through a key known only to Azure and the VM. The settings are saved to the VM as they were sent. That is, if the settings were encrypted, they're saved encrypted on the VM. The certificate that's used to decrypt the encrypted values is stored on the VM. The certificate is also used to decrypt settings (if necessary) at runtime.

#### Property: `managedIdentity`

#### NOTE

This property *must* be specified in protected settings only.

The Custom Script Extension (version 1.10 and later) supports [managed identities](#) for downloading files from URLs provided in the `fileUris` setting. It allows the Custom Script Extension to access Azure Storage private blobs or containers without the user having to pass secrets like SAS tokens or storage account keys.

To use this feature, the user must add a [system-assigned](#) or [user-assigned](#) identity to the VM or virtual machine scale set where the Custom Script Extension is expected to run. The user must then [grant the managed identity access to the Azure Storage container or blob](#).

To use the system-assigned identity on the target VM or virtual machine scale set, set `managedIdentity` to an empty JSON object.

Example:

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],  
    "commandToExecute": "powershell.exe script1.ps1",  
    "managedIdentity": {}  
}
```

To use the user-assigned identity on the target VM or virtual machine scale set, configure `managedIdentity` with the client ID or the object ID of the managed identity.

Examples:

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],  
    "commandToExecute": "powershell.exe script1.ps1",  
    "managedIdentity": { "clientId": "31b403aa-c364-4240-a7ff-d85fb6cd7232" }  
}
```

```
{  
    "fileUris": ["https://mystorage.blob.core.windows.net/privatecontainer/script1.ps1"],  
    "commandToExecute": "powershell.exe script1.ps1",  
    "managedIdentity": { "objectId": "12dd289c-0583-46e5-b9b4-115d5c19ef4b" }  
}
```

#### NOTE

The `managedIdentity` property *must not* be used in conjunction with the `storageAccountName` or `storageAccountKey` property.

## Template deployment

You can deploy Azure VM extensions by using Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Custom Script Extension during the template's deployment. The following samples show how to use the Custom Script Extension:

- [Tutorial: Deploy virtual machine extensions with Azure Resource Manager templates](#)
- [Deploy Two Tier Application on Windows and Azure SQL Database](#)

## PowerShell deployment

You can use the `Set-AzVMCustomScriptExtension` command to add the Custom Script Extension to an existing virtual machine. For more information, see [Set-AzVMCustomScriptExtension](#).

```
Set-AzVMCustomScriptExtension -ResourceGroupName <resourceGroupName> `  
    -VMName <vmName> `  
    -Location myLocation `  
    -FileUri <fileUrl> `  
    -Run 'myScript.ps1' `  
    -Name DemoScriptExtension
```

## Additional examples

### Using multiple scripts

In this example, you're using three scripts to build your server. The `commandToExecute` property calls the first script. You then have options on how the others are called. For example, you can have a master script that controls the execution, with the right error handling, logging, and state management. The scripts are downloaded to the local machine for execution.

For example, in `1_Add_Tools.ps1`, you would call `2_Add_Features.ps1` by adding `.\2_Add_Features.ps1` to the script. You would repeat this process for the other scripts that you define in `$settings`.

```

$fileUri = @("https://xxxxxxxx.blob.core.windows.net/buildServer1/1_Add_Tools.ps1",
"https://xxxxxxxx.blob.core.windows.net/buildServer1/2_Add_Features.ps1",
"https://xxxxxxxx.blob.core.windows.net/buildServer1/3_CompleteInstall.ps1")

$settings = @{$fileUris" = $fileUri};

$storageAcctName = "xxxxxxxx"
$storageKey = "1234ABCD"
$protectedSettings = @{$storageAcctName" = $storageAcctName; "storageAccountKey" = $storageKey;
"commandToExecute" = "powershell -ExecutionPolicy Unrestricted -File 1_Add_Tools.ps1"};

#run command
Set-AzVMExtension -ResourceGroupName <resourceGroupName> ` 
-Location <locationName> ` 
-VMName <vmName> ` 
-Name "buildserver1" ` 
-Publisher "Microsoft.Compute" ` 
-ExtensionType "CustomScriptExtension" ` 
-TypeHandlerVersion "1.10" ` 
-Settings $settings ` 
-ProtectedSettings $protectedSettings

```

### Running scripts from a local share

In this example, you might want to use a local Server Message Block (SMB) server for your script location. You then don't need to provide any other settings, except `commandToExecute`.

```

$protectedSettings = @{$"commandToExecute" = "powershell -ExecutionPolicy Unrestricted -File
\\filesrv\build\serverUpdate1.ps1"};

Set-AzVMExtension -ResourceGroupName <resourceGroupName> ` 
-Location <locationName> ` 
-VMName <vmName> ` 
-Name "serverUpdate" ` 
-Publisher "Microsoft.Compute" ` 
-ExtensionType "CustomScriptExtension" ` 
-TypeHandlerVersion "1.10" ` 
-ProtectedSettings $protectedSettings

```

### Running a custom script more than once by using the CLI

The Custom Script Extension handler will prevent rerunning a script if the *exact* same settings have been passed. This behavior prevents accidental rerunning, which might cause unexpected behaviors if the script isn't idempotent. You can confirm if the handler has blocked the rerunning by looking at `C:\Windows\Azure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension<HandlerVersion>\CustomScriptHandler.log` and searching for a warning like this one:

```
Current sequence number, <SequenceNumber>, is not greater than the sequence number of the most recently
executed configuration. Exiting...
```

If you want to run the Custom Script Extension more than once, you can do that only under these conditions:

- The extension's `Name` parameter is the same as the previous deployment of the extension.
- You've updated the configuration. You can add a dynamic property to the command, such as a timestamp. If the handler detects a change in the configuration settings, it will consider that change as an explicit desire to rerun the script.

Alternatively, you can set the `ForceUpdateTag` property to `true`.

### Using Invoke-WebRequest

If you're using `Invoke-WebRequest` in your script, you must specify the parameter `-UseBasicParsing`. If you don't specify the parameter, you'll get the following error when checking the detailed status:

```
The response content cannot be parsed because the Internet Explorer engine is not available, or Internet
Explorer's first-launch configuration is not complete. Specify the UseBasicParsing parameter and try again.
```

## Virtual machine scale sets

If you deploy the Custom Script Extension from the Azure portal, you don't have control over the expiration of the SAS token for accessing the script in your storage account. The result is that the initial deployment works, but when the storage account's SAS token expires, any subsequent scaling operation fails because the Custom Script Extension can no longer access the storage account.

We recommend that you use [PowerShell](#), the [Azure CLI](#), or an Azure Resource Manager template when you deploy the Custom Script Extension on a virtual machine scale set. This way, you can choose to use a managed identity or have direct control of the expiration of the SAS token for accessing the script in your storage account for as long as you need.

## Troubleshoot and support

You can retrieve data about the state of extension deployments from the Azure portal and by using the Azure PowerShell module. To see the deployment state of extensions for a VM, run the following command:

```
Get-AzVMExtension -ResourceGroupName <resourceGroupName> -VMName <vmName> -Name myExtensionName
```

Extension output is logged to files found under the following folder on the target virtual machine:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension
```

The specified files are downloaded into the following folder on the target virtual machine:

```
C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.*\Downloads\<n>
```

In the preceding path, `<n>` is a decimal integer that might change between executions of the extension. The `1.*` value matches the actual, current `typeHandlerVersion` value of the extension. For example, the actual directory could be `C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.8\Downloads\2`.

When you run the `commandToExecute` command, the extension sets this directory (for example, `...\Downloads\2`) as the current working directory. This process enables the use of relative paths to locate the files downloaded via the `fileURIs` property. Here are examples of downloaded files:

URI IN FILEURIS	RELATIVE DOWNLOAD LOCATION	ABSOLUTE DOWNLOAD LOCATION <sup>1</sup>
<code>https://someAcct.blob.core.windows.net/.scripts/myscript.ps1 cript.ps1</code>		<code>C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.8\Downloads\2\myscript.ps1 cript.ps1</code>
<code>https://someAcct.blob.core.windows.net/.topLevel.ps1 Level.ps1</code>		<code>C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.8\Downloads\2\topLevel.ps1 Level.ps1</code>

<sup>1</sup> The absolute directory paths change over the lifetime of the VM, but not within a single execution of the Custom Script Extension.

Because the absolute download path might vary over time, it's better to opt for relative script/file paths in the `commandToExecute` string, whenever possible. For example:

```
"commandToExecute": "powershell.exe . . . -File \"./scripts/myscript.ps1\""
```

Path information after the first URI segment is kept for files downloaded via the `fileURIs` property list. As shown in the earlier table, downloaded files are mapped into download subdirectories to reflect the structure of the `fileURIs` values.

## Support

If you need help with any part of this article, you can contact the Azure experts at [Azure Community Support](#).

You can also file an Azure support incident. Go to the [Azure support site](#) and select **Get support**. For information about using Azure support, read the [Microsoft Azure support FAQ](#).

# Microsoft Antimalware Extension for Windows

9/21/2022 • 5 minutes to read • [Edit Online](#)

## Overview

The modern threat landscape for cloud environments is extremely dynamic, increasing the pressure on business IT cloud subscribers to maintain effective protection in order to meet compliance and security requirements. Microsoft Antimalware for Azure is free real-time protection capability that helps identify and remove viruses, spyware, and other malicious software, with configurable alerts when known malicious or unwanted software attempts to install itself or run on your Azure systems. The solution is built on the same antimalware platform as Microsoft Security Essentials (MSE), Microsoft Forefront Endpoint Protection, Microsoft System Center Endpoint Protection, Windows Intune, and Windows Defender for Windows 8.0 and higher. Microsoft Antimalware for Azure is a single-agent solution for applications and tenant environments, designed to run in the background without human intervention. You can deploy protection based on the needs of your application workloads, with either basic secure-by-default or advanced custom configuration, including antimalware monitoring.

## Prerequisites

### Operating system

The Microsoft Antimalware for Azure solution includes the Microsoft Antimalware Client, and Service, Antimalware classic deployment model, Antimalware PowerShell cmdlets, and Azure Diagnostics Extension. The Microsoft Antimalware solution is supported on Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 operating system families. It is not supported on the Windows Server 2008 operating system, and also is not supported in Linux.

Windows Defender is the built-in Antimalware enabled in Windows Server 2016. The Windows Defender Interface is also enabled by default on some Windows Server 2016 SKU's. The Azure VM Antimalware extension can still be added to a Windows Server 2016 Azure VM with Windows Defender, but in this scenario the extension will apply any optional configuration policies to be used by Windows Defender, the extension will not deploy any additional antimalware service. For more information, see [Update to Azure Antimalware Extension for Cloud Services](#).

### Internet connectivity

The Microsoft Antimalware for Windows requires that the target virtual machine is connected to the internet to receive regular engine and signature updates.

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration such as onboarding to Azure Antimalware.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the VM extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(parameters('vmName'), '/', parameters('vmExtensionName'))]",
  "apiVersion": "2019-07-01",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', parameters('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Security",
    "type": "IaaSAntimalware",
    "typeHandlerVersion": "1.3",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "AntimalwareEnabled": "true",
      "Exclusions": {
        "Extensions": ".ext1;.ext2",
        "Paths": "c:\excluded-path-1;c:\excluded-path-2",
        "Processes": "excludedproc1.exe;excludedproc2.exe"
      },
      "RealtimeProtectionEnabled": "true",
      "ScheduledScanSettings": {
        "isEnabled": "true",
        "scanType": "Quick",
        "day": "7",
        "time": "120"
      }
    },
    "protectedSettings": null
  }
}
```

You must include, at a minimum, the following content to enable the Microsoft Antimalware extension:

```
{ "AntimalwareEnabled": true }
```

Microsoft Antimalware JSON configuration sample:

```
{
  "AntimalwareEnabled": true,
  "RealtimeProtectionEnabled": true,
  "ScheduledScanSettings": {
    "isEnabled": true,
    "day": 1,
    "time": 120,
    "scanType": "Full"
  },
  "Exclusions": {
    "Extensions": ".ext1;.ext2",
    "Paths": "c:\excluded-path-1;c:\excluded-path-2",
    "Processes": "excludedproc1.exe;excludedproc2.exe"
  }
}
```

#### AntimalwareEnabled

- required parameter
- Values: true/false
  - true = Enable
  - false = Error out, as false is not a supported value

#### RealtimeProtectionEnabled

- Values: true/false, default is true
  - true = Enable
  - false = Disable

## ScheduledScanSettings

- isEnabled = true/false
- day = 0-8 (0=daily, 1=Sunday, 2=Monday, ..., 7=Saturday, 8=Disabled)
- time = 0-1440 (measured in minutes after midnight - 60->1AM, 120 -> 2AM, ... )
- scanType = Quick/Full, default is Quick
- If isEnabled = true is the only setting provided, the following defaults are set: day=7 (Saturday), time=120 (2 AM), scanType="Quick"

## Exclusions

- Multiple exclusions in the same list are specified by using semicolon delimiters
- If no exclusions are specified, then the existing exclusions, if any, are overwritten by blank on the system

## PowerShell deployment

Depends on your type of deployment, use the corresponding commands to deploy the Azure Antimalware virtual machine extension to an existing virtual machine.

- [Azure Resource Manager based Virtual Machine](#)
- [Azure Service Fabric Clusters](#)
- [Classic Cloud Service](#)

## Troubleshoot and support

### Troubleshoot

Microsoft Antimalware extension logs are available at -

%Systemdrive%\WindowsAzure\Logs\Plugins\Microsoft.Azure.Security.IaaSAntimalware(Or  
PaaSAntimalware)\1.5.5.x(version#)\CommandExecution.log

### Error codes and their meanings

ERROR CODE	MEANING	POSSIBLE ACTION
-2147156224	MSI is busy with different installation	Try running installation later
-2147156221	MSE setup already running	Run only one instance at a time
-2147156208	Low disk space < 200 MB	Delete unused files, and retry installation
-2147156187	Last installation, upgrade, update, or uninstall requested reboot	Reboot, and retry installation
-2147156121	Setup tried to remove competitor product. But competitor product uninstall failed	Try to remove the competitor product manually, reboot, and retry installation
-2147156116	Policy file validation failed	Make sure you pass a valid policy XML file to setup
-2147156095	Setup couldn't start the Antimalware service	Verify all binaries are correctly signed, and right licensing file is installed

ERROR CODE	MEANING	POSSIBLE ACTION
-2147023293	A fatal error occurred during installation. In most cases, it will. Epp.msi, can't register\start\stop AM service or mini filter driver	MSI logs from EPP.msi are required here for future investigation
-2147023277	Installation package could not be opened	Verify that the package exists, and is accessible, or contact the application vendor to verify that this is a valid Windows Installer package
-2147156109	Windows Defender is required as a prerequisite

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#), and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# VM Snapshot Linux extension for Azure Backup

9/21/2022 • 3 minutes to read • [Edit Online](#)

Azure Backup provides support for backing up workloads from on-premises to cloud and backing up cloud resources to Recovery Services vault. Azure Backup uses VM snapshot extension to take an application consistent backup of the Azure virtual machine without the need to shutdown the VM. VM Snapshot Linux extension is published and supported by Microsoft as part of Azure Backup service. Azure Backup will install the extension as part of first scheduled backup triggered post enabling backup. This document details the supported platforms, configurations, and deployment options for the VM Snapshot extension.

The VMSnapshot extension appears in the Azure portal only for non-managed VMs.

## Prerequisites

### Operating system

For a list of supported operating systems, please refer to [Operating Systems supported by Azure Backup](#)

## Extension schema

The following JSON shows the schema for the VM snapshot extension. The extension requires the task ID - this identifies the backup job which triggered snapshot on the VM, status blob uri - where status of the snapshot operation is written, scheduled start time of the snapshot, logs blob uri - where logs corresponding to snapshot task are written, objstr- representation of VM disks and meta data. Because these settings should be treated as sensitive data, it should be stored in a protected setting configuration. Azure VM extension protected setting data is encrypted, and only decrypted on the target virtual machine. Please note that these settings are recommended to be passed from Azure Backup service only as part of Backup job.

```
{
  "type": "extensions",
  "name": "VMSnapshot",
  "location": "<myLocation>",
  "properties": {
    "publisher": "Microsoft.RecoveryServices",
    "type": "VMSnapshot",
    "typeHandlerVersion": "1.9",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "locale": "<location>",
      "taskId": "<taskId used by Azure Backup service to communicate with extension>",
      "commandToExecute": "snapshot",
      "commandStartTimeUTCTicks": "<scheduled start time of the snapshot task>",
      "vmType": "microsoft.compute/virtualmachines"
    },
    "protectedSettings": {
      "objectStr": "<blob SAS uri representation of VM sent by Azure Backup service to extension>",
      "logsBlobUri": "<blob uri where logs of command execution by extension are written to>",
      "statusBlobUri": "<blob uri where status of the command executed by extension is written>"
    }
  }
}
```

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. However, the recommended way of adding a VM snapshot extension to a virtual machine is by enabling backup on the virtual machine. This can be achieved through a Resource Manager template. A sample Resource Manager template that enables backup on a virtual machine can be found on the [Azure Quick Start Gallery](#).

## Azure CLI deployment

The Azure CLI can be used to enable backup on a virtual machine. Post enable backup, first scheduled backup job will install the Vm snapshot extension on the VM.

```
az backup protection enable-for-vm \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--vm myVM \
--policy-name DefaultPolicy
```

## Azure PowerShell deployment

Azure PowerShell can be used to enable backup on a virtual machine. Once the backup is configured, first scheduled backup job will install the Vm snapshot extension on the VM.

```
$targetVault = Get-AzRecoveryServicesVault -ResourceGroupName "myResourceGroup" -Name "myRecoveryServicesVault"
$pol = Get-AzRecoveryServicesBackupProtectionPolicy Name DefaultPolicy -VaultId $targetVault.ID
Enable-AzRecoveryServicesBackupProtection -Policy $pol -Name "myVM" -ResourceGroupName "myVMResourceGroup" -VaultId $targetVault.ID
```

# Troubleshoot and support

## Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
/var/log/waagent.log
```

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. However, the recommended way of adding a VM snapshot extension to a virtual machine is by enabling backup on the virtual machine. This can be achieved through a Resource Manager template. A sample Resource Manager template that enables backup on a virtual machine can be found on the [Azure Quick Start Gallery](#).

## Azure CLI deployment

The Azure CLI can be used to enable backup on a virtual machine. Post enable backup, first scheduled backup job will install the Vm snapshot extension on the VM.

```
az backup protection enable-for-vm \
--resource-group myResourceGroup \
--vault-name myRecoveryServicesVault \
--vm myVM \
--policy-name DefaultPolicy
```

## Azure PowerShell deployment

Azure PowerShell can be used to enable backup on a virtual machine. Once the backup is configured, first scheduled backup job will install the Vm snapshot extension on the VM.

```
$targetVault = Get-AzRecoveryServicesVault -ResourceGroupName "myResourceGroup" -Name "myRecoveryServicesVault"
$pol = Get-AzRecoveryServicesBackupProtectionPolicy Name DefaultPolicy -VaultId $targetVault.ID
Enable-AzRecoveryServicesBackupProtection -Policy $pol -Name "myVM" -ResourceGroupName "myVMResourceGroup" -VaultId $targetVault.ID
```

# Troubleshoot and support

## Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot
```

## Error codes and their meanings

Troubleshooting information can be found on the [Azure VM backup troubleshooting guide](#).

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Network Watcher Agent virtual machine extension for Linux

9/21/2022 • 2 minutes to read • [Edit Online](#)

## Overview

[Azure Network Watcher](#) is a network performance monitoring, diagnostic, and analytics service that allows monitoring for Azure networks. The Network Watcher Agent virtual machine (VM) extension is a requirement for some of the Network Watcher features on Azure VMs, such as capturing network traffic on demand, and other advanced functionality.

This article details the supported platforms and deployment options for the Network Watcher Agent VM extension for Linux. Installation of the agent does not disrupt, or require a reboot, of the VM. You can deploy the extension into virtual machines that you deploy. If the virtual machine is deployed by an Azure service, check the documentation for the service to determine whether or not it permits installing extensions in the virtual machine.

## Prerequisites

### Operating system

The Network Watcher Agent extension can be configured for the following Linux distributions:

DISTRIBUTION	VERSION
Ubuntu	12+
Debian	7 and 8
Red Hat	6 and 7
Oracle Linux	6.8+, 7 and 8+
SUSE Linux Enterprise Server	11, 12 and 15
OpenSUSE Leap	42.3+
CentOS	6.5+ and 7
CoreOS	899.17.0+

### Internet connectivity

Some of the Network Watcher Agent functionality requires that a VM is connected to the Internet. Without the ability to establish outgoing connections, some of the Network Watcher Agent features may malfunction, or become unavailable. For more information about Network Watcher functionality that requires the agent, see the [Network Watcher documentation](#).

## Extension schema

The following JSON shows the schema for the Network Watcher Agent extension. The extension doesn't require,

or support, any user-supplied settings. The extension relies on its default configuration.

```
{  
  "type": "extensions",  
  "name": "Microsoft.Azure.NetworkWatcher",  
  "apiVersion": "[variables('apiVersion')]",  
  "location": "[resourceGroup().location]",  
  "dependsOn": [  
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"  
  ],  
  "properties": {  
    "publisher": "Microsoft.Azure.NetworkWatcher",  
    "type": "NetworkWatcherAgentLinux",  
    "typeHandlerVersion": "1.4",  
    "autoUpgradeMinorVersion": true  
  }  
}
```

## Property values

NAME	VALUE / EXAMPLE
apiVersion	2015-06-15
publisher	Microsoft.Azure.NetworkWatcher
type	NetworkWatcherAgentLinux
typeHandlerVersion	1.4

## Template deployment

You can deploy Azure VM extensions with an Azure Resource Manager template. To deploy the Network Watcher Agent extension, use the previous json schema in your template.

## Azure classic CLI deployment

### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

The following example deploys the Network Watcher Agent VM extension to an existing VM deployed through the classic deployment model:

```
azure config mode asm  
azure vm extension set myVM1 NetworkWatcherAgentLinux Microsoft.Azure.NetworkWatcher 1.4
```

## Azure CLI deployment

The following example deploys the Network Watcher Agent VM extension to an existing VM deployed through Resource Manager:

```
az vm extension set --resource-group myResourceGroup1 --vm-name myVM1 --name NetworkWatcherAgentLinux --publisher Microsoft.Azure.NetworkWatcher --version 1.4
```

## Troubleshooting and support

### Troubleshooting

You can retrieve data about the state of extension deployments using either the Azure portal or Azure CLI.

The following example shows the deployment state of the NetworkWatcherAgentLinux extension for a VM deployed through Resource Manager, using the Azure CLI:

```
az vm extension show --name NetworkWatcherAgentLinux --resource-group myResourceGroup1 --vm-name myVM1
```

### Support

If you need more help at any point in this article, you can refer to the [Network Watcher documentation](#), or contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select **Get support**. For information about using Azure Support, see the [Microsoft Azure support FAQ](#).

# Network Watcher Agent virtual machine extension for Windows

9/21/2022 • 2 minutes to read • [Edit Online](#)

## Overview

[Azure Network Watcher](#) is a network performance monitoring, diagnostic, and analytics service that allows monitoring of Azure networks. The Network Watcher Agent virtual machine extension is a requirement for capturing network traffic on demand, and other advanced functionality on Azure virtual machines.

This document details the supported platforms and deployment options for the Network Watcher Agent virtual machine extension for Windows. Installation of the agent does not disrupt, or require a reboot, of the virtual machine. You can deploy the extension into virtual machines that you deploy. If the virtual machine is deployed by an Azure service, check the documentation for the service to determine whether or not it permits installing extensions in the virtual machine.

## Prerequisites

### Operating system

The Network Watcher Agent extension for Windows can be run against Windows Server 2008 R2, 2012, 2012 R2, 2016 and 2019 releases. Nano Server is not supported at this time.

### Internet connectivity

Some of the Network Watcher Agent functionality requires that the target virtual machine be connected to the Internet. Without the ability to establish outgoing connections, the Network Watcher Agent will not be able to upload packet captures to your storage account. For more details, please see the [Network Watcher documentation](#).

## Extension schema

The following JSON shows the schema for the Network Watcher Agent extension. The extension neither requires, nor supports, any user-supplied settings, and relies on its default configuration.

```
{
  "type": "extensions",
  "name": "Microsoft.Azure.NetworkWatcher",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.NetworkWatcher",
    "type": "NetworkWatcherAgentWindows",
    "typeHandlerVersion": "1.4",
    "autoUpgradeMinorVersion": true
  }
}
```

## Property values

NAME	VALUE / EXAMPLE
apiVersion	2015-06-15
publisher	Microsoft.Azure.NetworkWatcher
type	NetworkWatcherAgentWindows
typeHandlerVersion	1.4

## Template deployment

You can deploy Azure VM extensions with Azure Resource Manager templates. You can use the JSON schema detailed in the previous section in an Azure Resource Manager template to run the Network Watcher Agent extension during an Azure Resource Manager template deployment.

## PowerShell deployment

Use the `Set-AzVMExtension` command to deploy the Network Watcher Agent virtual machine extension to an existing virtual machine:

```
Set-AzVMExtension ` 
-ResourceGroupName "myResourceGroup1" ` 
-Location "WestUS" ` 
-VMName "myVM1" ` 
-Name "networkWatcherAgent" ` 
-Publisher "Microsoft.Azure.NetworkWatcher" ` 
-Type "NetworkWatcherAgentWindows" ` 
-TypeHandlerVersion "1.4"
```

## Troubleshooting and support

### Troubleshooting

You can retrieve data about the state of extension deployments from the Azure portal and PowerShell. To see the deployment state of extensions for a given VM, run the following command using the Azure PowerShell module:

```
Get-AzVMExtension -ResourceGroupName myResourceGroup1 -VMName myVM1 -Name networkWatcherAgent
```

Extension execution output is logged to files found in the following directory:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.NetworkWatcher.NetworkWatcherAgentWindows\
```

### Support

If you need more help at any point in this article, you can refer to the Network Watcher User Guide documentation or contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Update the Network Watcher extension to the latest version

9/21/2022 • 4 minutes to read • [Edit Online](#)

## Overview

Azure Network Watcher is a network performance monitoring, diagnostic, and analytics service that monitors Azure networks. The Network Watcher Agent virtual machine (VM) extension is a requirement for capturing network traffic on demand and using other advanced functionality on Azure VMs. The Network Watcher extension is used by features like Connection Monitor, Connection Monitor (preview), connection troubleshoot, and packet capture.

## Prerequisites

This article assumes you have the Network Watcher extension installed in your VM.

## Latest version

The latest version of the Network Watcher extension is currently [1.4.2146.1](#).

## Update your extension using a PowerShell script

Customers with large deployments who need to update multiple VMs at once. For updating select VMs manually, please see the next section

```
<#
 .SYNOPSIS
 This script will scan all VMs in the provided subscription and upgrade any out of date
 AzureNetworkWatcherExtensions

 .DESCRIPTION
 This script should be no-op if AzureNetworkWatcherExtensions are up to date
 Requires Azure PowerShell 4.2 or higher to be installed (e.g. Install-Module AzureRM).

 .EXAMPLE
 .\UpdateVMAgentsInSub.ps1 -SubID F4BC4873-5DAB-491E-B713-1358EF4992F2 -NoUpdate

 #>
 [CmdletBinding()]
 param(
     [Parameter(Mandatory=$true)]
     [string] $SubID,
     [Parameter(Mandatory=$false)]
     [Switch] $NoUpdate = $false,
     [Parameter(Mandatory=$false)]
     [string] $MinVersion = "1.4.1974.1"
 )

 function NeedsUpdate($version)
 {
     if ($version -eq $MinVersion)
     {
         return $false
     }
 }
```

```

$lessThan = $true;
$versionParts = $version -split '\.';
$minVersionParts = $MinVersion -split '\.';
for ($i = 0; $i -lt $versionParts.Length; $i++)
{
    if ([int]$versionParts[$i] -gt [int]$minVersionParts[$i])
    {
        $lessThan = $false;
        break;
    }
}

return $lessThan
}

Write-Host "Scanning all VMs in the subscription: $($SubID)"
Select-AzSubscription -SubscriptionId $SubID;
$vms = Get-AzVM;
$foundVMs = $false;
Write-Host "Starting VM search, this may take a while"

foreach ($vmName in $vms)
{
    # Get Detailed VM info
    $vm = Get-AzVM -ResourceGroupName $vmName.ResourceGroupName -Name $vmName.name -Status;
    $isWindows = $vm.OsVersion -match "Windows";
    foreach ($extension in $vm.Extensions)
    {
        if ($extension.Name -eq "AzureNetworkWatcherExtension")
        {
            if (NeedsUpdate($extension.TypeHandlerVersion))
            {
                $foundVMs = $true;
                if (-not ($NoUpdate))
                {
                    Write-Host "Found VM that needs to be updated:
subscriptions/$($SubID)/resourceGroups/$($vm.ResourceGroupName)/providers/Microsoft.Compute/virtualMachines/
 $($vm.Name) -> Updating " -NoNewline
                    Remove-AzVMEExtension -ResourceGroupName $vm.ResourceGroupName -VMName $vm.Name -Name
"AzureNetworkWatcherExtension" -Force
                    Write-Host "... " -NoNewline
                    $type = if ($isWindows) { "NetworkWatcherAgentWindows" } else {
"NetworkWatcherAgentLinux" };
                    Set-AzVMEExtension -ResourceGroupName $vm.ResourceGroupName -Location $vmName.Location -
VMName $vm.Name -Name "AzureNetworkWatcherExtension" -Publisher "Microsoft.Azure.NetworkWatcher" -Type $type
-typeHandlerVersion "1.4"
                    Write-Host "Done"
                }
                else
                {
                    Write-Host "Found $($if ($isWindows) {"Windows"} else {"Linux"}) VM that needs to be
updated:
subscriptions/$($SubID)/resourceGroups/$($vm.ResourceGroupName)/providers/Microsoft.Compute/virtualMachines/
 $($vm.Name)"
                }
            }
        }
    }
}

if ($foundVMs)
{
    Write-Host "Finished $($if ($NoUpdate) {"searching"} else {"updating"}) out of date
AzureNetworkWatcherExtension on VMs"
}
else
{
    Write-Host "All AzureNetworkWatcherExtensions up to date"
}

```

# Update your extension manually

To update your extension, you need to know your extension version.

## Check your extension version

You can check your extension version by using the Azure portal, the Azure CLI, or PowerShell.

### Use the Azure portal

1. Go to the Extensions pane of your VM in the Azure portal.
2. Select the **AzureNetworkWatcher** extension to see the details pane.
3. Locate the version number in the **Version** field.

### Use the Azure CLI

Run the following command from an Azure CLI prompt:

```
az vm get-instance-view --resource-group "SampleRG" --name "Sample-VM"
```

Locate "AzureNetworkWatcherExtension" in the output and identify the version number from the "TypeHandlerVersion" field in the output. Please note: Information about the extension appears multiple times in the JSON output. Please look under the "extensions" block and you should see the full version number of the extension.

You should see something like the below:

```
{  
  "status": {  
    "code": "ProvisioningState/succeeded",  
    "displayStatus": "Ready",  
    "level": "Info",  
    "message": null,  
    "time": null  
  },  
  "type": "Microsoft.Azure.NetworkWatcher.NetworkWatcherAgentWindows",  
  "typeHandlerVersion": "1.4.1654.1"  
},
```

### Use PowerShell

Run the following commands from a PowerShell prompt:

```
Get-AzVM -ResourceGroupName "SampleRG" -Name "Sample-VM" -Status
```

Locate the Azure Network Watcher extension in the output and identify the version number from the "TypeHandlerVersion" field in the output.

You should see something like the below:

```
ExtensionHandlers[1] :  
  Type : Microsoft.Azure.NetworkWatcher.NetworkWatcherAgentWindows  
  TypeHandlerVersion : 1.4.1654.1  
  Status :  
  Code : ProvisioningState/succeeded  
  Level : Info
```

## Update your extension

If your version is below the latest version mentioned above, update your extension by using any of the following options.

#### Option 1: Use PowerShell

Run the following commands:

```
#Linux command
Set-AzVMExtension -ResourceGroupName "myResourceGroup1" -Location "WestUS" -VMName "myVM1" -Name
"AzureNetworkWatcherExtension" -Publisher "Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentLinux"

#Windows command
Set-AzVMExtension -ResourceGroupName "myResourceGroup1" -Location "WestUS" -VMName "myVM1" -Name "
AzureNetworkWatcherExtension" -Publisher "Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentWindows"
-ForceRerun "True"
```

If that doesn't work, remove and install the extension again, using the steps below. This will automatically add the latest version.

Removing the extension

```
#Same command for Linux and Windows
Remove-AzVMExtension -ResourceGroupName "SampleRG" -VMName "Sample-VM" -Name "AzureNetworkWatcherExtension"
```

Installing the extension again

```
#Linux command
Set-AzVMExtension -ResourceGroupName "SampleRG" -Location "centralus" -VMName "Sample-VM" -Name
"AzureNetworkWatcherExtension" -Publisher "Microsoft.Azure.NetworkWatcher" -Type "NetworkWatcherAgentLinux"
-typeHandlerVersion "1.4"

#Windows command
Set-AzVMExtension -ResourceGroupName "SampleRG" -Location "centralus" -VMName "Sample-VM" -Name
"AzureNetworkWatcherExtension" -Publisher "Microsoft.Azure.NetworkWatcher" -Type
"NetworkWatcherAgentWindows" -typeHandlerVersion "1.4"
```

#### Option 2: Use the Azure CLI

Force an upgrade.

```
#Linux command
az vm extension set --resource-group "myResourceGroup1" --vm-name "myVM1" --name "NetworkWatcherAgentLinux"
--publisher "Microsoft.Azure.NetworkWatcher" --force-update

#Windows command
az vm extension set --resource-group "myResourceGroup1" --vm-name "myVM1" --name
"NetworkWatcherAgentWindows" --publisher "Microsoft.Azure.NetworkWatcher" --force-update
```

If that doesn't work, remove and install the extension again, and follow these steps to automatically add the latest version.

Remove the extension.

```
#Same for Linux and Windows
az vm extension delete --resource-group "myResourceGroup1" --vm-name "myVM1" -n
"AzureNetworkWatcherExtension"
```

Install the extension again.

```
#Linux command  
az vm extension set --resource-group "DALANDEMO" --vm-name "Linux-01" --name "NetworkWatcherAgentLinux" --  
publisher "Microsoft.Azure.NetworkWatcher"  
  
#Windows command  
az vm extension set --resource-group "DALANDEMO" --vm-name "Linux-01" --name "NetworkWatcherAgentWindows" --  
publisher "Microsoft.Azure.NetworkWatcher"
```

#### Option 3: Reboot your VMs

If you have auto-upgrade set to true for the Network Watcher extension, reboot your VM installation to the latest extension.

## Support

If you need more help at any point in this article, see the Network Watcher extension documentation for [Linux](#) or [Windows](#). You can also contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, file an Azure support incident. Go to the [Azure support site](#), and select **Get support**. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# InfiniBand Driver Extension for Linux

9/21/2022 • 3 minutes to read • [Edit Online](#)

This extension installs InfiniBand OFED drivers on InfiniBand and SR-IOV-enabled ('r' sizes) [H-series](#) and [N-series](#) VMs running Linux. Depending on the VM family, the extension installs the appropriate drivers for the Connect-X NIC. It does not install the InfiniBand ND drivers on the non-SR-IOV enabled [H-series](#) and [N-series](#) VMs.

Instructions on manual installation of the OFED drivers are available in [Enable InfiniBand on HPC VMs](#).

An extension is also available to install InfiniBand drivers for [Windows VMs](#).

## Prerequisites

### Operating system

This extension supports the following OS distros, depending on driver support for specific OS version.

DISTRIBUTION	VERSION	INFINIBAND NIC DRIVERS
Ubuntu	16.04 LTS, 18.04 LTS, 20.04 LTS	CX3-Pro, CX5, CX6
CentOS	7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.1, 8.2	CX3-Pro, CX5, CX6
Red Hat Enterprise Linux	7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.1, 8.2	CX3-Pro, CX5, CX6

For latest list of supported OS and driver versions, refer to [resources.json](#)

### Internet connectivity

The Microsoft Azure Extension for InfiniBand Drivers requires that the target VM is connected to and has access to the internet.

## Extension schema

The following JSON shows the schema for the extension.

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverLinux",
    "typeHandlerVersion": "1.2",
    "autoUpgradeMinorVersion": true,
    "settings": {}
  }
}
```

## Properties

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	InfiniBandDriverLinux	string
typeHandlerVersion	1.2	int

## Deployment

### Azure Resource Manager Template

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{  
  "name": "myExtensionName",  
  "type": "extensions",  
  "location": "[resourceGroup().location]",  
  "apiVersion": "2015-06-15",  
  "dependsOn": [  
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"  
  ],  
  "properties": {  
    "publisher": "Microsoft.HpcCompute",  
    "type": "InfiniBandDriverLinux",  
    "typeHandlerVersion": "1.2",  
    "autoUpgradeMinorVersion": true,  
    "settings": {}  
  }  
}
```

### PowerShell

```
Set-AzVMEextension  
  -ResourceGroupName "myResourceGroup" `  
  -VMName "myVM" `  
  -Location "southcentralus" `  
  -Publisher "Microsoft.HpcCompute" `  
  -ExtensionName "InfiniBandDriverLinux" `  
  -ExtensionType "InfiniBandDriverLinux" `  
  -TypeHandlerVersion 1.2 `  
  -SettingString '{ '  
}'
```

### Azure CLI

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name InfiniBandDriverLinux \
--publisher Microsoft.HpcCompute \
--version 1.2
```

## Add extension to a Virtual Machine Scale Set

The following example installs the latest version 1.2 InfiniBandDriverLinux extension on all RDMA-capable VMs in an existing virtual machine scale set named *myVMSS* deployed in the resource group named *myResourceGroup*:

```
$VMSS = Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
Add-AzVmssExtension -VirtualMachineScaleSet $VMSS -Name "InfiniBandDriverLinux" -Publisher
"Microsoft.HpcCompute" -Type "InfiniBandDriverLinux" -TypeHandlerVersion "1.2"
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "MyVMSS" -VirtualMachineScaleSet $VMSS
Update-AzVmssInstance -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS" -InstanceId "*"
```

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using Azure PowerShell and Azure CLI. To see the deployment state of extensions for a given VM, run the following command.

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of the installation as well as for troubleshooting any failures.

```
/var/log/azure/ib-vmext-status
```

### Exit codes

The following table describes the meaning and recommended action based on the exit codes of the extension installation process.

EXIT CODE	MEANING	POSSIBLE ACTION
0	Operation successful	
1	Incorrect usage of extension	Check execution output log
10	Linux Integration Services for Hyper-V and Azure not available or installed	Check output of lspci
11	Mellanox InfiniBand not found on this VM size	Use a <a href="#">supported VM size and OS</a>

EXIT CODE	MEANING	POSSIBLE ACTION
12	Image offer not supported	
13	VM size not supported	Use an InfiniBand-enabled ('r' size) <a href="#">H-series</a> and <a href="#">N-series</a> VM to deploy
14	Operation unsuccessful	Check execution output log

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file a support incident through the [Azure support site](#). For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

## Next steps

For more information about InfiniBand-enabled ('r' sizes), see [H-series](#) and [N-series](#) VMs.

[Learn more about Linux VMs extensions and features](#)

# InfiniBand Driver Extension for Windows

9/21/2022 • 3 minutes to read • [Edit Online](#)

This extension installs InfiniBand ND drivers (for non-SR-IOV enabled) and OFED drivers (for SR-IOV-enabled) ('r' sizes) [H-series](#) and [N-series](#) VMs running Windows. Depending on the VM family, the extension installs the appropriate drivers for the Connect-X NIC.

An extension is also available to install InfiniBand drivers for [Linux VMs](#).

## Prerequisites

### Operating system

This extension supports the following OS distros, depending on driver support for specific OS version. Note the appropriate InfiniBand NIC for the H and N-series VM sizes of interest.

DISTRIBUTION	INFINIBAND NIC DRIVERS
Windows 10	CX3-Pro, CX5, CX6
Windows Server 2019	CX3-Pro, CX5, CX6
Windows Server 2016	CX3-Pro, CX5, CX6
Windows Server 2012 R2	CX3-Pro, CX5, CX6
Windows Server 2012	CX3-Pro, CX5, CX6

For latest list of supported OS and driver versions, refer to [resources.json](#)

### Internet connectivity

The Microsoft Azure Extension for InfiniBand Drivers requires that the target VM is connected to and has access to the internet.

## Extension schema

The following JSON shows the schema for the extension.

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverWindows",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

## Properties

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	InfiniBandDriverWindows	string
typeHandlerVersion	1.5	int

## Deployment

### Azure Resource Manager Template

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{
  "name": "myExtensionName",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2015-06-15",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "InfiniBandDriverWindows",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

## PowerShell

```
Set-AzVMExtension
  -ResourceGroupName "myResourceGroup" ` 
  -VMName "myVM" ` 
  -Location "southcentralus" ` 
  -Publisher "Microsoft.HpcCompute" ` 
  -ExtensionName "InfiniBandDriverWindows" ` 
  -ExtensionType "InfiniBandDriverWindows" ` 
  -TypeHandlerVersion 1.5 ` 
  -SettingString '{` 
}'
```

## Azure CLI

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name InfiniBandDriverWindows \
  --publisher Microsoft.HpcCompute \
  --version 1.5
```

## Add extension to a Virtual Machine Scale Set

The following example installs the latest version 1.5 InfiniBandDriverWindows extension on all RDMA-capable VMs in an existing virtual machine scale set named *myVMSS* deployed in the resource group named *myResourceGroup*.

```
$VMSS = Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS"
Add-AzVmssExtension -VirtualMachineScaleSet $VMSS -Name "InfiniBandDriverWindows" -Publisher
"Microsoft.HpcCompute" -Type "InfiniBandDriverWindows" -TypeHandlerVersion "1.5"
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "MyVMSS" -VirtualMachineScaleSet $VMSS
Update-AzVmssInstance -ResourceGroupName "myResourceGroup" -VMScaleSetName "myVMSS" -InstanceId "*"
```

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using Azure PowerShell and Azure CLI. To see the deployment state of extensions for a given VM, run the following command.

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of the installation as well as for troubleshooting any failures.

```
C:\WindowsAzure\Logs\Plugins\Microsoft.HpcCompute.InfiniBandDriverWindows\
```

## Exit codes

The following table describes the meaning and recommended action based on the exit codes of the extension installation process.

ERROR CODE	MEANING	POSSIBLE ACTION
0	Operation successful	
3010	Operation successful. Reboot required.	
100	Operation not supported or could not be completed.	Possible causes: PowerShell version not supported, VM size is not an InfiniBand-enabled VM, Failure downloading data. Check the log files to determine cause of error.
240, 840	Operation timeout.	Retry operation.
-1	Exception occurred.	Check the log files to determine cause of exception.

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file a support incident through the [Azure support site](#). For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

## Next steps

For more information about InfiniBand-enabled ('r' sizes), see [H-series](#) and [N-series](#) VMs.

[Learn more about Linux VMs extensions and features](#)

# NVIDIA GPU Driver Extension for Linux

9/21/2022 • 4 minutes to read • [Edit Online](#)

This extension installs NVIDIA GPU drivers on Linux N-series virtual machines (VMs). Depending on the VM family, the extension installs CUDA or GRID drivers. When you install NVIDIA drivers by using this extension, you're accepting and agreeing to the terms of the [NVIDIA End-User License Agreement](#). During the installation process, the VM might reboot to complete the driver setup.

Instructions on manual installation of the drivers and the current supported versions are available. For more information, see [Azure N-series GPU driver setup for Linux](#). An extension is also available to install NVIDIA GPU drivers on [Windows N-series VMs](#).

## Prerequisites

### Operating system

This extension supports the following OS distros, depending on driver support for the specific OS version:

DISTRIBUTION	VERSION
Linux: Ubuntu	16.04 LTS, 18.04 LTS, 20.04 LTS
Linux: Red Hat Enterprise Linux	7.3, 7.4, 7.5, 7.6, 7.7, 7.8
Linux: CentOS	7.3, 7.4, 7.5, 7.6, 7.7, 7.8

#### NOTE

The latest supported CUDA drivers for NC-series VMs are currently 470.82.01. Later driver versions aren't supported on the K80 cards in NC. While the extension is being updated with this end of support for NC, install CUDA drivers manually for K80 cards on the NC-series.

### Internet connectivity

The Microsoft Azure Extension for NVIDIA GPU Drivers requires that the target VM is connected to the internet and has access.

## Extension schema

The following JSON shows the schema for the extension:

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "NvidiaGpuDriverLinux",
    "typeHandlerVersion": "1.6",
    "autoUpgradeMinorVersion": true,
    "settings": {
    }
  }
}
```

## Properties

NAME	VALUE/EXAMPLE	DATA TYPE
apiVersion	2015-06-15	date
publisher	Microsoft.HpcCompute	string
type	NvidiaGpuDriverLinux	string
typeHandlerVersion	1.6	int

## Settings

All settings are optional. The default behavior is to not update the kernel if not required for driver installation and install the latest supported driver and the CUDA toolkit (as applicable).

NAME	DESCRIPTION	DEFAULT VALUE	VALID VALUES	DATA TYPE
updateOS	Update the kernel even if not required for driver installation.	false	true, false	boolean
driverVersion	NV: GRID driver version. NC/ND: CUDA toolkit version. The latest drivers for the chosen CUDA are installed automatically.	latest	<a href="#">List</a> of supported driver versions	string
installCUDA	Install CUDA toolkit. Only relevant for NC/ND series VMs.	true	true, false	boolean

## Deployment

### Azure portal

You can deploy Azure NVIDIA VM extensions in the Azure portal.

1. In a browser, go to the [Azure portal](#).
2. Go to the virtual machine on which you want to install the driver.
3. On the left menu, select **Extensions**.

**MyTestVM - Microsoft Azure**

## Azure Resource Manager template

You can use Azure Resource Manager templates to deploy Azure VM extensions. Templates are ideal when you deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{  
  "name": "myExtensionName",  
  "type": "extensions",  
  "location": "[resourceGroup().location]",  
  "apiVersion": "2015-06-15",  
  "dependsOn": [  
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"  
  ],  
  "properties": {  
    "publisher": "Microsoft.HpcCompute",  
    "type": "NvidiaGpuDriverLinux",  
    "typeHandlerVersion": "1.6",  
    "autoUpgradeMinorVersion": true,  
    "settings": {}  
  }  
}
```

## PowerShell

```
Set-AzVMExtension
  -ResourceGroupName "myResourceGroup" ` 
  -VMName "myVM" ` 
  -Location "southcentralus" ` 
  -Publisher "Microsoft.HpcCompute" ` 
  -ExtensionName "NvidiaGpuDriverLinux" ` 
  -ExtensionType "NvidiaGpuDriverLinux" ` 
  -TypeHandlerVersion 1.6 ` 
  -SettingString '{ ` 
}'
```

## Azure CLI

The following example mirrors the preceding Resource Manager and PowerShell examples:

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name NvidiaGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.6
```

The following example also adds two optional custom settings as an example for nondefault driver installation. Specifically, it updates the OS kernel to the latest and installs a specific CUDA toolkit version driver. Again, note the `--settings` are optional and default. Updating the kernel might increase the extension installation times. Also, choosing a specific (older) CUDA toolkit version might not always be compatible with newer kernels.

```
az vm extension set \
  --resource-group myResourceGroup \
  --vm-name myVM \
  --name NvidiaGpuDriverLinux \
  --publisher Microsoft.HpcCompute \
  --version 1.6 \
  --settings '{ \
    "updateOS": true, \
    "driverVersion": "10.0.130" \
}'
```

## Troubleshoot and support

### Troubleshoot

You can retrieve data about the state of extension deployments from the Azure portal and by using Azure PowerShell and the Azure CLI. To see the deployment state of extensions for a given VM, run the following command:

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file. Refer to this file to track the status of any long-running installation and for troubleshooting any failures.

```
/var/log/azure/nvidia-vmext-status
```

## Exit codes

EXIT CODE	MEANING	POSSIBLE ACTION
0	Operation successful	
1	Incorrect usage of extension	Check the execution output log.
10	Linux Integration Services for Hyper-V and Azure not available or installed	Check the output of <code>lspci</code> .
11	NVIDIA GPU not found on this VM size	Use a <a href="#">supported VM size and OS</a> .
12	Image offer not supported	
13	VM size not supported	Use an N-series VM to deploy.
14	Operation unsuccessful	Check the execution output log.

## Support

If you need more help at any point in this article, contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to [Azure support](#) and select **Get support**. For information about using Azure support, read the [Azure support FAQ](#).

# AMD GPU Driver Extension for Windows

9/21/2022 • 3 minutes to read • [Edit Online](#)

This article provides an overview of the virtual machine (VM) extension to deploy AMD GPU drivers on Windows NVv4-series VMs. When you install AMD drivers by using this extension, you're accepting and agreeing to the terms of the [AMD End-User License Agreement](#). During the installation process, the VM might reboot to complete the driver setup.

Instructions on manual installation of the drivers and the current supported versions are available. For more information, see [Azure N-series AMD GPU driver setup for Windows](#).

## Prerequisites

### Operating system

This extension supports the following OSs:

DISTRIBUTION	VERSION
Windows 10 EMS	Build 1909
Windows 10	Build 1909
Windows Server 2016	Core
Windows Server 2019	Core

### Internet connectivity

The Microsoft Azure Extension for AMD GPU Drivers requires that the target VM is connected to the internet and has access.

## Extension schema

The following JSON shows the schema for the extension:

```
{
  "name": "<myExtensionName>",
  "type": "extensions",
  "apiVersion": "2015-06-15",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <myVM>)]"
  ],
  "properties": {
    "publisher": "Microsoft.HpcCompute",
    "type": "AmdGpuDriverWindows",
    "typeHandlerVersion": "1.1",
    "autoUpgradeMinorVersion": true,
    "settings": {}
  }
}
```

## Properties

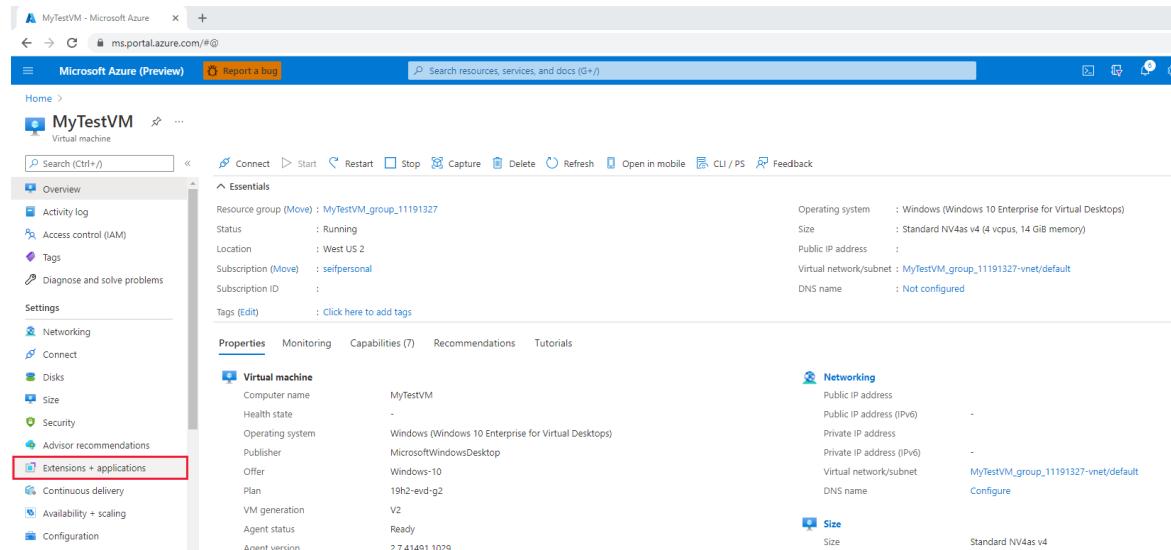

Name	Value/Example	Data Type
apiVersion	2015-06-15	date

### Azure Resource Manager template

You can use Azure Resource Manager templates to deploy Azure VM extensions. Templates are ideal when you

deploy one or more virtual machines that require post-deployment configuration.

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the extension is nested inside the virtual machine resource. When the extension resource is nested, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{  
  "name": "myExtensionName",  
  "type": "extensions",  
  "location": "[resourceGroup().location]",  
  "apiVersion": "2015-06-15",  
  "dependsOn": [  
    "[concat('Microsoft.Compute/virtualMachines/', myVM)]"  
  ],  
  "properties": {  
    "publisher": "Microsoft.HpcCompute",  
    "type": "AmdGpuDriverWindows",  
    "typeHandlerVersion": "1.1",  
    "autoUpgradeMinorVersion": true,  
    "settings": {}  
  }  
}
```

## PowerShell

```
Set-AzVMExtension  
  -ResourceGroupName "myResourceGroup" `  
  -VMName "myVM" `  
  -Location "southcentralus" `  
  -Publisher "Microsoft.HpcCompute" `  
  -ExtensionName "AmdGpuDriverWindows" `  
  -ExtensionType "AmdGpuDriverWindows" `  
  -TypeHandlerVersion 1.1 `  
  -SettingString '{`  
}'
```

## Azure CLI

```
az vm extension set `  
  --resource-group myResourceGroup `  
  --vm-name myVM `  
  --name AmdGpuDriverWindows `  
  --publisher Microsoft.HpcCompute `  
  --version 1.1 `  
  --settings '{`  
}'
```

## Troubleshoot and support

### Troubleshoot

You can retrieve data about the state of extension deployments from the Azure portal and by using Azure PowerShell and the Azure CLI. To see the deployment state of extensions for a given VM, run the following command:

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following directory:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.HpcCompute.AmdGpuDriverMicrosoft\
```

## Error codes

ERROR CODE	MEANING	POSSIBLE ACTION
0	Operation successful.	
1	Operation successful. Reboot required.	
100	Operation not supported or couldn't be completed.	Possible causes are that the PowerShell version isn't supported, the VM size isn't an N-series VM, and a failure occurred in downloading data. Check the log files to determine the cause of the error.
240, 840	Operation timeout.	Retry operation.
-1	Exception occurred.	Check the log files to determine the cause of the exception.
-5x	Operation interrupted due to pending reboot.	Reboot VM. Installation continues after the reboot. Uninstall should be invoked manually.

## Support

If you need more help at any point in this article, contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to [Azure support](#) and select **Get support**. For information about using Azure support, read the [Azure support FAQ](#).

## Next steps

- For more information about extensions, see [Virtual machine extensions and features for Windows](#).
- For more information about N-series VMs, see [GPU optimized virtual machine sizes](#).

# Manage the Azure Monitor agent

9/21/2022 • 11 minutes to read • [Edit Online](#)

This article provides the different options currently available to install, uninstall, and update the [Azure Monitor agent](#). This agent extension can be installed on Azure virtual machines, scale sets, and Azure Arc-enabled servers. It also lists the options to create [associations with data collection rules](#) that define which data the agent should collect. Installing, upgrading, or uninstalling the Azure Monitor agent won't require you to restart your server.

## Virtual machine extension details

The Azure Monitor agent is implemented as an [Azure VM extension](#) with the details in the following table. You can install it by using any of the methods to install virtual machine extensions including the methods described in this article.

PROPERTY	WINDOWS	LINUX
Publisher	Microsoft.Azure.Monitor	Microsoft.Azure.Monitor
Type	AzureMonitorWindowsAgent	AzureMonitorLinuxAgent
TypeHandlerVersion	See <a href="#">Azure Monitor agent extension versions</a>	<a href="#">Azure Monitor agent extension versions</a>

## Extension versions

View [Azure Monitor agent extension versions](#).

## Prerequisites

The following prerequisites must be met prior to installing the Azure Monitor agent.

- **Permissions:** For methods other than using the Azure portal, you must have the following role assignments to install the agent:

BUILT-IN ROLE	SCOPES	REASON
• <a href="#">Virtual Machine Contributor</a> • <a href="#">Azure Connected Machine Resource Administrator</a>	• Virtual machines, scale sets, • Azure Arc-enabled servers	To deploy the agent
Any role that includes the action <code>Microsoft.Resources/deployments/*</code>	• Subscription and/or • Resource group and/or	To deploy Azure Resource Manager templates

- **Non-Azure:** To install the agent on physical servers and virtual machines hosted *outside* of Azure (that is, on-premises) or in other clouds, you must [install the Azure Arc Connected Machine agent](#) first, at no added cost.
- **Authentication:** [Managed identity](#) must be enabled on Azure virtual machines. Both user-assigned and

system-assigned managed identities are supported.

- **User-assigned:** This managed identity is recommended for large-scale deployments, configurable via [built-in Azure policies](#). You can create a user-assigned managed identity once and share it across multiple VMs, which means it's more scalable than a system-assigned managed identity. If you use a user-assigned managed identity, you must pass the managed identity details to the Azure Monitor agent via extension settings:

```
{  
  "authentication": {  
    "managedIdentity": {  
      "identifier-name": "mi_res_id" or "object_id" or "client_id",  
      "identifier-value": "<resource-id-of-uai>" or "<guid-object-or-client-id>"  
    }  
  }  
}
```

We recommend that you use `mi_res_id` as the `identifier-name`. The following sample commands only show usage with `mi_res_id` for the sake of brevity. For more information on `mi_res_id`, `object_id`, and `client_id`, see the [Managed identity documentation](#).

- **System-assigned:** This managed identity is suited for initial testing or small deployments. When used at scale, for example, for all VMs in a subscription, it results in a substantial number of identities created (and deleted) in Azure Active Directory. To avoid this churn of identities, use user-assigned managed identities instead. *For Azure Arc-enabled servers, system-assigned managed identity is enabled automatically as soon as you install the Azure Arc agent. It's the only supported type for Azure Arc-enabled servers.*
- **Not required for Azure Arc-enabled servers:** The system identity is enabled automatically if the agent is installed via [creating and assigning a data collection rule by using the Azure portal](#).
- **Networking:** If you use network firewalls, the [AzureResourceManager service tag](#) must be enabled on the virtual network for the virtual machine. The virtual machine must also have access to the following HTTPS endpoints:
  - `global.handler.control.monitor.azure.com`
  - `<virtual-machine-region-name>.handler.control.monitor.azure.com` (example: `westus.handler.control.azure.com`)
  - `<log-analytics-workspace-id>.ods.opinsights.azure.com` (example: `12345a01-b1cd-1234-e1f2-1234567g8h99.ods.opinsights.azure.com`)  
(If you use private links on the agent, you must also add the [dce endpoints](#)).

#### NOTE

This article only pertains to agent installation or management. After you install the agent, you must review the next article to [configure data collection rules and associate them with the machines](#) with agents installed. *The Azure Monitor agents can't function without being associated with data collection rules.*

## Use the Azure portal

Follow these instructions to use the Azure portal.

### Install

To install the Azure Monitor agent by using the Azure portal, follow the process to [create a data collection rule](#) in the Azure portal. This process creates the rule, associates it to the selected resources, and installs the Azure

Monitor agent on them if it's not already installed.

## Uninstall

To uninstall the Azure Monitor agent by using the Azure portal, go to your virtual machine, scale set, or Azure Arc-enabled server. Select the **Extensions** tab and select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Uninstall**.

## Update

To perform a one-time update of the agent, you must first uninstall the existing agent version. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature. Go to your virtual machine or scale set, select the **Extensions** tab and select **AzureMonitorWindowsAgent** or **AzureMonitorLinuxAgent**. In the dialog that opens, select **Enable automatic upgrade**.

# Use Resource Manager templates

Follow these instructions to use Azure Resource Manager templates.

## Install

You can use Resource Manager templates to install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers and to create an association with data collection rules. You must create any data collection rule prior to creating the association.

Get sample templates for installing the agent and creating the association from the following resources:

- [Template to install Azure Monitor agent \(Azure and Azure Arc\)](#)
- [Template to create association with data collection rule](#)

Install the templates by using [any deployment method for Resource Manager templates](#), such as the following commands.

- [PowerShell](#)
- [CLI](#)

```
New-AzResourceGroupDeployment -ResourceGroupName "<resource-group-name>" -TemplateFile "<template-filename.json>" -TemplateParameterFile "<parameter-filename.json>"
```

# Use PowerShell

You can install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers by using the PowerShell command for adding a virtual machine extension.

## Install on Azure virtual machines

Use the following PowerShell commands to install the Azure Monitor agent on Azure virtual machines. Choose the appropriate command based on your chosen authentication method.

### User-assigned managed identity

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Location <location> -TypeHandlerVersion <version-number> -SettingString '{"authentication":{"managedIdentity":{"identifier-name":"mi_res_id","identifier-value":/subscriptions/<my-subscription-id>/resourceGroups/<my-resource-group>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<my-user-assigned-identity>"}}}'
```

### System-assigned managed identity

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Location <location> -TypeHandlerVersion <version-number>
```

### Uninstall on Azure virtual machines

Use the following PowerShell commands to uninstall the Azure Monitor agent on Azure virtual machines.

- [Windows](#)
- [Linux](#)

```
Remove-AzVMExtension -Name AzureMonitorWindowsAgent -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name>
```

### Update on Azure virtual machines

To perform a one-time update of the agent, you must first uninstall the existing agent version,. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
Set-AzVMExtension -ExtensionName AzureMonitorWindowsAgent -ResourceGroupName <resource-group-name> -VMName <virtual-machine-name> -Publisher Microsoft.Azure.Monitor -ExtensionType AzureMonitorWindowsAgent -TypeHandlerVersion <version-number> -Location <location> -EnableAutomaticUpgrade $true
```

### Install on Azure Arc-enabled servers

Use the following PowerShell commands to install the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
New-AzConnectedMachineExtension -Name AzureMonitorWindowsAgent -ExtensionType AzureMonitorWindowsAgent -Publisher Microsoft.Azure.Monitor -ResourceGroupName <resource-group-name> -MachineName <arc-server-name> -Location <arc-server-location>
```

### Uninstall on Azure Arc-enabled servers

Use the following PowerShell commands to uninstall the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
Remove-AzConnectedMachineExtension -MachineName <arc-server-name> -ResourceGroupName <resource-group-name> -Name AzureMonitorWindowsAgent
```

## Upgrade on Azure Arc-enabled servers

To perform a one-time upgrade of the agent, use the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
$target = @{"Microsoft.Azure.Monitor.AzureMonitorWindowsAgent" = @{"targetVersion"=<target-version-number>}}
Update-AzConnectedExtension -ResourceGroupName $env.ResourceGroupName -MachineName <arc-server-name> -ExtensionTarget $target
```

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade \(preview\)](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
Update-AzConnectedMachineExtension -ResourceGroup <resource-group-name> -MachineName <arc-server-name> -Name AzureMonitorWindowsAgent -EnableAutomaticUpgrade
```

# Use the Azure CLI

You can install the Azure Monitor agent on Azure virtual machines and on Azure Arc-enabled servers by using the Azure CLI command for adding a virtual machine extension.

## Install on Azure virtual machines

Use the following CLI commands to install the Azure Monitor agent on Azure virtual machines. Choose the appropriate command based on your chosen authentication method.

### User-assigned managed identity

- [Windows](#)
- [Linux](#)

```
az vm extension set --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --ids <vm-resource-id> --settings '{"authentication":{"managedIdentity":{"identifier-name":"mi_res_id","identifier-value":/subscriptions/<my-subscription-id>/resourceGroups/<my-resource-group>/providers/Microsoft.ManagedIdentity/userAssignedIdentities/<my-user-assigned-identity>"}}}'
```

### System-assigned managed identity

- [Windows](#)
- [Linux](#)

```
az vm extension set --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --ids <vm-resource-id>
```

## Uninstall on Azure virtual machines

Use the following CLI commands to uninstall the Azure Monitor agent on Azure virtual machines.

- [Windows](#)
- [Linux](#)

```
az vm extension delete --resource-group <resource-group-name> --vm-name <virtual-machine-name> -name AzureMonitorWindowsAgent
```

## Update on Azure virtual machines

To perform a one-time update of the agent, you must first uninstall the existing agent version,. Then install the new version as described.

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade](#) feature by using the following CLI commands.

- [Windows](#)
- [Linux](#)

```
az vm extension set -name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --vm-name <virtual-machine-name> --resource-group <resource-group-name> --enable-auto-upgrade true
```

## Install on Azure Arc-enabled servers

Use the following CLI commands to install the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension create --name AzureMonitorWindowsAgent --publisher Microsoft.Azure.Monitor --type AzureMonitorWindowsAgent --machine-name <arc-server-name> --resource-group <resource-group-name> --location <arc-server-location>
```

## Uninstall on Azure Arc-enabled servers

Use the following CLI commands to uninstall the Azure Monitor agent on Azure Arc-enabled servers.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension delete --name AzureMonitorWindowsAgent --machine-name <arc-server-name> --resource-group <resource-group-name>
```

## Upgrade on Azure Arc-enabled servers

To perform a one-time upgrade of the agent, use the following CLI commands.

- [Windows](#)
- [Linux](#)

```
az connectedmachine upgrade-extension --extension-targets "  
{\"Microsoft.Azure.Monitor.AzureMonitorWindowsAgent\":{\"targetVersion\":\"<target-version-number>\"},\"}  
--machine-name <arc-server-name> --resource-group <resource-group-name>
```

We recommend that you enable automatic update of the agent by enabling the [Automatic Extension Upgrade \(preview\)](#) feature by using the following PowerShell commands.

- [Windows](#)
- [Linux](#)

```
az connectedmachine extension update --name AzureMonitorWindowsAgent --machine-name <arc-server-name> --  
resource-group <resource-group-name> --enable-auto-upgrade true
```

## Use Azure Policy

Use the following policies and policy initiatives to automatically install the agent and associate it with a data collection rule every time you create a virtual machine, scale set, or Azure Arc-enabled server.

### NOTE

As per Microsoft Identity best practices, policies for installing the Azure Monitor agent on virtual machines and scale sets rely on user-assigned managed identity. This option is the more scalable and resilient managed identity for these resources. For Azure Arc-enabled servers, policies rely on system-assigned managed identity as the only supported option today.

### Built-in policy initiatives

Before you proceed, review [prerequisites for agent installation](#).

Policy initiatives for Windows and Linux virtual machines, scale sets consist of individual policies that:

- (Optional) Create and assign built-in user-assigned managed identity, per subscription, per region. [Learn more](#).
  - **Bring Your Own User-Assigned Identity** : If set to `true`, it creates the built-in user-assigned managed identity in the predefined resource group and assigns it to all machines that the policy is applied to. If set to `false`, you can instead use existing user-assigned identity that *you must assign* to the machines beforehand.
- Install the Azure Monitor agent extension on the machine, and configure it to use user-assigned identity as specified by the following parameters.
  - **Bring Your Own User-Assigned Managed Identity** : If set to `false`, it configures the agent to use the built-in user-assigned managed identity created by the preceding policy. If set to `true`, it configures the agent to use an existing user-assigned identity that *you must assign* to the machines in scope beforehand.
  - **User-Assigned Managed Identity Name** : If you use your own identity (selected `true`), specify the name of the identity that's assigned to the machines.
  - **User-Assigned Managed Identity Resource Group** : If you use your own identity (selected `true`), specify the resource group where the identity exists.
  - **Additional Virtual Machine Images** : Pass additional VM image names that you want to apply the policy to, if not already included.
- Create and deploy the association to link the machine to specified data collection rule.

- **Data Collection Rule Resource Id** : The Azure Resource Manager resourceId of the rule you want to associate via this policy to all machines the policy is applied to.

Home > Policy >

**Deploy Windows Azure Monitor Agent with user-assigned managed identity-based auth and associate with Data Collection Rule**

Initiative Definition

[Configure Windows Machines to be associated with a Data Collection Rule]	[parameters('effect')]	Built-in	associateDataCollectionRuleV

## Known issues

- Managed Identity default behavior. [Learn more](#).
- Possible race condition with using built-in user-assigned identity creation policy. [Learn more](#).
- Assigning policy to resource groups. If the assignment scope of the policy is a resource group and not a subscription, the identity used by policy assignment (different from the user-assigned identity used by agent) must be manually granted [these roles](#) prior to assignment/remediation. Failing to do this step will result in *deployment failures*.
- Other [Managed Identity limitations](#).

## Built-in policies

You can choose to use the individual policies from the preceding policy initiative to perform a single action at scale. For example, if you *only* want to automatically install the agent, use the second agent installation policy from the initiative, as shown.

Home > Policy > Deploy Windows Azure Monitor Agent with user-assigned managed identity-based auth and associate with Data Collection Rule >

**Configure Windows virtual machines to run Azure Monitor Agent with user-assigned managed identity-based authentication**

6     "description": "Automate the deployment of Azure Monitor Agent extension on your Windows virtual machines for collecting telemetry data from the guest OS. This policy is triggered when a new VM is created or updated. It deploys the Azure Monitor Agent extension to the VM and associates it with a Data Collection Rule defined in the same policy set. This ensures that the agent is installed and configured automatically for every new VM instance."}
```

## Remediation

The initiatives or policies will apply to each virtual machine as it's created. A [remediation task](#) deploys the policy definitions in the initiative to existing resources, so you can configure the Azure Monitor agent for any resources that were already created.

When you create the assignment by using the Azure portal, you have the option of creating a remediation task at the same time. For information on the remediation, see [Remediate non-compliant resources with Azure Policy](#).

## Configure Azure Monitor Agent to Linux virtual machines and associate to Data Collection Rule

[Assign initiative](#)[Basics](#)   [Parameters](#)   [Remediation](#)   [Non-compliance messages](#)   [Review + create](#)

By default, this assignment will only take effect on newly created resources. Existing resources can be updated via a remediation task after the policy is assigned. For deployIfNotExists policies, the remediation task will deploy the specified template. For modify policies, the remediation task will edit tags on the existing resources.

 Create a remediation task [\(?\)](#)

Policy to remediate

[Configure Linux virtual machines with Azure Monitor Agent](#) [\(?\)](#)

### Managed Identity

Policies with the deployIfNotExists and modify effect types need the ability to deploy resources and edit tags on existing resources respectively. To do this, a managed identity will be created for you.

[Learn more about Managed Identity.](#) Create a Managed Identity [\(?\)](#)

Managed identity location \*

[East US](#) [\(?\)](#)

### Permissions

This identity will also be given the following permissions:

[Virtual Machine Contributor, Monitoring Contributor](#) [\(?\)](#)

 Role assignments (permissions) are created based on the role definitions specified in the policies.

[Review + create](#)[Cancel](#)[Previous](#)[Next](#)

## Next steps

[Create a data collection rule](#) to collect data from the agent and send it to Azure Monitor.

# Azure Diagnostics extension overview

9/21/2022 • 5 minutes to read • [Edit Online](#)

Azure Diagnostics extension is an [agent in Azure Monitor](#) that collects monitoring data from the guest operating system of Azure compute resources including virtual machines. This article provides an overview of Azure Diagnostics extension including specific functionality that it supports and options for installation and configuration.

## NOTE

Azure Diagnostics extension is one of the agents available to collect monitoring data from the guest operating system of compute resources. See [Overview of the Azure Monitor agents](#) for a description of the different agents and guidance on selecting the appropriate agents for your requirements.

## Primary scenarios

The primary scenarios addressed by the diagnostics extension are:

Use the Azure Diagnostics extension if you need to:

- Send data to Azure Storage for archiving or to analyze it with tools such as [Azure Storage Explorer](#).
- Send data to [Azure Monitor Metrics](#) to analyze it with [Metrics Explorer](#) and to take advantage of features such as near-real-time [metric alerts](#) and [autoscale](#) (Windows only).
- Send data to third-party tools by using [Azure Event Hubs](#).
- Collect [Boot Diagnostics](#) to investigate VM boot issues.

Limitations of the Azure Diagnostics extension:

- Can only be used with Azure resources.
- Limited ability to send data to Azure Monitor Logs.

## Comparison to Log Analytics agent

The Log Analytics agent in Azure Monitor can also be used to collect monitoring data from the guest operating system of virtual machines. You may choose to use either or both depending on your requirements. See [Overview of the Azure Monitor agents](#) for a detailed comparison of the Azure Monitor agents.

The key differences to consider are:

- Azure Diagnostics Extension can be used only with Azure virtual machines. The Log Analytics agent can be used with virtual machines in Azure, other clouds, and on-premises.
- Azure Diagnostics extension sends data to Azure Storage, [Azure Monitor Metrics](#) (Windows only) and Event Hubs. The Log Analytics agent collects data to [Azure Monitor Logs](#).
- The Log Analytics agent is required for [solutions](#), [VM insights](#), and other services such as [Microsoft Defender for Cloud](#).

## Costs

There is no cost for Azure Diagnostic Extension, but you may incur charges for the data ingested. Check [Azure Monitor pricing](#) for the destination where you're collecting data.

## Data collected

The following tables list the data that can be collected by the Windows and Linux diagnostics extension.

### Windows diagnostics extension (WAD)

DATA SOURCE	DESCRIPTION
Windows Event logs	Events from Windows event log.
Performance counters	Numerical values measuring performance of different aspects of operating system and workloads.
IIS Logs	Usage information for IIS web sites running on the guest operating system.
Application logs	Trace messages written by your application.
.NET EventSource logs	Code writing events using the .NET <a href="#">EventSource</a> class
Manifest based ETW logs	Event Tracing for Windows events generated by any process.
Crash dumps (logs)	Information about the state of the process if an application crashes.
File based logs	Logs created by your application or service.
Agent diagnostic logs	Information about Azure Diagnostics itself.

### Linux diagnostics extension (LAD)

DATA SOURCE	DESCRIPTION
Syslog	Events sent to the Linux event logging system.
Performance counters	Numerical values measuring performance of different aspects of operating system and workloads.
Log files	Entries sent to a file based log.

## Data destinations

The Azure Diagnostic extension for both Windows and Linux always collect data into an Azure Storage account.

See [Install and configure Windows Azure diagnostics extension \(WAD\)](#) and [Use Linux Diagnostic Extension to monitor metrics and logs](#) for a list of specific tables and blobs where this data is collected.

Configure one or more *data sinks* to send data to other additional destinations. The following sections list the sinks available for the Windows and Linux diagnostics extension.

### Windows diagnostics extension (WAD)

DESTINATION	DESCRIPTION

DESTINATION	DESCRIPTION
Azure Monitor Metrics	Collect performance data to Azure Monitor Metrics. See <a href="#">Send Guest OS metrics to the Azure Monitor metric database</a> .
Event hubs	Use Azure Event Hubs to send data outside of Azure. See <a href="#">Streaming Azure Diagnostics data to Event Hubs</a>
Azure Storage blobs	Write to data to blobs in Azure Storage in addition to tables.
Application Insights	Collect data from applications running in your VM to Application Insights to integrate with other application monitoring. See <a href="#">Send diagnostic data to Application Insights</a> .

You can also collect WAD data from storage into a Log Analytics workspace to analyze it with Azure Monitor Logs although the Log Analytics agent is typically used for this functionality. It can send data directly to a Log Analytics workspace and supports solutions and insights that provide additional functionality. See [Collect Azure diagnostic logs from Azure Storage](#).

### Linux diagnostics extension (LAD)

LAD writes data to tables in Azure Storage. It supports the sinks in the following table.

DESTINATION	DESCRIPTION
Event hubs	Use Azure Event Hubs to send data outside of Azure.
Azure Storage blobs	Write to data to blobs in Azure Storage in addition to tables.
Azure Monitor Metrics	Install the Telegraf agent in addition to LAD. See <a href="#">Collect custom metrics for a Linux VM with the InfluxData Telegraf agent</a> .

## Installation and configuration

The Diagnostic extension is implemented as a [virtual machine extension](#) in Azure, so it supports the same installation options using Resource Manager templates, PowerShell, and CLI. See [Virtual machine extensions and features for Windows](#) and [Virtual machine extensions and features for Linux](#) for general details on installing and maintaining virtual machine extensions.

You can also install and configure both the Windows and Linux diagnostic extension in the Azure portal under **Diagnostic settings** in the **Monitoring** section of the virtual machine's menu.

See the following articles for details on installing and configuring the diagnostics extension for Windows and Linux.

- [Install and configure Windows Azure diagnostics extension \(WAD\)](#)
- [Use Linux Diagnostic Extension to monitor metrics and logs](#)

# Log Analytics virtual machine extension for Linux

9/21/2022 • 7 minutes to read • [Edit Online](#)

## Overview

Azure Monitor Logs provides monitoring, alerting, and alert remediation capabilities across cloud and on-premises assets. The Log Analytics virtual machine extension for Linux is published and supported by Microsoft. The extension installs the Log Analytics agent on Azure virtual machines, and enrolls virtual machines into an existing Log Analytics workspace. This document details the supported platforms, configurations, and deployment options for the Log Analytics virtual machine extension for Linux.

### NOTE

Azure Arc-enabled servers enables you to deploy, remove, and update the Log Analytics agent VM extension to non-Azure Windows and Linux machines, simplifying the management of your hybrid machine through their lifecycle. For more information, see [VM extension management with Azure Arc-enabled servers](#).

## Prerequisites

### Operating system

For details about the supported Linux distributions, refer to the [Overview of Azure Monitor agents](#) article.

### Agent and VM Extension version

The following table provides a mapping of the version of the Log Analytics VM extension and Log Analytics agent bundle for each release. A link to the release notes for the Log Analytics agent bundle version is included. Release notes include details on bug fixes and new features available for a given agent release.

LOG ANALYTICS LINUX VM EXTENSION VERSION	LOG ANALYTICS AGENT BUNDLE VERSION
1.14.19	<a href="#">1.14.19</a>
1.14.16	<a href="#">1.14.16</a>

## Microsoft Defender for Cloud

Microsoft Defender for Cloud automatically provisions the Log Analytics agent and connects it to a default Log Analytics workspace created by Defender for Cloud in your Azure subscription. If you are using Microsoft Defender for Cloud, do not run through the steps in this document. Doing so overwrites the configured workspace and breaks the connection with Microsoft Defender for Cloud.

## Internet connectivity

The Log Analytics agent extension for Linux requires that the target virtual machine is connected to the internet.

## Extension schema

The following JSON shows the schema for the Log Analytics agent extension. The extension requires the workspace ID and workspace key from the target Log Analytics workspace; these values can be [found in your Log Analytics workspace](#) in the Azure portal. Because the workspace key should be treated as sensitive data, it should be stored in a protected setting configuration. Azure VM extension protected setting data is encrypted,

and only decrypted on the target virtual machine. Note that **workspaceId** and **workspaceKey** are case-sensitive.

#### NOTE

Because the [Container Monitoring solution](#) is being retired, the following documentation uses the optional setting "skipDockerProviderInstall": true.

```
{  
  "type": "Microsoft.Compute/virtualMachines/extensions",  
  "name": "OMSExtension",  
  "apiVersion": "2018-06-01",  
  "location": "<location>",  
  "dependsOn": [  
    "[concat('Microsoft.Compute/virtualMachines/', <vm-name>)]"  
  ],  
  "properties": {  
    "publisher": "Microsoft.EnterpriseCloud.Monitoring",  
    "type": "OmsAgentForLinux",  
    "typeHandlerVersion": "1.13",  
    "autoUpgradeMinorVersion": true,  
    "settings": {  
      "workspaceId": "myWorkspaceId",  
      "skipDockerProviderInstall": true  
    },  
    "protectedSettings": {  
      "workspaceKey": "myWorkSpaceKey"  
    }  
  }  
}
```

#### NOTE

The schema above assumes that it will be placed at the root level of the template. If you put it inside the virtual machine resource in the template, the `type` and `name` properties should be changed, as described [further down](#).

## Property values

NAME	VALUE / EXAMPLE
apiVersion	2018-06-01
publisher	Microsoft.EnterpriseCloud.Monitoring
type	OmsAgentForLinux
typeHandlerVersion	1.13
workspaceId (e.g.)	6f680a37-00c6-41c7-a93f-1437e3462574
workspaceKey (e.g.)	z4bU3p1/GrnWpQkky4gdabWXAhbWSTz70hm4m2Xt92XI+rSRgE8qVvRhsGo9TXffbrTahyrvw35W0pOqQAU7uQ==

## Template deployment

#### NOTE

Certain components of the Log Analytics VM extension are also shipped in the [Diagnostics VM extension](#). Due to this architecture, conflicts can arise if both extensions are instantiated in the same ARM template. To avoid these install-time conflicts, use the `dependsOn` directive to ensure the extensions are installed sequentially. The extensions can be installed in either order.

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration such as onboarding to Azure Monitor Logs. A sample Resource Manager template that includes the Log Analytics agent VM extension can be found on the [Azure Quickstart Gallery](#).

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the VM extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{
  "type": "extensions",
  "name": "OMSExtension",
  "apiVersion": "2018-06-01",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <vm-name>)]"
  ],
  "properties": {
    "publisher": "Microsoft.EnterpriseCloud.Monitoring",
    "type": "OmsAgentForLinux",
    "typeHandlerVersion": "1.13",
    "settings": {
      "workspaceId": "myWorkspaceId",
      "skipDockerProviderInstall": true
    },
    "protectedSettings": {
      "workspaceKey": "myWorkSpaceKey"
    }
  }
}
```

When placing the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine, and the type reflects the nested configuration.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<parentVmResource>/OMSExtension",
  "apiVersion": "2018-06-01",
  "location": "<location>",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', <vm-name>)]"
  ],
  "properties": {
    "publisher": "Microsoft.EnterpriseCloud.Monitoring",
    "type": "OmsAgentForLinux",
    "typeHandlerVersion": "1.13",
    "settings": {
      "workspaceId": "myWorkspaceId",
      "skipDockerProviderInstall": true
    },
    "protectedSettings": {
      "workspaceKey": "myWorkSpaceKey"
    }
  }
}
```

## Azure CLI deployment

The Azure CLI can be used to deploy the Log Analytics agent VM extension to an existing virtual machine. Replace the *myWorkspaceKey* value below with your workspace key and the *myWorkspaceId* value with your workspace ID. These values can be found in your Log Analytics workspace in the Azure portal under *Advanced Settings*. Replace the *latestVersion* value with a version from [Log Analytics Linux VM extension version](#).

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name OmsAgentForLinux \
--publisher Microsoft.EnterpriseCloud.Monitoring \
--protected-settings '{"workspaceKey":"myWorkSpaceKey"}' \
--settings '{"workspaceId":"myWorkspaceId","skipDockerProviderInstall": true}' \
--version latestVersion
```

## Azure PowerShell deployment

The Azure Powershell cmdlets can be used to deploy the Log Analytics agent VM extension to an existing virtual machine. Replace the *myWorkspaceKey* value below with your workspace key and the *myWorkspaceId* value with your workspace ID. These values can be found in your Log Analytics workspace in the Azure portal under *Advanced Settings*. Replace the *latestVersion* value with a version from [Log Analytics Linux VM extension version](#).

```
Set-AzVMExtension \
-ResourceGroupName myResourceGroup \
-VMName myVM \
-ExtensionName OmsAgentForLinux \
-ExtensionType OmsAgentForLinux \
-Publisher Microsoft.EnterpriseCloud.Monitoring \
-TypeHandlerVersion latestVersion \
-ProtectedSettingString '{"workspaceKey":"myWorkSpaceKey"}' \
-SettingString '{"workspaceId":"myWorkspaceId","skipDockerProviderInstall": true}'
```

## Troubleshoot and support

## Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI or Azure Powershell. To see the deployment state of extensions for a given VM, run the following command if you are using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
/var/log/azure/Microsoft.EnterpriseCloud.Monitoring.OmsAgentForLinux/extension.log
```

To retrieve the OMS extension version installed on a VM, run the following command if you are using Azure CLI.

```
az vm extension show --resource-group myResourceGroup --vm-name myVM -instance-view
```

To retrieve the OMS extension version installed on a VM, run the following command if you are using Azure PowerShell.

```
Get-AzVMExtension -ResourceGroupName my_resource_group -VMName my_vm_name -Name OmsAgentForLinux -Status
```

### Error codes and their meanings

ERROR CODE	MEANING	POSSIBLE ACTION
9	Enable called prematurely	<a href="#">Update the Azure Linux Agent</a> to the latest available version.
10	VM is already connected to a Log Analytics workspace	To connect the VM to the workspace specified in the extension schema, set stopOnMultipleConnections to false in public settings or remove this property. This VM gets billed once for each workspace it is connected to.
11	Invalid config provided to the extension	Follow the preceding examples to set all property values necessary for deployment.
17	Log Analytics package installation failure	
18	Installation of OMSConfig package failed.	Look through the command output for the root failure.
19	OMI package installation failure	
20	SCX package installation failure	
33	Error generating metaconfiguration for omsconfig.	File a <a href="#">GitHub Issue</a> with details from the output.
51	This extension is not supported on the VM's operation system	

ERROR CODE	MEANING	POSSIBLE ACTION
52	This extension failed due to a missing dependency or permission	Check the output and logs for more information about which dependency or permission is missing.
53	This extension failed due to missing or wrong configuration parameters	Check the output and logs for more information about what went wrong. Additionally, check the correctness of the workspace ID, and verify that the machine is connected to the internet.
55	Cannot connect to the Azure Monitor service or required packages missing or dpkg package manager is locked	Check that the system either has internet access, or that a valid HTTP proxy has been provided. Additionally, check the correctness of the workspace ID, and verify that curl and tar utilities are installed.

Additional troubleshooting information can be found on the [Log Analytics-Agent-for-Linux Troubleshooting Guide](#).

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Log Analytics virtual machine extension for Windows

9/21/2022 • 5 minutes to read • [Edit Online](#)

Azure Monitor Logs provides monitoring capabilities across cloud and on-premises assets. The Log Analytics agent virtual machine extension for Windows is published and supported by Microsoft. The extension installs the Log Analytics agent on Azure virtual machines, and enrolls virtual machines into an existing Log Analytics workspace. This document details the supported platforms, configurations, and deployment options for the Log Analytics virtual machine extension for Windows.

## NOTE

Azure Arc-enabled servers enables you to deploy, remove, and update the Log Analytics agent VM extension to non-Azure Windows and Linux machines, simplifying the management of your hybrid machine through their lifecycle. For more information, see [VM extension management with Azure Arc-enabled servers](#).

## Prerequisites

### Operating system

For details about the supported Windows operating systems, refer to the [Overview of Azure Monitor agents](#) article.

### Agent and VM Extension version

The following table provides a mapping of the version of the Windows Log Analytics VM extension and Log Analytics agent for each release.

LOG ANALYTICS WINDOWS AGENT VERSION	LOG ANALYTICS WINDOWS VM EXTENSION VERSION	RELEASE DATE	RELEASE NOTES
10.20.18067.0	1.0.18067	March 2022	<ul style="list-style-type: none"><li>Bug fix for perf counters</li><li>Enhancements to Agent Troubleshooter</li></ul>

## Microsoft Defender for Cloud

Microsoft Defender for Cloud automatically provisions the Log Analytics agent and connects it with the default Log Analytics workspace of the Azure subscription. If you are using Microsoft Defender for Cloud, do not run through the steps in this document. Doing so overwrites the configured workspace and break the connection with Microsoft Defender for Cloud.

## Internet connectivity

The Log Analytics agent extension for Windows requires that the target virtual machine is connected to the

internet.

## Extension schema

The following JSON shows the schema for the Log Analytics agent extension. The extension requires the workspace ID and workspace key from the target Log Analytics workspace. These can be found in the settings for the workspace in the Azure portal. Because the workspace key should be treated as sensitive data, it should be stored in a protected setting configuration. Azure VM extension protected setting data is encrypted, and only decrypted on the target virtual machine. Note that **workspaceld** and **workspaceKey** are case-sensitive.

```
{  
    "type": "extensions",  
    "name": "OMSExtension",  
    "apiVersion": "[variables('apiVersion')]",  
    "location": "[resourceGroup().location]",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"  
    ],  
    "properties": {  
        "publisher": "Microsoft.EnterpriseCloud.Monitoring",  
        "type": "MicrosoftMonitoringAgent",  
        "typeHandlerVersion": "1.0",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "workspaceId": "myWorkSpaceId"  
        },  
        "protectedSettings": {  
            "workspaceKey": "myworkspaceKey"  
        }  
    }  
}
```

### Property values

NAME	VALUE / EXAMPLE
apiVersion	2015-06-15
publisher	Microsoft.EnterpriseCloud.Monitoring
type	MicrosoftMonitoringAgent
typeHandlerVersion	1.0
workspaceld (e.g.)*	6f680a37-00c6-41c7-a93f-1437e3462574
workspaceKey (e.g.)	z4bU3p1/GrnWpQkky4gdabWXAhbWSTz70hm4m2Xt92XI+rSRgE8qVvRhsGo9TXffbrTahyrwv35W0pOqQAU7uQ==

\* The workspaceld is called the consumerId in the Log Analytics API.

#### NOTE

For additional properties see Azure [Connect Windows Computers to Azure Monitor](#).

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Log Analytics agent extension during an Azure Resource Manager template deployment. A sample template that includes the Log Analytics agent VM extension can be found on the [Azure Quickstart Gallery](#).

**NOTE**

The template does not support specifying more than one workspace ID and workspace key when you want to configure the agent to report to multiple workspaces. To configure the agent to report to multiple workspaces, see [Add or remove a workspace](#).

The JSON for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the Log Analytics extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{  
    "type": "extensions",  
    "name": "OMSExtension",  
    "apiVersion": "[variables('apiVersion')]",  
    "location": "[resourceGroup().location]",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"  
    ],  
    "properties": {  
        "publisher": "Microsoft.EnterpriseCloud.Monitoring",  
        "type": "MicrosoftMonitoringAgent",  
        "typeHandlerVersion": "1.0",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "workspaceId": "myWorkSpaceId"  
        },  
        "protectedSettings": {  
            "workspaceKey": "myWorkspaceKey"  
        }  
    }  
}
```

When placing the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine, and the type reflects the nested configuration.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<parentVmResource>/OMSExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.EnterpriseCloud.Monitoring",
    "type": "MicrosoftMonitoringAgent",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "workspaceId": "myWorkSpaceId"
    },
    "protectedSettings": {
      "workspaceKey": "myWorkspaceKey"
    }
  }
}
```

## PowerShell deployment

The `Set-AzVMExtension` command can be used to deploy the Log Analytics agent virtual machine extension to an existing virtual machine. Before running the command, the public and private configurations need to be stored in a PowerShell hash table.

```
$PublicSettings = @{"workspaceId" = "myWorkSpaceId"}
$ProtectedSettings = @{"workspaceKey" = "myWorkspaceKey"}

Set-AzVMExtension -ExtensionName "MicrosoftMonitoringAgent" ` 
  -ResourceGroupName "myResourceGroup" ` 
  -VMName "myVM" ` 
  -Publisher "Microsoft.EnterpriseCloud.Monitoring" ` 
  -ExtensionType "MicrosoftMonitoringAgent" ` 
  -TypeHandlerVersion 1.0 ` 
  -Settings $PublicSettings ` 
  -ProtectedSettings $ProtectedSettings ` 
  -Location WestUS
```

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure PowerShell module. To see the deployment state of extensions for a given VM, run the following command using the Azure PowerShell module.

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

Extension execution output is logged to files found in the following directory:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.EnterpriseCloud.Monitoring.MicrosoftMonitoringAgent\
```

### Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and](#)

[Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Azure Monitor Dependency virtual machine extension for Linux

9/21/2022 • 3 minutes to read • [Edit Online](#)

The Azure Monitor for VMs Map feature gets its data from the Microsoft Dependency agent. The Azure VM Dependency agent virtual machine extension for Linux is published and supported by Microsoft. The extension installs the Dependency agent on Azure virtual machines. This document details the supported platforms, configurations, and deployment options for the Azure VM Dependency agent virtual machine extension for Linux.

## Prerequisites

### Operating system

The Azure VM Dependency agent extension for Linux can be run against the supported operating systems listed in the [Supported operating systems](#) section of the Azure Monitor for VMs deployment article.

## Extension schema

The following JSON shows the schema for the Azure VM Dependency agent extension on an Azure Linux VM.

```
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
        "vmName": {
            "type": "string",
            "metadata": {
                "description": "The name of existing Linux Azure VM."
            }
        }
    },
    "variables": {
        "vmExtensionsApiVersion": "2017-03-30"
    },
    "resources": [
        {
            "type": "Microsoft.Compute/virtualMachines/extensions",
            "name": "[concat(parameters('vmName'), '/DAExtension')]",
            "apiVersion": "[variables('vmExtensionsApiVersion')]",
            "location": "[resourceGroup().location]",
            "dependsOn": [
            ],
            "properties": {
                "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
                "type": "DependencyAgentLinux",
                "typeHandlerVersion": "9.5",
                "autoUpgradeMinorVersion": true
            }
        }
    ],
    "outputs": {}
}
```

## Property values

NAME	VALUE/EXAMPLE
apiVersion	2015-01-01
publisher	Microsoft.Azure.Monitoring.DependencyAgent
type	DependencyAgentLinux
typeHandlerVersion	9.5

## Template deployment

You can deploy Azure VM extensions with Azure Resource Manager templates. You can use the JSON schema detailed in the previous section in an Azure Resource Manager template to run the Azure VM Dependency agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource. Or, you can place it at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the Dependency agent extension is nested inside the virtual machine resource. When you nest the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{
  "type": "extensions",
  "name": "DAExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
    "type": "DependencyAgentLinux",
    "typeHandlerVersion": "9.5",
    "autoUpgradeMinorVersion": true
  }
}
```

When you place the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine. The type reflects the nested configuration.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<parentVmResource>/DAExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
    "type": "DependencyAgentLinux",
    "typeHandlerVersion": "9.5",
    "autoUpgradeMinorVersion": true
  }
}
```

# Azure CLI deployment

You can use the Azure CLI to deploy the Dependency agent VM extension to an existing virtual machine.

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name DependencyAgentLinux \
--publisher Microsoft.Azure.Monitoring.DependencyAgent \
--version 9.5
```

## Automatic extension upgrade

A new feature to [automatically upgrade minor versions](#) of Dependency extension is now available.

To enable automatic extension upgrade for an extension, you must ensure the property `enableAutomaticUpgrade` is set to `true` and added to the extension template. This property must be enabled on every VM or VM scale set individually. Use one of the methods described in the [enablement](#) section enable the feature for your VM or VM scale set.

When automatic extension upgrade is enabled on a VM or VM scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that extension. The upgrade is applied safely following availability-first principles as described [here](#).

The `enableAutomaticUpgrade` attribute's functionality is different from that of the `autoUpgradeMinorVersion`. The `autoUpgradeMinorVersion` attributes does not automatically trigger a minor version update when the extension publisher releases a new version. The `autoUpgradeMinorVersion` attribute indicates whether the extension should use a newer minor version if one is available at deployment time. Once deployed, however, the extension will not upgrade minor versions unless redeployed, even with this property set to true.

To keep your extension version updated, we recommend using `enableAutomaticUpgrade` with your extension deployment.

### IMPORTANT

If you add the `enableAutomaticUpgrade` to your template, make sure that you use at API version 2019-12-01 or higher.

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command by using the Azure CLI:

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
/var/opt/microsoft/dependency-agent/log/install.log
```

### Support

If you need more help at any point in this article, contact the Azure experts on the [Microsoft Q & A and Stack](#)

[Overflow forums](#). Or, you can file an Azure support incident. Go to the [Azure support site](#) and select **Get support**. For information about how to use Azure Support, read the [Microsoft Azure support FAQ](#).

# Azure Monitor Dependency virtual machine extension for Windows

9/21/2022 • 4 minutes to read • [Edit Online](#)

The Azure Monitor for VMs Map feature gets its data from the Microsoft Dependency agent. The Azure VM Dependency agent virtual machine extension for Windows is published and supported by Microsoft. The extension installs the Dependency agent on Azure virtual machines. This document details the supported platforms, configurations, and deployment options for the Azure VM Dependency agent virtual machine extension for Windows.

## Operating system

The Azure VM Dependency agent extension for Windows can be run against the supported operating systems listed in the [Supported operating systems](#) section of the Azure Monitor for VMs deployment article.

## Extension schema

The following JSON shows the schema for the Azure VM Dependency agent extension on an Azure Windows VM.

```
{  
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",  
    "contentVersion": "1.0.0.0",  
    "parameters": {  
        "vmName": {  
            "type": "string",  
            "metadata": {  
                "description": "The name of existing Azure VM. Supported Windows Server versions: 2008 R2 and above  
(x64)."  
            }  
        }  
    },  
    "variables": {  
        "vmExtensionsApiVersion": "2017-03-30"  
    },  
    "resources": [  
        {  
            "type": "Microsoft.Compute/virtualMachines/extensions",  
            "name": "[concat(parameters('vmName'), '/DAExtension')]",  
            "apiVersion": "[variables('vmExtensionsApiVersion')]",  
            "location": "[resourceGroup().location]",  
            "dependsOn": [  
            ],  
            "properties": {  
                "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",  
                "type": "DependencyAgentWindows",  
                "typeHandlerVersion": "9.10",  
                "autoUpgradeMinorVersion": true  
            }  
        }  
    ],  
    "outputs": {}  
}
```

## Property values

NAME	VALUE/EXAMPLE
apiVersion	2015-01-01
publisher	Microsoft.Azure.Monitoring.DependencyAgent
type	DependencyAgentWindows
typeHandlerVersion	9.10

## Template deployment

You can deploy the Azure VM extensions with Azure Resource Manager templates. You can use the JSON schema detailed in the previous section in an Azure Resource Manager template to run the Azure VM Dependency agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource. Or, you can place it at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the Dependency agent extension is nested inside the virtual machine resource. When you nest the extension resource, the JSON is placed in the `"resources": []` object of the virtual machine.

```
{
  "type": "extensions",
  "name": "DAExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
    "type": "DependencyAgentWindows",
    "typeHandlerVersion": "9.10",
    "autoUpgradeMinorVersion": true
  }
}
```

When you place the extension JSON at the root of the template, the resource name includes a reference to the parent virtual machine. The type reflects the nested configuration.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "<parentVmResource>/DAExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
    "type": "DependencyAgentWindows",
    "typeHandlerVersion": "9.10",
    "autoUpgradeMinorVersion": true
  }
}
```

## PowerShell deployment

You can use the `Set-AzVMExtension` command to deploy the Dependency agent virtual machine extension to an existing virtual machine. Before you run the command, the public and private configurations need to be stored in a PowerShell hash table.

```
Set-AzVMExtension -ExtensionName "Microsoft.Azure.Monitoring.DependencyAgent" ` 
  -ResourceGroupName "myResourceGroup" ` 
  -VMName "myVM" ` 
  -Publisher "Microsoft.Azure.Monitoring.DependencyAgent" ` 
  -ExtensionType "DependencyAgentWindows" ` 
  -TypeHandlerVersion 9.10 ` 
  -Location WestUS
```

## Automatic extension upgrade

A new feature to [automatically upgrade minor versions](#) of Dependency extension is now available.

To enable automatic extension upgrade for an extension, you must ensure the property `enableAutomaticUpgrade` is set to `true` and added to the extension template. This property must be enabled on every VM or VM scale set individually. Use one of the methods described in the [enablement](#) section enable the feature for your VM or VM scale set.

When automatic extension upgrade is enabled on a VM or VM scale set, the extension is upgraded automatically whenever the extension publisher releases a new version for that extension. The upgrade is applied safely following availability-first principles as described [here](#).

The `enableAutomaticUpgrade` attribute's functionality is different from that of the `autoUpgradeMinorVersion`. The `autoUpgradeMinorVersion` attributes does not automatically trigger a minor version update when the extension publisher releases a new version. The `autoUpgradeMinorVersion` attribute indicates whether the extension should use a newer minor version if one is available at deployment time. Once deployed, however, the extension will not upgrade minor versions unless redeployed, even with this property set to true.

To keep your extension version updated, we recommend using `enableAutomaticUpgrade` with your extension deployment.

### IMPORTANT

If you add the `enableAutomaticUpgrade` to your template, make sure that you use at API version 2019-12-01 or higher.

# Troubleshoot and support

## Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal and by using the Azure PowerShell module. To see the deployment state of extensions for a given VM, run the following command by using the Azure PowerShell module:

```
Get-AzVMExtension -ResourceGroupName myResourceGroup -VMName myVM -Name myExtensionName
```

Extension execution output is logged to files found in the following directory:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.Monitoring.DependencyAgent\
```

## Support

If you need more help at any point in this article, you can contact the Azure experts on the [Microsoft Q & A and Stack Overflow forums](#). Or, you can file an Azure support incident. Go to the [Azure support site](#) and select **Get support**. For information about how to use Azure Support, read the [Microsoft Azure support FAQ](#).

# Introduction to the Azure Desired State Configuration extension handler

9/21/2022 • 9 minutes to read • [Edit Online](#)

The Azure VM Agent and associated extensions are part of Microsoft Azure infrastructure services. VM extensions are software components that extend VM functionality and simplify various VM management operations.

## NOTE

Before you enable the DSC extension, we would like you to know that a newer version of DSC is now available in preview, managed by a feature of Azure Policy named [guest configuration](#). The guest configuration feature combines features of the Desired State Configuration (DSC) extension handler, Azure Automation State Configuration, and the most commonly requested features from customer feedback. Guest configuration also includes hybrid machine support through [Arc-enabled servers](#).

The primary use case for the Azure Desired State Configuration (DSC) extension is to bootstrap a VM to the [Azure Automation State Configuration \(DSC\) service](#). The service provides [benefits](#) that include ongoing management of the VM configuration and integration with other operational tools, such as Azure Monitoring. Using the extension to register VM's to the service provides a flexible solution that even works across Azure subscriptions.

You can use the DSC extension independently of the Automation DSC service. However, this will only push a configuration to the VM. No ongoing reporting is available, other than locally in the VM.

This article provides information about both scenarios: using the DSC extension for Automation onboarding, and using the DSC extension as a tool for assigning configurations to VMs by using the Azure SDK.

## Prerequisites

- **Local machine:** To interact with the Azure VM extension, you must use either the Azure portal or the Azure PowerShell SDK.
- **Guest Agent:** The Azure VM that's configured by the DSC configuration must be an OS that supports Windows Management Framework (WMF) 4.0 or later. For the full list of supported OS versions, see the [DSC extension version history](#).

## Terms and concepts

This guide assumes familiarity with the following concepts:

- **Configuration:** A DSC configuration document.
- **Node:** A target for a DSC configuration. In this document, *node* always refers to an Azure VM.
- **Configuration data:** A .psd1 file that has environmental data for a configuration.

## Architecture

The Azure DSC extension uses the Azure VM Agent framework to deliver, enact, and report on DSC configurations running on Azure VMs. The DSC extension accepts a configuration document and a set of parameters. If no file is provided, a [default configuration script](#) is embedded with the extension. The default

configuration script is used only to set metadata in [Local Configuration Manager](#).

When the extension is called for the first time, it installs a version of WMF by using the following logic:

- If the Azure VM OS is Windows Server 2016, no action is taken. Windows Server 2016 already has the latest version of PowerShell installed.
- If the **wmfVersion** property is specified, that version of WMF is installed, unless that version is incompatible with the VM's OS.
- If no **wmfVersion** property is specified, the latest applicable version of WMF is installed.

Installing WMF requires a restart. After restarting, the extension downloads the .zip file that's specified in the **modulesUrl** property, if provided. If this location is in Azure Blob storage, you can specify an SAS token in the **sasToken** property to access the file. After the .zip is downloaded and unpacked, the configuration function defined in **configurationFunction** runs to generate an .mof([Managed Object Format](#)) file. The extension then runs `Start-DscConfiguration -Force` by using the generated .mof file. The extension captures output and writes it to the Azure status channel.

### Default configuration script

The Azure DSC extension includes a default configuration script that's intended to be used when you onboard a VM to the Azure Automation DSC service. The script parameters are aligned with the configurable properties of [Local Configuration Manager](#). For script parameters, see [Default configuration script in Desired State Configuration extension with Azure Resource Manager templates](#). For the full script, see the [Azure quickstart template in GitHub](#).

## Information for registering with Azure Automation State Configuration (DSC) service

When using the DSC Extension to register a node with the State Configuration service, three values will need to be provided.

- **RegistrationUrl** - the https address of the Azure Automation account
- **RegistrationKey** - a shared secret used to register nodes with the service
- **NodeConfigurationName** - the name of the Node Configuration (MOF) to pull from the service to configure the server role

This information can be seen in the Azure portal or you can use PowerShell.

```
(Get-AzAutomationRegistrationInfo -ResourceGroupName <resourcegroupname> -AutomationAccountName <accountname>).Endpoint  
(Get-AzAutomationRegistrationInfo -ResourceGroupName <resourcegroupname> -AutomationAccountName <accountname>).PrimaryKey
```

For the Node Configuration name, make sure the node configuration exists in Azure State Configuration. If it does not, the extension deployment will return a failure. Also make sure you are using the name of the *Node Configuration* and not the Configuration. A Configuration is defined in a script that is used [to compile the Node Configuration \(MOF file\)](#). The name will always be the Configuration followed by a period `.` and either `localhost` or a specific computer name.

## DSC extension in Resource Manager templates

In most scenarios, Resource Manager deployment templates are the expected way to work with the DSC extension. For more information and for examples of how to include the DSC extension in Resource Manager deployment templates, see [Desired State Configuration extension with Azure Resource Manager templates](#).

## DSC extension PowerShell cmdlets

The PowerShell cmdlets that are used to manage the DSC extension are best used in interactive troubleshooting and information-gathering scenarios. You can use the cmdlets to package, publish, and monitor DSC extension deployments. Cmdlets for the DSC extension aren't yet updated to work with the [default configuration script](#).

The **Publish-AzVMDscConfiguration** cmdlet takes in a configuration file, scans it for dependent DSC resources, and then creates a .zip file. The .zip file contains the configuration and DSC resources that are needed to enact the configuration. The cmdlet can also create the package locally by using the *-OutputArchivePath* parameter. Otherwise, the cmdlet publishes the .zip file to blob storage, and then secures it with an SAS token.

The .ps1 configuration script that the cmdlet creates is in the .zip file at the root of the archive folder. The module folder is placed in the archive folder in resources.

The **Set-AzVMDscExtension** cmdlet injects the settings that the PowerShell DSC extension requires into a VM configuration object.

The **Get-AzVMDscExtension** cmdlet retrieves the DSC extension status of a specific VM.

The **Get-AzVMDscExtensionStatus** cmdlet retrieves the status of the DSC configuration that's enacted by the DSC extension handler. This action can be performed on a single VM or on a group of VMs.

The **Remove-AzVMDscExtension** cmdlet removes the extension handler from a specific VM. This cmdlet does *not* remove the configuration, uninstall WMF, or change the applied settings on the VM. It only removes the extension handler.

Important information about Resource Manager DSC extension cmdlets:

- Azure Resource Manager cmdlets are synchronous.
- The *ResourceGroupName*, *VMName*, *ArchiveStorageAccountName*, *Version*, and *Location* parameters are all required.
- *ArchiveResourceGroupName* is an optional parameter. You can specify this parameter when your storage account belongs to a different resource group than the one where the VM is created.
- Use the **AutoUpdate** switch to automatically update the extension handler to the latest version when it's available. This parameter has the potential to cause restarts on the VM when a new version of WMF is released.

### Get started with cmdlets

The Azure DSC extension can use DSC configuration documents to directly configure Azure VMs during deployment. This step doesn't register the node to Automation. The node is *not* centrally managed.

The following example shows a simple example of a configuration. Save the configuration locally as `iisInstall.ps1`.

```
configuration IISInstall
{
    node "localhost"
    {
        WindowsFeature IIS
        {
            Ensure = "Present"
            Name = "Web-Server"
        }
    }
}
```

The following commands place the `iisInstall.ps1` script on the specified VM. The commands also execute the configuration, and then report back on status.

```

$resourceGroup = 'dscVmDemo'
$vmName = 'myVM'
$storageName = 'demostorage'
#Publish the configuration script to user storage
Publish-AzVMDscConfiguration -ConfigurationPath .\iisInstall.ps1 -ResourceGroupName $resourceGroup -
StorageAccountName $storageName -force
#Set the VM to run the DSC configuration
Set-AzVMDscExtension -Version '2.76' -ResourceGroupName $resourceGroup -VMName $vmName -
ArchiveStorageAccountName $storageName -ArchiveBlobName 'iisInstall.ps1.zip' -AutoUpdate -ConfigurationName
'IISInstall'

```

## Azure CLI deployment

The Azure CLI can be used to deploy the DSC extension to an existing virtual machine.

For a virtual machine running Windows:

```

az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name DSC \
--publisher Microsoft.PowerShell \
--version 2.77 --protected-settings '{}' \
--settings '{}'

```

For a virtual machine running Linux:

```

az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name DSCForLinux \
--publisher Microsoft.OSTCExtensions \
--version 2.7 --protected-settings '{}' \
--settings '{}'

```

## Azure portal functionality

To set up DSC in the portal:

1. Go to a VM.
2. Under **Settings**, select **Extensions**.
3. In the new page that's created, select + **Add**, and then select **PowerShell Desired State Configuration**.
4. Click **Create** at the bottom of the extension information page.

The portal collects the following input:

- **Configuration Modules or Script:** This field is mandatory (the form has not been updated for the [default configuration script](#)). Configuration modules and scripts require a .ps1 file that has a configuration script or a .zip file with a .ps1 configuration script at the root. If you use a .zip file, all dependent resources must be included in module folders in the .zip. You can create the .zip file by using the **Publish-AzureVMDscConfiguration -OutputArchivePath** cmdlet that's included in the Azure PowerShell SDK. The .zip file is uploaded to your user blob storage and secured by an SAS token.
- **Module-qualified Name of Configuration:** You can include multiple configuration functions in a .ps1 file. Enter the name of the configuration .ps1 script followed by \ and the name of the configuration function. For example, if your .ps1 script has the name configuration.ps1 and the configuration is

lisInstall, enter `configuration.ps1\lisInstall`.

- **Configuration Arguments:** If the configuration function takes arguments, enter them here in the format `argumentName1=value1,argumentName2=value2`. This format is a different format in which configuration arguments are accepted in PowerShell cmdlets or Resource Manager templates.
- **Configuration Data PSD1 File:** If your configuration requires a configuration data file in `.psd1`, use this field to select the data file and upload it to your user blob storage. The configuration data file is secured by an SAS token in blob storage.
- **WMF Version:** Specifies the version of Windows Management Framework (WMF) that should be installed on your VM. Setting this property to latest installs the most recent version of WMF. Currently, the only possible values for this property are 4.0, 5.0, 5.1, and latest. These possible values are subject to updates. The default value is **latest**.
- **Data Collection:** Determines if the extension will collect telemetry. For more information, see [Azure DSC extension data collection](#).
- **Version:** Specifies the version of the DSC extension to install. For information about versions, see [DSC extension version history](#).
- **Auto Upgrade Minor Version:** This field maps to the **AutoUpdate** switch in the cmdlets and enables the extension to automatically update to the latest version during installation. **Yes** will instruct the extension handler to use the latest available version and **No** will force the **Version** specified to be installed. Selecting neither **Yes** nor **No** is the same as selecting **No**.

## Logs

Logs for the extension are stored in the following location:

```
C:\WindowsAzure\Logs\Plugins\Microsoft.Powershell.DSC\<version number>
```

## Next steps

- For more information about PowerShell DSC, go to the [PowerShell documentation center](#).
- Examine the [Resource Manager template for the DSC extension](#).
- For more functionality that you can manage by using PowerShell DSC, and for more DSC resources, browse the [PowerShell gallery](#).
- For details about passing sensitive parameters into configurations, see [Manage credentials securely with the DSC extension handler](#).

# DSC extension for Linux (Microsoft.OSTCExtensions.DSCForLinux)

9/21/2022 • 7 minutes to read • [Edit Online](#)

Desired State Configuration (DSC) is a management platform that you can use to manage your IT and development infrastructure with configuration as code.

## NOTE

The DSC extension for Linux and the [Log Analytics virtual machine extension for Linux](#) currently present a conflict and aren't supported in a side-by-side configuration. Don't use the two solutions together on the same VM.

Before you enable the DSC extension, we would like you to know that a newer version of DSC is now available in preview, managed by a feature of Azure Policy named [guest configuration](#). The guest configuration feature combines features of the Desired State Configuration (DSC) extension handler, Azure Automation State Configuration, and the most commonly requested features from customer feedback. Guest configuration also includes hybrid machine support through [Arc-enabled servers](#).

The DSCForLinux extension is published and supported by Microsoft. The extension installs the OMI and DSC agent on Azure virtual machines. The DSC extension can also do the following actions:

- Register the Linux VM to an Azure Automation account to pull configurations from the Azure Automation service (Register ExtensionAction).
- Push MOF configurations to the Linux VM (Push ExtensionAction).
- Apply meta MOF configuration to the Linux VM to configure a pull server in order to pull node configuration (Pull ExtensionAction).
- Install custom DSC modules to the Linux VM (Install ExtensionAction).
- Remove custom DSC modules from the Linux VM (Remove ExtensionAction).

## Prerequisites

### Operating system

For nodes running Linux, the DSC Linux extension supports all the Linux distributions listed in the [PowerShell DSC documentation](#).

### Internet connectivity

The DSCForLinux extension requires the target virtual machine to be connected to the internet. For example, the Register extension requires connectivity to the Automation service. For other actions such as Pull, Pull, Install requires connectivity to Azure Storage and GitHub. It depends on settings provided by the customer.

## Extension schema

### Public configuration

Here are all the supported public configuration parameters:

- `FileUri` : (optional, string) The uri of the MOF file, meta MOF file, or custom resource zip file.
- `ResourceName` : (optional, string) The name of the custom resource module.
- `ExtensionAction` : (optional, string) Specifies what an extension does. Valid values are Register, Push, Pull, Install, and Remove. If not specified, it's considered a Push Action by default.

- `NodeConfigurationName` : (optional, string) The name of a node configuration to apply.
- `RefreshFrequencyMins` : (optional, int) Specifies how often (in minutes) that DSC attempts to obtain the configuration from the pull server. If configuration on the pull server differs from the current one on the target node, it's copied to the pending store and applied.
- `ConfigurationMode` : (optional, string) Specifies how DSC should apply the configuration. Valid values are `ApplyOnly`, `ApplyAndMonitor`, and `ApplyAndAutoCorrect`.
- `ConfigurationModeFrequencyMins` : (optional, int) Specifies how often (in minutes) DSC ensures that the configuration is in the desired state.

#### **NOTE**

If you use a version earlier than 2.3, the mode parameter is the same as ExtensionAction. Mode seems to be an overloaded term. To avoid confusion, ExtensionAction is used from version 2.3 onward. For backward compatibility, the extension supports both mode and ExtensionAction.

## Protected configuration

Here are all the supported protected configuration parameters:

- `StorageAccountName` : (optional, string) The name of the storage account that contains the file
- `StorageAccountKey` : (optional, string) The key of the storage account that contains the file
- `RegistrationUrl` : (optional, string) The URL of the Azure Automation account
- `RegistrationKey` : (optional, string) The access key of the Azure Automation account

## Scenarios

### Register an Azure Automation account

protected.json

```
{
  "RegistrationUrl": "<azure-automation-account-url>",
  "RegistrationKey": "<azure-automation-account-key>"
}
```

public.json

```
{
  "ExtensionAction" : "Register",
  "NodeConfigurationName" : "<node-configuration-name>",
  "RefreshFrequencyMins" : "<value>",
  "ConfigurationMode" : "<ApplyAndMonitor | ApplyAndAutoCorrect | ApplyOnly>",
  "ConfigurationModeFrequencyMins" : "<value>"
}
```

PowerShell format

```

$privateConfig = '{
    "RegistrationUrl": "<azure-automation-account-url>",
    "RegistrationKey": "<azure-automation-account-key>"
}'

$publicConfig = '{
    "ExtensionAction" : "Register",
    "NodeConfigurationName": "<node-configuration-name>",
    "RefreshFrequencyMins": "<value>",
    "ConfigurationMode": "<ApplyAndMonitor | ApplyAndAutoCorrect | ApplyOnly>",
    "ConfigurationModeFrequencyMins": "<value>"
}'

```

### Apply an MOF configuration file (in an Azure storage account) to the VM

protected.json

```
{
    "StorageAccountName": "<storage-account-name>",
    "StorageAccountKey": "<storage-account-key>"
}
```

public.json

```
{
    "FileUri": "<mof-file-uri>",
    "ExtensionAction": "Push"
}
```

PowerShell format

```

$privateConfig = '{
    "StorageAccountName": "<storage-account-name>",
    "StorageAccountKey": "<storage-account-key>"
}'

$publicConfig = '{
    "FileUri": "<mof-file-uri>",
    "ExtensionAction": "Push"
}'

```

### Apply an MOF configuration file (in public storage) to the VM

public.json

```
{
    "FileUri": "<mof-file-uri>"
}
```

PowerShell format

```

$publicConfig = '{
    "FileUri": "<mof-file-uri>"
}'

```

### Apply a meta MOF configuration file (in an Azure storage account) to the VM

protected.json

```
{  
  "StorageAccountName": "<storage-account-name>",  
  "StorageAccountKey": "<storage-account-key>"  
}
```

public.json

```
{  
  "ExtensionAction": "Pull",  
  "FileUri": "<meta-mof-file-uri>"  
}
```

PowerShell format

```
$privateConfig = '{  
  "StorageAccountName": "<storage-account-name>",  
  "StorageAccountKey": "<storage-account-key>"  
}'  
  
$publicConfig = '{  
  "ExtensionAction": "Pull",  
  "FileUri": "<meta-mof-file-uri>"  
}'
```

## Apply a meta MOF configuration file (in public storage) to the VM

public.json

```
{  
  "FileUri": "<meta-mof-file-uri>",  
  "ExtensionAction": "Pull"  
}
```

PowerShell format

```
$publicConfig = '{  
  "FileUri": "<meta-mof-file-uri>",  
  "ExtensionAction": "Pull"  
}'
```

## Install a custom resource module (a zip file in an Azure storage account) to the VM

protected.json

```
{  
  "StorageAccountName": "<storage-account-name>",  
  "StorageAccountKey": "<storage-account-key>"  
}
```

public.json

```
{  
  "ExtensionAction": "Install",  
  "FileUri": "<resource-zip-file-uri>"  
}
```

PowerShell format

```
$privateConfig = '{
  "StorageAccountName": "<storage-account-name>",
  "StorageAccountKey": "<storage-account-key>"
}'

$publicConfig = '{
  "ExtensionAction": "Install",
  "FileUri": "<resource-zip-file-uri>"
}'
```

### Install a custom resource module (a zip file in public storage) to the VM

public.json

```
{
  "ExtensionAction": "Install",
  "FileUri": "<resource-zip-file-uri>"
}
```

PowerShell format

```
$publicConfig = '{
  "ExtensionAction": "Install",
  "FileUri": "<resource-zip-file-uri>"
}'
```

### Remove a custom resource module from the VM

public.json

```
{
  "ResourceName": "<resource-name>",
  "ExtensionAction": "Remove"
}
```

PowerShell format

```
$publicConfig = '{
  "ResourceName": "<resource-name>",
  "ExtensionAction": "Remove"
}'
```

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when you deploy one or more virtual machines that require post-deployment configuration, such as onboarding to Azure Automation.

The sample Resource Manager template is [dsc-linux-azure-storage-on-ubuntu](#) and [dsc-linux-public-storage-on-ubuntu](#).

For more information about the Azure Resource Manager template, see [Authoring Azure Resource Manager templates](#).

# Azure CLI deployment

## Use [Azure CLI][azure-cli]

Before you deploy the DSCForLinux extension, configure your `public.json` and `protected.json` according to the different scenarios in section 3.

### Classic

#### IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

The classic deployment mode is also called Azure Service Management mode. You can switch to it by running:

```
$ azure config mode asm
```

You can deploy the DSCForLinux extension by running:

```
$ azure vm extension set <vm-name> DSCForLinux Microsoft.OSTCExtensions <version> \
--private-config-path protected.json --public-config-path public.json
```

To learn the latest extension version available, run:

```
$ azure vm extension list
```

### Resource Manager

You can switch to Azure Resource Manager mode by running:

```
$ azure config mode arm
```

You can deploy the DSCForLinux extension by running:

```
$ azure vm extension set <resource-group> <vm-name> \
DSCForLinux Microsoft.OSTCExtensions <version> \
--private-config-path protected.json --public-config-path public.json
```

#### NOTE

In Azure Resource Manager mode, `azure vm extension list` isn't available for now.

## Use [Azure PowerShell][azure-powershell]

### Classic

You can sign in to your Azure account in Azure Service Management mode by running:

```
Add-AzureAccount
```

And deploy the DSCForLinux extension by running:

```
$vmname = '<vm-name>'  
$vm = Get-AzureVM -ServiceName $vmname -Name $vmname  
$extensionName = 'DSCForLinux'  
$publisher = 'Microsoft.OSTCExtensions'  
$version = '< version>'
```

Change the content of \$privateConfig and \$publicConfig according to different scenarios in the previous section.

```
$privateConfig = '{  
    "StorageAccountName": "<storage-account-name>",  
    "StorageAccountKey": "<storage-account-key>"  
'
```

```
$publicConfig = '{  
    "ExtensionAction": "Push",  
    "FileUri": "<mof-file-uri>"  
'
```

```
Set-AzureVMExtension -ExtensionName $extensionName -VM $vm -Publisher $publisher `  
-Version $version -PrivateConfiguration $privateConfig `  
-PublicConfiguration $publicConfig | Update-AzureVM
```

## Resource Manager

You can sign in to your Azure account in Azure Resource Manager mode by running:

```
Login-AzAccount
```

To learn more about how to use Azure PowerShell with Azure Resource Manager, see [Manage Azure resources by using Azure PowerShell](#).

You can deploy the DSCForLinux extension by running:

```
$rgName = '<resource-group-name>'  
$vmName = '<vm-name>'  
$location = '< location>'  
$extensionName = 'DSCForLinux'  
$publisher = 'Microsoft.OSTCExtensions'  
$version = '< version>'
```

Change the content of \$privateConfig and \$publicConfig according to different scenarios in the previous section.

```
$privateConfig = '{  
    "StorageAccountName": "<storage-account-name>",  
    "StorageAccountKey": "<storage-account-key>"  
'
```

```
$publicConfig = '{
    "ExtensionAction": "Push",
    "FileUri": "<mof-file-uri>"
}'
```

```
Set-AzVMExtension -ResourceGroupName $rgName -VMName $vmName -Location $location ` 
    -Name $extensionName -Publisher $publisher -ExtensionType $extensionName ` 
    -TypeHandlerVersion $version -SettingString $publicConfig -ProtectedSettingString $privateConfig
```

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command by using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension execution output is logged to the following file:

```
/var/log/azure/<extension-name>/<version>/extension.log file.
```

Error code: 51 represents either unsupported distribution or unsupported extension action. In some cases, DSC Linux extension fails to install OMI when a higher version of OMI already exists in the machine. [error response: (000003)Downgrade not allowed]

### Support

If you need more help at any point in this article, contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure Support incident. Go to the [Azure Support site](#), and select **Get support**. For information about using Azure Support, read the [Microsoft Azure Support FAQ](#).

## Next steps

For more information about extensions, see [Virtual machine extensions and features for Linux](#).

# PowerShell DSC Extension

9/21/2022 • 5 minutes to read • [Edit Online](#)

## Overview

The PowerShell DSC Extension for Windows is published and supported by Microsoft. The extension uploads and applies a PowerShell DSC Configuration on an Azure VM. The DSC Extension calls into PowerShell DSC to enact the received DSC configuration on the VM. This document details the supported platforms, configurations, and deployment options for the DSC virtual machine extension for Windows.

### NOTE

Before you enable the DSC extension, we would like you to know that a newer version of DSC is now available in preview, managed by a feature of Azure Policy named [guest configuration](#). The guest configuration feature combines features of the Desired State Configuration (DSC) extension handler, Azure Automation State Configuration, and the most commonly requested features from customer feedback. Guest configuration also includes hybrid machine support through [Arc-enabled servers](#).

## Prerequisites

### Operating system

The DSC Extension supports the following OS's

Windows Server 2019, Windows Server 2016, Windows Server 2012R2, Windows Server 2012, Windows Server 2008 R2 SP1, Windows Client 7/8.1/10

### Internet connectivity

The DSC extension for Windows requires that the target virtual machine is able to communicate with Azure and the location of the configuration package (.zip file) if it is stored in a location outside of Azure.

## Extension schema

The following JSON shows the schema for the settings portion of the DSC Extension in an Azure Resource Manager template.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "Microsoft.Powershell.DSC",
  "apiVersion": "2018-10-01",
  "location": "<location>",
  "properties": {
    "publisher": "Microsoft.Powershell",
    "type": "DSC",
    "typeHandlerVersion": "2.77",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "wmfVersion": "latest",
      "configuration": {
        "url": "http://validURLToConfigLocation",
        "script": "ConfigurationScript.ps1",
        "function": "ConfigurationFunction"
      },
      "configurationArguments": {
        "argument1": "Value1",
        "argument2": "Value2"
      },
      "configurationData": {
        "url": "https://foo.psd1"
      },
      "privacy": {
        "dataCollection": "enable"
      },
      "advancedOptions": {
        "forcePullAndApply": false,
        "downloadMappings": {
          "specificDependencyKey": "https://myCustomDependencyLocation"
        }
      }
    },
    "protectedSettings": {
      "configurationArguments": {
        "parameterOfTypePSCredential1": {
          "userName": "UsernameValue1",
          "password": "PasswordValue1"
        },
        "parameterOfTypePSCredential2": {
          "userName": "UsernameValue2",
          "password": "PasswordValue2"
        }
      },
      "configurationUrlSasToken": "?g!bber1sht0k3n",
      "configurationDataUrlSasToken": "?dataAcC355T0k3N"
    }
  }
}
```

## Property values

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2018-10-01	date
publisher	Microsoft.Powershell.DSC	string
type	DSC	string
typeHandlerVersion	2.77	int

## Settings Property values

NAME	DATA TYPE	DESCRIPTION
settings.wmfVersion	string	Specifies the version of the Windows Management Framework that should be installed on your VM. Setting this property to 'latest' will install the most updated version of WMF. The only current possible values for this property are '4.0', '5.0', and 'latest'. These possible values are subject to updates. The default value is 'latest'.
settings.configuration.url	string	Specifies the URL location from which to download your DSC configuration zip file. If the URL provided requires a SAS token for access, you will need to set the <code>protectedSettings.configurationUrlSasToken</code> property to the value of your SAS token. This property is required if <code>settings.configuration.script</code> and/or <code>settings.configuration.function</code> are defined.
settings.configuration.script	string	Specifies the file name of the script that contains the definition of your DSC configuration. This script must be in the root folder of the zip file downloaded from the URL specified by the <code>configuration.url</code> property. This property is required if <code>settings.configuration.url</code> and/or <code>settings.configuration.script</code> are defined.
settings.configuration.function	string	Specifies the name of your DSC configuration. The configuration named must be contained in the script defined by <code>configuration.script</code> . This property is required if <code>settings.configuration.url</code> and/or <code>settings.configuration.function</code> are defined.
settings.configurationArguments	Collection	Defines any parameters you would like to pass to your DSC configuration. This property will not be encrypted.
settings.configurationData.url	string	Specifies the URL from which to download your configuration data (.pds1) file to use as input for your DSC configuration. If the URL provided requires a SAS token for access, you will need to set the <code>protectedSettings.configurationDataUrlSasToken</code> property to the value of your SAS token.

NAME	DATA TYPE	DESCRIPTION
settings.privacy.dataEnabled	string	Enables or disables telemetry collection. The only possible values for this property are 'Enable', 'Disable', "", or \$null. Leaving this property blank or null will enable telemetry
settings.advancedOptions.forcePullAndApply	Bool	This setting is designed to enhance the experience of working with the extension to register nodes with Azure Automation DSC. If the value is <code>\$true</code> , the extension will wait for the first run of the configuration pulled from the service before returning success/failure. If the value is set to <code>\$false</code> , the status returned by the extension will only refer to whether the node was registered with Azure Automation State Configuration successfully and the node configuration will not be run during the registration.
settings.advancedOptions.downloadMappings	Collection	Defines alternate locations to download dependencies such as WMF and .NET

### Protected Settings Property values

NAME	DATA TYPE	DESCRIPTION
protectedSettings.configurationArguments	string	Defines any parameters you would like to pass to your DSC configuration. This property will be encrypted.
protectedSettings.configurationUrlSasToken	string	Specifies the SAS token to access the URL defined by configuration.url. This property will be encrypted.
protectedSettings.configurationDataUrlSasToken	string	Specifies the SAS token to access the URL defined by configurationData.url. This property will be encrypted.

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates are ideal when deploying one or more virtual machines that require post deployment configuration. A sample Resource Manager template that includes the DSC extension for Windows can be found on the [Azure Quick Start Gallery](#).

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

Extension package is downloaded and deployed to this location on the Azure VM

```
C:\Packages\Plugins\{Extension_Name}\{Extension_Version}
```

Extension status file contains the sub status and status success/error codes along with the detailed error and description for each extension run.

```
C:\Packages\Plugins\{Extension_Name}\{Extension_Version}\Status\{0}.Status -> {0} being the sequence number
```

Extension output logs are logged to the following directory:

```
C:\WindowsAzure\Logs\Plugins\{Extension_Name}\{Extension_Version}
```

### Error codes and their meanings

ERROR CODE	MEANING	POSSIBLE ACTION
1000	Generic error	The message for this error is provided by the specific exception in extension logs
52	Extension Install Error	The message for this error is provided by the specific exception
1002	Wmf Install Error	Error while installing WMF.
1004	Invalid Zip Package	Invalid zip ; Error unpacking the zip
1100	Argument Error	Indicates a problem in the input provided by the user. The message for the error is provided by the specific exception

### Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Pass credentials to the Azure DSCExtension handler

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article covers the Desired State Configuration (DSC) extension for Azure. For an overview of the DSC extension handler, see [Introduction to the Azure Desired State Configuration extension handler](#).

## Pass in credentials

As part of the configuration process, you might need to set up user accounts, access services, or install a program in a user context. To do these things, you need to provide credentials.

You can use DSC to set up parameterized configurations. In a parameterized configuration, credentials are passed into the configuration and securely stored in .mof files. The Azure extension handler simplifies credential management by providing automatic management of certificates.

The following DSC configuration script creates a local user account with the specified password:

```
configuration Main
{
    param(
        [Parameter(Mandatory=$true)]
        [ValidateNotNullOrEmpty()]
        [PsCredential]
        $Credential
    )
    Node localhost {
        User LocalUserAccount
        {
            Username = $Credential.UserName
            Password = $Credential
            Disabled = $false
            Ensure = "Present"
            FullName = "Local User Account"
            Description = "Local User Account"
            PasswordNeverExpires = $true
        }
    }
}
```

It's important to include **node localhost** as part of the configuration. The extension handler specifically looks for the **node localhost** statement. If this statement is missing, the following steps don't work. It's also important to include the typecast **[PsCredential]**. This specific type triggers the extension to encrypt the credential.

To publish this script to Azure Blob storage:

```
Publish-AzVMDscConfiguration -ConfigurationPath .\user_configuration.ps1
```

To set the Azure DSC extension and provide the credential:

```
$configurationName = 'Main'  
$configurationArguments = @{ Credential = Get-Credential }  
$configurationArchive = 'user_configuration.ps1.zip'  
$vm = Get-AzVM -Name 'example-1'  
  
$vm = Set-AzVMDscExtension -VMName $vm -ConfigurationArchive $configurationArchive -ConfigurationName  
$configurationName -ConfigurationArgument @configurationArguments  
  
$vm | Update-AzVM
```

## How a credential is secured

Running this code prompts for a credential. After the credential is provided, it's briefly stored in memory. When the credential is published by using the **Set-AzVMDscExtension** cmdlet, the credential is transmitted over HTTPS to the VM. In the VM, Azure stores the credential encrypted on disk by using the local VM certificate. The credential is briefly decrypted in memory, and then it's re-encrypted to pass it to DSC.

This process is different than [using secure configurations without the extension handler](#). The Azure environment gives you a way to transmit configuration data securely via certificates. When you use the DSC extension handler, you don't need to provide **\$CertificatePath** or a **\$CertificateID**/ **\$Thumbprint** entry in **ConfigurationData**.

## Next steps

- Get an [introduction to Azure DSC extension handler](#).
- Examine the [Azure Resource Manager template for the DSC extension](#).
- For more information about PowerShell DSC, go to the [PowerShell documentation center](#).
- For more functionality that you can manage by using PowerShell DSC, and for more DSC resources, browse the [PowerShell gallery](#).

# Desired State Configuration extension with Azure Resource Manager templates

9/21/2022 • 10 minutes to read • [Edit Online](#)

This article describes the Azure Resource Manager template for the Desired State Configuration (DSC) extension handler. Many of the examples use **RegistrationURL** (provided as a String) and **RegistrationKey** (provided as a **PSCredential**) to onboard with Azure Automation. For details about obtaining those values, see [Use DSC metaconfiguration to register hybrid machines](#).

## NOTE

You might encounter slightly different schema examples. The change in schema occurred in the October 2016 release. For details, see [Update from a previous format](#).

Before you enable the DSC extension, we would like you to know that a newer version of DSC is now available in preview, managed by a feature of Azure Policy named [guest configuration](#). The guest configuration feature combines features of the Desired State Configuration (DSC) extension handler, Azure Automation State Configuration, and the most commonly requested features from customer feedback. Guest configuration also includes hybrid machine support through [Arc-enabled servers](#).

## Template example for a Windows VM

The following snippet goes in the **Resource** section of the template. The DSC extension inherits default extension properties. For more information, see [VirtualMachineExtension class](#).

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(parameters('VMName'), '/Microsoft.Powershell.DSC')]",
  "apiVersion": "2018-06-01",
  "location": "[parameters('location')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', parameters('VMName'))]"
  ],
  "properties": {
    "publisher": "Microsoft.Powershell",
    "type": "DSC",
    "typeHandlerVersion": "2.77",
    "autoUpgradeMinorVersion": true,
    "protectedSettings": {
      "Items": {
        "registrationKeyPrivate": "[listKeys(resourceId('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName')), '2018-06-30').Keys[0].value]"
      }
    },
    "settings": {
      "Properties": [
        {
          "Name": "RegistrationKey",
          "Value": {
            "UserName": "PLACEHOLDER_DONOTUSE",
            "Password": "PrivateSettingsRef:registrationKeyPrivate"
          },
          "TypeName": "System.Management.Automation.PSCredential"
        },
        {
          "Name": "RegistrationUrl",
          "Value": "[reference(concat('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName'))).registrationUrl]",
          "TypeName": "System.String"
        },
        {
          "Name": "NodeConfigurationName",
          "Value": "[parameters('nodeConfigurationName')]",
          "TypeName": "System.String"
        }
      ]
    }
  }
}
```

## Template example for Windows virtual machine scale sets

A virtual machine scale set node has a **properties** section that has a **VirtualMachineProfile**, **extensionProfile** attribute. Under **extensions**, add the details for DSC Extension.

The DSC extension inherits default extension properties. For more information, see [VirtualMachineScaleSetExtension class](#).

```

"extensionProfile": {
  "extensions": [
    {
      "name": "Microsoft.Powershell.DSC",
      "properties": {
        "publisher": "Microsoft.Powershell",
        "type": "DSC",
        "typeHandlerVersion": "2.77",
        "autoUpgradeMinorVersion": true,
        "protectedSettings": {
          "Items": [
            "registrationKeyPrivate": "[listKeys(resourceId('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName')), '2018-06-30').Keys[0].value]"
          ]
        },
        "settings": {
          "Properties": [
            {
              "Name": "RegistrationKey",
              "Value": {
                "UserName": "PLACEHOLDER_DONOTUSE",
                "Password": "PrivateSettingsRef:registrationKeyPrivate"
              },
              "TypeName": "System.Management.Automation.PSCredential"
            },
            {
              "Name": "RegistrationUrl",
              "Value": "[reference(concat('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName'))).registrationUrl]",
              "TypeName": "System.String"
            },
            {
              "Name": "NodeConfigurationName",
              "Value": "[parameters('nodeConfigurationName')]",
              "TypeName": "System.String"
            }
          ]
        }
      }
    ]
  }
}

```

## Detailed settings information

Use the following schema in the **settings** section of the Azure DSC extension in a Resource Manager template.

For a list of the arguments that are available for the default configuration script, see [Default configuration script](#).

```

"settings": {
    "wmfVersion": "latest",
    "configuration": {
        "url": "http://validURLToConfigLocation",
        "script": "ConfigurationScript.ps1",
        "function": "ConfigurationFunction"
    },
    "configurationArguments": {
        "argument1": "Value1",
        "argument2": "Value2"
    },
    "configurationData": {
        "url": "https://foo.psd1"
    },
    "privacy": {
        "dataCollection": "enable"
    },
    "advancedOptions": {
        "downloadMappings": {
            "customWmfLocation": "http://myWMFlocation"
        }
    }
},
"protectedSettings": {
    "configurationArguments": {
        "parameterOfTypePSCredential1": {
            "userName": "UsernameValue1",
            "password": "PasswordValue1"
        },
        "parameterOfTypePSCredential2": {
            "userName": "UsernameValue2",
            "password": "PasswordValue2"
        }
    },
    "configurationUrlSasToken": "?g!bber1sh0k3n",
    "configurationDataUrlSasToken": "?dataAcc355T0k3N"
}
}

```

## Details

PROPERTY NAME	TYPE	DESCRIPTION
settings.wmfVersion	string	Specifies the version of Windows Management Framework (WMF) that should be installed on your VM. Setting this property to <b>latest</b> installs the most recent version of WMF. Currently, the only possible values for this property are <b>4.0</b> , <b>5.0</b> , <b>5.1</b> , and <b>latest</b> . These possible values are subject to updates. The default value is <b>latest</b> .

PROPERTY NAME	TYPE	DESCRIPTION
settings.configuration.url	string	Specifies the URL location from which to download your DSC configuration .zip file. If the URL provided requires an SAS token for access, set the <b>protectedSettings.configurationUrlIsSasToken</b> property to the value of your SAS token. This property is required if <b>settings.configuration.script</b> or <b>settings.configuration.function</b> are defined. If no value is given for these properties, the extension calls the default configuration script to set Location Configuration Manager (LCM) metadata, and arguments should be supplied.
settings.configuration.script	string	Specifies the file name of the script that contains the definition of your DSC configuration. This script must be in the root folder of the .zip file that's downloaded from the URL specified by the <b>settings.configuration.url</b> property. This property is required if <b>settings.configuration.url</b> or <b>settings.configuration.script</b> are defined. If no value is given for these properties, the extension calls the default configuration script to set LCM metadata, and arguments should be supplied.
settings.configuration.function	string	Specifies the name of your DSC configuration. The configuration that is named must be included in the script that <b>settings.configuration.script</b> defines. This property is required if <b>settings.configuration.url</b> or <b>settings.configuration.function</b> are defined. If no value is given for these properties, the extension calls the default configuration script to set LCM metadata, and arguments should be supplied.
settings.configurationArguments	Collection	Defines any parameters that you want to pass to your DSC configuration. This property is not encrypted.
settings.configurationData.url	string	Specifies the URL from which to download your configuration data (.psd1) file to use as input for your DSC configuration. If the URL provided requires an SAS token for access, set the <b>protectedSettings.configurationDataUrlIsSasToken</b> property to the value of your SAS token.

PROPERTY NAME	TYPE	DESCRIPTION
settings.privacy.dataCollection	string	Enables or disables telemetry collection. The only possible values for this property are <b>Enable</b> , <b>Disable</b> , "", or <b>\$null</b> . Leaving this property blank or null enables telemetry. The default value is "". For more information, see <a href="#">Azure DSC extension data collection</a> .
settings.advancedOptions.downloadMappings	Collection	Defines alternate locations from which to download WMF. For more information, see <a href="#">Azure DSC extension 2.8 and how to map downloads of the extension dependencies to your own location</a> .
protectedSettings.configurationArguments	Collection	Defines any parameters that you want to pass to your DSC configuration. This property is encrypted.
protectedSettings.configurationUrlSasToken	string	Specifies the SAS token to use to access the URL that <b>settings.configuration.url</b> defines. This property is encrypted.
protectedSettings.configurationDataUrlSasToken	string	Specifies the SAS token to use to access the URL that <b>settings.configurationData.url</b> defines. This property is encrypted.

## Default configuration script

For more information about the following values, see [Local Configuration Manager basic settings](#). You can use the DSC extension default configuration script to configure only the LCM properties that are listed in the following table.

PROPERTY NAME	TYPE	DESCRIPTION
protectedSettings.configurationArguments.RegistrationKey	PSCredential	Required property. Specifies the key that's used for a node to register with the Azure Automation service as the password of a PowerShell credential object. This value can be automatically discovered by using the <b>listkeys</b> method against the Automation account. See the <a href="#">example</a> .
settings.configurationArguments.RegistrationUrl	string	Required property. Specifies the URL of the Automation endpoint where the node attempts to register. This value can be automatically discovered by using the <b>reference</b> method against the Automation account.
settings.configurationArguments.NodeConfigurationName	string	Required property. Specifies the node configuration in the Automation account to assign to the node.

PROPERTY NAME	TYPE	DESCRIPTION
settings.configurationArguments.ConfigurationMode	string	Specifies the mode for LCM. Valid options include <b>ApplyOnly</b> , <b>ApplyandMonitor</b> , and <b>ApplyandAutoCorrect</b> . The default value is <b>ApplyandMonitor</b> .
settings.configurationArguments.RefreshFrequencyMins	uint32	Specifies how often LCM attempts to check with the Automation account for updates. Default value is <b>30</b> . Minimum value is <b>15</b> .
settings.configurationArguments.ConfigurationModeFrequencyMins	uint32	Specifies how often LCM validates the current configuration. Default value is <b>15</b> . Minimum value is <b>15</b> .
settings.configurationArguments.RebootNodeIfNeeded	boolean	Specifies whether a node can be automatically rebooted if a DSC operation requests it. Default value is <b>false</b> .
settings.configurationArguments.ActionAfterReboot	string	Specifies what happens after a reboot when applying a configuration. Valid options are <b>ContinueConfiguration</b> and <b>StopConfiguration</b> . Default value is <b>ContinueConfiguration</b> .
settings.configurationArguments.AllowModuleOverwrite	boolean	Specifies whether LCM overwrites existing modules on the node. Default value is <b>false</b> .

## settings vs. protectedSettings

All settings are saved in a settings text file on the VM. Properties listed under **settings** are public properties. Public properties aren't encrypted in the settings text file. Properties listed under **protectedSettings** are encrypted with a certificate and are not shown in plain text in the settings file on the VM.

If the configuration needs credentials, you can include the credentials in **protectedSettings**:

```
"protectedSettings": {
    "configurationArguments": {
        "parameterOfTypePSCredential1": {
            "userName": "UsernameValue1",
            "password": "PasswordValue1"
        }
    }
}
```

## Example configuration script

The following example shows the default behavior for the DSC extension, which is to provide metadata settings to LCM and register with the Automation DSC service. Configuration arguments are required. Configuration arguments are passed to the default configuration script to set LCM metadata.

```

"settings": {
    "configurationArguments": {
        "RegistrationUrl" : "[parameters('registrationUrl1')]",
        "NodeConfigurationName" : "nodeConfigurationNameValue1"
    }
},
"protectedSettings": {
    "configurationArguments": {
        "RegistrationKey": {
            "userName": "NOT_USED",
            "Password": "registrationKey"
        }
    }
}
}

```

## Example using the configuration script in Azure Storage

The following example is from the [DSC extension handler overview](#). This example uses Resource Manager templates instead of cmdlets to deploy the extension. Save the lisInstall.ps1 configuration, place it in a .zip file (example: `iisinstall.zip`), and then upload the file in an accessible URL. This example uses Azure Blob storage, but you can download .zip files from any arbitrary location.

In the Resource Manager template, the following code instructs the VM to download the correct file, and then run the appropriate PowerShell function:

```

"settings": {
    "configuration": {
        "url": "https://demo.blob.core.windows.net/iisinstall.zip",
        "script": "IisInstall.ps1",
        "function": "IISInstall"
    }
},
"protectedSettings": {
    "configurationUrlsSasToken": "odLPL/U1p9lvcnp..."
}

```

## Example using referenced Azure Automation registration values

The following example gets the **RegistrationUrl** and **RegistrationKey** by referencing the Azure Automation account properties and using the `listkeys` method to retrieve the Primary Key (0). In this example, the parameters **automationAccountName** and **NodeConfigName** were provided to the template.

```

"settings": {
    "RegistrationUrl" : "[reference(concat('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName'))).registrationUrl]",
    "NodeConfigurationName" : "[parameters('NodeConfigName')]"
},
"protectedSettings": {
    "configurationArguments": {
        "RegistrationKey": {
            "userName": "NOT_USED",
            "Password": "[listKeys(resourceId('Microsoft.Automation/automationAccounts/',
parameters('automationAccountName')), '2018-01-15').Keys[0].value]"
        }
    }
}

```

## Update from a previous format

Any settings in a previous format of the extension (and which have the public properties **ModulesUrl**, **ModuleSource**, **ModuleVersion**, **ConfigurationFunction**, **SasToken**, or **Properties**) automatically adapt to the current format of the extension. They run just as they did before.

The following schema shows what the previous settings schema looked like:

```
"settings": {
    "WMFVersion": "latest",
    "ModulesUrl": "https://UrlToZipContainingConfigurationScript.ps1.zip",
    "SasToken": "SAS Token if ModulesUrl points to private Azure Blob Storage",
    "ConfigurationFunction": "ConfigurationScript.ps1\\ConfigurationFunction",
    "Properties": {
        "ParameterToConfigurationFunction1": "Value1",
        "ParameterToConfigurationFunction2": "Value2",
        "ParameterOfTypePSCredential1": {
            "UserName": "UsernameValue1",
            "Password": "PrivateSettingsRef:Key1"
        },
        "ParameterOfTypePSCredential2": {
            "UserName": "UsernameValue2",
            "Password": "PrivateSettingsRef:Key2"
        }
    }
},
"protectedSettings": {
    "Items": {
        "Key1": "PasswordValue1",
        "Key2": "PasswordValue2"
    },
    "DataBlobUri": "https://UrlToConfigurationDataWithOptionalSasToken.psd1"
}
```

Here's how the previous format adapts to the current format:

CURRENT PROPERTY NAME	PREVIOUS SCHEMA EQUIVALENT
settings.wmfVersion	settings.WMFVersion
settings.configuration.url	settings.ModulesUrl
settings.configuration.script	First part of settings.ConfigurationFunction (before \\)
settings.configuration.function	Second part of settings.ConfigurationFunction (after \\)
settings.configuration.module.name	settings.ModuleSource
settings.configuration.module.version	settings.ModuleVersion
settings.configurationArguments	settings.Properties
settings.configurationData.url	protectedSettings.DataBlobUri (without SAS token)
settings.privacy.dataCollection	settings.Privacy.dataCollection
settings.advancedOptions.downloadMappings	settings.AdvancedOptions.DownloadMappings

CURRENT PROPERTY NAME	PREVIOUS SCHEMA EQUIVALENT
protectedSettings.configurationArguments	protectedSettings.Properties
protectedSettings.configurationUrlSasToken	settings.SasToken
protectedSettings.configurationDataUrlSasToken	SAS token from protectedSettings.DataBlobUri

## Troubleshooting

Here are some of the errors you might run into and how you can fix them.

### Invalid values

"Privacy.dataCollection is '{0}'. The only possible values are '', 'Enable', and 'Disable'". "WmfVersion is '{0}'. Only possible values are ... and 'latest'".

**Problem:** A provided value is not allowed.

**Solution:** Change the invalid value to a valid value. For more information, see the table in [Details](#).

### Invalid URL

"ConfigurationData.url is '{0}'. This is not a valid URL" "DataBlobUri is '{0}'. This is not a valid URL"

"Configuration.url is '{0}'. This is not a valid URL"

**Problem:** A provided URL is not valid.

**Solution:** Check all your provided URLs. Ensure that all URLs resolve to valid locations that the extension can access on the remote machine.

### Invalid RegistrationKey type

"Invalid type for parameter RegistrationKey of type PSCredential."

**Problem:** The *RegistrationKey* value in protectedSettings.configurationArguments cannot be provided as any type other than a PSCredential.

**Solution:** Change your protectedSettings.configurationArguments entry for RegistrationKey to a PSCredential type using the following format:

```

"configurationArguments": {
    "RegistrationKey": {
        "userName": "NOT_USED",
        "Password": "RegistrationKey"
    }
}

```

### Invalid ConfigurationArgument type

"Invalid configurationArguments type {0}"

**Problem:** The *ConfigurationArguments* property can't resolve to a **Hash table** object.

**Solution:** Make your *ConfigurationArguments* property a **Hash table**. Follow the format provided in the preceding examples. Watch for quotes, commas, and braces.

### Duplicate ConfigurationArguments

"Found duplicate arguments '{0}' in both public and protected configurationArguments"

**Problem:** The *ConfigurationArguments* in public settings and the *ConfigurationArguments* in protected settings

have properties with the same name.

**Solution:** Remove one of the duplicate properties.

### **Missing properties**

"settings.Configuration.function requires that settings.configuration.url or settings.configuration.module is specified"

"settings.Configuration.url requires that settings.configuration.script is specified"

"settings.Configuration.script requires that settings.configuration.url is specified"

"settings.Configuration.url requires that settings.configuration.function is specified"

"protectedSettings.ConfigurationUrlSasToken requires that settings.configuration.url is specified"

"protectedSettings.ConfigurationDataUrlSasToken requires that settings.configurationData.url is specified"

**Problem:** A defined property needs another property, which is missing.

**Solutions:**

- Provide the missing property.
- Remove the property that needs the missing property.

# Manage administrative users, SSH, and check or repair disks on Linux VMs using the VMAccess Extension with the Azure CLI

9/21/2022 • 5 minutes to read • [Edit Online](#)

## Overview

The disk on your Linux VM is showing errors. You somehow reset the root password for your Linux VM or accidentally deleted your SSH private key. If that happened back in the days of the datacenter, you would need to drive there and then open the KVM to get at the server console. Think of the Azure VMAccess extension as that KVM switch that allows you to access the console to reset access to Linux or perform disk level maintenance.

This article shows you how to use the Azure VMAccess Extension to check or repair a disk, reset user access, manage administrative user accounts, or update the SSH configuration on Linux when they are running as Azure Resource Manager virtual machines. If you need to manage Classic virtual machines - you can follow the instructions found in the [classic VM documentation](#).

### NOTE

If you use the VMAccess Extension to reset the password of your VM after installing the AAD Login Extension you will need to rerun the AAD Login Extension to re-enable AAD Login for your machine.

## Prerequisites

### Operating system

The VM Access extension can be run against these Linux distributions:

DISTRIBUTION	VERSION
Ubuntu	16.04 LTS, 14.04 LTS and 12.04 LTS
Debian	Debian 7.9+, 8.2+
Red Hat	RHEL 6.7+, 7.1+
Oracle Linux	6.4+, 7.0+
Suse	11 and 12
OpenSuse	openSUSE Leap 42.2+
CentOS	CentOS 6.3+, 7.0+
CoreOS	494.4.0+

## Ways to use the VMAccess Extension

There are two ways that you can use the VMAccess Extension on your Linux VMs:

- Use the Azure CLI and the required parameters.
- [Use raw JSON files that the VMAccess Extension process](#) and then act on.

The following examples use `az vm user` commands. To perform these steps, you need the latest [Azure CLI](#) installed and logged in to an Azure account using `az login`.

## Update SSH key

The following example updates the SSH key for the user `azureuser` on the VM named `myVM`:

```
az vm user update \
--resource-group myResourceGroup \
--name myVM \
--username azureuser \
--ssh-key-value ~/.ssh/id_rsa.pub
```

**NOTE:** The `az vm user update` command appends the new public key text to the `~/.ssh/authorized_keys` file for the admin user on the VM. This does not replace or remove any existing SSH keys. This will not remove prior keys set at deployment time or subsequent updates via the VMAccess Extension.

## Reset password

The following example resets the password for the user `azureuser` on the VM named `myVM`:

```
az vm user update \
--resource-group myResourceGroup \
--name myVM \
--username azureuser \
--password myNewPassword
```

## Restart SSH

The following example restarts the SSH daemon and resets the SSH configuration to default values on a VM named `myVM`:

```
az vm user reset-ssh \
--resource-group myResourceGroup \
--name myVM
```

## Create an administrative/sudo user

The following example creates a user named `myNewUser` with **sudo** permissions. The account uses an SSH key for authentication on the VM named `myVM`. This method is designed to help you regain access to a VM in the event that current credentials are lost or forgotten. As a best practice, accounts with **sudo** permissions should be limited.

```
az vm user update \
--resource-group myResourceGroup \
--name myVM \
--username myNewUser \
--ssh-key-value ~/.ssh/id_rsa.pub
```

# Delete a user

The following example deletes a user named `myNewUser` on the VM named `myVM`:

```
az vm user delete \
--resource-group myResourceGroup \
--name myVM \
--username myNewUser
```

# Use JSON files and the VMAccess Extension

The following examples use raw JSON files. Use [az vm extension set](#) to then call your JSON files. These JSON files can also be called from Azure templates.

## Reset user access

If you have lost access to root on your Linux VM, you can launch a VMAccess script to update a user's SSH key or password.

To update the SSH public key of a user, create a file named `update_ssh_key.json` and add settings in the following format. Replace `username` and `ssh_key` with your own information:

```
{
  "username": "azureuser",
  "ssh_key": "ssh-rsa"
  AAAAB3NzaC1yc2EAAAQABAAQACZ3S7gGp3rcbKmG2Y4vGZFMuMZCwoUzZNGxxxxxx2XV2x9FfAh8igD+1F8UdjFX3t5ebMm6BnnMh8
  fHwkTRd0t3LDQq8o8ElTBrzAKPxZN2tMzn0Ds5H1emb2UX0oRIGRcvWqsd4oJmxsXa/Si98Wa6RHwbc9Qzhw80KAc0VhmndZAZAGR+Wq6ys
  1No5TMOr1/ZyQAook5C4FtcSGn3Y+WczaogWIxG4ZaWk128g79VIeJcIQqOjPodHvQAh117qD1ItVvBFM0ben3GyhYTm7k4Yw1Edk0Nm4yV/
  UIW0la1rmyztSBQIm9sZmSq44XXgjVmDHNF8UFcz1ToE4r2SdwTmZv00T2i5faeYnHzxiLPA3Enub7xxxxxxxxFArnqad7M01SY1kLemhX9eF
  jLNW4mJe56Fu4NiWjkR9APSZqrYeKaqr4KUC68QpVasNjhbxPSf/PcjF3cj01+X+4x6L1H5TPuqUkyZ6gD04ynUhbko4dhlanALcriF7t
  IfQR9i2r2x0yv5gxJEW/zztGqlwma/d4rBoPjnf6t07rlFHXMt/DVTkAfn5wxxtLdwkn5FMyvThRmex3BDf0gujoI1y6c0WLe9Y5geNX0oj+M
  Xg/W0cXAtzSFocstV1PoVqy883hNoeQZ3mIGB3Q0rIUUm5d9MA2bMMt31m1g3Sin6EQ== azureuser@myVM"
}
```

Execute the VMAccess script with:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name VMAccessForLinux \
--publisher Microsoft.OSTCExtensions \
--version 1.4 \
--protected-settings update_ssh_key.json
```

To reset a user password, create a file named `reset_user_password.json` and add settings in the following format. Replace `username` and `password` with your own information:

```
{
  "username": "azureuser",
  "password": "myNewPassword"
}
```

Execute the VMAccess script with:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name VMAccessForLinux \
--publisher Microsoft.OSTCExtensions \
--version 1.4 \
--protected-settings reset_user_password.json
```

## Restart SSH

To restart the SSH daemon and reset the SSH configuration to default values, create a file named `reset_sshd.json`. Add the following text:

```
{  
  "reset_ssh": true  
}
```

Execute the VMAccess script with:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name VMAccessForLinux \
--publisher Microsoft.OSTCExtensions \
--version 1.4 \
--protected-settings reset_sshd.json
```

## Manage administrative users

To create a user with `sudo` permissions that uses an SSH key for authentication, create a file named `create_new_user.json` and add settings in the following format. Substitute your own values for the `username` and `ssh_key` parameters. This method is designed to help you regain access to a VM in the event that current credentials are lost or forgotten. As a best practice, accounts with `sudo` permissions should be limited.

```
{  
  "username": "myNewUser",  
  "ssh_key": "ssh-rsa  
AAAAAB3NzaC1yc2EAAAQABAAQACQZ3S7gGp3rcbKmG2Y4vGZFMuMZCwoUzZNG1vHY7P2XV2x9FfAhy8iGD+1F8UdjFX3t5ebMm6BnnMh8  
fHwkTRd0t3LDQq8o8ElTBrZaKPxZN2tMZh0Ds5H1emb2UX0oRIGRcvWqsd4oJmxsXa/Si98Wa6RHwbc9QZhw80KAcoVhmndZAZAGR+Hq6ys  
lN05TMOr1/ZyQAook5C4FtcSGn3Y+WczaogWIxG4Zawk128g79VIeJcIQq0jPodHvQAh117qD1ItVvBfM0ben3GyhYTm7k4Yw1EdkONm4yV/  
UIW0la1rmyztSBQIm9sZmSq44XgjVmDHNF8UFcz1ToE4r2SdwTmZv00T2i5faeYnHzxiLPA3Enub7iUo5IdwFArnqad7M01SY1kLemhX9eF  
jLWN4mJe56Fu4NiWJkr9APSZQrYeKaqr4KUC68QpVasNjhbxPSf/PcjF3cj01+X+4x6L1H5HTPuqUkyZggD04ynUhbko4dhlanALcriF7t  
IfQR9i2r2x0yv5gxJEW/zztGqWma/d4rBoPjnf6t07rLFHXMt/DVTkAfn5woYtLDwkn5FMyvThRmex3BDf0gujoI1y6c0WLe9Y5geNX0oj+M  
Xg/W0cXAtzSFocstV1PoVqy883hNoeQZ3mIGB3Q0rIUm5d9MA2bMMt31m1g3Sin6EQ== myNewUser@myVM",  
  "password": "myNewUserPassword"  
}
```

Execute the VMAccess script with:

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myVM \
--name VMAccessForLinux \
--publisher Microsoft.OSTCExtensions \
--version 1.4 \
--protected-settings create_new_user.json
```

To delete a user, create a file named `delete_user.json` and add the following content. Change the data for

`remove_user` to the user you're trying to delete:

```
{  
  "remove_user": "myNewUser"  
}
```

Execute the VMAccess script with:

```
az vm extension set \  
  --resource-group myResourceGroup \  
  --vm-name myVM \  
  --name VMAccessForLinux \  
  --publisher Microsoft.OSTCExtensions \  
  --version 1.4 \  
  --protected-settings delete_user.json
```

## Check or repair the disk

Using VMAccess you can also check and repair a disk that you added to the Linux VM.

To check and then repair the disk, create a file named `disk_check_repair.json` and add settings in the following format. Change the data for `repair_disk` to the disk you're trying to repair:

```
{  
  "check_disk": "true",  
  "repair_disk": "true, mydiskname"  
}
```

Execute the VMAccess script with:

```
az vm extension set \  
  --resource-group myResourceGroup \  
  --vm-name myVM \  
  --name VMAccessForLinux \  
  --publisher Microsoft.OSTCExtensions \  
  --version 1.4 \  
  --protected-settings disk_check_repair.json
```

## Troubleshoot and support

### Troubleshoot

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myVM -o table
```

### Support

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Chef VM Extension for Linux and Windows

9/21/2022 • 3 minutes to read • [Edit Online](#)

Chef Software provides a DevOps automation platform for Linux and Windows that enables the management of both physical and virtual server configurations. The Chef VM Extension is an extension that enables Chef on virtual machines.

## Prerequisites

### Operating system

The Chef VM Extension is supported on all the [Extension Supported OS's](#) in Azure.

### Internet connectivity

The Chef VM Extension requires that the target virtual machine is connected to the internet in order to retrieve the Chef Client payload from the content delivery network (CDN).

## Extension schema

The following JSON shows the schema for the Chef VM Extension. The extension requires at a minimum the Chef Server URL, the Validation Client Name and the Validation Key for the Chef Server; these values can be found in the `knife.rb` file in the starter-kit.zip that is downloaded when you install [Chef Automate](#) or a standalone [Chef Server](#). Because the validation key should be treated as sensitive data, it should be configured under the `protectedSettings` element, meaning that it will only be decrypted on the target virtual machine.

```
{
  "type": "Microsoft.Compute/virtualMachines/extensions",
  "name": "[concat(variables('vmName'), '/', parameters('chef_vm_extension_type'))]",
  "apiVersion": "2017-12-01",
  "location": "[parameters('location')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Chef.Bootstrap.WindowsAzure",
    "type": "[parameters('chef_vm_extension_type')]",
    "typeHandlerVersion": "1210.13",
    "settings": {
      "bootstrap_options": {
        "chef_server_url": "[parameters('chef_server_url')]",
        "validation_client_name": "[parameters('chef_validation_client_name')]"
      },
      "runlist": "[parameters('chef_runlist')]"
    },
    "protectedSettings": {
      "validation_key": "[parameters('chef_validation_key')]"
    }
  }
}
```

### Core property values

NAME	VALUE / EXAMPLE	DATA TYPE
apiVersion	2017-12-01	string (date)

NAME	VALUE / EXAMPLE	DATA TYPE
publisher	Chef.Bootstrap.WindowsAzure	string
type	LinuxChefClient (Linux), ChefClient (Windows)	string
typeHandlerVersion	1210.13	string (double)

## Settings

NAME	VALUE / EXAMPLE	DATA TYPE	REQUIRED?
settings/bootstrap_options/chef_server_url	https://api.chef.io/organizations/myorg	string (myorg)	Y
settings/bootstrap_options/validation_client_name	myorg-validator	string	Y
settings/runlist	recipe[mycookbook::default]	string	Y

## Protected settings

NAME	EXAMPLE	DATA TYPE	REQUIRED?
protectedSettings/validation_key	-----BEGIN RSA PRIVATE KEY-----\nKEYDATA\n-----END RSA PRIVATE KEY-----	string	Y

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. Templates can be used to deploy one or more virtual machines, install the Chef Client, connect to the Chef Server and the perform the initial configuration on the server as defined by the [Run-list](#)

A sample Resource Manager template that includes the Chef VM Extension can be found in the [Azure quickstart gallery](#).

The JSON configuration for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON configuration affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

## Azure CLI deployment

The Azure CLI can be used to deploy the Chef VM Extension to an existing VM. Replace the `validation_key` with the contents of your validation key (this file as a `.pem` extension). Replace `validation_client_name`, `chef_server_url` and `run_list` with those values from the `knife.rb` file in your Starter Kit.

```
az vm extension set \
--resource-group myResourceGroup \
--vm-name myExistingVM \
--name LinuxChefClient \
--publisher Chef.Bootstrap.WindowsAzure \
--version 1210.13 --protected-settings '{"validation_key": "<validation_key>"}' \
--settings '{ "bootstrap_options": { "chef_server_url": "<chef_server_url>", "validation_client_name": "<validation_client_name>" }, "runlist": "<run_list>" }'
```

## Troubleshooting and support

Data about the state of extension deployments can be retrieved from the Azure portal, and by using the Azure CLI. To see the deployment state of extensions for a given VM, run the following command using the Azure CLI.

```
az vm extension list --resource-group myResourceGroup --vm-name myExistingVM -o table
```

Extension execution output is logged to the following file:

### Linux

```
/var/lib/waagent/Chef.Bootstrap.WindowsAzure.LinuxChefClient
```

### Windows

```
C:\Packages\Plugins\Chef.Bootstrap.WindowsAzure.ChefClient\
```

### Error codes and their meanings

ERROR CODE	MEANING	POSSIBLE ACTION
51	This extension is not supported on the VM's operating system	

Additional troubleshooting information can be found in the [Chef VM Extension readme](#).

#### NOTE

For anything else directly related to Chef, contact [Chef Support](#).

## Next steps

If you need more help at any point in this article, you can contact the Azure experts on the [MSDN Azure and Stack Overflow forums](#). Alternatively, you can file an Azure support incident. Go to the [Azure support site](#) and select Get support. For information about using Azure Support, read the [Microsoft Azure support FAQ](#).

# Stackify Retrace Linux Agent Extension

9/21/2022 • 3 minutes to read • [Edit Online](#)

## Overview

Stackify provides products that track details about your application to help find and fix problems quickly. For developer teams, Retrace is a fully integrated, multi-environment, app performance super-power. It combines several tools every development team needs.

Retrace is the ONLY tool that delivers all of the following capabilities across all environments in a single platform.

- Application performance management (APM)
- Application and server logging
- Error tracking and monitoring
- Server, application, and custom metrics

### About Stackify Linux Agent Extension

This extension provides an install path for the Linux Agent for Retrace.

## Prerequisites

### Operating system

The Retrace agent can be run against these Linux distributions

DISTRIBUTION	VERSION
Ubuntu	16.04 LTS, 14.04 LTS, 16.10 and 17.04
Debian	7.9+ and 8.2+, 9
Red Hat	6.7+, 7.1+
CentOS	6.3+, 7.0+

### Internet connectivity

The Stackify Agent extension for Linux requires that the target virtual machine is connected to the internet.

You may need to adjust your network configuration to allow connections to Stackify, see <https://support.stackify.com/hc/en-us/articles/207891903-Adding-Exceptions-to-a-Firewall>.

## Extension schema

The following JSON shows the schema for the Stackify Retrace Agent extension. The extension requires the `environment` and `activationKey`.

```
{
  "type": "extensions",
  "name": "StackifyExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[resourceId('Microsoft.Compute/virtualMachines',variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Stackify.LinuxAgent.Extension",
    "type": "StackifyLinuxAgentExtension",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "environment": "myEnvironment"
    },
    "protectedSettings": {
      "activationKey": "myActivationKey"
    }
  }
}
```

## Template deployment

Azure VM extensions can be deployed with Azure Resource Manager templates. The JSON schema detailed in the previous section can be used in an Azure Resource Manager template to run the Stackify Retrace Linux Agent extension during an Azure Resource Manager template deployment.

The JSON for a virtual machine extension can be nested inside the virtual machine resource, or placed at the root or top level of a Resource Manager JSON template. The placement of the JSON affects the value of the resource name and type. For more information, see [Set name and type for child resources](#).

The following example assumes the Stackify Retrace Linux extension is nested inside the virtual machine resource. When nesting the extension resource, the JSON is placed in the "resources": [] object of the virtual machine.

The extension requires the `environment` and `activationKey`.

```
{
  "type": "extensions",
  "name": "StackifyExtension",
  "apiVersion": "[variables('apiVersion')]",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[resourceId('Microsoft.Compute/virtualMachines',variables('vmName'))]"
  ],
  "properties": {
    "publisher": "Stackify.LinuxAgent.Extension",
    "type": "StackifyLinuxAgentExtension",
    "typeHandlerVersion": "1.0",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "environment": "myEnvironment"
    },
    "protectedSettings": {
      "activationKey": "myActivationKey"
    }
  }
}
```

When placing the extension JSON at the root of the template, the resource name includes a reference to the

parent virtual machine, and the type reflects the nested configuration.

```
{  
    "type": "Microsoft.Compute/virtualMachines/extensions",  
    "name": "<parentVmResource>/StackifyExtension",  
    "apiVersion": "[variables('apiVersion')]",  
    "location": "[resourceGroup().location]",  
    "dependsOn": [  
        "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"  
    ],  
    "properties": {  
        "publisher": "Stackify.LinuxAgent.Extension",  
        "type": "StackifyLinuxAgentExtension",  
        "typeHandlerVersion": "1.0",  
        "autoUpgradeMinorVersion": true,  
        "settings": {  
            "environment": "myEnvironment"  
        },  
        "protectedSettings": {  
            "activationKey": "myActivationKey"  
        }  
    }  
}
```

## PowerShell deployment

The `Set-AzVMExtension` command can be used to deploy the Stackify Retrace Linux Agent virtual machine extension to an existing virtual machine. Before running the command, the public and private configurations need to be stored in a PowerShell hash table.

The extension requires the `environment` and `activationKey`.

```
$PublicSettings = @{"environment" = "myEnvironment"}  
$ProtectedSettings = @{"activationKey" = "myActivationKey"}  
  
Set-AzVMExtension -ExtensionName "Stackify.LinuxAgent.Extension" `  
    -ResourceGroupName "myResourceGroup" `  
    -VMName "myVM" `  
    -Publisher "Stackify.LinuxAgent.Extension" `  
    -ExtensionType "StackifyLinuxAgentExtension" `  
    -TypeHandlerVersion 1.0 `  
    -Settings $PublicSettings `  
    -ProtectedSettings $ProtectedSettings `  
    -Location WestUS `
```

## Azure CLI deployment

The Azure CLI tool can be used to deploy the Stackify Retrace Linux Agent virtual machine extension to an existing virtual machine.

The extension requires the `environment` and `activationKey`.

```
az vm extension set --publisher 'Stackify.LinuxAgent.Extension' --version 1.0 --name  
'StackifyLinuxAgentExtension' --protected-settings '{"activationKey":"myActivationKey"}' --settings  
'{"environment":"myEnvironment"}' --resource-group 'myResourceGroup' --vm-name 'myVmName'
```

## Troubleshoot and support

## Error codes

ERROR CODE	MEANING	POSSIBLE ACTION
10	Install Error	wget is required
20	Install Error	Python is required
30	Install Error	sudo is required
40	Install Error	activationKey is required
51	Install Error	OS distro not supported
60	Install Error	environment is required
70	Install Error	Unknown
80	Enable Error	Service setup failed
90	Enable Error	Service startup failed
100	Disable Error	Service Stop Failed
110	Disable Error	Service Removal Failed
120	Uninstall Error	Service Stop Failed

If you need more help you can contact Stackify support at <https://support.stackify.com>.

# How to install and configure Symantec Endpoint Protection on a Windows VM

9/21/2022 • 2 minutes to read • [Edit Online](#)

## IMPORTANT

VMs created through the classic deployment model will be retired on March 1, 2023.

If you use IaaS resources from Azure Service Management, please complete your migration by March 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.

For more information, see [Migrate your IaaS resources to Azure Resource Manager by March 1, 2023](#).

Azure has two different deployment models for creating and working with resources: [Resource Manager and Classic](#). This article covers using the Classic deployment model. Microsoft recommends that most new deployments use the Resource Manager model.

This article shows you how to install and configure the Symantec Endpoint Protection client on an existing virtual machine (VM) running Windows Server. This full client includes services such as virus and spyware protection, firewall, and intrusion prevention. The client is installed as a security extension by using the VM Agent.

If you have an existing subscription from Symantec for an on-premises solution, you can use it to protect your Azure virtual machines. If you're not a customer yet, you can sign up for a trial subscription. For more information about this solution, see [Symantec Endpoint Protection on Microsoft's Azure platform](#). This page also has links to licensing information and instructions for installing the client if you're already a Symantec customer.

## Install Symantec Endpoint Protection on an existing VM

Before you begin, you need the following:

- The Azure PowerShell module, version 0.8.2 or later, on your work computer. You can check the version of Azure PowerShell that you have installed with the `Get-Module azure | format-table version` command. For instructions and a link to the latest version, see [How to Install and Configure Azure PowerShell](#). Log in to your Azure subscription using `Add-AzureAccount`.
- The VM Agent running on the Azure Virtual Machine.

First, verify that the VM Agent is already installed on the virtual machine. Fill in the cloud service name and virtual machine name, and then run the following commands at an administrator-level Azure PowerShell command prompt. Replace everything within the quotes, including the < and > characters.

## TIP

If you don't know the cloud service and virtual machine names, run `Get-AzureVM` to list the names for all virtual machines in your current subscription.

```
$CSName = "<cloud service name>"  
$VMName = "<virtual machine name>"  
$vm = Get-AzureVM -ServiceName $CSName -Name $VMName  
write-host $vm.VM.ProvisionGuestAgent
```

If the **write-host** command displays **True**, the VM Agent is installed. If it displays **False**, see the instructions and a link to the download in the Azure blog post [VM Agent and Extensions - Part 2](#).

If the VM Agent is installed, run these commands to install the Symantec Endpoint Protection agent.

```
$Agent = Get-AzureVMAvailableExtension -Publisher Symantec -ExtensionName SymantecEndpointProtection  
  
Set-AzureVMExtension -Publisher Symantec -Version $Agent.Version -ExtensionName SymantecEndpointProtection \  
-VM $vm | Update-AzureVM
```

To verify that the Symantec security extension has been installed and is up-to-date:

1. Log on to the virtual machine. For instructions, see [How to Log on to a Virtual Machine Running Windows Server](#).
2. For Windows Server 2008 R2, click **Start > Symantec Endpoint Protection**. For Windows Server 2012 or Windows Server 2012 R2, from the start screen, type **Symantec**, and then click **Symantec Endpoint Protection**.
3. From the **Status** tab of the **Status-Symantec Endpoint Protection** window, apply updates or restart if needed.

[How to Log on to a Virtual Machine Running Windows Server](#)

[Azure VM Extensions and Features](#)

# Use Azure Policy to restrict extensions installation on Linux VMs

9/21/2022 • 3 minutes to read • [Edit Online](#)

If you want to prevent the installation of certain extensions on your Linux VMs, you can create an Azure Policy definition using the Azure CLI to restrict extensions for VMs within a resource group. To learn the basics of Azure VM extensions for Linux, see [Virtual machine extensions and features for Linux](#).

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. If you want to run the Azure CLI locally, you need to install version 2.0.26 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create a rules file

In order to restrict what extensions are available, you need to create a [rule](#) to identify the extension.

This example demonstrates how to deny the installation of disallowed VM extensions by defining a rules file in Azure Cloud Shell. However, if you're working in Azure CLI locally, you can create a local file and replace the path (~/.clouddrive) with the path to the file on your local file system.

In a [bash Cloud Shell](#), type:

```
vim ~/.clouddrive/azurepolicy.rules.json
```

Copy and paste the following `.json` data into the file.

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Compute/virtualMachines/extensions"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
        "equals": "Microsoft.OSTCExtensions"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/type",
        "in": "[parameters('notAllowedExtensions')]"
      }
    ]
  },
  "then": {
    "effect": "deny"
  }
}
```

When you're finished, press `Esc`, and then type `:wq` to save and close the file.

## Create a parameters file

You also need a [parameters](#) file that creates a structure for you to use for passing in a list of the unauthorized

extensions.

This example shows you how to create a parameter file for Linux VMs in Cloud Shell.

In the bash Cloud Shell opened before type:

```
vim ~/clouddrive/azurepolicy.parameters.json
```

Copy and paste the following `.json` data into the file.

```
{
  "notAllowedExtensions": {
    "type": "Array",
    "metadata": {
      "description": "The list of extensions that will be denied. Example: CustomScriptForLinux, VMAccessForLinux etc.",
      "displayName": "Denied extension"
    }
  }
}
```

When you're finished, press `Esc`, and then type `:wq` to save and close the file.

## Create the policy

A *policy definition* is an object used to store the configuration that you would like to use. The policy definition uses the rules and parameters files to define the policy. Create the policy definition using [az policy definition create](#).

In this example, the rules and parameters are the files you created and stored as `.json` files in Cloud Shell or in your local file system.

```
az policy definition create \
  --name 'not-allowed-vmextension-linux' \
  --display-name 'Block VM Extensions' \
  --description 'This policy governs which VM extensions that are blocked.' \
  --rules '~/clouddrive/azurepolicy.rules.json' \
  --params '~/clouddrive/azurepolicy.parameters.json' \
  --mode All
```

## Assign the policy

This example assigns the policy to a resource group using `az policy assignment create`. Any VM created in the `myResourceGroup` resource group will be unable to install the Linux VM Access or the Custom Script Extensions for Linux.

### NOTE

The resource group must exist before you can assign the policy.

Use `az account list` to find your subscription ID and replace the placeholder in the following example:

```
az policy assignment create \
    --name 'not-allowed-vmextension-linux' \
    --scope /subscriptions/<subscription Id>/resourceGroups/myResourceGroup \
    --policy "not-allowed-vmextension-linux" \
    --params '{
    "notAllowedExtensions": {
        "value": [
            "VMAccessForLinux",
            "CustomScriptForLinux"
        ]
    }
}'
```

## Test the policy

Test the policy by creating a new VM and adding a new user.

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image UbuntuLTS \
    --generate-ssh-keys
```

Try to create a new user named **myNewUser** using the VM Access extension.

```
az vm user update \
    --resource-group myResourceGroup \
    --name myVM \
    --username myNewUser \
    --password 'mynewuserpwd123!'
```

## Remove the assignment

```
az policy assignment delete --name 'not-allowed-vmextension-linux' --resource-group myResourceGroup
```

## Remove the policy

```
az policy definition delete --name 'not-allowed-vmextension-linux'
```

## Next steps

For more information, see [Azure Policy](#).

# Use Azure Policy to restrict extensions installation on Windows VMs

9/21/2022 • 2 minutes to read • [Edit Online](#)

If you want to prevent the use or installation of certain extensions on your Windows VMs, you can create an Azure Policy definition using PowerShell to restrict extensions for VMs within a resource group.

This tutorial uses Azure PowerShell within the Cloud Shell, which is constantly updated to the latest version.

## Create a rules file

In order to restrict what extensions can be installed, you need to have a [rule](#) to provide the logic to identify the extension.

This example shows you how to deny extensions published by 'Microsoft.Compute' by creating a rules file in Azure Cloud Shell, but if you are working in PowerShell locally, you can also create a local file and replace the path (\$home/clouddrive) with the path to the local file on your machine.

In a [Cloud Shell](#), type:

```
nano $home/clouddrive/rules.json
```

Copy and paste the following json into the file.

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Compute/virtualMachines/extensions"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/publisher",
        "equals": "Microsoft.Compute"
      },
      {
        "field": "Microsoft.Compute/virtualMachines/extensions/type",
        "in": "[parameters('notAllowedExtensions')]"
      }
    ]
  },
  "then": {
    "effect": "deny"
  }
}
```

When you are done, hit the **Ctrl + O** and then **Enter** to save the file. Hit **Ctrl + X** to close the file and exit.

## Create a parameters file

You also need a [parameters](#) file that creates a structure for you to use for passing in a list of the extensions to block.

This example shows you how to create a parameters file for VMs in Cloud Shell, but if you are working in

PowerShell locally, you can also create a local file and replace the path (\$home/clouddrive) with the path to the local file on your machine.

In [Cloud Shell](#), type:

```
nano $home/clouddrive/parameters.json
```

Copy and paste the following json into the file.

```
{
  "notAllowedExtensions": {
    "type": "Array",
    "metadata": {
      "description": "The list of extensions that will be denied.",
      "displayName": "Denied extension"
    }
  }
}
```

When you are done, hit the **Ctrl + O** and then **Enter** to save the file. Hit **Ctrl + X** to close the file and exit.

## Create the policy

A policy definition is an object used to store the configuration that you would like to use. The policy definition uses the rules and parameters files to define the policy. Create a policy definition using the [New-AzPolicyDefinition](#) cmdlet.

The policy rules and parameters are the files you created and stored as .json files in your cloud shell.

```
$definition = New-AzPolicyDefinition ` 
  -Name "not-allowed-vmextension-windows" ` 
  -DisplayName "Not allowed VM Extensions" ` 
  -description "This policy governs which VM extensions that are explicitly denied." ` 
  -Policy 'C:\Users\ContainerAdministrator\clouddrive\rules.json' ` 
  -Parameter 'C:\Users\ContainerAdministrator\clouddrive\parameters.json'
```

## Assign the policy

This example assigns the policy to a resource group using [New-AzPolicyAssignment](#). Any VM created in the **myResourceGroup** resource group will not be able to install the VM Access Agent or Custom Script extensions.

Use the [Get-AzSubscription | Format-Table](#) cmdlet to get your subscription ID to use in place of the one in the example.

```
$scope = "/subscriptions/<subscription id>/resourceGroups/myResourceGroup"
$assignment = New-AzPolicyAssignment ` 
    -Name "not-allowed-vmextension-windows" ` 
    -Scope $scope ` 
    -PolicyDefinition $definition ` 
    -PolicyParameter '{
        "notAllowedExtensions": {
            "value": [
                "VMAccessAgent",
                "CustomScriptExtension"
            ]
        }
    }'
$assignment
```

## Test the policy

To test the policy, try to use the VM Access extension. The following should fail with the message "Set-AzVMAccessExtension : Resource 'myVMAccess' was disallowed by policy."

```
Set-AzVMAccessExtension ` 
    -ResourceGroupName "myResourceGroup" ` 
    -VMName "myVM" ` 
    -Name "myVMAccess" ` 
    -Location EastUS
```

In the portal, the password change should fail with the "The template deployment failed because of policy violation." message.

## Remove the assignment

```
Remove-AzPolicyAssignment -Name not-allowed-vmextension-windows -Scope $scope
```

## Remove the policy

```
Remove-AzPolicyDefinition -Name not-allowed-vmextension-windows
```

## Next steps

For more information, see [Azure Policy](#).

# How to update the Azure Linux Agent on a VM

9/21/2022 • 5 minutes to read • [Edit Online](#)

To update your [Azure Linux Agent](#) on a Linux VM in Azure, you must already have:

- A running Linux VM in Azure.
- A connection to that Linux VM using SSH.

You should always check for a package in the Linux distro repository first. It is possible the package available may not be the latest version, however, enabling autoupdate will ensure the Linux Agent will always get the latest update. Should you have issues installing from the package managers, you should seek support from the distro vendor.

## NOTE

For more information see [Endorsed Linux distributions on Azure](#)

Verify the [Minimum version support for virtual machine agents in Azure](#) before proceeding.

## Ubuntu

Check your current package version

```
apt list --installed | grep walinuxagent
```

Update package cache

```
sudo apt-get -qq update
```

Install the latest package version

```
sudo apt-get install walinuxagent
```

Ensure auto update is enabled. First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=y
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/# AutoUpdate.Enabled=n/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

Restart waagent service for 14.04

```
initctl restart walinuxagent
```

Restart waagent service for 16.04 / 17.04

```
systemctl restart walinuxagent.service
```

## Red Hat / CentOS

### RHEL/CentOS 6

Check your current package version

```
sudo yum list WALinuxAgent
```

Check available updates

```
sudo yum check-update WALinuxAgent
```

Install the latest package version

```
sudo yum install WALinuxAgent
```

Ensure auto update is enabled

First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=y
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/\# AutoUpdate.Enabled=y/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

Restart the waagent service

```
sudo service waagent restart
```

## RHEL/CentOS 7

Check your current package version

```
sudo yum list WALinuxAgent
```

Check available updates

```
sudo yum check-update WALinuxAgent
```

Install the latest package version

```
sudo yum install WALinuxAgent
```

Ensure auto update is enabled. First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=y  
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/# AutoUpdate.Enabled=n/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

Restart the waagent service

```
sudo systemctl restart waagent.service
```

## SUSE SLES

### SUSE SLES 11 SP4

Check your current package version

```
zypper info python-azure-agent
```

Check available updates. The above output will show you if the package is up to date.

Install the latest package version

```
sudo zypper install python-azure-agent
```

Ensure auto update is enabled

First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=y  
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/# AutoUpdate.Enabled=n/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

Restart the waagent service

```
sudo /etc/init.d/waagent restart
```

## SUSE SLES 12 SP2

Check your current package version

```
zypper info python-azure-agent
```

Check available updates

In the output from the above, this will show you if the package is up-to-date.

Install the latest package version

```
sudo zypper install python-azure-agent
```

Ensure auto update is enabled

First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/AutoUpdate.Enabled=n.*/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

Restart the waagent service

```
sudo systemctl restart waagent.service
```

## Debian

### Debian 7 "Jesse"/ Debian 7 "Stretch"

Check your current package version

```
dpkg -l | grep waagent
```

Update package cache

```
sudo apt-get -qq update
```

Install the latest package version

```
sudo apt-get install waagent
```

Enable agent auto update This version of Debian does not have a version >= 2.0.16, therefore AutoUpdate is not available for it. The output from the above command will show you if the package is up-to-date.

### **Debian 8 “Jessie” / Debian 9 “Stretch”**

Check your current package version

```
apt list --installed | grep waagent
```

Update package cache

```
sudo apt-get -qq update
```

Install the latest package version

```
sudo apt-get install waagent
```

Ensure auto update is enabled First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
AutoUpdate.Enabled=y  
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/AutoUpdate.Enabled=n.*/AutoUpdate.Enabled=y/g' /etc/waagent.conf  
Restart the waagent service  
sudo systemctl restart walinuxagent.service
```

## Oracle Linux 6 and Oracle Linux 7

For Oracle Linux, make sure that the `Addons` repository is enabled. Choose to edit the file

`/etc/yum.repos.d/public-yum-ol6.repo` (Oracle Linux 6) or `/etc/yum.repos.d/oracle-linux-ol7.repo` (Oracle Linux), and change the line `enabled=0` to `enabled=1` under `[ol6_addons]` or `[ol7_addons]` in this file.

Then, to install the latest version of the Azure Linux Agent, type:

```
sudo yum install WALinuxAgent
```

If you don't find the add-on repository you can simply add these lines at the end of your .repo file according to your Oracle Linux release:

For Oracle Linux 6 virtual machines:

```
[ol6_addons]
name=Add-Ons for Oracle Linux $releasever ($basearch)
baseurl=https://public-yum.oracle.com/repo/OracleLinux/OL6/addons/x86_64
gpgkey=https://public-yum.oracle.com/RPM-GPG-KEY-oracle-ol6
gpgcheck=1
enabled=1
```

For Oracle Linux 7 virtual machines:

```
[ol7_addons]
name=Oracle Linux $releasever Add ons ($basearch)
baseurl=http://public-yum.oracle.com/repo/OracleLinux/OL7/addons/$basearch/
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
gpgcheck=1
enabled=1
```

Then type:

```
sudo yum update WALinuxAgent
```

Typically this is all you need, but if for some reason you need to install it from <https://github.com> directly, use the following steps.

## Update the Linux Agent when no agent package exists for distribution

Install wget (there are some distros that don't install it by default, such as Red Hat, CentOS, and Oracle Linux versions 6.4 and 6.5) by typing `sudo yum install wget` on the command line.

### 1. Download the latest version

Open [the release of Azure Linux Agent in GitHub](https://github.com/Azure/WALinuxAgent/releases) in a web page, and find out the latest version number. (You can locate your current version by typing `waagent --version`.)

For version 2.2.x or later, type:

```
wget https://github.com/Azure/WALinuxAgent/archive/refs/tags/v2.2.x.zip
unzip v2.2.x.zip
cd WALinuxAgent-2.2.x
```

The following line uses version 2.2.14 as an example:

```
wget https://github.com/Azure/WALinuxAgent/archive/refs/tags/v2.2.14.zip
unzip v2.2.14.zip
cd WALinuxAgent-2.2.14
```

### 2. Install the Azure Linux Agent

For version 2.2.x, use: You may need to install the package `setuptools` first--see [setuptools](#). Then run:

```
sudo python setup.py install
```

Ensure auto update is enabled. First, check to see if it is enabled:

```
cat /etc/waagent.conf
```

Find 'AutoUpdate.Enabled'. If you see this output, it is enabled:

```
# AutoUpdate.Enabled=y  
AutoUpdate.Enabled=y
```

To enable run:

```
sudo sed -i 's/# AutoUpdate.Enabled=n/AutoUpdate.Enabled=y/g' /etc/waagent.conf
```

### 3. Restart the waagent service

For most of Linux distros:

```
sudo service waagent restart
```

For Ubuntu, use:

```
sudo service walinuxagent restart
```

For CoreOS, use:

```
sudo systemctl restart waagent
```

### 4. Confirm the Azure Linux Agent version

```
waagent -version
```

For CoreOS, the above command may not work.

You will see that the Azure Linux Agent version has been updated to the new version.

For more information regarding the Azure Linux Agent, see [Azure Linux Agent README](#).

# Exporting Resource Groups that contain VM extensions

9/21/2022 • 3 minutes to read • [Edit Online](#)

Azure Resource Groups can be exported into a new Resource Manager template that can then be redeployed. The export process interprets existing resources, and creates a Resource Manager template that when deployed results in a similar Resource Group. When using the Resource Group export option against a Resource Group containing Virtual Machine extensions, several items need to be considered such as extension compatibility and protected settings.

This document details how the Resource Group export process works regarding virtual machine extensions, including a list of supported extensions, and details on handling secured data.

## Supported Virtual Machine Extensions

Many Virtual Machine extensions are available. Not all extensions can be exported into a Resource Manager template using the "Automation Script" feature. If a virtual machine extension is not supported, it needs to be manually placed back into the exported template.

The following extensions can be exported with the automation script feature.

Acronis Backup, Acronis Backup Linux, Bg Info, BMC CTM Agent Linux, BMC CTM Agent Windows, Chef Client, Custom Script, Custom Script Extension, Custom Script for Linux, Datadog Linux Agent, Datadog Windows Agent, Docker Extension, DSC Extension, Dynatrace Linux, Dynatrace Windows, HPE Security Application Defender for Cloud, IaaS Antimalware, IaaS Diagnostics, Linux Chef Client, Linux Diagnostic, OS Patching For Linux, Puppet Agent, Site 24x7 Apm Insight, Site 24x7 Linux Server, Site 24x7 Windows Server, Trend Micro DSA, Trend Micro DSA Linux, VM Access For Linux, VM Access For Linux, VM Snapshot, VM Snapshot Linux

## Export the Resource Group

To export a Resource Group into a reusable template, complete the following steps:

1. Sign in to the Azure portal
2. On the Hub Menu, click Resource Groups
3. Select the target resource group from the list
4. In the Resource Group blade, click Automation Script

The screenshot shows the Azure Resource Manager template export interface. At the top, there are buttons for Download, Add to library, and Deploy. Below that is a header bar with an info icon and the text: "Automate deploying resources with Azure Resource Manager templates in a single, coordinated operation. Define resources and configurable input parameters and deploy with script or code. [Learn more about template deployment](#)". The main area has tabs for Template, Parameters, CLI, PowerShell, .NET, and Ruby. The Template tab is selected, showing a tree view of resources: Parameters (8), Variables (0), and Resources (6). The Resources section contains items like [parameters('virtualMachines\_My...'), [parameters('networkInterfaces\_m...'), [parameters('publicIPAddresses\_m...'), [parameters('virtualNetworks\_MyV...'), [parameters('storageAccounts\_dia...'), and AzureDiagnostics (Microsoft.Com...]. Below the tree is a large block of JSON code:

```

1 {
2   "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
3   "contentVersion": "1.0.0.0",
4   "parameters": {
5     "virtualMachines_MyWindowsVM_adminPassword": {
6       "defaultValue": null,
7       "type": "SecureString"
8     },
9     "extensions_Microsoft.Insights.VMDiagnosticsSettings_protectedSettings": {
10       "defaultValue": null,
11       "type": "SecureObject"
12     },
13     "virtualMachines_MyWindowsVM_name": {
14       "defaultValue": "MyWindowsVM",
15       "type": "String"
16     },
17     "networkInterfaces_myVMNic_name": {
18       "defaultValue": "myVMNic",
19       "type": "String"
20     },
21     "publicIPAddresses_myPublicIP_name": {
22       "defaultValue": "myPublicIP",
23       "type": "String"
24     },
25     "virtualNetworks_MyVNET_name": {
26       "defaultValue": "MyVNET",
27     }
}

```

The Azure Resource Manager automations script produces a Resource Manager template, a parameters file, and several sample deployment scripts such as PowerShell and Azure CLI. At this point, the exported template can be downloaded using the download button, added as a new template to the template library, or redeployed using the deploy button.

## Configure protected settings

Many Azure virtual machine extensions include a protected settings configuration, that encrypts sensitive data such as credentials and configuration strings. Protected settings are not exported with the automation script. If necessary, protected settings need to be reinserted into the exported template.

### Step 1 - Remove template parameter

When the Resource Group is exported, a single template parameter is created to provide a value to the exported protected settings. This parameter can be removed. To remove the parameter, look through the parameter list and delete the parameter that looks similar to this JSON example.

```
"extensions_extensionname_protectedSettings": {
  "defaultValue": null,
  "type": "SecureObject"
}
```

### Step 2 - Get protected settings properties

Because each protected setting has a set of required properties, a list of these properties need to be gathered. Each parameter of the protected settings configuration can be found in the [Azure Resource Manager schema on GitHub](#). This schema only includes the parameter sets for the extensions listed in the overview section of this document.

From within the schema repository, search for the desired extension, for this example `IaaSDiagnistics`. Once the extensions `protectedSettings` object has been located, take note of each parameter. In the example of the `IaaSDiagnostic` extension, the require parameters are `storageAccountName`, `storageAccountKey`, and `storageAccountEndPoint`.

```
"protectedSettings": {  
  "type": "object",  
  "properties": {  
    "storageAccountName": {  
      "type": "string"  
    },  
    "storageAccountKey": {  
      "type": "string"  
    },  
    "storageAccountEndPoint": {  
      "type": "string"  
    }  
  },  
  "required": [  
    "storageAccountName",  
    "storageAccountKey",  
    "storageAccountEndPoint"  
  ]  
}
```

### Step 3 - Re-create the protected configuration

On the exported template, search for `protectedSettings` and replace the exported protected setting object with a new one that includes the required extension parameters and a value for each one.

In the example of the `IaaSDiagnostic` extension, the new protected setting configuration would look like the following example:

```
"protectedSettings": {  
  "storageAccountName": "[parameters('storageAccountName')]",  
  "storageAccountKey": "[parameters('storageAccountKey')]",  
  "storageAccountEndPoint": "https://core.windows.net"  
}
```

The final extension resource looks similar to the following JSON example:

```
{
  "name": "Microsoft.Insights.VMDiagnosticsSettings",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "[variables('apiVersion')]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/', variables('vmName'))]"
  ],
  "tags": {
    "displayName": "AzureDiagnostics"
  },
  "properties": {
    "publisher": "Microsoft.Azure.Diagnostics",
    "type": "IaaS.Diagnostics",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "xmlCfg": "[base64(concat(variables('wadcfgxstart'), variables('wadmetricsresourceid'),
variables('vmName'), variables('wadcfgxend')))]",
      "storageAccount": "[parameters('existingdiagnosticsStorageAccountName')]"
    },
    "protectedSettings": {
      "storageAccountName": "[parameters('storageAccountName')]",
      "storageAccountKey": "[parameters('storageAccountKey')]",
      "storageAccountEndPoint": "https://core.windows.net"
    }
  }
}
```

If using template parameters to provide property values, these need to be created. When creating template parameters for protected setting values, make sure to use the `SecureString` parameter type so that sensitive values are secured. For more information on using parameters, see [Authoring Azure Resource Manager templates](#).

In the example of the `IaaSDiagnostic` extension, the following parameters would be created in the parameters section of the Resource Manager template.

```
"storageAccountName": {
  "defaultValue": null,
  "type": "SecureString"
},
"storageAccountKey": {
  "defaultValue": null,
  "type": "SecureString"
}
```

At this point, the template can be deployed using any template deployment method.

# Troubleshooting Azure Windows VM extension failures

9/21/2022 • 7 minutes to read • [Edit Online](#)

## Overview of Azure Resource Manager templates

Azure Resource Manager templates allows you to declaratively specify the Azure IaaS infrastructure in JSON language by defining the dependencies between resources.

See [Authoring extension templates](#) to learn more about authoring templates for using extensions.

In this article we'll learn about troubleshooting some of the common VM extension failures.

## Viewing extension status

Azure Resource Manager templates can be executed from Azure PowerShell. Once the template is executed, the extension status can be viewed from Azure Resource Explorer or the command-line tools.

Here's an example:

Azure PowerShell:

```
Get-AzVM -ResourceGroupName $RGName -Name $vmName -Status
```

Here's the sample output:

```
Extensions: {
  "ExtensionType": "Microsoft.Compute.CustomScriptExtension",
  "Name": "myCustomScriptExtension",
  "SubStatuses": [
    {
      "Code": "ComponentStatus/StdOut/succeeded",
      "DisplayStatus": "Provisioning succeeded",
      "Level": "Info",
      "Message": "Directory: C:\\\\temp\\\\n\\\\n\\\\nMode
\\n---- ----- -----
9/1/2015 2:03 AM 11
test.txt \\n\\n",
      "Time": null
    },
    {
      "Code": "ComponentStatus/StdErr/succeeded",
      "DisplayStatus": "Provisioning succeeded",
      "Level": "Info",
      "Message": "",
      "Time": null
    }
  ]
}
```

## Troubleshooting extension failures

### Verify that the VM Agent is running and Ready

The VM Agent is required to manage, install and execute extensions. If the VM Agent isn't running or is failing to

report a Ready status to the Azure platform, then the extensions won't work correctly.

Please refer to the following pages to troubleshoot the VM Agent:

- [Troubleshooting Windows Azure Guest Agent](#) for a Windows VM
- [Troubleshoot the Azure Linux Agent](#) for a Linux VM

### Check for your specific extension troubleshooting guide

Some extensions have a specific page describing how to troubleshoot them. You can find the list of these extensions and pages on [Troubleshoot extensions](#).

### View the extension's status

As explained above, the extension's status can be found by running the PowerShell cmdlet:

```
Get-AzVM -ResourceGroupName $RGName -Name $vmName -Status
```

or the CLI command:

```
az vm extension show -g <RG Name> --vm-name <VM Name> --name <Extension Name>
```

or in the Azure portal, by browsing to the VM Blade / Settings / Extensions. You can then click on the extension and check its status and message.

### Rerun the extension on the VM

If you're running scripts on the VM using Custom Script Extension, you could sometimes run into an error where VM was created successfully but the script has failed. Under these conditions, the recommended way to recover from this error is to remove the extension and rerun the template again. Note: In future, this functionality would be enhanced to remove the need for uninstalling the extension.

#### Remove the extension from Azure PowerShell

```
Remove-AzVMExtension -ResourceGroupName $RGName -VMName $vmName -Name "myCustomScriptExtension"
```

Once the extension has been removed, the template can be re-executed to run the scripts on the VM.

### Trigger a new GoalState to the VM

You might notice that an extension hasn't been executed, or is failing to execute because of a missing "Windows Azure CRP Certificate Generator" (that certificate is used to secure the transport of the extension's protected settings). That certificate will be automatically regenerated by restarting the Windows Guest Agent from inside the Virtual Machine:

- Open the Task Manager
- Go to the Details tab
- Locate the WindowsAzureGuestAgent.exe process
- Right-click, and select "End Task". The process will be automatically restarted

You can also trigger a new GoalState to the VM, by executing a "VM Reapply". VM [Reapply](#) is an API introduced in 2020 to reapply a VM's state. We recommend doing this at a time when you can tolerate a short VM downtime. While Reapply itself doesn't cause a VM reboot, and the vast majority of times calling Reapply won't reboot the VM, there's a very small risk that some other pending update to the VM model gets applied when Reapply triggers a new goal state, and that other change could require a restart.

Azure portal:

In the portal, select the VM and in the left pane under the **Support + troubleshooting**, select **Redeploy +**

**reapply**, then select **Reapply**.

Azure PowerShell (*replace the RG Name and VM Name with your values*):

```
Set-AzVM -ResourceGroupName <RG Name> -Name <VM Name> -Reapply
```

Azure CLI (*replace the RG Name and VM Name with your values*):

```
az vm reapply -g <RG Name> -n <VM Name>
```

If a "VM Reapply" didn't work, you can add a new empty Data Disk to the VM from the Azure Management Portal, and then remove it later once the certificate has been added back.

### Look at the extension logs inside the VM

If the previous steps didn't work and if your extension is still in a failed state, the next step is to look at its logs inside the Virtual Machine.

On a **Windows** VM, the extension logs will typically reside in

```
C:\WindowsAzure\Logs\Plugins
```

And the Extension settings and status files will be in

```
C:\Packages\Plugins
```

On a **Linux** VM, the extension logs will typically reside in

```
/var/log/azure/
```

And the Extension settings and status files will be in

```
/var/lib/waagent/
```

Each extension is different, but they usually follow similar principles:

Extension packages and binaries are downloaded on the VM (eg. `"/var/lib/waagent/custom-script/download/1"` for Linux or `"C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\Downloads\0"` for Windows).

Their configuration and settings are passed from Azure Platform to the extension handler through the VM Agent (eg. `"/var/lib/waagent/Microsoft.Azure.Extensions.CustomScript-2.1.3/config"` for Linux or `"C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\RuntimeSettings"` for Windows)

Extension handlers inside the VM are writing to a status file (eg. `"/var/lib/waagent/Microsoft.Azure.Extensions.CustomScript-2.1.3/status/1.status"` for Linux or `"C:\Packages\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12>Status"` for Windows) which will then be reported to the Azure Platform. That status is the one reported through PowerShell, CLI or in the VM's extension blade in the Azure portal.

They also write detailed logs of their execution (eg. `"/var/log/azure/custom-script/handler.log"` for Linux or `"C:\WindowsAzure\Logs\Plugins\Microsoft.Compute.CustomScriptExtension\1.10.12\CustomScriptHandler.log"`

for Windows).

## If the VM is recreated from an existing VM

It could happen that you're creating an Azure VM based on a specialized Disk coming from another Azure VM. In that case, it's possible that the old VM contained extensions, and so will have binaries, logs and status files left over. The new VM model won't be aware of the previous VM's extensions states, and it might report an incorrect status for these extensions. We strongly recommend you to remove the extensions from the old VM before creating the new one, and then reinstall these extensions once the new VM is created. The same can happen when you create a generalized image from an existing Azure VM. We invite you to remove extensions to avoid inconsistent state from the extensions.

## Known issues

### PowerShell isn't recognized as an internal or external command

You notice the following error entries in the RunCommand extension's output:

```
RunCommandExtension failed with "'powershell' isn't recognized as an internal or external command,"
```

### Analysis

Extensions run under Local System account, so it's very possible that powershell.exe works fine when you RDP into the VM, but fails when run with RunCommand.

### Solution

- Check that PowerShell is properly listed in the PATH environment variable:
  - Open Control Panel
  - System and Security
  - System
  - Advanced tab -> Environmental Variables
- Under 'System variables' click edit and ensure that PowerShell is in the PATH environment variable (usually: "C:\Windows\System32\WindowsPowerShell\v1.0")
- Reboot the VM or restart the WindowsAzureGuestAgent service then try the Run Command again.

### Command isn't recognized as an internal or external command

You see the following in the C:\WindowsAzure\Logs\Plugins<ExtensionName><Version>\CommandExecution.log file:

```
Execution Error: '<command>' isn't recognized as an internal or external command, operable program or batch file.
```

### Analysis

Extensions run under Local System account, so it's very possible that powershell.exe works fine when you RDP into the VM, but fails when run with RunCommand.

### Solution

- Open a Command Prompt in the VM and execute a command to reproduce the error. The VM Agent uses the Administrator cmd.exe and you may have some preconfigured command to execute every time cmd is started.
- It's also likely that your PATH variable is misconfigured, but this will depend on the command that is having the problem.

**VMAccessAgent is failing with Cannot update Remote Desktop Connection settings for Administrator account. Error: System.Runtime.InteropServices.COMException (0x800706D9): There are no more endpoints available from the endpoint mapper.**

You see the following in the extension's status:

```
Type Microsoft.Compute.VMAccessAgent
Version 2.4.8
Status Provisioning failed
Status level Error
Status message Cannot update Remote Desktop Connection settings for Administrator account. Error:
System.Runtime.InteropServices.COMException (0x800706D9): There are no more endpoints available from the
endpoint mapper. (Exception from HRESULT: 0x800706D9) at NetFwTypeLib.INetFwRules.GetEnumerator() at
Microsoft.WindowsAzure.GuestAgent.Plugins.JsonExtensions.VMAccess.RemoteDesktopManager.EnableRemoteDesktopFi
rewallRules()
at
Microsoft.WindowsAzure.GuestAgent.Plugins.JsonExtensions.VMAccess.RemoteDesktopManager.EnableRemoteDesktop()
at
```

## Analysis

This error can happen when the Windows Firewall service isn't running.

## Solution

Check if the Windows Firewall service is enabled and running. If it's not, please enable and start it - then try again to run the VMAccessAgent.

## The remote certificate is invalid according to the validation procedure.

You see the following in the WaAppAgent.log

```
System.Net.WebException: The underlying connection was closed: Could not establish trust relationship for
the SSL/TLS secure channel. ---> System.Security.AuthenticationException: The remote certificate is invalid according to the validation
procedure.
```

## Analysis

Your VM is probably missing the Baltimore CyberTrust Root certificate in "Trusted Root Certification Authorities".

## Solution

Open the certificates console with certmgr.msc, and check if the certificate is there.

Another possible issue is that the certificate chain is broken by a third party SSL Inspection tool, like ZScaler. That kind of tool should be configured to bypass SSL inspection.

# Issues using VM extensions in Python 3-enabled Linux Azure Virtual Machines systems

9/21/2022 • 2 minutes to read • [Edit Online](#)

## NOTE

Microsoft encourages users to adopt **Python 3.x** in their systems unless your workload requires **Python 2.x** support. Examples of this requirement might include legacy administration scripts, or extensions such as **Azure Disk Encryption** and **Azure Monitor**.

Before installing **Python 2.x** in production, consider the question of long-term support of Python 2.x, particularly their ability to receive security updates. As products, including some of the extension mentioned, update with **Python 3.8** support, you should discontinue use of Python 2.x.

Some Linux distributions have transitioned to Python 3.8 and removed the legacy `/usr/bin/python` entrypoint for Python altogether. This transition impacts the out-of-the-box, automated deployment of certain virtual machine (VM) extensions with these two conditions:

- Extensions that are still transitioning to Python 3.x support
- Extensions that use the legacy `/usr/bin/python` entrypoint

Linux distribution users who have transitioned to **Python 3.x** must ensure the legacy `/usr/bin/python` entrypoint exists before attempting to deploy those extensions to their VMs. Otherwise, the extension deployment might fail.

- Endorsed Linux distributions that are affected include **Ubuntu Server 20.04 LTS** and **Ubuntu Pro 20.04 LTS**.
- Affected VM Extensions include **Azure Disk Encryption**, **Log Analytics**, **VM Access** (used for Password Reset), and **Guest Diagnostics** (used for additional performance counters).

In-place upgrades, such as upgrading from **Ubuntu 18.04 LTS** to **Ubuntu 20.04 LTS**, should retain the `/usr/bin/python` symlink, and remain unaffected.

## Resolution

Consider these general recommendations before deploying extensions in the known-affected scenarios described previously in the Summary:

1. Before deploying the extension, reinstate the `/usr/bin/python` symlink by using the Linux distribution vendor-provided method.
  - For example, for **Python 2.7**, use: `sudo apt update && sudo apt install python-is-python2`
2. This recommendation is for Azure customers and is not supported in Azure Stack:
  - If you've already deployed an instance that exhibits this problem, use the Run command functionality in the VM blade to run the commands mentioned above. The Run command extension itself is not affected by the transition to Python 3.8.
3. If you are deploying a new instance, and need to set an extension at provisioning time, use **cloud-init** user data to install the packages mentioned above.

For example, for Python 2.7:

```
# create cloud-init config
cat > cloudinitConfig.json <<EOF
#cloud-config
package_update: true

runcmd:
- sudo apt update
- sudo apt install python-is-python2
EOF

# create VM
az vm create \
--resource-group <resourceGroupName> \
--name <vmName> \
--image <Ubuntu 20.04 Image URN> \
--admin-username azadmin \
--ssh-key-value "<sshPubKey>" \
--custom-data ./cloudinitConfig.json
```

4. If your organization's policy administrators determine that extensions shouldn't be deployed in VMs, you can disable extension support at provisioning time:

- REST API

To disable and enable extensions when you can deploy a VM with this property:

```
"osProfile": {
    "allowExtensionOperations": false
},
```

## Next steps

Please refer to [Other base system changes since 18.04 LTS - Python 3 by default](#) for additional information.

# Migrate your IaaS resources to Azure Resource Manager by March 1, 2023

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

In 2014, we launched infrastructure as a service (IaaS) on [Azure Resource Manager](#). We've been enhancing capabilities ever since. Because Azure Resource Manager now has full IaaS capabilities and other advancements, we deprecated the management of IaaS virtual machines (VMs) through [Azure Service Manager](#) (ASM) on February 28, 2020. This functionality will be fully retired on March 1, 2023.

Today, about 90 percent of the IaaS VMs are using Azure Resource Manager. If you use IaaS resources through ASM, start planning your migration now. Complete it by March 1, 2023, to take advantage of [Azure Resource Manager](#).

VMs created using the classic deployment model will follow the [Modern Lifecycle Policy](#) for retirement.

## How does this affect me?

- As of February 28, 2020, customers who didn't utilize IaaS VMs through ASM in the month of February 2020 can no longer create VMs (classic).
- On March 1, 2023, customers will no longer be able to start IaaS VMs by using ASM. Any that are still running or allocated will be stopped and deallocated.
- On March 1, 2023, subscriptions that are not migrated to Azure Resource Manager will be informed regarding timelines for deleting any remaining VMs (classic).

This retirement does *not* affect the following Azure services and functionality:

- Storage accounts *not* used by VMs (classic)
- Virtual networks *not* used by VMs (classic)
- Other classic resources

Azure Cloud Services (classic) retirement was announced in August 2021 [here](#)

## What resources are available for this migration?

- [Microsoft Q&A](#): Microsoft and community support for migration.
- [Azure Migration Support](#): Dedicated support team for technical assistance during migration. Customers without technical support can use [free support capability](#) provided specifically for this migration.
- [Microsoft Fast Track](#): Fast track can assist eligible customers with planning & execution for this migration. [Nominate yourself](#) for DC Migration Program.
- If your company/organization has partnered with Microsoft or works with Microsoft representatives (like cloud solution architects (CSAs) or customer success account managers (CSAMs)), please work with them for additional resources for migration.

## What actions should I take?

Start planning your migration to Azure Resource Manager, today.

1. Make a list of all affected VMs:
  - The VMs of type **virtual machines (classic)** on the [Azure portal's VM pane](#) are all the affected VMs within the subscription.
  - You can also query Azure Resource Graph by using the [portal](#) or [PowerShell](#) to view the list of all flagged VMs (classic) and related information for the selected subscriptions.
  - On February 8 and September 2, 2020, we sent out emails with subject "Start planning your IaaS VM migration to Azure Resource Manager" to subscription owners. The email provides a list of all subscriptions and VMs (classic) VMs in it. Please use them to build this list.
2. [Learn more](#) about migrating your [Linux](#) and [Windows](#) VMs (classic) to Azure Resource Manager. For more information, see [Frequently asked questions about classic to Azure Resource Manager migration](#).
3. We recommend starting the planning by using the [platform support migration tool](#) to migrate your existing VMs with three easy steps: validate, prepare, and commit. The tool is designed to migrate your VMs within minimal to no downtime.
  - The first step, validate, has no impact on your existing deployment and provides a list of all unsupported scenarios for migration.
  - Go through the [list of workarounds](#) to fix your deployment and make it ready for migration.
  - Ideally after all validation errors are fixed, you should not encounter any issues during the prepare and commit steps. After the commit is successful, your deployment is live migrated to Azure Resource Manager and can then be managed through new APIs exposed by Azure Resource Manager.If the migration tool is not suitable for your migration, you can explore [other compute offerings](#) for the migration. Because there are many Azure compute offerings, and they're different from one another, we can't provide a platform-supported migration path to them.
4. For technical questions, issues, and help with adding subscriptions to the allowlist, [contact support](#).
5. Complete the migration as soon as possible to prevent business impact and to take advantage of the improved performance, security, and new features of Azure Resource Manager.

# Platform-supported migration of IaaS resources from classic to Azure Resource Manager

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

This article provides overview on platform-supported migration tool, how to migrate resources from the Azure Service Manager (ASM) also known as Classic to Resource Manager (ARM) deployment models and details how to connect resources from the two deployment models that coexist in your subscription by using virtual network site-to-site gateways. You can read more about [Azure Resource Manager features and benefits](#).

ASM supports two different compute products, Azure Virtual Machines (classic) also known as IaaS VMs & [Azure Cloud Services \(classic\)](#) also known as PaaS VMs or Web/Worker Roles. This document only talks about migrating Azure Virtual Machines (classic).

## Goal for migration

Resource Manager enables deploying complex applications through templates, configures virtual machines by using VM extensions, and incorporates access management and tagging. Azure Resource Manager includes scalable, parallel deployment for virtual machines into availability sets. The new deployment model also provides lifecycle management of compute, network, and storage independently. Finally, there's a focus on enabling security by default with the enforcement of virtual machines in a virtual network.

Almost all the features from the classic deployment model are supported for compute, network, and storage under Azure Resource Manager. To benefit from the new capabilities in Azure Resource Manager, you can migrate existing deployments from the Classic deployment model.

## Supported resources & configurations for migration

### Supported resources for migration

- Virtual Machines (Cloud Service with VMs)
- [Cloud Services \(with Web/Worker Roles\)](#)
- Availability Sets
- Storage Accounts
- Virtual Networks
- VPN Gateways
- [Express Route Gateways](#) (*in the same subscription as Virtual Network only*)
- Network Security Groups
- Route Tables
- Reserved IPs

## Supported configurations for migration

These classic IaaS resources are supported during migration

SERVICE	CONFIGURATION
Azure AD Domain Services	Virtual networks that contain Azure AD Domain services

## Supported scopes of migration

There are four different ways to complete migration of compute, network, and storage resources:

- [Migration of virtual machines \(NOT in a virtual network\)](#)
- [Migration of virtual machines \(in a virtual network\)](#)
- [Migration of storage accounts](#)
- [Migration of unattached resources](#)

### Migration of virtual machines (NOT in a virtual network)

In the Resource Manager deployment model, security is enforced for your applications by default. All VMs need to be in a virtual network in the Resource Manager model. The Azure platform restarts (`Stop`, `Deallocate`, and `Start`) the VMs as part of the migration. You have two options for the virtual networks that the Virtual Machines will be migrated to:

- You can request the platform to create a new virtual network and migrate the virtual machine into the new virtual network.
- You can migrate the virtual machine into an existing virtual network in Resource Manager.

#### NOTE

In this migration scope, both the management-plane operations and the data-plane operations may not be allowed for a period of time during the migration.

### Migration of virtual machines (in a virtual network)

For most VM configurations, only the metadata is migrating between the Classic and Resource Manager deployment models. The underlying VMs are running on the same hardware, in the same network, and with the same storage. The management-plane operations may not be allowed for a certain period of time during the migration. However, the data plane continues to work. That is, your applications running on top of VMs (classic) do not incur downtime during the migration.

The following configurations are not currently supported. If support is added in the future, some VMs in this configuration might incur downtime (go through stop, deallocate, and restart VM operations).

- You have more than one availability set in a single cloud service.
- You have one or more availability sets and VMs that are not in an availability set in a single cloud service.

#### NOTE

In this migration scope, the management plane may not be allowed for a period of time during the migration. For certain configurations as described earlier, data-plane downtime occurs.

### Migration of storage accounts

To allow seamless migration, you can deploy Resource Manager VMs in a classic storage account. With this capability, compute and network resources can and should be migrated independently of storage accounts. Once you migrate over your Virtual Machines and Virtual Network, you need to migrate over your storage accounts to complete the migration process.

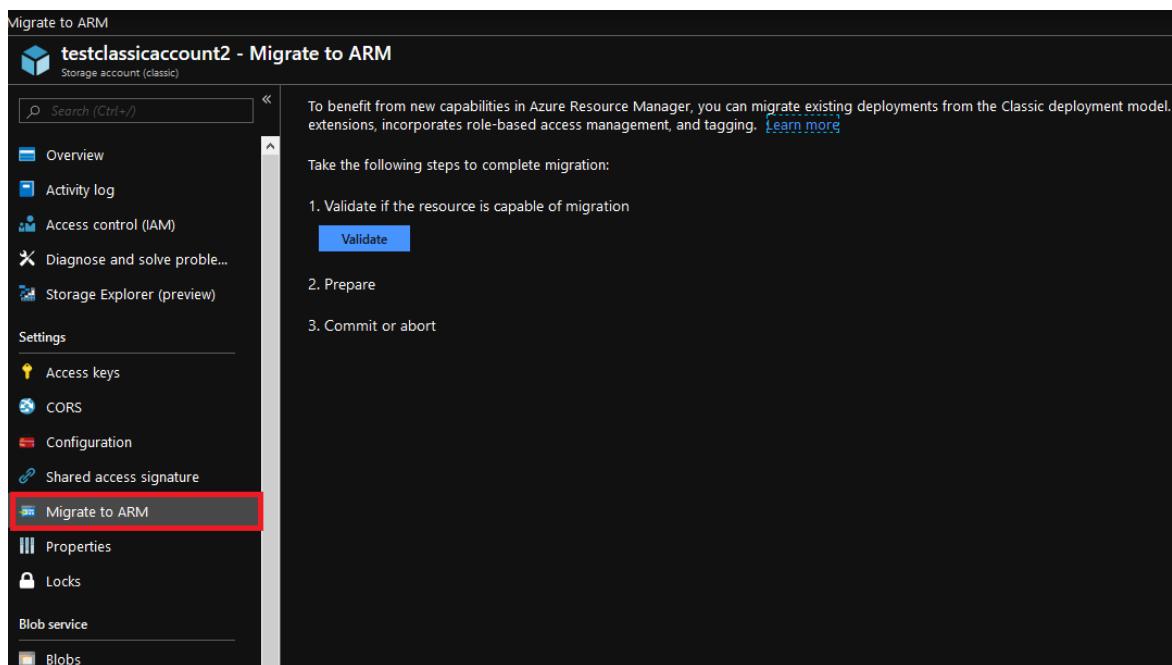

If your storage account does not have any associated disks or Virtual Machines data and only has blobs, files, tables, and queues then the migration to Azure Resource Manager can be done as a standalone migration without dependencies.

**NOTE**

The Resource Manager deployment model doesn't have the concept of Classic images and disks. When the storage account is migrated, Classic images and disks are no longer visible in the Azure portal, but the backing VHDs remain in the storage account.

The following screenshots show how to upgrade a Classic storage account to an Azure Resource Manager storage account using Azure portal:

1. Sign in to the [Azure portal](#).
2. Navigate to your storage account.
3. In the **Settings** section, click **Migrate to Azure Resource Manager**.
4. Click on **Validate** to determine migration feasibility.
5. If validation passes, click on **Prepare** to create a migrated storage account.
6. Type **yes** to confirm migration and click **Commit** to finish the migration.

The screenshot shows the 'Migrate to ARM' wizard for a storage account named 'testclassicaccount2'. The left sidebar lists options like Overview, Activity log, Access control (IAM), Diagnose and solve problems, Storage Explorer (preview), Settings (Access keys, CORS, Configuration, Shared access signature), Migrate to ARM, Properties, Locks, Blob service, and Queue service. The 'Migrate to ARM' option is selected. The main pane displays a green header bar with a checkmark and the text 'Validation passed.' Below it, a message encourages migrating to ARM for new capabilities. It lists three steps: 1. Validate if the resource is capable of migration (Validation passed, 1 storage account will be migrated), 2. Prepare (Simulate transformation, Prepare button), and 3. Commit or abort.

This screenshot continues the migration process. The validation step is complete. The preparation step shows that the storage account has been migrated to a resource group named 'testclassicaccount2-Migrated'. The commit step shows a dropdown menu set to 'yes' for confirming the migration. The 'Commit' and 'Abort' buttons are visible at the bottom.

## Migration of unattached resources

Storage Accounts with no associated disks or Virtual Machines data may be migrated independently.

Network Security Groups, Route Tables & Reserved IPs that are not attached to any Virtual Machines and Virtual Networks can also be migrated independently.

## Unsupported features and configurations

Some features and configurations are not currently supported; the following sections describe our recommendations around them.

### Unsupported features

The following features are not currently supported. You can optionally remove these settings, migrate the VMs, and then re-enable the settings in the Resource Manager deployment model.

RESOURCE PROVIDER	FEATURE	RECOMMENDATION
Compute	Unassociated virtual machine disks.	The VHD blobs behind these disks will get migrated when the Storage Account is migrated

RESOURCE PROVIDER	FEATURE	RECOMMENDATION
Compute	Virtual machine images.	The VHD blobs behind these disks will get migrated when the Storage Account is migrated
Network	Endpoint ACLs.	Remove Endpoint ACLs and retry migration.
Network	Application Gateway	Remove the Application Gateway before beginning migration and then recreate the Application Gateway once migration is complete.
Network	Virtual networks using VNet Peering.	Migrate Virtual Network to Resource Manager, then peer. Learn more about <a href="#">VNet Peering</a> .

## Unsupported configurations

The following configurations are not currently supported.

SERVICE	CONFIGURATION	RECOMMENDATION
Resource Manager	Role-Based Access Control (RBAC) for classic resources	Because the URI of the resources is modified after migration, it is recommended that you plan the RBAC policy updates that need to happen after migration.
Compute	Multiple subnets associated with a VM	Update the subnet configuration to reference only one subnet. This may require you to remove a secondary NIC (that is referring to another subnet) from the VM and reattach it after migration has completed.
Compute	Virtual machines that belong to a virtual network but don't have an explicit subnet assigned	You can optionally delete the VM.
Compute	Virtual machines that have alerts, Autoscale policies	The migration goes through and these settings are dropped. It is highly recommended that you evaluate your environment before you do the migration. Alternatively, you can reconfigure the alert settings after migration is complete.
Compute	XML VM extensions (BGInfo 1.*., Visual Studio Debugger, Web Deploy, and Remote Debugging)	This is not supported. It is recommended that you remove these extensions from the virtual machine to continue migration or they will be dropped automatically during the migration process.

Service	Configuration	Recommendation
Compute	Boot diagnostics with Premium storage	Disable Boot Diagnostics feature for the VMs before continuing with migration. You can re-enable boot diagnostics in the Resource Manager stack after the migration is complete. Additionally, blobs that are being used for screenshot and serial logs should be deleted so you are no longer charged for those blobs.
Compute	Cloud services that contain more than one availability set or multiple availability sets.	This is currently not supported. Please move the Virtual Machines to the same availability set before migrating.
Compute	VM with Microsoft Defender for Cloud extension	Microsoft Defender for Cloud automatically installs extensions on your Virtual Machines to monitor their security and raise alerts. These extensions usually get installed automatically if the Microsoft Defender for Cloud policy is enabled on the subscription. To migrate the Virtual Machines, disable the Defender for Cloud policy on the subscription, which will remove the Defender for Cloud monitoring extension from the Virtual Machines.
Compute	VM with backup or snapshot extension	These extensions are installed on a Virtual Machine configured with the Azure Backup service. While the migration of these VMs is not supported, follow the guidance in <a href="#">Frequently asked questions about classic to Azure Resource Manager migration</a> to keep backups that were taken prior to migration.
Compute	VM with Azure Site Recovery extension	These extensions are installed on a Virtual Machine configured with the Azure Site Recovery service. While the migration of storage used with Site Recovery will work, current replication will be impacted. You need to disable and enable VM replication after storage migration.
Network	Virtual networks that contain virtual machines and web/worker roles	This is currently not supported. Please move the Web/Worker roles to their own Virtual Network before migrating. Once the classic Virtual Network is migrated, the migrated Azure Resource Manager Virtual Network can be peered with the classic Virtual Network to achieve similar configuration as before.

Service	Configuration	Recommendation
Network	Classic Express Route circuits	This is currently not supported. These circuits need to be migrated to Azure Resource Manager before beginning IaaS migration. To learn more, see <a href="#">Moving ExpressRoute circuits from the classic to the Resource Manager deployment model</a> .
Azure App Service	Virtual networks that contain App Service environments	This is currently not supported.
Azure HDInsight	Virtual networks that contain HDInsight services	This is currently not supported.
Microsoft Dynamics Lifecycle Services	Virtual networks that contain virtual machines that are managed by Dynamics Lifecycle Services	This is currently not supported.
Azure API Management	Virtual networks that contain Azure API Management deployments	This is currently not supported. To migrate the IaaS VNET, change the VNET of the API Management deployment, which is a no downtime operation.

# Technical deep dive on platform-supported migration from classic to Azure Resource Manager

9/21/2022 • 13 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

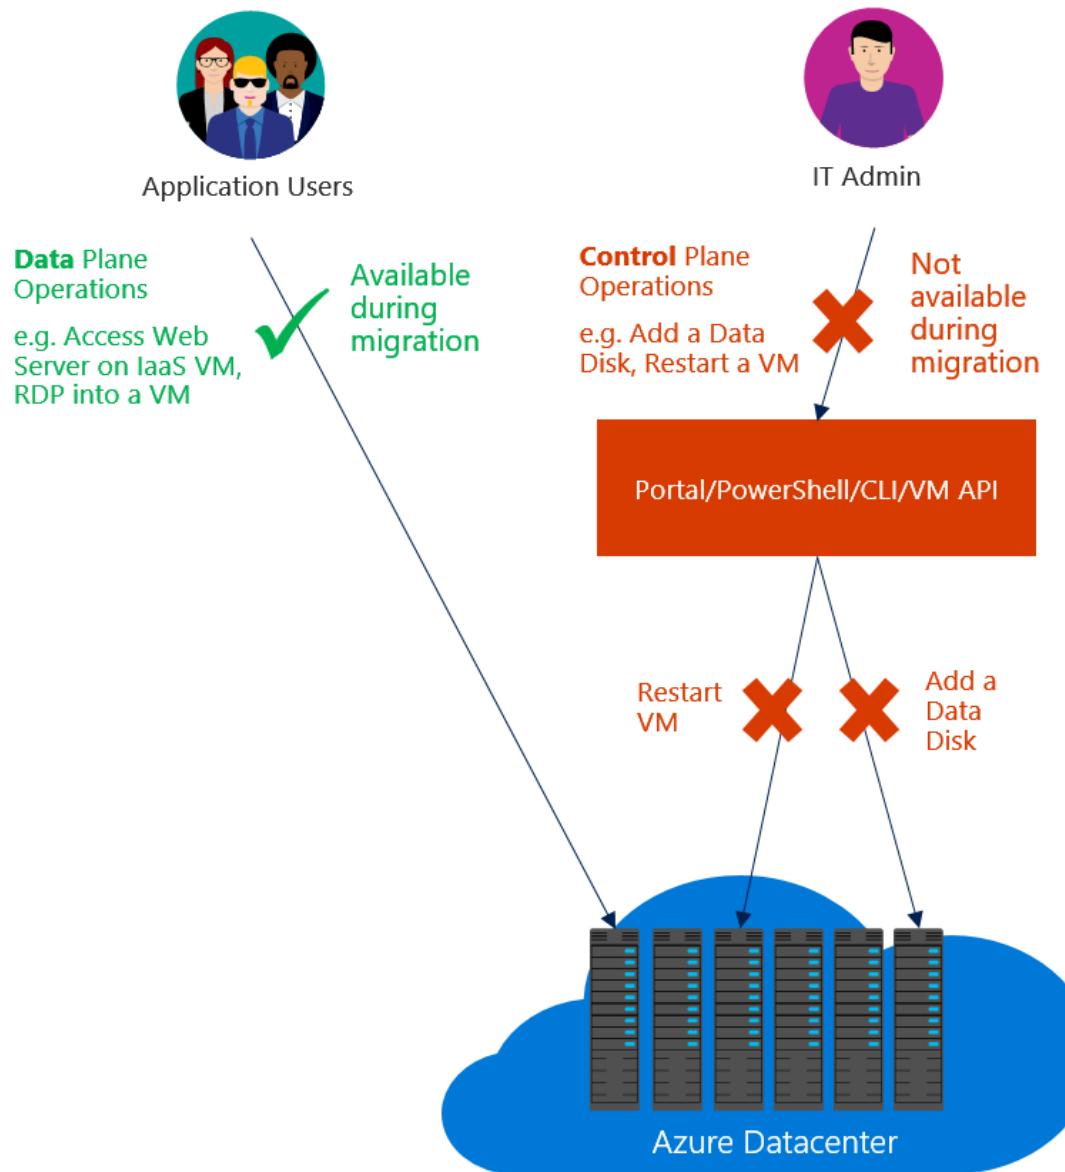

Let's take a deep-dive on migrating from the Azure classic deployment model to the Azure Resource Manager deployment model. We look at resources at a resource and feature level to help you understand how the Azure platform migrates resources between the two deployment models. For more information, please read the service announcement article: [Platform-supported migration of IaaS resources from classic to Azure Resource Manager](#).

## Migrate IaaS resources from the classic deployment model to Azure Resource Manager

First, it's important to understand the difference between data-plane and management-plane operations on the infrastructure as a service (IaaS) resources.

- *Management/control plane* describes the calls that come into the management/control plane or the API for modifying resources. For example, operations like creating a VM, restarting a VM, and updating a virtual network with a new subnet manage the running resources. They don't directly affect connecting to the VMs.
- *Data plane* (application) describes the runtime of the application itself, and involves interaction with instances that don't go through the Azure API. For example, accessing your website, or pulling data from a running SQL Server instance or a MongoDB server, are data plane or application interactions. Other examples include copying a blob from a storage account, and accessing a public IP address to use Remote Desktop Protocol (RDP) or Secure Shell (SSH) into the virtual machine. These operations keep the application running across compute, networking, and storage.

The data plane is the same between the classic deployment model and Resource Manager stacks. The difference is that during the migration process, Microsoft translates the representation of the resources from the classic deployment model to that in the Resource Manager stack. As a result, you need to use new tools, APIs, and SDKs to manage your resources in the Resource Manager stack.

#### NOTE

In some migration scenarios, the Azure platform stops, deallocates, and restarts your virtual machines. This causes a brief data-plane downtime.

## The migration experience

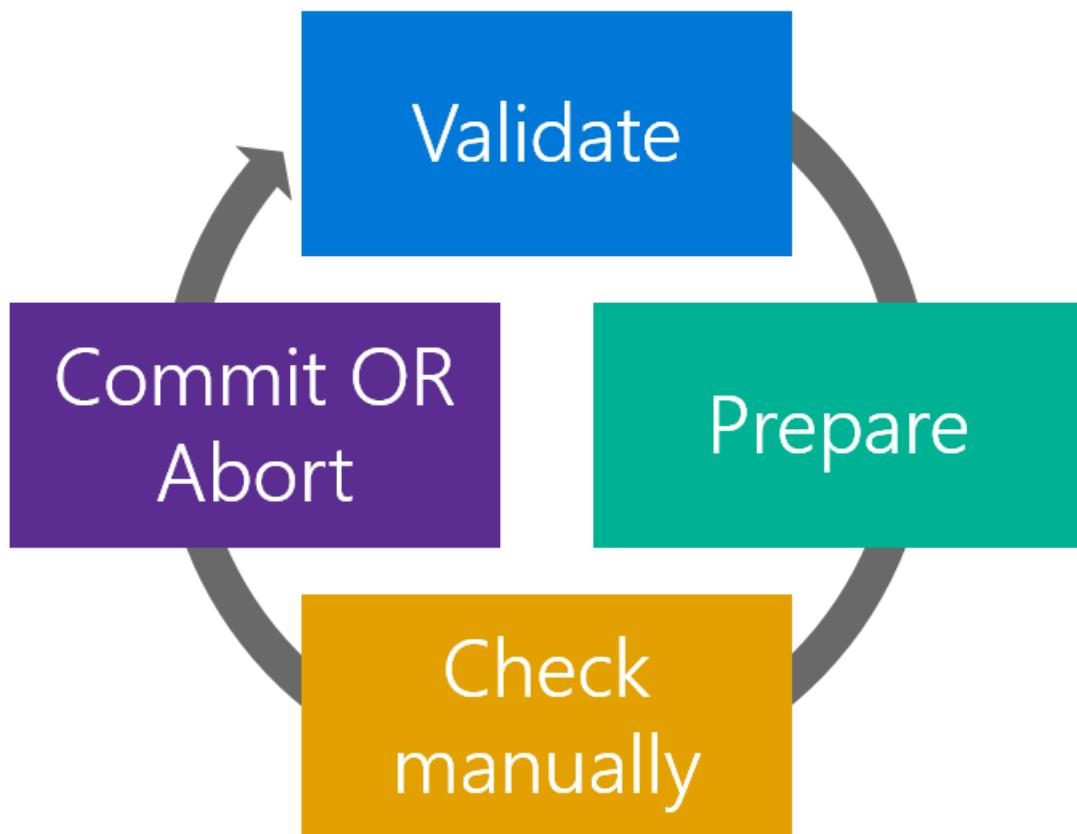

Before you start the migration:

- Ensure that the resources that you want to migrate don't use any unsupported features or configurations. Usually the platform detects these issues and generates an error.
- If you have VMs that are not in a virtual network, they are stopped and deallocated as part of the prepare operation. If you don't want to lose the public IP address, consider reserving the IP address before triggering the prepare operation. If the VMs are in a virtual network, they are not stopped and deallocated.
- Plan your migration during non-business hours to accommodate for any unexpected failures that might happen during migration.
- Download the current configuration of your VMs by using PowerShell, command-line interface (CLI) commands, or REST APIs to make it easier for validation after the prepare step is complete.
- Update your automation and operationalization scripts to handle the Resource Manager deployment model,

before you start the migration. You can optionally do GET operations when the resources are in the prepared state.

- Evaluate the Azure role-based access control (Azure RBAC) policies that are configured on the IaaS resources in the classic deployment model, and plan for after the migration is complete.

The migration workflow is as follows:

#### NOTE

The operations described in the following sections are all idempotent. If you have a problem other than an unsupported feature or a configuration error, retry the prepare, abort, or commit operation. Azure tries the action again.

## Validate

The validate operation is the first step in the migration process. The goal of this step is to analyze the state of the resources you want to migrate in the classic deployment model. The operation evaluates whether the resources are capable of migration (success or failure).

You select the virtual network or a cloud service (if it's not in a virtual network) that you want to validate for migration. If the resource is not capable of migration, Azure lists the reasons why.

#### Checks not done in the validate operation

The validate operation only analyzes the state of the resources in the classic deployment model. It can check for all failures and unsupported scenarios due to various configurations in the classic deployment model. It is not possible to check for all issues that the Azure Resource Manager stack might impose on the resources during migration. These issues are only checked when the resources undergo transformation in the next step of migration (the prepare operation). The following table lists all the issues not checked in the validate operation:

#### NETWORKING CHECKS NOT IN THE VALIDATE OPERATION

A virtual network having both ER and VPN gateways.

A virtual network gateway connection in a disconnected state.

All ER circuits are pre-migrated to Azure Resource Manager stack.

Azure Resource Manager quota checks for networking resources. For example: static public IP, dynamic public IPs, load balancer, network security groups, route tables, and network interfaces.

All load balancer rules are valid across deployment and the virtual network.

Conflicting private IPs between stop-deallocated VMs in the same virtual network.

## Prepare

The prepare operation is the second step in the migration process. The goal of this step is to simulate the transformation of the IaaS resources from the classic deployment model to Resource Manager resources. Further, the prepare operation presents this side-by-side for you to visualize.

### NOTE

Your resources in the classic deployment model are not modified during this step. It's a safe step to run if you're trying out migration.

You select the virtual network or the cloud service (if it's not a virtual network) that you want to prepare for migration.

- If the resource is not capable of migration, Azure stops the migration process and lists the reason why the prepare operation failed.
- If the resource is capable of migration, Azure locks down the management-plane operations for the resources under migration. For example, you are not able to add a data disk to a VM under migration.

Azure then starts the migration of metadata from the classic deployment model to Resource Manager for the migrating resources.

After the prepare operation is complete, you have the option of visualizing the resources in both the classic deployment model and Resource Manager. For every cloud service in the classic deployment model, the Azure platform creates a resource group name that has the pattern `cloud-service-name>-Migrated`.

### NOTE

It is not possible to select the name of a resource group created for migrated resources (that is, "-Migrated"). After migration is complete, however, you can use the move feature of Azure Resource Manager to move resources to any resource group you want. For more information, see [Move resources to new resource group or subscription](#).

The following two screenshots show the result after a successful prepare operation. The first one shows a resource group that contains the original cloud service. The second one shows the new "-Migrated" resource group that contains the equivalent Azure Resource Manager resources.

Here is a behind-the-scenes look at your resources after the completion of the prepare phase. Note that the resource in the data plane is the same. It's represented in both the management plane (classic deployment model) and the control plane (Resource Manager).

# Prepare

## NOTE

VMs that are not in a virtual network in the classic deployment model are stopped and deallocated in this phase of migration.

## Check (manual or scripted)

In the check step, you have the option to use the configuration that you downloaded earlier to validate that the migration looks correct. Alternatively, you can sign in to the portal, and spot check the properties and resources to validate that metadata migration looks good.

If you are migrating a virtual network, most configuration of virtual machines is not restarted. For applications on those VMs, you can validate that the application is still running.

You can test your monitoring and operational scripts to see if the VMs are working as expected, and if your updated scripts work correctly. Only GET operations are supported when the resources are in the prepared state.

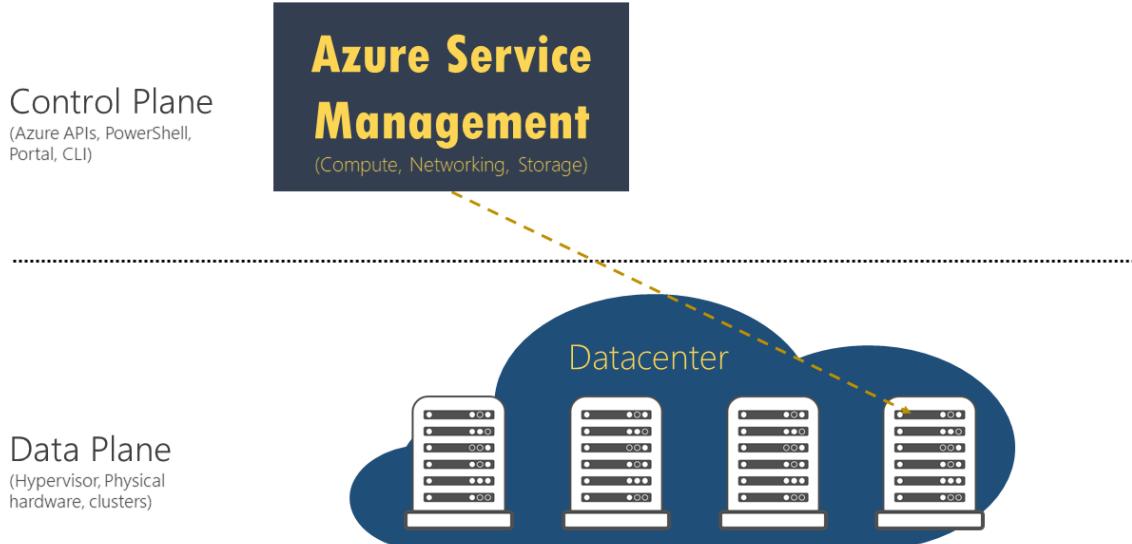

There is no set window of time before which you need to commit the migration. You can take as much time as you want in this state. However, the management plane is locked for these resources until you either abort or commit.

If you see any issues, you can always abort the migration and go back to the classic deployment model. After you go back, Azure opens the management-plane operations on the resources, so that you can resume normal operations on those VMs in the classic deployment model.

## Abort

This is an optional step if you want to revert your changes to the classic deployment model and stop the migration. This operation deletes the Resource Manager metadata (created in the prepare step) for your resources.

# Abort

## NOTE

This operation can't be done after you have triggered the commit operation.

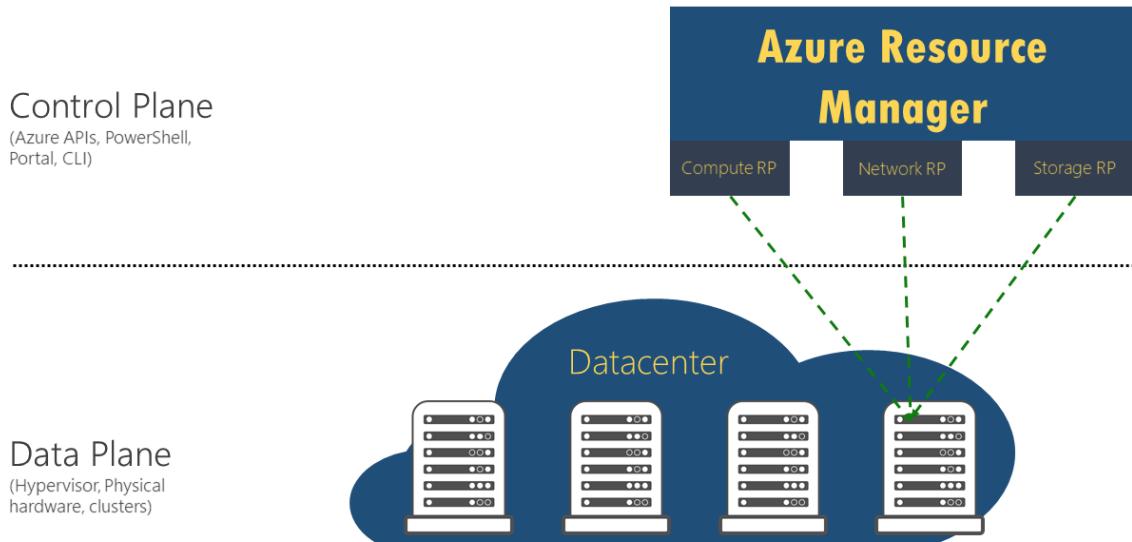

## Commit

After you finish the validation, you can commit the migration. Resources do not appear anymore in the classic deployment model, and are available only in the Resource Manager deployment model. The migrated resources can be managed only in the new portal.

## NOTE

This is an idempotent operation. If it fails, retry the operation. If it continues to fail, create a support ticket or create a forum on [Microsoft Q&A](#)

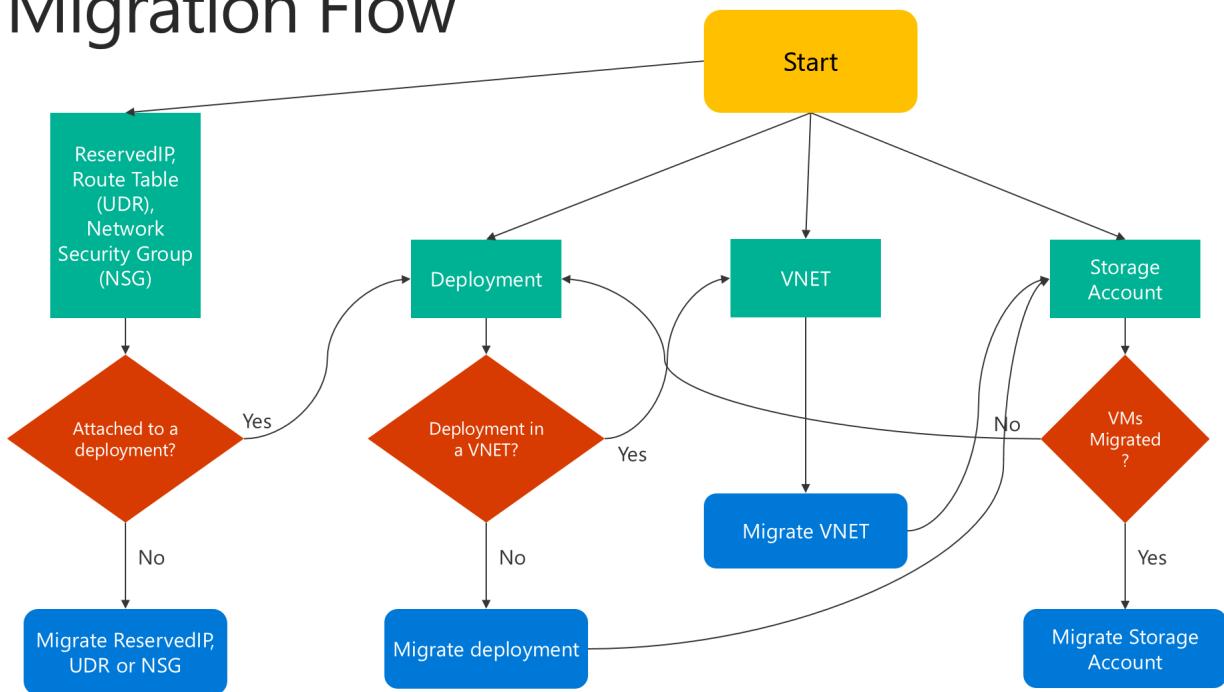

# Commit

## Migration flowchart

Here is a flowchart that shows how to proceed with migration:

# Migration Flow

## Translation of the classic deployment model to Resource Manager resources

You can find the classic deployment model and Resource Manager representations of the resources in the following table. Other features and resources are not currently supported.

CLASSIC REPRESENTATION	RESOURCE MANAGER REPRESENTATION	NOTES
Cloud service name (Hosted Service Name)	DNS name	During migration, a new resource group is created for every cloud service with the naming pattern <code>&lt;cloudservicename&gt;-migrated</code> . This resource group contains all your resources. The cloud service name becomes a DNS name that is associated with the public IP address.
Virtual machine	Virtual machine	VM-specific properties are migrated unchanged. Certain osProfile information, like computer name, is not stored in the classic deployment model, and remains empty after migration.

CLASSIC REPRESENTATION	RESOURCE MANAGER REPRESENTATION	NOTES
Disk resources attached to VM	Implicit disks attached to VM	Disks are not modeled as top-level resources in the Resource Manager deployment model. They are migrated as implicit disks under the VM. Only disks that are attached to a VM are currently supported. Resource Manager VMs can now use storage accounts in the classic deployment model, which allows the disks to be easily migrated without any updates.
VM extensions	VM extensions	All the resource extensions, except XML extensions, are migrated from the classic deployment model.
Virtual machine certificates	Certificates in Azure Key Vault	If a cloud service contains service certificates, the migration creates a new Azure key vault per cloud service, and moves the certificates into the key vault. The VMs are updated to reference the certificates from the key vault.  Do not delete the key vault. This can cause the VM to go into a failed state.
WinRM configuration	WinRM configuration under osProfile	Windows Remote Management configuration is moved unchanged, as part of the migration.
Availability-set property	Availability-set resource	Availability-set specification is a property on the VM in the classic deployment model. Availability sets become a top-level resource as part of the migration. The following configurations are not supported: multiple availability sets per cloud service, or one or more availability sets along with VMs that are not in any availability set in a cloud service.
Network configuration on a VM	Primary network interface	Network configuration on a VM is represented as the primary network interface resource after migration. For VMs that are not in a virtual network, the internal IP address changes during migration.
Multiple network interfaces on a VM	Network interfaces	If a VM has multiple network interfaces associated with it, each network interface becomes a top-level resource as part of the migration, along with all the properties.

CLASSIC REPRESENTATION	RESOURCE MANAGER REPRESENTATION	NOTES
Load-balanced endpoint set	Load balancer	In the classic deployment model, the platform assigned an implicit load balancer for every cloud service. During migration, a new load-balancer resource is created, and the load-balancing endpoint set becomes load-balancer rules.
Inbound NAT rules	Inbound NAT rules	Input endpoints defined on the VM are converted to inbound network address translation rules under the load balancer during the migration.
VIP address	Public IP address with DNS name	The virtual IP address becomes a public IP address, and is associated with the load balancer. A virtual IP can only be migrated if there is an input endpoint assigned to it. To retain the IP, you can <a href="#">convert it to Reserved IP</a> before migration. There will be downtime of about 60 seconds during this change.
Virtual network	Virtual network	The virtual network is migrated, with all its properties, to the Resource Manager deployment model. A new resource group is created with the name <code>-migrated</code> .
Reserved IPs	Public IP address with static allocation method	Reserved IPs associated with the load balancer are migrated, along with the migration of the cloud service or the virtual machine. Unassociated reserved IPs can be migrated using <a href="#">Move-AzureReservedIP</a> .
Public IP address per VM	Public IP address with dynamic allocation method	The public IP address associated with the VM is converted as a public IP address resource, with the allocation method set to dynamic.
NSGs	NSGs	Network security groups associated with a virtual machine or subnet are cloned as part of the migration to the Resource Manager deployment model. The NSG in the classic deployment model is not removed during the migration. However, the management-plane operations for the NSG are blocked when the migration is in progress. Unassociated NSGs can be migrated using <a href="#">Move-AzureNetworkSecurityGroup</a> .

CLASSIC REPRESENTATION	RESOURCE MANAGER REPRESENTATION	NOTES
DNS servers	DNS servers	DNS servers associated with a virtual network or the VM are migrated as part of the corresponding resource migration, along with all the properties.
UDRs	UDRs	User-defined routes associated with a subnet are cloned as part of the migration to the Resource Manager deployment model. The UDR in the classic deployment model is not removed during the migration. The management-plane operations for the UDR are blocked when the migration is in progress. Unassociated UDRs can be migrated using <a href="#">Move-AzureRouteTable</a> .
IP forwarding property on a VM's network configuration	IP forwarding property on the NIC	The IP forwarding property on a VM is converted to a property on the network interface during the migration.
Load balancer with multiple IPs	Load balancer with multiple public IP resources	Every public IP associated with the load balancer is converted to a public IP resource, and associated with the load balancer after migration.
Internal DNS names on the VM	Internal DNS names on the NIC	During migration, the internal DNS suffixes for the VMs are migrated to a read-only property named "InternalDomainNameSuffix" on the NIC. The suffix remains unchanged after migration, and VM resolution should continue to work as previously.
Virtual network gateway	Virtual network gateway	Virtual network gateway properties are migrated unchanged. The VIP associated with the gateway does not change either.
Local network site	Local network gateway	Local network site properties are migrated unchanged to a new resource called a local network gateway. This represents on-premises address prefixes and the remote gateway IP.

CLASSIC REPRESENTATION	RESOURCE MANAGER REPRESENTATION	NOTES
Connections references	Connection	Connectivity references between the gateway and the local network site in network configuration is represented by a new resource called Connection. All properties of connectivity reference in network configuration files are copied unchanged to the Connection resource. Connectivity between virtual networks in the classic deployment model is achieved by creating two IPsec tunnels to local network sites representing the virtual networks. This is transformed to the virtual-network-to-virtual-network connection type in the Resource Manager model, without requiring local network gateways.

## Changes to your automation and tooling after migration

As part of migrating your resources from the classic deployment model to the Resource Manager deployment model, you must update your existing automation or tooling to ensure that it continues to work after the migration.

# Planning for migration of IaaS resources from classic to Azure Resource Manager

9/21/2022 • 14 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

While Azure Resource Manager offers a lot of amazing features, it is critical to plan out your migration journey to make sure things go smoothly. Spending time on planning will ensure that you do not encounter issues while executing migration activities.

## NOTE

The following guidance was heavily contributed to by the Azure Customer Advisory team and Cloud Solution architects working with customers on migrating large environments. As such this document will continue to get updated as new patterns of success emerge, so check back from time to time to see if there are any new recommendations.

There are four general phases of the migration journey:

## Plan

### Technical considerations and tradeoffs

Depending on your technical requirements size, geographies and operational practices, you might want to consider:

1. Why is Azure Resource Manager desired for your organization? What are the business reasons for a migration?
2. What are the technical reasons for Azure Resource Manager? What (if any) additional Azure services would you like to leverage?
3. Which application (or sets of virtual machines) is included in the migration?
4. Which scenarios are supported with the migration API? Review the [unsupported features and configurations](#).
5. Will your operational teams now support applications/VMs in both Classic and Azure Resource Manager?
6. How (if at all) does Azure Resource Manager change your VM deployment, management, monitoring, and reporting processes? Do your deployment scripts need to be updated?
7. What is the communications plan to alert stakeholders (end users, application owners, and infrastructure owners)?
8. Depending on the complexity of the environment, should there be a maintenance period where the application is unavailable to end users and to application owners? If so, for how long?
9. What is the training plan to ensure stakeholders are knowledgeable and proficient in Azure Resource

Manager?

10. What is the program management or project management plan for the migration?
11. What are the timelines for the Azure Resource Manager migration and other related technology road maps? Are they optimally aligned?

### Patterns of success

Successful customers have detailed plans where the preceding questions are discussed, documented and governed. Ensure the migration plans are broadly communicated to sponsors and stakeholders. Equip yourself with knowledge about your migration options; reading through this migration document set below is highly recommended.

- [Overview of platform-supported migration of IaaS resources from classic to Azure Resource Manager](#)
- [Technical deep dive on platform-supported migration from classic to Azure Resource Manager](#)
- [Planning for migration of IaaS resources from classic to Azure Resource Manager](#)
- [Use PowerShell to migrate IaaS resources from classic to Azure Resource Manager](#)
- [Use CLI to migrate IaaS resources from classic to Azure Resource Manager](#)
- [Community tools for assisting with migration of IaaS resources from classic to Azure Resource Manager](#)
- [Review most common migration errors](#)
- [Review the most frequently asked questions about migrating IaaS resources from classic to Azure Resource Manager](#)

### Pitfalls to avoid

- Failure to plan. The technology steps of this migration are proven and the outcome is predictable.
- Assumption that the platform supported migration API will account for all scenarios. Read the [unsupported features and configurations](#) to understand what scenarios are supported.
- Not planning potential application outage for end users. Plan enough buffer to adequately warn end users of potentially unavailable application time.

## Lab Test

Replicate your environment and do a test migration

#### NOTE

Exact replication of your existing environment is executed by using a community-contributed tool which is not officially supported by Microsoft Support. Therefore, it is an [optional](#) step but it is the best way to find out issues without touching your production environments. If using a community-contributed tool is not an option, then read about the Validate/Prepare/Abort Dry Run recommendation below.

Conducting a lab test of your exact scenario (compute, networking, and storage) is the best way to ensure a smooth migration. This will help ensure:

- A wholly separate lab or an existing non-production environment to test. We recommend a wholly separate lab that can be migrated repeatedly and can be destructively modified. Scripts to collect/hydrate metadata from the real subscriptions are listed below.
- It's a good idea to create the lab in a separate subscription. The reason is that the lab will be torn down repeatedly, and having a separate, isolated subscription will reduce the chance that something real will get accidentally deleted.

This can be accomplished by using the AsmMetadataParser tool. [Read more about this tool here](#)

### Patterns of success

The following were issues discovered in many of the larger migrations. This is not an exhaustive list and you should refer to the [unsupported features and configurations](#) for more detail. You may or may not encounter these technical issues but if you do solving these before attempting migration will ensure a smoother experience.

- **Do a Validate/Prepare/Abort Dry Run** - This is perhaps the most important step to ensure Classic to Azure Resource Manager migration success. The migration API has three main steps: Validate, Prepare and Commit. Validate will read the state of your classic environment and return a result of all issues. However, because some issues might exist in the Azure Resource Manager stack, Validate will not catch everything. The next step in migration process, Prepare will help expose those issues. Prepare will move the metadata from Classic to Azure Resource Manager, but will not commit the move, and will not remove or change anything on the Classic side. The dry run involves preparing the migration, then aborting (**not committing**) the migration prepare. The goal of validate/prepare/abort dry run is to see all of the metadata in the Azure Resource Manager stack, examine it (*programmatically or in Portal*), and verify that everything migrates correctly, and work through technical issues. It will also give you a sense of migration duration so you can plan for downtime accordingly. A validate/prepare/abort does not cause any user downtime; therefore, it is non-disruptive to application usage.
  - The items below will need to be solved before the dry run, but a dry run test will also safely flush out these preparation steps if they are missed. During enterprise migration, we've found the dry run to be a safe and invaluable way to ensure migration readiness.
  - When prepare is running, the control plane (Azure management operations) will be locked for the whole virtual network, so no changes can be made to VM metadata during validate/prepare/abort. But otherwise any application function (RD, VM usage, etc.) will be unaffected. Users of the VMs will not know that the dry run is being executed.
- **Express Route Circuits and VPN**. Currently Express Route Gateways with authorization links cannot be migrated without downtime. For the workaround, see [Migrate ExpressRoute circuits and associated virtual networks from the classic to the Resource Manager deployment model](#).
- **VM Extensions** - Virtual Machine extensions are potentially one of the biggest roadblocks to migrating running VMs. Remediation of VM Extensions could take upwards of 1-2 days, so plan accordingly. A working Azure agent is needed to report back VM Extension status of running VMs. If the status comes back as bad for a running VM, this will halt migration. The agent itself does not need to be in working order to enable migration, but if extensions exist on the VM, then both a working agent AND outbound internet connectivity (with DNS) will be needed for migration to move forward.
  - If connectivity to a DNS server is lost during migration, all VM Extensions except BGInfo v1.\* need to first be removed from every VM before migration prepare, and subsequently re-added back to the VM after Azure Resource Manager migration. **This is only for VMs that are running.** If the VMs are stopped deallocated, VM Extensions do not need to be removed. **Note:** Many extensions like Azure diagnostics and Defender for Cloud monitoring will reinstall themselves after migration, so removing them is not a problem.
  - In addition, make sure Network Security Groups are not restricting outbound internet access. This can happen with some Network Security Groups configurations. Outbound internet access (and DNS) is needed for VM Extensions to be migrated to Azure Resource Manager.
  - There are two versions of the BGInfo extension: v1 and v2. If the VM was created using the Azure portal or PowerShell, the VM will likely have the v1 extension on it. This extension does not need to be removed and will be skipped (not migrated) by the migration API. However, if the Classic VM was created with the new Azure portal, it will likely have the JSON-based v2 version of BGInfo, which can be migrated to Azure Resource Manager provided the agent is working and has outbound internet access (and DNS).
  - **Remediation Option 1.** If you know your VMs will not have outbound internet access, a working

DNS service, and working Azure agents on the VMs, then uninstall all VM extensions as part of the migration before Prepare, then reinstall the VM Extensions after migration.

- **Remediation Option 2.** If VM extensions are too big of a hurdle, another option is to shutdown/deallocate all VMs before migration. Migrate the deallocated VMs, then restart them on the Azure Resource Manager side. The benefit here is that VM extensions will migrate. The downside is that all public facing Virtual IPs will be lost (this may be a non-starter), and obviously the VMs will shut down causing a much greater impact on working applications.

**NOTE**

If a Microsoft Defender for Cloud policy is configured against the running VMs being migrated, the security policy needs to be stopped before removing extensions, otherwise the security monitoring extension will be reinstalled automatically on the VM after removing it.

- **Availability Sets** - For a virtual network (vNet) to be migrated to Azure Resource Manager, the Classic deployment (i.e. cloud service) contained VMs must all be in one availability set, or the VMs must all not be in any availability set. Having more than one availability set in the cloud service is not compatible with Azure Resource Manager and will halt migration. Additionally, there cannot be some VMs in an availability set, and some VMs not in an availability set. To resolve this, you will need to remediate or reshuffle your cloud service. Plan accordingly as this might be time consuming.
- **Web/Worker Role Deployments** - Cloud Services containing web and worker roles cannot migrate to Azure Resource Manager. The web/worker roles must first be removed from the virtual network before migration can start. A typical solution is to just move web/worker role instances to a separate Classic virtual network that is also linked to an ExpressRoute circuit, or to migrate the code to newer PaaS App Services (this discussion is beyond the scope of this document). In the former redeploy case, create a new Classic virtual network, move/redeploy the web/worker roles to that new virtual network, then delete the deployments from the virtual network being moved. No code changes required. The new [Virtual Network Peering](#) capability can be used to peer together the classic virtual network containing the web/worker roles and other virtual networks in the same Azure region such as the virtual network being migrated (**after virtual network migration is completed as peered virtual networks cannot be migrated**), hence providing the same capabilities with no performance loss and no latency/bandwidth penalties. Given the addition of [Virtual Network Peering](#), web/worker role deployments can now easily be mitigated and not block the migration to Azure Resource Manager.
- **Azure Resource Manager Quotas** - Azure regions have separate quotas/limits for both Classic and Azure Resource Manager. Even though in a migration scenario new hardware isn't being consumed (*we're swapping existing VMs from Classic to Azure Resource Manager*), Azure Resource Manager quotas still need to be in place with enough capacity before migration can start. Listed below are the major limits we've seen cause problems. Open a quota support ticket to raise the limits.

**NOTE**

These limits need to be raised in the same region as your current environment to be migrated.

- Network Interfaces
- Load Balancers
- Public IPs
- Static Public IPs
- Cores

- Network Security Groups
- Route Tables

You can check your current Azure Resource Manager quotas using the following commands with the latest version of Azure CLI.

#### **Compute (Cores, Availability Sets)**

```
az vm list-usage -l <azure-region> -o jsonc
```

#### **Network (Virtual Networks, Static Public IPs, Public IPs, Network Security Groups, Network Interfaces, Load Balancers, Route Tables)**

```
az network list-usages -l <azure-region> -o jsonc
```

#### **Storage (Storage Account)**

```
az storage account show-usage
```

- **Azure Resource Manager API throttling limits** - If you have a large enough environment (eg. > 400 VMs in a VNET), you might hit the default API throttling limits for writes (currently **1200 writes/hour**) in Azure Resource Manager. Before starting migration, you should raise a support ticket to increase this limit for your subscription.
- **Provisioning Timed Out VM Status** - If any VM has the status of **provisioning timed out**, this needs to be resolved pre-migration. The only way to do this is with downtime by deprovisioning/reprovisioning the VM (delete it, keep the disk, and recreate the VM).
- **RoleStateUnknown VM Status** - If migration halts due to a **role state unknown** error message, inspect the VM using the portal and ensure it is running. This error will typically go away on its own (no remediation required) after a few minutes and is often a transient type often seen during a Virtual Machine **start, stop, restart** operations. **Recommended practice:** re-try migration again after a few minutes.
- **Fabric Cluster does not exist** - In some cases, certain VMs cannot be migrated for various odd reasons. One of these known cases is if the VM was recently created (within the last week or so) and happened to land an Azure cluster that is not yet equipped for Azure Resource Manager workloads. You will get an error that says **fabric cluster does not exist** and the VM cannot be migrated. Waiting a couple of days will usually resolve this particular problem as the cluster will soon get Azure Resource Manager enabled. However, one immediate workaround is to **stop-deallocate** the VM, then continue forward with migration, and start the VM back up in Azure Resource Manager after migrating.

#### **Pitfalls to avoid**

- Do not take shortcuts and omit the validate/prepare/abort dry run migrations.
- Most, if not all, of your potential issues will surface during the validate/prepare/abort steps.

## **Migration**

#### **Technical considerations and tradeoffs**

Now you are ready because you have worked through the known issues with your environment.

For the real migrations, you might want to consider:

1. Plan and schedule the virtual network (smallest unit of migration) with increasing priority. Do the simple virtual networks first, and progress with the more complicated virtual networks.
2. Most customers will have non-production and production environments. Schedule production last.
3. (OPTIONAL) Schedule a maintenance downtime with plenty of buffer in case unexpected issues arise.
4. Communicate with and align with your support teams in case issues arise.

### Patterns of success

The technical guidance from the Lab Test section above should be considered and mitigated prior to a real migration. With adequate testing, the migration is actually a non-event. For production environments, it might be helpful to have additional support, such as a trusted Microsoft partner or Microsoft Premier services.

### Pitfalls to avoid

Not fully testing may cause issues and delay in the migration.

## Beyond Migration

### Technical considerations and tradeoffs

Now that you are in Azure Resource Manager, maximize the platform. Read the [overview of Azure Resource Manager](#) to find out about additional benefits.

Things to consider:

- Bundling the migration with other activities. Most customers opt for an application maintenance window. If so, you might want to use this downtime to enable other Azure Resource Manager capabilities like encryption and migration to Managed Disks.
- Revisit the technical and business reasons for Azure Resource Manager; enable the additional services available only on Azure Resource Manager that apply to your environment.
- Modernize your environment with PaaS services.

### Patterns of success

Be purposeful on what services you now want to enable in Azure Resource Manager. Many customers find the below compelling for their Azure environments:

- [Azure role-based access control \(Azure RBAC\)](#).
- [Azure Resource Manager templates for easier and more controlled deployment](#).
- [Tags](#).
- [Activity Control](#)
- [Azure Policies](#)

### Pitfalls to avoid

Remember why you started this Classic to Azure Resource Manager migration journey. What were the original business reasons? Did you achieve the business reason?

Manager

# Migrate IaaS resources from classic to Azure Resource Manager by using Azure CLI

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

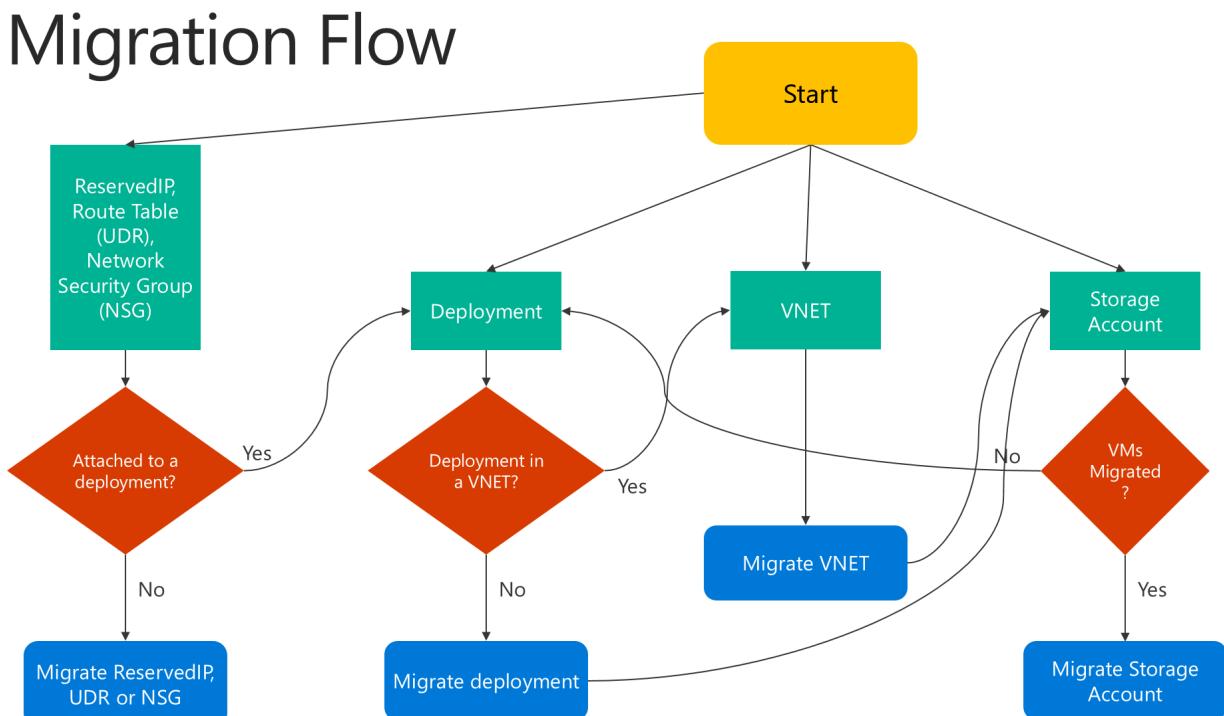

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

These steps show you how to use CLI commands to migrate infrastructure as a service (IaaS) resources from the classic deployment model to the Azure Resource Manager deployment model. The article requires the [Azure classic CLI](#). Since Azure CLI only applies to Azure Resource Manager resources, it cannot be used for this migration.

## NOTE

All the operations described here are idempotent. If you have a problem other than an unsupported feature or a configuration error, we recommend that you retry the prepare, abort, or commit operation. The platform will then try the action again.

Here is a flowchart to identify the order in which steps need to be executed during a migration process

## Step 1: Prepare for migration

Here are a few best practices that we recommend as you evaluate migrating IaaS resources from classic to Resource Manager:

- Read through the [list of unsupported configurations or features](#). If you have virtual machines that use unsupported configurations or features, we recommend that you wait for the feature/configuration support to be announced. Alternatively, you can remove that feature or move out of that configuration to enable migration if it suits your needs.
- If you have automated scripts that deploy your infrastructure and applications today, try to create a similar test setup by using those scripts for migration. Alternatively, you can set up sample environments by using the Azure portal.

#### IMPORTANT

Application Gateways are not currently supported for migration from classic to Resource Manager. To migrate a classic virtual network with an Application gateway, remove the gateway before running a Prepare operation to move the network. After you complete the migration, reconnect the gateway in Azure Resource Manager.

ExpressRoute gateways connecting to ExpressRoute circuits in another subscription cannot be migrated automatically. In such cases, remove the ExpressRoute gateway, migrate the virtual network and recreate the gateway. Please see [Migrate ExpressRoute circuits and associated virtual networks from the classic to the Resource Manager deployment model](#) for more information.

## Step 2: Set your subscription and register the provider

For migration scenarios, you need to set up your environment for both classic and Resource Manager. [Install the Azure classic CLI](#) and [select your subscription](#).

Sign-in to your account.

```
azure login
```

Select the Azure subscription by using the following command.

```
azure account set "<azure-subscription-name>"
```

#### NOTE

Registration is a one time step but it needs to be done once before attempting migration. Without registering you'll see the following error message

*BadRequest : Subscription is not registered for migration.*

Register with the migration resource provider by using the following command. Note that in some cases, this command times out. However, the registration will be successful.

```
azure provider register Microsoft.ClassicInfrastructureMigrate
```

Please wait five minutes for the registration to finish. You can check the status of the approval by using the following command. Make sure that RegistrationState is `Registered` before you proceed.

```
azure provider show Microsoft.ClassicInfrastructureMigrate
```

Now switch CLI to the `asm` mode.

```
azure config mode asm
```

## Step 3: Make sure you have enough Azure Resource Manager Virtual Machine vCPUs in the Azure region of your current deployment or VNET

For this step you'll need to switch to `arm` mode. Do this with the following command.

```
azure config mode arm
```

You can use the following CLI command to check the current number of vCPUs you have in Azure Resource Manager. To learn more about vCPU quotas, see [Limits and the Azure Resource Manager](#).

```
azure vm list-usage -l "<Your VNET or Deployment's Azure region"
```

Once you're done verifying this step, you can switch back to `asm` mode.

```
azure config mode asm
```

## Step 4: Option 1 - Migrate virtual machines in a cloud service

Get the list of cloud services by using the following command, and then pick the cloud service that you want to migrate. Note that if the VMs in the cloud service are in a virtual network or if they have web/worker roles, you will get an error message.

```
azure service list
```

Run the following command to get the deployment name for the cloud service from the verbose output. In most cases, the deployment name is the same as the cloud service name.

```
azure service show <serviceName> -vv
```

First, validate if you can migrate the cloud service using the following commands:

```
azure service deployment validate-migration <serviceName> <deploymentName> new "" "" ""
```

Prepare the virtual machines in the cloud service for migration. You have two options to choose from.

If you want to migrate the VMs to a platform-created virtual network, use the following command.

```
azure service deployment prepare-migration <serviceName> <deploymentName> new "" "" ""
```

If you want to migrate to an existing virtual network in the Resource Manager deployment model, use the following command.

```
azure service deployment prepare-migration <serviceName> <deploymentName> existing
<destinationVNETResourceGroupName> <subnetName> <vnetName>
```

After the prepare operation is successful, you can look through the verbose output to get the migration state of the VMs and ensure that they are in the `Prepared` state.

```
azure vm show <vmName> -vv
```

Check the configuration for the prepared resources by using either CLI or the Azure portal. If you are not ready for migration and you want to go back to the old state, use the following command.

```
azure service deployment abort-migration <serviceName> <deploymentName>
```

If the prepared configuration looks good, you can move forward and commit the resources by using the following command.

```
azure service deployment commit-migration <serviceName> <deploymentName>
```

## Step 4: Option 2 - Migrate virtual machines in a virtual network

Pick the virtual network that you want to migrate. Note that if the virtual network contains web/worker roles or VMs with unsupported configurations, you will get a validation error message.

Get all the virtual networks in the subscription by using the following command.

```
azure network vnet list
```

The output will look something like this:

```
info: Executing command network vnet list
+ Looking up the virtual network sites
data: Name                           Location  Affinity gr
data: -----
data: Group classicubuntu16 classicubuntu16   East US
data: Group Group LinuxHost           East US
data: Group LinuxRG LinuxRG          East US
data: Group SUSEClassicRG SUSEClassicRG    East US
info: network vnet list command OK
```

In the above example, the **virtualNetworkName** is the entire name "**Group classicubuntu16 classicubuntu16**".

First, validate if you can migrate the virtual network using the following command:

```
azure network vnet validate-migration <virtualNetworkName>
```

Prepare the virtual network of your choice for migration by using the following command.

```
azure network vnet prepare-migration <virtualNetworkName>
```

Check the configuration for the prepared virtual machines by using either CLI or the Azure portal. If you are not ready for migration and you want to go back to the old state, use the following command.

```
azure network vnet abort-migration <virtualNetworkName>
```

If the prepared configuration looks good, you can move forward and commit the resources by using the

following command.

```
azure network vnet commit-migration <virtualNetworkName>
```

## Step 5: Migrate a storage account

Once you're done migrating the virtual machines, we recommend you migrate the storage account.

Prepare the storage account for migration by using the following command

```
azure storage account prepare-migration <storageAccountName>
```

Check the configuration for the prepared storage account by using either CLI or the Azure portal. If you are not ready for migration and you want to go back to the old state, use the following command.

```
azure storage account abort-migration <storageAccountName>
```

If the prepared configuration looks good, you can move forward and commit the resources by using the following command.

```
azure storage account commit-migration <storageAccountName>
```

## Next steps

# Migrate IaaS resources from classic to Azure Resource Manager by using PowerShell

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

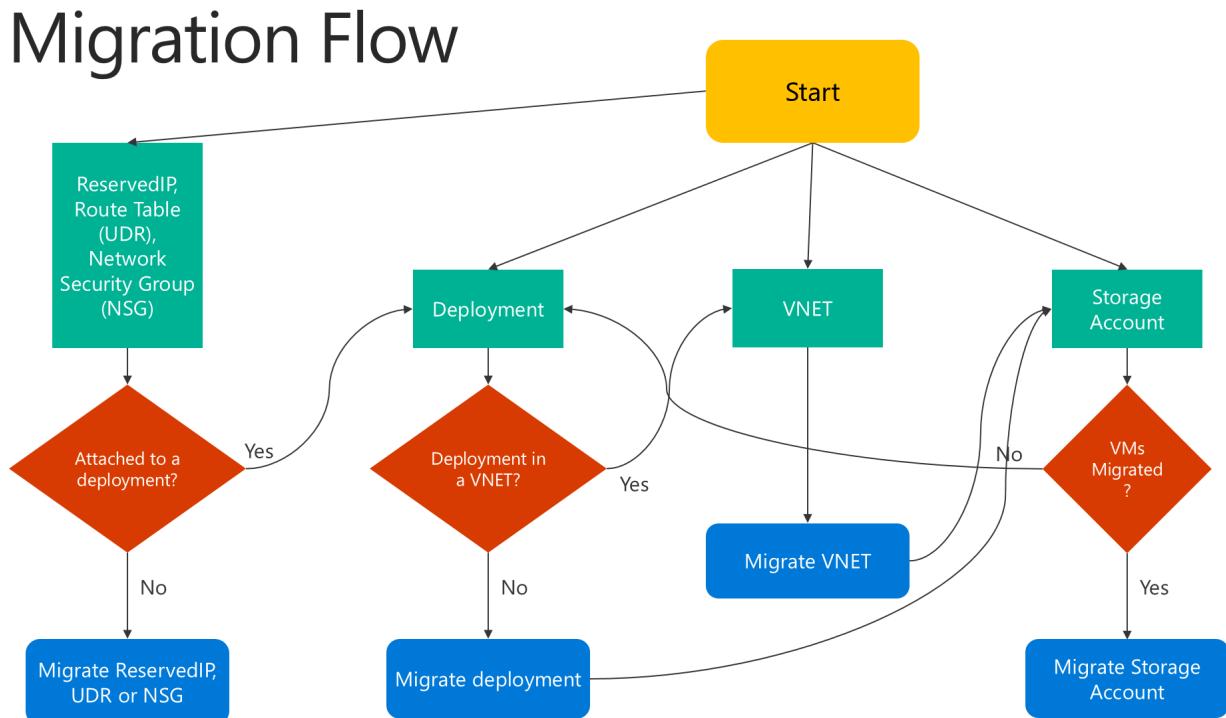

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

These steps show you how to use Azure PowerShell commands to migrate infrastructure as a service (IaaS) resources from the classic deployment model to the Azure Resource Manager deployment model.

If you want, you can also migrate resources by using the [Azure CLI](#).

- For background on supported migration scenarios, see [Platform-supported migration of IaaS resources from classic to Azure Resource Manager](#).
- For detailed guidance and a migration walkthrough, see [Technical deep dive on platform-supported migration from classic to Azure Resource Manager](#).
- Review the [most common migration errors](#).

Here's a flowchart to identify the order in which steps need to be executed during a migration process.

## Step 1: Plan for migration

Here are a few best practices that we recommend as you evaluate whether to migrate IaaS resources from classic to Resource Manager:

- Read through the [supported and unsupported features and configurations](#). If you have virtual machines that use unsupported configurations or features, wait for the configuration or feature support to be announced. Alternatively, if it suits your needs, remove that feature or move out of that configuration to enable migration.
- If you have automated scripts that deploy your infrastructure and applications today, try to create a similar test setup by using those scripts for migration. Alternatively, you can set up sample environments by using the Azure portal.

#### IMPORTANT

Application gateways aren't currently supported for migration from classic to Resource Manager. To migrate a virtual network with an application gateway, remove the gateway before you run a Prepare operation to move the network. After you complete the migration, reconnect the gateway in Azure Resource Manager.

Azure ExpressRoute gateways that connect to ExpressRoute circuits in another subscription can't be migrated automatically. In such cases, remove the ExpressRoute gateway, migrate the virtual network, and re-create the gateway. For more information, see [Migrate ExpressRoute circuits and associated virtual networks from the classic to the Resource Manager deployment model](#).

## Step 2: Install the latest version of PowerShell

There are two main options to install Azure PowerShell: [PowerShell Gallery](#) or [Web Platform Installer \(WebPI\)](#). WebPI receives monthly updates. PowerShell Gallery receives updates on a continuous basis. This article is based on Azure PowerShell version 2.1.0.

For installation instructions, see [How to install and configure Azure PowerShell](#).

## Step 3: Ensure that you're an administrator for the subscription

To perform this migration, you must be added as a coadministrator for the subscription in the [Azure portal](#).

1. Sign in to the [Azure portal](#).
2. On the **Hub** menu, select **Subscription**. If you don't see it, select **All services**.
3. Find the appropriate subscription entry, and then look at the **MY ROLE** field. For a coadministrator, the value should be *Account admin*.

If you're not able to add a co-administrator, contact a service administrator or co-administrator for the subscription to get yourself added.

## Step 4: Set your subscription, and sign up for migration

First, start a PowerShell prompt. For migration, set up your environment for both classic and Resource Manager.

Sign in to your account for the Resource Manager model.

```
Connect-AzAccount
```

Get the available subscriptions by using the following command:

```
Get-AzSubscription | Sort Name | Select Name
```

Set your Azure subscription for the current session. This example sets the default subscription name to **My Azure Subscription**. Replace the example subscription name with your own.

```
Select-AzSubscription -SubscriptionName "My Azure Subscription"
```

#### NOTE

Registration is a one-time step, but you must do it once before you attempt migration. Without registering, you see the following error message:

*BadRequest : Subscription is not registered for migration.*

Register with the migration resource provider by using the following command:

```
Register-AzResourceProvider -ProviderNamespace Microsoft.ClassicInfrastructureMigrate
```

Wait five minutes for the registration to finish. Check the status of the approval by using the following command:

```
Get-AzResourceProvider -ProviderNamespace Microsoft.ClassicInfrastructureMigrate
```

Make sure that RegistrationState is `Registered` before you proceed.

Before switching to the classic deployment model, make sure that you have enough Azure Resource Manager virtual machine vCPUs in the Azure region of your current deployment or virtual network. You can use the following PowerShell command to check the current number of vCPUs you have in Azure Resource Manager. To learn more about vCPU quotas, see [Limits and the Azure Resource Manager](#).

This example checks the availability in the **West US** region. Replace the example region name with your own.

```
Get-AzVMUsage -Location "West US"
```

Now, sign in to your account for the classic deployment model.

```
Add-AzureAccount
```

Get the available subscriptions by using the following command:

```
Get-AzureSubscription | Sort SubscriptionName | Select SubscriptionName
```

Set your Azure subscription for the current session. This example sets the default subscription to **My Azure Subscription**. Replace the example subscription name with your own.

```
Select-AzureSubscription -SubscriptionName "My Azure Subscription"
```

## Step 5: Run commands to migrate your IaaS resources

- [Migrate VMs in a cloud service \(not in a virtual network\)](#)
- [Migrate VMs in a virtual network](#)
- [Migrate a storage account](#)

**NOTE**

All the operations described here are idempotent. If you have a problem other than an unsupported feature or a configuration error, we recommend that you retry the prepare, abort, or commit operation. The platform then tries the action again.

**Step 5.1: Option 1 - Migrate virtual machines in a cloud service (not in a virtual network)**

Get the list of cloud services by using the following command. Then pick the cloud service that you want to migrate. If the VMs in the cloud service are in a virtual network or if they have web or worker roles, the command returns an error message.

```
Get-AzureService | ft Servicename
```

Get the deployment name for the cloud service. In this example, the service name is **My Service**. Replace the example service name with your own service name.

```
$serviceName = "My Service"  
$deployment = Get-AzureDeployment -ServiceName $serviceName  
$deploymentName = $deployment.DeploymentName
```

Prepare the virtual machines in the cloud service for migration. You have two options to choose from.

- **Option 1: Migrate the VMs to a platform-created virtual network.**

First, validate that you can migrate the cloud service by using the following commands:

```
$validate = Move-AzureService -Validate -ServiceName $serviceName `  
    -DeploymentName $deploymentName -CreateNewVirtualNetwork  
$validate.ValidationMessages
```

The following command displays any warnings and errors that block migration. If validation messages do not contain message of type error, you can move on to the Prepare step.

```
Move-AzureService -Prepare -ServiceName $serviceName `  
    -DeploymentName $deploymentName -CreateNewVirtualNetwork
```

- **Option 2: Migrate to an existing virtual network in the Resource Manager deployment model.**

This example sets the resource group name to **myResourceGroup**, the virtual network name to **myVirtualNetwork**, and the subnet name to **mySubNet**. Replace the names in the example with the names of your own resources.

```
$existingVnetRGName = "myResourceGroup"  
$vnetName = "myVirtualNetwork"  
$subnetName = "mySubNet"
```

First, validate that you can migrate the virtual network by using the following command:

```
$validate = Move-AzureService -Validate -ServiceName $serviceName `  
    -DeploymentName $deploymentName -UseExistingVirtualNetwork -VirtualNetworkResourceGroupName  
$existingVnetRGName -VirtualNetworkName $vnetName -SubnetName $subnetName  
$validate.ValidationMessages
```

The following command displays any warnings and errors that block migration. If validation messages do not contain errors, you can proceed with the following Prepare step:

```
Move-AzureService -Prepare -ServiceName $serviceName -DeploymentName $deploymentName `  
    -UseExistingVirtualNetwork -VirtualNetworkResourceGroupName $existingVnetRGName `  
    -VirtualNetworkName $vnetName -SubnetName $subnetName
```

After the Prepare operation succeeds with either of the preceding options, query the migration state of the VMs. Ensure that they're in the **Prepared** state.

This example sets the VM name to **myVM**. Replace the example name with your own VM name.

```
$vmName = "myVM"  
$vm = Get-AzureVM -ServiceName $serviceName -Name $vmName  
$vm.VM.MigrationState
```

Check the configuration for the prepared resources by using either PowerShell or the Azure portal. If you're not ready for migration and you want to go back to the old state, use the following command:

```
Move-AzureService -Abort -ServiceName $serviceName -DeploymentName $deploymentName
```

If the prepared configuration looks good, you can move forward and commit the resources by using the following command:

```
Move-AzureService -Commit -ServiceName $serviceName -DeploymentName $deploymentName
```

### Step 5.1: Option 2 - Migrate virtual machines in a virtual network

To migrate virtual machines in a virtual network, you migrate the virtual network. The virtual machines automatically migrate with the virtual network. Pick the virtual network that you want to migrate.

#### NOTE

Migrate a single virtual machine created using the classic deployment model by creating a new Resource Manager virtual machine with Managed Disks by using the VHD (OS and data) files of the virtual machine.

#### NOTE

The virtual network name might be different from what is shown in the new portal. The new Azure portal displays the name as `[vnet-name]`, but the actual virtual network name is of type `Group [resource-group-name] [vnet-name]`. Before you start the migration, look up the actual virtual network name by using the command

```
Get-AzureVnetSite | Select -Property Name
```

This example sets the virtual network name to **myVnet**. Replace the example virtual network name with your own.

```
$vnetName = "myVnet"
```

#### NOTE

If the virtual network contains web or worker roles, or VMs with unsupported configurations, you get a validation error message.

First, validate that you can migrate the virtual network by using the following command:

```
Move-AzureVirtualNetwork -Validate -VirtualNetworkName $vnetName
```

The following command displays any warnings and errors that block migration. If validation is successful, you can proceed with the following Prepare step:

```
Move-AzureVirtualNetwork -Prepare -VirtualNetworkName $vnetName
```

Check the configuration for the prepared virtual machines by using either Azure PowerShell or the Azure portal. If you're not ready for migration and you want to go back to the old state, use the following command:

```
Move-AzureVirtualNetwork -Abort -VirtualNetworkName $vnetName
```

If the prepared configuration looks good, you can move forward and commit the resources by using the following command:

```
Move-AzureVirtualNetwork -Commit -VirtualNetworkName $vnetName
```

### Step 5.2: Migrate a storage account

After you're done migrating the virtual machines, perform the following prerequisite checks before you migrate the storage accounts.

#### NOTE

If your storage account has no associated disks or VM data, you can skip directly to the "Validate storage accounts and start migration" section. Also note that deleting the classic disks, VM images or OS images does not remove the source VHD files in the storage account. However, it does break the lease on those VHD files so that they can be reused to create ARM disks or images after migration.

- Prerequisite checks if you migrated any VMs or your storage account has disk resources:

- Migrate virtual machines whose disks are stored in the storage account.

The following command returns RoleName and DiskName properties of all the VM disks in the storage account. RoleName is the name of the virtual machine to which a disk is attached. If this command returns disks, then ensure that virtual machines to which these disks are attached are migrated before you migrate the storage account.

```
$storageAccountName = 'yourStorageAccountName'  
Get-AzureDisk | where-Object {$_.MediaLink.Host.Contains($storageAccountName)} | Select-  
Object -ExpandProperty AttachedTo -Property `  
DiskName | Format-List -Property RoleName, DiskName
```

- Delete unattached VM disks stored in the storage account.

Find unattached VM disks in the storage account by using the following command:

```
$storageAccountName = 'yourStorageAccountName'  
Get-AzureDisk | where-Object {$_.MediaLink.Host.Contains($storageAccountName)} | Where-  
Object -Property AttachedTo -EQ $null | Format-List -Property DiskName
```

If the previous command returns disks, delete these disks by using the following command:

```
Remove-AzureDisk -DiskName 'yourDiskName'
```

- Delete VM images stored in the storage account.

The following command returns all the VM images with OS disks stored in the storage account.

```
Get-AzureVmImage | Where-Object { $_.OSDiskConfiguration.MediaLink -ne $null -and  
$_.OSDiskConfiguration.MediaLink.Host.Contains($storageAccountName)`  
} | Select-Object -Property ImageName, ImageLabel
```

The following command returns all the VM images with data disks stored in the storage account.

```
Get-AzureVmImage | Where-Object {$_.DataDiskConfigurations -ne $null `  
-and ($_.DataDiskConfigurations | Where-Object  
{$_.MediaLink -ne $null -and $_.MediaLink.Host.Contains($storageAccountName)}).Count -gt 0 `  
} | Select-Object -Property ImageName, ImageLabel
```

Delete all the VM images returned by the previous commands by using this command:

```
Remove-AzureVMImage -ImageName 'yourImageName'
```

- Validate storage accounts and start migration.

Validate each storage account for migration by using the following command. In this example, the storage account name is **myStorageAccount**. Replace the example name with the name of your own storage account.

```
$storageAccountName = "myStorageAccount"  
Move-AzureStorageAccount -Validate -StorageAccountName $storageAccountName
```

The next step is to prepare the storage account for migration.

```
$storageAccountName = "myStorageAccount"  
Move-AzureStorageAccount -Prepare -StorageAccountName $storageAccountName
```

Check the configuration for the prepared storage account by using either Azure PowerShell or the Azure portal. If you're not ready for migration and you want to go back to the old state, use the following command:

```
Move-AzureStorageAccount -Abort -StorageAccountName $storageAccountName
```

If the prepared configuration looks good, you can move forward and commit the resources by using the following command:

```
Move-AzureStorageAccount -Commit -StorageAccountName $storageAccountName
```

# Errors that commonly occur during Classic to Azure Resource Manager migration

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

This article catalogs the most common errors and mitigations during the migration of IaaS resources from Azure classic deployment model to the Azure Resource Manager stack.

## List of errors

ERROR STRING	MITIGATION
Internal server error	<p>In some cases, this is a transient error that goes away with a retry. If it continues to persist, <a href="#">contact Azure support</a> as it needs investigation of platform logs.</p> <p><b>NOTE:</b> Once the incident is tracked by the support team, please don't attempt any self-mitigation as this might have unintended consequences on your environment.</p>
Migration isn't supported for Deployment {deployment-name} in HostedService {hosted-service-name} because it's a PaaS deployment (Web/Worker).	<p>This happens when a deployment contains a web/worker role. Since migration is only supported for Virtual Machines, please remove the web/worker role from the deployment and try migration again.</p>
Template {template-name} deployment failed. CorrelationId={guid}	<p>In the backend of migration service, we use Azure Resource Manager templates to create resources in the Azure Resource Manager stack. Since templates are idempotent, usually you can safely retry the migration operation to get past this error. If this error continues to persist, please <a href="#">contact Azure support</a> and give them the CorrelationId.</p> <p><b>NOTE:</b> Once the incident is tracked by the support team, please don't attempt any self-mitigation as this might have unintended consequences on your environment.</p>
The virtual network {virtual-network-name} doesn't exist.	<p>This can happen if you created the Virtual Network in the new Azure portal. The actual Virtual Network name follows the pattern "Group * &lt;VNET name&gt;"</p>
VM {vm-name} in HostedService {hosted-service-name} contains Extension {extension-name} which isn't supported in Azure Resource Manager. It's recommended to uninstall it from the VM before continuing with migration.	<p>XML extensions such as BGInfo 1.* aren't supported in Azure Resource Manager. Therefore, these extensions can't be migrated. If these extensions are left installed on the virtual machine, they're automatically uninstalled before completing the migration.</p>

ERROR STRING	MITIGATION
<p>VM {vm-name} in HostedService {hosted-service-name} contains Extension VMSnapshot/VMSnapshotLinux, which is currently not supported for Migration. Uninstall it from the VM and add it back using Azure Resource Manager after the Migration is Complete</p>	<p>This is the scenario where the virtual machine is configured for Azure Backup. Since this is currently an unsupported scenario, please follow the workaround at <a href="https://aka.ms/vmbackupmigration">https://aka.ms/vmbackupmigration</a></p>
<p>VM {vm-name} in HostedService {hosted-service-name} contains Extension {extension-name} whose Status isn't being reported from the VM. Hence, this VM can't be migrated. Ensure that the Extension status is being reported or uninstall the extension from the VM and retry migration.</p>	<p>Azure guest agent &amp; VM Extensions need outbound internet access to the VM storage account to populate their status. Common causes of status failure include</p> <ul style="list-style-type: none"> <li>• a Network Security Group that blocks outbound access to the internet</li> <li>• If the VNET has on premises DNS servers and DNS connectivity is lost</li> </ul>
<p>VM {vm-name} in HostedService {hosted-service-name} contains Extension {extension-name} reporting Handler Status: {handler-status}. Hence, the VM can't be migrated. Ensure that the Extension handler status being reported is {handler-status} or uninstall it from the VM and retry migration.</p>	<p>If you continue to see an unsupported status, you can uninstall the extensions to skip this check and move forward with migration.</p>
<p>VM Agent for VM {vm-name} in HostedService {hosted-service-name} is reporting the overall agent status as Not Ready. Hence, the VM may not be migrated, if it has a migratable extension. Ensure that the VM Agent is reporting overall agent status as Ready. Refer to <a href="https://aka.ms/classiciaasmigrationfaqs">https://aka.ms/classiciaasmigrationfaqs</a>.</p>	
<p>Migration isn't supported for Deployment {deployment-name} in HostedService {hosted-service-name} because it has multiple Availability Sets.</p>	<p>Currently, only hosted services that have 1 or less Availability sets can be migrated. To work around this problem, move the additional availability sets, and Virtual machines in those availability sets, to a different hosted service.</p>
<p>Migration isn't supported for Deployment {deployment-name} in HostedService {hosted-service-name} because it has VMs that are not part of the Availability Set even though the HostedService contains one.</p>	<p>The workaround for this scenario is to either move all the virtual machines into a single Availability set or remove all Virtual machines from the Availability set in the hosted service.</p>
<p>Storage account/HostedService/Virtual Network {virtual-network-name} is in the process of being migrated and hence cannot be changed</p>	<p>This error happens when the "Prepare" migration operation has been completed on the resource and an operation that would make a change to the resource is triggered. Because of the lock on the management plane after "Prepare" operation, any changes to the resource are blocked. To unlock the management plane, you can run the "Commit" migration operation to complete migration or the "Abort" migration operation to roll back the "Prepare" operation.</p>
<p>Migration isn't allowed for HostedService {hosted-service-name} because it has VM {vm-name} in State: RoleStateUnknown. Migration is allowed only when the VM is in one of the following states - Running, Stopped, Stopped Deallocated.</p>	<p>The VM might be undergoing through a state transition, which usually happens when during an update operation on the HostedService such as a reboot, extension installation etc. It is recommended for the update operation to complete on the HostedService before trying migration.</p>
<p>Deployment {deployment-name} in HostedService {hosted-service-name} contains a VM {vm-name} with Data Disk {data-disk-name} whose physical blob size {size-of-the-vhd-blob-backing-the-data-disk} bytes doesn't match the VM Data Disk logical size {size-of-the-data-disk-specified-in-the-vm-api} bytes. Migration will proceed without specifying a size for the data disk for the Azure Resource Manager VM.</p>	<p>This error happens if you've resized the VHD blob without updating the size in the VM API model. Detailed mitigation steps are outlined <a href="#">below</a>.</p>

ERROR STRING	MITIGATION
A storage exception occurred while validating data disk {data disk name} with media link {data disk Uri} for VM {VM name} in Cloud Service {Cloud Service name}. Please ensure that the VHD media link is accessible for this virtual machine	This error can happen if the disks of the VM have been deleted or are not accessible anymore. Please make sure the disks for the VM exist.
VM {vm-name} in HostedService {cloud-service-name} contains Disk with MediaLink {vhd-uri} which has blob name {vhd-blob-name} that isn't supported in Azure Resource Manager.	This error occurs when the name of the blob has a "/" in it which isn't supported in Compute Resource Provider currently.
Migration isn't allowed for Deployment {deployment-name} in HostedService {cloud-service-name} as it isn't in the regional scope. Please refer to <a href="https://aka.ms/regionalscope">https://aka.ms/regionalscope</a> for moving this deployment to regional scope.	In 2014, Azure announced that networking resources will move from a cluster level scope to regional scope. See <a href="https://aka.ms/regionalscope">https://aka.ms/regionalscope</a> for more details. This error happens when the deployment being migrated has not had an update operation, which automatically moves it to a regional scope. The best work-around is to either add an endpoint to a VM, or a data disk to the VM, and then retry migration. See <a href="#">How to set up endpoints on a classic virtual machine in Azure</a> or <a href="#">Attach a data disk to a virtual machine created with the classic deployment model</a>
Migration isn't supported for Virtual Network {vnet-name} because it has non-gateway PaaS deployments.	This error occurs when you have non-gateway PaaS deployments such as Application Gateway or API Management services that are connected to the Virtual Network.
Management operations on VM are disallowed because migration is in progress	This error occurs because the VM is in Prepare state and therefore locked for any update/delete operation. Call Abort using PS/CLI on the VM to rollback the migration and unlock the VM for update/delete operations. Calling commit will also unlock the VM but will commit the migration to ARM.

## Detailed mitigations

### **VM with Data Disk whose physical blob size bytes does not match the VM Data Disk logical size bytes.**

This happens when the Data disk logical size can get out of sync with the actual VHD blob size. This can be easily verified using the following commands:

#### **Verifying the issue**

```

# Store the VM details in the VM object
$vm = Get-AzureVM -ServiceName $servicename -Name $vmname

# Display the data disk properties
# NOTE the data disk LogicalDiskSizeInGB below which is 11GB. Also note the MediaLink Uri of the VHD blob as
we'll use this in the next step
$vm.VM.DataVirtualHardDisks

HostCaching      : None
DiskLabel        :
DiskName         : coreosvm-coreosvm-0-201611230636240687
Lun              : 0
LogicalDiskSizeInGB : 11
MediaLink        : https://contosostorage.blob.core.windows.net/vhds/coreosvm-dd1.vhd
SourceMediaLink   :
IOType           : Standard
ExtensionData    :

# Now get the properties of the blob backing the data disk above
# NOTE the size of the blob is about 15 GB which is different from LogicalDiskSizeInGB above
blob = Get-AzStorageblob -Blob "coreosvm-dd1.vhd" -Container vhds

blob

ICloudBlob      : Microsoft.WindowsAzure.Storage.Blob.CloudPageBlob
BlobType        : PageBlob
Length          : 16106127872
ContentType     : application/octet-stream
LastModified    : 11/23/2016 7:16:22 AM +00:00
SnapshotTime    :
ContinuationToken :
Context          : Microsoft.WindowsAzure.Commands.Common.Storage.AzureStorageContext
Name            : coreosvm-dd1.vhd

```

## Mitigating the issue

```

# Convert the blob size in bytes to GB into a variable which we'll use later
$newSize = [int]($blob.Length / 1GB)

# See the calculated size in GB
$newSize

15

# Store the disk name of the data disk as we'll use this to identify the disk to be updated
$diskName = $vm.VM.DataVirtualHardDisks[0].DiskName

# Identify the LUN of the data disk to remove
$lunToRemove = $vm.VM.DataVirtualHardDisks[0].Lun

# Now remove the data disk from the VM so that the disk isn't leased by the VM and it's size can be updated
Remove-AzureDataDisk -LUN $lunToRemove -VM $vm | Update-AzureVm -Name $vmname -ServiceName $servicename

OperationDescription OperationId          OperationStatus
----- ----- -----
Update-AzureVM      213xx1-b44b-1v6n-23gg-591f2a13cd16 Succeeded

# Verify we have the right disk that's going to be updated
Get-AzureDisk -DiskName $diskName

AffinityGroup      :
AttachedTo        :
IsCorrupted      : False
Label             :
Location          : East US
DiskSizeInGB      : 11

```

```

DISKSIZEINGB          : 11
MediaLink              : https://contosostorage.blob.core.windows.net/vhds/coreosvm-dd1.vhd
DiskName               : coreosvm-coreosvm-0-201611230636240687
SourceImageName        :
OS                     :
IOType                 : Standard
OperationDescription   : Get-AzureDisk
OperationId            : 0c56a2b7-a325-123b-7043-74c27d5a61fd
OperationStatus         : Succeeded

# Now update the disk to the new size
Update-AzureDisk -DiskName $diskName -ResizedSizeInGB $newSize -Label $diskName

OperationDescription OperationId          OperationStatus
-----  -----  -----
Update-AzureDisk      cv134b65-1b6n-8908-abuo-ce9e395ac3e7 Succeeded

# Now verify that the "DiskSizeInGB" property of the disk matches the size of the blob
Get-AzureDisk -DiskName $diskName

AffinityGroup          :
AttachedTo              :
IsCorrupted             : False
Label                  : coreosvm-coreosvm-0-201611230636240687
Location                : East US
DiskSizeInGB            : 15
MediaLink               : https://contosostorage.blob.core.windows.net/vhds/coreosvm-dd1.vhd
DiskName                : coreosvm-coreosvm-0-201611230636240687
SourceImageName         :
OS                     :
IOType                 : Standard
OperationDescription   : Get-AzureDisk
OperationId            : 1v53bde5-cv56-5621-9078-16b9c8a0bad2
OperationStatus         : Succeeded

# Now we'll add the disk back to the VM as a data disk. First we need to get an updated VM object
$vm = Get-AzureVM -ServiceName $servicename -Name $vmname

Add-AzureDataDisk -Import -DiskName $diskName -LUN 0 -VM $vm -HostCaching ReadWrite | Update-AzureVm -Name
$vmname -ServiceName $servicename

OperationDescription OperationId          OperationStatus
-----  -----  -----
Update-AzureVM       b0ad3d4c-4v68-45vb-xxc1-134fd010d0f8 Succeeded

```

## Moving a VM to a different subscription after completing migration

After you complete the migration process, you may want to move the VM to another subscription. However, if you have a secret/certificate on the VM that references a Key Vault resource, the move is currently not supported. The below instructions will allow you to work around the issue.

### PowerShell

```

$vm = Get-AzVM -ResourceGroupName "MyRG" -Name "MyVM"
Remove-AzVMSecret -VM $vm
Update-AzVM -ResourceGroupName "MyRG" -VM $vm

```

### Azure CLI

```
az vm update -g "myrg" -n "myvm" --set osProfile.Secrets=[]
```

# Community tools to migrate IaaS resources from classic to Azure Resource Manager

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## IMPORTANT

Today, about 90% of IaaS VMs are using [Azure Resource Manager](#). As of February 28, 2020, classic VMs have been deprecated and will be fully retired on March 1, 2023. [Learn more](#) about this deprecation and [how it affects you](#).

This article catalogs the tools that have been provided by the community to assist with migration of IaaS resources from classic to the Azure Resource Manager deployment model.

## NOTE

These tools are not officially supported by Microsoft Support. Therefore they are open sourced on GitHub and we're happy to accept PRs for fixes or additional scenarios. To report an issue, use the GitHub issues feature.

Migrating with these tools will cause downtime for your classic Virtual Machine. If you're looking for platform supported migration, visit

- [Platform supported migration of IaaS resources from Classic to Azure Resource Manager stack](#)
- [Technical Deep Dive on Platform supported migration from Classic to Azure Resource Manager](#)
- [Migrate IaaS resources from Classic to Azure Resource Manager using Azure PowerShell](#)

## AsmMetadataParser

This is a collection of helper tools created as part of enterprise migrations from Azure Service Management to Azure Resource Manager. This tool allows you to replicate your infrastructure into another subscription which can be used for testing migration and iron out any issues before running the migration on your Production subscription.

[Link to the tool documentation](#)

## migAz

migAz is an additional option to migrate a complete set of classic IaaS resources to Azure Resource Manager IaaS resources. The migration can occur within the same subscription or between different subscriptions and subscription types (ex: CSP subscriptions).

# Availability options for Azure Virtual Machines

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article provides an overview of the availability options for Azure virtual machines (VMs).

## Availability zones

[Availability zones](#) expands the level of control you have to maintain the availability of the applications and data on your VMs. An Availability Zone is a physically separate zone, within an Azure region. There are three Availability Zones per supported Azure region.

Each Availability Zone has a distinct power source, network, and cooling. By designing your solutions to use replicated VMs in zones, you can protect your apps and data from the loss of a data center. If one zone is compromised, then replicated apps and data are instantly available in another zone.

## Virtual Machines Scale Sets

[Azure virtual machine scale sets](#) let you create and manage a group of load balanced VMs. The number of VM instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide high availability to your applications, and allow you to centrally manage, configure, and update many VMs. There is no cost for the scale set itself, you only pay for each VM instance that you create.

Virtual machines in a scale set can also be deployed into multiple availability zones, a single availability zone, or regionally. Availability zone deployment options may differ based on the [orchestration mode](#).

## Availability sets

An [availability set](#) is a logical grouping of VMs that allows Azure to understand how your application is built to provide for redundancy and availability. We recommend that two or more VMs are created within an availability set to provide for a highly available application and to meet the [99.95% Azure SLA](#). There is no cost for the Availability Set itself, you only pay for each VM instance that you create.

## Load balancer

Combine the [Azure Load Balancer](#) with an availability zone or availability set to get the most application resiliency. The Azure Load Balancer distributes traffic between multiple virtual machines. For our Standard tier virtual machines, the Azure Load Balancer is included. Not all virtual machine tiers include the Azure Load Balancer. For more information about load balancing your virtual machines, see [Load Balancing virtual machines](#) for [Linux](#) or [Windows](#).

## Azure Storage redundancy

Azure Storage always stores multiple copies of your data so that it is protected from planned and unplanned events, including transient hardware failures, network or power outages, and massive natural disasters. Redundancy ensures that your storage account meets its availability and durability targets even in the face of failures.

When deciding which redundancy option is best for your scenario, consider the tradeoffs between lower costs and higher availability. The factors that help determine which redundancy option you should choose include:

- How your data is replicated in the primary region
- Whether your data is replicated to a second region that is geographically distant to the primary region, to protect against regional disasters
- Whether your application requires read access to the replicated data in the secondary region if the primary region becomes unavailable for any reason

For more information, see [Azure Storage redundancy](#)

## Azure Site Recovery

As an organization you need to adopt a business continuity and disaster recovery (BCDR) strategy that keeps your data safe, and your apps and workloads online, when planned and unplanned outages occur.

[Azure Site Recovery](#) helps ensure business continuity by keeping business apps and workloads running during outages. Site Recovery replicates workloads running on physical and virtual machines (VMs) from a primary site to a secondary location. When an outage occurs at your primary site, you fail over to secondary location, and access apps from there. After the primary location is running again, you can fail back to it.

Site Recovery can manage replication for:

- Azure VMs replicating between Azure regions.
- On-premises VMs, Azure Stack VMs, and physical servers.

## Next steps

- [Create a virtual machine in an availability set](#)
- [Create a virtual machine scale set](#)

# Regions and availability zones

9/21/2022 • 3 minutes to read • [Edit Online](#)

Azure regions and availability zones are designed to help you achieve resiliency and reliability for your business-critical workloads. Azure maintains multiple geographies. These discrete demarcations define disaster recovery and data residency boundaries across one or multiple Azure regions. Maintaining many regions ensures customers are supported across the world.

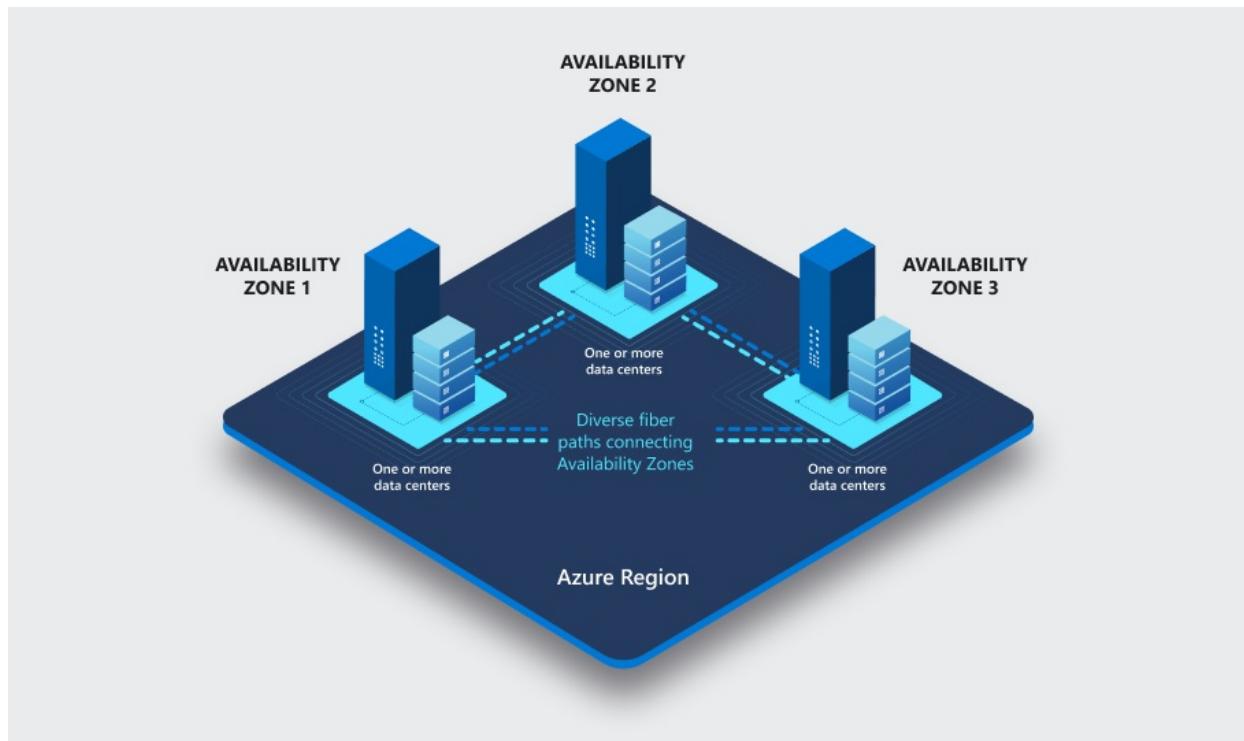

## Regions

Each Azure region features datacenters deployed within a latency-defined perimeter. They're connected through a dedicated regional low-latency network. This design ensures that Azure services within any region offer the best possible performance and security.

## Availability zones

Azure *availability zones* are physically separate locations within each Azure region that are tolerant to local failures. Failures can range from software and hardware failures to events such as earthquakes, floods, and fires. Tolerance to failures is achieved because of redundancy and logical isolation of Azure services. To ensure resiliency, a minimum of three separate availability zones are present in all availability zone-enabled regions.

Azure availability zones are connected by a high-performance network with a round-trip latency of less than 2ms. They help your data stay synchronized and accessible when things go wrong. Each zone is composed of one or more datacenters equipped with independent power, cooling, and networking infrastructure. Availability zones are designed so that if one zone is affected, regional services, capacity, and high availability are supported by the remaining two zones.

Datacenter locations are selected by using rigorous vulnerability risk assessment criteria. This process identifies all significant datacenter-specific risks and considers shared risks between availability zones.

With availability zones, you can design and operate applications and databases that automatically transition

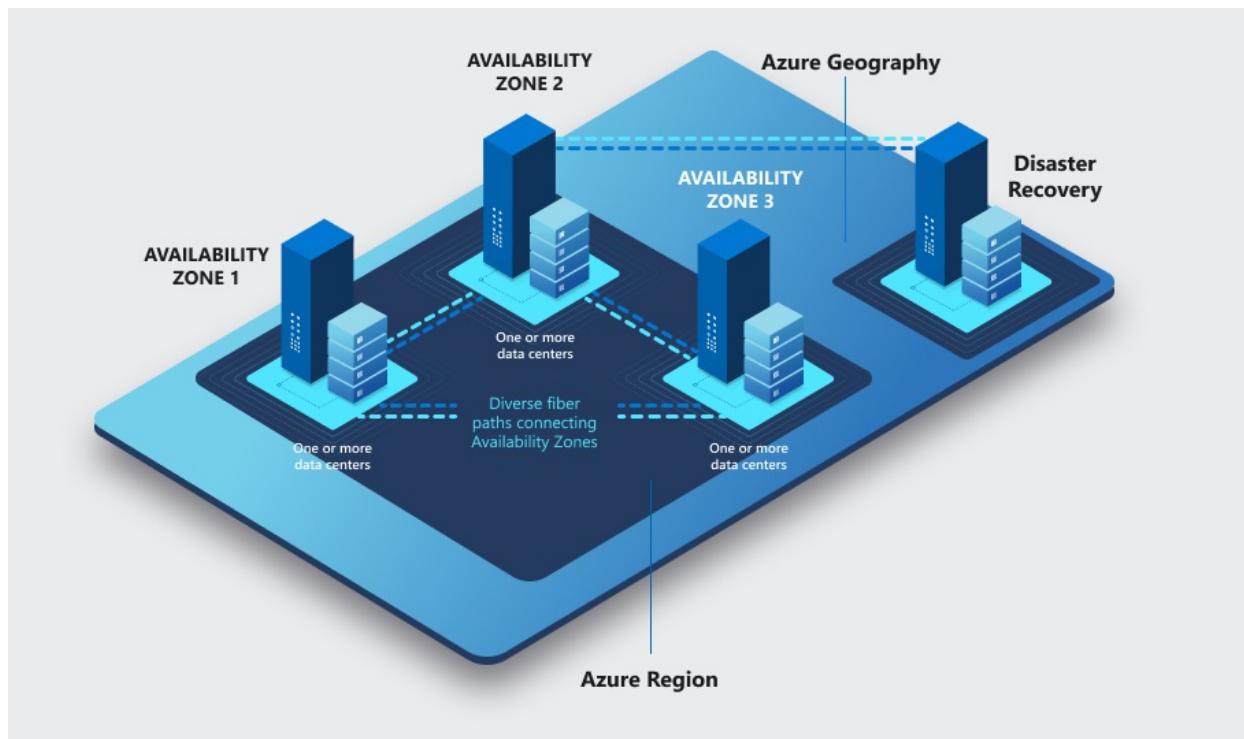

between zones without interruption. Azure availability zones are highly available, fault tolerant, and more scalable than traditional single or multiple datacenter infrastructures.

Each data center is assigned to a physical zone. Physical zones are mapped to logical zones in your Azure subscription. Azure subscriptions are automatically assigned this mapping at the time a subscription is created. You can use the dedicated ARM API called: [checkZonePeers](#) to compare zone mapping for resilient solutions that span across multiple subscriptions.

You can design resilient solutions by using Azure services that use availability zones. Co-locate your compute, storage, networking, and data resources across an availability zone, and replicate this arrangement in other availability zones.

Azure *availability zones-enabled services* are designed to provide the right level of resiliency and flexibility. They can be configured in two ways. They can be either *zone redundant*, with automatic replication across zones, or *zonal*, with instances pinned to a specific zone. You can also combine these approaches.

Some organizations require high availability of availability zones and protection from large-scale phenomena and regional disasters. Azure regions are designed to offer protection against localized disasters with availability zones and protection from regional or large geography disasters with disaster recovery, by making use of another region. To learn more about business continuity, disaster recovery, and cross-region replication, see [Cross-region replication in Azure](#).

## Azure regions with availability zones

Azure provides the most extensive global footprint of any cloud provider and is rapidly opening new regions and availability zones. Azure has availability zones in every country in which Azure operates a datacenter region. The following regions currently support availability zones.

AMERICAS	EUROPE	MIDDLE EAST	AFRICA	ASIA PACIFIC
Brazil South	France Central	Qatar Central	South Africa North	Australia East
Canada Central	Germany West Central	UAE North		Central India

AMERICAS	EUROPE	MIDDLE EAST	AFRICA	ASIA PACIFIC
Central US	North Europe			Japan East
East US	Norway East			Korea Central
East US 2	UK South			Southeast Asia
South Central US	West Europe			East Asia
US Gov Virginia	Sweden Central			China North 3
West US 2	Switzerland North			
West US 3				

## Next steps

- Microsoft commitment to expand Azure availability zones to more regions
- Azure services that support availability zones
- Azure services

# Create a virtual machine in an availability zone using Azure CLI

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article steps through using the Azure CLI to create a Linux VM in an Azure availability zone. An [availability zone](#) is a physically separate zone in an Azure region. Use availability zones to protect your apps and data from an unlikely failure or loss of an entire datacenter.

To use an availability zone, create your virtual machine in a [supported Azure region](#).

Make sure that you have installed the latest [Azure CLI](#) and logged in to an Azure account with [az login](#).

## Check VM SKU availability

The availability of VM sizes, or SKUs, may vary by region and zone. To help you plan for the use of Availability Zones, you can list the available VM SKUs by Azure region and zone. This ability makes sure that you choose an appropriate VM size, and obtain the desired resiliency across zones. For more information on the different VM types and sizes, see [VM Sizes overview](#).

You can view the available VM SKUs with the `az vm list-skus` command. The following example lists available VM SKUs in the `eastus2` region:

```
az vm list-skus --location eastus2 --output table
```

The output is similar to the following condensed example, which shows the Availability Zones in which each VM size is available:

ResourceType	Locations	Name	[...]	Tier	Size	Zones
virtualMachines	eastus2	Standard_DS1_v2		Standard	DS1_v2	1,2,3
virtualMachines	eastus2	Standard_DS2_v2		Standard	DS2_v2	1,2,3
[...]						
virtualMachines	eastus2	Standard_F1s		Standard	F1s	1,2,3
virtualMachines	eastus2	Standard_F2s		Standard	F2s	1,2,3
[...]						
virtualMachines	eastus2	Standard_D2s_v3		Standard	D2_v3	1,2,3
virtualMachines	eastus2	Standard_D4s_v3		Standard	D4_v3	1,2,3
[...]						
virtualMachines	eastus2	Standard_E2_v3		Standard	E2_v3	1,2,3
virtualMachines	eastus2	Standard_E4_v3		Standard	E4_v3	1,2,3

## Create resource group

Create a resource group with the `az group create` command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In this example, a resource group named `myResourceGroupVM` is created in the `eastus2` region. East US 2 is one of the Azure regions that supports availability zones.

```
az group create --name myResourceGroupVM --location eastus2
```

The resource group is specified when creating or modifying a VM, which can be seen throughout this article.

## Create virtual machine

Create a virtual machine with the [az vm create](#) command.

When creating a virtual machine, several options are available such as operating system image, disk sizing, and administrative credentials. In this example, a virtual machine is created with a name of *myVM* running Ubuntu Server. The VM is created in availability zone 1. By default, the VM is created in the *Standard\_DS1\_v2* size.

```
az vm create --resource-group myResourceGroupVM --name myVM --location eastus2 --image UbuntuLTS --generate-ssh-keys --zone 1
```

It may take a few minutes to create the VM. Once the VM has been created, the Azure CLI outputs information about the VM. Take note of the `zones` value, which indicates the availability zone in which the VM is running.

```
{
  "fqdns": "",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "eastus2",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroupVM",
  "zones": "1"
}
```

## Confirm zone for managed disk and IP address

When the VM is deployed in an availability zone, a managed disk for the VM is created in the same availability zone. By default, a public IP address is also created in that zone. The following examples get information about these resources.

To verify that the VM's managed disk is in the availability zone, use the [az vm show](#) command to return the disk ID. In this example, the disk ID is stored in a variable that is used in a later step.

```
osdiskname=$(az vm show -g myResourceGroupVM -n myVM --query "storageProfile.osDisk.name" -o tsv)
```

Now you can get information about the managed disk:

```
az disk show --resource-group myResourceGroupVM --name $osdiskname
```

The output shows that the managed disk is in the same availability zone as the VM:

```
{
  "creationData": {
    "createOption": "FromImage",
    "imageReference": {
      "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxx/Providers/Microsoft.Compute/Locations/westeurope/Publishers/Canonical/ArtifactTypes/VMImage/Off
ers/UbuntuServer/Skus/16.04-LTS/Versions/latest",
      "lun": null
    },
    "sourceResourceId": null,
    "sourceUri": null,
    "storageAccountId": null
  },
  "diskSizeGb": 30,
  "encryptionSettings": null,
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/disks/osdisk_761c570dab",
  "location": "eastus2",
  "managedBy": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Compute/virtualMachines/myVM",
  "name": "myVM_osdisk_761c570dab",
  "osType": "Linux",
  "provisioningState": "Succeeded",
  "resourceGroup": "myResourceGroupVM",
  "sku": {
    "name": "Premium_LRS",
    "tier": "Premium"
  },
  "tags": {},
  "timeCreated": "2018-03-05T22:16:06.892752+00:00",
  "type": "Microsoft.Compute/disks",
  "zones": [
    "1"
  ]
}
```

Use the [az vm list-ip-addresses](#) command to return the name of public IP address resource in *myVM*. In this example, the name is stored in a variable that is used in a later step.

```
ipaddressname=$(az vm list-ip-addresses -g myResourceGroupVM -n myVM --query "
[].virtualMachine.network.publicIpAddresses[].name" -o tsv)
```

Now you can get information about the IP address:

```
az network public-ip show --resource-group myResourceGroupVM --name $ipaddressname
```

The output shows that the IP address is in the same availability zone as the VM:

```
{  
  "dnsSettings": null,  
  "etag": "W/\"b7ad25eb-3191-4c8f-9cec-c5e4a3a37d35\"",  
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-  
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Network/publicIPAddresses/myVMPublicIP",  
  "idleTimeoutInMinutes": 4,  
  "ipAddress": "52.174.34.95",  
  "ipConfiguration": {  
    "etag": null,  
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-  
xxxxxxxxxxxx/resourceGroups/myResourceGroupVM/providers/Microsoft.Network/networkInterfaces/myVMVMNic/ipConf

## Next steps

In this article, you learned how to create a VM in an availability zone. Learn more about [availability](#) for Azure VMs.

# Create a virtual machine in an availability zone using Azure PowerShell

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article details using Azure PowerShell to create an Azure virtual machine running Windows Server 2016 in an Azure availability zone. An [availability zone](#) is a physically separate zone in an Azure region. Use availability zones to protect your apps and data from an unlikely failure or loss of an entire datacenter.

To use an availability zone, create your virtual machine in a [supported Azure region](#).

## Sign in to Azure

Sign in to your Azure subscription with the `Connect-AzAccount` command and follow the on-screen directions.

```
Connect-AzAccount
```

## Check VM SKU availability

The availability of VM sizes, or SKUs, may vary by region and zone. To help you plan for the use of Availability Zones, you can list the available VM SKUs by Azure region and zone. This ability makes sure that you choose an appropriate VM size, and obtain the desired resiliency across zones. For more information on the different VM types and sizes, see [VM Sizes overview](#).

You can view the available VM SKUs with the `Get-AzComputeResourceSku` command. The following example lists available VM SKUs in the *eastus2* region:

```
Get-AzComputeResourceSku | where {$_.Locations.Contains("eastus2")};
```

The output is similar to the following condensed example, which shows the Availability Zones in which each VM size is available:

ResourceType	Name	Location	Zones	[...]
-----	---	-----	-----	-----
virtualMachines	Standard_DS1_v2	eastus2	{1, 2, 3}	
virtualMachines	Standard_DS2_v2	eastus2	{1, 2, 3}	
[...]				
virtualMachines	Standard_F1s	eastus2	{1, 2, 3}	
virtualMachines	Standard_F2s	eastus2	{1, 2, 3}	
[...]				
virtualMachines	Standard_D2s_v3	eastus2	{1, 2, 3}	
virtualMachines	Standard_D4s_v3	eastus2	{1, 2, 3}	
[...]				
virtualMachines	Standard_E2_v3	eastus2	{1, 2, 3}	
virtualMachines	Standard_E4_v3	eastus2	{1, 2, 3}	

## Create resource group

Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which

Azure resources are deployed and managed. In this example, a resource group named *myResourceGroup* is created in the *eastus2* region.

```
New-AzResourceGroup -Name myResourceGroup -Location EastUS2
```

## Create networking resources

### Create a virtual network, subnet, and a public IP address

These resources are used to provide network connectivity to the virtual machine and connect it to the internet. Create the IP address in an availability zone, 2 in this example. In a later step, you create the VM in the same zone used to create the IP address.

```
# Create a subnet configuration
$subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -AddressPrefix 192.168.1.0/24

# Create a virtual network
$vnet = New-AzVirtualNetwork -ResourceGroupName myResourceGroup -Location eastus2 ` 
    -Name myVNet -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig

# Create a public IP address in an availability zone and specify a DNS name
$pip = New-AzPublicIpAddress -ResourceGroupName myResourceGroup -Location eastus2 -Zone 2 ` 
    -AllocationMethod Static -IdleTimeoutInMinutes 4 -Name "mypublicdns$(Get-Random)" -Sku Standard
```

### Create a network security group and a network security group rule

The network security group secures the virtual machine using inbound and outbound rules. In this case, an inbound rule is created for port 3389, which allows incoming remote desktop connections. We also want to create an inbound rule for port 80, which allows incoming web traffic.

```
# Create an inbound network security group rule for port 3389 - change -Access to "Allow" if you want to
allow RDP access
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name myNetworkSecurityGroupRuleRDP -Protocol Tcp ` 
    -Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange * -DestinationAddressPrefix * ` 
    -DestinationPortRange 3389 -Access Deny

# Create an inbound network security group rule for port 80 - - change -Access to "Allow" if you want to
allow TCP traffic over port 80
$nsgRuleWeb = New-AzNetworkSecurityRuleConfig -Name myNetworkSecurityGroupRuleWWW -Protocol Tcp ` 
    -Direction Inbound -Priority 1001 -SourceAddressPrefix * -SourcePortRange * -DestinationAddressPrefix * ` 
    -DestinationPortRange 80 -Access Deny

# Create a network security group
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName myResourceGroup -Location eastus2 ` 
    -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP,$nsgRuleWeb
```

### Create a network card for the virtual machine

Create a network card with [New-AzNetworkInterface](#) for the virtual machine. The network card connects the virtual machine to a subnet, network security group, and public IP address.

```
# Create a virtual network card and associate with public IP address and NSG
$nic = New-AzNetworkInterface -Name myNic -ResourceGroupName myResourceGroup -Location eastus2 ` 
    -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -NetworkSecurityGroupId $nsg.Id
```

## Create virtual machine

Create a virtual machine configuration. This configuration includes the settings that are used when deploying the virtual machine such as a virtual machine image, size, and authentication configuration. The *Standard\_DS1\_v2* size in this example is supported in availability zones. This configuration also specifies the availability zone you set when creating the IP address. When running this step, you are prompted for credentials. The values that you enter are configured as the user name and password for the virtual machine.

```
# Define a credential object
$cred = Get-Credential

# Create a virtual machine configuration
$vmConfig = New-AzVMConfig -VMName myVM -VMSize Standard_DS1_v2 -Zone 2 | ` 
    Set-AzVMOperatingSystem -Windows -ComputerName myVM -Credential $cred | ` 
    Set-AzVMSourceImage -PublisherName MicrosoftWindowsServer -Offer WindowsServer ` 
    -Sku 2016-Datacenter -Version latest | Add-AzVMNetworkInterface -Id $nic.Id
```

Create the virtual machine with [New-AzVM](#).

```
New-AzVM -ResourceGroupName myResourceGroup -Location eastus2 -VM $vmConfig
```

## Confirm zone for managed disk

You created the VM's IP address resource in the same availability zone as the VM. The managed disk resource for the VM is created in the same availability zone. You can verify this with [Get-AzDisk](#):

```
Get-AzDisk -ResourceGroupName myResourceGroup
```

The output shows that the managed disk is in the same availability zone as the VM:

```
ResourceGroupName : myResourceGroup
AccountType      : PremiumLRS
OwnerId          : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroup/providers/Microsoft. 
                    Compute/virtualMachines/myVM
ManagedBy        : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx//resourceGroups/myResourceGroup/providers/Microsoft. 
                    Compute/virtualMachines/myVM
Sku              : Microsoft.Azure.Management.Compute.Models.DiskSku
Zones            : {2}
TimeCreated      : 9/7/2017 6:57:26 PM
OsType           : Windows
CreationData     : Microsoft.Azure.Management.Compute.Models.CreationData
DiskSizeGB       : 127
EncryptionSettings :
ProvisioningState : Succeeded
Id               : /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myResourceGroup/providers/Microsoft. 
                    Compute/disks/myVM_OsDisk_1_bd921920bb0a4650becfc2d830000000
Name             : myVM_OsDisk_1_bd921920bb0a4650becfc2d830000000
Type             : Microsoft.Compute/disks
Location         : eastus2
Tags             : {}
```

## Next steps

# Create virtual machines in an availability zone using the Azure portal

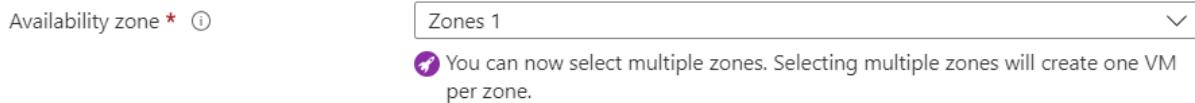

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

This article steps through using the Azure portal to create highly resilient virtual machines in [availability zones](#). Azure availability zones are physically separate locations within each Azure region that are tolerant to local failures. Use availability zones to protect your applications and data against unlikely datacenter failures.

To use availability zones, create your virtual machines in a [supported Azure region](#).

Some users will now see the option to create VMs in multiple zones. If you see the following message, use the **Preview** tab below.

- [Standard](#)
- [Preview](#)

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Click **Create a resource > Compute > Virtual machine**.
3. Enter the virtual machine information. The user name and password or SSH key is used to sign in to the virtual machine.
4. Choose a region such as East US 2 that supports availability zones.
5. Under **Availability options**, select **Availability zone** dropdown.
6. Under **Availability zone**, select a zone from the drop-down list.
7. Choose a size for the VM. Select a recommended size, or filter based on features. Confirm the size is available in the zone you want to use.
8. Finish filling in the information for your VM. When you are done, select **Review + create**.
9. Once the information is verified, select **Create**.
10. After the VM is created, you can see the availability zone listed in the **Essentials section** on the page for the VM.

# Migrate Virtual Machines and Virtual Machine Scale Sets to availability zone support

9/21/2022 • 6 minutes to read • [Edit Online](#)

This guide describes how to migrate Virtual Machines (VMs) and Virtual Machine Scale Sets (VMSS) from non-availability zone support to availability zone support. We'll take you through the different options for migration, including how you can use availability zone support for Disaster Recovery solutions.

Virtual Machine (VM) and Virtual Machine Scale Sets (VMSS) are zonal services, which means that VM resources can be deployed by using one of the following methods:

- VM resources are deployed to a specific, self-selected availability zone to achieve more stringent latency or performance requirements.
- VM resources are replicated to one or more zones within the region to improve the resiliency of the application and data in a High Availability (HA) architecture.

When you migrate resources to availability zone support, we recommend that you select multiple zones for your new VMs and VMSS, to ensure high-availability of your compute resources.

## Prerequisites

To migrate to availability zone support, your VM SKUs must be available across the zones in for your region. To check for VM SKU availability, use one of the following methods:

- Use PowerShell to [Check VM SKU availability](#).
- Use the Azure CLI to [Check VM SKU availability](#).
- Go to [Foundational Services](#).

## Downtime requirements

Because zonal VMs are created across the availability zones, all migration options mentioned in this article require downtime during deployment.

## Migration Option 1: Redeployment

### When to use redeployment

Use the redeployment option if you have set up good Infrastructure as Code (IaC) practices to manage infrastructure. This redeployment option gives you more control and the ability to automate various processes within your deployment pipelines.

### Redeployment considerations

- When you redeploy your VM and VMSS resources, the underlying resources such as managed disk and IP address for the VM are created in the same availability zone. You must use a Standard SKU public IP address and load balancer to create zone-redundant network resources.
- Existing managed disks without availability zone support can't be attached to a VM with availability zone support. To attach existing managed disks to a VM with availability zone support, you'll need to take a snapshot of the current disks, and then create your VM with the new managed disks attached.
- For zonal deployments that require reasonably low network latency and good performance between

application tier and data tier, use [proximity placement groups](#). Proximity groups can force grouping of different VM resources under a single network spine. For an example of an SAP workload that uses proximity placement groups, see [Azure proximity placement groups for optimal network latency with SAP applications](#)

## How to redeploy

If you want to migrate the data on your current managed disks when creating a new VM, follow the directions in [Migrate your managed disks](#).

If you only want to create new VM with new managed disks in an availability zone, see:

- [Create VM using Azure CLI](#)
- [Create VM using Azure PowerShell](#)
- [Create VM using Azure portal](#)

To learn how to create VMSS in an availability zone, see [Create a virtual machine scale set that uses Availability Zones](#).

## Migrate your managed disks

In this section, you'll migrate the data from your current managed disks to either zone-redundant storage (ZRS) managed disks or zonal managed disks.

### Step 1: Create your snapshot

The easiest and cleanest way to create a snapshot is to do so while the VM is offline. See [Create snapshots while the VM is offline](#). If you choose this approach, some downtime should be expected. To create a snapshot of your VM using the Azure portal, PowerShell, or Azure CLI, see [Create a snapshot of a virtual hard disk](#)

If you'll be taking a snapshot of a disk that's attached to a running VM, read the guidance in [Create snapshots while the VM is running](#) before proceeding.

#### NOTE

The source managed disks remain intact with their current configurations and you'll continue to be billed for them. To avoid this, you must manually delete the disks once you've finished your migration and confirmed the new disks are working. For more information, see [Find and delete unattached Azure managed and unmanaged disks](#).

### Step 2: Migrate the data on your managed disks

Now that you have snapshots of your original disks, you can use them to create either ZRS managed disks or zonal managed disks.

#### Migrate your data to zonal managed disks

To migrate a non-zonal managed disk to zonal:

1. Create a zonal managed disk from the source disk snapshot. The zone parameter should match your zonal VM. To create a zonal managed disk from the snapshot, you can use [Azure CLI](#)(example below), [PowerShell](#), or the [Azure Portal](#).

```
az disk create --resource-group $resourceGroupName --name $diskName --location $location --zone  
$zone --sku $storageType --size-gb $diskSize --source $snapshotId
```

#### Migrate your data to ZRS managed disks

#### IMPORTANT

Zone-redundant storage (ZRS) for managed disks has some restrictions. For more information see [Limitations](#).

1. Create a ZRS managed disk from the source disk snapshot by using the following Azure CLI snippet:

```
# Create a new ZRS Managed Disks using the snapshot Id and the SKU supported  
storageType=Premium_ZRS  
location=westus2  
  
az disk create --resource-group $resourceGroupName --name $diskName --sku $storageType --size-gb  
$diskSize --source $snapshotId
```

### Step 3: Create a new VM with your new disks

Now that you have migrated your data to ZRS managed disks or zonal managed disks, create a new VM with these new disks set as the OS and data disks:

```
az vm create -g MyResourceGroup -n MyVm --attach-os-disk newZonalOSDiskCopy --attach-data-disks  
newZonalDataDiskCopy --os-type linux
```

## Migration Option 2: Azure Resource Mover

### When to use Azure Resource Mover

Use Azure Resource Mover for an easy way to move VMs or encrypted VMs from one region without availability zones to another with availability zone support. If you want to learn more about the benefits of using Azure Resource Mover, see [Why use Azure Resource Mover?](#).

### Azure Resource Mover considerations

When you use Azure Resource mover, all keys and secrets are copied from the source key vault to the newly created destination key vault in your target region. All resources related to your customer-managed keys, such as Azure Key Vaults, disk encryption sets, VMs, disks, and snapshots, must be in the same subscription and region. Azure Key Vault's default availability and redundancy feature can't be used as the destination key vault for the moved VM resources, even if the target region is a secondary region to which your source key vault is replicated.

### How to use Azure Resource Mover

To learn how to move VMs to another region, see [Move Azure VMs to an availability zone in another region](#)

To learn how to move encrypted VMs to another region, see [Tutorial: Move encrypted Azure VMs across regions](#)

## Disaster Recovery Considerations

Typically, availability zones are used to deploy VMs in a High Availability configuration. They may be too close to each other to serve as a Disaster Recovery solution during a natural disaster. However, there are scenarios where availability zones can be used for Disaster Recovery. To learn more, see [Using Availability Zones for Disaster Recovery](#).

The following requirements should be part of a disaster recovery strategy that helps your organization run its workloads during planned or unplanned outages across zones:

- The source VM must already be a zonal VM, which means that it's placed in a logical zone.
- You'll need to replicate your VM from one zone to another zone using Azure Site Recovery service.
- Once your VM is replicated to another zone, you can follow steps to run a Disaster Recovery drill, fail over, reprotect, and failback.
- To enable VM disaster recovery between availability zones, follow the instructions in [Enable Azure VM](#)

disaster recovery between availability zones .

[Regions and Availability Zones in Azure](#)

[Azure Services that support Availability Zones](#)

# Proximity placement groups

9/21/2022 • 9 minutes to read • [Edit Online](#)

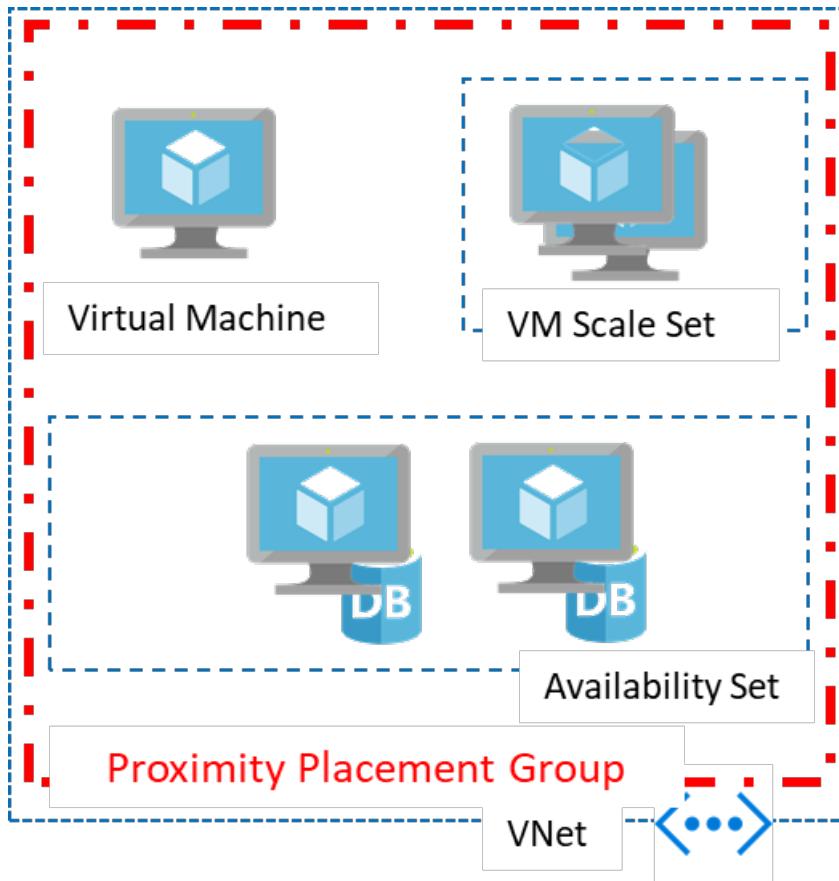

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Placing VMs in a single region reduces the physical distance between the instances. Placing them within a single availability zone will also bring them physically closer together. However, as the Azure footprint grows, a single availability zone may span multiple physical data centers, which may result in a network latency impacting your application.

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a proximity placement group.

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

- Low latency between stand-alone VMs.
- Low Latency between VMs in a single availability set or a virtual machine scale set.
- Low latency between stand-alone VMs, VMs in multiple Availability Sets, or multiple scale sets. You can have multiple compute resources in a single placement group to bring together a multi-tiered application.
- Low latency between multiple application tiers using different hardware types. For example, running the backend using M-series in an availability set and the front end on a D-series instance, in a scale set, in a single proximity placement group.

## Using Proximity Placement Groups

A proximity placement group is a resource in Azure. You need to create one before using it with other resources. Once created, it could be used with virtual machines, availability sets, or virtual machine scale sets. You specify a proximity placement group when creating compute resources providing the proximity placement group ID.

You can also move an existing resource into a proximity placement group. When moving a resource into a proximity placement group, you should stop (deallocate) the asset first since it will be redeployed potentially into a different data center in the region to satisfy the colocation constraint.

In the case of availability sets and virtual machine scale sets, you should set the proximity placement group at the resource level rather than the individual virtual machines.

A proximity placement group is a colocation constraint rather than a pinning mechanism. It's pinned to a specific data center with the deployment of the first resource to use it. Once all resources using the proximity placement group have been stopped (deallocated) or deleted, it's no longer pinned. Therefore, whenever you use a proximity placement group with multiple VM series, it's important to specify all the required types upfront in a template if possible or follow a deployment sequence, which will improve your chances for a successful deployment. If your deployment fails, restart the deployment with the VM size, which has failed as the first size to be deployed.

## Use intent to specify VM sizes

You can use the optional `intent` parameter to provide the intended [VM Sizes](#) to be part of the proximity placement group. This parameter can be specified at the time of creating a proximity placement group or it can be added/modified while updating a proximity placement group after deallocating all of the VMs.

When specifying `intent`, you can also add the optional `zone` parameter to specify an availability zone, indicating that the proximity placement group must be created within a specific availability zone. Note the following points when providing the `zone` parameter:

- The availability zone parameter can only be provided during the creation of the proximity placement group and can't be modified later.
- The `zone` parameter can only be used with `intent`, it can't be used alone.
- Only one availability zone can be specified.

Proximity Placement Group creation or update will succeed only when at least one data center supports all the VM Sizes specified in the intent. Otherwise, the creation or update will fail with "OverconstrainedAllocationRequest", indicating that the combination of VM Sizes can't be supported within a proximity placement group. The **intent does not provide any capacity reservation or guarantee**. The VM Sizes and zone given in `intent` are used to select an appropriate data center, reducing the chances of failure if the desired VM size isn't available in a data center. Allocation failures can still occur if there is no more capacity for a VM size at the time of deployment.

### NOTE

To use intent for your proximity placement groups, ensure that the API version is 2021-11-01 or higher

### Best Practices while using intent

- Provide an availability zone for your proximity placement group only when you provide an intent. Providing an availability zone without an intent will result in an error when creating the proximity placement group.
- If you provide an availability zone in the intent, ensure that the availability zone of the VMs you deploy match with what is specified in the intent, to avoid errors while deploying VMs.
- Creating or adding VMs with sizes that are not included in the intent is allowed, but not recommended. The size may not exist in the selected datacenter and can result in failures at the time of VM deployment.
- For existing placement groups, we recommend you include the sizes of the existing VMs when updating the

intent, in order to avoid failure when redeploying the VMs.

### Intent can be affected with decommissioning

- It is possible that after creating a proximity placement group with intent and before deploying VMs, planned maintenance events such as hardware decommissioning at an Azure datacenter could occur, resulting in the combination of VM Sizes specified in the intent not being available in the data center. In such cases, an "OverconstrainedAllocationRequest" error will occur, even while deploying VMs of sizes specified in the intent. You can try deallocated all the resources in the proximity placement group and recreate them to get a data center that can accommodate the intent. If there is no datacenter with the specified VM Sizes after the decommissioning, you may have to modify the intent to use a different combination of VM Sizes, since the combination of VM sizes is no longer supported.
- Azure may retire an entire VM family or a specific set of VM sizes. If you have such a VM size in the intent, you may have to either remove it or replace it with a different size before the retirement date for the original VM size. Otherwise, the intent will no longer be valid.

## What to expect when using Proximity Placement Groups

Proximity placement groups offer colocation in the same data center. However, because proximity placement groups represent an additional deployment constraint, allocation failures can occur. There are few use cases where you may see allocation failures when using proximity placement groups:

- When you ask for the first virtual machine in the proximity placement group, the data center is automatically selected. In some cases, a second request for a different VM size, may fail if it doesn't exist in that data center. In this case, an **OverconstrainedAllocationRequest** error is returned. To avoid this error, try changing the order in which you deploy your VM sizes or have both resources deployed using a single ARM template.
- If the proximity placement group is created with intent, the VMs are not required to be deployed in any particular order and are not required to be batched using a single ARM template, since the intent is used to select a datacenter that supports all VM sizes indicated in the intent.
- In the case of elastic workloads, where you add and remove VM instances, having a proximity placement group constraint on your deployment may result in a failure to satisfy the request resulting in **AllocationFailure** error.
- Stopping (deallocate) and starting your VMs as needed is another way to achieve elasticity. Since the capacity is not kept once you stop (deallocate) a VM, starting it again may result in an **AllocationFailure** error.
- VM start and redeploy operations will continue to respect the Proximity Placement Group once successfully configured.

## Planned maintenance and Proximity Placement Groups

Planned maintenance events, like hardware decommissioning at an Azure datacenter, could potentially affect the alignment of resources in proximity placement groups. Resources may be moved to a different data center, disrupting the collocation and latency expectations associated with the proximity placement group.

### Check the alignment status

You can do the following to check the alignment status of your proximity placement groups.

- Proximity placement group colocation status can be viewed using the portal, CLI, and PowerShell.
  - PowerShell - colocation status can be obtained through `Get-AzProximityPlacementGroup` cmdlet by including the optional parameter '`-ColocationStatus`'.
  - CLI - colocation status can be obtained through `az ppg show` by including the optional parameter '`--include-colocation-status`'.
- For each proximity placement group, a **colocation status** property provides the current alignment

status summary of the grouped resources.

- **Aligned:** Resource is within the same latency envelop of the proximity placement group.
- **Unknown:** At least one of the VM resources are deallocated. After re-starting them successfully, the status should go back to **Aligned**.
- **Not aligned:** At least one VM resource is not aligned with the proximity placement group. The specific resources that are not aligned will also be called out separately in the membership section
- For Availability Sets, you can see information about alignment of individual VMs in the Availability Set Overview page.
- For scale sets, information about alignment of individual instances can be seen in the **Instances** tab of the Overview page for the scale set.

### Realign resources

If a proximity placement group is **Not Aligned**, you can stop\deallocate, and then restart the affected resources. If the VM is in an availability set or a scale set, all VMs in the availability set or scale set must be stopped\deallocated first before restarting them.

If there is an allocation failure due to deployment constraints, you may have to stop\deallocate all resources in the affected proximity placement group (including the aligned resources) first, and then restart them to restore alignment.

## Best practices

- For the lowest latency, use proximity placement groups together with accelerated networking. For more information, see [Create a Linux virtual machine with Accelerated Networking](#) or [Create a Windows virtual machine with Accelerated Networking](#).
- In order to avoid landing on hardware that doesn't support all the VM SKUs and sizes you require, use intent for proximity placement groups. If it is an already existing proximity placement group without intent, you can use a single ARM template with all VM sizes specified to avoid this issue.
- When reusing an existing placement group from which VMs were deleted, wait for the deletion to fully complete before adding VMs to it.
- If latency is your first priority, put VMs in a proximity placement group and the entire solution in an availability zone. But, if resiliency is your top priority, spread your instances across multiple availability zones (a single proximity placement group cannot span zones).

## Next steps

- Deploy a VM to a proximity placement group using the [Azure CLI](#) or [PowerShell](#).

# Deploy VMs to proximity placement groups using Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a [proximity placement group](#).

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

## Create the proximity placement group

Create a proximity placement group using `az ppg create`.

```
az group create --name myPPGGroup --location eastus
az ppg create \
  -n myPPG \
  -g myPPGGroup \
  -l eastus \
  -t standard
  --intent-vm-sizes Standard_E64s_v4 Standard_M416ms_v2 \
  -z 1
```

## List proximity placement groups

You can list all of your proximity placement groups using `az ppg list`.

```
az ppg list -o table
```

## Show proximity placement group

You can see the proximity placement group details and resources using `az ppg show`

```
az ppg show --name myPPG --resource-group myPPGGroup
{
  "availabilitySets": [],
  "colocationStatus": null,
  "id": "/subscriptions/[subscriptionId]/resourceGroups/myPPGGroup/providers/Microsoft.Compute/proximityPlacementGroups/MyPPG",
  "intent": {
    "vmSizes": [
      "Standard_E64s_v4",
      "Standard_M416ms_v2"
    ]
  },
  "location": "eastus",
  "name": "MyPPG",
  "proximityPlacementGroupType": "Standard",
  "resourceGroup": "myPPGGroup",
  "tags": {},
  "type": "Microsoft.Compute/proximityPlacementGroups",
  "virtualMachineScaleSets": [],
  "virtualMachines": [],
  "zones": [
    "1"
  ]
}
```

## Create a VM

Create a VM within the proximity placement group using [new az vm](#).

```
az vm create \
  -n myVM \
  -g myPPGGroup \
  --image UbuntuLTS \
  --ppg myPPG \
  --generate-ssh-keys \
  --size Standard_E64s_v4 \
  -l eastus
```

You can see the VM in the proximity placement group using [az ppg show](#).

```
az ppg show --name myppg --resource-group myppggroup --query "virtualMachines"
```

## Availability Sets

You can also create an availability set in your proximity placement group. Use the same `--ppg` parameter with [az vm availability-set create](#) to create an availability set and all of the VMs in the availability set will also be created in the same proximity placement group.

## Scale sets

You can also create a scale set in your proximity placement group. Use the same `--ppg` parameter with [az vmss create](#) to create a scale set and all of the instances will be created in the same proximity placement group.

## Next steps

Learn more about the [Azure CLI](#) commands for proximity placement groups.

# Deploy VMs to proximity placement groups using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a [proximity placement group](#).

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

## Create a proximity placement group

Create a proximity placement group using the [New-AzProximityPlacementGroup](#) cmdlet.

```
$resourceGroup = "myPPGResourceGroup"
$location = "East US"
$ppgName = "myPPG"
$zone = "1"
$vmSize1 = "Standard_E64s_v4"
$vmSize2 = "Standard_M416ms_v2"
New-AzResourceGroup -Name $resourceGroup -Location $location
$ppg = New-AzProximityPlacementGroup ` 
    -Location $location ` 
    -Name $ppgName ` 
    -ResourceGroupName $resourceGroup ` 
    -ProximityPlacementGroupType Standard 
    -Zone $zone 
    -IntentVmSizeList $vmSize1, $vmSize2
```

## List proximity placement groups

You can list all of the proximity placement groups using the [Get-AzProximityPlacementGroup](#) cmdlet.

```
Get-AzProximityPlacementGroup -ResourceGroupName $resourceGroup -Name $ppgName

ResourceGroupName      : myPPGResourceGroup
ProximityPlacementGroupType : Standard
Id                   :
/subscriptions/[subscriptionId]/resourceGroups/myPPGResourceGroup/providers/Microsoft.Compute/proximityPlace
mentGroups/myPPG
Name                 : myPPG
Type                : Microsoft.Compute/proximityPlacementGroups
Location             : eastus
Tags                : {}
Intent               :
VmSizes[0]           : Standard_E64s_v4
VmSizes[1]           : Standard_M416ms_v2
Zones[0]              : 1
```

## Create a VM

Create a VM in the proximity placement group using `-ProximityPlacementGroup $ppg.Id` to refer to the proximity placement group ID when you use [New-AzVM](#) to create the VM.

```
$vmName = "myVM"

New-AzVm `-
    -ResourceGroupName $resourceGroup `-
    -Name $vmName `-
    -Location $location `-
    -ProximityPlacementGroup $ppg.Id
```

You can see the VM in the placement group using [Get-AzProximityPlacementGroup](#).

```
Get-AzProximityPlacementGroup -ResourceId $ppg.Id | 
    Format-Table -Property VirtualMachines -Wrap
```

### Move an existing VM into a proximity placement group

You can also add an existing VM to a proximity placement group. You need to stop\deallocate the VM first, then update the VM and restart.

```
$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPGResourceGroup -Name myPPG
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Stop-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
Update-AzVM -VM $vm -ResourceGroupName $vm.ResourceGroupName -ProximityPlacementGroupId $ppg.Id
Start-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
```

### Move an existing VM out of a proximity placement group

To remove a VM from a proximity placement group, you need to stop\deallocate the VM first, then update the VM and restart.

```
$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPGResourceGroup -Name myPPG
$vm = Get-AzVM -ResourceGroupName myResourceGroup -Name myVM
Stop-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
$vm.ProximityPlacementGroup = ""
Update-AzVM -VM $vm -ResourceGroupName $vm.ResourceGroupName
Start-AzVM -Name $vm.Name -ResourceGroupName $vm.ResourceGroupName
```

## Availability Sets

You can also create an availability set in your proximity placement group. Use the same `-ProximityPlacementGroup` parameter with the [New-AzAvailabilitySet](#) cmdlet to create an availability set and all of the VMs created in the availability set will also be created in the same proximity placement group.

To add or remove an existing availability set to a proximity placement group, you first need to stop all of the VMs in the availability set.

### Move an existing availability set into a proximity placement group

```

$resourceGroup = "myResourceGroup"
$avSetName = "myAvailabilitySet"
$avSet = Get-AzAvailabilitySet -ResourceGroupName $resourceGroup -Name $avSetName
$vmIDs = $avSet.VirtualMachineReferences
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Stop-AzVM -ResourceGroupName $resourceGroup -Name $vmName -Force
}

$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPG -Name myPPG
Update-AzAvailabilitySet -AvailabilitySet $avSet -ProximityPlacementGroupId $ppg.Id
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Start-AzVM -ResourceGroupName $resourceGroup -Name $vmName
}

```

## Move an existing availability set out of a proximity placement group

```

$resourceGroup = "myResourceGroup"
$avSetName = "myAvailabilitySet"
$avSet = Get-AzAvailabilitySet -ResourceGroupName $resourceGroup -Name $avSetName
$vmIDs = $avSet.VirtualMachineReferences
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Stop-AzVM -ResourceGroupName $resourceGroup -Name $vmName -Force
}

$avSet.ProximityPlacementGroup = ""
Update-AzAvailabilitySet -AvailabilitySet $avSet
foreach ($vmId in $vmIDs){
    $string = $vmID.Id.Split("/")
    $vmName = $string[8]
    Start-AzVM -ResourceGroupName $resourceGroup -Name $vmName
}

```

## Scale sets

You can also create a scale set in your proximity placement group. Use the same `-ProximityPlacementGroup` parameter with [New-AzVmss](#) to create a scale set and all of the instances will be created in the same proximity placement group.

To add or remove an existing scale set to a proximity placement group, you first need to stop the scale set.

## Move an existing scale set into a proximity placement group

```

$ppg = Get-AzProximityPlacementGroup -ResourceGroupName myPPG -Name myPPG
$vmss = Get-AzVmss -ResourceGroupName myVMSResourceGroup -VMScaleSetName myScaleSet
Stop-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName $vmss.ResourceGroupName
Update-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName $vmss.ResourceGroupName -
ProximityPlacementGroupId $ppg.Id
Start-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName $vmss.ResourceGroupName

```

## Move an existing scale set out of a proximity placement group

```
$vmss = Get-AzVmss -ResourceGroupName myVMSSResourceGroup -VMScaleSetName myScaleSet
Stop-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName $vmss.ResourceGroupName
$vmss.ProximityPlacementGroup = ""
Update-AzVmss -VirtualMachineScaleSet $vmss -VMScaleSetName $vmss.Name -ResourceGroupName
$vmss.ResourceGroupName
Start-AzVmss -VMScaleSetName $vmss.Name -ResourceGroupName $vmss.ResourceGroupName
```

## Next steps

You can also use the [Azure CLI](#) to create proximity placement groups.

# Create a proximity placement group using the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

To get VMs as close as possible, achieving the lowest possible latency, you should deploy them within a [proximity placement group](#).

A proximity placement group is a logical grouping used to make sure that Azure compute resources are physically located close to each other. Proximity placement groups are useful for workloads where low latency is a requirement.

## NOTE

Proximity placement groups cannot be used with dedicated hosts.

Intent for proximity placement groups is not supported on Azure portal. Use ARM templates or other client tools like Powershell or CLI to provide intent for proximity placement groups.

If you want to use availability zones together with placement groups, you need to make sure that the VMs in the placement group are also all in the same availability zone.

## Create the proximity placement group

1. Type **proximity placement group** in the search.
2. Under **Services** in the search results, select **Proximity placement groups**.
3. In the **Proximity placement groups** page, select **Add**.
4. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected.
5. In **Resource group** either select **Create new** to create a new group or select an empty resource group that already exists, from the drop-down.
6. In **Region** select the location where you want the proximity placement group to be created.
7. In **Proximity placement group name** type a name and then select **Review + create**.
8. After validation passes, select **Create** to create the proximity placement group.

Home > New > Proximity Placement Group > Create Proximity Placement Group

## Create Proximity Placement Group

[Basics](#) [Tags](#) [Review + create](#)

Fill out the required fields and then review the information on the Review + create tab. Once you're satisfied, click Create to deploy.

**Project details**

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	Pay-As-You-Go
Resource group *	(New) myPPG
	<a href="#">Create new</a>

**Instance details**

Region *	East US
Proximity placement group name *	myPPG

[Review + create](#) [Previous](#) [Next : Tags >](#)

## Create a VM

1. While creating a VM in the portal, go to the **Advanced** tab.
2. In the **Proximity placement group** selection, select the correct placement group.

**Proximity placement group**

Proximity placement groups allow you to group Azure resources physically closer together in the same region. [Learn more](#)

Proximity placement group	myPPG
---------------------------	-------

3. When you are done making all of the other required selections, select **Review + create**.
4. After it passes validation, select **Create** to deploy the VM in the placement group.

## Add VMs in an availability set to a proximity placement group

If the VM is part of the Availability set, you need to add the availability set into the the placement group, before adding the VMs.

1. In the [portal](#) search for *Availability sets* and select your availability set from the results.
2. Stop\deallocate each VM in the availability set by selecting the VM, then selecting **Stop** on the page for the VM, and then select **OK** to stop the VM.
3. On the page for your availability set, make sure all of the VMs have the **Status** listed as **Stopped (deallocated)**.
4. In the left menu, select **Configuration**.
5. Under **Proximity placement group**, select a placement group from the drop-down, and then select **Save**.
6. Select **Overview** from the left menu to see the list of VMs again.
7. Select each VM in the availability set, and then select **Start** on the page for each VM.

## Add existing VM to placement group

1. On the page for the VM, select **Stop**.
2. Once the status of the VM is listed as **Stopped (deallocated)**, select **Configuration** on the left menu.
3. Under **Proximity placement group**, select a placement group from the drop-down, and then select **Save**.
4. Select **Overview** from the left menu, then select **Start** to restart the VM.

## Next steps

You can also use the [Azure PowerShell](#) to create proximity placement groups.

# Understand VM reboots - maintenance vs. downtime

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

There are three scenarios that can lead to virtual machines in Azure being impacted: unplanned hardware maintenance, unexpected downtime, and planned maintenance.

## Unplanned hardware maintenance event

Unplanned hardware maintenance occurs when the Azure platform predicts that the hardware or any platform component associated to a physical machine, is about to fail. When the platform predicts a failure, it will issue an unplanned hardware maintenance event to reduce the impact to the virtual machines hosted on that hardware. Azure uses [Live Migration](#) technology to migrate the Virtual Machines from the failing hardware to a healthy physical machine. Live Migration is a VM preserving operation that only pauses the Virtual Machine for a short time. Memory, open files, and network connections are maintained, but performance might be reduced before and/or after the event. In cases where Live Migration cannot be used, the VM will experience Unexpected Downtime, as described below.

## Unexpected downtime

Unexpected downtime is when the hardware or the physical infrastructure for the virtual machine fails unexpectedly. This can include local network failures, local disk failures, or other rack level failures. When detected, the Azure platform automatically migrates (heals) your virtual machine to a healthy physical machine in the same data center. During the healing procedure, virtual machines experience downtime (reboot) and in some cases loss of the temporary drive. The attached OS and data disks are always preserved.

Virtual machines can also experience downtime in the unlikely event of an outage or disaster that affects an entire data center, or even an entire region. For these scenarios, Azure provides protection options including [availability zones](#) and [paired regions](#).

## Planned maintenance events

Planned maintenance events are periodic updates made by Microsoft to the underlying Azure platform to improve overall reliability, performance, and security of the platform infrastructure that your virtual machines run on. Most of these updates are performed without any impact upon your Virtual Machines or Cloud Services (see [Maintenance that doesn't require a reboot](#)). While the Azure platform attempts to use VM Preserving Maintenance in all possible occasions, there are rare instances when these updates require a reboot of your virtual machine to apply the required updates to the underlying infrastructure. In this case, you can perform Azure Planned Maintenance with Maintenance-Redeploy operation by initiating the maintenance for their VMs in the suitable time window. For more information, see [Planned Maintenance for Virtual Machines](#).

## Reduce downtime

To reduce the impact of downtime due to one or more of these events, we recommend the following high availability best practices for your virtual machines:

- Use [Availability Zones](#) to protect from data center failures
- Configure multiple virtual machines in an [availability set](#) for redundancy

- Use [scheduled events for Linux](#) or [scheduled events for Windows](#) to proactively respond to VM impacting events
- Configure each application tier into separate availability sets
- Combine a [load balancer](#) with availability zones or sets

## Next steps

To learn more about availability options in Azure see, see [Availability overview](#).

# Regions for virtual machines in Azure

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

It is important to understand how and where your virtual machines (VMs) operate in Azure, along with your options to maximize performance, availability, and redundancy. This article provides you with an overview of the availability and redundancy features of Azure.

## What are Azure regions?

Azure operates in multiple datacenters around the world. These datacenters are grouped in to geographic regions, giving you flexibility in choosing where to build your applications.

You create Azure resources in defined geographic regions like 'West US', 'North Europe', or 'Southeast Asia'. You can review the [list of regions and their locations](#). Within each region, multiple datacenters exist to provide for redundancy and availability. This approach gives you flexibility as you design applications to create VMs closest to your users and to meet any legal, compliance, or tax purposes.

## Special Azure regions

Azure has some special regions that you may wish to use when building out your applications for compliance or legal purposes. These special regions include:

- **US Gov Virginia and US Gov Iowa**
  - A physical and logical network-isolated instance of Azure for US government agencies and partners, operated by screened US persons. Includes additional compliance certifications such as [FedRAMP](#) and [DISA](#). Read more about [Azure Government](#).
- **China East and China North**
  - These regions are available through a unique partnership between Microsoft and 21Vianet, whereby Microsoft does not directly maintain the datacenters. See more about [Azure China 21Vianet](#).
- **Germany Central and Germany Northeast**
  - These regions are available via a data trustee model whereby customer data remains in Germany under control of T-Systems, a Deutsche Telekom company, acting as the German data trustee.

## Region pairs

Each Azure region is paired with another region within the same geography (such as US, Europe, or Asia). This approach allows for the replication of resources, such as VM storage, across a geography that should reduce the likelihood of natural disasters, civil unrest, power outages, or physical network outages affecting both regions at once. Additional advantages of region pairs include:

- In the event of a wider Azure outage, one region is prioritized out of every pair to help reduce the time to restore for applications.
- Planned Azure updates are rolled out to paired regions one at a time to minimize downtime and risk of application outage.
- Data continues to reside within the same geography as its pair (except for Brazil South) for tax and law enforcement jurisdiction purposes.

Examples of region pairs include:

PRIMARY	SECONDARY
West US	East US
North Europe	West Europe
Southeast Asia	East Asia

You can see the full [list of regional pairs here](#).

## Feature availability

Some services or VM features are only available in certain regions, such as specific VM sizes or storage types. There are also some global Azure services that do not require you to select a particular region, such as [Azure Active Directory](#), [Traffic Manager](#), or [Azure DNS](#). To assist you in designing your application environment, you can check the [availability of Azure services across each region](#). You can also [programmatically query the supported VM sizes and restrictions in each region](#).

## Storage availability

Understanding Azure regions and geographies becomes important when you consider the available storage replication options. Depending on the storage type, you have different replication options.

### Azure Managed Disks

- Locally redundant storage (LRS)
  - Replicates your data three times within the region in which you created your storage account.

### Storage account-based disks

- Locally redundant storage (LRS)
  - Replicates your data three times within the region in which you created your storage account.
- Zone redundant storage (ZRS)
  - Replicates your data three times across two to three facilities, either within a single region or across two regions.
- Geo-redundant storage (GRS)
  - Replicates your data to a secondary region that is hundreds of miles away from the primary region.
- Read-access geo-redundant storage (RA-GRS)
  - Replicates your data to a secondary region, as with GRS, but also then provides read-only access to the data in the secondary location.

The following table provides a quick overview of the differences between the storage replication types:

REPLICATION STRATEGY	LRS	ZRS	GRS	RA-GRS
Data is replicated across multiple facilities.	No	Yes	Yes	Yes
Data can be read from the secondary location and from the primary location.	No	No	No	Yes

REPLICATION STRATEGY	LRS	ZRS	GRS	RA-GRS
Number of copies of data maintained on separate nodes.	3	3	6	6

You can read more about [Azure Storage replication options here](#). For more information about managed disks, see [Azure Managed Disks overview](#).

### Storage costs

Prices vary depending on the storage type and availability that you select.

#### Azure Managed Disks

- Premium Managed Disks are backed by Solid-State Drives (SSDs) and Standard Managed Disks are backed by regular spinning disks. Both Premium and Standard Managed Disks are charged based on the provisioned capacity for the disk.

#### Unmanaged disks

- Premium storage is backed by Solid-State Drives (SSDs) and is charged based on the capacity of the disk.
- Standard storage is backed by regular spinning disks and is charged based on the in-use capacity and desired storage availability.
  - For RA-GRS, there is an additional Geo-Replication Data Transfer charge for the bandwidth of replicating that data to another Azure region.

See [Azure Storage Pricing](#) for pricing information on the different storage types and availability options.

## Next steps

For more information, see [Azure regions](#).

# Availability sets overview

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

## NOTE

We recommend that new customers choose [virtual machine scale sets with flexible orchestration mode](#) for high availability with the widest range of features. Virtual machine scale sets allow VM instances to be centrally managed, configured, and updated, and will automatically increase or decrease the number of VM instances in response to demand or a defined schedule. Availability sets only offer high availability.

This article provides you with an overview of the availability features of Azure virtual machines (VMs).

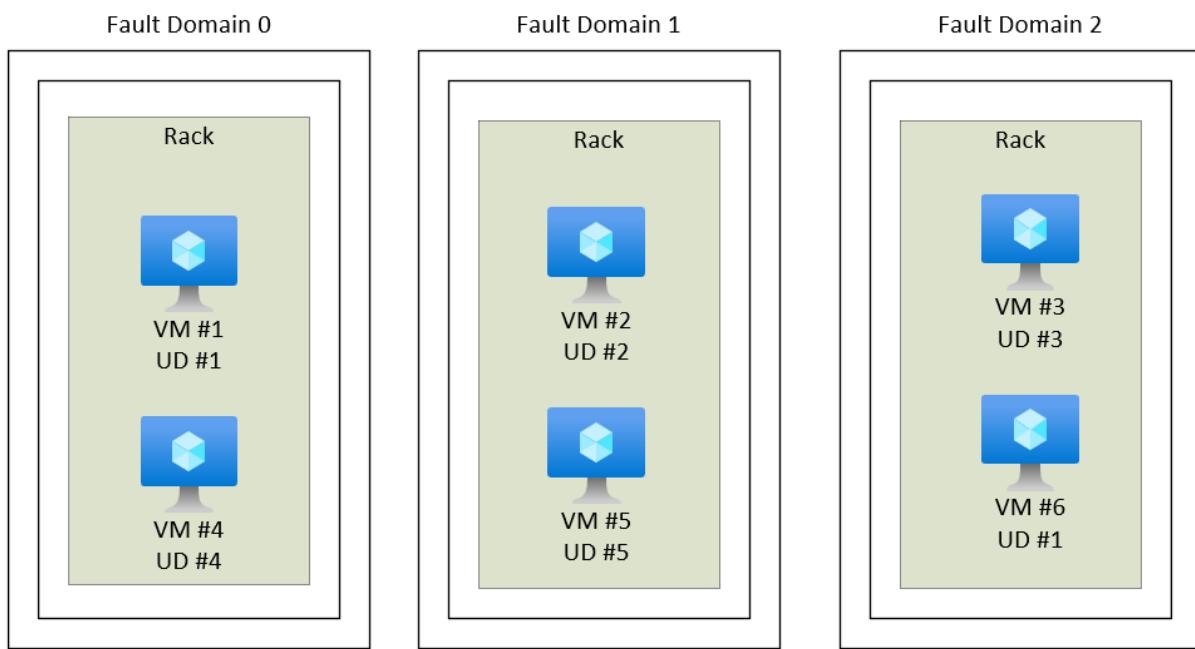

## What is an availability set?

An availability set is a logical grouping of VMs that allows Azure to understand how your application is built to provide for redundancy and availability. We recommended that two or more VMs are created within an availability set to provide for a highly available application and to meet the [99.95% Azure SLA](#). There is no cost for the Availability Set itself, you only pay for each VM instance that you create.

## How do availability sets work?

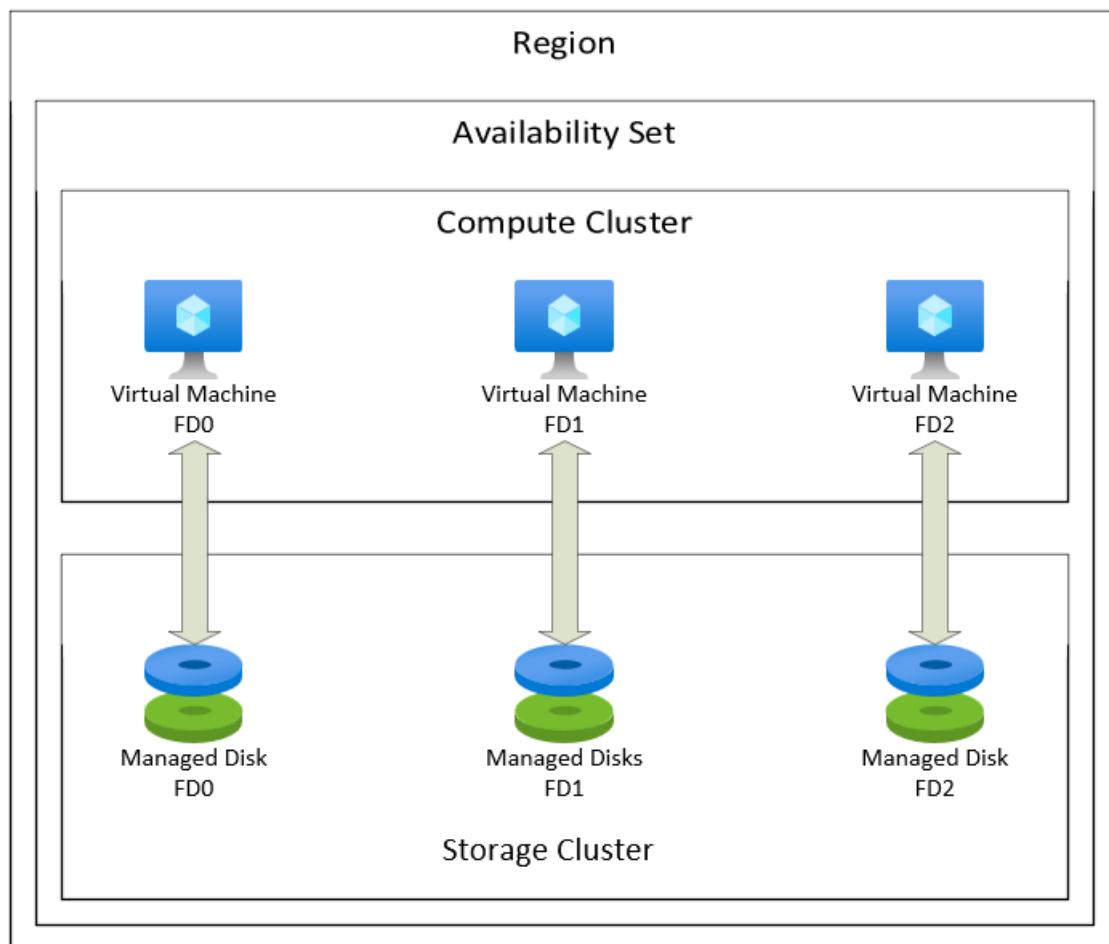

Each virtual machine in your availability set is assigned an **update domain** and a **fault domain** by the underlying Azure platform. Each availability set can be configured with up to three fault domains and twenty update domains. These configurations cannot be changed once the availability set has been created. Update domains indicate groups of virtual machines and underlying physical hardware that can be rebooted at the same time. When more than five virtual machines are configured within a single availability set with five update domains, the sixth virtual machine is placed into the same update domain as the first virtual machine, the seventh in the same update domain as the second virtual machine, and so on. The order of update domains being rebooted may not proceed sequentially during planned maintenance, but only one update domain is rebooted at a time. A rebooted update domain is given 30 minutes to recover before maintenance is initiated on a different update domain.

Fault domains define the group of virtual machines that share a common power source and network switch. By default, the virtual machines configured within your availability set are separated across up to three fault domains. While placing your virtual machines into an availability set does not protect your application from operating system or application-specific failures, it does limit the impact of potential physical hardware failures, network outages, or power interruptions.

VMs are also aligned with disk fault domains. This alignment ensures that all the managed disks attached to a VM are within the same fault domains.

Only VMs with managed disks can be created in a managed availability set. The number of managed disk fault domains varies by region - either two or three managed disk fault domains per region.

## Next steps

You can now start to use these availability and redundancy features to build your Azure environment. For best

practices information, see [Azure availability best practices](#).

# Create and deploy virtual machines in an availability set using Azure CLI

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

In this tutorial, you learn how to increase the availability and reliability of your Virtual Machine solutions on Azure using a capability called Availability Sets. Availability sets ensure that the VMs you deploy on Azure are distributed across multiple isolated hardware clusters. Doing this ensures that if a hardware or software failure within Azure happens, only a subset of your VMs is impacted and that your overall solution remains available and operational.

In this tutorial, you learn how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes

This tutorial uses the CLI within the [Azure Cloud Shell](#), which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create an availability set

You can create an availability set using `az vm availability-set create`. In this example, the number of update and fault domains is set to 2 for the availability set named *myAvailabilitySet* in the *myResourceGroupAvailability* resource group.

First, create a resource group with [az group create](#), then create the availability set:

```
az group create --name myResourceGroupAvailability --location eastus

az vm availability-set create \
    --resource-group myResourceGroupAvailability \
    --name myAvailabilitySet \
    --platform-fault-domain-count 2 \
    --platform-update-domain-count 2
```

Availability Sets allow you to isolate resources across fault domains and update domains. A **fault domain** represents an isolated collection of server + network + storage resources. In the preceding example, the availability set is distributed across at least two fault domains when the VMs are deployed. The availability set is also distributed across two **update domains**. Two update domains ensure that when Azure performs software updates, the VM resources are isolated, preventing all the software that runs on the VM from being updated at the same time.

## Create VMs inside an availability set

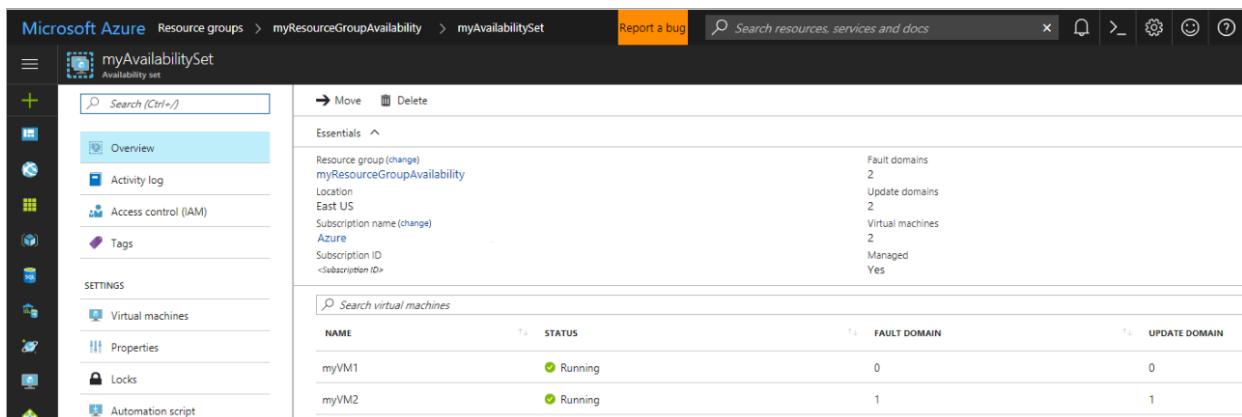

VMs must be created within the availability set to make sure they are correctly distributed across the hardware. An existing VM cannot be added to an availability set after it is created.

When a VM is created with [az vm create](#), use the `--availability-set` parameter to specify the name of the availability set.

```
for i in `seq 1 2`; do
    az vm create \
        --resource-group myResourceGroupAvailability \
        --name myVM$i \
        --availability-set myAvailabilitySet \
        --size Standard_DS1_v2 \
        --vnet-name myVnet \
        --subnet mySubnet \
        --image UbuntuLTS \
        --admin-username azureuser \
        --generate-ssh-keys
done
```

There are now two virtual machines within the availability set. Because they are in the same availability set, Azure ensures that the VMs and all their resources (including data disks) are distributed across isolated physical hardware. This distribution helps ensure much higher availability of the overall VM solution.

The availability set distribution can be viewed in the portal by going to Resource Groups > myResourceGroupAvailability > myAvailabilitySet. The VMs are distributed across the two fault and update domains, as shown in the following example:

NAME	STATUS	FAULT DOMAIN	UPDATE DOMAIN
myVM1	Running	0	0
myVM2	Running	1	1

## Check for available VM sizes

Additional VMs can be added to the availability set later, where VM sizes are available on the hardware. Use [az vm availability-set list-sizes](#) to list all the available sizes on the hardware cluster for the availability set:

```
az vm availability-set list-sizes \
    --resource-group myResourceGroupAvailability \
    --name myAvailabilitySet \
    --output table
```

## Next steps

In this tutorial, you learned how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes

Advance to the next tutorial to learn about virtual machine scale sets.

[Create a virtual machine scale set](#)

- To learn more about availability zones, visit the [Availability Zones documentation](#).
- More documentation about both availability sets and availability zones is also available at [Availability options for Azure Virtual Machines](#).
- To try out availability zones, visit [Create a Linux virtual machine in an availability zone with the Azure CLI](#)

# Create and deploy virtual machines in an availability set using Azure PowerShell

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this tutorial, you learn how to increase the availability and reliability of your Virtual Machines (VMs) using Availability Sets. Availability Sets make sure the VMs you deploy on Azure are distributed across multiple, isolated hardware nodes, in a cluster.

In this tutorial, you learn how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes
- Check Azure Advisor

## Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to <https://shell.azure.com/powershell>. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

## Create an availability set

The hardware in a location is divided in to multiple update domains and fault domains. An **update domain** is a group of VMs and underlying physical hardware that can be rebooted at the same time. VMs in the same **fault domain** share common storage as well as a common power source and network switch.

You can create an availability set using [New-AzAvailabilitySet](#). In this example, the number of both update and fault domains is 2 and the availability set is named *myAvailabilitySet*.

Create a resource group.

```
New-AzResourceGroup ` 
-Name myResourceGroupAvailability ` 
-Location EastUS
```

Create a managed availability set using [New-AzAvailabilitySet](#) with the `-sku aligned` parameter.

```
New-AzAvailabilitySet ` 
-Location "EastUS" ` 
-Name "myAvailabilitySet" ` 
-ResourceGroupName "myResourceGroupAvailability" ` 
-Sku aligned ` 
-PlatformFaultDomainCount 2 ` 
-PlatformUpdateDomainCount 2
```

# Create VMs inside an availability set

VMs must be created within the availability set to make sure they're correctly distributed across the hardware. You can't add an existing VM to an availability set after it's created.

When you create a VM with [New-AzVM](#), you use the `-AvailabilitySetName` parameter to specify the name of the availability set.

First, set an administrator username and password for the VM with [Get-Credential](#):

```
$cred = Get-Credential
```

Now create two VMs with [New-AzVM](#) in the availability set.

```
for ($i=1; $i -le 2; $i++)
{
    New-AzVm ` 
        -ResourceGroupName "myResourceGroupAvailability" ` 
        -Name "myVM$i" ` 
        -Location "East US" ` 
        -VirtualNetworkName "myVnet" ` 
        -SubnetName "mySubnet" ` 
        -SecurityGroupName "myNetworkSecurityGroup" ` 
        -PublicIpAddressName "myPublicIpAddress$i" ` 
        -AvailabilitySetName "myAvailabilitySet" ` 
        -Credential $cred
}
```

It takes a few minutes to create and configure both VMs. When finished, you have two virtual machines distributed across the underlying hardware.

If you look at the availability set in the portal by going to **Resource Groups > myResourceGroupAvailability > myAvailabilitySet**, you should see how the VMs are distributed across the two fault and update domains.

The screenshot shows the Azure portal interface for managing an availability set. The top navigation bar includes 'Microsoft Azure', 'Resource groups', 'myResourceGroupAvailability', 'myAvailabilitySet', and a search bar. The main content area displays the 'myAvailabilitySet' details under the 'Essentials' tab. It lists the resource group as 'myResourceGroupAvailability', location as 'East US', subscription name as 'Azure', and subscription ID as '<Subscription ID>'. It also indicates 'Fault domains: 2', 'Update domains: 2', 'Virtual machines: 2', and 'Managed: Yes'. Below this, a table titled 'Search virtual machines' lists two entries: 'myVM1' and 'myVM2', both marked as 'Running'. The table includes columns for NAME, STATUS, FAULT DOMAIN, and UPDATE DOMAIN.

NAME	STATUS	FAULT DOMAIN	UPDATE DOMAIN
myVM1	Running	0	0
myVM2	Running	1	1

#### NOTE

Under certain circumstances, 2 VMs in the same AvailabilitySet could share the same FaultDomain. This can be confirmed by going into your availability set and checking the Fault Domain column. This can be caused by the following sequence of events while deploying the VMs:

1. The 1st VM is Deployed
2. The 1st VM is Stopped/Deallocated
3. The 2nd VM is Deployed. Under these circumstances, the OS Disk of the 2nd VM might be created on the same Fault Domain as the 1st VM, and so the 2nd VM will also land on the same FaultDomain. To avoid this issue, it's recommended to not stop/deallocate the VMs between deployments.

## Check for available VM sizes

When you create a VM inside a availability set, you need to know what VM sizes are available on the hardware. Use [Get-AzVMSize](#) command to get all available sizes for virtual machines that you can deploy in the availability set.

```
Get-AzVMSize ` 
    -ResourceGroupName "myResourceGroupAvailability" ` 
    -AvailabilitySetName "myAvailabilitySet"
```

## Check Azure Advisor

You can also use Azure Advisor to get more information on how to improve the availability of your VMs. Azure Advisor analyzes your configuration and usage telemetry, then recommends solutions that can help you improve the cost effectiveness, performance, availability, and security of your Azure resources.

Sign in to the [Azure portal](#), select **All services**, and type **Advisor**. The Advisor dashboard shows personalized recommendations for the selected subscription. For more information, see [Get started with Azure Advisor](#).

## Next steps

In this tutorial, you learned how to:

- Create an availability set
- Create a VM in an availability set
- Check available VM sizes
- Check Azure Advisor

Advance to the next tutorial to learn about virtual machine scale sets.

[Create a VM scale set](#)

# Change the availability set for a VM using Azure PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

The following steps describe how to change the availability set of a VM using Azure PowerShell. A VM can only be added to an availability set when it is created. To change the availability set, you need to delete and then recreate the virtual machine.

This article was last tested on 2/12/2019 using the [Azure Cloud Shell](#) and the [Az PowerShell module](#) version 1.2.0.

## WARNING

This is just an example and in some cases it will need to be updated for your specific deployment.

Make sure the disks are set to `detach` as the `delete` option. If they are set to `delete`, update the VMs before deleting the VMs.

If your VM is attached to a load balancer, you will need to update the script to handle that case.

Some extensions may also need to be reinstalled after you finish this process.

If your VM uses hybrid benefits, you will need to update the example to enable hybrid benefits on the new VM.

## Change the availability set

The following script provides an example of gathering the required information, deleting the original VM and then recreating it in a new availability set.

```
# Set variables
$resourceGroup = "myResourceGroup"
$vmName = "myVM"
$newAvailSetName = "myAvailabilitySet"

# Get the details of the VM to be moved to the Availability Set
$originalVM = Get-AzVM `-
    -ResourceGroupName $resourceGroup `-
    -Name $vmName

# Create new availability set if it does not exist
$availSet = Get-AzAvailabilitySet `-
    -ResourceGroupName $resourceGroup `-
    -Name $newAvailSetName `-
    -ErrorAction Ignore
if (-Not $availSet) {
    $availSet = New-AzAvailabilitySet `-
        -Location $originalVM.Location `-
        -Name $newAvailSetName `-
        -ResourceGroupName $resourceGroup `-
        -PlatformFaultDomainCount 2 `-
        -PlatformUpdateDomainCount 2 `-
        -Sku Aligned
}

# Remove the original VM
```

```

Remove-AzVM -ResourceGroupName $resourceGroup -Name $vmName

# Create the basic configuration for the replacement VM.
$newVM = New-AzVMConfig ` 
    -VMName $originalVM.Name ` 
    -VmSize $originalVM.HardwareProfile.VmSize ` 
    -AvailabilitySetId $availSet.Id

# For a Linux VM, change the last parameter from -Windows to -Linux
Set-AzVMOSDisk ` 
    -VM $newVM -CreateOption Attach ` 
    -ManagedDiskId $originalVM.StorageProfile.OsDisk.ManagedDisk.Id ` 
    -Name $originalVM.StorageProfile.OsDisk.Name ` 
    -Windows

# Add Data Disks
foreach ($disk in $originalVM.StorageProfile.DataDisks) {
    Add-AzVMDisk -VM $newVM ` 
        -Name $disk.Name ` 
        -ManagedDiskId $disk.ManagedDisk.Id ` 
        -Caching $disk.Caching ` 
        -Lun $disk.Lun ` 
        -DiskSizeInGB $disk.DiskSizeGB ` 
        -CreateOption Attach
}

# Add NIC(s) and keep the same NIC as primary; keep the Private IP too, if it exists.
foreach ($nic in $originalVM.NetworkProfile.NetworkInterfaces) {
    if ($nic.Primary -eq "True")
    {
        Add-AzVMNetworkInterface ` 
            -VM $newVM ` 
            -Id $nic.Id -Primary
    }
    else
    {
        Add-AzVMNetworkInterface ` 
            -VM $newVM ` 
            -Id $nic.Id
    }
}

# Recreate the VM
New-AzVM ` 
    -ResourceGroupName $resourceGroup ` 
    -Location $originalVM.Location ` 
    -VM $newVM ` 
    -DisableBginfoExtension

```

## Next steps

Add additional storage to your VM by adding an additional [data disk](#).

# Introduction to Azure managed disks

9/21/2022 • 12 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure managed disks are block-level storage volumes that are managed by Azure and used with Azure Virtual Machines. Managed disks are like a physical disk in an on-premises server but, virtualized. With managed disks, all you have to do is specify the disk size, the disk type, and provision the disk. Once you provision the disk, Azure handles the rest.

The available types of disks are ultra disks, premium solid-state drives (SSD), standard SSDs, and standard hard disk drives (HDD). For information about each individual disk type, see [Select a disk type for IaaS VMs](#).

## Benefits of managed disks

Let's go over some of the benefits you gain by using managed disks.

### Highly durable and available

Managed disks are designed for 99.999% availability. Managed disks achieve this by providing you with three replicas of your data, allowing for high durability. If one or even two replicas experience issues, the remaining replicas help ensure persistence of your data and high tolerance against failures. This architecture has helped Azure consistently deliver enterprise-grade durability for infrastructure as a service (IaaS) disks, with an industry-leading ZERO% annualized failure rate.

### Simple and scalable VM deployment

Using managed disks, you can create up to 50,000 VM **disks** of a type in a subscription per region, allowing you to create thousands of **VMs** in a single subscription. This feature also further increases the scalability of [virtual machine scale sets](#) by allowing you to create up to 1,000 VMs in a virtual machine scale set using a Marketplace image.

### Integration with availability sets

Managed disks are integrated with availability sets to ensure that the disks of [VMs in an availability set](#) are sufficiently isolated from each other to avoid a single point of failure. Disks are automatically placed in different storage scale units (stamps). If a stamp fails due to hardware or software failure, only the VM instances with disks on those stamps fail. For example, let's say you have an application running on five VMs, and the VMs are in an Availability Set. The disks for those VMs won't all be stored in the same stamp, so if one stamp goes down, the other instances of the application continue to run.

### Integration with Availability Zones

Managed disks support [Availability Zones](#), which is a high-availability offering that protects your applications from datacenter failures. Availability Zones are unique physical locations within an Azure region. Each zone is made up of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there's a minimum of three separate zones in all enabled regions. With Availability Zones, Azure offers industry best 99.99% VM uptime SLA.

### Azure Backup support

To protect against regional disasters, [Azure Backup](#) can be used to create a backup job with time-based backups and backup retention policies. This allows you to perform VM or managed disk restorations at will. Currently Azure Backup supports disk sizes up to 32 tebibyte (TiB) disks. [Learn more](#) about Azure VM backup support.

### Azure Disk Backup

Azure Backup offers Azure Disk Backup (preview) as a native, cloud-based backup solution that protects your data in managed disks. It's a simple, secure, and cost-effective solution that enables you to configure protection for managed disks in a few steps. Azure Disk Backup offers a turnkey solution that provides snapshot lifecycle management for managed disks by automating periodic creation of snapshots and retaining it for configured duration using backup policy. For details on Azure Disk Backup, see [Overview of Azure Disk Backup \(in preview\)](#).

## Granular access control

You can use [Azure role-based access control \(Azure RBAC\)](#) to assign specific permissions for a managed disk to one or more users. Managed disks expose a variety of operations, including read, write (create/update), delete, and retrieving a [shared access signature \(SAS\) URI](#) for the disk. You can grant access to only the operations a person needs to perform their job. For example, if you don't want a person to copy a managed disk to a storage account, you can choose not to grant access to the export action for that managed disk. Similarly, if you don't want a person to use an SAS URI to copy a managed disk, you can choose not to grant that permission to the managed disk.

## Upload your vhd

Direct upload makes it easy to transfer your vhd to an Azure managed disk. Previously, you had to follow a more involved process that included staging your data in a storage account. Now, there are fewer steps. It is easier to upload on premises VMs to Azure, upload to large managed disks, and the backup and restore process is simplified. It also reduces cost by allowing you to upload data to managed disks directly without attaching them to VMs. You can use direct upload to upload vhds up to 32 TiB in size.

To learn how to transfer your vhd to Azure, see the [CLI](#) or [PowerShell](#) articles.

# Security

## Private Links

Private Link support for managed disks can be used to import or export a managed disk internal to your network. Private Links allow you to generate a time bound Shared Access Signature (SAS) URI for unattached managed disks and snapshots that you can use to export the data to other regions for regional expansion, disaster recovery, and forensic analysis. You can also use the SAS URI to directly upload a VHD to an empty disk from on-premises. Now you can leverage [Private Links](#) to restrict the export and import of managed disks so that it can only occur within your Azure virtual network. Private Links allows you to ensure your data only travels within the secure Microsoft backbone network.

To learn how to enable Private Links for importing or exporting a managed disk, see the [CLI](#) or [Portal](#) articles.

## Encryption

Managed disks offer two different kinds of encryption. The first is Server Side Encryption (SSE), which is performed by the storage service. The second one is Azure Disk Encryption (ADE), which you can enable on the OS and data disks for your VMs.

### Server-side encryption

Server-side encryption provides encryption-at-rest and safeguards your data to meet your organizational security and compliance commitments. Server-side encryption is enabled by default for all managed disks, snapshots, and images, in all the regions where managed disks are available. (Temporary disks, on the other hand, are not encrypted by server-side encryption unless you enable encryption at host; see [Disk Roles: temporary disks](#)).

You can either allow Azure to manage your keys for you, these are platform-managed keys, or you can manage the keys yourself, these are customer-managed keys. Visit the [Server-side encryption of Azure Disk Storage](#) article for details.

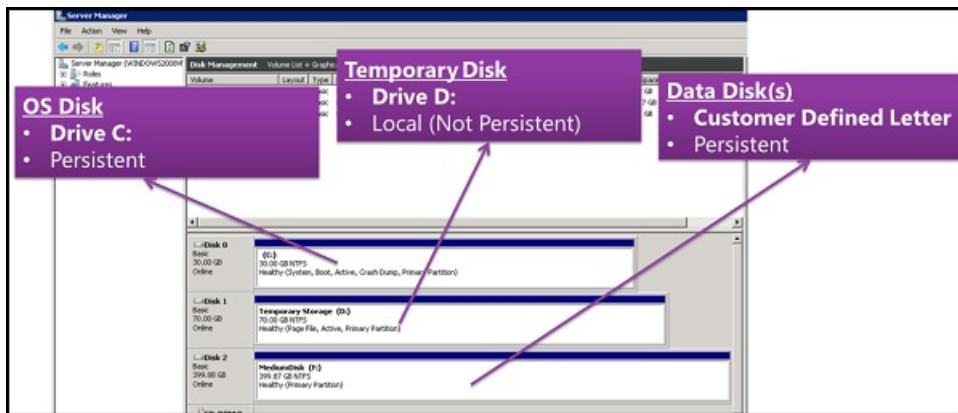

### Azure Disk Encryption

Azure Disk Encryption allows you to encrypt the OS and Data disks used by an IaaS Virtual Machine. This

encryption includes managed disks. For Windows, the drives are encrypted using industry-standard BitLocker encryption technology. For Linux, the disks are encrypted using the DM-Crypt technology. The encryption process is integrated with Azure Key Vault to allow you to control and manage the disk encryption keys. For more information, see [Azure Disk Encryption for Linux VMs](#) or [Azure Disk Encryption for Windows VMs](#).

## Disk roles

There are three main disk roles in Azure: the data disk, the OS disk, and the temporary disk. These roles map to disks that are attached to your virtual machine.

### Data disk

A data disk is a managed disk that's attached to a virtual machine to store application data, or other data you need to keep. Data disks are registered as SCSI drives and are labeled with a letter that you choose. Each data disk has a maximum capacity of 32,767 gibibytes (GiB). The size of the virtual machine determines how many data disks you can attach to it and the type of storage you can use to host the disks.

### OS disk

Every virtual machine has one attached operating system disk. That OS disk has a pre-installed OS, which was selected when the VM was created. This disk contains the boot volume.

This disk has a maximum capacity of 4,095 GiB, however, many operating systems are partitioned with [master boot record \(MBR\)](#) by default. MBR limits the usable size to 2 TiB. If you need more than 2 TiB, create and attach [data disks](#) and use them for data storage. If you need to store data on the OS disk and require the additional space, [convert it to GUID Partition Table \(GPT\)](#). To learn about the differences between MBR and GPT on Windows deployments, see [Windows and GPT FAQ](#).

### Temporary disk

Most VMs contain a temporary disk, which is not a managed disk. The temporary disk provides short-term storage for applications and processes, and is intended to only store data such as page or swap files. Data on the temporary disk may be lost during a [maintenance event](#) or when you [redeploy a VM](#). During a successful standard reboot of the VM, data on the temporary disk will persist. For more information about VMs without temporary disks, see [Azure VM sizes with no local temporary disk](#).

On Azure Linux VMs, the temporary disk is typically /dev/sdb and on Windows VMs the temporary disk is D: by default. The temporary disk is not encrypted by server side encryption unless you enable encryption at host.

## Managed disk snapshots

A managed disk snapshot is a read-only crash-consistent full copy of a managed disk that is stored as a standard managed disk by default. With snapshots, you can back up your managed disks at any point in time. These snapshots exist independent of the source disk and can be used to create new managed disks.

Snapshots are billed based on the used size. For example, if you create a snapshot of a managed disk with

provisioned capacity of 64 GiB and actual used data size of 10 GiB, that snapshot is billed only for the used data size of 10 GiB. You can see the used size of your snapshots by looking at the [Azure usage report](#). For example, if the used data size of a snapshot is 10 GiB, the **daily** usage report will show  $10 \text{ GiB}/(31 \text{ days}) = 0.3226$  as the consumed quantity.

To learn more about how to create snapshots for managed disks, see the [Create a snapshot of a managed disk](#) article.

## Images

Managed disks also support creating a managed custom image. You can create an image from your custom VHD in a storage account or directly from a generalized (sysprepped) VM. This process captures a single image. This image contains all managed disks associated with a VM, including both the OS and data disks. This managed custom image enables creating hundreds of VMs using your custom image without the need to copy or manage any storage accounts.

For information on creating images, see the following articles:

- [How to capture a managed image of a generalized VM in Azure](#)
- [How to generalize and capture a Linux virtual machine using the Azure CLI](#)

### Images versus snapshots

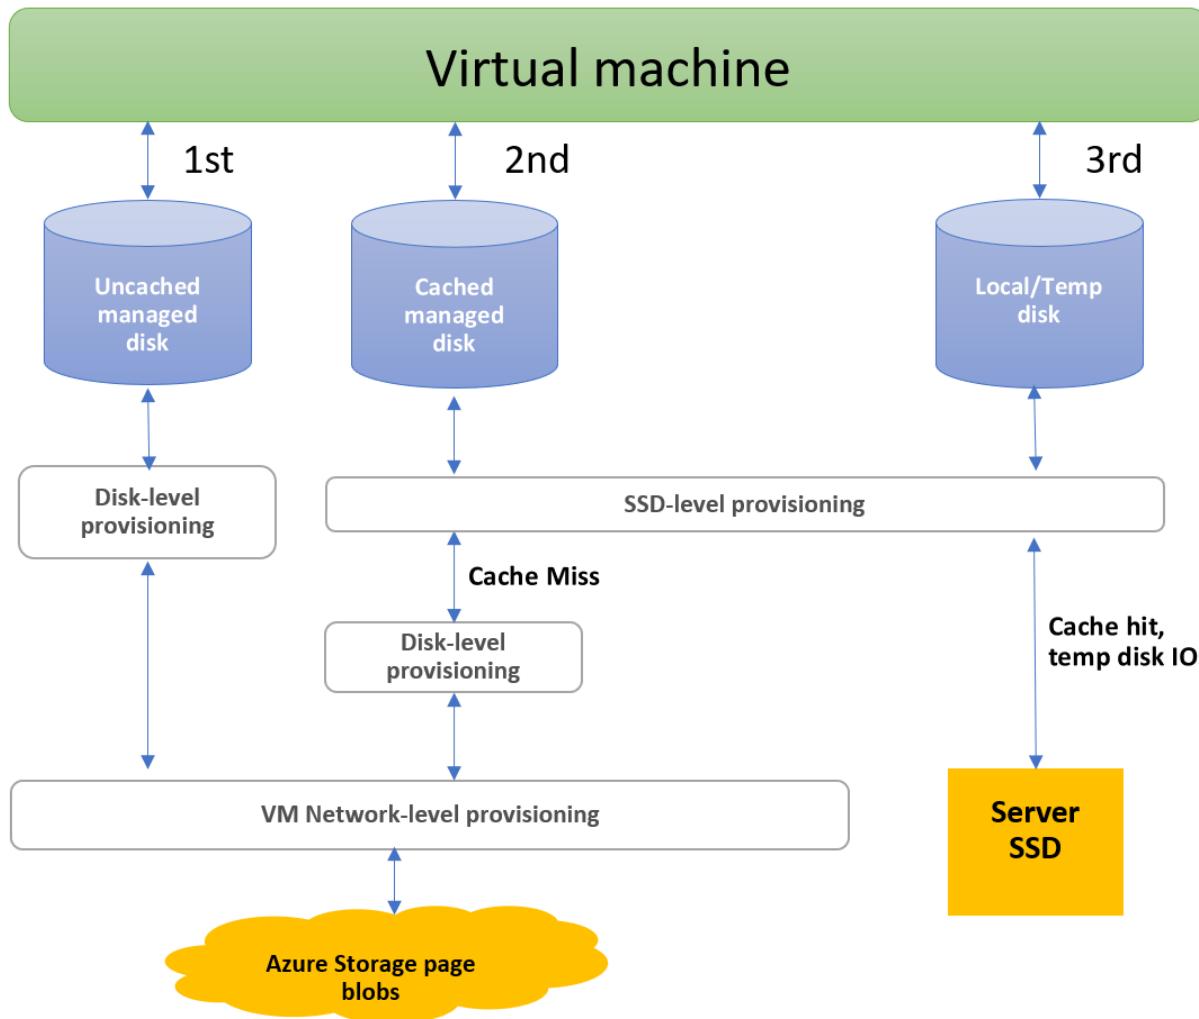

It's important to understand the difference between images and snapshots. With managed disks, you can take an image of a generalized VM that has been deallocated. This image includes all of the disks attached to the VM. You can use this image to create a VM, and it includes all of the disks.

A snapshot is a copy of a disk at the point in time the snapshot is taken. It applies only to one disk. If you have a VM that has one disk (the OS disk), you can take a snapshot or an image of it and create a VM from either the snapshot or the image.

A snapshot doesn't have awareness of any disk except the one it contains. This makes it problematic to use in scenarios that require the coordination of multiple disks, such as striping. Snapshots would need to be able to coordinate with each other and this is currently not supported.

## Disk allocation and performance

The following diagram depicts real-time allocation of bandwidth and IOPS for disks, with three different paths an IO can take:

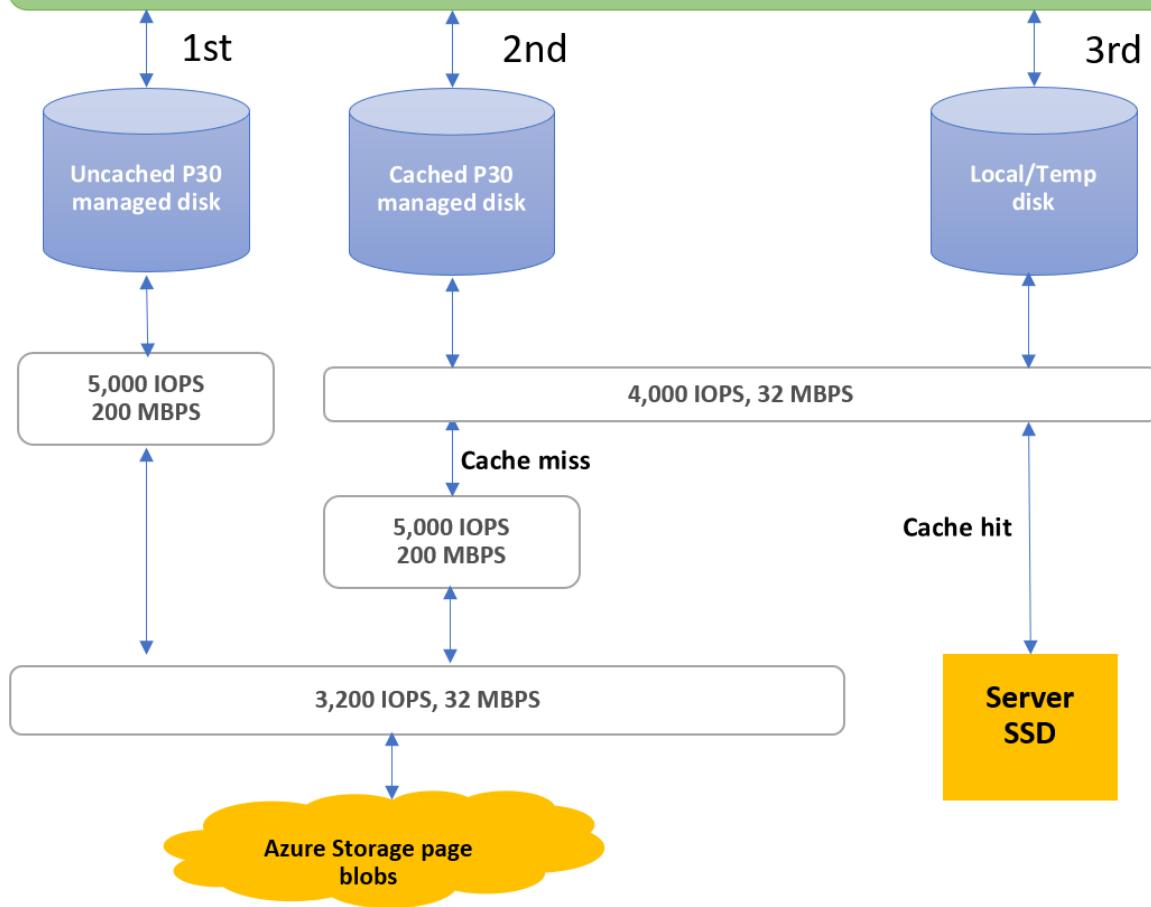

The first IO path is the uncached managed disk path. This path is taken if you are using a managed disk and set the host caching to none. An IO using this path will execute based on disk-level provisioning and then VM network-level provisioning for IOPs and throughput.

The second IO Path is the cached managed disk path. Cached managed disk IO uses an SSD close to the VM, which have their own IOPs and throughput provisioned, and is labeled SSD-level provisioning in the diagram. When a cached managed disk initiates a read, the request first checks to see if the data is in the server SSD. If the data isn't present, this creates a cached miss and the IO then executes based on SSD-level provisioning, disk-level provisioning and then VM network-level provisioning for IOPs and throughput. When the server SSD initiates reads on cached IO that are present on the server SSD, it creates a cache hit and the IO will then execute based on the SSD-level provisioning. Writes initiated by a cached managed disk always follow the path of a cached-miss, and need to go through SSD-level, disk-level, and VM network-level provisioning.

Finally, the third path is for the local/temp disk. This is available only on VMs that support local/temp disks. An IO using this path will execute based on SSD-Level Provisioning for IOPs and throughput.

As an example of these limitations, a Standard\_DS1v1 VM is prevented from achieving the 5,000 IOPS potential of a P30 disk, whether it is cached or not, because of limits at the SSD and network levels:

## Virtual machine: Standard\_DS1v1

Azure uses prioritized network channel for disk traffic, which gets the precedence over other low priority of network traffic. This helps disks maintain their expected performance in case of network contentions. Similarly, Azure Storage handles resource contentions and other issues in the background with automatic load balancing. Azure Storage allocates required resources when you create a disk, and applies proactive and reactive balancing of resources to handle the traffic level. This further ensures disks can sustain their expected IOPS and throughput targets. You can use the VM-level and Disk-level metrics to track the performance and setup alerts as needed.

Refer to our [design for high performance](#) article, to learn the best practices for optimizing VM + Disk configurations so that you can achieve your desired performance

## Next steps

If you'd like a video going into more detail on managed disks, check out: [Better Azure VM Resiliency with Managed Disks].

Learn more about the individual disk types Azure offers, which type is a good fit for your needs, and learn about their performance targets in our article on disk types.

[Select a disk type for IaaS VMs](#)

# Azure managed disk types

9/21/2022 • 18 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure managed disks currently offers five disk types, each intended to address a specific customer scenario:

- [Ultra disks](#)
- [Premium SSD v2 \(preview\)](#)
- [Premium SSDs \(solid-state drives\)](#)
- [Standard SSDs](#)
- [Standard HDDs \(hard disk drives\)](#)

## Disk type comparison

The following table provides a comparison of the five disk types to help you decide which to use.

	ULTRA DISK	PREMIUM SSD V2	PREMIUM SSD	STANDARD SSD	STANDARD HDD
Disk type	SSD	SSD	SSD	SSD	HDD
Scenario	IO-intensive workloads such as <a href="#">SAP HANA</a> , top tier databases (for example, SQL, Oracle), and other transaction-heavy workloads.	Production and performance-sensitive workloads that consistently require low latency and high IOPS and throughput	Production and performance sensitive workloads	Web servers, lightly used enterprise applications and dev/test	Backup, non-critical, infrequent access
Max disk size	65,536 gibibyte (GiB)	65,536 GiB	32,767 GiB	32,767 GiB	32,767 GiB
Max throughput	4,000 MB/s	1,200 MB/s	900 MB/s	750 MB/s	500 MB/s
Max IOPS	160,000	80,000	20,000	6,000	2,000
Usable as OS Disk?	No	No	Yes	Yes	Yes

## Ultra disks

Azure ultra disks are the highest-performing storage option for Azure virtual machines (VMs). You can change the performance parameters of an ultra disk without having to restart your VMs. Ultra disks are suited for data-intensive workloads such as SAP HANA, top-tier databases, and transaction-heavy workloads.

Ultra disks must be used as data disks and can only be created as empty disks. You should use Premium solid-state drives (SSDs) as operating system (OS) disks.

## Ultra disk size

Azure ultra disks offer up to 32-TiB per region per subscription by default, but ultra disks support higher capacity by request. To request an increase in capacity, request a quota increase or contact Azure Support.

The following table provides a comparison of disk sizes and performance caps to help you decide which to use.

DISK SIZE (GiB)	IOPS CAP	THROUGHPUT CAP (MBPS)
4	1,200	300
8	2,400	600
16	4,800	1,200
32	9,600	2,400
64	19,200	4,000
128	38,400	4,000
256	76,800	4,000
512	153,600	4,000
1,024-65,536 (sizes in this range increasing in increments of 1 TiB)	160,000	4,000

Ultra disks are designed to provide submillisecond latencies and target IOPS and throughput described in the preceding table 99.99% of the time.

## Ultra disk performance

Ultra disks feature a flexible performance configuration model that allows you to independently configure IOPS and throughput both before and after you provision the disk. Ultra disks come in several fixed sizes, ranging from 4 GiB up to 64 TiB.

### Ultra disk IOPS

Ultra disks support IOPS limits of 300 IOPS/GiB, up to a maximum of 160,000 IOPS per disk. To achieve the target IOPS for the disk, ensure that the selected disk IOPS are less than the VM IOPS limit.

The current maximum limit for IOPS for a single VM in generally available sizes is 80,000. Ultra disks with greater IOPS can be used as shared disks to support multiple VMs.

The minimum guaranteed IOPS per disk are 1 IOPS/GiB, with an overall baseline minimum of 100 IOPS. For example, if you provisioned a 4-GiB ultra disk, the minimum IOPS for that disk is 100, instead of four.

For more information about IOPS, see [Virtual machine and disk performance](#).

### Ultra disk throughput

The throughput limit of a single ultra disk is 256-KiB/s for each provisioned IOPS, up to a maximum of 4000 MBps per disk (where MBps =  $10^6$  Bytes per second). The minimum guaranteed throughput per disk is 4KiB/s for each provisioned IOPS, with an overall baseline minimum of 1 MBps.

You can adjust ultra disk IOPS and throughput performance at runtime without detaching the disk from the virtual machine. After a performance resize operation has been issued on a disk, it can take up to an hour for the change to take effect. Up to four performance resize operations are permitted during a 24-hour window.

It's possible for a performance resize operation to fail because of a lack of performance bandwidth capacity.

## Ultra disk limitations

Ultra disks can't be used as OS disks, they can only be created as empty data disks. Ultra disks also can't be used with some features and functionality, including disk snapshots, disk export, changing disk type, VM images, availability sets, Azure Dedicated Hosts, or Azure disk encryption. Azure Backup and Azure Site Recovery do not support ultra disks. In addition, only un-cached reads and un-cached writes are supported.

Ultra disks support a 4k physical sector size by default. A 512E sector size is available as a generally available offering with no sign-up required. While most applications are compatible with 4k sector sizes, some require 512 byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks. For older versions of Oracle DB, 512 byte sector size is required.

The only infrastructure redundancy options currently available to ultra disks are availability zones. VMs using any other redundancy options cannot attach an ultra disk.

The following table outlines the regions ultra disks are available in, as well as their corresponding availability options.

### NOTE

If a region in the following list lacks availability zones that support ultra disks, then a VM in that region must be deployed without infrastructure redundancy in order to attach an ultra disk.

REDUNDANCY OPTIONS	REGIONS
Single VMs	Australia Central Brazil South Central India East Asia Germany West Central Korea Central North Central US, South Central US, West US US Gov Arizona, US Gov Texas, US Gov Virginia
One availability zone	China North 3 Qatar Central
Two availability zones	France Central
Three availability zones	Australia East Canada Central North Europe, West Europe Japan East Southeast Asia Sweden Central UK South Central US, East US, East US 2, West US 2, West US 3

Not every VM size is available in every supported region with ultra disks. The following table lists VM series which are compatible with ultra disks.

VM TYPE	SIZES	DESCRIPTION
---------	-------	-------------

VM TYPE	SIZES	DESCRIPTION
General purpose	<a href="#">DSv3-series</a> , <a href="#">Ddsv4-series</a> , <a href="#">Dsv4-series</a> , <a href="#">Dasv4-series</a> , <a href="#">Dsv5-series</a> , <a href="#">Ddsv5-series</a> , <a href="#">Dasv5-series</a>	Balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.
Compute optimized	<a href="#">FSv2-series</a>	High CPU-to-memory ratio. Good for medium traffic web servers, network appliances, batch processes, and application servers.
Memory optimized	<a href="#">ESv3-series</a> , <a href="#">Easv4-series</a> , <a href="#">Edsv4-series</a> , <a href="#">Esv4-series</a> , <a href="#">Esv5-series</a> , <a href="#">Edsv5-series</a> , <a href="#">Easv5-series</a> , <a href="#">Ebsv5 series</a> , <a href="#">Ebdsv5 series</a> , <a href="#">M-series</a> , <a href="#">Mv2-series</a> , <a href="#">Msv2/Mdsv2-series</a>	High memory-to-CPU ratio. Great for relational database servers, medium to large caches, and in-memory analytics.
Storage optimized	<a href="#">LSv2-series</a>	High disk throughput and IO ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases.
GPU optimized	<a href="#">NCv2-series</a> , <a href="#">NCv3-series</a> , <a href="#">NCasT4_v3-series</a> , <a href="#">ND-series</a> , <a href="#">NDv2-series</a> , <a href="#">NVv3-series</a> , <a href="#">NVv4-series</a> , <a href="#">NVadsA10 v5-series</a>	Specialized virtual machines targeted for heavy graphic rendering and video editing, as well as model training and inferencing (ND) with deep learning. Available with single or multiple GPUs.
Performance optimized	<a href="#">HB-series</a> , <a href="#">HC-series</a> , <a href="#">HBv2-series</a>	The fastest and most powerful CPU virtual machines with optional high-throughput network interfaces (RDMA).

If you would like to start using ultra disks, see the article on [using Azure ultra disks](#).

## Premium SSD v2 (preview)

Azure Premium SSD v2 (preview) is designed for IO-intense enterprise workloads that require consistent sub-millisecond disk latencies and high IOPS and throughput at a low cost. The performance (capacity, throughput, and IOPS) of Premium SSD v2 disks can be independently configured at any time, making it easier for more scenarios to be cost efficient while meeting performance needs. For example, a transaction-intensive database workload may need a large amount of IOPS at a small size, or a gaming application may need a large amount of IOPS during peak hours. Premium SSD v2 is suited for a broad range of workloads such as SQL server, Oracle, MariaDB, SAP, Cassandra, Mongo DB, big data/analytics, and gaming, on virtual machines or stateful containers.

### Differences between Premium SSD and Premium SSD v2

Unlike Premium SSDs, Premium SSD v2 doesn't have dedicated sizes. You can set a Premium SSD v2 to any supported size you prefer, and make granular adjustments to the performance without downtime. Premium SSD v2 doesn't support host caching but, benefits significantly from lower latency which addresses some of the same core problems host caching addresses. The ability to adjust IOPS, throughput, and size at any time also means you can avoid the maintenance overhead of having to stripe disks to meet your needs.

### Premium SSD v2 limitations

- Premium SSD v2 disks can't be used as an OS disk.
- Currently, Premium SSD v2 disks can only be attached to zonal VMs.

- Currently, Premium SSD v2 disks can't be attached to VMs in virtual machine scale sets.
- Currently, taking snapshots aren't supported, and you can't create a Premium SSD v2 from the snapshot of another disk type.
- Currently, Premium SSD v2 disks can't be attached to VMs with encryption at host enabled.
- Currently, Premium SSD v2 disks can't be attached to VMs in Availability Sets.
- Azure Disk Encryption isn't supported for VMs with Premium SSD v2 disks.
- Azure Backup and Azure Site Recovery aren't supported for VMs with Premium SSD v2 disks.

#### **Regional availability**

Currently only available in the following regions:

- US East
- West Europe

#### **Premium SSD v2 performance**

With Premium SSD v2 disks, you can individually set the capacity, throughput, and IOPS of a disk based on your workload needs, providing you more flexibility and reduced costs. Each of these values determine the cost of your disk.

#### **Premium SSD v2 capacities**

Premium SSD v2 capacities range from 1 GiB to 64 TiBs, in 1-GiB increments. You're billed on a per GiB ratio, see the [pricing page](#) for details.

Premium SSD v2 offers up to 32 TiBs per region per subscription by default in the public preview, but supports higher capacity by request. To request an increase in capacity, request a quota increase or contact Azure Support.

#### **Premium SSD v2 IOPS**

All Premium SSD v2 disks have a baseline IOPS of 3000 that is free of charge. After 6 GiB, the maximum IOPS a disk can have increases at a rate of 500 per GiB, up to 80,000 IOPS. So an 8 GiB disk can have up to 4,000 IOPS, and a 10 GiB can have up to 5,000 IOPS. To be able to set 80,000 IOPS on a disk, that disk must have at least 160 GiBs. Increasing your IOPS beyond 3000 increases the price of your disk.

#### **Premium SSD v2 throughput**

All Premium SSD v2 disks have a baseline throughput of 125 MB/s, that is free of charge. After 6 GiB, the maximum throughput that can be set increases by 0.25 MB/s per set IOPS. If a disk has 3,000 IOPS, the max throughput it can set is 750 MB/s. To raise the throughput for this disk beyond 750 MB/s, its IOPS must be increased. For example, if you increased the IOPS to 4,000, then the max throughput that can be set is 1,000. 1,200 MB/s is the maximum throughput supported for disks that have 5,000 IOPS or more. Increasing your throughput beyond 125 increases the price of your disk.

#### **Premium SSD v2 Sector Sizes**

Premium SSD v2 supports a 4k physical sector size by default. A 512E sector size is also supported. While most applications are compatible with 4k sector sizes, some require 512-byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks. For older versions of Oracle DB, 512-byte sector size is required.

#### **Summary**

The following table provides a comparison of disk capacities and performance maximums to help you decide which to use.

DISK SIZE	MAXIMUM AVAILABLE IOPS	MAXIMUM AVAILABLE THROUGHPUT (MB/S)
1 GiB-64 TiBs	3,000-80,000 (Increases by 500 IOPS per GiB)	125-1,200 (increases by 0.25 MB/s per set IOPS)

To deploy a Premium SSD v2, see [Deploy a Premium SSD v2 \(preview\)](#).

## Premium SSDs

Azure Premium SSDs deliver high-performance and low-latency disk support for virtual machines (VMs) with input/output (IO)-intensive workloads. To take advantage of the speed and performance of Premium SSDs, you can migrate existing VM disks to Premium SSDs. Premium SSDs are suitable for mission-critical production applications, but you can use them only with compatible VM series.

To learn more about individual Azure VM types and sizes for Windows or Linux, including size compatibility for premium storage, see [Sizes for virtual machines in Azure](#). You'll need to check each individual VM size article to determine if it's premium storage-compatible.

### Premium SSD size

PRE MIU M SSD SIZ ES	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
Disk size in GiB	4	8	16	32	64	128	256	512	1,024	2,048	4,096	8,192	16,384	32,767
Provisioned IOPS per disk	120	120	120	120	240	500	1,100	2,300	5,000	7,500	7,500	16,000	18,000	20,000
Provisioned Throughput per disk	25 MB/sec	25 MB/sec	25 MB/sec	25 MB/sec	50 MB/sec	100 MB/sec	125 MB/sec	150 MB/sec	200 MB/sec	250 MB/sec	250 MB/sec	500 MB/sec	750 MB/sec	900 MB/sec
Max burst IOPS per disk	3,500	3,500	3,500	3,500	3,500	3,500	3,500	3,500	30,000*	30,000*	30,000*	30,000*	30,000*	30,000*

PRE MIU M SSD SIZ ES	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
Max burst throughput per disk	170 MB/sec	1,000 MB/sec*												
Max burst duration	30 min	Unlimited*	Unlimited*	Unlimited*	Unlimited*	Unlimited*	Unlimited*							
Eligible for reservation	No	Yes, up to one year												

\*Applies only to disks with on-demand bursting enabled.

Capacity, IOPS, and throughput are guaranteed when a premium storage disk is provisioned. For example, if you create a P50 disk, Azure provisions 4,095-GB storage capacity, 7,500 IOPS, and 250-MB/s throughput for that disk. Your application can use all or part of the capacity and performance. Premium SSDs are designed to provide the single-digit millisecond latencies, target IOPS, and throughput described in the preceding table 99.9% of the time.

### Premium SSD bursting

Premium SSDs offer disk bursting, which provides better tolerance on unpredictable changes of IO patterns. Disk bursting is especially useful during OS disk boot and for applications with spiky traffic. To learn more about how bursting for Azure disks works, see [Disk-level bursting](#).

### Premium SSD transactions

For Premium SSDs, each I/O operation less than or equal to 256 KiB of throughput is considered a single I/O operation. I/O operations larger than 256 KiB of throughput are considered multiple I/Os of size 256 KiB.

## Standard SSDs

Azure standard SSDs are optimized for workloads that need consistent performance at lower IOPS levels. They're an especially good choice for customers with varying workloads supported by on-premises hard disk drive (HDD) solutions. Compared to standard HDDs, standard SSDs deliver better availability, consistency, reliability, and latency. Standard SSDs are suitable for web servers, low IOPS application servers, lightly used enterprise applications, and non-production workloads. Like standard HDDs, standard SSDs are available on all Azure VMs.

## Standard SSD size

STAN NDAR DSSD SIZES	E1	E2	E3	E4	E6	E10	E15	E20	E30	E40	E50	E60	E70	E80
Disk size in GiB	4	8	16	32	64	128	256	512	1,024	2,048	4,096	8,192	16,384	32,767
IOPS per disk	Up to 500	Up to 2,000	Up to 4,000	Up to 6,000										
Throughput per disk	Up to 60 MB/sec	Up to 400 MB/sec	Up to 600 MB/sec	Up to 750 MB/sec										
Max burst IOPS per disk	600	600	600	600	600	600	600	600	1000					
Max burst throughput per disk	150 MB/sec	250 MB/sec												
Max burst duration	30 min													

Standard SSDs are designed to provide single-digit millisecond latencies and the IOPS and throughput up to the limits described in the preceding table 99% of the time. Actual IOPS and throughput may vary sometimes depending on the traffic patterns. Standard SSDs will provide more consistent performance than the HDD disks with the lower latency.

## Standard SSD transactions

For standard SSDs, each I/O operation less than or equal to 256 KiB of throughput is considered a single I/O operation. I/O operations larger than 256 KiB of throughput are considered multiple I/Os of size 256 KiB. These transactions incur a billable cost.

### Standard SSD Bursting

Standard SSDs offer disk bursting, which provides better tolerance for the unpredictable IO pattern changes. OS boot disks and applications prone to traffic spikes will both benefit from disk bursting. To learn more about how bursting for Azure disks works, see [Disk-level bursting](#).

## Standard HDDs

Azure standard HDDs deliver reliable, low-cost disk support for VMs running latency-tolerant workloads. With standard storage, your data is stored on HDDs, and performance may vary more widely than that of SSD-based disks. Standard HDDs are designed to deliver write latencies of less than 10 ms and read latencies of less than 20 ms for most IO operations. Actual performance may vary depending on IO size and workload pattern, however. When working with VMs, you can use standard HDD disks for dev/test scenarios and less critical workloads. Standard HDDs are available in all Azure regions and can be used with all Azure VMs.

### Standard HDD size

STANDARD DISK TYPE	S4	S6	S10	S15	S20	S30	S40	S50	S60	S70	S80
Disk size in GiB	32	64	128	256	512	1,024	2,048	4,096	8,192	16,384	32,767
IOPS per disk	Up to 500	Up to 1,300	Up to 2,000	Up to 2,000							
Throughput per disk	Up to 60 MB/sec	Up to 300 MB/sec	Up to 500 MB/sec	Up to 500 MB/sec							

### Standard HDD Transactions

For Standard HDDs, each I/O operation is considered as a single transaction, whatever the I/O size. These transactions have a billing impact.

## Billing

When using managed disks, the following billing considerations apply:

- Disk type
- Managed disk Size
- Snapshots
- Outbound data transfers
- Number of transactions

**Managed disk size:** Managed disks are billed according to their provisioned size. Azure maps the provisioned size (rounded up) to the nearest offered disk size. For details of the disk sizes offered, see the previous tables. Each disk maps to a supported provisioned disk-size offering and is billed accordingly. For example, if you provisioned a 200-GiB standard SSD, it maps to the disk size offer of E15 (256 GiB). Billing for any provisioned

disk is prorated hourly by using the monthly price for the storage offering. For example, you provision an E10 disk and delete it after 20 hours of use. In this case, you're billed for the E10 offering prorated to 20 hours, regardless of the amount of data written to the disk.

**Snapshots:** Snapshots are billed based on the size used. For example, you create a snapshot of a managed disk with provisioned capacity of 64 GiB and actual used data size of 10 GiB. In this case, the snapshot is billed only for the used data size of 10 GiB.

For more information on snapshots, see the section on snapshots in the [managed disk overview](#).

**Outbound data transfers:** [Outbound data transfers](#) (data going out of Azure data centers) incur billing for bandwidth usage.

**Transactions:** You're billed for the number of transactions performed on a standard managed disk. For standard SSDs, each I/O operation less than or equal to 256 KiB of throughput is considered a single I/O operation. I/O operations larger than 256 KiB of throughput are considered multiple I/Os of size 256 KiB. For Standard HDDs, each IO operation is considered a single transaction, whatever the I/O size.

For detailed information on pricing for managed disks (including transaction costs), see [Managed Disks Pricing](#).

### Ultra disks VM reservation fee

Azure VMs have the capability to indicate if they're compatible with ultra disks. An ultra disk-compatible VM allocates dedicated bandwidth capacity between the compute VM instance and the block storage scale unit to optimize the performance and reduce latency. When you add this capability on the VM, it results in a reservation charge. The reservation charge is only imposed if you enabled ultra disk capability on the VM without an attached ultra disk. When an ultra disk is attached to the ultra disk compatible VM, the reservation charge wouldn't be applied. This charge is per vCPU provisioned on the VM.

#### NOTE

For [constrained core VM sizes](#), the reservation fee is based on the actual number of vCPUs and not the constrained cores. For Standard\_E32-8s\_v3, the reservation fee will be based on 32 cores.

Refer to the [Azure Disks pricing page](#) for ultra disk pricing details.

### Azure disk reservation

Disk reservation provides you a discount on the advance purchase of one year's of disk storage, reducing your total cost. When you purchase a disk reservation, you select a specific disk SKU in a target region. For example, you may choose five P30 (1 TiB) Premium SSDs in the Central US region for a one year term. The disk reservation experience is similar to Azure reserved VM instances. You can bundle VM and Disk reservations to maximize your savings. For now, Azure Disks Reservation offers one year commitment plan for Premium SSD SKUs from P30 (1 TiB) to P80 (32 TiB) in all production regions. For more information about reserved disks pricing, see [Azure Disks pricing page](#).

## Next steps

See [Managed Disks pricing](#) to get started.

# Redundancy options for managed disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure managed disks offer two storage redundancy options, zone-redundant storage (ZRS), and locally-redundant storage. ZRS provides higher availability for managed disks than locally-redundant storage (LRS) does. However, the write latency for LRS disks is better than ZRS disks because LRS disks synchronously write data to three copies in a single data center.

## Locally-redundant storage for managed disks

Locally-redundant storage (LRS) replicates your data three times within a single data center in the selected region. LRS protects your data against server rack and drive failures. To protect an LRS disk from a zonal failure like a natural disaster or other issues, take the following steps:

- Use applications that can synchronously write data to two zones, and automatically failover to another zone during a disaster.
  - An example would be SQL Server Always On.
- Take frequent backups of LRS disks with ZRS snapshots.
- Enable cross-zone disaster recovery for LRS disks via [Azure Site Recovery](#). However, cross-zone disaster recovery doesn't provide zero Recovery Point Objective (RPO).

If your workflow doesn't support application-level synchronous writes across zones, or your application must meet zero RPO, then ZRS disks would ideal.

## Zone-redundant storage for managed disks

Zone-redundant storage (ZRS) synchronously replicates your Azure managed disk across three Azure availability zones in the region you select. Each availability zone is a separate physical location with independent power, cooling, and networking.

A ZRS disk lets you recover from failures in availability zones. If a zone went down, a ZRS disk can be attached to a virtual machine (VM) in a different zone. ZRS disks can also be shared between VMs for improved availability with clustered or distributed applications like SQL FCI, SAP ASCS/SCS, or GFS2. A shared ZRS disk can be attached to primary and secondary VMs in different zones to take advantage of both ZRS and [availability zones](#). If your primary zone fails, you can quickly fail over to the secondary VM using [SCSI persistent reservation](#).

For more information on ZRS disks, see [Zone Redundant Storage \(ZRS\) option for Azure Disks for high availability](#).

### Billing implications

For details see the [Azure pricing page](#).

### Comparison with other disk types

Except for more write latency, disks using ZRS are identical to disks using LRS, they have the same scale targets. [Benchmark your disks](#) to simulate the workload of your application and compare the latency between LRS and ZRS disks.

### Limitations

ZRS for managed disks have the following restrictions:

- Only supported with premium solid-state drives (SSD) and standard SSDs.
- Currently available only in the West US 2, West Europe, North Europe, and France Central regions.

## Next steps

- To learn how to create a ZRS disk, see [Deploy a ZRS managed disk](#).

# Deploy a managed disk that uses zone-redundant storage

9/21/2022 • 6 minutes to read • [Edit Online](#)

This article covers how to deploy a disk that uses zone-redundant storage (ZRS) as a redundancy option. ZRS replicates your Azure managed disk synchronously across three Azure availability zones in the selected region. Each availability zone is a separate physical location with independent power, cooling, and networking.

For conceptual information on ZRS, see [Zone-redundant storage for managed disks](#)

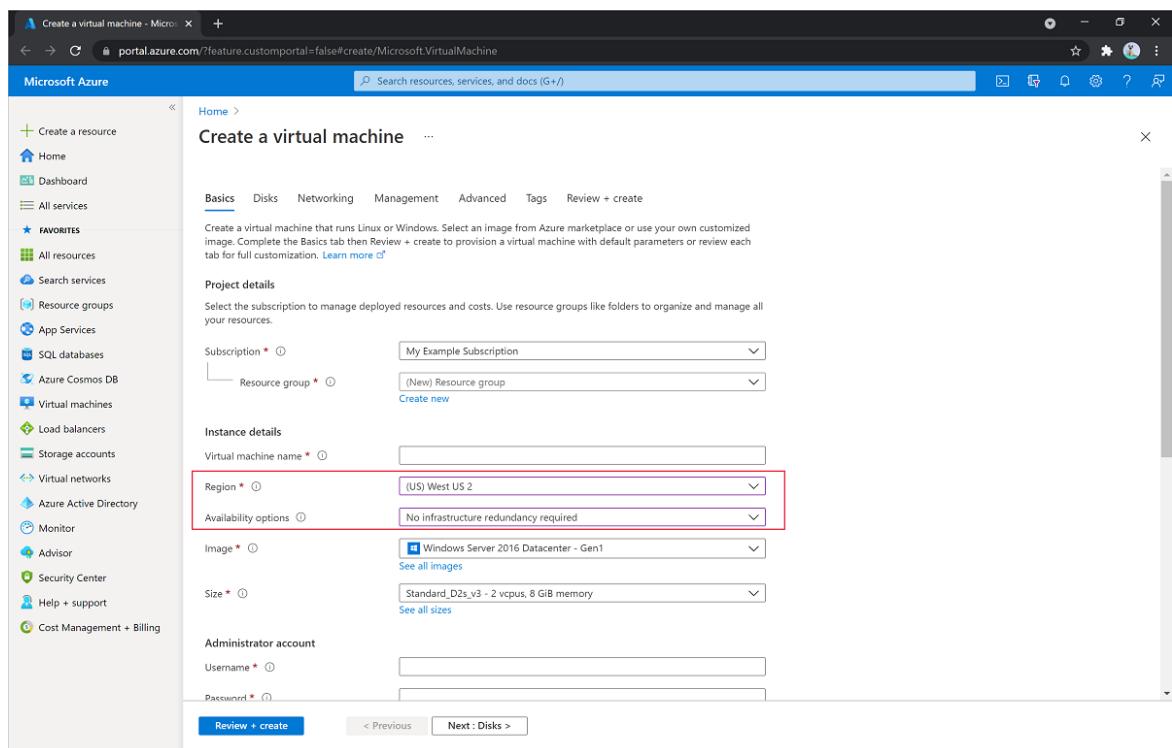

## Limitations

ZRS for managed disks have the following restrictions:

- Only supported with premium solid-state drives (SSD) and standard SSDs.
- Currently available only in the West US 2, West Europe, North Europe, and France Central regions.
- [Azure portal](#)
- [Azure CLI](#)
- [Azure PowerShell](#)
- [Resource Manager Template](#)

## Create a VM with a ZRS OS disk

1. Sign in to the [Azure portal](#).
2. Navigate to **Virtual machines** and follow the normal VM creation process.
3. Select a supported region and set **Availability options** to **No infrastructure redundancy required**.

4. Proceed to the **Disks** pane.

- Select your disk and select one of the ZRS disks in the drop-down.

**Create a virtual machine**

Basics Disks Networking Management Advanced Tags Review + create

Azure VMs have one operating system disk and a temporary disk for short-term storage. You can attach additional data disks. The size of the VM determines the type of storage you can use and the number of data disks allowed. [Learn more](#)

**Disk options**

OS disk type *	Premium SSD (locally-redundant storage)
Encryption type *	Locally-redundant storage (data is replicated within a single datacenter)
Enable Ultra Disk compatibility	Premium SSD Best for production and performance sensitive workloads
Data disks	Standard SSD Best for web servers, lightly used enterprise applications and dev/test
You can add and configure additional data disks or temporary disk.	Standard HDD Best for backup, non-critical, and infrequent access
LUN Name	Zone-redundant storage (data is replicated within multiple datacenters)
Create and attach a new disk	Premium SSD Best for the production workloads that need storage resiliency against zone failures
Advanced	Standard SSD Best for web servers, lightly used enterprise applications and dev/test that need storage resiliency against zone failures

- Proceed through the rest of the VM deployment, making any choices that you desire.

You've now deployed a VM with a ZRS OS disk.

### Create a ZRS disk

- In the Azure portal, search for and select **Disks**.
- Select **+ Add** to create a new disk.
- Select a supported region and **Availability zone** to **None**.
- Select **Change size**.

Subscription *	My Example Subscription
Resource group *	<input type="text"/> Create new
<b>Disk details</b>	
Disk name *	<input type="text"/>
Region *	(US) West US 2
Availability zone	None
Source type	None
Size *	1024 GiB Premium SSD LRS <a href="#">Change size</a>

- Select one of the available ZRS disks and select **OK**.

Disk SKU ⓘ

Premium SSD (locally-redundant storage) ^

Locally-redundant storage (data is replicated within a single datacenter)

Premium SSD

Best for production and performance sensitive workloads

Standard SSD

Best for web servers, lightly used enterprise applications and dev/test

Standard HDD

Best for backup, non-critical, and infrequent access

Zone-redundant storage (data is replicated within multiple datacenters)

Premium SSD

Best for the production workloads that need storage resiliency against zone failures

Standard SSD

Best for web servers, lightly used enterprise applications and dev/test that need storage resiliency against zone failures

6. Continue through the deployment process.

You have now created a managed disk that uses ZRS.

## Next steps

- Check out more [Azure Resource Manager templates to create a VM with ZRS disks](#).

# Share an Azure managed disk

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure shared disks is a feature for Azure managed disks that allow you to attach a managed disk to multiple virtual machines (VMs) simultaneously. Attaching a managed disk to multiple VMs allows you to either deploy new or migrate existing clustered applications to Azure.

## How it works

VMs in the cluster can read or write to their attached disk based on the reservation chosen by the clustered application using [SCSI Persistent Reservations](#) (SCSI PR). SCSI PR is an industry standard used by applications running on Storage Area Network (SAN) on-premises. Enabling SCSI PR on a managed disk allows you to migrate these applications to Azure as-is.

Shared managed disks offer shared block storage that can be accessed from multiple VMs, these are exposed as logical unit numbers (LUNs). LUNs are then presented to an initiator (VM) from a target (disk). These LUNs look like direct-attached-storage (DAS) or a local drive to the VM.

Shared managed disks don't natively offer a fully managed file system that can be accessed using SMB/NFS. You need to use a cluster manager, like Windows Server Failover Cluster (WSFC), or Pacemaker, that handles cluster node communication and write locking.

## Limitations

### General limitations

Enabling shared disks is only available to a subset of disk types. Currently only ultra disks, premium SSD v2 (preview), premium SSDs, and standard SSDs can enable shared disks. Shared disks can be attached to individual VMSS instances but can't be defined in the VMSS models or automatically deployed.

Each managed disk that has shared disks enabled are also subject to the following limitations, organized by disk type:

### Ultra disks

Ultra disks have their own separate list of limitations, unrelated to shared disks. For ultra disk limitations, refer to [Using Azure ultra disks](#).

When sharing ultra disks, they have the following additional limitations:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Can't be shared across availability zones.

### Premium SSD v2 (preview)

Premium SSD v2 disks have their own separate list of limitations, unrelated to shared disks. For these limitations, see [Premium SSD v2 limitations](#).

When sharing Premium SSD v2 disks, they have the following additional limitation:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).

- Can't be shared across availability zones.

## Premium SSD

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for premium SSD disks with `maxShares>1`.
- Disk bursting isn't available for premium SSD disks with `maxShares>1`.
- When using Availability sets or virtual machine scale sets with Azure shared disks, [storage fault domain alignment](#) with virtual machine fault domain isn't enforced for the shared data disk.
- When using [proximity placement groups \(PPG\)](#), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through [Azure Disk Backup](#).
- Only [server-side encryption](#) is supported, [Azure Disk Encryption](#) isn't currently supported.
- Can only be shared across availability zones if using [Zone-redundant storage for managed disks](#).

## Standard SSDs

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for standard SSDs with `maxShares>1`.
- When using Availability sets and virtual machine scale sets with Azure shared disks, [storage fault domain alignment](#) with virtual machine fault domain isn't enforced for the shared data disk.
- When using [proximity placement groups \(PPG\)](#), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through [Azure Disk Backup](#).
- Only [server-side encryption](#) is supported, [Azure Disk Encryption](#) isn't currently supported.
- Can only be shared across availability zones if using [Zone-redundant storage for managed disks](#).

## Operating system requirements

Shared disks support several operating systems. See the [Windows](#) or [Linux](#) sections for the supported operating systems.

## Billing implications

When you share a disk, your billing could be impacted in two different ways, depending on the type of disk.

For shared premium SSD disks, in addition to cost of the disk's tier, there's an extra charge that increases with each VM the SSD is mounted to. See [managed disks pricing](#) for details.

Ultra disks don't have an extra charge for each VM that they're mounted to. They're billed on the total IOPS and MBps that the disk is configured for. Normally, an ultra disk has two performance throttles that determine its total IOPS/MBps. However, when configured as a shared ultra disk, two more performance throttles are exposed, for a total of four. These two additional throttles allow for increased performance at an extra expense and each meter has a default value, which raises the performance and cost of the disk.

The four performance throttles a shared ultra disk has are `diskMBpsReadWrite`, `diskIOPSReadOnly`, `diskMBpsReadWrite`, and `diskMBpsReadOnly`. Each performance throttle can be configured to change the performance of your disk. The performance for shared ultra disk is calculated in the following ways: total provisioned IOPS (`diskIOPSReadWrite + diskIOPSReadOnly`) and for total provisioned throughput MBps

(diskMBpsReadWrite + diskMBpsReadOnly).

Once you've determined your total provisioned IOPS and total provisioned throughput, you can use them in the [pricing calculator](#) to determine the cost of an ultra shared disk.

## Disk sizes

For now, only ultra disks, premium SSD v2 (preview), premium SSD, and standard SSDs can enable shared disks. Different disk sizes may have a different `maxShares` limit, which you can't exceed when setting the `maxShares` value.

For each disk, you can define a `maxShares` value that represents the maximum number of nodes that can simultaneously share the disk. For example, if you plan to set up a 2-node failover cluster, you would set `maxShares=2`. The maximum value is an upper bound. Nodes can join or leave the cluster (mount or unmount the disk) as long as the number of nodes is lower than the specified `maxShares` value.

### NOTE

The `maxShares` value can only be set or edited when the disk is detached from all nodes.

### Premium SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by premium SSD sizes:

DISK SIZES	MAXSHARES LIMIT
P1,P2,P3,P4,P6,P10,P15,P20	3
P30, P40, P50	5
P60, P70, P80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a P15 disk is 1100 whether `maxShares = 1` or `maxShares > 1`.

### Standard SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by standard SSD sizes:

DISK SIZES	MAXSHARES LIMIT
E1,E2,E3,E4,E6,E10,E15,E20	3
E30, E40, E50	5
E60, E70, E80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a E15 disk is 500 whether `maxShares = 1` or `maxShares > 1`.

### Ultra disk ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on ultra disks, any size ultra disk can use any value for `maxShares`, up to and including the maximum value.

### Premium SSD v2 ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on

Premium SSD v2, any size Premium SSD v2 disk can use any value for `maxShares`, up to and including the maximum value.

## Sample workloads

### Windows

Azure shared disks are supported on Windows Server 2008 and newer. Most Windows-based clustering builds on WSFC, which handles all core infrastructure for cluster node communication, allowing your applications to take advantage of parallel access patterns. WSFC enables both CSV and non-CSV-based options depending on your version of Windows Server. For details, refer to [Create a failover cluster](#).

Some popular applications running on WSFC include:

- [Create an FCI with Azure shared disks \(SQL Server on Azure VMs\)](#)
  - [Migrate your failover cluster instance to SQL Server on Azure VMs with shared disks](#)
- Scale-out File Server (SoFS) [template](#)
- SAP ASCS/SCS [template](#)
- File Server for General Use (IW workload)
- Remote Desktop Server User Profile Disk (RDS UPD)

### Linux

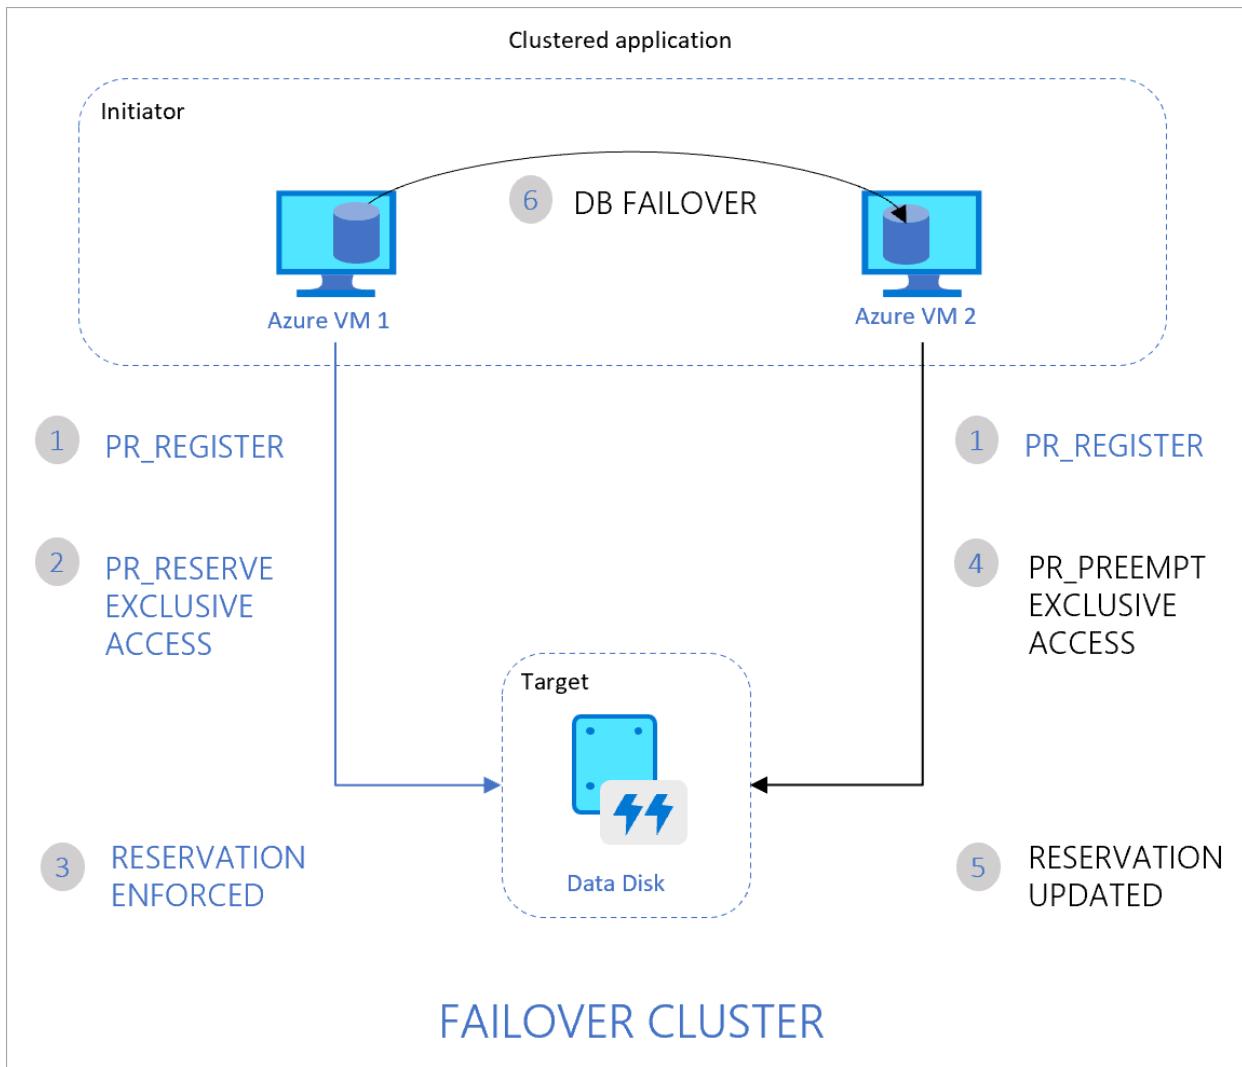

Azure shared disks are supported on:

- [SUSE SLE HA 15 SP1 and above](#)
- [Ubuntu 18.04 and above](#)
- Red Hat Enterprise Linux (RHEL) ([support policy](#))
  - [RHEL 7.9](#)
  - [RHEL 8.3 and above](#)
- [Oracle Enterprise Linux](#)

Linux clusters can use cluster managers such as [Pacemaker](#). Pacemaker builds on [Corosync](#), enabling cluster communications for applications deployed in highly available environments. Some common clustered filesystems include [ocfs2](#) and [gfs2](#). You can use SCSI Persistent Reservation (SCSI PR) and/or STONITH Block Device (SBD) based clustering models for arbitrating access to the disk. When using SCSI PR, you can manipulate reservations and registrations using utilities such as [fence\\_scsi](#) and [sg\\_persist](#).

## Persistent reservation flow

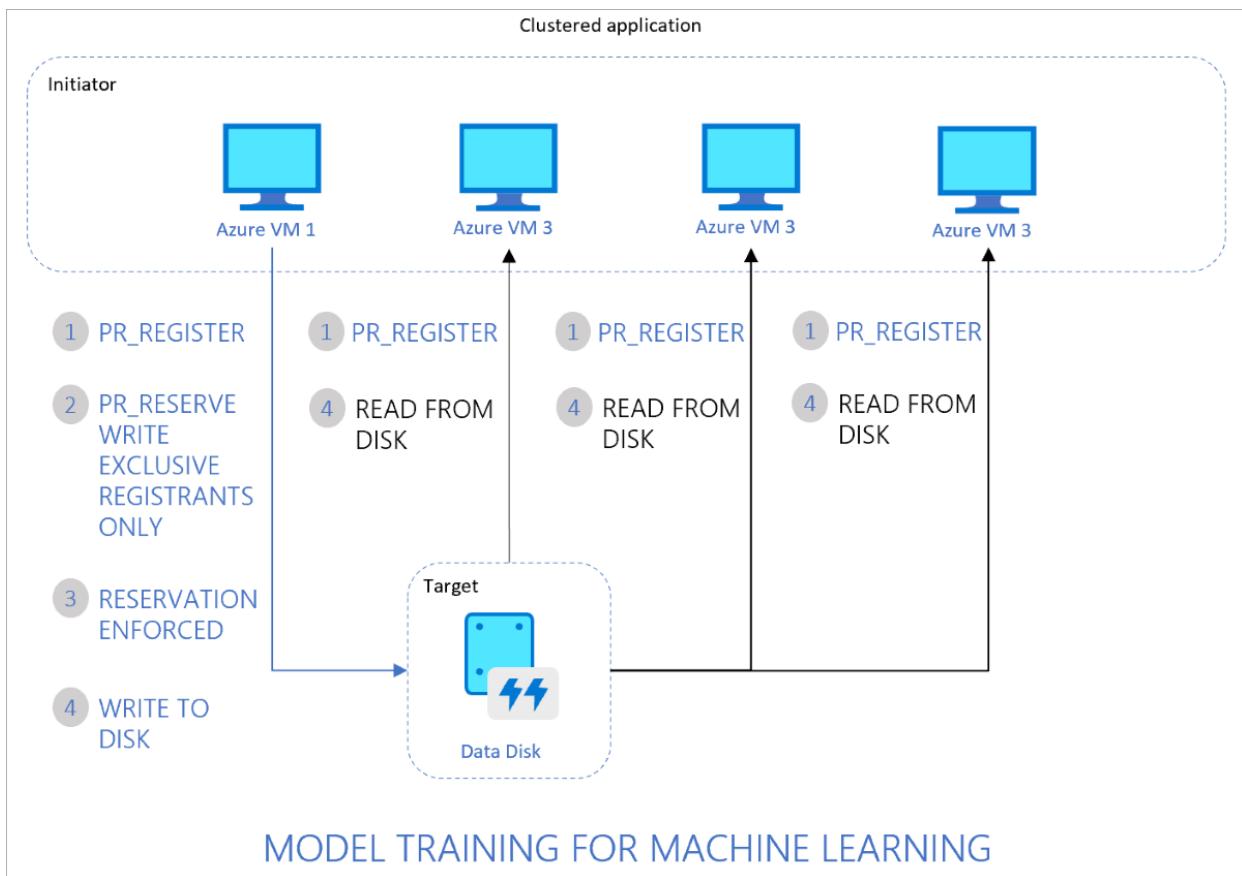

The following diagram illustrates a sample 2-node clustered database application that uses SCSI PR to enable failover from one node to the other.

The flow is as follows:

1. The clustered application running on both Azure VM1 and VM2 registers its intent to read or write to the disk.
2. The application instance on VM1 then takes exclusive reservation to write to the disk.
3. This reservation is enforced on your Azure disk and the database can now exclusively write to the disk. Any writes from the application instance on VM2 won't succeed.
4. If the application instance on VM1 goes down, the instance on VM2 can now initiate a database failover and take-over of the disk.
5. This reservation is now enforced on the Azure disk and the disk will no longer accept writes from VM1. It will only accept writes from VM2.
6. The clustered application can complete the database failover and serve requests from VM2.

The following diagram illustrates another common clustered workload consisting of multiple nodes reading data from the disk for running parallel processes, such as training of machine learning models.

The flow is as follows:

1. The clustered application running on all VMs registers the intent to read or write to the disk.
2. The application instance on VM1 takes an exclusive reservation to write to the disk while opening up reads to the disk from other VMs.
3. This reservation is enforced on your Azure disk.
4. All nodes in the cluster can now read from the disk. Only one node writes back results to the disk, on behalf of all nodes in the cluster.

### Ultra disks reservation flow

Ultra disks offer two extra throttles, for a total of four throttles. Due to this, ultra disks reservation flow can work as described in the earlier section, or it can throttle and distribute performance more granularly.

Reservation Type	Reservation Holder		Registered		Others	
	ReadOnly	ReadWrite	ReadOnly	ReadWrite	ReadOnly	ReadWrite
No Reservation	N/A	N/A	N/A	Yes	N/A	Yes
Write Exclusive	N/A	Yes	Yes	N/A	Yes	N/A
Exclusive Access	N/A	Yes	N/A	N/A	N/A	N/A
Write Exclusive – Registrants Only	N/A	Yes	N/A	Yes	Yes	N/A
Exclusive Access – Registrants Only	N/A	Yes	N/A	Yes	N/A	N/A
Write Exclusive – All Registrants	N/A	Yes	N/A	Yes	Yes	N/A
Exclusive Access – All Registrants	N/A	Yes	N/A	Yes	N/A	N/A

## Performance throttles

### Premium SSD performance throttles

With premium SSD, the disk IOPS and throughput is fixed, for example, IOPS of a P30 is 5000. This value remains whether the disk is shared across 2 VMs or 5 VMs. The disk limits can be reached from a single VM or divided across two or more VMs.

## Ultra disk performance throttles

Ultra disks have the unique capability of allowing you to set your performance by exposing modifiable attributes and allowing you to modify them. By default, there are only two modifiable attributes but, shared ultra disks have two more attributes.

ATTRIBUTE	DESCRIPTION
DiskIOPSReadWrite	The total number of IOPS allowed across all VMs mounting the shared disk with write access.
DiskMBpsReadWrite	The total throughput (MB/s) allowed across all VMs mounting the shared disk with write access.
DiskIOPSReadOnly*	The total number of IOPS allowed across all VMs mounting the shared disk as <code>ReadOnly</code> .
DiskMBpsReadOnly*	The total throughput (MB/s) allowed across all VMs mounting the shared disk as <code>ReadOnly</code> .

\* Applies to shared ultra disks only

The following formulas explain how the performance attributes can be set, since they're user modifiable:

- DiskIOPSReadWrite/DiskIOPSReadOnly:
  - IOPS limits of 300 IOPS/GiB, up to a maximum of 160 K IOPS per disk
  - Minimum of 100 IOPS
  - DiskIOPSReadWrite + DiskIOPSReadOnly is at least 2 IOPS/GiB
- DiskMBpsReadWrite/DiskMBpsReadOnly:
  - The throughput limit of a single disk is 256 KiB/s for each provisioned IOPS, up to a maximum of 2000 MBps per disk
  - The minimum guaranteed throughput per disk is 4KiB/s for each provisioned IOPS, with an overall baseline minimum of 1 MBps

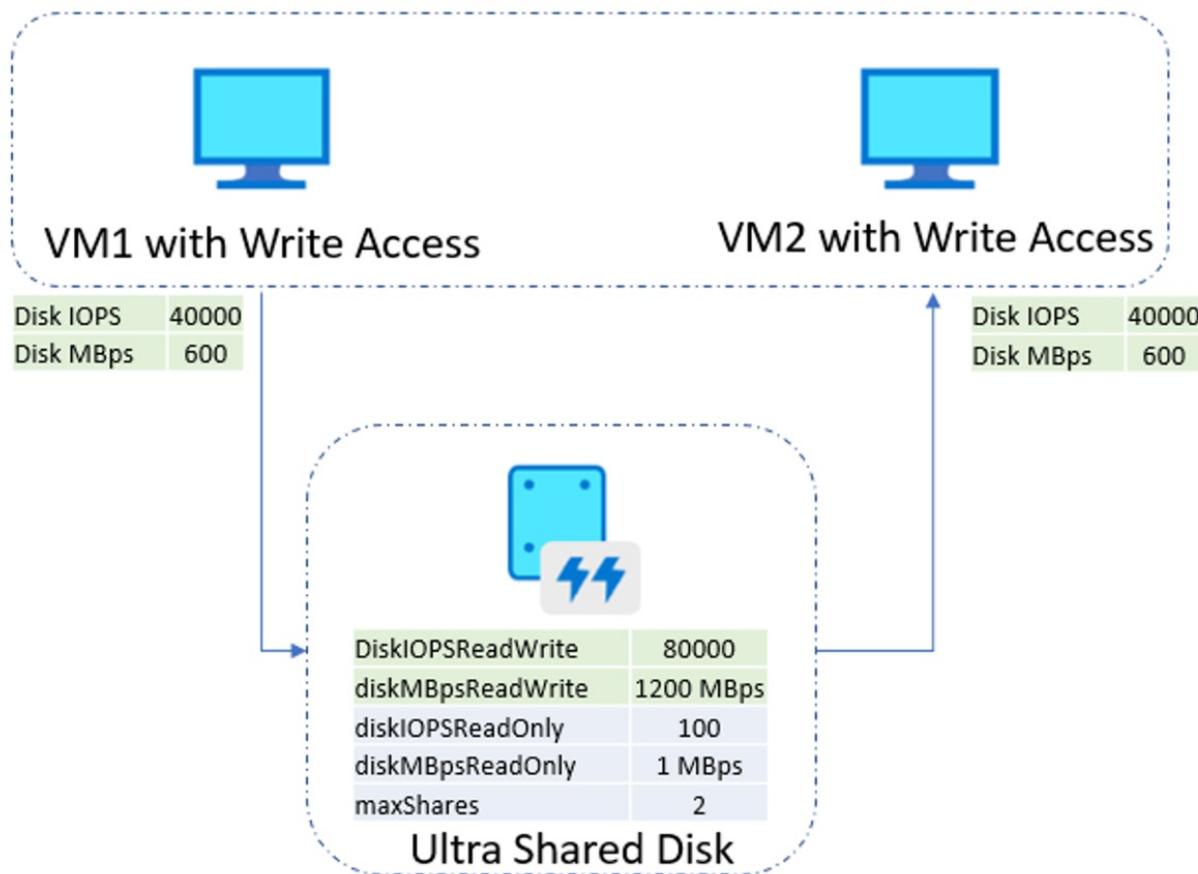

### Examples

The following examples depict a few scenarios that show how the throttling can work with shared ultra disks, specifically.

#### Two nodes cluster using cluster shared volumes

The following is an example of a 2-node WSFC using clustered shared volumes. With this configuration, both VMs have simultaneous write-access to the disk, which results in the `ReadWrite` throttle being split across the two VMs and the `ReadOnly` throttle not being used.

## 2 nodes Windows Cluster using CSV

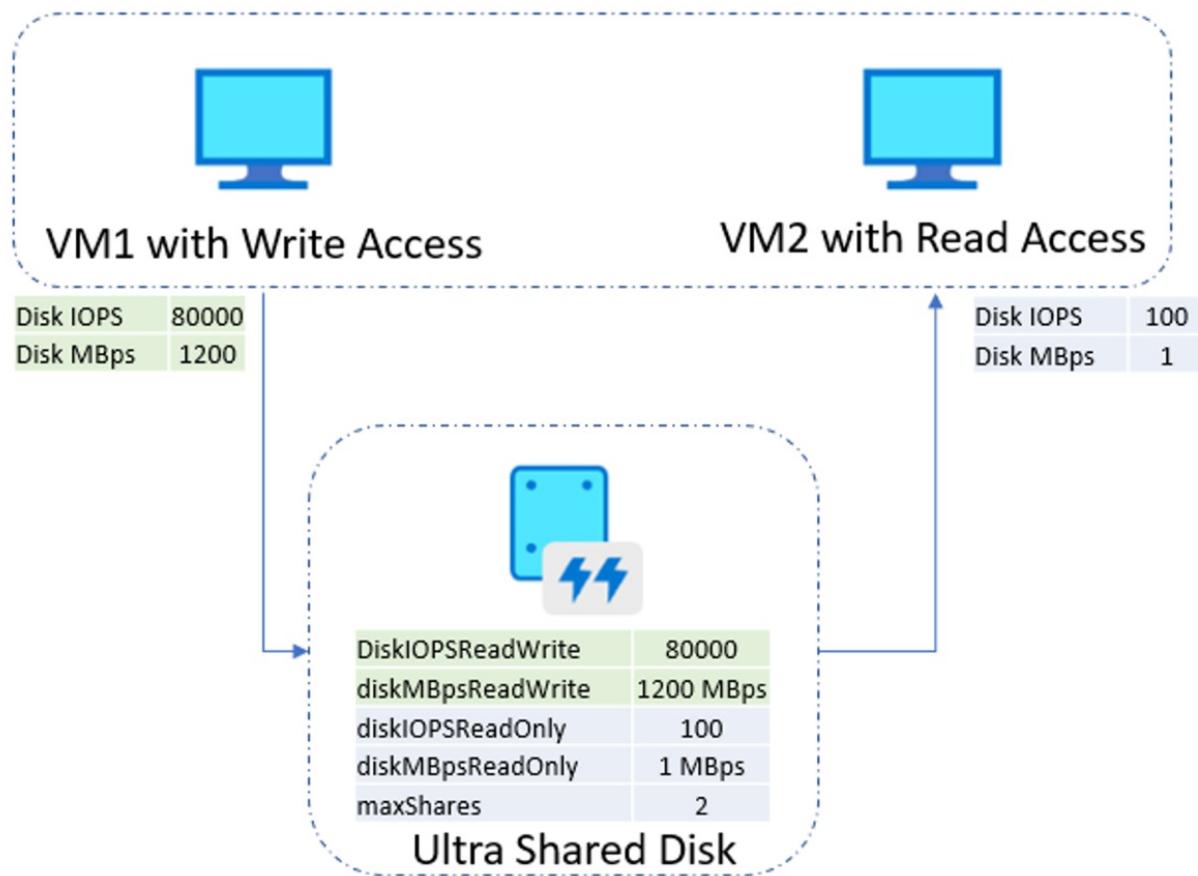

ReadWrite throttles equally split across VMs with write access (2 VMs in this case)

ReadOnly throttles equally split across VMs without write access (None in this case)

### Two node cluster without cluster share volumes

The following is an example of a 2-node WSFC that isn't using clustered shared volumes. With this configuration, only one VM has write-access to the disk. This results in the `ReadWrite` throttle being used exclusively for the primary VM and the `ReadOnly` throttle only being used by the secondary.

## 2 nodes Windows Cluster for Failover not using CSV

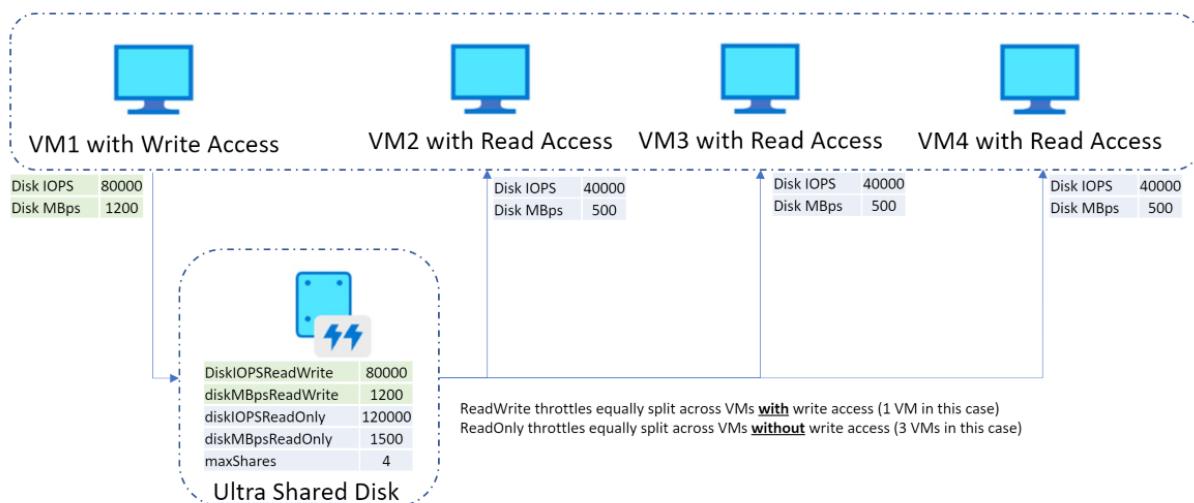

ReadWrite throttles equally split across VMs with write access (1 VM in this case)

ReadOnly throttles equally split across VMs without write access (1 VM in this case)

### Four node Linux cluster

The following is an example of a 4-node Linux cluster with a single writer and three scale-out readers. With this configuration, only one VM has write-access to the disk. This results in the `ReadWrite` throttle being used exclusively for the primary VM and the `ReadOnly` throttle being split by the secondary VMs.

4 nodes Linux cluster with a single Writer and 3 scale out Readers

4 nodes Linux cluster with a single Writer and 3 scale out Readers. ReadWrite throttle will be used for the primary VM while the ReadOnly throttle will be split across the secondary VMs

### Ultra pricing

Ultra shared disks are priced based on provisioned capacity, total provisioned IOPS (diskIOPSReadWrite +

`diskIOPSReadOnly`) and total provisioned Throughput MBps (`diskMBpsReadWrite + diskMBpsReadOnly`). There's no extra charge for each additional VM mount. For example, an ultra shared disk with the following configuration (`diskSizeGB: 1024, DiskIOPSReadWrite: 10000, DiskMBpsReadWrite: 600, DiskIOPSReadOnly: 100, DiskMBpsReadOnly: 1`) is charged with 1024 GiB, 10100 IOPS, and 601 MBps regardless of whether it is mounted to two VMs or five VMs.

## Next steps

If you're interested in enabling and using shared disks for your managed disks, proceed to our article [Enable shared disk](#)

# Enable shared disk

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article covers how to enable the shared disks feature for Azure managed disks. Azure shared disks is a new feature for Azure managed disks that enables you to attach a managed disk to multiple virtual machines (VMs) simultaneously. Attaching a managed disk to multiple VMs allows you to either deploy new or migrate existing clustered applications to Azure.

If you are looking for conceptual information on managed disks that have shared disks enabled, see [Azure shared disks](#).

## Prerequisites

The scripts and commands in this article require either:

- Version 6.0.0 or newer of the Azure PowerShell module.

Or

- The latest version of the Azure CLI.

## Limitations

### General limitations

Enabling shared disks is only available to a subset of disk types. Currently only ultra disks, premium SSD v2 (preview), premium SSDs, and standard SSDs can enable shared disks. Shared disks can be attached to individual VMSS instances but can't be defined in the VMSS models or automatically deployed.

Each managed disk that has shared disks enabled are also subject to the following limitations, organized by disk type:

### Ultra disks

Ultra disks have their own separate list of limitations, unrelated to shared disks. For ultra disk limitations, refer to [Using Azure ultra disks](#).

When sharing ultra disks, they have the following additional limitations:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Can't be shared across availability zones.

### Premium SSD v2 (preview)

Premium SSD v2 disks have their own separate list of limitations, unrelated to shared disks. For these limitations, see [Premium SSD v2 limitations](#).

When sharing Premium SSD v2 disks, they have the following additional limitation:

- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Can't be shared across availability zones.

### Premium SSD

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for premium SSD disks with `maxShares>1`.
- Disk bursting isn't available for premium SSD disks with `maxShares>1`.
- When using Availability sets or virtual machine scale sets with Azure shared disks, [storage fault domain alignment](#) with virtual machine fault domain isn't enforced for the shared data disk.
- When using [proximity placement groups \(PPG\)](#), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through [Azure Disk Backup](#).
- Only [server-side encryption](#) is supported, [Azure Disk Encryption](#) isn't currently supported.
- Can only be shared across availability zones if using [Zone-redundant storage for managed disks](#).

## Standard SSDs

- Can only be enabled on data disks, not OS disks.
- Host caching isn't available for standard SSDs with `maxShares>1`.
- When using Availability sets and virtual machine scale sets with Azure shared disks, [storage fault domain alignment](#) with virtual machine fault domain isn't enforced for the shared data disk.
- When using [proximity placement groups \(PPG\)](#), all virtual machines sharing a disk must be part of the same PPG.
- Only basic disks can be used with some versions of Windows Server Failover Cluster, for details see [Failover clustering hardware requirements and storage options](#).
- Azure Site Recovery support isn't yet available.
- Azure Backup is available through [Azure Disk Backup](#).
- Only [server-side encryption](#) is supported, [Azure Disk Encryption](#) isn't currently supported.
- Can only be shared across availability zones if using [Zone-redundant storage for managed disks](#).

## Supported operating systems

Shared disks support several operating systems. See the [Windows](#) and [Linux](#) sections of the conceptual article for the supported operating systems.

## Disk sizes

For now, only ultra disks, premium SSD v2 (preview), premium SSD, and standard SSDs can enable shared disks. Different disk sizes may have a different `maxShares` limit, which you can't exceed when setting the `maxShares` value.

For each disk, you can define a `maxShares` value that represents the maximum number of nodes that can simultaneously share the disk. For example, if you plan to set up a 2-node failover cluster, you would set `maxShares=2`. The maximum value is an upper bound. Nodes can join or leave the cluster (mount or unmount the disk) as long as the number of nodes is lower than the specified `maxShares` value.

### NOTE

The `maxShares` value can only be set or edited when the disk is detached from all nodes.

## Premium SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by premium SSD sizes:

DISK SIZES	MAXSHARES LIMIT
P1,P2,P3,P4,P6,P10,P15,P20	3
P30, P40, P50	5
P60, P70, P80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a P15 disk is 1100 whether `maxShares` = 1 or `maxShares` > 1.

### Standard SSD ranges

The following table illustrates the allowed maximum values for `maxShares` by standard SSD sizes:

DISK SIZES	MAXSHARES LIMIT
E1,E2,E3,E4,E6,E10,E15,E20	3
E30, E40, E50	5
E60, E70, E80	10

The IOPS and bandwidth limits for a disk aren't affected by the `maxShares` value. For example, the max IOPS of a E15 disk is 500 whether `maxShares` = 1 or `maxShares` > 1.

### Ultra disk ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on ultra disks, any size ultra disk can use any value for `maxShares`, up to and including the maximum value.

### Premium SSD v2 ranges

The minimum `maxShares` value is 1, while the maximum `maxShares` value is 15. There are no size restrictions on Premium SSD v2, any size Premium SSD v2 disk can use any value for `maxShares`, up to and including the maximum value.

## Deploy shared disks

### Deploy a premium SSD as a shared disk

To deploy a managed disk with the shared disk feature enabled, use the new property `maxShares` and define a value greater than 1. This makes the disk shareable across multiple VMs.

#### IMPORTANT

The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the [Disk sizes](#) for the allowed values for `maxShares`.

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)
- [Resource Manager Template](#)

1. Sign in to the Azure portal.

2. Search for and Select Disks.
3. Select + Create to create a new managed disk.
4. Fill in the details and select an appropriate region, then select Change size.

The screenshot shows the 'Create a managed disk' wizard in the Microsoft Azure portal. The 'Basics' tab is selected. In the 'Disk details' section, the 'Size' dropdown is set to '16 GiB' and 'Premium SSD LRS'. A red box highlights the 'Change size' link below the dropdown. The left sidebar shows various Azure services like App Services, SQL databases, and Virtual machines.

5. Select the premium SSD size and SKU that you want and select OK.

Locally-redundant storage (data is replicated within a single datacenter)	
<b>Premium SSD</b>	Best for production and performance sensitive workloads
<b>Standard SSD</b>	Best for web servers, lightly used enterprise applications and dev/test
<b>Standard HDD</b>	Best for backup, non-critical, and infrequent access

Zone-redundant storage (data is replicated within multiple datacenters)	
<b>Premium SSD</b>	Best for the production workloads that need storage resiliency against zone failures
<b>Standard SSD</b>	Best for web servers, lightly used enterprise applications and dev/test that need storage resiliency against zone failures

6. Proceed through the deployment until you get to the Advanced pane.
7. Select Yes for Enable shared disk and select the amount of Max shares you want.

**Shared disk**

Allow this disk to be attached to two or more virtual machines, depending on storage type and disk size. When shared disk is enabled host caching is unavailable. [Learn more about shared disks](#)

Yes  No

Max shares ⓘ

8. Select **Review + Create**.

### Deploy a standard SSD as a shared disk

To deploy a managed disk with the shared disk feature enabled, use the new property `maxShares` and define a value greater than 1. This makes the disk shareable across multiple VMs.

#### IMPORTANT

The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the [Disk sizes](#) for the allowed values for `maxShares`.

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)
- [Resource Manager Template](#)

1. Sign in to the Azure portal.
2. Search for and **Select Disks**.
3. Select **+ Create** to create a new managed disk.
4. Fill in the details and select an appropriate region, then select **Change size**.

The screenshot shows the 'Create a managed disk' wizard in the Microsoft Azure portal. The 'Basics' tab is selected. In the 'Disk details' section, the 'Size' field is highlighted with a red box, showing '16 GiB Premium SSD LRS' and a 'Change size' link. Other fields include 'Subscription' (My Example Subscription), 'Resource group' (Create new), 'Disk name' (empty), 'Region' (US West US), 'Availability zone' (None), and 'Source type' (None). At the bottom, there are 'Review + create' and 'Next : Encryption >' buttons.

5. Select the standard SSD size and SKU that you want and select **OK**.

<b>Locally-redundant storage (data is replicated within a single datacenter)</b>
Premium SSD
Best for production and performance sensitive workloads
<b>Standard SSD</b>
Best for web servers, lightly used enterprise applications and dev/test
Standard HDD
Best for backup, non-critical, and infrequent access
<b>Zone-redundant storage (data is replicated within multiple datacenters)</b>
Premium SSD
Best for the production workloads that need storage resiliency against zone failures
<b>Standard SSD</b>
Best for web servers, lightly used enterprise applications and dev/test that need storage resiliency against zone failures

6. Proceed through the deployment until you get to the **Advanced** pane.

7. Select **Yes** for **Enable shared disk** and select the amount of **Max shares** you want.

<b>Shared disk</b>
Allow this disk to be attached to two or more virtual machines, depending on storage type and disk size. When shared disk is enabled host caching is unavailable. <a href="#">Learn more about shared disks</a>
<input checked="" type="radio"/> Yes <input type="radio"/> No
Max shares <a href="#">(i)</a> <input type="text" value="2"/> <a href="#">▼</a>

8. Select **Review + Create**.

### Deploy an ultra disk as a shared disk

To deploy a managed disk with the shared disk feature enabled, change the `maxShares` parameter to a value greater than 1. This makes the disk shareable across multiple VMs.

#### IMPORTANT

The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the [Disk sizes](#) for the allowed values for `maxShares`.

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)
- [Resource Manager Template](#)

1. Sign in to the Azure portal.
2. Search for and Select Disks.
3. Select **+ Create** to create a new managed disk.

4. Fill in the details, then select **Change size**.

5. Select ultra disk for the **Disk SKU**.

The screenshot shows a dropdown menu titled "Disk SKU ⓘ". The "Ultra Disk (locally-redundant storage)" option is selected, indicated by a blue border. Below it, other options are listed: "Locally-redundant storage (data is replicated within a single datacenter)", "Premium SSD", "Standard SSD", "Standard HDD", and "Ultra Disk". The "Ultra Disk" option is highlighted with a grey background. Descriptions for each option are provided below them.

Disk SKU	Description
Ultra Disk (locally-redundant storage)	Locally-redundant storage (data is replicated within a single datacenter) Best for production and performance sensitive workloads
Premium SSD	Standard SSD Best for web servers, lightly used enterprise applications and dev/test
Standard SSD	Standard HDD Best for backup, non-critical, and infrequent access
Standard HDD	Ultra Disk Best for IO-intensive workloads such as SAP HANA, top tier databases (for example, SQL, Oracle), and other transaction-heavy workloads

6. Select the disk size that you want and select **OK**.

7. Proceed through the deployment until you get to the **Advanced** pane.

8. Select **Yes** for **Enable shared disk** and select the amount of **Max shares** you want.

9. Select **Review + Create**.

Add additional configurations for your managed disk

## Share an existing disk

To share an existing disk, or update how many VMs it can mount to, set the `maxShares` parameter with either the Azure PowerShell module or Azure CLI. You can also set `maxShares` to 1, if you want to disable sharing.

#### IMPORTANT

The value of `maxShares` can only be set or changed when a disk is unmounted from all VMs. See the [Disk sizes](#) for the allowed values for `maxShares`. Before detaching a disk, record the LUN ID for when you re-attach it.

## PowerShell

```
$datadiskconfig = Get-AzDisk -DiskName "mySharedDisk"
$datadiskconfig.maxShares = 3

Update-AzDisk -ResourceGroupName 'myResourceGroup' -DiskName 'mySharedDisk' -Disk $datadiskconfig
```

## CLI

```
#Modifying a disk to enable or modify sharing configuration

az disk update --name mySharedDisk --max-shares 5
```

# Using Azure shared disks with your VMs

Once you've deployed a shared disk with `maxShares>1`, you can mount the disk to one or more of your VMs.

## NOTE

If you are deploying an ultra disk, make sure it matches the necessary requirements. See [Using Azure ultra disks](#) for details.

```
$resourceGroup = "myResourceGroup"
$location = "WestCentralUS"

$vm = New-AzVm -ResourceGroupName $resourceGroup -Name "myVM" -Location $location -VirtualNetworkName
"myVnet" -SubnetName "mySubnet" -SecurityGroupName "myNetworkSecurityGroup" -PublicIpAddressName
"myPublicIpAddress"

$dataDisk = Get-AzDisk -ResourceGroupName $resourceGroup -DiskName "mySharedDisk"

$vm = Add-AzVMDataDisk -VM $vm -Name "mySharedDisk" -CreateOption Attach -ManagedDiskId $dataDisk.Id -Lun 0

update-AzVm -VM $vm -ResourceGroupName $resourceGroup
```

## Supported SCSI PR commands

Once you've mounted the shared disk to your VMs in your cluster, you can establish quorum and read/write to the disk using SCSI PR. The following PR commands are available when using Azure shared disks:

To interact with the disk, start with the persistent-reservation-action list:

```
PR_REGISTER_KEY
PR_REGISTER_AND_IGNORE
PR_GET_CONFIGURATION
PR_RESERVE
PR_PREEMPT_RESERVATION
PR_CLEAR_RESERVATION
PR_RELEASE_RESERVATION
```

When using PR\_RESERVE, PR\_PREEMPT\_RESERVATION, or PR\_RELEASE\_RESERVATION, provide one of the following persistent-reservation-type:

```
PR_NONE  
  
PR_WRITE_EXCLUSIVE  
  
PR_EXCLUSIVE_ACCESS  
  
PR_WRITE_EXCLUSIVE_REGISTRANTS_ONLY  
  
PR_EXCLUSIVE_ACCESS_REGISTRANTS_ONLY  
  
PR_WRITE_EXCLUSIVE_ALL_REGISTRANTS  
  
PR_EXCLUSIVE_ACCESS_ALL_REGISTRANTS
```

You also need to provide a persistent-reservation-key when using PR\_RESERVE, PR\_REGISTER\_AND\_IGNORE, PR\_REGISTER\_KEY, PR\_PREEMPT\_RESERVATION, PR\_CLEAR\_RESERVATION, or PR\_RELEASE\_RESERVATION.

## Next steps

If you prefer to use Azure Resource Manager templates to deploy your disk, the following sample templates are available:

- [Premium SSD](#)
- [Regional ultra disks](#)
- [Zonal ultra disks](#)

# Azure disk pools (preview)

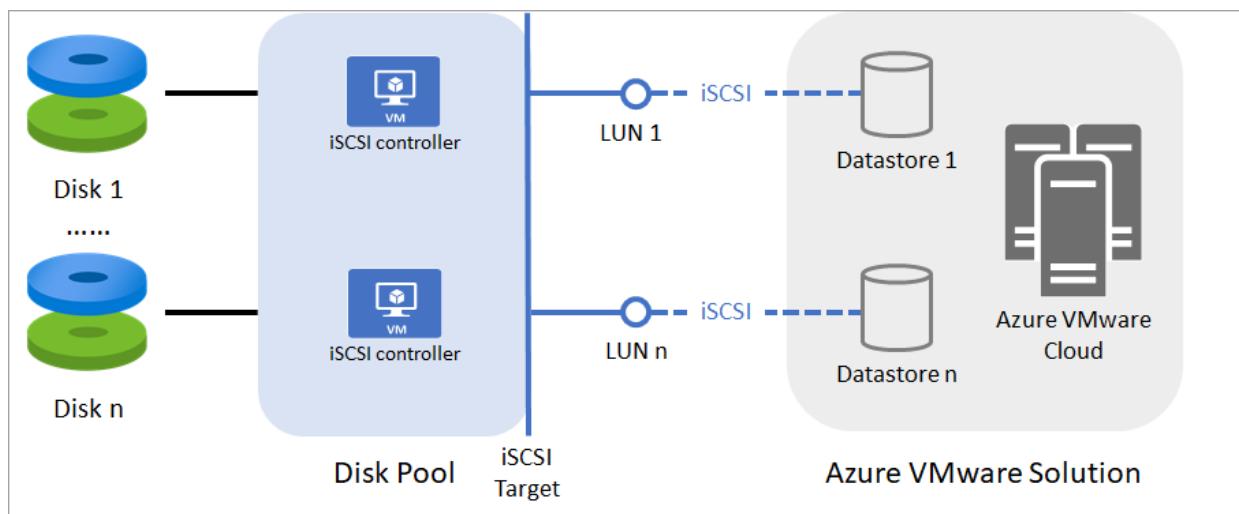

9/21/2022 • 2 minutes to read • [Edit Online](#)

An Azure disk pool (preview) is an Azure resource that allows your applications and workloads to access a group of managed disks from a single endpoint. A disk pool can expose an Internet Small Computer Systems Interface (iSCSI) target to enable data access to disks inside this pool over iSCSI. Each disk pool can have one iSCSI target and each disk can be exposed as an iSCSI LUN. You can connect disks under the disk pool to Azure VMware Solution hosts as datastores. This allows you to scale your storage independent of your Azure VMware Solution hosts. Once a datastore is configured, you can create volumes on it and attach them to your VMware instances.

## How it works

When a disk pool is deployed, a managed resource group is automatically created for you. This managed resource group contains all Azure resources necessary for the operation of a disk pool. The naming convention for these resource groups is: MSP\_(resource-group-name)\_(diskpool-name)\_(region-name).

When you add a managed disk to the disk pool, the disk is attached to managed iSCSI controllers. Multiple managed disks can be added as storage targets to a disk pool, each storage target is presented as an iSCSI LUN under the disk pool's iSCSI target. Disk pools offer native support for Azure VMware Solution. An Azure VMware Solution cluster can connect to a disk pool, which would encompass all Azure VMware Solution hosts in that environment. The following diagram shows how you can use disk pools with Azure VMware Solution.

## Restrictions

In preview, disk pools have the following restrictions:

- Only premium SSDs and standard SSDs, or ultra disks can be added to a disk pool.
  - A disk pool can't be configured to contain both ultra disks and premium/standard SSDs. If a disk pool is configured to use ultra disks, it can only contain ultra disks. Likewise, a disk pool configured to use premium and standard SSDs can only contain premium and standard SSDs.
- Disks using [zone-redundant storage \(ZRS\)](#) aren't currently supported.

## Regional availability

Disk pools are currently available in the following regions:

- Australia East

- Canada Central
- Central US
- East US
- East US 2
- West US 2
- Japan East
- North Europe
- West Europe
- Southeast Asia
- UK South
- Korea Central
- Sweden Central
- Central India

## Billing

When you deploy a disk pool, there are two areas that will incur billing costs: The price of the disk pool service fee itself, and the price of each individual disk added to the pool. For example, if you have a disk pool with one P30 disk added, you will be billed for the P30 disk and the disk pool. Other than the disk pool and your disks, there are no extra service charges for a disk pool and you will not be billed for the resources deployed in the managed resource group: `MSP_(resource-group-name)(diskpool-name)(region-name)`.

See the [Azure managed disk pricing page](#) for regional pricing on disk pools and disks to evaluate the cost of a disk pool for you.

## Next steps

See the [disk pools planning guide](#).

# Azure disk pools (preview) planning guide

9/21/2022 • 4 minutes to read • [Edit Online](#)

It's important to understand the performance requirements of your workload before you deploy an Azure disk pool (preview). Determining your requirements in advance allows you to get the most performance out of your disk pool. The performance of a disk pool is determined by three main factors, adjusting any of them will tweak your disk pool's performance:

- The disk pool's scalability target
- The scalability targets of individual disks contained in the disk pool
- The networking connection between the client machines to the disk pool.

## Optimize for low latency

If you're prioritizing for low latency, add ultra disks to your disk pool. Ultra disks provide sub-millisecond disk latency. To get the lowest latency possible, you must also evaluate your network configuration and ensure it's using the most optimal path. Consider using [ExpressRoute FastPath](#) to minimize network latency.

## Optimize for high throughput

If you're prioritizing throughput, begin by evaluating the performance targets of the different disk pool SKUs, as well as the number of disk pools required to deliver your throughput targets. If your performance needs exceed what a premium disk pool can provide, you can split your deployment across multiple disk pools. Then, you can decide how to best utilize the performance offered on a disk pool amongst each individual disk and their types. For a disk pool, you can either mix and match between premium and standard SSDs, or use ultra disks only. Ultra disks can't be used with premium or standard SSDs. Select the disk type that best fits your needs. Also, confirm the network connectivity from your clients to the disk pool is not a bottleneck, especially the throughput.

## Use cases

The following table lists some typical use cases for disk pools with Azure VMware Solution and a recommended configuration.

AZURE VMWARE SOLUTION USE CASES	SUGGESTED DISK TYPE	SUGGESTED DISK POOL SKU	SUGGESTED NETWORK CONFIGURATION
Block storage for active working sets, like an extension of Azure VMware Solution vSAN.	Ultra disks	Premium	Use ExpressRoute virtual network gateway: Ultra Performance or ErGw3AZ (10 Gbps) to connect the disk pool virtual network to the Azure VMware Solution cloud and enable FastPath to minimize network latency.

AZURE VMWARE SOLUTION USE CASES	SUGGESTED DISK TYPE	SUGGESTED DISK POOL SKU	SUGGESTED NETWORK CONFIGURATION
Tiering - tier infrequently accessed data from the Azure VMware Solution vSAN to the disk pool.	Premium SSD, standard SSD	Standard	Use ExpressRoute virtual network gateway: Standard (1 Gbps) or High Performance (2 Gbps) to connect the disk pool virtual network to the Azure VMware Solution cloud.
Data storage for disaster recovery site on Azure VMware Solution: replicate data from on-premises or primary VMware environment to the disk pool as a secondary site.	Premium SSD, standard SSD	Standard, Basic	Use ExpressRoute virtual network gateway: Standard (1 Gbps) or High Performance (2 Gbps) to connect the disk pool virtual network to the Azure VMware Solution cloud.

Refer to the [Networking planning checklist for Azure VMware Solution](#) to plan for your networking setup, along with other Azure VMware Solution considerations.

## Disk pool scalability and performance targets

RESOURCE	BASIC DISK POOL	STANDARD DISK POOL	PREMIUM DISK POOL
Maximum number of disks per disk pool	16	32	32
Maximum IOPS per disk pool	12,800	25,600	51,200
Maximum MBps per disk pool	192	384	768

The following example should give you an idea of how the different performance factors work together:

As an example, if you add two 1-TiB premium SSDs (P30, with a provisioned target of 5000 IOPS and 200 Mbps) into a standard disk pool, you can achieve  $2 \times 5000 = 10,000$  IOPS. However, throughput would be capped at 384 MBps by the disk pool. To exceed this 384-MBps limit, you can deploy more disk pools to scale out for extra throughput. Your network throughput will limit the effectiveness of scaling out.

Disk pools created without specifying the SKU in the REST API are the standard disk pool, by default.

## Availability

Disk pools are currently in preview, and shouldn't be used for production workloads. By default, a disk pool only supports premium and standard SSDs. You can enable support for ultra disks on a disk pool instead but, a disk pool with ultra disks isn't compatible with premium or standard SSDs.

Disk pools with support for premium and standard SSDs are based on a highly available architecture, with multiples hosting the iSCSI endpoint. Disk pools with support for ultra disks are hosted on a single instance deployment.

If your disk pool becomes inaccessible to your Azure VMware Solution cloud for any reason, you will experience the following:

- All datastores associated to the disk pool will no longer be accessible.
- All VMware VMs hosted in the Azure VMware Solution cloud that is using the impacted datastores will be in an unhealthy state.
- The health of clusters in the Azure VMware Solution cloud won't be impacted, except for one operation: You won't be able to place a host into maintenance mode. Azure VMware Solution will handle this failure and attempt recovery by disconnecting the impacted datastores.

## Next steps

- [Deploy a disk pool](#).
- To learn about how Azure VMware Solutions integrates disk pools, see [Attach disk pools to Azure VMware Solution hosts \(Preview\)](#).

# Deploy an Azure disk pool (preview)

9/21/2022 • 8 minutes to read • [Edit Online](#)

This article covers how to deploy and configure an Azure disk pool (preview). Before deploying a disk pool, read the [conceptual](#) and [planning](#) articles.

For a disk pool to work correctly, you must complete the following steps:

- Register your subscription for the preview.
- Delegate a subnet to your disk pool.
- Assign the resource provider of disk pool role-based access control (RBAC) permissions for managing your disk resources.
- Create the disk pool.
  - Add disks to your disk pool.

## Prerequisites

To successfully deploy a disk pool, you must have:

- A set of managed disks you want to add to a disk pool.
  - A virtual network with a dedicated subnet deployed for your disk pool.
    - Outbound ports 53, 443, and 5671 must be open.
    - Ensure that your network setting don't block any of your disk pool's required outbound dependencies.
- You can use either the [Azure PowerShell module](#) or [Azure CLI](#) to get the complete list of all outbound dependencies.

If you're going to use the Azure PowerShell module, install [version 6.1.0 or newer](#).

If you're going to use the Azure CLI, install [the latest version](#).

## Register your subscription for the preview

Register your subscription to the **Microsoft.StoragePool** provider, to be able to create and use disk pools.

1. Sign in to the [Azure portal](#).
2. On the Azure portal menu, search for and select **Subscriptions**.
3. Select the subscription you want to use for disk pools.
4. On the left menu, under **Settings**, select **Resource providers**.
5. Find the resource provider **Microsoft.StoragePool** and select **Register**.

Once your subscription has been registered, you can deploy a disk pool.

## Delegate subnet permission

For your disk pool to work with your client machines, you must delegate a subnet to your Azure disk pool. When creating a disk pool, you specify a virtual network and the delegated subnet. You may either create a new subnet or use an existing one and delegate to the **Microsoft.StoragePool/diskPools** resource provider.

1. Go to the virtual networks pane in the Azure portal and select the virtual network to use for the disk pool.
2. Select **Subnets** from the virtual network pane and select **+ Subnet**.
3. Create a new subnet by completing the following required fields in the **Add subnet** pane: - Subnet

delegation: Select Microsoft.StoragePool/diskPools

For more information on subnet delegation, see [Add or remove a subnet delegation](#).

## Assign StoragePool resource provider permissions

For a disk to be able to be used in a disk pool, it must meet the following requirements:

- The **StoragePool** resource provider must have been assigned an RBAC role that contains **Read** and **Write** permissions for every managed disk in the disk pool.
- Must be either a premium SSD, standard SSD, or an ultra disk in the same availability zone as the disk pool.
  - For ultra disks, it must have a disk sector size of 512 bytes.
- Disk pools can't be configured to contain both premium/standard SSDs and ultra disks. A disk pool configured for ultra disks can only contain ultra disks. Likewise, a disk pool configured for premium or standard SSDs can only contain premium and standard SSDs.
- Must be a shared disk with a maxShares value of two or greater.

1. Sign in to the [Azure portal](#).
2. Search for and select either the resource group that contains the disks or each disk themselves.
3. Select **Access control (IAM)**.
4. Select **Add role assignment (Preview)**, and select **Disk Pool Operator** in the role list.

If you prefer, you may create your own custom role instead. A custom role for disk pools must have the following RBAC permissions to function: **Microsoft.Compute/disks/write** and **Microsoft.Compute/disks/read**.

5. For **Assign access to**, select **User, group, or service principal**.
6. Select **+ Select members** and then search for **StoragePool Resource Provider**, select it, and save.

## Create a disk pool

For optimal performance, deploy the disk pool in the same Availability Zone of your clients. If you are deploying a disk pool for an Azure VMware Solution cloud and need guidance on identifying the Availability Zone, fill in this [form](#).

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Search for and select **Disk pool**.
2. Select **+ Add** to create a new disk pool.
3. Fill in the details requested, select the same region and availability zone as the clients that will use the disk pool.
4. Select the subnet that has been delegated to the **StoragePool** resource provider, and its associated virtual network.
5. Select **Next** to add disks to your disk pool.

The screenshot shows the Microsoft Azure portal interface for creating a disk pool. The left sidebar includes links for 'Create a resource', 'Home', 'Dashboard', 'All services', 'FAVORITES' (with items like All resources, Resource groups, Cognitive Search, App Services, SQL databases, Azure Cosmos DB, Virtual machines, Load balancers, Storage accounts, Virtual networks, Azure Active Directory, Monitor, Advisor, Security Center, Help + support, and Cost Management + Billing), and a search bar at the top.

The main content area is titled 'Create a disk pool'. The 'Basics' tab is active. A sub-instruction says 'Create a disk pool with iSCSI support and scale block storage independent of compute.' with a 'Learn more' link. The 'Project details' section asks to select a subscription to manage deployed resources and costs, using resource groups to organize and manage all your resources. It shows 'Subscription \*' set to 'My Example Subscription' and 'Resource group \*' as an empty dropdown with a 'Create new' button.

The 'Instance details' section contains fields for 'Name \*' (empty input), 'Region \*' (set to '(US) West US 2'), 'Availability zone \*' (set to '1'), 'Virtual network \*' (empty dropdown), and 'Disk pool SKU \*' (empty dropdown). At the bottom are buttons for 'Review + create' (highlighted in blue), '< Previous', and 'Next : Disks >'.

## Add disks

### Prerequisites

To add a disk, it must meet the following requirements:

- Must be either a premium SSD, standard SSD, or an ultra disk in the same availability zone as the disk pool.
  - Currently, you can only add premium SSDs and Standard SSDs in the portal. Ultra disks must be added with either the Azure PowerShell module or the Azure CLI.
  - For ultra disks, it must have a disk sector size of 512 bytes.
- Must be a shared disk with a maxShares value of two or greater.
- Disk pools can't be configured to contain both premium/standard SSDs and ultra disks. A disk pool configured for ultra disks can only contain ultra disks. Likewise, a disk pool configured for premium or standard SSDs can only contain premium and standard SSDs.
- You must grant RBAC permissions to the resource provider of disk pool to manage the disk you plan to add.

If your disk meets these requirements, you can add it to a disk pool by selecting **+ Add disk** in the disk pool pane.

# Create a disk pool

- If you encounter any issues deploying a disk pool, see [Troubleshoot Azure disk pools \(preview\)](#).
- [Attach disk pools to Azure VMware Solution hosts \(Preview\)](#).
- [Manage a disk pool](#).

# Move a disk pool (preview) to a different subscription

9/21/2022 • 2 minutes to read • [Edit Online](#)

Moving an Azure disk pool (preview) involves moving the disk pool itself, the disks contained in the disk pool, the disk pool's managed resource group, and all the resources contained in the managed resource group. Currently, Azure doesn't support moving multiple resource groups to another subscription at once.

- Export the template of your existing disk pool.
- Delete the old disk pool.
- Move the Azure resources necessary to create a disk pool.
- Redeploy the disk pool.

## Export your existing disk pool template

To make the redeployment process simpler, export the template from your existing disk pool. You can use this template to redeploy the disk pool in a subscription of your choice, with the same configuration. See [this article](#) to learn how to export a template from a resource.

## Delete the old disk pool

Now that you've exported the template, delete the old disk pool. Deleting the disk pool removes the disk pool resource and its managed resource group. See [this article](#) for guidance on how to delete a disk pool.

## Move your disks and virtual network

Now that the disk pool is deleted, you can move the virtual network and your disks, and potentially your clients, to the subscription you want to change to. See [this article](#) to learn how to move Azure resources to another subscription.

## Redeploy your disk pool

Once you've moved your other resources into the subscription, update the template of your old disk pool so that all the references to your disks, virtual network, subnet, and clients, all now point to their new resource URIs. Once you've done that, redeploy the template to the new subscription. To learn how to edit and deploy a template, see [this article](#).

## Next steps

To learn how to manage your disk pool, see [Manage a disk pool](#).

# Manage an Azure disk pool (preview)

9/21/2022 • 6 minutes to read • [Edit Online](#)

This article covers how to add a managed disk to an Azure disk pool (preview) and how to disable iSCSI support on a disk that has been added to a disk pool.

## Add a disk to a pool

Your disk must meet the following requirements in order to be added to the disk pool:

- Must be either a premium SSD, standard SSD, or an ultra disk in the same region and availability zone as the disk pool.
    - Ultra disks must have a disk sector size of 512 bytes.
  - Must be a shared disk, with a maxShares value of two or greater.
  - You must [provide the StoragePool resource provider RBAC permissions to the disks that will be added to the disk pool](#).
- [Portal](#)
  - [PowerShell](#)
  - [Azure CLI](#)

1. Sign in to the [Azure portal](#).
2. Navigate to your disk pool, and select **Disks** under **Settings**.
3. Select **Attach existing disk** and select your disks.
4. When you have chosen all the disks you'd like to attach, select **Save**.

Disk name	Size (GiB)	Disk type	IOPS	Bandwidth (Mbps)
poolOne	1024	Premium SSD LRS	5000	200
poolThree	1024 GiB	Premium SSD LRS (5000 IOPS, 200 Mbps bandwidth)	-	-
poolTwo	1024 GiB	Premium SSD LRS (5000 IOPS, 200 Mbps bandwidth)	0	0

Now that you've attached your disk, you must enable their LUNS.

5. Select **iSCSI** under **Settings**.
6. Select **Add LUN** under **Disks enabled for iSCSI**.

7. Select the disk you attached earlier.

8. Select **Save**.

The screenshot shows the Azure portal interface for managing a disk pool. The left sidebar lists various tabs: Overview, Activity log, Access control (IAM), Tags, Settings, Disks, iSCSI (which is selected and highlighted in grey), Properties, Locks, Automation, Tasks (preview), Export template, Support + troubleshooting, and New Support Request. The main content area is titled 'yourdiskpool | iSCSI'. It includes sections for enabling iSCSI support, setting the iSCSI target name (example), iSCSI target IQN (iqn.2021-10.com.example:example), iSCSI resource ID, and endpoints (1.1.1.2:1 | 1.1.1.1:1). Below these, the 'Access control list (ACL) options' section shows 'ACL mode' set to 'Dynamic'. The 'Disks enabled for iSCSI' section lists four disks: poolOne, poolThree (selected and highlighted with a red border), and poolTwo. The 'Save' button at the bottom is also highlighted with a red border.

Now that you've attached your disk and enabled the LUN, you must create and attach it as an iSCSI datastore to your Azure VMware Solution private cloud. See [Attach the iSCSI LUN](#) for details.

## Disable iSCSI on a disk and remove it from the pool

Before you disable iSCSI support on a disk, confirm there is no outstanding iSCSI connections to the iSCSI LUN the disk is exposed as. When a disk is removed from the disk pool, it isn't automatically deleted. This prevents any data loss but you will still be billed for storing data. If you don't need the data stored in a disk, you can manually delete the disk. This will delete the disk and all data stored on it and will prevent further charges.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Sign in to the [Azure portal](#).
2. Navigate to your disk pool and select iSCSI under **Settings**.
3. Under **Disks enabled for iSCSI** select the disks you'd like to remove and select **Remove LUN**.
4. Select **Save** and wait for the operation to complete.

## Next steps

- To learn how to move a disk pool to another subscription, see [Move a disk pool to a different subscription](#).
- To learn how to deprovision a disk pool, see [Deprovision an Azure disk pool](#).

# Deprovision an Azure disk pool (preview)

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article covers the deletion process for an Azure disk pool (preview) and how to disable iSCSI support.

## Stop a disk pool

You can stop a disk pool to save costs and preserve all configurations. When a disk pool is stopped, you can no longer connect to it over iSCSI. The managed resources deployed to support the disk pool will not be deleted. You must disconnect all clients with iSCSI connections to the disk pool first before stopping a disk pool. You can start a disk pool at any time. This will reactivate the iSCSI target exposed on this disk pool.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Sign in to the [Azure portal](#).
2. Navigate to your disk pool, and select **Stop**.

## Disable iSCSI support

If you disable iSCSI support on a disk pool, you can no longer connect to a disk pool.

When you first enable iSCSI support on a disk pool, an iSCSI target is created as the endpoint for the iSCSI connection. You can disable iSCSI support on the disk pool by deleting the iSCSI target. Each disk pool can only have one iSCSI target configured.

You can re-enable iSCSI support on an existing disk pool. iSCSI support cannot be disabled on the disk pool if there are outstanding iSCSI connections to the disk pool.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Search for **Disk pool** and select your disk pool.
2. Select **iSCSI** under **Settings**.
3. Clear the **Enable iSCSI** checkbox and select **Save**.

## Delete a disk pool

When you delete a disk pool, all the resources in the managed resource group are also deleted. If there are outstanding iSCSI connections to the disk pool, you cannot delete the disk pool. You must disconnect all clients with iSCSI connections to the disk pool first. Disks that have been added to the disk pool will not be deleted.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Sign in to the [Azure portal](#).
2. Search for **Disk pool** and select it, then select the disk pool you want to delete.

3. Select **Delete** at the top of the pane.

## Next steps

Learn about [Azure managed disks](#).

# Troubleshoot Azure disk pools (preview)

9/21/2022 • 2 minutes to read • [Edit Online](#)

This article lists some common failure codes related to Azure disk pools (preview). It also provides possible resolutions and some clarity on disk pool statuses.

## Disk pool status

Disk pools and iSCSI targets each have four states: **Unknown**, **Running**, **Updating**, and **Stopped (deallocated)**.

**Unknown** means that the resource is in a bad or unknown state. To attempt recovery, perform an update operation on the resource (such as adding or removing disks/LUNS) or delete and redeploy your disk pool.

**Running** means the resource is running and in a healthy state.

**Updating** means that the resource is going through an update. This usually happens during deployment or when applying an update like adding disks or LUNs.

**Stopped (deallocated)** means that the resource is stopped and its underlying resources have been deallocated. You can restart the resource to recover your disk pool or iSCSI target.

## Common failure codes when deploying a disk pool

CODE	DESCRIPTION
UnexpectedError	Usually occurs when a backend unrecoverable error occurs. Retry the deployment. If the issue isn't resolved, contact Azure Support and provide the tracking ID of the error message.
DeploymentFailureZonalAllocationFailed	This occurs when Azure runs out of capacity to provision a VM in the specified region/zone. Retry the deployment at another time.
DeploymentFailureQuotaExceeded	The subscription used to deploy the disk pool is out of VM core quota in this region. You can <a href="#">request an increase in vCPU quota limits per Azure VM series</a> for Dsv3 series.
DeploymentFailurePolicyViolation	A policy on the subscription prevented the deployment of Azure resources that are required to support a disk pool. See the error for more details.
DeploymentTimeout	This occurs when the deployment of the disk pool infrastructure gets stuck and doesn't complete in the allotted time. Retry the deployment. If the issue persists, contact Azure support and provide the tracking ID of the error message.

CODE	DESCRIPTION
GoalStateApplicationTimeoutError	Occurs when the disk pool infrastructure stops responding to the resource provider. Confirm you meet the <a href="#">networking prerequisites</a> and then retry the deployment. If the issue persists, contact Azure support and provide the tracking ID of the error.
OngoingOperationInProgress	An ongoing operation is in-progress on the disk pool. Wait until that operation completes, then retry deployment.

## Common failure codes when enabling iSCSI on disk pools

CODE	DESCRIPTION
GoalStateApplicationError	Occurs when the iSCSI target configuration is invalid and cannot be applied to the disk pool. Retry the deployment. If the issue persists, contact Azure support and provide the tracking ID of the error.
GoalStateApplicationTimeoutError	Occurs when the disk pool infrastructure stops responding to the resource provider. Confirm you meet the <a href="#">networking prerequisites</a> and then retry the deployment. If the issue persists, contact Azure support and provide the tracking ID of the error.
OngoingOperationInProgress	An ongoing operation is in-progress on the disk pool. Wait until that operation completes, then retry deployment.

## Next steps

[Manage a disk pool \(preview\)](#)

# Overview of managed disk encryption options

9/21/2022 • 2 minutes to read • [Edit Online](#)

There are several types of encryption available for your managed disks, including Azure Disk Encryption (ADE), Server-Side Encryption (SSE) and encryption at host.

- **Azure Disk Encryption** helps protect and safeguard your data to meet your organizational security and compliance commitments. ADE encrypts the OS and data disks of Azure virtual machines (VMs) inside your VMs by using the [DM-Crypt](#) feature of Linux or the [BitLocker](#) feature of Windows. ADE is integrated with Azure Key Vault to help you control and manage the disk encryption keys and secrets. For full details, see [Azure Disk Encryption for Linux VMs](#) or [Azure Disk Encryption for Windows VMs](#).
- **Azure Disk Storage Server-Side Encryption** (also referred to as encryption-at-rest or Azure Storage encryption) automatically encrypts data stored on Azure managed disks (OS and data disks) when persisting on the Storage Clusters. When configured with a Disk Encryption Set (DES), it supports customer-managed keys as well. For full details, see [Server-side encryption of Azure Disk Storage](#).
- **Encryption at host** ensures that data stored on the VM host hosting your VM is encrypted at rest and flows encrypted to the Storage clusters. For full details, see [Encryption at host - End-to-end encryption for your VM data](#).
- **Confidential disk encryption** binds disk encryption keys to the virtual machine's TPM and makes the protected disk content accessible only to the VM. The TPM and VM guest state is always encrypted in attested code using keys released by a secure protocol that bypasses the hypervisor and host operating system. Currently only available for the OS disk. Encryption at host may be used for other disks on a Confidential VM in addition to Confidential Disk Encryption. For full details, see [DCasv5 and ECasv5 series confidential VMs](#).

Encryption is part of a layered approach to security and should be used with other recommendations to secure Virtual Machines and their disks. For full details, see [Security recommendations for virtual machines in Azure](#) and [Restrict import/export access to managed disks](#).

## Comparison

Here's a comparison of Disk Storage SSE, ADE, encryption at host, and Confidential disk encryption.

	ENCRYPTION AT REST (OS AND DATA DISKS)	TEMP DISK ENCRYPTION	ENCRYPTION OF CACHES	DATA FLOWS ENCRYPTED BETWEEN COMPUTE AND STORAGE	CUSTOMER CONTROL OF KEYS	DOES NOT USE YOUR VM'S CPU	WORKS FOR CUSTOM IMAGES	ENHANCED KEY PROTECTION	MICROSOFT DEFENDER FOR CLOUD DISK ENCRYPTION STATUS
Azure Disk Storage Server-Side Encryption at rest	✓	✗	✗	✗	✓ When configured with DES	✓	✓	✗	Unhealthy, not applicable if exempt
Azure Disk Encryption	✓	✓	✓	✓	✓	✗	✗ Does not work for custom Linux images	✗	Healthy
Encryption at Host	✓	✓	✓	✓	✓	✓	✓	✗	Unhealthy, not applicable if exempt
Confidential disk encryption	✓ For the OS disk only	✗	✓ For the OS disk only	✓ For the OS disk only	✓ For the OS disk only	✗	✓	✓	Unhealthy, not applicable if exempt

#### IMPORTANT

For Encryption at host and Confidential disk encryption, Microsoft Defender for Cloud does not detect the encryption state. We are in the process of updating Microsoft Defender

## Next steps

- [Azure Disk Encryption for Linux VMs](#)

# Server-side encryption of Azure Disk Storage

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Most Azure managed disks are encrypted with Azure Storage encryption, which uses server-side encryption (SSE) to protect your data and to help you meet your organizational security and compliance commitments. Azure Storage encryption automatically encrypts your data stored on Azure managed disks (OS and data disks) at rest by default when persisting it to the cloud. Disks with encryption at host enabled, however, are not encrypted through Azure Storage. For disks with encryption at host enabled, the server hosting your VM provides the encryption for your data, and that encrypted data flows into Azure Storage.

Data in Azure managed disks is encrypted transparently using 256-bit [AES encryption](#), one of the strongest block ciphers available, and is FIPS 140-2 compliant. For more information about the cryptographic modules underlying Azure managed disks, see [Cryptography API: Next Generation](#)

Azure Storage encryption does not impact the performance of managed disks and there is no additional cost. For more information about Azure Storage encryption, see [Azure Storage encryption](#).

## NOTE

Temporary disks are not managed disks and are not encrypted by SSE, unless you enable encryption at host.

## About encryption key management

You can rely on platform-managed keys for the encryption of your managed disk, or you can manage encryption using your own keys. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all data in managed disks.

The following sections describe each of the options for key management in greater detail.

### Platform-managed keys

By default, managed disks use platform-managed encryption keys. All managed disks, snapshots, images, and data written to existing managed disks are automatically encrypted-at-rest with platform-managed keys.

### Customer-managed keys

You can choose to manage encryption at the level of each managed disk, with your own keys. When you specify a customer-managed key, that key is used to protect and control access to the key that encrypts your data. Customer-managed keys offer greater flexibility to manage access controls.

You must use one of the following Azure key stores to store your customer-managed keys:

- [Azure Key Vault](#)
- [Azure Key Vault Managed Hardware Security Module \(HSM\)](#)

You can either import [your RSA keys](#) to your Key Vault or generate new RSA keys in Azure Key Vault. Azure managed disks handles the encryption and decryption in a fully transparent fashion using envelope encryption. It encrypts data using an [AES](#) 256 based data encryption key (DEK), which is, in turn, protected using your keys. The Storage service generates data encryption keys and encrypts them with customer-managed keys using RSA encryption. The envelope encryption allows you to rotate (change) your keys periodically as per your compliance policies without impacting your VMs. When you rotate your keys, the Storage service re-encrypts

the data encryption keys with the new customer-managed keys.

Managed Disks and the Key Vault or managed HSM must be in the same Azure region, but they can be in different subscriptions. They must also be in the same Azure Active Directory (Azure AD) tenant, unless you're using [Encrypt managed disks with cross-tenant customer-managed keys \(preview\)](#).

#### Full control of your keys

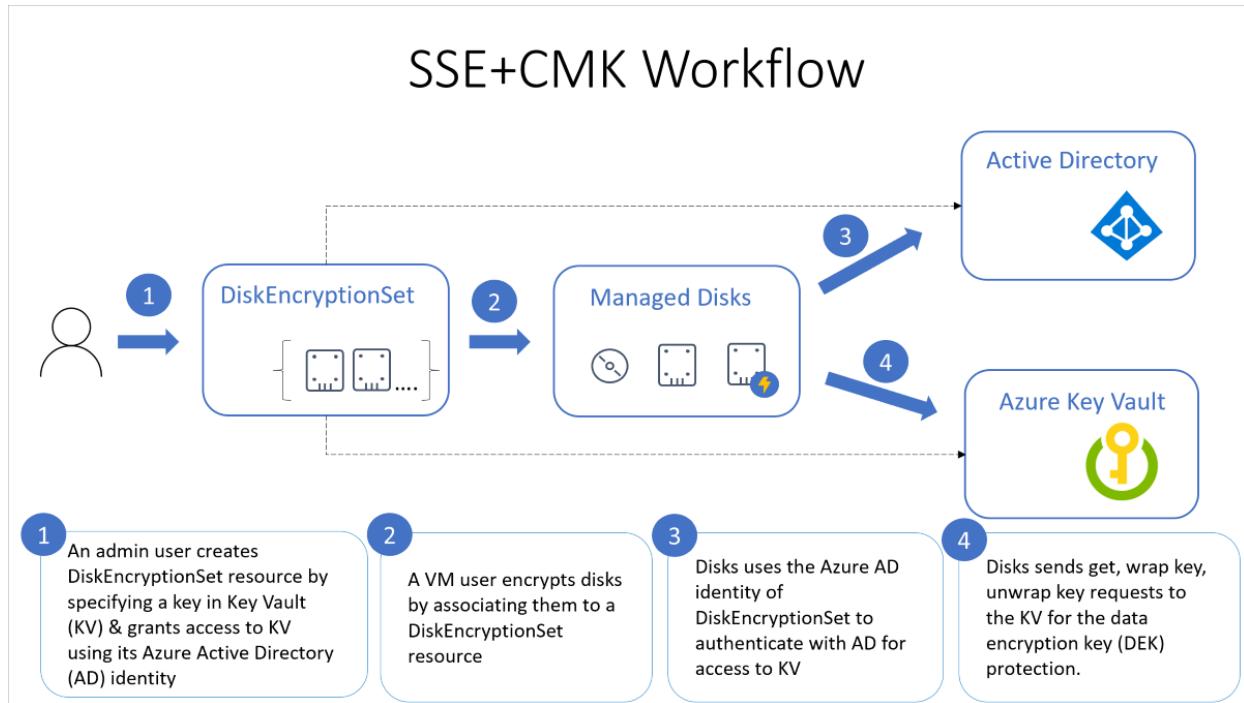

You must grant access to managed disks in your Key Vault or managed HSM to use your keys for encrypting and decrypting the DEK. This allows you full control of your data and keys. You can disable your keys or revoke access to managed disks at any time. You can also audit the encryption key usage with Azure Key Vault monitoring to ensure that only managed disks or other trusted Azure services are accessing your keys.

When a key is either disabled, deleted, or expired, any VMs with disks using that key will automatically shut down. After this, the VMs will not be usable unless the key is enabled again or you assign a new key.

#### NOTE

It is generally expected that Disk I/O (read or write operations) will start to fail 1 hour after a key is either disabled, deleted, or expired.

The following diagram shows how managed disks use Azure Active Directory and Azure Key Vault to make requests using the customer-managed key:

The following list explains the diagram in more detail:

1. An Azure Key Vault administrator creates key vault resources.
2. The key vault admin either imports their RSA keys to Key Vault or generate new RSA keys in Key Vault.
3. That administrator creates an instance of Disk Encryption Set resource, specifying an Azure Key Vault ID and a key URL. Disk Encryption Set is a new resource introduced for simplifying the key management for managed disks.
4. When a disk encryption set is created, a [system-assigned managed identity](#) is created in Azure Active Directory (AD) and associated with the disk encryption set.
5. The Azure key vault administrator then grants the managed identity permission to perform operations in the key vault.
6. A VM user creates disks by associating them with the disk encryption set. The VM user can also enable

server-side encryption with customer-managed keys for existing resources by associating them with the disk encryption set.

7. Managed disks use the managed identity to send requests to the Azure Key Vault.
8. For reading or writing data, managed disks sends requests to Azure Key Vault to encrypt (wrap) and decrypt (unwrap) the data encryption key in order to perform encryption and decryption of the data.

To revoke access to customer-managed keys, see [Azure Key Vault PowerShell](#) and [Azure Key Vault CLI](#). Revoking access effectively blocks access to all data in the storage account, as the encryption key is inaccessible by Azure Storage.

#### **Automatic key rotation of customer-managed keys**

You can choose to enable automatic key rotation to the latest key version. A disk references a key via its disk encryption set. When you enable automatic rotation for a disk encryption set, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour. To learn how to enable customer-managed keys with automatic key rotation, see [Set up an Azure Key Vault and DiskEncryptionSet with automatic key rotation](#).

#### **NOTE**

Virtual Machines will not be rebooted during automatic key rotation.

#### **Restrictions**

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for your disk, you cannot disable it. If you need to work around this, you must copy all the data using either the [Azure PowerShell module](#) or the [Azure CLI](#), to an entirely different managed disk that isn't using customer-managed keys.
- Only [software](#) and [HSM RSA keys](#) of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - [HSM](#) keys require the [premium](#) tier of Azure Key vaults.
- Disks created from custom images that are encrypted using server-side encryption and customer-managed keys must be encrypted using the same customer-managed keys and must be in the same subscription.
- Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.
- Disks, snapshots, and images encrypted with customer-managed keys cannot move to another resource group and subscription.
- Managed disks currently or previously encrypted using Azure Disk Encryption cannot be encrypted using customer-managed keys.
- Can only create up to 1000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see [Preview: Use customer-managed keys for encrypting images](#).

#### **Supported regions**

Customer-managed keys are available in all regions that managed disks are available.

## **IMPORTANT**

Customer-managed keys rely on managed identities for Azure resources, a feature of Azure Active Directory (Azure AD). When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Azure AD directory to another, the managed identity associated with managed disks isn't transferred to the new tenant, so customer-managed keys may no longer work. For more information, see [Transferring a subscription between Azure AD directories](#).

To enable customer-managed keys for managed disks, see our articles covering how to enable it with either the [Azure PowerShell module](#), the [Azure CLI](#) or the [Azure portal](#).

## Encryption at host - End-to-end encryption for your VM data

When you enable encryption at host, that encryption starts on the VM host itself, the Azure server that your VM is allocated to. The data for your temporary disk and OS/data disk caches are stored on that VM host. After enabling encryption at host, all this data is encrypted at rest and flows encrypted to the Storage service, where it is persisted. Essentially, encryption at host encrypts your data from end-to-end. Encryption at host does not use your VM's CPU and doesn't impact your VM's performance.

Temporary disks and ephemeral OS disks are encrypted at rest with platform-managed keys when you enable end-to-end encryption. The OS and data disk caches are encrypted at rest with either customer-managed or platform-managed keys, depending on the selected disk encryption type. For example, if a disk is encrypted with customer-managed keys, then the cache for the disk is encrypted with customer-managed keys, and if a disk is encrypted with platform-managed keys then the cache for the disk is encrypted with platform-managed keys.

### **Restrictions**

- Doesn't support ultra disks.
- Cannot be enabled if Azure Disk Encryption (guest-VM encryption using bitlocker/DM-Crypt) is enabled on your VMs/virtual machine scale sets.
- Azure Disk Encryption cannot be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale set. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.
- Supports ephemeral OS disks but only with platform-managed keys.

### **Supported VM sizes**

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, refer to the finding supported VM sizes section of either the [Azure PowerShell module](#) or [Azure CLI](#) articles.

To enable end-to-end encryption using encryption at host, see our articles covering how to enable it with either the [Azure PowerShell module](#), the [Azure CLI](#), or the [Azure portal](#).

## Double encryption at rest

High security sensitive customers who are concerned of the risk associated with any particular encryption algorithm, implementation, or key being compromised can now opt for additional layer of encryption using a different encryption algorithm/mode at the infrastructure layer using platform managed encryption keys. This new layer can be applied to persisted OS and data disks, snapshots, and images, all of which will be encrypted at rest with double encryption.

### **Supported regions**

Double encryption is available in all regions that managed disks are available.

To enable double encryption at rest for managed disks, see our articles covering how to enable it with either the [Azure PowerShell module](#), the [Azure CLI](#) or the [Azure portal](#).

## Server-side encryption versus Azure disk encryption

[Azure Disk Encryption](#) leverages either the [DM-Crypt](#) feature of Linux or the [BitLocker](#) feature of Windows to encrypt managed disks with customer-managed keys within the guest VM. Server-side encryption with customer-managed keys improves on ADE by enabling you to use any OS types and images for your VMs by encrypting data in the Storage service.

### IMPORTANT

Customer-managed keys rely on managed identities for Azure resources, a feature of Azure Active Directory (Azure AD). When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Azure AD directory to another, the managed identity associated with managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see [Transferring a subscription between Azure AD directories](#).

## Next steps

- Enable end-to-end encryption using encryption at host with either the [Azure PowerShell module](#), the [Azure CLI](#), or the [Azure portal](#).
- Enable double encryption at rest for managed disks with either the [Azure PowerShell module](#), the [Azure CLI](#) or the [Azure portal](#).
- Enable customer-managed keys for managed disks with either the [Azure PowerShell module](#), the [Azure CLI](#) or the [Azure portal](#).
- [Explore the Azure Resource Manager templates for creating encrypted disks with customer-managed keys](#)
- [What is Azure Key Vault?](#)

# Use the Azure portal to enable server-side encryption with customer-managed keys for managed disks

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓

Azure Disk Storage allows you to manage your own keys when using server-side encryption (SSE) for managed disks, if you choose. For conceptual information on SSE with customer managed keys, as well as other managed disk encryption types, see the **Customer-managed keys** section of our disk encryption article: [Customer-managed keys](#)

## Restrictions

For now, customer-managed keys have the following restrictions:

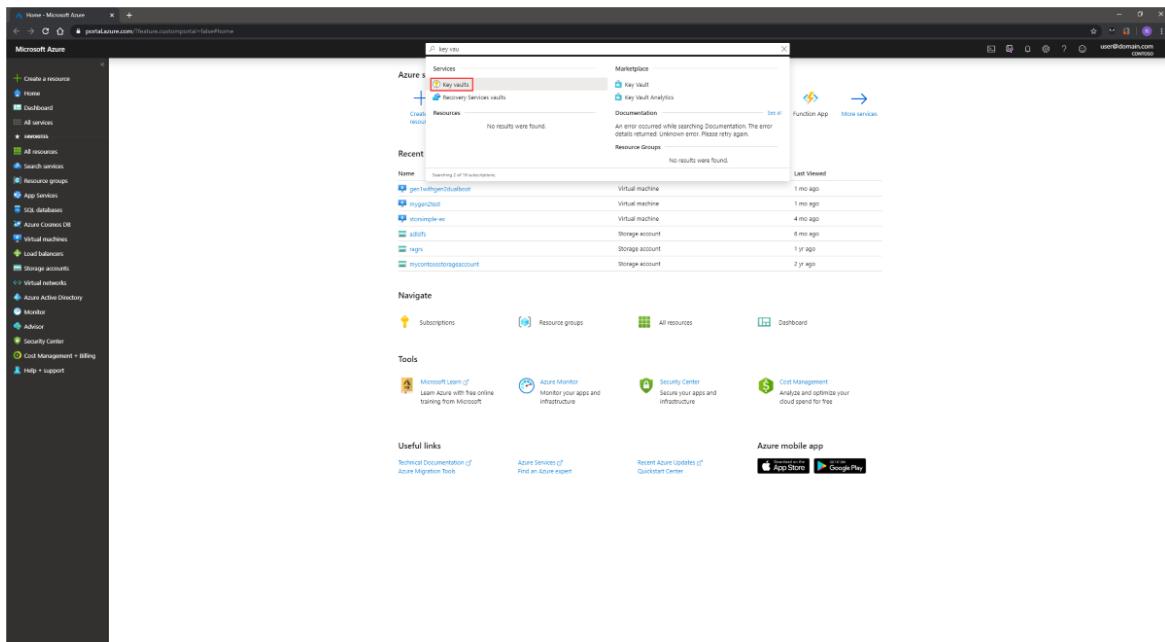

- If this feature is enabled for your disk, you cannot disable it. If you need to work around this, you must copy all the data to an entirely different managed disk that isn't using customer-managed keys:
  - For Linux: [Copy a managed disk](#)
  - For Windows: [Copy a managed disk](#)
- Only **software and HSM RSA keys** of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - **HSM** keys require the **premium** tier of Azure Key vaults.
- Disks created from custom images that are encrypted using server-side encryption and customer-managed keys must be encrypted using the same customer-managed keys and must be in the same subscription.
- Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.
- Disks, snapshots, and images encrypted with customer-managed keys cannot move to another resource group and subscription.
- Managed disks currently or previously encrypted using Azure Disk Encryption cannot be encrypted using customer-managed keys.
- Can only create up to 1000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see [Preview: Use customer-managed keys for encrypting images](#).

The following sections cover how to enable and use customer-managed keys for managed disks:

Setting up customer-managed keys for your disks will require you to create resources in a particular order, if you're doing it for the first time. First, you will need to create and set up an Azure Key Vault.

## Set up your Azure Key Vault

1. Sign into the Azure portal.
2. Search for and select Key Vaults.

### IMPORTANT

Your disk encryption set, VM, disks, and snapshots must all be in the same region and subscription for deployment to succeed. Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.

3. Select **+Create** to create a new Key Vault.
4. Create a new resource group.
5. Enter a key vault name, select a region, and select a pricing tier.

### NOTE

When creating the Key Vault instance, you must enable soft delete and purge protection. Soft delete ensures that the Key Vault holds a deleted key for a given retention period (90 day default). Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

6. Select **Review + Create**, verify your choices, then select **Create**.

Dashboard > Key vaults > Create key vault

## Create key vault

**Basics** [Access policy](#) [Networking](#) [Tags](#) [Review + create](#)

Azure Key Vault is a cloud service used to manage keys, secrets, and certificates. Key Vault eliminates the need for developers to store security information in their code. It allows you to centralize the storage of your application secrets which greatly reduces the chances that secrets may be leaked. Key Vault also allows you to securely store secrets and keys backed by Hardware Security Modules or HSMs. The HSMs used are Federal Information Processing Standards (FIPS) 140-2 Level 2 validated. In addition, key vault provides logs of all access and usage attempts of your secrets so you have a complete audit trail for compliance. [Learn more](#)

**Project details**

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

**Subscription \*** My Example Subscription

**Create**

### Add an Azure RBAC role

Now that you've created the Azure key vault and a key, you must add an Azure RBAC role, so you can use your Azure key vault with your disk encryption set.

1. Select **Access control (IAM)** and add a role.
2. Add either the **Key Vault Administrator**, **Owner**, or **Contributor** roles.

### Set up your disk encryption set

1. Search for **Disk Encryption Sets** and select it.
2. On the **Disk Encryption Sets** pane select **+Create**.
3. Select your resource group, name your encryption set, and select the same region as your key vault.
4. For **SSE Encryption type**, select **Encryption at-rest with a customer-managed key**.

**NOTE**

Once you create a disk encryption set with a particular encryption type, it cannot be changed. If you want to use a different encryption type, you must create a new disk encryption set.

5. Select **Click to select a key**.
6. Select the key vault and key you created previously, and the version.
7. Press **Select**.
8. If you want to enable [automatic rotation of customer managed keys](#), select **Auto key rotation**.
9. Select **Review + Create** and then **Create**.

## Create a disk encryption set

Basics Tags Review + create

Disk encryption sets allow you to manage encryption keys using server-side encryption for Standard HDD, Standard SSD, and Premium SSD managed disks. It will give you control of the encryption keys to meet your security and compliance needs in a few clicks. [Learn more about disk encryption sets.](#)

10. Navigate to the disk encryption set once it is deployed, and select the displayed alert.

The screenshot shows a deployment blade with a search bar and a delete button. Below the search bar are three tabs: Overview (selected), Activity log, and Overview. A red box highlights a message: "To associate a disk, image, or snapshot with this disk encryption set, you must grant permissions to the key vault my-example-key-vault. →".

11. This will grant your key vault permissions to the disk encryption set.

The screenshot shows a modal window with a green checkmark icon and the text "Successfully granted permissions". Below it says "Successfully granted permissions to the key vault 'my-example-key-vault'. a few seconds ago".

## Deploy a VM

Now that you've created and set up your key vault and the disk encryption set, you can deploy a VM using the encryption. The VM deployment process is similar to the standard deployment process, the only differences are that you need to deploy the VM in the same region as your other resources and you opt to use a customer managed key.

1. Search for **Virtual Machines** and select **+ Add** to create a VM.
2. On the **Basic** blade, select the same region as your disk encryption set and Azure Key Vault.
3. Fill in the other values on the **Basic** blade as you like.

## Create a virtual machine

Learn more about disk encryption.

Disk encryption set \*

exampleSetName

6. Repeat this process for any other disks attached to the VM you'd like to encrypt.

7. When your disks finish switching over to customer-managed keys, if there are no other attached disks you'd like to encrypt, you may start your VM.

#### IMPORTANT

Customer-managed keys rely on managed identities for Azure resources, a feature of Azure Active Directory (Azure AD). When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Azure AD directory to another, the managed identity associated with the managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see [Transferring a subscription between Azure AD directories](#).

#### Enable automatic key rotation on an existing disk encryption set

1. Navigate to the disk encryption set that you want to enable **automatic key rotation** on.
2. Under **Settings**, select **Key**.

3. Select **Auto key rotation** and select **Save**.

## Next steps

- Explore the Azure Resource Manager templates for creating encrypted disks with customer-managed keys
- What is Azure Key Vault?
- Replicate machines with customer-managed keys enabled disks

- Set up disaster recovery to Azure for Hyper-V VMs using PowerShell and Azure Resource Manager

# Azure PowerShell - Enable customer-managed keys with server-side encryption - managed disks

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure Disk Storage allows you to manage your own keys when using server-side encryption (SSE) for managed disks, if you choose. For conceptual information on SSE with customer-managed keys, and other managed disk encryption types, see the [Customer-managed keys](#) section of our disk encryption article.

## Restrictions

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for your disk, you cannot disable it. If you need to work around this, you must [copy all the data](#) to an entirely different managed disk that isn't using customer-managed keys.
- Only [software and HSM RSA keys](#) of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - [HSM](#) keys require the [premium](#) tier of Azure Key vaults.
- Disks created from custom images that are encrypted using server-side encryption and customer-managed keys must be encrypted using the same customer-managed keys and must be in the same subscription.
- Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.
- Disks, snapshots, and images encrypted with customer-managed keys cannot move to another resource group and subscription.
- Managed disks currently or previously encrypted using Azure Disk Encryption cannot be encrypted using customer-managed keys.
- Can only create up to 1000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see [Preview: Use customer-managed keys for encrypting images](#).

## Set up an Azure Key Vault and DiskEncryptionSet optionally with automatic key rotation

To use customer-managed keys with SSE, you must set up an Azure Key Vault and a DiskEncryptionSet resource.

1. Make sure that you have installed latest [Azure PowerShell version](#), and you are signed in to an Azure account in with Connect-AzAccount
2. Create an instance of Azure Key Vault and encryption key.

When creating the Key Vault instance, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for

encrypting managed disks.

```
$ResourceGroupName="yourResourceGroupName"  
$LocationName="westcentralus"  
$keyVaultName="yourKeyVaultName"  
$keyName="yourKeyName"  
$keyDestination="Software"  
$diskEncryptionSetName="yourDiskEncryptionSetName"  
  
$keyVault = New-AzKeyVault -Name $keyVaultName `  
-ResourceGroupName $ResourceGroupName `  
-Location $LocationName `  
-EnablePurgeProtection  
  
$key = Add-AzKeyVaultKey -VaultName $keyVaultName `  
-Name $keyName `  
-Destination $keyDestination
```

3. Create an instance of a DiskEncryptionSet. You can set RotationToLatestKeyVersionEnabled equal to \$true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

```
$desConfig=New-AzDiskEncryptionSetConfig -Location $LocationName `  
-SourceVaultId $keyVault.ResourceId `  
-KeyUrl $key.Key.Kid `  
-IdentityType SystemAssigned `  
-RotationToLatestKeyVersionEnabled $false  
  
$des=New-AzDiskEncryptionSet -Name $diskEncryptionSetName `  
-ResourceGroupName $ResourceGroupName `  
-InputObject $desConfig
```

4. Grant the DiskEncryptionSet resource access to the key vault.

**NOTE**

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ObjectId $des.Identity.PrincipalId -  
PermissionsToKeys wrapkey,unwrapkey,get
```

### Use a key vault in a different subscription

Alternatively, you can manage your Azure Key Vaults centrally from a single subscription, and use the keys stored in the Key Vault to encrypt managed disks and snapshots in other subscriptions in your organization. This allows your security team to enforce and easily manage a robust security policy to a single subscription.

**IMPORTANT**

For this configuration, both your Key Vault and your disk encryption set must be in the same region and be using the same tenant.

The following script is an example of how you would configure a disk encryption set to use a key from a Key Vault in a different subscription, but same region:

```

$sourceSubscriptionId=<sourceSubID>
$sourceKeyVaultName=<sourceKVName>
$sourceKeyName=<sourceKeyName>

$targetSubscriptionId=<targetSubID>
$targetResourceGroupName=<targetRGName>
$targetDiskEncryptionSetName=<targetDiskEncSetName>
$location=<targetRegion>

Set-AzContext -Subscription $sourceSubscriptionId

$key = Get-AzKeyVaultKey -VaultName $sourceKeyVaultName -Name $sourceKeyName

Set-AzContext -Subscription $targetSubscriptionId

$desConfig=New-AzDiskEncryptionSetConfig -Location $location ` 
-KeyUrl $key.Key.Kid ` 
-IdentityType SystemAssigned ` 
-RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $targetDiskEncryptionSetName ` 
-ResourceGroupName $targetResourceGroupName ` 
-InputObject $desConfig

```

## Examples

Now that you've created and configured these resources, you can use them to secure your managed disks. The following are example scripts, each with a respective scenario, that you can use to secure your managed disks.

### **Create a VM using a Marketplace image, encrypting the OS and data disks with customer-managed keys**

Copy the script, replace all of the example values with your own parameters, and then run it.

```

$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText -Force
$LocationName = "yourRegion"
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"
$VMName = "yourVMName"
$VMSize = "yourVMSize"
$diskEncryptionSetName="yourdiskEncryptionSetName"

$NetworkName = "yourNetworkName"
$NICName = "yourNICName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -AddressPrefix $SubnetAddressPrefix
$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName $ResourceGroupName -Location
$LocationName -AddressPrefix $VnetAddressPrefix -Subnet $SingleSubnet
$NIC = New-AzNetworkInterface -Name $NICName -ResourceGroupName $ResourceGroupName -Location $LocationName -
SubnetId $Vnet.Subnets[0].Id

$Credential = New-Object System.Management.Automation.PSCredential ($VMLocalAdminUser,
$VMLocalAdminSecurePassword);

$VirtualMachine = New-AzVMConfig -VMName $VMName -VMSize $VMSize
$VirtualMachine = Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -ComputerName $ComputerName -
Credential $Credential -ProvisionVMAgent -EnableAutoUpdate
$VirtualMachine = Add-AzVMNetworkInterface -VM $VirtualMachine -Id $NIC.Id
$VirtualMachine = Set-AzVMSourceImage -VM $VirtualMachine -PublisherName 'MicrosoftWindowsServer' -Offer
'WindowsServer' -Skus '2012-R2-Datacenter' -Version latest

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName $ResourceGroupName -Name
$diskEncryptionSetName

$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name $($VMName +"_OSDisk") -DiskEncryptionSetId
$diskEncryptionSet.Id -CreateOption FromImage

$VirtualMachine = Add-AzVMDataDisk -VM $VirtualMachine -Name $($VMName +"DataDisk1") -DiskSizeInGB 128 -
StorageAccountType Premium_LRS -CreateOption Empty -Lun 0 -DiskEncryptionSetId $diskEncryptionSet.Id

New-AzVM -ResourceGroupName $ResourceGroupName -Location $LocationName -VM $VirtualMachine -Verbose

```

## Create an empty disk encrypted using server-side encryption with customer-managed keys and attach it to a VM

Copy the script, replace all of the example values with your own parameters, and then run it.

```

$vmName = "yourVMName"
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$diskName = "yourDiskName"
$diskSKU = "Premium_LRS"
$diskSizeinGiB = 30
$diskLUN = 1
$diskEncryptionSetName="yourDiskEncryptionSetName"

$vm = Get-AzVM -Name $vmName -ResourceGroupName $ResourceGroupName

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName $ResourceGroupName -Name
$diskEncryptionSetName

$vm = Add-AzVMDataDisk -VM $vm -Name $diskName -CreateOption Empty -DiskSizeInGB $diskSizeinGiB -
StorageAccountType $diskSKU -Lun $diskLUN -DiskEncryptionSetId $diskEncryptionSet.Id

Update-AzVM -ResourceGroupName $ResourceGroupName -VM $vm

```

## Encrypt existing managed disks

Your existing disks must not be attached to a running VM in order for you to encrypt them using the following script:

```

$rgName = "yourResourceGroupName"
$diskName = "yourDiskName"
$diskEncryptionSetName = "yourDiskEncryptionSetName"

$diskEncryptionSet = Get-AzDiskEncryptionSet -ResourceGroupName $rgName -Name $diskEncryptionSetName

New-AzDiskUpdateConfig -EncryptionType "EncryptionAtRestWithCustomerKey" -DiskEncryptionSetId
$diskEncryptionSet.Id | Update-AzDisk -ResourceGroupName $rgName -DiskName $diskName

```

## Encrypt an existing virtual machine scale set (uniform orchestration mode) with SSE and customer-managed keys

This script will work for scale sets in uniform orchestration mode only. For scale sets in flexible orchestration mode, follow the Encrypt existing managed disks for each VM.

Copy the script, replace all the example values with your own parameters, and then run it:

```

#set variables
$vmssname = "name of the vmss that is already created"
$diskencryptionsetname = "name of the diskencryptionset already created"
$vmssrgname = "vmss resourcegroup name"
$diskencryptionsetrgname = "diskencryptionset resourcegroup name"

#get vmss object and create diskencryptionset object attach to vmss os disk
$ssevmss = get-azvmss -ResourceGroupName $vmssrgname -VMScaleSetName $vmssname
$ssevmss.VirtualMachineProfile.StorageProfile.OsDisk.ManagedDisk.DiskEncryptionSet = New-Object -TypeName
Microsoft.Azure.Management.Compute.Models.DiskEncryptionSetParameters

#get diskencryption object and retrieve the resource id
$des = Get-AzDiskEncryptionSet -ResourceGroupName $diskencryptionsetrgname -Name $diskencryptionsetname
write-host "the diskencryptionset resource id is:" $des.Id

#associate DES resource id to os disk and update vmss
$ssevmss.VirtualMachineProfile.StorageProfile.OsDisk.ManagedDisk.DiskEncryptionSet.id = $des.Id
$ssevmss | update-azvmss

```

## Create a virtual machine scale set using a Marketplace image, encrypting the OS and data disks with

## customer-managed keys

Copy the script, replace all of the example values with your own parameters, and then run it.

```
$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
$VMSScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"

New-AzVmss -VirtualMachineScaleSet $VMSS -ResourceGroupName $ResourceGroupName -VMSScaleSetName
$VMSScaleSetName
```

## Change the key of a DiskEncryptionSet to rotate the key for all the resources referencing the DiskEncryptionSet

Copy the script, replace all of the example values with your own parameters, and then run it.

```
$ResourceGroupName="yourResourceGroupName"
$keyVaultName="yourKeyVaultName"
$keyName="yourKeyName"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $ResourceGroupName

$keyVaultKey = Get-AzKeyVaultKey -VaultName $keyVaultName -Name $keyName

Update-AzDiskEncryptionSet -Name $diskEncryptionSetName -ResourceGroupName $ResourceGroupName -SourceVaultId
$keyVault.ResourceId -KeyUrl $keyVaultKey.Id
```

## Find the status of server-side encryption of a disk

```
$ResourceGroupName="yourResourceGroupName"
$DiskName="yourDiskName"

$disk=Get-AzDisk -ResourceGroupName $ResourceGroupName -DiskName $DiskName
$disk.Encryption.Type
```

### IMPORTANT

Customer-managed keys rely on managed identities for Azure resources, a feature of Azure Active Directory (Azure AD). When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Azure AD directory to another, the managed identity associated with the managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see [Transferring a subscription between Azure AD directories](#).

## Next steps

- [Explore the Azure Resource Manager templates for creating encrypted disks with customer-managed keys](#)
- [Replicate machines with customer-managed keys enabled disks](#)
- [Set up disaster recovery of VMware VMs to Azure with PowerShell](#)
- [Set up disaster recovery to Azure for Hyper-V VMs using PowerShell and Azure Resource Manager](#)

# Use the Azure CLI to enable server-side encryption with customer-managed keys for managed disks

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure Disk Storage allows you to manage your own keys when using server-side encryption (SSE) for managed disks, if you choose. For conceptual information on SSE with customer managed keys, as well as other managed disk encryption types, see the [Customer-managed keys](#) section of our disk encryption article.

## Restrictions

For now, customer-managed keys have the following restrictions:

- If this feature is enabled for your disk, you cannot disable it. If you need to work around this, you must [copy all the data](#) to an entirely different managed disk that isn't using customer-managed keys.
- Only [software and HSM RSA keys](#) of sizes 2,048-bit, 3,072-bit and 4,096-bit are supported, no other keys or sizes.
  - [HSM](#) keys require the [premium](#) tier of Azure Key vaults.
- Disks created from custom images that are encrypted using server-side encryption and customer-managed keys must be encrypted using the same customer-managed keys and must be in the same subscription.
- Snapshots created from disks that are encrypted with server-side encryption and customer-managed keys must be encrypted with the same customer-managed keys.
- Most resources related to your customer-managed keys (disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
  - Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.
- Disks, snapshots, and images encrypted with customer-managed keys cannot move to another resource group and subscription.
- Managed disks currently or previously encrypted using Azure Disk Encryption cannot be encrypted using customer-managed keys.
- Can only create up to 1000 disk encryption sets per region per subscription.
- For information about using customer-managed keys with shared image galleries, see [Preview: Use customer-managed keys for encrypting images](#).

## Create resources

Once the feature is enabled, you'll need to set up a DiskEncryptionSet and either an [Azure Key Vault](#) or an [Azure Key Vault Managed HSM](#).

### Azure Key Vault

- Install the latest [Azure CLI](#) and log to an Azure account in with [az login](#).
- Create an Azure Key Vault and encryption key.

When creating the Key Vault, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

## IMPORTANT

Don't camel case the region, if you do so, you may experience problems when assigning additional disks to the resource in the Azure portal.

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault create -n $keyVaultName \
-g $rgName \
-l $location \
--enable-purge-protection true

az keyvault key create --vault-name $keyVaultName \
-n $keyName \
--protection software
```

- Create a DiskEncryptionSet. You can set enable-auto-key-rotation equal to true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

- Grant the DiskEncryptionSet resource access to the key vault.

## NOTE

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query
[identity.principalId] -o tsv)

az keyvault set-policy -n $keyVaultName \
-g $rgName \
--object-id $desIdentity \
--key-permissions wrapkey unwrapkey get
```

## Azure Key Vault Managed HSM

Alternatively, you can use a Managed HSM to handle your keys.

To do this, you must complete the following prerequisites:

- Install the latest [Azure CLI](#) and log in to an Azure account in with [az login](#).
- [Create and configure a managed HSM](#).
- [Assign permissions to a user, so they can manage your Managed HSM](#).

#### Configuration

Once you've created a Managed HSM and added permissions, enable purge protection and create an encryption key.

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault update-hsm --subscription $subscriptionId -g $rgName --hsm-name $keyVaultName --enable-purge-protection true

az keyvault key create --hsm-name $keyVaultName --name $keyName --ops wrapKey unwrapKey --kty RSA-HSM --size 2048
```

Then, create a DiskEncryptionSet.

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

Finally, grant the DiskEncryptionSet access to the Managed HSM.

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [identity.principalId] -o tsv)

az keyvault role assignment create --hsm-name $keyVaultName --role "Managed HSM Crypto Service Encryption User" --assignee $desIdentity --scope /keys
```

Now that you've created and configured these resources, you can use them to secure your managed disks. The following links contain example scripts, each with a respective scenario, that you can use to secure your managed disks.

## Examples

[Create a VM using a Marketplace image, encrypting the OS and data disks with customer-managed keys](#)

```
rgName=yourResourceGroupName
vmName=yourVMName
location=westcentralus
vmSize=Standard_DS3_V2
image=UbuntuLTS
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [id] -o tsv)

az vm create -g $rgName -n $vmName -l $location --image $image --size $vmSize --generate-ssh-keys --os-disk-encryption-set $diskEncryptionSetId --data-disk-sizes-gb 128 128 --data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

### Encrypt existing managed disks

Your existing disks must not be attached to a running VM in order for you to encrypt them using the following script:

```
rgName=yourResourceGroupName
diskName=yourDiskName
diskEncryptionSetName=yourDiskEncryptionSetName

az disk update -n $diskName -g $rgName --encryption-type EncryptionAtRestWithCustomerKey --disk-encryption-set $diskEncryptionSetId
```

### Create a virtual machine scale set using a Marketplace image, encrypting the OS and data disks with customer-managed keys

```
rgName=yourResourceGroupName
vmssName=yourVMSSName
location=westcentralus
vmSize=Standard_DS3_V2
image=UbuntuLTS
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [id] -o tsv)
az vmss create -g $rgName -n $vmssName --image UbuntuLTS --upgrade-policy automatic --admin-username azureuser --generate-ssh-keys --os-disk-encryption-set $diskEncryptionSetId --data-disk-sizes-gb 64 128 --data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

### Create an empty disk encrypted using server-side encryption with customer-managed keys and attach it to a VM

```

vmName=yourVMName
rgName=yourResourceGroupName
diskName=yourDiskName
diskSkuName=Premium_LRS
diskSizeinGiB=30
location=westcentralus
diskLUN=2
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [id] -o tsv)

az disk create -n $diskName -g $rgName -l $location --encryption-type EncryptionAtRestWithCustomerKey --
disk-encryption-set $diskEncryptionSetId --size-gb $diskSizeinGiB --sku $diskSkuName

diskId=$(az disk show -n $diskName -g $rgName --query [id] -o tsv)

az vm disk attach --vm-name $vmName --lun $diskLUN --ids $diskId

```

## Change the key of a DiskEncryptionSet to rotate the key for all the resources referencing the DiskEncryptionSet

```

rgName=yourResourceGroupName
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName

keyVaultId=$(az keyvault show --name $keyVaultName --query [id] -o tsv)

keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName --query [key.kid] -o tsv)

az disk-encryption-set update -n keyrotationdes -g keyrotationtesting --key-url $keyVaultKeyUrl --source-
vault $keyVaultId

```

## Find the status of server-side encryption of a disk

```
az disk show -g yourResourceGroupName -n yourDiskName --query [encryption.type] -o tsv
```

### IMPORTANT

Customer-managed keys rely on managed identities for Azure resources, a feature of Azure Active Directory (Azure AD). When you configure customer-managed keys, a managed identity is automatically assigned to your resources under the covers. If you subsequently move the subscription, resource group, or managed disk from one Azure AD directory to another, the managed identity associated with the managed disks is not transferred to the new tenant, so customer-managed keys may no longer work. For more information, see [Transferring a subscription between Azure AD directories](#).

## Next steps

- Explore the Azure Resource Manager templates for creating encrypted disks with customer-managed keys
- Replicate machines with customer-managed keys enabled disks
- Set up disaster recovery of VMware VMs to Azure with PowerShell
- Set up disaster recovery to Azure for Hyper-V VMs using PowerShell and Azure Resource Manager

# Use the Azure portal to enable end-to-end encryption using encryption at host

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, and other managed disk encryption types, see: [Encryption at host - End-to-end encryption for your VM data](#).

Temporary disks and ephemeral OS disks are encrypted at rest with platform-managed keys when you enable end-to-end encryption. The OS and data disk caches are encrypted at rest with either customer-managed or platform-managed keys, depending on what you select as the disk encryption type. For example, if a disk is encrypted with customer-managed keys, then the cache for the disk is encrypted with customer-managed keys, and if a disk is encrypted with platform-managed keys then the cache for the disk is encrypted with platform-managed keys.

## Restrictions

- Doesn't support ultra disks.
- Cannot be enabled if Azure Disk Encryption (guest-VM encryption using bitlocker/DM-Crypt) is enabled on your VMs/virtual machine scale sets.
- Azure Disk Encryption cannot be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale set. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.
- Supports ephemeral OS disks but only with platform-managed keys.

## Supported VM sizes

Legacy VM Sizes are not supported. You can find the list of supported VM sizes by either using the [Azure PowerShell module](#) or [Azure CLI](#).

## Prerequisites

You must enable the feature for your subscription before you use the EncryptionAtHost property for your VM/VMSS. Follow the steps below to enable the feature for your subscription:

1. **Azure portal:** Select the Cloud Shell icon on the [Azure portal](#):

2. Execute the following command to register the feature for your subscription

- [Azure PowerShell](#)
- [Azure CLI](#)

```
Register-AzProviderFeature -FeatureName "EncryptionAtHost" -ProviderNamespace "Microsoft.Compute"
```

3. Confirm that the registration state is **Registered** (takes a few minutes) using the command below before trying out the feature.

- Azure PowerShell
- Azure CLI

```
Get-AzProviderFeature -FeatureName "EncryptionAtHost" -ProviderNamespace "Microsoft.Compute"
```

Sign in to the Azure portal using the [provided link](#).

#### IMPORTANT

You must use the [provided link](#) to access the Azure portal. Encryption at host is not currently visible in the public Azure portal without using the link.

## Deploy a VM with platform-managed keys

1. Sign in to the [Azure portal](#).
2. Search for **Virtual Machines** and select **+ Add** to create a VM.
3. Create a new virtual machine, select an appropriate region and a supported VM size.
4. Fill in the other values on the **Basic** pane as you like, then proceed to the  pane.

### Create a virtual machine

 Changing Basic options may reset selections you have made. Review all options prior to creating the virtual machine.

[Basics](#)   [Disks](#)   [Networking](#)   [Management](#)   [Advanced](#)   [Tags](#)   [Review + create](#)

Create a virtual machine that runs Linux or Windows. Select an image from Azure marketplace or use your own customized image. Complete the Basics tab then Review + create to provision a virtual machine with default parameters or review each tab for full customization. [Learn more](#)

#### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription \* 

My Example Subscription 

Resource group \*

[Browse all public and private images](#)

Azure Spot instance 

Yes  No

Size \* 

Standard\_DS2\_v2 - 2 vcpus, 7 GiB memory 

[Select size](#)

5. On the Disks pane, select **Encryption at host**.

6. Make the remaining selections as you like.

The screenshot shows the 'Disks' tab selected in the top navigation bar. Under 'Disk options', the 'OS disk type' is set to 'Premium SSD (locally-redundant storage)' and the 'SSE encryption type' is set to '(Default) Encryption at-rest with a platform-managed key'. A checkbox for 'Encryption at host' is checked. The overall message indicates that Azure VMs have one operating system disk and a temporary disk for short-term storage, with the size of the VM determining the type of storage allowed.

7. Finish the VM deployment process, make selections that fit your environment.

You have now deployed a VM with encryption at host enabled, and the cache for the disk is encrypted using platform-managed keys.

## Deploy a VM with customer-managed keys

Alternatively, you can use customer-managed keys to encrypt your disk caches.

### Create an Azure Key Vault and disk encryption set

Once the feature is enabled, you'll need to set up an Azure Key Vault and a disk encryption set, if you haven't already.

Setting up customer-managed keys for your disks will require you to create resources in a particular order, if you're doing it for the first time. First, you will need to create and set up an Azure Key Vault.

## Set up your Azure Key Vault

1. Sign into the [Azure portal](#).

2. Search for and select Key Vaults.

The screenshot shows the Azure portal search results for 'Key Vaults'. The search bar at the top has 'Key Vaults' typed into it. Below the search bar, there is a 'Services' section with a red box highlighting the 'Key Vault' item. Other services listed include Recovery Services vaults, Marketplace, Key Vault Analytics, Documentation, Function App, and More services. The 'Recent' section shows a list of recent resources, including 'gen-hvagen1Vault', 'myrgen1Vault', 'azurerm', 'adots', 'regis', and 'mycontosostorageaccount'. The 'Last Viewed' section shows 'Virtual machine' and 'Storage account' with their last viewed times. The bottom of the page features a 'Navigate' section with links to Microsoft Learn, Azure Monitor, Security Center, and Cost Management, along with 'Useful links' and 'Azure mobile app' sections.

### IMPORTANT

Your disk encryption set, VM, disks, and snapshots must all be in the same region and subscription for deployment to succeed. Azure Key Vaults may be used from a different subscription but must be in the same region and tenant as your disk encryption set.

3. Select **+Create** to create a new Key Vault.
4. Create a new resource group.
5. Enter a key vault name, select a region, and select a pricing tier.

### NOTE

When creating the Key Vault instance, you must enable soft delete and purge protection. Soft delete ensures that the Key Vault holds a deleted key for a given retention period (90 day default). Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

6. Select **Review + Create**, verify your choices, then select **Create**.

The screenshot shows the 'Create key vault' wizard interface. The 'Access policy' tab is selected. The 'Subscription' dropdown is set to 'My Example Subscription'. The 'Resource group' dropdown has 'Select existing...' and 'Create new' options. A tooltip for 'Resource group' explains it's a container for related resources. The 'Instance details' section includes fields for 'Key vault name', 'Region', and 'Pricing tier'. At the bottom, there are 'Review + create', '< Prev', 'OK', and 'Cancel' buttons.

7. Once your key vault finishes deploying, select it.
8. Select **Keys** under **Settings**.

9. Select **Generate/Import**.

The screenshot shows the 'my-example-vault - Keys' page in the Azure portal. On the left, there's a sidebar with icons for Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, Events (preview), Settings, Keys (which is highlighted with a red box), Secrets, and Certificates. At the top right, there are buttons for Generate/Import (highlighted with a red box), Refresh, and Restore Backup. The main area displays a table with one row: 'Name' and 'There are no keys available.'

10. Leave both **Key Type** set to RSA and **RSA Key Size** set to 2048.

11. Fill in the remaining selections as you like and then select **Create**.

The screenshot shows the 'Create a key' dialog. It has sections for Options (Generate selected), Name (empty input field), Key Type (RSA selected), RSA Key Size (2048 selected), Set activation date? (unchecked), Set expiration date? (unchecked), Enabled? (Yes selected), and a 'Create' button at the bottom (highlighted with a red box).

### Add an Azure RBAC role

Now that you've created the Azure key vault and a key, you must add an Azure RBAC role, so you can use your Azure key vault with your disk encryption set.

1. Select **Access control (IAM)** and add a role.
2. Add either the **Key Vault Administrator**, **Owner**, or **Contributor** roles.

# Set up your disk encryption set

1. Search for **Disk Encryption Sets** and select it.
2. On the **Disk Encryption Sets** pane select **+Create**.
3. Select your resource group, name your encryption set, and select the same region as your key vault.
4. For **SSE Encryption type**, select **Encryption at-rest with a customer-managed key**.

## NOTE

Once you create a disk encryption set with a particular encryption type, it cannot be changed. If you want to use a different encryption type, you must create a new disk encryption set.

5. Select **Click to select a key**.
6. Select the key vault and key you created previously, and the version.
7. Press **Select**.
8. If you want to enable **automatic rotation of customer managed keys**, select **Auto key rotation**.
9. Select **Review + Create** and then **Create**.

## Create a disk encryption set ...

[Basics](#)   [Tags](#)   [Review + create](#)

Disk encryption sets allow you to manage encryption keys using server-side encryption for Standard HDD, Standard SSD, and Premium SSD managed disks. It will give you control of the encryption keys to meet your security and compliance needs in a few clicks. [Learn more about disk encryption sets](#).

### Project details

10. Navigate to the disk encryption set once it is deployed, and select the displayed alert.

11. This will grant your key vault permissions to the disk encryption set.

Successfully granted permissions  
Successfully granted permissions to the key vault 'my-example-key-vault'.  
a few seconds ago

## Deploy a VM

Now that you've setup an Azure Key Vault and disk encryption set, you can deploy a VM and it will use encryption at host.

1. Sign in to the [Azure portal](#).
2. Search for **Virtual Machines** and select **+ Add** to create a VM.
3. Create a new virtual machine, select an appropriate region and a supported VM size.
4. Fill in the other values on the **Basic** pane as you like, then proceed to the **Disks** pane.

**Create a virtual machine**

**Basics**   **Disks**   **Networking**   **Management**   **Advanced**   **Tags**   **Review + create**

⚠️ Changing Basic options may reset selections you have made. Review all options prior to creating the virtual machine.

Create a virtual machine that runs Linux or Windows. Select an image from Azure marketplace or use your own customized image. Complete the Basics tab then Review + create to provision a virtual machine with default parameters or review each tab for full customization. [Learn more ↗](#)

**Project details**

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

**Subscription** \* ⓘ My Example Subscription

**Resource group** \* ⓘ myexamplergroup [Create new](#)

**Instance details**

**Virtual machine name** \* ⓘ my-example-vm-name

**Region** \* ⓘ (US) West US 2

**Image** \* ⓘ Windows Server 2019 Datacenter [Browse all public and private images](#)

**Azure Spot instance** ⓘ  Yes  No

**Size** \* ⓘ Standard\_DS2\_v2 - 2 vcpus, 7 GiB memory [Select size](#)

5. On the **Disks** pane, select **Encryption at-rest for customer-managed key** for SSE encryption type and select your disk encryption set.

6. Select **Encryption at host**.

7. Make the remaining selections as you like.

Disk options	
OS disk type *	Premium SSD (locally-redundant storage)
SSE encryption type *	Encryption at-rest with a customer-managed key
Disk encryption set *	example-set
Encryption at host	<input checked="" type="checkbox"/>

8. Finish the VM deployment process, make selections that fit your environment.

You have now deployed a VM with encryption at host enabled.

## Disable host based encryption

Make sure your VM is deallocated first, you cannot disable encryption at host unless your VM is deallocated.

1. On your VM, select **Disks** and then select **Additional settings**.

The screenshot shows the Azure portal's Disks blade for a virtual machine. The left sidebar has a 'Settings' section with icons for Networking, Connect, Disks (which is selected and highlighted in grey), Size, Security, and Advisor recommendations. The main area has tabs for 'Save', 'Discard', 'Refresh', and 'Additional settings' (which is highlighted with a red box). The 'OS disk' section shows a table with columns 'Storage type', 'Size (GiB)', and 'Max IOPS'. One row shows 'Premium SSD LRS', '30', and '120'. The 'Data disks' section shows a table with columns 'LUN', 'Disk name', and 'Storage type'. A note says 'No data disks attached'. At the bottom, there are buttons for 'Create and attach a new disk' and 'Attach existing disks'.

2. Select **No** for **Encryption at host** then select **Save**.

## Next steps

[Azure Resource Manager template samples](#)

# Use the Azure PowerShell module to enable end-to-end encryption using encryption at host

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, as well as other managed disk encryption types, see [Encryption at host - End-to-end encryption for your VM data](#).

## Restrictions

- Doesn't support ultra disks.
- Cannot be enabled if Azure Disk Encryption (guest-VM encryption using bitlocker/DM-Crypt) is enabled on your VMs/virtual machine scale sets.
- Azure Disk Encryption cannot be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale set. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.
- Supports ephemeral OS disks but only with platform-managed keys.

## Supported VM sizes

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, refer to the [Finding supported VM sizes](#) section. Upgrading the VM size will result in validation to check if the new VM size supports the EncryptionAtHost feature.

## Prerequisites

You must enable the feature for your subscription before you use the EncryptionAtHost property for your VM/VMSS. Please follow the steps below to enable the feature for your subscription:

1. Execute the following command to register the feature for your subscription

```
Register-AzProviderFeature -FeatureName "EncryptionAtHost" -ProviderNamespace "Microsoft.Compute"
```

2. Please check that the registration state is Registered (takes a few minutes) using the command below before trying out the feature.

```
Get-AzProviderFeature -FeatureName "EncryptionAtHost" -ProviderNamespace "Microsoft.Compute"
```

## Create an Azure Key Vault and DiskEncryptionSet

Once the feature is enabled, you'll need to set up an Azure Key Vault and a DiskEncryptionSet, if you haven't already.

1. Make sure that you have installed latest [Azure PowerShell version](#), and you are signed in to an Azure account in with Connect-AzAccount
2. Create an instance of Azure Key Vault and encryption key.

When creating the Key Vault instance, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

```
$ResourceGroupName="yourResourceGroupName"
$LocationName="westcentralus"
$keyVaultName="yourKeyVaultName"
$keyName="yourKeyName"
$keyDestination="Software"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$keyVault = New-AzKeyVault -Name $keyVaultName ` 
-ResourceGroupName $ResourceGroupName ` 
-Location $LocationName ` 
-EnablePurgeProtection

$key = Add-AzKeyVaultKey -VaultName $keyVaultName ` 
-Name $keyName ` 
-Destination $keyDestination
```

3. Create an instance of a DiskEncryptionSet. You can set RotationToLatestKeyVersionEnabled equal to \$true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

```
$desConfig=New-AzDiskEncryptionSetConfig -Location $LocationName ` 
-SourceVaultId $keyVault.ResourceId ` 
-KeyUrl $key.Key.Kid ` 
-IdentityType SystemAssigned ` 
-RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $diskEncryptionSetName ` 
-ResourceGroupName $ResourceGroupName ` 
-InputObject $desConfig
```

4. Grant the DiskEncryptionSet resource access to the key vault.

#### NOTE

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ObjectId $des.Identity.PrincipalId - 
PermissionsToKeys wrapkey,unwrapkey,get
```

### Use a key vault in a different subscription

Alternatively, you can manage your Azure Key Vaults centrally from a single subscription, and use the keys stored in the Key Vault to encrypt managed disks and snapshots in other subscriptions in your organization. This allows your security team to enforce and easily manage a robust security policy to a single subscription.

## IMPORTANT

For this configuration, both your Key Vault and your disk encryption set must be in the same region and be using the same tenant.

The following script is an example of how you would configure a disk encryption set to use a key from a Key Vault in a different subscription, but same region:

```
$sourceSubscriptionId=<sourceSubID>
$sourceKeyVaultName=<sourceKVName>
$sourceKeyName=<sourceKeyName>

$targetSubscriptionId=<targetSubID>
$targetResourceGroupName=<targetRGName>
$targetDiskEncryptionSetName=<targetDiskEncSetName>
$location=<targetRegion>

Set-AzContext -Subscription $sourceSubscriptionId

$key = Get-AzKeyVaultKey -VaultName $sourceKeyVaultName -Name $sourceKeyName

Set-AzContext -Subscription $targetSubscriptionId

$desConfig=New-AzDiskEncryptionSetConfig -Location $location ` 
-KeyUrl $key.Key.Kid ` 
-IdentityType SystemAssigned ` 
-RotationToLatestKeyVersionEnabled $false

$des=New-AzDiskEncryptionSet -Name $targetDiskEncryptionSetName ` 
-ResourceGroupName $targetResourceGroupName ` 
-InputObject $desConfig
```

## Enable encryption at host for disks attached to VM and virtual machine scale sets

You can enable encryption at host by setting a new property EncryptionAtHost under securityProfile of VMs or virtual machine scale sets using the API version **2020-06-01** and above.

```
"securityProfile": { "encryptionAtHost": "true" }
```

## Examples

### Create a VM with encryption at host enabled with customer-managed keys.

Create a VM with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

```

$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText -Force
$LocationName = "yourRegion"
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"
$VMName = "yourVMName"
$VMSize = "yourVMSize"
$diskEncryptionSetName="yourdiskEncryptionSetName"

$NetworkName = "yourNetworkName"
$NICName = "yourNICName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -AddressPrefix $SubnetAddressPrefix
$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName $ResourceGroupName -Location
$LocationName -AddressPrefix $VnetAddressPrefix -Subnet $SingleSubnet
$NIC = New-AzNetworkInterface -Name $NICName -ResourceGroupName $ResourceGroupName -Location $LocationName -
SubnetId $Vnet.Subnets[0].Id

$Credential = New-Object System.Management.Automation.PSCredential ($VMLocalAdminUser,
$VMLocalAdminSecurePassword);

# Enable encryption at host by specifying EncryptionAtHost parameter

$VirtualMachine = New-AzVMConfig -VMName $VMName -VMSize $VMSize -EncryptionAtHost
$VirtualMachine = Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -ComputerName $ComputerName -
Credential $Credential -ProvisionVMAgent -EnableAutoUpdate
$VirtualMachine = Add-AzVMNetworkInterface -VM $VirtualMachine -Id $NIC.Id
$VirtualMachine = Set-AzVMSourceImage -VM $VirtualMachine -PublisherName 'MicrosoftWindowsServer' -Offer
'WindowsServer' -Skus '2012-R2-Datacenter' -Version latest

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName $ResourceGroupName -Name
$diskEncryptionSetName

# Enable encryption with a customer managed key for OS disk by setting DiskEncryptionSetId property

$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name $($VMName + "_OSDisk") -DiskEncryptionSetId
$diskEncryptionSet.Id -CreateOption FromImage

# Add a data disk encrypted with a customer managed key by setting DiskEncryptionSetId property

$VirtualMachine = Add-AzVMDataDisk -VM $VirtualMachine -Name $($VMName + "DataDisk1") -DiskSizeInGB 128 -
StorageAccountType Premium_LRS -CreateOption Empty -Lun 0 -DiskEncryptionSetId $diskEncryptionSet.Id

New-AzVM -ResourceGroupName $ResourceGroupName -Location $LocationName -VM $VirtualMachine -Verbose

```

### Create a VM with encryption at host enabled with platform-managed keys.

Create a VM with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

```

$VMLocalAdminUser = "yourVMLocalAdminUserName"
$VMLocalAdminSecurePassword = ConvertTo-SecureString <password> -AsPlainText -Force
$LocationName = "yourRegion"
$ResourceGroupName = "yourResourceGroupName"
$ComputerName = "yourComputerName"
$VMName = "yourVMName"
$VMSize = "yourVMSize"

$NetworkName = "yourNetworkName"
$NICName = "yourNICName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -AddressPrefix $SubnetAddressPrefix
$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName $ResourceGroupName -Location
$LocationName -AddressPrefix $VnetAddressPrefix -Subnet $SingleSubnet
$NIC = New-AzNetworkInterface -Name $NICName -ResourceGroupName $ResourceGroupName -Location $LocationName -
SubnetId $Vnet.Subnets[0].Id

$Credential = New-Object System.Management.Automation.PSCredential ($VMLocalAdminUser,
$VMLocalAdminSecurePassword);

# Enable encryption at host by specifying EncryptionAtHost parameter

$VirtualMachine = New-AzVMConfig -VMName $VMName -VMSize $VMSize -EncryptionAtHost

$VirtualMachine = Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -ComputerName $ComputerName -
Credential $Credential -ProvisionVMAgent -EnableAutoUpdate
$VirtualMachine = Add-AzVMNetworkInterface -VM $VirtualMachine -Id $NIC.Id
$VirtualMachine = Set-AzVMSourceImage -VM $VirtualMachine -PublisherName 'MicrosoftWindowsServer' -Offer
'WindowsServer' -Skus '2012-R2-Datacenter' -Version latest

$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name $($VMName + "_OSDisk") -CreateOption FromImage

$VirtualMachine = Add-AzVMDataDisk -VM $VirtualMachine -Name $($VMName + "DataDisk1") -DiskSizeInGB 128 -
StorageAccountType Premium_LRS -CreateOption Empty -Lun 0

New-AzVM -ResourceGroupName $ResourceGroupName -Location $LocationName -VM $VirtualMachine

```

## Update a VM to enable encryption at host.

```

$ResourceGroupName = "yourResourceGroupName"
$VMName = "yourVMName"

$VM = Get-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName

Stop-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName -Force

Update-AzVM -VM $VM -ResourceGroupName $ResourceGroupName -EncryptionAtHost $true

```

## Check the status of encryption at host for a VM

```

$ResourceGroupName = "yourResourceGroupName"
$VMName = "yourVMName"

$VM = Get-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName

$VM.SecurityProfile.EncryptionAtHost

```

## Disable encryption at host

You must deallocate your VM before you can disable encryption at host.

```

$ResourceGroupName = "yourResourceGroupName"
$VMName = "yourVMName"

$VM = Get-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName

Stop-AzVM -ResourceGroupName $ResourceGroupName -Name $VMName -Force

Update-AzVM -VM $VM -ResourceGroupName $ResourceGroupName -EncryptionAtHost $false

```

### Create a virtual machine scale set with encryption at host enabled with customer-managed keys.

Create a virtual machine scale set with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

```

$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
$VMSScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -AddressPrefix $SubnetAddressPrefix

$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName $ResourceGroupName -Location
$LocationName -AddressPrefix $VnetAddressPrefix -Subnet $SingleSubnet

$ipConfig = New-AzVmssIpConfig -Name "myIPConfig" -SubnetId $Vnet.Subnets[0].Id

# Enable encryption at host by specifying EncryptionAtHost parameter

$VMSS = New-AzVmssConfig -Location $LocationName -SkuCapacity 2 -SkuName $VMSize -UpgradePolicyMode
'Automatic' -EncryptionAtHost

$VMSS = Add-AzVmssNetworkInterfaceConfiguration -Name "myVMSSNetworkConfig" -VirtualMachineScaleSet $VMSS -
Primary $true -IpConfiguration $ipConfig

$diskEncryptionSet=Get-AzDiskEncryptionSet -ResourceGroupName $ResourceGroupName -Name
$diskEncryptionSetName

# Enable encryption with a customer managed key for the OS disk by setting DiskEncryptionSetId property

$VMSS = Set-AzVmssStorageProfile $VMSS -OsDiskCreateOption "FromImage" -DiskEncryptionSetId
$diskEncryptionSet.Id -ImageReferenceOffer 'WindowsServer' -ImageReferenceSku '2012-R2-Datacenter' -
ImageReferenceVersion latest -ImageReferencePublisher 'MicrosoftWindowsServer'

$VMSS = Set-AzVmssOsProfile $VMSS -ComputerNamePrefix $ComputerNamePrefix -AdminUsername $VMLocalAdminUser -
AdminPassword $VMLocalAdminSecurePassword

# Add a data disk encrypted with a customer managed key by setting DiskEncryptionSetId property

$VMSS = Add-AzVmssDataDisk -VirtualMachineScaleSet $VMSS -CreateOption Empty -Lun 1 -DiskSizeGB 128 -
StorageAccountType Premium_LRS -DiskEncryptionSetId $diskEncryptionSet.Id

```

### Create a virtual machine scale set with encryption at host enabled with platform-managed keys.

Create a virtual machine scale set with encryption at host enabled to encrypt cache of OS/data disks and temp

disks with platform-managed keys.

```
$VMLocalAdminUser = "yourLocalAdminUser"
$VMLocalAdminSecurePassword = ConvertTo-SecureString Password@123 -AsPlainText -Force
$LocationName = "westcentralus"
$ResourceGroupName = "yourResourceGroupName"
$ComputerNamePrefix = "yourComputerNamePrefix"
$VMSScaleSetName = "yourVMSSName"
$VMSize = "Standard_DS3_v2"

$NetworkName = "yourVNETName"
$SubnetName = "yourSubnetName"
$SubnetAddressPrefix = "10.0.0.0/24"
$VnetAddressPrefix = "10.0.0.0/16"

$SingleSubnet = New-AzVirtualNetworkSubnetConfig -Name $SubnetName -AddressPrefix $SubnetAddressPrefix

$Vnet = New-AzVirtualNetwork -Name $NetworkName -ResourceGroupName $ResourceGroupName -Location
$LocationName -AddressPrefix $VnetAddressPrefix -Subnet $SingleSubnet

$ipConfig = New-AzVmssIpConfig -Name "myIPConfig" -SubnetId $Vnet.Subnets[0].Id

# Enable encryption at host by specifying EncryptionAtHost parameter

$VMSS = New-AzVmssConfig -Location $LocationName -SkuCapacity 2 -SkuName $VMSize -UpgradePolicyMode
'Automatic' -EncryptionAtHost

$VMSS = Add-AzVmssNetworkInterfaceConfiguration -Name "myVMSSNetworkConfig" -VirtualMachineScaleSet $VMSS -
Primary $true -IpConfiguration $ipConfig

$VMSS = Set-AzVmssStorageProfile $VMSS -OsDiskCreateOption "FromImage" -ImageReferenceOffer 'WindowsServer'
-ImageReferenceSku '2012-R2-Datacenter' -ImageReferenceVersion latest -ImageReferencePublisher
'MicrosoftWindowsServer'

$VMSS = Set-AzVmssOsProfile $VMSS -ComputerNamePrefix $ComputerNamePrefix -AdminUsername $VMLocalAdminUser -
AdminPassword $VMLocalAdminSecurePassword

$VMSS = Add-AzVmssDataDisk -VirtualMachineScaleSet $VMSS -CreateOption Empty -Lun 1 -DiskSizeGB 128 -
StorageAccountType Premium_LRS

$Credential = New-Object System.Management.Automation.PSCredential ($VMLocalAdminUser,
$VMLocalAdminSecurePassword);

New-AzVmss -VirtualMachineScaleSet $VMSS -ResourceGroupName $ResourceGroupName -VMSScaleSetName
$VMSScaleSetName
```

### Update a virtual machine scale set to enable encryption at host.

```
$ResourceGroupName = "yourResourceGroupName"
$VMSScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name $VMSScaleSetName

Update-AzVmss -VirtualMachineScaleSet $VMSS -Name $VMSScaleSetName -ResourceGroupName $ResourceGroupName -
EncryptionAtHost $true
```

### Check the status of encryption at host for a virtual machine scale set

```
$ResourceGroupName = "yourResourceGroupName"
$VMSScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name $VMSScaleSetName

$VMSS.VirtualMachineProfile.SecurityProfile.EncryptionAtHost
```

### Update a virtual machine scale set to disable encryption at host.

You can disable encryption at host on your virtual machine scale set but, this will only affect VMs created after you disable encryption at host. For existing VMs, you must deallocate the VM, [disable encryption at host on that individual VM](#), then reallocate the VM.

```
$ResourceGroupName = "yourResourceGroupName"
$VMSScaleSetName = "yourVMSSName"

$VMSS = Get-AzVmss -ResourceGroupName $ResourceGroupName -Name $VMSScaleSetName

Update-AzVmss -VirtualMachineScaleSet $VMSS -Name $VMSScaleSetName -ResourceGroupName $ResourceGroupName -EncryptionAtHost $false
```

## Finding supported VM sizes

Legacy VM Sizes are not supported. You can find the list of supported VM sizes by either:

Calling the [Resource Skus API](#) and checking that the `EncryptionAtHostSupported` capability is set to `True`.

```
{
    "resourceType": "virtualMachines",
    "name": "Standard_DS1_v2",
    "tier": "Standard",
    "size": "DS1_v2",
    "family": "standardDSv2Family",
    "locations": [
        "CentralUSEUAP"
    ],
    "capabilities": [
        {
            "name": "EncryptionAtHostSupported",
            "value": "True"
        }
    ]
}
```

Or, calling the [Get-AzComputeResourceSku](#) PowerShell cmdlet.

```
$vmSizes=Get-AzComputeResourceSku | where{$_. ResourceType -eq 'virtualMachines' -and  
$_.Locations.Contains('CentralUSEUAP')}  
  
foreach($vmSize in $vmSizes)  
{  
    foreach($capability in $vmSize.capabilities)  
    {  
        if($capability.Name -eq 'EncryptionAtHostSupported' -and $capability.Value -eq 'true')  
        {  
            $vmSize  
  
        }  
    }  
}
```

## Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following link contains example scripts, each with a respective scenario, that you can use to secure your managed disks.

[Azure Resource Manager template samples](#)

# Use the Azure CLI to enable end-to-end encryption using encryption at host

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When you enable encryption at host, data stored on the VM host is encrypted at rest and flows encrypted to the Storage service. For conceptual information on encryption at host, as well as other managed disk encryption types, see [Encryption at host - End-to-end encryption for your VM data](#).

## Restrictions

- Doesn't support ultra disks.
- Cannot be enabled if Azure Disk Encryption (guest-VM encryption using bitlocker/DM-Crypt) is enabled on your VMs/virtual machine scale sets.
- Azure Disk Encryption cannot be enabled on disks that have encryption at host enabled.
- The encryption can be enabled on existing virtual machine scale set. However, only new VMs created after enabling the encryption are automatically encrypted.
- Existing VMs must be deallocated and reallocated in order to be encrypted.
- Supports ephemeral OS disks but only with platform-managed keys.

## Supported VM sizes

The complete list of supported VM sizes can be pulled programmatically. To learn how to retrieve them programmatically, see the [Finding supported VM sizes](#) section. Upgrading the VM size will result in validation to check if the new VM size supports the EncryptionAtHost feature.

## Prerequisites

You must enable the feature for your subscription before you use the EncryptionAtHost property for your VM/VMSS. Use the following steps to enable the feature for your subscription:

- Execute the following command to register the feature for your subscription

```
az feature register --namespace Microsoft.Compute --name EncryptionAtHost
```

- Check that the registration state is **Registered** (takes a few minutes) using the command below before trying out the feature.

```
az feature show --namespace Microsoft.Compute --name EncryptionAtHost
```

## Create resources

Once the feature is enabled, you'll need to set up a DiskEncryptionSet and either an [Azure Key Vault](#) or an [Azure Key Vault Managed HSM](#).

### Azure Key Vault

- Install the latest [Azure CLI](#) and log to an Azure account in with `az login`.
- Create an Azure Key Vault and encryption key.

When creating the Key Vault, you must enable purge protection. Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

#### IMPORTANT

Don't camel case the region, if you do so, you may experience problems when assigning additional disks to the resource in the Azure portal.

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault create -n $keyVaultName \
-g $rgName \
-l $location \
--enable-purge-protection true

az keyvault key create --vault-name $keyVaultName \
-n $keyName \
--protection software
```

- Create a DiskEncryptionSet. You can set enable-auto-key-rotation equal to true to enable automatic rotation of the key. When you enable automatic rotation, the system will automatically update all managed disks, snapshots, and images referencing the disk encryption set to use the new version of the key within one hour.

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

- Grant the DiskEncryptionSet resource access to the key vault.

#### NOTE

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [identity.principalId] -o tsv)

az keyvault set-policy -n $keyVaultName \
-g $rgName \
--object-id $desIdentity \
--key-permissions wrapkey unwrapkey get
```

## Azure Key Vault Managed HSM

Alternatively, you can use a Managed HSM to handle your keys.

To do this, you must complete the following prerequisites:

- Install the latest [Azure CLI](#) and log in to an Azure account in with `az login`.
- [Create and configure a managed HSM](#).
- [Assign permissions to a user, so they can manage your Managed HSM](#).

### Configuration

Once you've created a Managed HSM and added permissions, enable purge protection and create an encryption key.

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault update-hsm --subscription $subscriptionId -g $rgName --hsm-name $keyVaultName --enable-purge-protection true

az keyvault key create --hsm-name $keyVaultName --name $keyName --ops wrapKey unwrapKey --kty RSA-HSM --size 2048
```

Then, create a DiskEncryptionSet.

```
keyVaultKeyUrl=$(az keyvault key show --vault-name $keyVaultName --name $keyName --query [key.kid] -o tsv)

az disk-encryption-set create -n $diskEncryptionSetName
-l $location \
-g $rgName \
--key-url $keyVaultKeyUrl \
--enable-auto-key-rotation false
```

Finally, grant the DiskEncryptionSet access to the Managed HSM.

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [identity.principalId] -o tsv)

az keyvault role assignment create --hsm-name $keyVaultName --role "Managed HSM Crypto Service Encryption User" --assignee $desIdentity --scope /keys
```

## Examples

### Create a VM with encryption at host enabled with customer-managed keys.

Create a VM with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

```
rgName=yourRGName
vmName=yourVMName
location=eastus
vmSize=Standard_DS2_v2
image=UbuntuLTS
diskEncryptionSetName=yourDiskEncryptionSetName

diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [id] -o tsv)

az vm create -g $rgName \
-n $vmName \
-l $location \
--encryption-at-host \
--image $image \
--size $vmSize \
--generate-ssh-keys \
--os-disk-encryption-set $diskEncryptionSetId \
--data-disk-sizes-gb 128 128 \
--data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

### Create a VM with encryption at host enabled with platform-managed keys.

Create a VM with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

```
rgName=yourRGName
vmName=yourVMName
location=eastus
vmSize=Standard_DS2_v2
image=UbuntuLTS

az vm create -g $rgName \
-n $vmName \
-l $location \
--encryption-at-host \
--image $image \
--size $vmSize \
--generate-ssh-keys \
--data-disk-sizes-gb 128 128 \
```

### Update a VM to enable encryption at host.

```
rgName=yourRGName
vmName=yourVMName

az vm update -n $vmName \
-g $rgName \
--set securityProfile.encryptionAtHost=true
```

### Check the status of encryption at host for a VM

```
rgName=yourRGName
vmName=yourVMName

az vm show -n $vmName \
-g $rgName \
--query [securityProfile.encryptionAtHost] -o tsv
```

### Update a VM to disable encryption at host.

You must deallocate your VM before you can disable encryption at host.

```
rgName=yourRGName  
vmName=yourVMName  
  
az vm update -n $vmName \  
-g $rgName \  
--set securityProfile.encryptionAtHost=false
```

#### Create a virtual machine scale set with encryption at host enabled with customer-managed keys.

Create a virtual machine scale set with managed disks using the resource URI of the DiskEncryptionSet created earlier to encrypt cache of OS and data disks with customer-managed keys. The temp disks are encrypted with platform-managed keys.

```
rgName=yourRGName  
vmssName=yourVMSSName  
location=westus2  
vmSize=Standard_DS3_V2  
image=UbuntuLTS  
diskEncryptionSetName=yourDiskEncryptionSetName  
  
diskEncryptionSetId=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query [id] -o tsv)  
  
az vmss create -g $rgName \  
-n $vmssName \  
--encryption-at-host \  
--image UbuntuLTS \  
--upgrade-policy automatic \  
--admin-username azureuser \  
--generate-ssh-keys \  
--os-disk-encryption-set $diskEncryptionSetId \  
--data-disk-sizes-gb 64 128 \  
--data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

#### Create a virtual machine scale set with encryption at host enabled with platform-managed keys.

Create a virtual machine scale set with encryption at host enabled to encrypt cache of OS/data disks and temp disks with platform-managed keys.

```
rgName=yourRGName  
vmssName=yourVMSSName  
location=westus2  
vmSize=Standard_DS3_V2  
image=UbuntuLTS  
  
az vmss create -g $rgName \  
-n $vmssName \  
--encryption-at-host \  
--image UbuntuLTS \  
--upgrade-policy automatic \  
--admin-username azureuser \  
--generate-ssh-keys \  
--data-disk-sizes-gb 64 128 \  
--data-disk-encryption-sets $diskEncryptionSetId $diskEncryptionSetId
```

#### Update a virtual machine scale set to enable encryption at host.

```
rgName=yourRGName  
vmssName=yourVMSSName  
  
az vmss update -n $vmssName \  
-g $rgName \  
--set virtualMachineProfile.securityProfile.encryptionAtHost=true
```

## Check the status of encryption at host for a virtual machine scale set

```
rgName=yourRGName  
vmssName=yourVMName  
  
az vmss show -n $vmssName \  
-g $rgName \  
--query [virtualMachineProfile.securityProfile.encryptionAtHost] -o tsv
```

## Update a virtual machine scale set to disable encryption at host.

You can disable encryption at host on your virtual machine scale set but, this will only affect VMs created after you disable encryption at host. For existing VMs, you must deallocate the VM, [disable encryption at host on that individual VM](#), then reallocate the VM.

```
rgName=yourRGName  
vmssName=yourVMName  
  
az vmss update -n $vmssName \  
-g $rgName \  
--set virtualMachineProfile.securityProfile.encryptionAtHost=false
```

## Finding supported VM sizes

Legacy VM Sizes are not supported. You can find the list of supported VM sizes by either:

Calling the [Resource Skus API](#) and checking that the `EncryptionAtHostSupported` capability is set to `True`.

```
{  
    "resourceType": "virtualMachines",  
    "name": "Standard_DS1_v2",  
    "tier": "Standard",  
    "size": "DS1_v2",  
    "family": "standardDSv2Family",  
    "locations": [  
        "CentralUSEUAP"  
    ],  
    "capabilities": [  
        {  
            "name": "EncryptionAtHostSupported",  
            "value": "True"  
        }  
    ]  
}
```

Or, calling the [Get-AzComputeResourceSku](#) PowerShell cmdlet.

```
$vmSizes=Get-AzComputeResourceSku | where{$_. ResourceType -eq 'virtualMachines' -and  
$_.Locations.Contains('CentralUSEUAP')}  
  
foreach($vmSize in $vmSizes)  
{  
    foreach($capability in $vmSize.capabilities)  
    {  
        if($capability.Name -eq 'EncryptionAtHostSupported' -and $capability.Value -eq 'true')  
        {  
            $vmSize  
  
        }  
    }  
}
```

## Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following link contains example scripts, each with a respective scenario, that you can use to secure your managed disks.

[Azure Resource Manager template samples](#)

# Use the Azure portal to enable double encryption at rest for managed disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓

Azure Disk Storage supports double encryption at rest for managed disks. For conceptual information on double encryption at rest, as well as other managed disk encryption types, see the [Double encryption at rest](#) section of our disk encryption article.

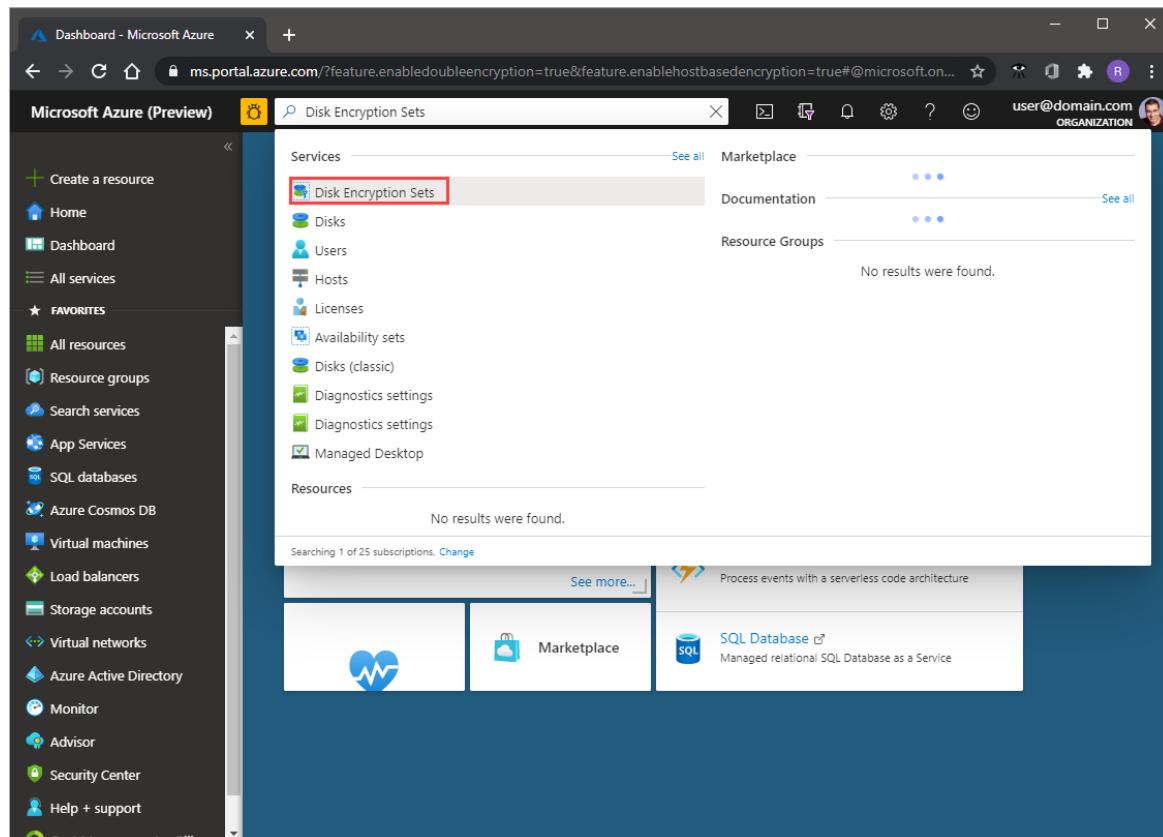

## Getting started

1. Sign in to the [Azure portal](#).

### IMPORTANT

You must use the [provided link](#) to access the Azure portal. Double encryption at rest is not currently visible in the public Azure portal without using the link.

2. Search for and select **Disk Encryption Sets**.

The screenshot shows the Microsoft Azure (Preview) portal interface. The left sidebar contains a list of services including Create a resource, Home, Dashboard, All services, Favorites, All resources, Resource groups, Search services, App Services, SQL databases, Azure Cosmos DB, Virtual machines, Load balancers, Storage accounts, Virtual networks, Azure Active Directory, Monitor, Advisor, Security Center, Help + support, and Cost Management + Bill. The main area has a search bar at the top with the text 'Disk Encryption Sets'. Below the search bar, there are two sections: 'Services' and 'Resources'. In the 'Services' section, 'Disk Encryption Sets' is highlighted with a red box. Other items listed include Disks, Users, Hosts, Licenses, Availability sets, Disks (classic), Diagnostics settings, Diagnostics settings, and Managed Desktop. In the 'Resources' section, it says 'No results were found.' At the bottom, there are cards for Process events with a serverless code architecture, Marketplace, and SQL Database.

3. Select **+ Add**.

The screenshot shows the 'Disk Encryption Sets' blade. At the top, it says 'Disk Encryption Sets' and 'Microsoft'. Below that are three buttons: '+ Add' (highlighted with a red box), 'Manage view', and 'Refresh'. The '+ Add' button has a blue plus icon and the word 'Add'.

4. Select one of the supported regions.
5. For **Encryption type**, select **Double encryption with platform-managed and customer-managed keys**.

**NOTE**

Once you create a disk encryption set with a particular encryption type, it cannot be changed. If you want to use a different encryption type, you must create a new disk encryption set.

6. Fill in the remaining info.

## Create a disk encryption set

Basics Tags Review + create

Disk encryption sets allow you to manage encryption keys using server-side encryption for Standard HDD, Standard SSD, and Premium SSD managed disks. It will give you control of the encryption keys to meet your security and compliance needs in a few clicks. [Learn more about disk encryption sets](#).

### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription \* ⓘ

My Example Subscription

Resource group \* ⓘ

myResourceGroup

[Create new](#)

### Instance details

Region \* ⓘ

(US) West US 2

Encryption type \* ⓘ

Double encryption with platform-managed and customer-managed keys

Key vault and key \*

Key vault: theexamplekeyvault  
Key: mykey  
Version: 3d033002b6d84006ad1db570dbc72f13  
[Click to select a key](#)

7. Select an Azure Key Vault and key, or create a new one if necessary.

**NOTE**

If you create a Key Vault instance, you must enable soft delete and purge protection. These settings are mandatory when using a Key Vault for encrypting managed disks, and protect you from losing data due to accidental deletion.

## Select key from Azure Key Vault

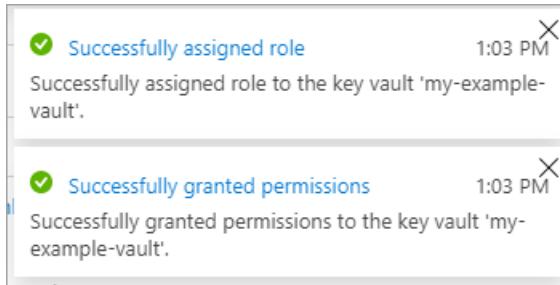

Key vault *	theexamplekeyvault
	<a href="#">Create new</a>
Key *	mykey
	<a href="#">Create new</a>
Version * ⓘ	
	<a href="#">Create new</a>

8. Select **Create**.

9. Navigate to the disk encryption set you created, and select the error that is displayed. This will configure your disk encryption set to work.

 To associate a disk, image, or snapshot with this disk encryption set, you must grant permissions to the key vault → theexamplekeyvault.

A notification should pop up and succeed. Doing this will allow you to use the disk encryption set with your key vault.

10. Navigate to your disk.

11. Select **Encryption**.

12. For **Encryption type**, select **Double encryption with platform-managed and customer-managed keys**.

13. Select your disk encryption set.

14. select **Save**.

- [Enable customer-managed keys with server-side encryption - Examples](#)

# Use the Azure PowerShell module to enable double encryption at rest for managed disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Azure Disk Storage supports double encryption at rest for managed disks. For conceptual information on double encryption at rest, as well as other managed disk encryption types, see the [Double encryption at rest](#) section of our disk encryption article.

## Prerequisites

Install the latest [Azure PowerShell version](#), and sign in to an Azure account using [Connect-AzAccount](#).

## Getting started

1. Create an instance of Azure Key Vault and encryption key.

When creating the Key Vault instance, you must enable soft delete and purge protection. Soft delete ensures that the Key Vault holds a deleted key for a given retention period (90 day default). Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

```
$ResourceGroupName="yourResourceGroupName"
$LocationName="westus2"
$keyVaultName="yourKeyVaultName"
$keyName="yourKeyName"
$keyDestination="Software"
$diskEncryptionSetName="yourDiskEncryptionSetName"

$keyVault = New-AzKeyVault -Name $keyVaultName -ResourceGroupName $ResourceGroupName -Location
$LocationName -EnableSoftDelete -EnablePurgeProtection

$key = Add-AzKeyVaultKey -VaultName $keyVaultName -Name $keyName -Destination $keyDestination
```

2. Create a DiskEncryptionSet with encryptionType set as EncryptionAtRestWithPlatformAndCustomerKeys.

Use API version **2020-05-01** in the Azure Resource Manager (ARM) template.

```
New-AzResourceGroupDeployment -ResourceGroupName $ResourceGroupName ` 
-TemplateUri "https://raw.githubusercontent.com/Azure-Samples/managed-disks-powershell-getting-` 
started/master/DoubleEncryption/CreateDiskEncryptionSetForDoubleEncryption.json" ` 
-diskEncryptionSetName $diskEncryptionSetName ` 
-keyVaultId $keyVault.ResourceId ` 
-keyVaultKeyUrl $key.Key.Kid ` 
-encryptionType "EncryptionAtRestWithPlatformAndCustomerKeys" ` 
-region $LocationName
```

3. Grant the DiskEncryptionSet resource access to the key vault.

#### **NOTE**

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
$des=Get-AzDiskEncryptionSet -name $diskEncryptionSetName -ResourceGroupName $ResourceGroupName  
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ObjectId $des.Identity.PrincipalId -  
PermissionsToKeys wrapkey,unwrapkey,get
```

## Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following links contain example scripts, each with a respective scenario, that you can use to secure your managed disks.

- [Azure PowerShell - Enable customer-managed keys with server-side encryption - managed disks](#)
- [Azure Resource Manager template samples](#)

# Use the Azure CLI to enable double encryption at rest for managed disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure Disk Storage supports double encryption at rest for managed disks. For conceptual information on double encryption at rest, as well as other managed disk encryption types, see the [Double encryption at rest](#) section of our disk encryption article.

## Prerequisites

Install the latest [Azure CLI](#) and log in to an Azure account with [az login](#).

## Getting started

1. Create an instance of Azure Key Vault and encryption key.

When creating the Key Vault instance, you must enable soft delete and purge protection. Soft delete ensures that the Key Vault holds a deleted key for a given retention period (90 day default). Purge protection ensures that a deleted key cannot be permanently deleted until the retention period lapses. These settings protect you from losing data due to accidental deletion. These settings are mandatory when using a Key Vault for encrypting managed disks.

```
subscriptionId=yourSubscriptionID
rgName=yourResourceGroupName
location=westcentralus
keyVaultName=yourKeyVaultName
keyName=yourKeyName
diskEncryptionSetName=yourDiskEncryptionSetName
diskName=yourDiskName

az account set --subscription $subscriptionId

az keyvault create -n $keyVaultName -g $rgName -l $location --enable-purge-protection true --enable-soft-delete true

az keyvault key create --vault-name $keyVaultName -n $keyName --protection software
```

2. Create a DiskEncryptionSet with encryptionType set as EncryptionAtRestWithPlatformAndCustomerKeys.

Use API version **2020-05-01** in the Azure Resource Manager (ARM) template.

```
az deployment group create -g $rgName \
--template-uri "https://raw.githubusercontent.com/Azure-Samples/managed-disks-powershell-getting-started/master/DoubleEncryption/CreateDiskEncryptionSetForDoubleEncryption.json" \
--parameters "diskEncryptionSetName=$diskEncryptionSetName"
"encryptionType=EncryptionAtRestWithPlatformAndCustomerKeys" "keyVaultId=$keyVaultId"
"keyVaultKeyUrl=$keyVaultKeyUrl" "region=$location"
```

3. Grant the DiskEncryptionSet resource access to the key vault.

#### NOTE

It may take few minutes for Azure to create the identity of your DiskEncryptionSet in your Azure Active Directory. If you get an error like "Cannot find the Active Directory object" when running the following command, wait a few minutes and try again.

```
desIdentity=$(az disk-encryption-set show -n $diskEncryptionSetName -g $rgName --query  
[identity.principalId] -o tsv)  
  
az keyvault set-policy -n $keyVaultName -g $rgName --object-id $desIdentity --key-permissions wrapkey  
unwrapkey get
```

## Next steps

Now that you've created and configured these resources, you can use them to secure your managed disks. The following links contain example scripts, each with a respective scenario, that you can use to secure your managed disks.

- [Azure Resource Manager template samples](#)
- [Enable customer-managed keys with server-side encryption - Examples](#)

# Azure Disk Encryption for Linux VMs

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure Disk Encryption helps protect and safeguard your data to meet your organizational security and compliance commitments. It uses the [DM-Crypt](#) feature of Linux to provide volume encryption for the OS and data disks of Azure virtual machines (VMs), and is integrated with [Azure Key Vault](#) to help you control and manage the disk encryption keys and secrets.

Azure Disk Encryption is zone resilient, the same way as Virtual Machines. For details, see [Azure Services that support Availability Zones](#).

If you use [Microsoft Defender for Cloud](#), you're alerted if you have VMs that aren't encrypted. The alerts show as High Severity and the recommendation is to encrypt these VMs.

VIRTUAL MACHINES RECOMMENDATIONS		TOTAL			
Missing disk encryption	2 of 2 VMs	<div style="width: 100%; background-color: red; height: 10px;"></div>			
Virtual machines					
NAME	ONBOARDING	SYSTEM UPDATES	ANTIMALWARE	BASELINE	DISK ENCRYPTION
ASC-VM1	✓	✓	✓	✓	!
ASC-VM2	✓	✓	✓	✓	!

## WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue to use this option to encrypt your VM. See [Azure Disk Encryption with Azure AD \(previous release\)](#) for details.
- Certain recommendations might increase data, network, or compute resource usage, resulting in additional license or subscription costs. You must have a valid active Azure subscription to create resources in Azure in the supported regions.

You can learn the fundamentals of Azure Disk Encryption for Linux in just a few minutes with the [Create and encrypt a Linux VM with Azure CLI quickstart](#) or the [Create and encrypt a Linux VM with Azure PowerShell quickstart](#).

## Supported VMs and operating systems

### Supported VMs

Linux VMs are available in a [range of sizes](#). Azure Disk Encryption is supported on Generation 1 and Generation 2 VMs. Azure Disk Encryption is also available for VMs with premium storage.

See [Azure VM sizes with no local temporary disk](#).

Azure Disk Encryption is also not available on [Basic, A-series VMs](#), or on virtual machines that do not meet these minimum memory requirements:

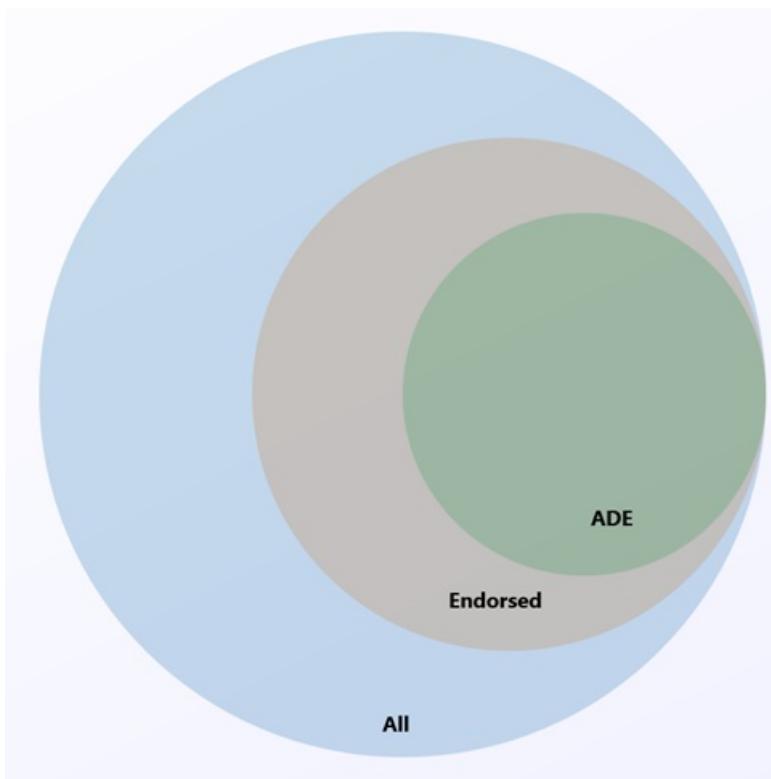

VIRTUAL MACHINE	MINIMUM MEMORY REQUIREMENT
Linux VMs when only encrypting data volumes	2 GB
Linux VMs when encrypting both data and OS volumes, and where the root (/) file system usage is 4GB or less	8 GB
Linux VMs when encrypting both data and OS volumes, and where the root (/) file system usage is greater than 4GB	The root file system usage * 2. For instance, a 16 GB of root file system usage requires at least 32GB of RAM

Once the OS disk encryption process is complete on Linux virtual machines, the VM can be configured to run with less memory.

For more exceptions, see [Azure Disk Encryption: Unsupported scenarios](#).

### Supported operating systems

Azure Disk Encryption is supported on a subset of the [Azure-endorsed Linux distributions](#), which is itself a subset of all Linux server possible distributions.

Linux server distributions that are not endorsed by Azure do not support Azure Disk Encryption; of those that are endorsed, only the following distributions and versions support Azure Disk Encryption:

PUBLISHER	OFFER	SKU	URN	VOLUME TYPE SUPPORTED FOR ENCRYPTION

#### NOTE

The new Azure Disk Encryption implementation is supported for RHEL OS and data disk for RHEL7 Pay-As-You-Go images.

ADE is also supported for RHEL Bring-Your-Own-Subscription Gold Images, but only **after** the subscription has been registered . For more information, see [Red Hat Enterprise Linux Bring-Your-Own-Subscription Gold Images in Azure](#)

ADE support for a particular offer type does not extend beyond the end-of-life date provided by the publisher.

The legacy ADE solution (using AAD credentials) is not recommended for new VM's and is not compatible with RHEL versions later than RHEL 7.8.

## Additional VM requirements

Azure Disk Encryption requires the dm-crypt and vfat modules to be present on the system. Removing or disabling vfat from the default image will prevent the system from reading the key volume and obtaining the key needed to unlock the disks on subsequent reboots. System hardening steps that remove the vfat module from the system or enforce expanding the OS mountpoints/folders on data drives are not compatible with Azure Disk Encryption.

Before enabling encryption, the data disks to be encrypted must be properly listed in /etc/fstab. Use the "nofail" option when creating entries, and choose a persistent block device name (as device names in the "/dev/sdX" format may not be associated with the same disk across reboots, particularly after encryption; for more detail on this behavior, see: [Troubleshoot Linux VM device name changes](#)).

Make sure the /etc/fstab settings are configured properly for mounting. To configure these settings, run the mount -a command or reboot the VM and trigger the remount that way. Once that is complete, check the output of the lsblk command to verify that the drive is still mounted.

- If the /etc/fstab file doesn't mount the drive properly before enabling encryption, Azure Disk Encryption won't be able to mount it properly.
- The Azure Disk Encryption process will move the mount information out of /etc/fstab and into its own configuration file as part of the encryption process. Don't be alarmed to see the entry missing from /etc/fstab after data drive encryption completes.
- Before starting encryption, be sure to stop all services and processes that could be writing to mounted data disks and disable them, so that they do not restart automatically after a reboot. These could keep files open on these partitions, preventing the encryption procedure to remount them, causing failure of the encryption.
- After reboot, it will take time for the Azure Disk Encryption process to mount the newly encrypted disks. They won't be immediately available after a reboot. The process needs time to start, unlock, and then mount the encrypted drives before being available for other processes to access. This process may take more than a minute after reboot depending on the system characteristics.

Here is an example of the commands used to mount the data disks and create the necessary /etc/fstab entries:

```

UUID0=$(blkid -s UUID -o value /dev/sda1)
UUID1=$(blkid -s UUID -o value /dev/sda2)
mkdir /data0
mkdir /data1
echo "UUID=$UUID0 /data0 ext4 defaults,nofail 0 0" >>/etc/fstab
echo "UUID=$UUID1 /data1 ext4 defaults,nofail 0 0" >>/etc/fstab
mount -a

```

## Networking requirements

To enable the Azure Disk Encryption feature, the Linux VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the Linux VM must be able to connect to an Azure Active Directory endpoint, [login.microsoftonline.com].
- To write the encryption keys to your key vault, the Linux VM must be able to connect to the key vault endpoint.
- The Linux VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see [Azure Key Vault behind a firewall](#).

## Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see [Creating and configuring a key vault for Azure Disk Encryption](#).

## Terminology

The following table defines some of the common terms used in Azure disk encryption documentation:

TERMINOLOGY	DEFINITION
Azure Key Vault	Key Vault is a cryptographic, key management service that's based on Federal Information Processing Standards (FIPS) validated hardware security modules. These standards help to safeguard your cryptographic keys and sensitive secrets. For more information, see the <a href="#">Azure Key Vault</a> documentation and <a href="#">Creating and configuring a key vault for Azure Disk Encryption</a> .
Azure CLI	The <a href="#">Azure CLI</a> is optimized for managing and administering Azure resources from the command line.
DM-Crypt	<a href="#">DM-Crypt</a> is the Linux-based, transparent disk-encryption subsystem that's used to enable disk encryption on Linux VMs.

TERMINOLOGY	DEFINITION
Key encryption key (KEK)	The asymmetric key (RSA 2048) that you can use to protect or wrap the secret. You can provide a hardware security module (HSM)-protected key or software-protected key. For more information, see the <a href="#">Azure Key Vault</a> documentation and <a href="#">Creating and configuring a key vault for Azure Disk Encryption</a> .
PowerShell cmdlets	For more information, see <a href="#">Azure PowerShell cmdlets</a> .

## Next steps

- [Quickstart - Create and encrypt a Linux VM with Azure CLI](#)
- [Quickstart - Create and encrypt a Linux VM with Azure PowerShell](#)
- [Azure Disk Encryption scenarios on Linux VMs](#)
- [Azure Disk Encryption prerequisites CLI script](#)
- [Azure Disk Encryption prerequisites PowerShell script](#)
- [Creating and configuring a key vault for Azure Disk Encryption](#)

# Quickstart: Create and encrypt a Linux VM with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to create and encrypt a Linux virtual machine (VM).

If you don't have an Azure subscription, create a [free account](#) before you begin.

If you choose to install and use the Azure CLI locally, this quickstart requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see [Install Azure CLI](#).

## Create a resource group

Create a resource group with the `az group create` command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

```
az group create --name "myResourceGroup" --location "eastus"
```

## Create a virtual machine

Create a VM with `az vm create`. The following example creates a VM named *myVM*.

```
az vm create \
  --resource-group "myResourceGroup" \
  --name "myVM" \
  --image "Canonical:UbuntuServer:16.04-LTS:latest" \
  --size "Standard_D2S_V3" \
  --generate-ssh-keys
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

```
{
  "fqdns": "",
  "id": "/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroup"
}
```

## Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with [az keyvault create](#). To enable the Key Vault to store encryption keys, use the --enabled-for-disk-encryption parameter.

#### IMPORTANT

Every key vault must have a name that is unique across Azure. In the examples below, replace <your-unique-keyvault-name> with the name you choose.

```
az keyvault create --name "<your-unique-keyvault-name>" --resource-group "myResourceGroup" --location "eastus" --enabled-for-disk-encryption
```

## Encrypt the virtual machine

Encrypt your VM with [az vm encryption](#), providing your unique Key Vault name to the --disk-encryption-keyvault parameter.

```
az vm encryption enable -g "MyResourceGroup" --name "myVM" --disk-encryption-keyvault "<your-unique-keyvault-name>"
```

After a moment the process will return, "The encryption request was accepted. Please use 'show' command to monitor the progress.". The "show" command is [az vm show](#).

```
az vm encryption show --name "myVM" -g "MyResourceGroup"
```

When encryption is enabled, you will see the following in the returned output:

```
"EncryptionOperation": "EnableEncryption"
```

## Clean up resources

When no longer needed, you can use the [az group delete](#) command to remove the resource group, VM, and Key Vault.

```
az group delete --name "myResourceGroup"
```

## Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enable for encryption keys, and encrypted the VM. Advance to the next article to learn more about more Azure Disk Encryption for Linux VMs.

[Azure Disk Encryption overview](#)

# Quickstart: Create and encrypt a Linux VM in Azure with Azure PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to create a Linux virtual machine (VM), create a Key Vault for the storage of encryption keys, and encrypt the VM. This quickstart uses the Ubuntu 16.04 LTS marketplace image from Canonical and a VM Standard\_D2S\_V3 size.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Create a resource group

Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which Azure resources are deployed and managed:

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

## Create a virtual machine

Create an Azure virtual machine with [New-AzVM](#), passing to it the VM configuration object you created above.

```
$cred = Get-Credential  
  
New-AzVM -Name MyVm -Credential $cred -ResourceGroupName MyResourceGroup -Image  
Canonical:UbuntuServer:18.04-LTS:latest -Size Standard_D2S_V3
```

It will take a few minutes for your VM to be deployed.

## Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with [New-AzKeyvault](#). To enable the Key Vault to store encryption keys, use the `-EnabledForDiskEncryption` parameter.

### IMPORTANT

Every key vault must have a name that is unique across Azure. In the examples below, replace `<your-unique-keyvault-name>` with the name you choose.

```
New-AzKeyvault -name "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup" -Location EastUS -  
EnabledForDiskEncryption
```

## Encrypt the virtual machine

Encrypt your VM with [Set-AzVmDiskEncryptionExtension](#).

Set-AzVmDiskEncryptionExtension requires some values from your Key Vault object. You can obtain these values by passing the unique name of your key vault to [Get-AzKeyvault](#).

```
$KeyVault = Get-AzKeyVault -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup"

Set-AzVmDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName "MyVM" -DiskEncryptionKeyVaultUrl
$KeyVault.VaultUri -DiskEncryptionKeyId $KeyVault.ResourceId -SkipVmBackup -VolumeType All
```

After a few minutes the process will return the following:

RequestId	IsSuccessStatusCode	StatusCode	ReasonPhrase
-----	-----	-----	-----
True		OK	OK

You can verify the encryption process by running [Get-AzVmDiskEncryptionStatus](#).

```
Get-AzVmDiskEncryptionStatus -VMName MyVM -ResourceGroupName MyResourceGroup
```

When encryption is enabled, you will see the following in the returned output:

OsVolumeEncrypted	:	EncryptionInProgress
DataVolumesEncrypted	:	NotMounted
OsVolumeEncryptionSettings	:	Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage	:	OS disk encryption started

## Clean up resources

When no longer needed, you can use the [Remove-AzResourceGroup](#) cmdlet to remove the resource group, VM, and all related resources:

```
Remove-AzResourceGroup -Name "myResourceGroup"
```

## Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enable for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption for Linux VMs.

[Azure Disk Encryption overview](#)

# Quickstart: Create and encrypt a virtual machine with the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create VMs and their associated resources. In this quickstart you will use the Azure portal to deploy a Linux virtual machine (VM) running Ubuntu 18.04 LTS, create a key vault for the storage of encryption keys, and encrypt the VM.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Sign in to Azure

Sign in to the [Azure portal](#).

## Create a virtual machine

1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the New page, under Popular, select **Ubuntu Server 18.04 LTS**.
3. In the Basics tab, under Project details, verify sure the correct subscription is selected.
4. For "Resource Group", select **Create new**. Enter *myResourceGroup* as the name and select **Ok**.
5. For **Virtual machine name**, enter *MyVM*.
6. For **Region**, select *(US) East US*.
7. Make sure the **Size** is *Standard D2s v3*.
8. Under **Administrator account**, select *Password* as the **Authentication type**. Enter a user name and a password.

## Create a virtual machine

Basics Disks Networking Management Advanced Tags Review + create

Create a virtual machine that runs Linux or Windows. Select an image from Azure marketplace or use your own customized image. Complete the Basics tab then Review + create to provision a virtual machine with default parameters or review each tab for full customization. [Learn more ↗](#)

### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription * ⓘ	<input type="text" value="Free trial"/>

Confirm password \* ⓘ  ✓

### WARNING

The "Disks" tab features an "Encryption Type" field under Disk options. This field is used to specify encryption options for [Managed Disks + CMK](#), not for Azure Disk Encryption.

To avoid confusion, we suggest you skip the *Disks* tab entirely while completing this tutorial.

9. Select the "Management" tab and verify that you have a Diagnostics Storage Account. If you have no storage accounts, select *Create New*, name your storage account *myStorageAccount*, and select "Ok"

The screenshot shows the Azure portal interface for creating a virtual machine. On the left, the 'Create a virtual machine' wizard is open, with the 'Management' tab selected (indicated by a red circle). The 'Networking' tab is also highlighted in blue. On the right, a separate 'Create storage account' dialog is displayed, also with the 'Management' tab selected. The 'Name' field contains 'adestorageaccount' with a green checkmark and '.core.windows.net'. The 'Account kind' dropdown is set to 'Storage (general purpose v1)'. Under 'Performance', 'Standard' is selected. Under 'Replication', 'Locally-redundant storage (LRS)' is selected. A red circle highlights the 'Create new' link under the 'Diagnostics storage account' section, which has a tooltip 'No existing storage accounts in current subscription'.

10. Click "Review + Create".
11. On the **Create a virtual machine** page, you can see the details about the VM you are about to create. When you are ready, select **Create**.

It will take a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

## Encrypt the virtual machine

1. When the VM deployment is complete, select **Go to resource**.
2. On the left-hand sidebar, select **Disks**.
3. On the top bar, select **Additional Settings**.
4. Under **Encryption settings > Disks to encrypt**, select OS and data disks.

## Disk settings

OS and data disks

5. Under **Encryption settings**, choose **Select a key vault and key for encryption**.

6. On the **Select key from Azure Key Vault** screen, select **Create New**.

Home > myVM - Disks > Encryption > Select key from Azure Key Vault

### Select key from Azure Key Vault

Key vault \*

Select the key vault.

Key

Select the key.

Version ⓘ

Select the version.

7. To the left of **Key vault** and **key**, select **Click to select a key**.

8. On the **Select key from Azure Key Vault**, under the **Key Vault** field, select **Create new**.

9. On the **Create key vault** screen, ensure that the Resource Group is *myResourceGroup*, and give your key vault a name. Every key vault across Azure must have an unique name.

10. On the **Access Policies** tab, check the **Azure Disk Encryption for volume encryption** box.

## Create key vault

Basics **Access policy** Networking Tags Review + create

Enable Access to:

- Azure Virtual Machines for deployment ⓘ
- Azure Resource Manager for template deployment ⓘ
- Azure Disk Encryption for volume encryption ⓘ

11. Select **Review + create**.
12. After the key vault has passed validation, select **Create**. This will return you to the **Select key from Azure Key Vault** screen.
13. Leave the **Key** field blank and choose **Select**.
14. At the top of the encryption screen, click **Save**. A popup will warn you that the VM will reboot. Click **Yes**.

## Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources. To do so, select the resource group for the virtual machine, select **Delete**, then confirm the name of the resource group to delete.

## Next steps

In this quickstart, you created a Key Vault that was enabled for encryption keys, created a virtual machine, and enabled the virtual machine for encryption.

[Azure Disk Encryption overview](#)

# Azure Disk Encryption scenarios on Linux VMs

9/21/2022 • 19 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure Disk Encryption for Linux virtual machines (VMs) uses the DM-Crypt feature of Linux to provide full disk encryption of the OS disk and data disks. Additionally, it provides encryption of the temporary disk when using the EncryptFormatAll feature.

Azure Disk Encryption is [integrated with Azure Key Vault](#) to help you control and manage the disk encryption keys and secrets. For an overview of the service, see [Azure Disk Encryption for Linux VMs](#).

You can only apply disk encryption to virtual machines of [supported VM sizes and operating systems](#). You must also meet the following prerequisites:

- [Additional requirements for VMs](#)
- [Networking requirements](#)
- [Encryption key storage requirements](#)

In all cases, you should [take a snapshot](#) and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the [Set-AzVMDiskEncryptionExtension cmdlet](#) to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see the [Azure Backup](#) article.

## WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM. See [Azure Disk Encryption with Azure AD \(previous release\)](#) for details.
- When encrypting Linux OS volumes, the VM should be considered unavailable. We strongly recommend to avoid SSH logins while the encryption is in progress to avoid issues blocking any open files that will need to be accessed during the encryption process. To check progress, use the the [Get-AzVMDiskEncryptionStatus](#) PowerShell cmdlet or the [vm encryption show](#) CLI command. This process can be expected to take a few hours for a 30GB OS volume, plus additional time for encrypting data volumes. Data volume encryption time will be proportional to the size and quantity of the data volumes unless the encrypt format all option is used.
- Disabling encryption on Linux VMs is only supported for data volumes. It is not supported on data or OS volumes if the OS volume has been encrypted.

## Install tools and connect to Azure

Azure Disk Encryption can be enabled and managed through the [Azure CLI](#) and [Azure PowerShell](#). To do so, you must install the tools locally and connect to your Azure subscription.

### Azure CLI

The [Azure CLI 2.0](#) is a command-line tool for managing Azure resources. The CLI is designed to flexibly query data, support long-running operations as non-blocking processes, and make scripting easy. You can install it locally by following the steps in [Install the Azure CLI](#).

To [Sign in to your Azure account with the Azure CLI](#), use the `az login` command.

```
az login
```

If you would like to select a tenant to sign in under, use:

```
az login --tenant <tenant>
```

If you have multiple subscriptions and want to specify a specific one, get your subscription list with [az account list](#) and specify with [az account set](#).

```
az account list  
az account set --subscription "<subscription name or ID>"
```

For more information, see [Get started with Azure CLI 2.0](#).

## Azure PowerShell

The [Azure PowerShell az module](#) provides a set of cmdlets that uses the [Azure Resource Manager](#) model for managing your Azure resources. You can use it in your browser with [Azure Cloud Shell](#), or you can install it on your local machine using the instructions in [Install the Azure PowerShell module](#).

If you already have it installed locally, make sure you use the latest version of Azure PowerShell SDK version to configure Azure Disk Encryption. Download the latest version of [Azure PowerShell release](#).

To [Sign in to your Azure account with Azure PowerShell](#), use the `Connect-AzAccount` cmdlet.

```
Connect-AzAccount
```

If you have multiple subscriptions and want to specify one, use the `Get-AzSubscription` cmdlet to list them, followed by the `Set-AzContext` cmdlet:

```
Set-AzContext -Subscription <SubscriptionId>
```

Running the `Get-AzContext` cmdlet will verify that the correct subscription has been selected.

To confirm the Azure Disk Encryption cmdlets are installed, use the `Get-command` cmdlet:

```
Get-command *diskencryption*
```

For more information, see [Getting started with Azure PowerShell](#).

## Enable encryption on an existing or running Linux VM

In this scenario, you can enable encryption by using the Resource Manager template, PowerShell cmdlets, or CLI commands. If you need schema information for the virtual machine extension, see the [Azure Disk Encryption for Linux extension](#) article.

## IMPORTANT

It is mandatory to snapshot and/or backup a managed disk based VM instance outside of, and prior to enabling Azure Disk Encryption. A snapshot of the managed disk can be taken from the portal, or through [Azure Backup](#). Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. Once a backup is made, the Set-AzVMDiskEncryptionExtension cmdlet can be used to encrypt managed disks by specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension command will fail against managed disk based VMs until a backup has been made and this parameter has been specified.

Encrypting or disabling encryption may cause the VM to reboot.

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

### Enable encryption on an existing or running Linux VM using Azure CLI

You can enable disk encryption on your encrypted VHD by installing and using the [Azure CLI](#) command-line tool. You can use it in your browser with [Azure Cloud Shell](#), or you can install it on your local machine and use it in any PowerShell session. To enable encryption on existing or running Linux VMs in Azure, use the following CLI commands:

Use the `az vm encryption enable` command to enable encryption on a running virtual machine in Azure.

- **Encrypt a running VM:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
```

- **Encrypt a running VM using KEK:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
```

## NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: [https://\[keyvault-name\].vault.azure.net/keys/\[kekname\]/\[kek-unique-id\]](https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id])

- **Verify the disks are encrypted:** To check on the encryption status of a VM, use the `az vm encryption show` command.

```
az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
```

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

### Enable encryption on an existing or running Linux VM using PowerShell

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet to enable encryption on a running virtual machine in Azure. Take a [snapshot](#) and/or back up the VM with [Azure Backup](#) before disks are encrypted. The -skipVmBackup parameter is already specified in the PowerShell scripts to encrypt a running Linux VM.

- **Encrypt a running VM:** The script below initializes your variables and runs the Set-

AzVMDiskEncryptionExtension cmdlet. The resource group, VM, and key vault, were created as prerequisites. Replace MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values. Modify the -VolumeType parameter to specify which disks you're encrypting.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyId $keyVaultResourceId -
VolumeType '[All|OS|Data]' -SequenceVersion $sequenceVersion -skipVmBackup;
```

- **Encrypt a running VM using KEK:** You may need to add the -VolumeType parameter if you're encrypting data disks and not the OS disk.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyId $keyVaultResourceId -
KeyEncryptionKeyUrl $keyEncryptionKeyUrl -KeyEncryptionKeyId $keyVaultResourceId -VolumeType
'[All|OS|Data]' -SequenceVersion $sequenceVersion -skipVmBackup;
```

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: [https://\[keyvault-name\].vault.azure.net/keys/\[kekname\]/\[kek-unique-id\]](https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id])

- **Verify the disks are encrypted:** To check on the encryption status of a VM, use the [Get-AzVmDiskEncryptionStatus](#) cmdlet.

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

#### Enable encryption on an existing or running Linux VM with a template

You can enable disk encryption on an existing or running Linux VM in Azure by using the [Resource Manager template](#).

1. Click Deploy to Azure on the Azure quickstart template.

- Select the subscription, resource group, resource group location, parameters, legal terms, and agreement.
- Click **Create** to enable encryption on the existing or running VM.

The following table lists Resource Manager template parameters for existing or running VMs:

PARAMETER	DESCRIPTION
vmName	Name of the VM to run the encryption operation.
keyVaultName	<p>Name of the key vault that the encryption key should be uploaded to. You can get it by using the cmdlet</p> <pre>(Get-AzKeyVault -ResourceGroupName &lt;MyKeyVaultResourceGroupName&gt;).Vaultname</pre> <p>or the Azure CLI command</p> <pre>az keyvault list --resource-group "MyKeyVaultResourceGroupName"</pre>
keyVaultResourceGroup	Name of the resource group that contains the key vault.
keyEncryptionKeyURL	<p>URL of the key encryption key that's used to encrypt the encryption key. This parameter is optional if you select <b>nokek</b> in the UseExistingKek drop-down list. If you select <b>kek</b> in the UseExistingKek drop-down list, you must enter the <i>keyEncryptionKeyURL</i> value.</p>
volumeType	Type of volume that the encryption operation is performed on. Valid values are <i>OS</i> , <i>Data</i> , and <i>All</i> .
forceUpdateTag	Pass in a unique value like a GUID every time the operation needs to be force run.
location	Location for all resources.

For more information about configuring the Linux VM disk encryption template, see [Azure Disk Encryption for Linux](#).

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

## Use EncryptFormatAll feature for data disks on Linux VMs

The **EncryptFormatAll** parameter reduces the time for Linux data disks to be encrypted. Partitions meeting certain criteria will be formatted, along with their current file systems, then remounted back to where they were before command execution. If you wish to exclude a data disk that meets the criteria, you can unmount it before running the command.

After running this command, any drives that were mounted previously will be reformatted, and the encryption layer will be started on top of the now empty drive. When this option is selected, the temporary disk attached to the VM will also be encrypted. If the temporary disk is reset, it will be reformatted and re-encrypted for the VM by the Azure Disk Encryption solution at the next opportunity. Once the resource disk gets encrypted, the [Microsoft Azure Linux Agent](#) will not be able to manage the resource disk and enable the swap file, but you may manually configure the swap file.

### WARNING

EncryptFormatAll shouldn't be used when there is needed data on a VM's data volumes. You may exclude disks from encryption by unmounting them. You should first try out the EncryptFormatAll first on a test VM, understand the feature parameter and its implication before trying it on the production VM. The EncryptFormatAll option formats the data disk and all the data on it will be lost. Before proceeding, verify that disks you wish to exclude are properly unmounted.

If you're setting this parameter while updating encryption settings, it might lead to a reboot before the actual encryption. In this case, you will also want to remove the disk you don't want formatted from the fstab file. Similarly, you should add the partition you want encrypt-formatted to the fstab file before initiating the encryption operation.

### EncryptFormatAll criteria

The parameter goes through all partitions and encrypts them as long as they meet **all** of the criteria below:

- Is not a root/OS/boot partition
- Is not already encrypted
- Is not a BEK volume
- Is not a RAID volume
- Is not an LVM volume
- Is mounted

Encrypt the disks that compose the RAID or LVM volume rather than the RAID or LVM volume.

### Use the EncryptFormatAll parameter with Azure CLI

Use the [az vm encryption enable](#) command to enable encryption on a running virtual machine in Azure.

- **Encrypt a running VM using EncryptFormatAll:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type "data" --encrypt-format-all
```

### Use the EncryptFormatAll parameter with a PowerShell cmdlet

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet with the EncryptFormatAll parameter.

**Encrypt a running VM using EncryptFormatAll:** As an example, the script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet with the EncryptFormatAll parameter. The resource group, VM, and key vault were created as prerequisites. Replace MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$KeyVaultName = 'MySecureVault';
$KeyVault = Get-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$keyVaultResourceId = $KeyVault.ResourceId;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -DiskEncryptionKeyVaultUrl
$diskEncryptionKeyVaultUrl -DiskEncryptionKeyId $keyVaultResourceId -VolumeType "data" -
EncryptFormatAll
```

### Use the EncryptFormatAll parameter with Logical Volume Manager (LVM)

We recommend an LVM-on-crypt setup. For all the following examples, replace the device-path and mountpoints with whatever suits your use-case. This setup can be done as follows:

1. Add the data disks that will compose the VM.
2. Format, mount, and add these disks to the fstab file.
3. Choose a partition standard, create a partition that spans the entire drive, and then format the partition.  
We use symlinks generated by Azure here. Using symlinks avoids problems related to device names changing. For more information, see the [Troubleshoot Device Names problems](#) article.

```
parted /dev/disk/azure/scsi1/lun0 mklabel gpt  
parted -a opt /dev/disk/azure/scsi1/lun0 mkpart primary ext4 0% 100%  
  
mkfs -t ext4 /dev/disk/azure/scsi1/lun0-part1
```

4. Mount the disks:

```
mount /dev/disk/azure/scsi1/lun0-part1 /mnt/mountpoint
```

Add to fstab file:

```
echo "/dev/disk/azure/scsi1/lun0-part1 /mnt/mountpoint ext4 defaults,nofail 0 2" >> /etc/fstab
```

5. Run the Azure PowerShell [Set-AzVMDiskEncryptionExtension](#) cmdlet with -EncryptFormatAll to encrypt these disks.

```
$KeyVault = Get-AzKeyVault -VaultName "MySecureVault" -ResourceGroupName "MySecureGroup"  
  
Set-AzVMDiskEncryptionExtension -ResourceGroupName "MySecureGroup" -VMName "MySecureVM" -  
DiskEncryptionKeyVaultUrl $KeyVault.VaultUri -DiskEncryptionKeyId $KeyVault.ResourceId -  
EncryptFormatAll -SkipVmBackup -VolumeType Data
```

If you wish to use a key encryption key (KEK), pass the URI of your KEK and the ResourceID of your key vault to the -KeyEncryptionKeyUrl and -KeyEncryptionKeyId parameters, respectively:

```
$KeyVault = Get-AzKeyVault -VaultName "MySecureVault" -ResourceGroupName "MySecureGroup"  
$KEKKeyVault = Get-AzKeyVault -VaultName "MyKEKVault" -ResourceGroupName "MySecureGroup"  
$KEK = Get-AzKeyVaultKey -VaultName "myKEKVault" -KeyName "myKEKName"  
  
Set-AzVMDiskEncryptionExtension -ResourceGroupName "MySecureGroup" -VMName "MySecureVM" -  
DiskEncryptionKeyVaultUrl $KeyVault.VaultUri -DiskEncryptionKeyId $KeyVault.ResourceId -  
EncryptFormatAll -SkipVmBackup -VolumeType Data -KeyEncryptionKeyUrl $$KEK.id -  
KeyEncryptionKeyId $KEKKeyVault.ResourceId
```

6. Set up LVM on top of these new disks. Note the encrypted drives are unlocked after the VM has finished booting. So, the LVM mounting will also have to be subsequently delayed.

## New VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using PowerShell cmdlets or CLI commands.

Use the instructions in the Azure Disk encryption same scripts for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- [Prepare a pre-encrypted Linux VHD](#)

## IMPORTANT

It is mandatory to snapshot and/or backup a managed disk based VM instance outside of, and prior to enabling Azure Disk Encryption. A snapshot of the managed disk can be taken from the portal, or [Azure Backup](#) can be used. Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. Once a backup is made, the Set-AzVMDiskEncryptionExtension cmdlet can be used to encrypt managed disks by specifying the -skipVmBackup parameter. The Set-AzVMDiskEncryptionExtension command will fail against managed disk based VMs until a backup has been made and this parameter has been specified.

Encrypting or disabling encryption may cause the VM to reboot.

## Use Azure PowerShell to encrypt VMs with pre-encrypted VHDs

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet [Set-AzVMOSDisk](#). The example below gives you some common parameters.

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri "os.vhd" Caching ReadWrite
-Linux -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaaaa"
-DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myresourcegroup/providers/Microsoft.KeyVault/vaults/mytestvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

## Enable encryption on a newly added data disk

You can add a new data disk using [az vm disk attach](#), or [through the Azure portal](#). Before you can encrypt, you need to mount the newly attached data disk first. You must request encryption of the data drive since the drive will be unusable while encryption is in progress.

### Enable encryption on a newly added disk with Azure CLI

If the VM was previously encrypted with "All" then the --volume-type parameter should remain "All". All includes both OS and data disks. If the VM was previously encrypted with a volume type of "OS", then the --volume-type parameter should be changed to "All" so that both the OS and the new data disk will be included. If the VM was encrypted with only the volume type of "Data", then it can remain "Data" as demonstrated below. Adding and attaching a new data disk to a VM is not sufficient preparation for encryption. The newly attached disk must also be formatted and properly mounted within the VM prior to enabling encryption. On Linux the disk must be mounted in /etc/fstab with a [persistent block device name](#).

In contrast to PowerShell syntax, the CLI does not require the user to provide a unique sequence version when enabling encryption. The CLI automatically generates and uses its own unique sequence version value.

- Encrypt data volumes of a running VM:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-
encryption-keyvault "MySecureVault" --volume-type "Data"
```

- Encrypt data volumes of a running VM using KEK:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-
encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault
"MySecureVaultContainingTheKEK" --volume-type "Data"
```

### Enable encryption on a newly added disk with Azure PowerShell

When using PowerShell to encrypt a new disk for Linux, a new sequence version needs to be specified. The

sequence version has to be unique. The script below generates a GUID for the sequence version. Take a [snapshot](#) and/or back up the VM with [Azure Backup](#) before disks are encrypted. The `-skipVmBackup` parameter is already specified in the PowerShell scripts to encrypt a newly added data disk.

- **Encrypt data volumes of a running VM:** The script below initializes your variables and runs the `Set-AzVMDiskEncryptionExtension` cmdlet. The resource group, VM, and key vault should have already been created as prerequisites. Replace `MyVirtualMachineResourceGroup`, `MySecureVM`, and `MySecureVault` with your values. Acceptable values for the `-VolumeType` parameter are All, OS, and Data. If the VM was previously encrypted with a volume type of "OS" or "All", then the `-VolumeType` parameter should be changed to "All" so that both the OS and the new data disk will be included.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId $keyVaultResourceId -
VolumeType 'data' -SequenceVersion $sequenceVersion -skipVmBackup;
```

- **Encrypt data volumes of a running VM using KEK:** Acceptable values for the `-VolumeType` parameter are All, OS, and Data. If the VM was previously encrypted with a volume type of "OS" or "All", then the `-VolumeType` parameter should be changed to All so that both the OS and the new data disk will be included.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId $keyVaultResourceId -
KeyEncryptionKeyUrl $keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $keyVaultResourceId -VolumeType
'data' -SequenceVersion $sequenceVersion -skipVmBackup;
```

#### NOTE

The syntax for the value of `disk-encryption-keyvault` parameter is the full identifier string:  
`/subscriptions/[subscription-id-guid]/resourceGroups/[KVresource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]`

The syntax for the value of the `key-encryption-key` parameter is the full URI to the KEK as in: `https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]`

## Disable encryption and remove the encryption extension

You can disable the Azure disk encryption extension, and you can remove the Azure disk encryption extension.

These are two distinct operations.

To remove ADE, it is recommended that you first disable encryption and then remove the extension. If you remove the encryption extension without disabling it, the disks will still be encrypted. If you disable encryption after removing the extension, the extension will be reinstalled (to perform the decrypt operation) and will need to be removed a second time.

#### WARNING

You can **not** disable encryption if the OS disk is encrypted. (OS disks are encrypted when the original encryption operation specifies `volumeType=ALL` or `volumeType=OS`.)

Disabling encryption works only when data disks are encrypted but the OS disk is not.

## Disable encryption

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template.

Disabling encryption does **not** remove the extension (see [Remove the encryption extension](#)).

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the [Disable-AzVMDiskEncryption](#) cmdlet.

```
Disable-AzVMDiskEncryption -ResourceGroupName "MyVirtualMachineResourceGroup" -VMName "MySecureVM" -VolumeType "data"
```

- **Disable encryption with the Azure CLI:** To disable encryption, use the [az vm encryption disable](#) command.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --volume-type "data"
```

- **Disable encryption with a Resource Manager template:**

1. Click **Deploy to Azure** from the [Disable disk encryption on running Linux VM](#) template.
2. Select the subscription, resource group, location, VM, volume type, legal terms, and agreement.
3. Click **Purchase** to disable disk encryption on a running Linux VM.

## Remove the encryption extension

If you want to decrypt your disks and remove the encryption extension, you must disable encryption **before** removing the extension; see [disable encryption](#).

You can remove the encryption extension using Azure PowerShell or the Azure CLI.

- **Disable disk encryption with Azure PowerShell:** To remove the encryption, use the [Remove-AzVMDiskEncryptionExtension](#) cmdlet.

```
Remove-AzVMDiskEncryptionExtension -ResourceGroupName "MyVirtualMachineResourceGroup" -VMName "MySecureVM"
```

- **Disable encryption with the Azure CLI:** To remove encryption, use the [az vm extension delete](#) command.

```
az vm extension delete -g "MyVirtualMachineResourceGroup" --vm-name "MySecureVM" -n "AzureDiskEncryptionForLinux"
```

## Unsupported scenarios

Azure Disk Encryption does not work for the following Linux scenarios, features, and technology:

- Encrypting basic tier VM or VMs created through the classic VM creation method.
- Disabling encryption on an OS drive or data drive of a Linux VM when the OS drive is encrypted.
- Encrypting the OS drive for Linux virtual machine scale sets.
- Encrypting custom images on Linux VMs.
- Integration with an on-premises key management system.
- Azure Files (shared file system).
- Network File System (NFS).
- Dynamic volumes.
- Ephemeral OS disks.
- Encryption of shared/distributed file systems like (but not limited to): DFS, GFS, DRDB, and CephFS.
- Moving an encrypted VM to another subscription or region.
- Creating an image or snapshot of an encrypted VM and using it to deploy additional VMs.
- Kernel Crash Dump (kdump).
- Oracle ACFS (ASM Cluster File System).
- NVMe disks such as those on [High performance computing VM sizes](#) or [Storage optimized VM sizes](#).
- A VM with "nested mount points"; that is, multiple mount points in a single path (such as "/1stmountpoint/data/2stmountpoint").
- A VM with a data drive mounted on top of an OS folder.
- A VM on which a root (OS disk) logical volume has been extended using a data disk.
- M-series VMs with Write Accelerator disks.
- Applying ADE to a VM that has disks encrypted with [server-side encryption with customer-managed keys](#) (SSE + CMK). Applying SSE + CMK to a data disk on a VM encrypted with ADE is an unsupported scenario as well.
- Migrating a VM that is encrypted with ADE, or has ever been encrypted with ADE, to [server-side encryption with customer-managed keys](#).
- Encrypting VMs in failover clusters.
- Encryption of [Azure ultra disks](#).

# Creating and configuring a key vault for Azure Disk Encryption

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#).

## WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM. See [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#) for details.

Creating and configuring a key vault for use with Azure Disk Encryption involves three steps:

1. Creating a resource group, if needed.
2. Creating a key vault.
3. Setting key vault advanced access policies.

These steps are illustrated in the following quickstarts:

- [Create and encrypt a Linux VM with Azure CLI](#)
- [Create and encrypt a Linux VM with Azure PowerShell](#)

You may also, if you wish, generate or import a key encryption key (KEK).

## NOTE

The steps in this article are automated in the [Azure Disk Encryption prerequisites CLI script](#) and [Azure Disk Encryption prerequisites PowerShell script](#).

## Install tools and connect to Azure

The steps in this article can be completed with the [Azure CLI](#), the [Azure PowerShell Az module](#), or the [Azure portal](#).

While the portal is accessible through your browser, Azure CLI and Azure PowerShell require local installation; see [Azure Disk Encryption for Linux: Install tools](#) for details.

### Connect to your Azure account

Before using the Azure CLI or Azure PowerShell, you must first connect to your Azure subscription. You do so by [Signing in with Azure CLI](#), [Signing in with Azure PowerShell](#), or supplying your credentials to the Azure portal when prompted.

```
az login
```

```
Connect-AzAccount
```

## Create a resource group

If you already have a resource group, you can skip to [Create a key vault](#).

A resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group using the [az group create](#) Azure CLI command, the [New-AzResourceGroup](#) Azure PowerShell command, or from the [Azure portal](#).

- [Azure portal](#)

### Azure CLI

```
az group create --name "myResourceGroup" --location eastus
```

### Azure PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

## Create a key vault

If you already have a key vault, you can skip to [Set key vault advanced access policies](#).

Create a key vault using the [az keyvault create](#) Azure CLI command, the [New-AzKeyvault](#) Azure PowerShell command, the [Azure portal](#), or a [Resource Manager template](#).

#### WARNING

To ensure that encryption secrets don't cross regional boundaries, you must create and use a key vault that's in the **same region and tenant** as the VMs to be encrypted.

Each Key Vault must have a unique name. Replace <your-unique-keyvault-name> with the name of your key vault in the following examples.

### Azure CLI

When creating a key vault by using the Azure CLI, add the "--enabled-for-disk-encryption" flag.

```
az keyvault create --name "<your-unique-keyvault-name>" --resource-group "myResourceGroup" --location "eastus" --enabled-for-disk-encryption
```

### Azure PowerShell

When creating a key vault using Azure PowerShell, add the "-EnabledForDiskEncryption" flag.

```
New-AzKeyvault -name "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup" -Location "eastus" -EnabledForDiskEncryption
```

### Resource Manager template

You can also create a key vault by using the [Resource Manager template](#).

1. On the Azure Quickstart Template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then click **Purchase**.

## Set key vault advanced access policies

### IMPORTANT

Newly-created key vaults have soft-delete on by default. If you are using a pre-existing key vault, you **must** enable soft-delete. See [Azure Key Vault soft-delete overview](#).

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes.

If you didn't enable your key vault for disk encryption, deployment, or template deployment at the time of creation (as demonstrated in the previous step), you must update its advanced access policies.

### Azure CLI

Use [az keyvault update](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-deployment "true"
```

- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-template-deployment "true"
```

### Azure PowerShell

Use the key vault PowerShell cmdlet [Set-AzKeyVaultAccessPolicy](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForDiskEncryption
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

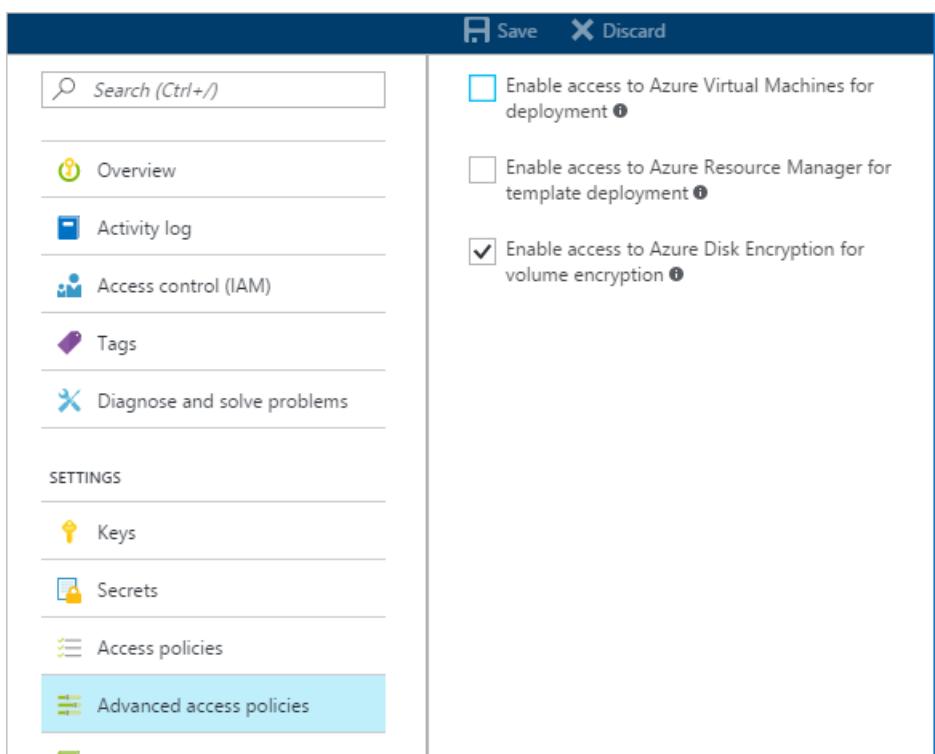

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForTemplateDeployment
```

## Azure portal

1. Select your key vault and go to **Access Policies**.
2. Under "Enable Access to", select the box labeled **Azure Disk Encryption for volume encryption**.
3. Select **Azure Virtual Machines for deployment** and/or **Azure Resource Manager for template deployment**, if needed.
4. Click **Save**.

## Azure Disk Encryption and auto-rotation

Although Azure Key Vault now has [key auto-rotation](#), it isn't currently compatible with Azure Disk Encryption. Specifically, Azure Disk Encryption will continue to use the original encryption key, even after it has been auto-rotated.

Rotating an encryption key won't break Azure Disk Encryption, but disabling the "old" encryption key (in other words, the key Azure Disk Encryption is still using) will.

## Set up a key encryption key (KEK)

### IMPORTANT

The account running to enable disk encryption over the key vault must have "reader" permissions.

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

You can generate a new KEK by using the Azure CLI `az keyvault key create` command, the Azure PowerShell `Add-AzKeyVaultKey` cmdlet, or the [Azure portal](#). You must generate an RSA key type; Azure Disk Encryption doesn't currently support using Elliptic Curve keys.

You can instead import a KEK from your on-premises key management HSM. For more information, see [Key Vault Documentation](#).

Your key vault KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:

- Example of a valid secret URL:

<https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

- Example of a valid KEK URL:

<https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

## Azure CLI

Use the Azure CLI `az keyvault key create` command to generate a new KEK and store it in your key vault.

```
az keyvault key create --name "myKEK" --vault-name "<your-unique-keyvault-name>" --kty RSA --size 4096
```

You may instead import a private key by using the Azure CLI `az keyvault key import` command:

In either case, you supply the name of your KEK to the Azure CLI `az vm encryption enable` `--key-encryption-key` parameter.

```
az vm encryption enable -g "MyResourceGroup" --name "myVM" --disk-encryption-keyvault "<your-unique-keyvault-name>" --key-encryption-key "myKEK"
```

## Azure PowerShell

Use the Azure PowerShell `Add-AzKeyVaultKey` cmdlet to generate a new KEK and store it in your key vault.

```
Add-AzKeyVaultKey -Name "myKEK" -VaultName "<your-unique-keyvault-name>" -Destination "HSM" -Size 4096
```

You may instead import a private key using the Azure PowerShell `az keyvault key import` command.

In either case, you will supply the ID of your KEK key Vault and the URL of your KEK to the Azure PowerShell `Set-AzVMDiskEncryptionExtension` `-KeyEncryptionKeyVaultId` and `-KeyEncryptionKeyUrl` parameters. This example assumes that you are using the same key vault for both the disk encryption key and the KEK.

```
$KeyVault = Get-AzKeyVault -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup"
$KEK = Get-AzKeyVaultKey -VaultName "<your-unique-keyvault-name>" -Name "myKEK"

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName "MyVM" -DiskEncryptionKeyVaultUrl
$KeyVault.VaultUri -DiskEncryptionKeyVaultId $KeyVault.ResourceId -KeyEncryptionKeyVaultId
$KeyVault.ResourceId -KeyEncryptionKeyUrl $KEK.Id -SkipVmBackup -VolumeType All
```

# Azure Disk Encryption sample scripts for Linux VMs

9/21/2022 • 13 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article provides sample scripts for preparing pre-encrypted VHDs and other tasks.

## NOTE

All scripts refer to the latest, non-AAD version of ADE, except where noted.

## Sample PowerShell scripts for Azure Disk Encryption

- **List all encrypted VMs in your subscription**

You can find all ADE-encrypted VMs and the extension version, in all resource groups present in a subscription, using [this PowerShell script](#).

Alternatively, these cmdlets will show all ADE-encrypted VMs (but not the extension version):

```
$osVolEncrypted = {(Get-AzVMDiskEncryptionStatus -ResourceGroupName $_.ResourceGroupName -VMName
$_.Name).OsVolumeEncrypted}
$dataVolEncrypted= {(Get-AzVMDiskEncryptionStatus -ResourceGroupName $_.ResourceGroupName -VMName
$_.Name).DataVolumesEncrypted}
Get-AzVm | Format-Table @{Label="MachineName"; Expression={$.Name}}, @{Label="OsVolumeEncrypted";
Expression=$osVolEncrypted}, @{Label="DataVolumesEncrypted"; Expression=$dataVolEncrypted}
```

- **List all encrypted VMSS instances in your subscription**

You can find all ADE-encrypted VMSS instances and the extension version, in all resource groups present in a subscription, using [this PowerShell script](#).

- **List all disk encryption secrets used for encrypting VMs in a key vault**

```
Get-AzKeyVaultSecret -VaultName $KeyVaultName | where
{$_.Tags.ContainsKey('DiskEncryptionKeyFileName')} | format-table @{Label="MachineName"; Expression=
{$_.Tags['MachineName']}}, @{Label="VolumeLetter"; Expression={$_.Tags['VolumeLetter']}},
@{Label="EncryptionKeyURL"; Expression={$_.Id}}
```

## Using the Azure Disk Encryption prerequisites PowerShell script

If you're already familiar with the prerequisites for Azure Disk Encryption, you can use the [Azure Disk Encryption prerequisites PowerShell script](#). For an example of using this PowerShell script, see the [Encrypt a VM Quickstart](#). You can remove the comments from a section of the script, starting at line 211, to encrypt all disks for existing VMs in an existing resource group.

The following table shows which parameters can be used in the PowerShell script:

PARAMETER	DESCRIPTION	MANDATORY?
-----------	-------------	------------

PARAMETER	DESCRIPTION	MANDATORY?
\$resourceGroupName	Name of the resource group to which the KeyVault belongs to. A new resource group with this name will be created if one doesn't exist.	True
\$keyVaultName	Name of the KeyVault in which encryption keys are to be placed. A new vault with this name will be created if one doesn't exist.	True
\$location	Location of the KeyVault. Make sure the KeyVault and VMs to be encrypted are in the same location. Get a location list with <a href="#">Get-AzLocation</a> .	True
\$subscriptionId	Identifier of the Azure subscription to be used. You can get your Subscription ID with <a href="#">Get-AzSubscription</a> .	True
\$aadAppName	Name of the Azure AD application that will be used to write secrets to KeyVault. A new application with this name will be created if one doesn't exist. If this app already exists, pass aadClientSecret parameter to the script.	False
\$aadClientSecret	Client secret of the Azure AD application that was created earlier.	False
\$keyEncryptionKeyName	Name of optional key encryption key in KeyVault. A new key with this name will be created if one doesn't exist.	False

### Encrypt or decrypt VMs without an Azure AD app

- [Enable disk encryption on an existing or running Linux VM](#)
- [Disable encryption on a running Linux VM](#)
  - Disabling encryption is only allowed on Data volumes for Linux VMs.

### Encrypt or decrypt VMs with an Azure AD app (previous release)

- [Enable disk encryption on an existing or running Linux VM](#)
- [Disable encryption on a running Linux VM](#)
  - Disabling encryption is only allowed on Data volumes for Linux VMs.
- [Create a new encrypted managed disk from a pre-encrypted VHD/storage blob](#)
  - Creates a new encrypted managed disk provided a pre-encrypted VHD and its corresponding encryption settings

## Encrypting an OS drive on a running Linux VM

### Prerequisites for OS disk encryption

- The VM must be using a distribution compatible with OS disk encryption as listed in the [Azure Disk Encryption supported operating systems](#)

- The VM must be created from the Marketplace image in Azure Resource Manager.
- Azure VM with at least 4 GB of RAM (recommended size is 7 GB).
- (For RHEL and CentOS) Disable SELinux. To disable SELinux, see "4.4.2. Disabling SELinux" in the [SELinux User's and Administrator's Guide](#) on the VM.
- After you disable SELinux, reboot the VM at least once.

## Steps

1. Create a VM by using one of the distributions specified previously.

For CentOS 7.2, OS disk encryption is supported via a special image. To use this image, specify "7.2n" as the SKU when you create the VM:

```
Set-AzVMSourceImage -VM $VirtualMachine -PublisherName "OpenLogic" -Offer "CentOS" -Skus "7.2n" - Version "latest"
```

2. Configure the VM according to your needs. If you're going to encrypt all the (OS + data) drives, the data drives need to be specified and mountable from /etc/fstab.

### NOTE

Use UUID=... to specify data drives in /etc/fstab instead of specifying the block device name (for example, /dev/sdb1). During encryption, the order of drives changes on the VM. If your VM relies on a specific order of block devices, it will fail to mount them after encryption.

3. Sign out of the SSH sessions.

4. To encrypt the OS, specify volumeType as All or OS when you enable encryption.

### NOTE

All user-space processes that are not running as `systemd` services should be killed with a `SIGKILL`. Reboot the VM. When you enable OS disk encryption on a running VM, plan on VM downtime.

5. Periodically monitor the progress of encryption by using the instructions in the [next section](#).

6. After `Get-AzVmDiskEncryptionStatus` shows "VMRestartPending", restart your VM either by signing in to it or by using the portal, PowerShell, or CLI.

```
C:\> Get-AzVmDiskEncryptionStatus -ResourceGroupName $ResourceGroupName -VMName $VMName -ExtensionName $ExtensionName

OsVolumeEncrypted      : VMRestartPending
DataVolumesEncrypted   : NotMounted
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage         : OS disk successfully encrypted, reboot the VM
```

Before you reboot, we recommend that you save [boot diagnostics](#) of the VM.

## Monitoring OS encryption progress

You can monitor OS encryption progress in three ways:

- Use the `Get-AzVmDiskEncryptionStatus` cmdlet and inspect the ProgressMessage field:

```

OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : NotMounted
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage        : OS disk encryption started

```

After the VM reaches "OS disk encryption started", it takes about 40 to 50 minutes on a Premium-storage backed VM.

Because of [issue #388](#) in WALinuxAgent, `osVolumeEncrypted` and `DataVolumesEncrypted` show up as `Unknown` in some distributions. With WALinuxAgent version 2.1.5 and later, this issue is fixed automatically. If you see `Unknown` in the output, you can verify disk-encryption status by using the Azure Resource Explorer.

Go to [Azure Resource Explorer](#), and then expand this hierarchy in the selection panel on left:

```

|-- subscriptions
  |-- [Your subscription]
    |-- resourceGroups
      |-- [Your resource group]
        |-- providers
          |-- Microsoft.Compute
            |-- virtualMachines
              |-- [Your virtual machine]
                |-- InstanceView

```

In the InstanceView, scroll down to see the encryption status of your drives.

```

{
  "code": "ProvisioningState/succeeded",
  "level": "Info",
  "displayStatus": "Provisioning succeeded",
  "time": "2016-09-22T02:19:41.4646766+00:00"
},
],
"extensions": [
  {
    "name": "AzureDiskEncryptionForLinux",
    "type": "Microsoft.Azure.Security.AzureDiskEncryptionForLinux",
    "typeHandlerVersion": "0.1.0.999190",
    "substatuses": [
      {
        "code": "ComponentStatus/Microsoft.Azure.Security.AzureDiskEncryptionForLinux",
        "level": "Info",
        "displayStatus": "Provisioning succeeded",
        "message": "{\"os\": \"NotEncrypted\", \"data\": \"EncryptionInProgress\"}"
      }
    ]
  }
]
}

```

- Look at [boot diagnostics](#). Messages from the ADE extension should be prefixed with `[AzureDiskEncryption]`.
- Sign in to the VM via SSH, and get the extension log from:

`/var/log/azure/Microsoft.Azure.Security.AzureDiskEncryptionForLinux`

We recommend that you don't sign-in to the VM while OS encryption is in progress. Copy the logs only when the other two methods have failed.

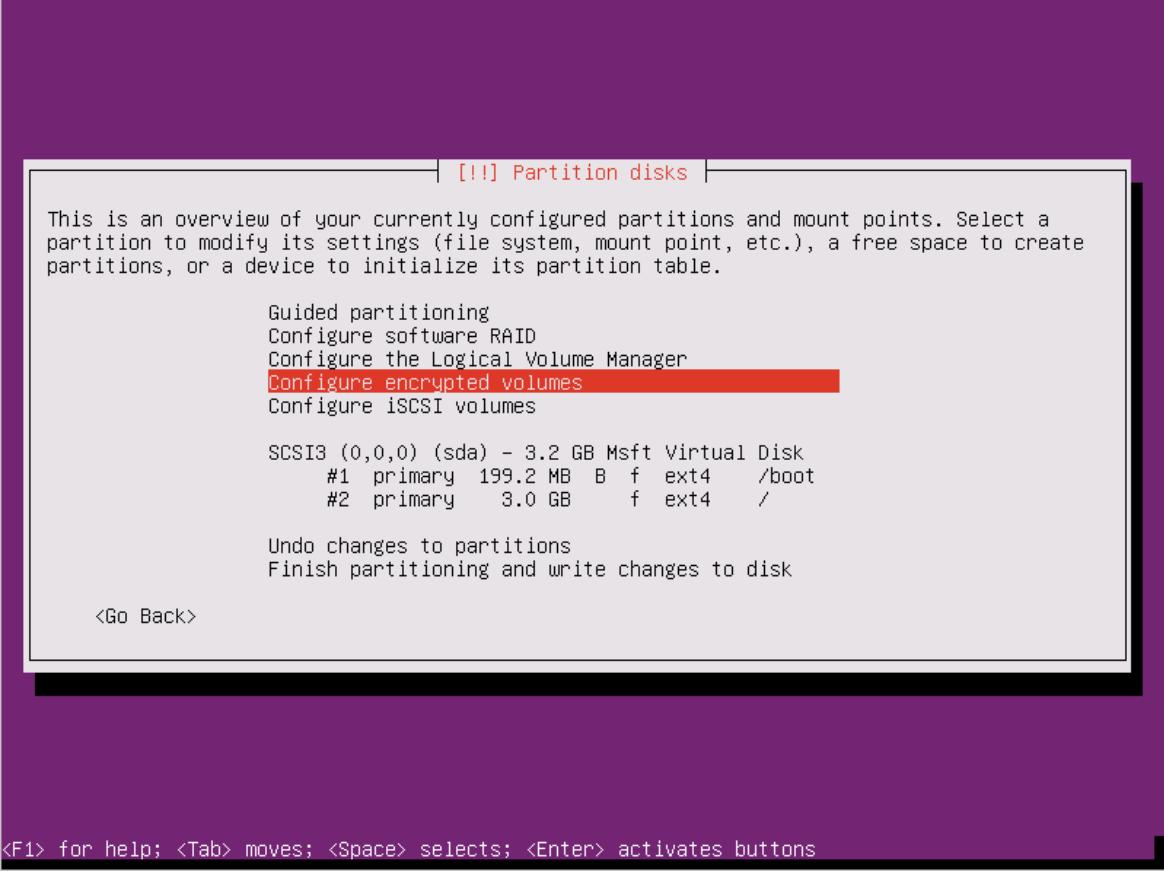

## Prepare a pre-encrypted Linux VHD

The preparation for pre-encrypted VHDs can vary depending on the distribution. Examples on preparing Ubuntu 16, openSUSE 13.2, and CentOS 7 are available.

### Ubuntu 16

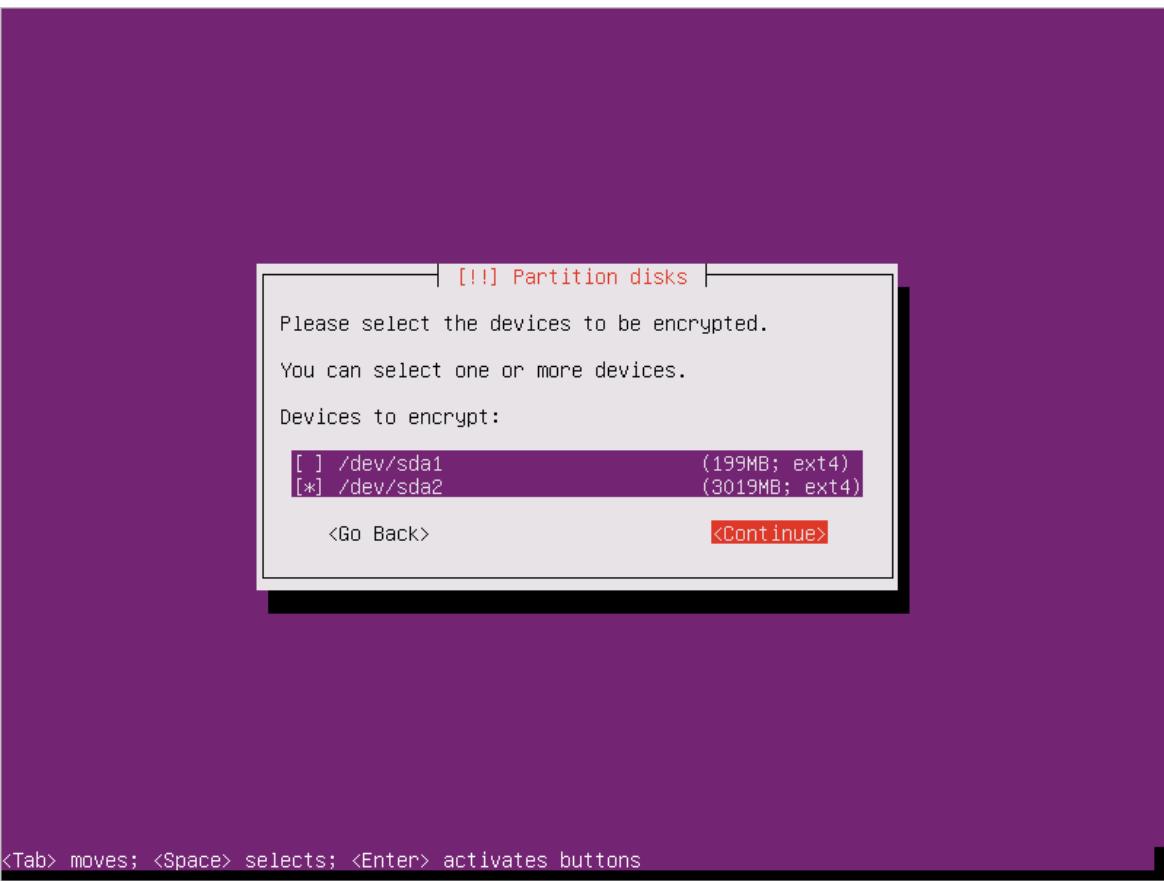

Configure encryption during the distribution installation by doing the following steps:

- Select **Configure encrypted volumes** when you partition the disks.

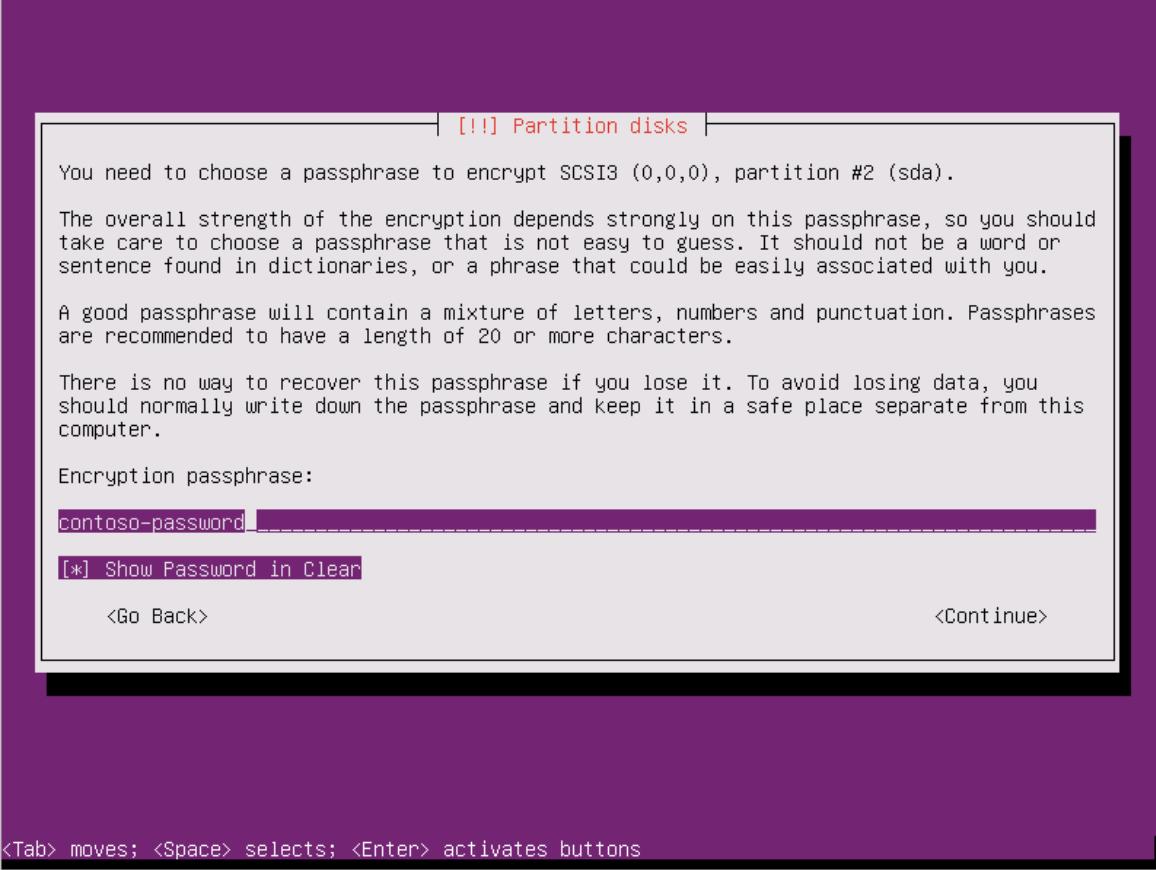

<F1> for help; <Tab> moves; <Space> selects; <Enter> activates buttons

2. Create a separate boot drive, which must not be encrypted. Encrypt your root drive.

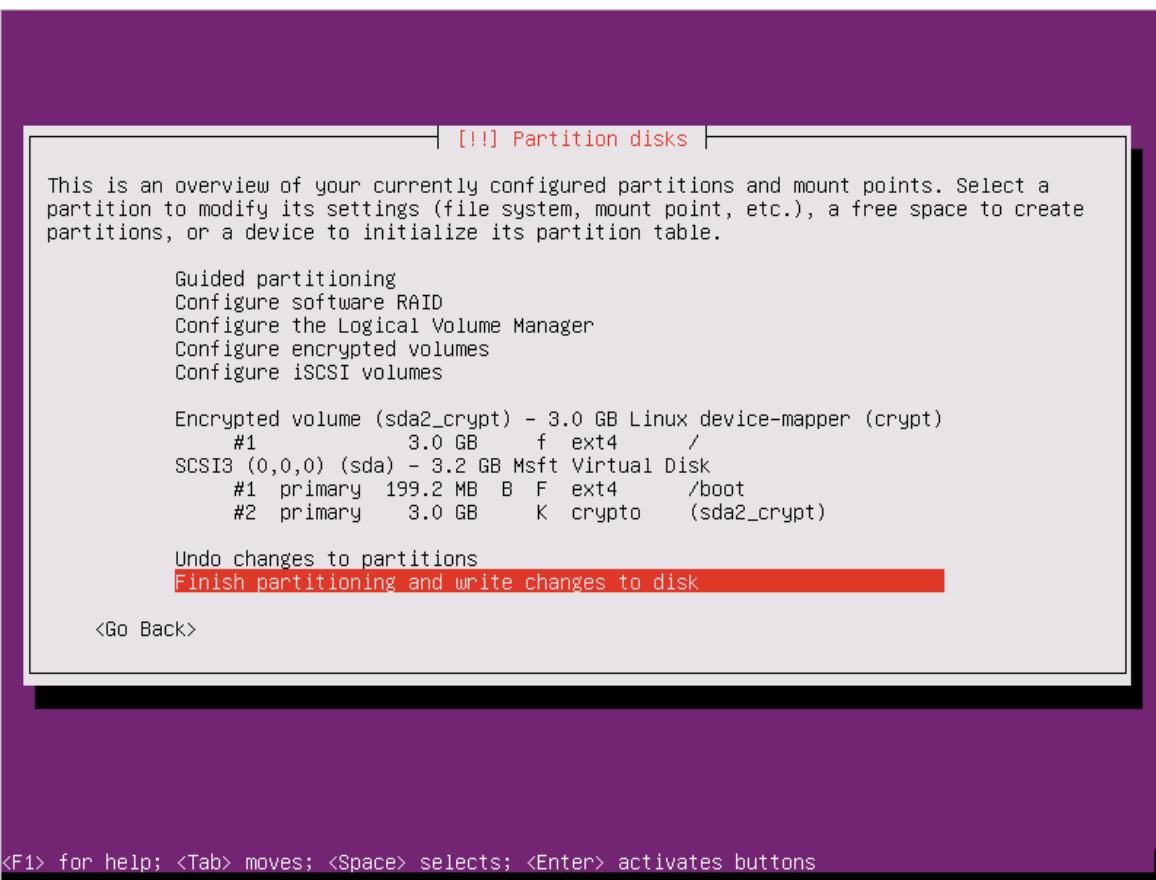

<Tab> moves; <Space> selects; <Enter> activates buttons

3. Provide a passphrase. This is the passphrase that you uploaded to the key vault.

4. Finish partitioning.

5. When you boot the VM and are asked for a passphrase, use the passphrase you provided in step 3.

```

```

6. Prepare the VM for uploading into Azure using [these instructions](#). Don't run the last step (deprovisioning the VM) yet.

Configure encryption to work with Azure by doing the following steps:

1. Create a file under /usr/local/sbin/azure\_crypt\_key.sh, with the content in the following script. Pay attention to the KeyFileName, because it's the passphrase file name used by Azure.

```

#!/bin/sh
MountPoint=/tmp-keydisk-mount
KeyFileName=LinuxPassPhraseFileName
echo "Trying to get the key from disks ..." >&2
mkdir -p $MountPoint
modprobe vfat >/dev/null 2>&1
modprobe ntfs >/dev/null 2>&1
sleep 2
OPENED=0
cd /sys/block
for DEV in sd*; do

    echo "> Trying device: $DEV ..." >&2
    mount -t vfat -r /dev/${DEV}1 $MountPoint >/dev/null ||
    mount -t ntfs -r /dev/${DEV}1 $MountPoint >/dev/null
    if [ -f $MountPoint/$KeyFileName ]; then
        cat $MountPoint/$KeyFileName
        umount $MountPoint 2>/dev/null
        OPENED=1
        break
    fi
    umount $MountPoint 2>/dev/null
done

if [ $OPENED -eq 0 ]; then
    echo "FAILED to find suitable passphrase file ..." >&2
    echo -n "Try to enter your password: " >&2
    read -s -r A </dev/console
    echo -n "$A"
else
    echo "Success loading keyfile!" >&2
fi

```

2. Change the crypt config in */etc/crypttab*. It should look like this:

```
xxx_crypt  uuid=xxxxxxxxxxxxxxxxxxxxxx none luks,discard,keyscript=/usr/local/sbin/azure_crypt_key.sh
```

3. Add executable permissions to the script:

```
chmod +x /usr/local/sbin/azure_crypt_key.sh
```

4. Edit */etc/initramfs-tools/modules* by appending lines:

```
vfat
ntfs
nls_cp437
nls_utf8
nls_iso8859-1
```

5. Run `update-initramfs -u -k all` to update the initramfs to make the `keyscript` take effect.

6. Now you can deprovision the VM.

```

root@ubuntu-preencrypted:~# ls -l /usr/local/sbin/azure_crypt_key.sh
-rwxr-xr-x 1 root root 860 Sep 18 16:57 /usr/local/sbin/azure_crypt_key.sh
root@ubuntu-preencrypted:~# cat /etc/crypttab

```

## 7. Continue to the next step and upload your VHD into Azure.

### openSUSE 13.2

To configure encryption during the distribution installation, do the following steps:

- When you partition the disks, select **Encrypt Volume Group**, and then enter a password. This is the password that you'll upload to your key vault.

2. Boot the VM using your password.

```
[ 0.000000] tsc: Fast TSC calibration failed
[ OK ] Found device Virtual_Disk.
[ OK ] Found device Virtual_Disk.
  Starting Cryptography Setup for cr_scsi-14d53465420202020fd10f64360...278fd632?ec-part2...
  Starting Setup Virtual Console...
[ OK ] Started Setup Virtual Console.
  Starting Dispatch Password Requests to Console...
[ OK ] Started Dispatch Password Requests to Console.
Please enter passphrase for disk Virtual_Disk (cr_scsi-14d53465420202020fd10f64360f5f14797052278fd632?ec-part2)! ****
```

3. Prepare the VM for uploading to Azure by following the instructions in [Prepare a SLES or openSUSE virtual machine for Azure](#). Don't run the last step (deprovisioning the VM) yet.

To configure encryption to work with Azure, do the following steps:

1. Edit the /etc/dracut.conf, and add the following line:

```
add_drivers+=" vfat ntfs nls_cp437 nls_iso8859-1"
```

2. Comment out these lines by the end of the file /usr/lib/dracut/modules.d/90crypt/module-setup.sh:

```
# inst_multiple -o \
#   $systemdutildir/system-generators/systemd-cryptsetup-generator \
#   $systemdutildir/systemd-cryptsetup \
#   $systemdsystemunitdir/systemd-ask-password-console.path \
#   $systemdsystemunitdir/systemd-ask-password-console.service \
#   $systemdsystemunitdir/cryptsetup.target \
#   $systemdsystemunitdir/sysinit.target.wants/cryptsetup.target \
#   # systemd-ask-password systemd-tty-ask-password-agent
#   inst_script "$moddir"/crypt-run-generator.sh /sbin/crypt-run-generator
```

3. Append the following line at the beginning of the file /usr/lib/dracut/modules.d/90crypt/parse-crypt.sh:

```
DRACUT_SYSTEMD=0
```

And change all occurrences of:

```
if [ -z "$DRACUT_SYSTEMD" ]; then
```

to:

```
if [ 1 ]; then
```

4. Edit `/usr/lib/dracut/modules.d/90crypt/cryptroot-ask.sh` and append it to "# Open LUKS device":

```
MountPoint=/tmp-keydisk-mount
KeyFileName=LinuxPassPhraseFileName
echo "Trying to get the key from disks ..." >&2
mkdir -p $MountPoint >&2
modprobe vfat >/dev/null >&2
modprobe ntfs >/dev/null >&2
for SFS in /dev/sd*; do
    echo "> Trying device:$SFS..." >&2
    mount ${SFS}1 $MountPoint -t vfat -r >&2 ||
    mount ${SFS}1 $MountPoint -t ntfs -r >&2
    if [ -f $MountPoint/$KeyFileName ]; then
        echo "> keyfile got..." >&2
        cp $MountPoint/$KeyFileName /tmp-keyfile >&2
        luksfile=/tmp-keyfile
        umount $MountPoint >&2
        break
    fi
done
```

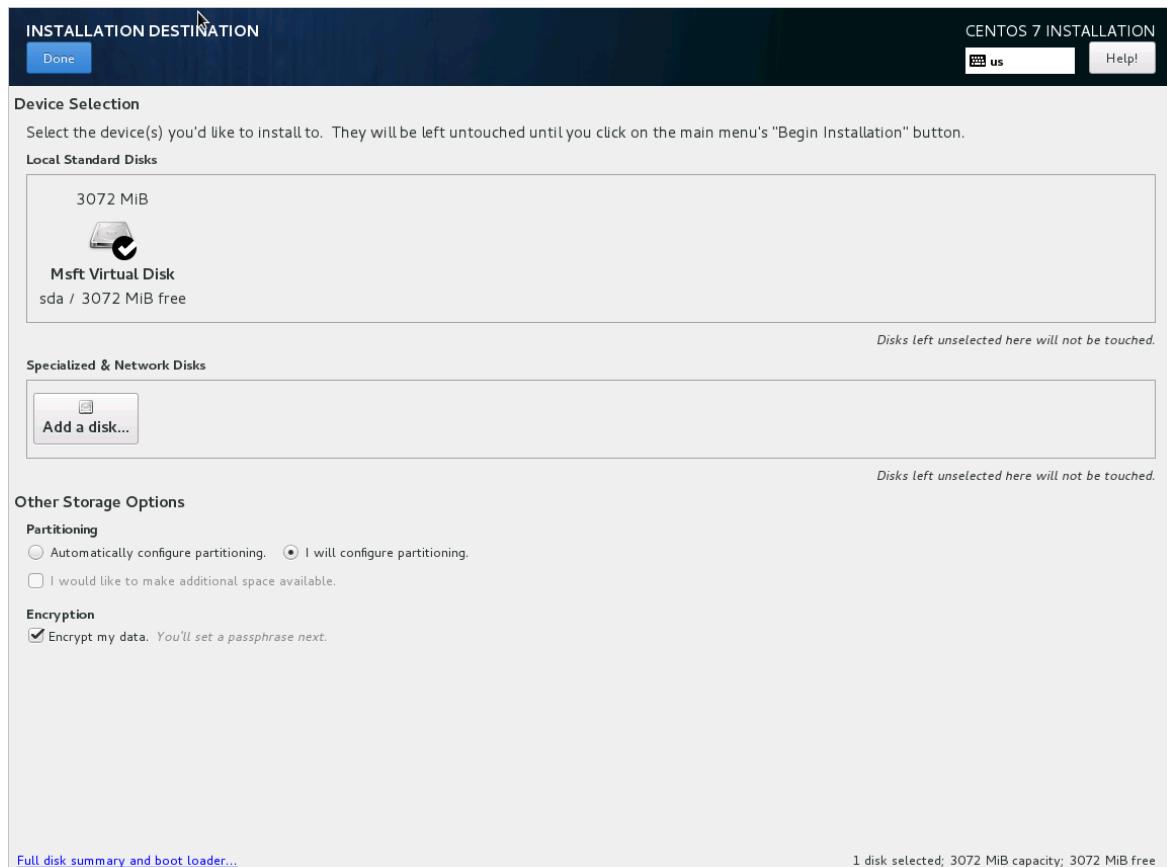

5. Run `/usr/sbin/dracut -f -v` to update the initrd.

6. Now you can deprovision the VM and upload your VHD into Azure.

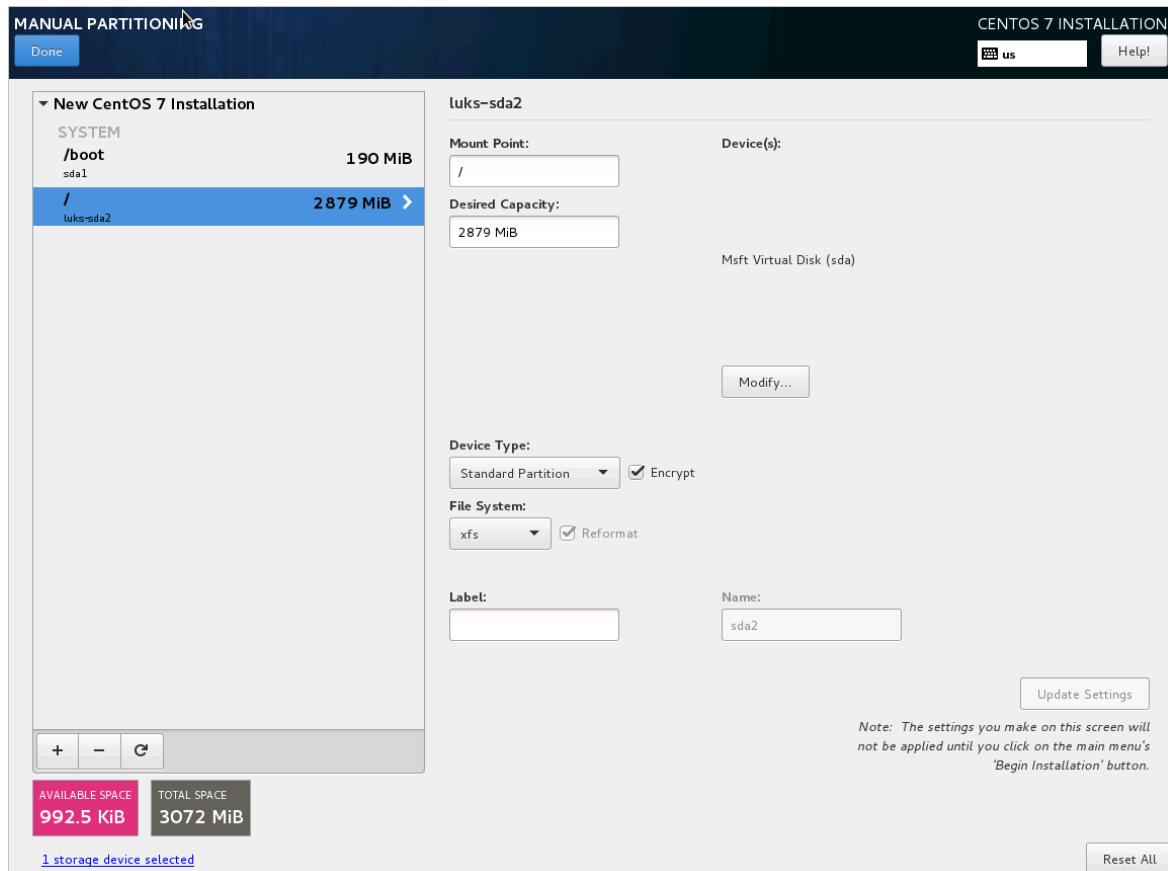

## CentOS 7 and RHEL 7

To configure encryption during the distribution installation, do the following steps:

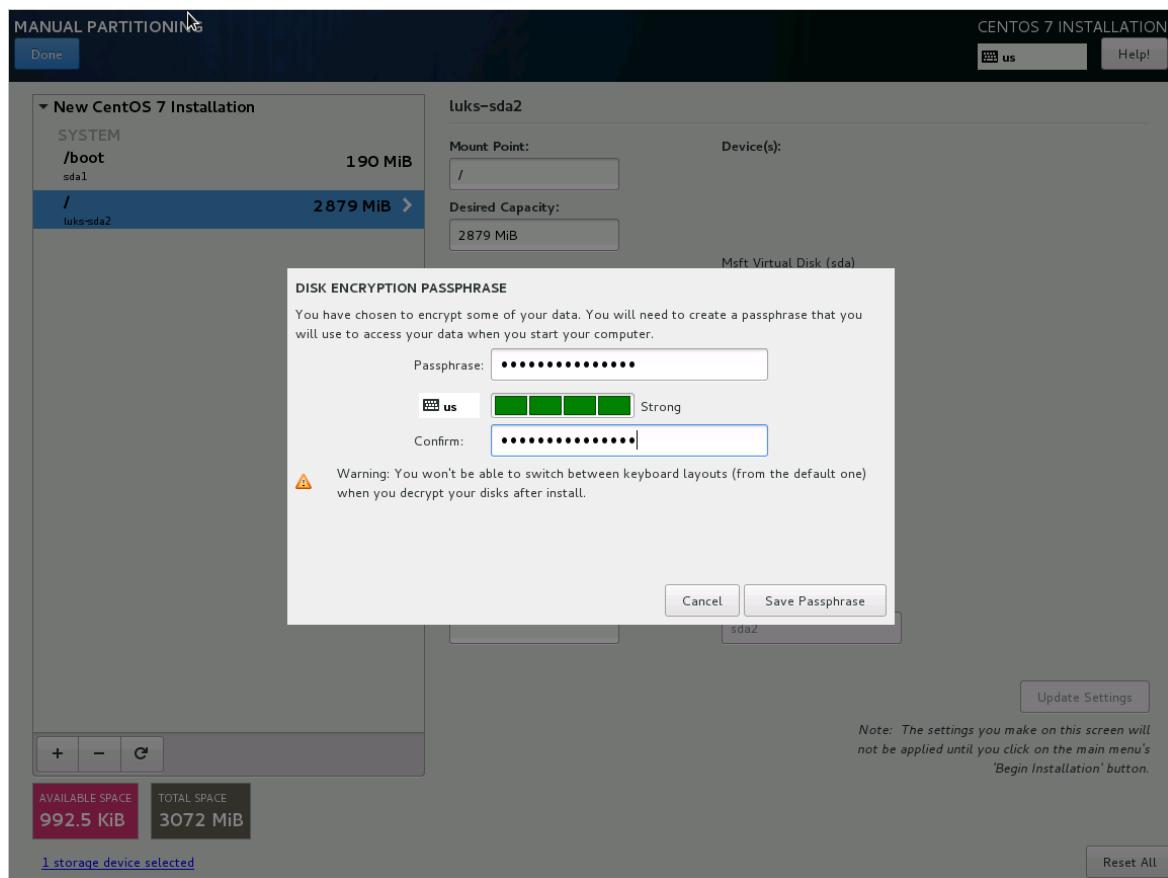

1. Select **Encrypt my data** when you partition disks.

2. Make sure Encrypt is selected for root partition.

3. Provide a passphrase. This is the passphrase that you'll upload to your key vault.

4. When you boot the VM and are asked for a passphrase, use the passphrase you provided in step 3.

```
Please enter passphrase for disk Virtual_Disk (luks-4e88b858-991e-4283-9ec5-130ec245cadf)!:*****
```

5. Prepare the VM for uploading into Azure by using the "CentOS 7.0+" instructions in [Prepare a CentOS-based virtual machine for Azure](#). Don't run the last step (deprovisioning the VM) yet.

6. Now you can deprovision the VM and upload your VHD into Azure.

To configure encryption to work with Azure, do the following steps:

1. Edit the /etc/dracut.conf, and add the following line:

```
add_drivers+=" vfat ntfs nls_cp437 nls_iso8859-1"
```

2. Comment out these lines by the end of the file /usr/lib/dracut/modules.d/90crypt/module-setup.sh:

```
# inst_multiple -o \
# $systemdutildir/system-generators/systemd-cryptsetup-generator \
# $systemdutildir/systemd-cryptsetup \
# $systemdsystemunitdir/systemd-ask-password-console.path \
# $systemdsystemunitdir/systemd-ask-password-console.service \
# $systemdsystemunitdir/cryptsetup.target \
# $systemdsystemunitdir/sysinit.target.wants/cryptsetup.target \
# systemd-ask-password systemd-tty-ask-password-agent
# inst_script "$moddir"/crypt-run-generator.sh /sbin/crypt-run-generator
```

3. Append the following line at the beginning of the file /usr/lib/dracut/modules.d/90crypt/parse-crypt.sh:

```
DRACUT_SYSTEMD=0
```

And change all occurrences of:

```
if [ -z "$DRACUT_SYSTEMD" ]; then
```

to

```
if [ 1 ]; then
```

4. Edit /usr/lib/dracut/modules.d/90crypt/cryptroot-ask.sh and append the following after the "# Open LUKS device":

```
MountPoint=/tmp-keydisk-mount
KeyFileName=LinuxPassPhraseFileName
echo "Trying to get the key from disks ..." >&2
mkdir -p $MountPoint >&2
modprobe vfat >/dev/null >&2
modprobe ntfs >/dev/null >&2
for SFS in /dev/sd*; do
echo "> Trying device:$SFS..." >&2
mount ${SFS}1 $MountPoint -t vfat -r >&2 ||
mount ${SFS}1 $MountPoint -t ntfs -r >&2
if [ -f $MountPoint/$KeyFileName ]; then
    echo "> keyfile got..." >&2
    cp $MountPoint/$KeyFileName /tmp-keyfile >&2
    luksfile=/tmp-keyfile
    umount $MountPoint >&2
    break
fi
done
```

5. Run the "/usr/sbin/dracut -f -v" to update the initrd.

```
[root@centos-preencrypted ~]# cat /etc/dracut.conf | grep add_drivers
add_drivers+=" vfat ntfs nls_cp437 nls_iso8859-1"
[root@centos-preencrypted ~]# cat /usr/lib/dracut/modules.d/90crypt/cryptroot-ask.sh | grep LinuxPassPhraseFileName -A 15 -B 1
MountPoint=/tmp-keydisk-mount
KeyFileName=LinuxPassPhraseFileName
echo "Trying to get the key from disks ..." >&2
mkdir -p $MountPoint >&2
modprobe vfat >/dev/null >&2
modprobe ntfs >/dev/null >&2
for SFS in /dev/sd*; do
echo "> Trying device:$SFS..." >&2
mount ${SFS}1 $MountPoint -t vfat -r >&2 ||
mount ${SFS}1 $MountPoint -t ntfs -r >&2
if [ -f $MountPoint/$KeyFileName ]; then
    echo "> keyfile got..." >&2
    cp $MountPoint/$KeyFileName /tmp-keyfile >&2
    luksfile=/tmp-keyfile
    umount $MountPoint >&2
    break
fi
[root@centos-preencrypted ~]# dracut -f -v_
```

## Upload encrypted VHD to an Azure storage account

After DM-Crypt encryption is enabled, the local encrypted VHD needs to be uploaded to your storage account.

```
Add-AzVhd [-Destination] <Uri> [-LocalFilePath] <FileInfo> [[-NumberOfUploaderThreads] <Int32> ] [[-BaseImageUriToPatch] <Uri> ] [[-OverWrite]] [ <CommonParameters>]
```

## Upload the secret for the pre-encrypted VM to your key vault

When encrypting using an Azure AD app (previous release), the disk-encryption secret that you obtained previously must be uploaded as a secret in your key vault. The key vault needs to have disk encryption and permissions enabled for your Azure AD client.

```
$AadClientId = "My-AAD-Client-Id"
$AadClientSecret = "My-AAD-Client-Secret"

$keyVault = New-AzKeyVault -VaultName $KeyVaultName -ResourceGroupName $ResourceGroupName -Location $Location

Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $ResourceGroupName -ServicePrincipalName $AadClientId -PermissionsToKeys all -PermissionsToSecrets all
Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $ResourceGroupName -EnabledForDiskEncryption
```

### Disk encryption secret not encrypted with a KEK

To set up the secret in your key vault, use [Set-AzKeyVaultSecret](#). The passphrase is encoded as a base64 string and then uploaded to the key vault. In addition, make sure that the following tags are set when you create the secret in the key vault.

```
# This is the passphrase that was provided for encryption during the distribution installation
$passphrase = "contoso-password"

$tags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP"; "DiskEncryptionKeyFileName" = "LinuxPassPhraseFileName"}
$secretName = [guid]::NewGuid().ToString()
$secretValue = [Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($passphrase))
$secureSecretValue = ConvertTo-SecureString $secretValue -AsPlainText -Force

$secret = Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $secretName -SecretValue $secureSecretValue -tags $tags
$secretUrl = $secret.Id
```

Use the `$secretUrl` in the next step for [attaching the OS disk without using KEK](#).

### Disk encryption secret encrypted with a KEK

Before you upload the secret to the key vault, you can optionally encrypt it by using a key encryption key. Use the wrap API to first encrypt the secret using the key encryption key. The output of this wrap operation is a base64 URL encoded string, which you can then upload as a secret by using the [Set-AzKeyVaultSecret](#) cmdlet.

```
# This is the passphrase that was provided for encryption during the distribution installation
$passphrase = "contoso-password"

Add-AzKeyVaultKey -VaultName $KeyVaultName -Name "keyencryptionkey" -Destination Software
$keyEncryptionKey = Get-AzKeyVaultKey -VaultName $KeyVault.OriginalVault.Name -Name "keyencryptionkey"

$apiversion = "2015-06-01"

#####
# Get Auth URI
#####
```

```

$uri = $KeyVault.VaultUri + "/keys"
$headers = @{}

$response = try { Invoke-RestMethod -Method GET -Uri $uri -Headers $headers } catch {
$_._Exception.Response }

$authHeader = $response.Headers["www-authenticate"]
$authUri = [regex]::match($authHeader, 'authorization="(.*)"').Groups[1].Value

Write-Host "Got Auth URI successfully"

#####
# Get Auth Token
#####

$uri = $authUri + "/oauth2/token"
$body = "grant_type=client_credentials"
$body += "&client_id=" + $AadClientId
$body += "&client_secret=" + [Uri]::EscapeDataString($AadClientSecret)
$body += "&resource=" + [Uri]::EscapeDataString("https://vault.azure.net")
$headers = @{}

$response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body $body

$access_token = $response.access_token

Write-Host "Got Auth Token successfully"

#####
# Get KEK info
#####

$uri = $KeyEncryptionKey.Id + "?api-version=" + $apiversion
$headers = @{"Authorization" = "Bearer " + $access_token}

$response = Invoke-RestMethod -Method GET -Uri $uri -Headers $headers

$keyid = $response.key.kid

Write-Host "Got KEK info successfully"

#####
# Encrypt passphrase using KEK
#####

$passphraseB64 = [Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Passphrase))
$uri = $keyid + "/encrypt?api-version=" + $apiversion
$headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" = "application/json"}
$bodyObj = @{"alg" = "RSA-OAEP"; "value" = $passphraseB64}
$body = $bodyObj | ConvertTo-Json

$response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body $body

$wrappedSecret = $response.value

Write-Host "Encrypted passphrase successfully"

#####
# Store secret
#####

$secretName = [guid]::NewGuid().ToString()
$uri = $KeyVault.VaultUri + "/secrets/" + $secretName + "?api-version=" + $apiversion
$secretAttributes = @{"enabled" = $true}
$secretTags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP"; "DiskEncryptionKeyFileName" =
"LinuxPassPhraseFileName"}
$headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" = "application/json"}
$bodyObj = @{"value" = $wrappedSecret; "attributes" = $secretAttributes; "tags" = $secretTags}
$body = $bodyObj | ConvertTo-Json

```

```
$response = Invoke-RestMethod -Method PUT -Uri $uri -Headers $headers -Body $body  
  
Write-Host "Stored secret successfully"  
  
$secretUrl = $response.id
```

Use `$KeyEncryptionKey` and `$secretUrl` in the next step for [attaching the OS disk using KEK](#).

## Specify a secret URL when you attach an OS disk

### Without using a KEK

While you're attaching the OS disk, you need to pass `$secretUrl`. The URL was generated in the "Disk-encryption secret not encrypted with a KEK" section.

```
Set-AzVMOSDisk `  
    -VM $VirtualMachine `  
    -Name $OSDiskName `  
    -SourceImageUri $VhdUri `  
    -VhdUri $OSDiskUri `  
    -Linux `  
    -CreateOption FromImage `  
    -DiskEncryptionKeyVaultId $KeyVault.ResourceId `  
    -DiskEncryptionKeyUrl $SecretUrl
```

### Using a KEK

When you attach the OS disk, pass `$KeyEncryptionKey` and `$secretUrl`. The URL was generated in the "Disk-encryption secret encrypted with a KEK" section.

```
Set-AzVMOSDisk `  
    -VM $VirtualMachine `  
    -Name $OSDiskName `  
    -SourceImageUri $CopiedTemplateBlobUri `  
    -VhdUri $OSDiskUri `  
    -Linux `  
    -CreateOption FromImage `  
    -DiskEncryptionKeyVaultId $KeyVault.ResourceId `  
    -DiskEncryptionKeyUrl $SecretUrl `  
    -KeyEncryptionKeyVaultId $KeyVault.ResourceId `  
    -KeyEncryptionKeyURL $KeyEncryptionKey.Id
```

# Azure Disk Encryption on an isolated network

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

When connectivity is restricted by a firewall, proxy requirement, or network security group (NSG) settings, the ability of the extension to perform needed tasks might be disrupted. This disruption can result in status messages such as "Extension status not available on the VM."

## Package management

Azure Disk Encryption depends on a number of components, which are typically installed as part of ADE enablement if not already present. When behind a firewall or otherwise isolated from the Internet, these packages must be pre-installed or available locally.

Here are the packages necessary for each distribution. For a full list of supported distros and volume types, see [supported VMs and operating systems](#).

- **Ubuntu 14.04, 16.04, 18.04:** lsscsi, psmisc, at, cryptsetup-bin, python-parted, python-six, procps, grub-pc-bin
- **CentOS 7.2 - 7.9, 8.1, 8.2:** lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup, cryptsetup-reencrypt, pyparted, procps-ng, util-linux
- **CentOS 6.8:** lsscsi, psmisc, lvm2, uuid, at, cryptsetup-reencrypt, pyparted, python-six
- **RedHat 7.2 - 7.9, 8.1, 8.2:** lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup, cryptsetup-reencrypt, procps-ng, util-linux
- **RedHat 6.8:** lsscsi, psmisc, lvm2, uuid, at, patch, cryptsetup-reencrypt
- **openSUSE 42.3, SLES 12-SP4, 12-SP3:** lsscsi, cryptsetup

On Red Hat, when a proxy is required, you must make sure that the subscription-manager and yum are set up properly. For more information, see [How to troubleshoot subscription-manager and yum problems](#).

When packages are installed manually, they must also be manually upgraded as new versions are released.

## Network security groups

Any network security group settings that are applied must still allow the endpoint to meet the documented network configuration prerequisites for disk encryption. See [Azure Disk Encryption: Networking requirements](#)

## Azure Disk Encryption with Azure AD (previous version)

If using [Azure Disk Encryption with Azure AD \(previous version\)](#), the [Azure Active Directory Library](#) will need to be installed manually for all distros (in addition to the packages appropriate for the distro, as [listed above](#)).

When encryption is being enabled with [Azure AD credentials](#), the target VM must allow connectivity to both Azure Active Directory endpoints and Key Vault endpoints. Current Azure Active Directory authentication endpoints are maintained in sections 56 and 59 of the [Microsoft 365 URLs and IP address ranges](#) documentation. Key Vault instructions are provided in the documentation on how to [Access Azure Key Vault behind a firewall](#).

### Azure Instance Metadata Service

The virtual machine must be able to access the [Azure Instance Metadata service](#) endpoint, which uses a well-

known non-routable IP address ( `169.254.169.254` ) that can be accessed only from within the VM. Proxy configurations that alter local HTTP traffic to this address (for example, adding an X-Forwarded-For header) are not supported.

## Next steps

- See more steps for [Azure disk encryption troubleshooting](#)
- [Azure data encryption at rest](#)

# Verify encryption status for Linux

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The scope of this article is to validate the encryption status of a virtual machine by using different methods: the Azure portal, PowerShell, the Azure CLI, or the operating system of the virtual machine (VM).

You can validate the encryption status during or after the encryption, by either:

- Checking the disks attached to a particular VM.
- Querying the encryption settings on each disk, whether the disk is attached or unattached.

This scenario applies for Azure Disk Encryption dual-pass and single-pass extensions. Linux distributions are the only environment for this scenario.

## NOTE

We're using variables throughout the article. Replace the values accordingly.

## Portal

In the Azure portal, inside the **Extensions** section, select the Azure Disk Encryption extension in the list. The information for **Status message** indicates the current encryption status:

A screenshot of the Azure portal showing the Azure Disk Encryption extension details. The extension name is 'AzureDiskEncryptionForLinux' and it is associated with the resource group 'vmadebackup'. The 'Status' field shows 'Provisioning succeeded'. The 'Version' field shows '1.1.0.48'. The 'Status message' field shows 'Install Succeeded'. The 'Detailed status' link is visible. The 'Handler status' is 'Ready' and the 'Handler status level' is 'Info'. The 'Resource ID' is a long URL starting with '/subscriptions/...'. The 'Status' and 'Version' fields are highlighted with red boxes.

Type	Microsoft.Azure.Security.AzureDiskEncryptionForLinux
Status	Provisioning succeeded
Version	1.1.0.48
Status level	Info
Status message	Install Succeeded
Detailed status	<a href="#">View detailed status</a>
Handler status	Ready
Handler status level	Info
Resource ID	/subscriptions/<subscription id>/

In the list of extensions, you'll see the corresponding Azure Disk Encryption extension version. Version 0.x corresponds to Azure Disk Encryption dual pass, and version 1.x corresponds to Azure Disk Encryption single pass.

You can get more details by selecting the extension and then selecting **View detailed status**. The detailed status of the encryption process appears in JSON format.

## AzureDiskEncryptionForLinux

vmadebackup

8 }
```

Another way to validate the encryption status is by looking at the **Disk settings** section.

Disk settings

Enable Ultra Disk compatibility  Yes  No

**OS disk**

Name	Size	Storage account ...	Encryption	Host caching
vmadebackup_OsDisk_1_7ffb0997763c483...	32 GiB	Premium SSD	<b>Enabled</b>	Read/write

**Data disks**

LUN	Name	Size	Storage account ...	Encryption	Host caching
0	vmadebackup_datadisk0	5 GiB	Standard HDD	<b>Enabled</b>	None

### NOTE

This status means the disks have encryption settings stamped, not that they were actually encrypted at the OS level.

By design, the disks are stamped first and encrypted later. If the encryption process fails, the disks may end up stamped but not encrypted.

To confirm if the disks are truly encrypted, you can double check the encryption of each disk at the OS level.

## PowerShell

You can validate the *general* encryption status of an encrypted VM by using the following PowerShell commands:

```
$VMNAME="VMNAME"
$RGNAME="RGNAME"
Get-AzVmDiskEncryptionStatus -ResourceGroupName ${RGNAME} -VMName ${VMNAME}
```

```
PS Azure:\> Get-AzVmDiskEncryptionStatus -ResourceGroupName ${RGNAME} -VMName ${VMNAME}

OsVolumeEncrypted      : NotEncrypted
DataVolumesEncrypted   : Encrypted
OsVolumeEncryptionSettings :
ProgressMessage        : Provisioning succeeded
```

You can capture the encryption settings from each disk by using the following PowerShell commands.

### Single pass

In a single pass, the encryption settings are stamped on each of the disks (OS and data). You can capture the encryption settings for an OS disk in a single pass as follows:

```
$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$VM = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}
$Sourcedisk = Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName $VM.StorageProfile.OsDisk.Name
Write-Host
=====
=====
Write-Host "Encryption Settings:"
Write-Host
=====
=====
Write-Host "Enabled:" $Sourcedisk.EncryptionSettingsCollection.Enabled
Write-Host "Version:" $Sourcedisk.EncryptionSettingsCollection.EncryptionSettingsVersion
Write-Host "Source Vault:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.SourceVault.Id
Write-Host "Secret URL:"
$Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.DiskEncryptionKey.SecretUrl
Write-Host "Key URL:" $Sourcedisk.EncryptionSettingsCollection.EncryptionSettings.KeyEncryptionKey.KeyUrl
Write-Host
=====
=====
```

```
===== Encryption Settings:
=====
Enabled: True
Version: 1.0
Source Vault: /subscriptions/ <subscription id> /resourceGroups/rgadabackup/providers/Microsoft.KeyVault/vaults/kvdualadebackup
Secret URL: https://kvdualadebackup.vault.azure.net/secrets/fa721375-4682-42e3-9ab3-bfe3f6ec8e4b/4f60f2eac6fa492f8272593030c4bbb9
Key URL: https://kvdualadebackup.vault.azure.net/keys/keydualadebackup/d656f60357fb491e902961a1eea6409c
=====
```

If the disk doesn't have encryption settings stamped, the output will be empty:

```
lvmincreaseremovedataenc_OsDisk_1_a73e76483c144d4886c217df200b2f3a
Encryption Settings:
PS C:\WINDOWS\system32> |
```

Use the following commands to capture encryption settings for data disks:

```

$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$VM = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}
clear
foreach ($i in $VM.StorageProfile.DataDisks|ForEach-Object{$__.Name})

```

## Dual pass

In a dual pass, the encryption settings are stamped in the VM model and not on each individual disk.

To verify that the encryption settings were stamped in a dual pass, use the following commands:

```

$RGNAME = "RGNAME"
$VMNAME = "VMNAME"

$vm = Get-AzVm -ResourceGroupName ${RGNAME} -Name ${VMNAME};
$Sourcedisk = Get-AzDisk -ResourceGroupName ${RGNAME} -DiskName $VM.StorageProfile.OsDisk.Name
clear

## Azure CLI

You can validate the *general*/encryption status of an encrypted VM by using the following Azure CLI commands:

```
VMNAME="VMNAME"
RGNAME="RGNAME"
az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} --query "substatus"
```

```
Code          $ az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} --query "substatus" -o table
              Level   DisplayStatus      Message
----- -----
ComponentStatus/Microsoft.Azure.Security.AzureDiskEncryptionForLinux/succeeded  Info    Provisioning succeeded {"os": "Encrypted", "data": "Encrypted"}
```

### Single pass

You can validate the encryption settings for each disk by using the following Azure CLI commands:

```
az vm encryption show -g ${RGNAME} -n ${VMNAME} --query "disks[*].[name, statuses[*].displayStatus]" -o table
```

Column1	Column2
lvmincreaseremovedataenc_OsDisk_1_a73e76483c144d4886c217df200b2f3a	['Disk is not encrypted']
lvmincreaseremovedataenc_datadisk1	['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk2	['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk3	['Encryption is enabled on disk']
lvmincreaseremovedataenc_datadisk4	['Encryption is enabled on disk']

### IMPORTANT

If the disk doesn't have encryption settings stamped, you'll see the text **Disk is not encrypted**.

Use the following commands to get detailed status and encryption settings.

OS disk:

```

RGNAME="RGNAME"
VMNAME="VNAME"

disk=`az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.osDisk.name -o tsv`  

for disk in $disk; do \  

echo  

=====
=====  

echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${disk} --query name -o tsv; \  

echo -ne "Encryption Enabled: "; az disk show -g ${RGNAME} -n ${disk} --query  

encryptionSettingsCollection.enabled -o tsv; \  

echo -ne "Version: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query  

encryptionSettingsCollection.encryptionSettingsVersion -o tsv; \  

echo -ne "Disk Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query  

encryptionSettingsCollection.encryptionSettings[].diskEncryptionKey.secretUrl -o tsv; \  

echo -ne "key Encryption Key: "; az disk show -g ${RGNAME} -n ${disk} --query  

encryptionSettingsCollection.encryptionSettings[].keyEncryptionKey.keyUrl -o tsv; \  

echo  

=====
=====  

done

```

```

=====

=====
```

## Dual pass

```
az vm encryption show --name ${VMNAME} --resource-group ${RGNAME} -o table
```

OsDisk	DataDisk	OsType	ProgressMessage
Encrypted	Encrypted	Linux	https://kv dual a backup.vault.azure.net/secrets/fa721375-4682-42e3-9ab3-bfe3f6ec8e4b/4f60f2eac6fa492f8272593030c4bb9

You can also check the encryption settings on the VM Model Storage profile of the OS disk:

```
disk=`az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.osDisk.name -o tsv`  
for disk in $disk; do \  
echo  
"=====  
====="; \  
echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${disk} --query name -o tsv; \

## Unattached disks

Check the encryption settings for disks that aren't attached to a VM.

## Managed disks

```
RGNAME="RGNAME"  
TARGETDISKNAME="DISKNAME"  
echo  
"=====  
====="; \  
echo -ne "Disk Name: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query name -o tsv; \  
echo -ne "Encryption Enabled: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query  
encryptionSettingsCollection.enabled -o tsv; \  
echo -ne "Version: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query  
encryptionSettingsCollection.encryptionSettingsVersion -o tsv; \  
echo -ne "Disk Encryption Key: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query  
encryptionSettingsCollection.encryptionSettings[].diskEncryptionKey.secretUrl -o tsv; \  
echo -ne "key Encryption Key: "; az disk show -g ${RGNAME} -n ${TARGETDISKNAME} --query  
encryptionSettingsCollection.encryptionSettings[].keyEncryptionKey.keyUrl -o tsv; \  
echo  
"=====  
====="
```

## Unmanaged disks

Unmanaged disks are VHD files that are stored as page blobs in Azure storage accounts.

To get the details for a specific disk, you need to provide:

- The ID of the storage account that contains the disk.
- A connection string for that particular storage account.
- The name of the container that stores the disk.
- The disk name.

This command lists all the IDs for all your storage accounts:

```
az storage account list --query [].[id] -o tsv
```

The storage account IDs are listed in the following form:

```
/subscriptions/<subscription id>/resourceGroups/<resource group  
name>/providers/Microsoft.Storage/storageAccounts/<storage account name>
```

Select the appropriate ID and store it on a variable:

```
id="/subscriptions/<subscription id>/resourceGroups/<resource group  
name>/providers/Microsoft.Storage/storageAccounts/<storage account name>"
```

This command gets the connection string for one particular storage account and stores it on a variable:

```
ConnectionString=$(az storage account show-connection-string --ids $id --query connectionString -o tsv)
```

The following command lists all the containers under a storage account:

```
az storage container list --connection-string $ConnectionString --query [].[name] -o tsv
```

The container used for disks is normally named "vhds."

Store the container name on a variable:

```
ContainerName="name of the container"
```

Use this command to list all the blobs on a particular container:

```
az storage blob list -c ${ContainerName} --connection-string $ConnectionString --query [].[name] -o tsv
```

Choose the disk that you want to query and store its name on a variable:

```
DiskName="diskname.vhd"
```

Query the disk encryption settings:

```
az storage blob show -c ${ContainerName} --connection-string ${ConnectionString} -n ${DiskName} --query  
metadata.DiskEncryptionSettings
```

## Operating system

Validate if the data disk partitions are encrypted (and the OS disk isn't).

When a partition or disk is encrypted, it's displayed as a **crypt** type. When it's not encrypted, it's displayed as a **part/disk** type.

```
lsblk
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT
fd0	2:0	1	4K	0	disk	
sda	8:0	0	32G	0	disk	
└─sda1	8:1	0	500M	0	part	/boot
└─sda2	8:2	0	31.5G	0	part	
└─osencrypt	253:0	0	31.5G	0	crypt	/
sdb	8:16	0	32G	0	disk	
└─sdb1	8:17	0	32G	0	part	/mnt/resource
sdc	8:32	0	48M	0	disk	
└─sdc1	8:33	0	47M	0	part	/mnt/azure_bek_disk
sdd	8:48	0	5G	0	disk	
└─sdd1	8:49	0	5G	0	part	
└─myencrypteddisk	253:1	0	5G	0	crypt	/data4tb

You can get more details by using the following `lsblk` variant.

You'll see a `crypt` type layer that is mounted by the extension. The following example shows logical volumes and normal disks having `crypto_LUKS` FSTYPE.

```
lsblk -o NAME,TYPE,FSTYPE,LABEL,SIZE,RO,MOUNTPOINT
```

NAME	TYPE	FSTYPE	LABEL	SIZE	RO	MOUNTPOINT
fd0	disk			4K	0	
sda	disk			32G	0	
└─sda1	part	xfs		500M	0	/boot
└─sda2	part			31.5G	0	
└─osencrypt	crypt	xfs		31.5G	0	/
sdb	disk			32G	0	
└─sdb1	part	ext4		32G	0	/mnt/resource
sdc	disk			48M	0	
└─sdc1	part	vfat	BEK VOLUME	47M	0	/mnt/azure_bek_disk
sdd	disk			5G	0	
└─sdd1	part	crypto_LUKS		5G	0	
└─myencrypteddisk	crypt	ext4		5G	0	/data4tb

As an extra step, you can validate if the data disk has any keys loaded:

```
cryptsetup luksDump /dev/VGNAME/LVNAME
```

```
cryptsetup luksDump /dev/sdd1
```

And you can check which `dm` devices are listed as `crypt`:

```
dmsetup ls --target crypt
```

## Next steps

- [Azure Disk Encryption troubleshooting](#)

# Configure LVM and RAID on encrypted devices

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This article is a step-by-step process for how to perform Logical Volume Management (LVM) and RAID on encrypted devices. The process applies to the following environments:

- Linux distributions
  - RHEL 7.6+
  - Ubuntu 18.04+
  - SUSE 12+
- Azure Disk Encryption single-pass extension
- Azure Disk Encryption dual-pass extension

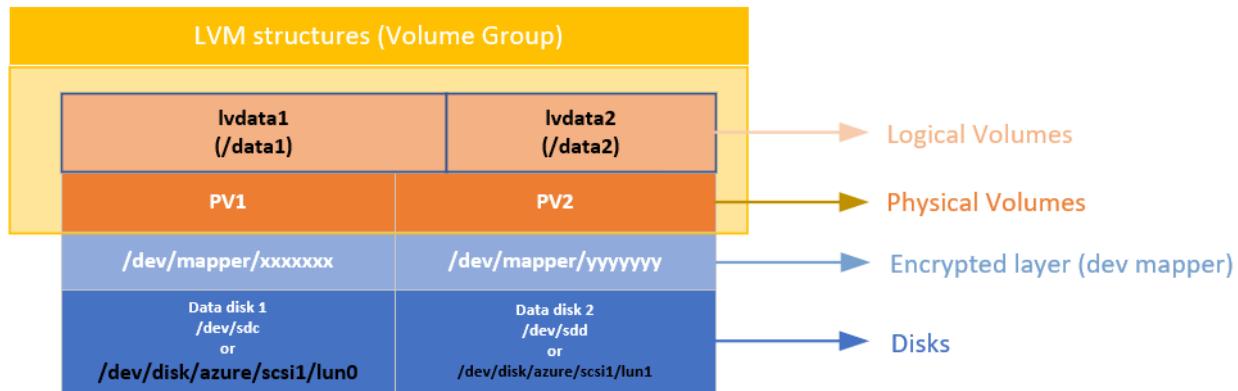

## Scenarios

The procedures in this article support the following scenarios:

- Configure LVM on top of encrypted devices (LVM-on-crypt)
- Configure RAID on top of encrypted devices (RAID-on-crypt)

After the underlying device or devices are encrypted, then you can create the LVM or RAID structures on top of that encrypted layer.

The physical volumes (PVs) are created on top of the encrypted layer. The physical volumes are used to create the volume group. You create the volumes and add the required entries on /etc/fstab.

In a similar way, the RAID device is created on top of the encrypted layer on the disks. A file system is created on top of the RAID device and added to /etc/fstab as a regular device.

## Considerations

We recommend that you use LVM-on-crypt. RAID is an option when LVM can't be used because of specific application or environment limitations.

You'll use the **EncryptFormatAll** option. For more information about this option, see [Use the EncryptFormatAll feature for data disks on Linux VMs](#).

Although you can use this method when you're also encrypting the OS, we're just encrypting data drives here.

The procedures assume that you already reviewed the prerequisites in [Azure Disk Encryption scenarios on Linux VMs](#) and in [Quickstart: Create and encrypt a Linux VM with the Azure CLI](#).

The Azure Disk Encryption dual-pass version is on a deprecation path and should no longer be used on new encryptions.

## General steps

When you're using the "on-crypt" configurations, use the process outlined in the following procedures.

### NOTE

We're using variables throughout the article. Replace the values accordingly.

### Deploy a VM

The following commands are optional, but we recommend that you apply them on a newly deployed virtual machine (VM).

PowerShell:

```
New-AzVm -ResourceGroupName ${RGNAME} `  
-Name ${VMNAME} `  
-Location ${LOCATION} `  
-Size ${VMSIZE} `  
-Image ${OSIMAGE} `  
-Credential ${creds} `  
-Verbose
```

Azure CLI:

```
az vm create \  
-n ${VMNAME} \  
-g ${RGNAME} \  
--image ${OSIMAGE} \  
--admin-username ${username} \  
--admin-password ${password} \  
-l ${LOCATION} \  
--size ${VMSIZE} \  
-o table
```

### Attach disks to the VM

Repeat the following commands for `$N` number of new disks that you want to attach to the VM.

PowerShell:

```
$storageType = 'Standard_LRS'  
$dataDiskName = ${VMNAME} + '_datadisk0'  
$diskConfig = New-AzDiskConfig -SkuName $storageType -Location $LOCATION -CreateOption Empty -DiskSizeGB 5  
$dataDisk1 = New-AzDisk -DiskName $dataDiskName -Disk $diskConfig -ResourceGroupName ${RGNAME}  
$vm = Get-AzVM -Name ${VMNAME} -ResourceGroupName ${RGNAME}  
$vm = Add-AzVMDataDisk -VM $vm -Name $dataDiskName -CreateOption Attach -ManagedDiskId $dataDisk1.Id -Lun 0  
Update-AzVM -VM ${VM} -ResourceGroupName ${RGNAME}
```

Azure CLI:

```

az vm disk attach \
-g ${RGNAME} \
--vm-name ${VMNAME} \
--name ${VMNAME}datadisk1 \
--size-gb 5 \
--new \
-o table

```

## Verify that the disks are attached to the VM

PowerShell:

```

$VM = Get-AzVM -ResourceGroupName ${RGNAME} -Name ${VMNAME}
$VM.StorageProfile.DataDisks | Select-Object Lun,Name,DiskSizeGB

```

Lun	Name	DiskSizeGB
0	vmlvmoncrypt_datadisk0	5
1	vmlvmoncrypt_datadisk1	5
2	vmlvmoncrypt_datadisk2	5
3	vmlvmoncrypt_datadisk3	5

Azure CLI:

```

az vm show -g ${RGNAME} -n ${VMNAME} --query storageProfile.dataDisks -o table

```

Lun	Name	Caching	WriteAcceleratorEnabled	CreateOption	DiskSizeGb	ToBeDetached
0	vmlvmoncrypt_datadisk0	None	False	Attach	5	False
1	vmlvmoncrypt_datadisk1	None	False	Attach	5	False
2	vmlvmoncrypt_datadisk2	None	False	Attach	5	False
3	vmlvmoncrypt_datadisk3	None	False	Attach	5	False

Portal:

Data disks

LUN	Name	Size	Storage account ...	Encryption	Host caching
0	vmlvmoncrypt_datadisk0	5 GiB	Standard HDD	Not enabled	None
1	vmlvmoncrypt_datadisk1	5 GiB	Standard HDD	Not enabled	None
2	vmlvmoncrypt_datadisk2	5 GiB	Standard HDD	Not enabled	None
3	vmlvmoncrypt_datadisk3	5 GiB	Standard HDD	Not enabled	None

OS:

```

lsblk

```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT
fd0	2:0	1	4K	0	disk	
sda	8:0	0	32G	0	disk	
└─sda1	8:1	0	500M	0	part	/boot
└─sda2	8:2	0	31.5G	0	part	/
sdb	8:16	0	32G	0	disk	
└─sdb1	8:17	0	32G	0	part	/mnt/resource
sdc	8:32	0	5G	0	disk	
sdd	8:48	0	5G	0	disk	
sde	8:64	0	5G	0	disk	
sdf	8:80	0	5G	0	disk	
sr0	11:0	1	628K	0	rom	

## Configure the disks to be encrypted

This configuration is done at the operating system level. The corresponding disks are configured for a traditional encryption through Azure Disk Encryption:

- File systems are created on top of the disks.
- Temporary mount points are created to mount the file systems.
- File systems are configured on /etc/fstab to be mounted at boot time.

Check the device letter assigned to the new disks. In this example, we're using four data disks.

```
lsblk
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT
fd0	2:0	1	4K	0	disk	
sda	8:0	0	32G	0	disk	
└─sda1	8:1	0	500M	0	part	/boot
└─sda2	8:2	0	31.5G	0	part	/
sdb	8:16	0	32G	0	disk	
└─sdb1	8:17	0	32G	0	part	/mnt/resource
sdc	8:32	0	5G	0	disk	
sdd	8:48	0	5G	0	disk	
sde	8:64	0	5G	0	disk	
sdf	8:80	0	5G	0	disk	
sr0	11:0	1	628K	0	rom	

## Create a file system on top of each disk

This command iterates the creation of an ext4 file system on each disk defined on the "in" part of the "for" cycle.

```
for disk in c d e f; do echo mkfs.ext4 -F /dev/sd${disk}; done |bash
```

```
[root@vmlvmoncrypt ~]# for disk in c d e; do echo mkfs.ext4 -F /dev/sd${disk}; done |bash
mke2fs 1.42.9 (28-Dec-2013)
Discarding device blocks: done
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)

      32768, 98304, 163840, 229376, 294912, 819200, 884736

Allocating group tables: done
Writing inode tables: done
Creating journal (32768 blocks): done
Writing superblocks and filesystem accounting information: done
```

Find the universally unique identifier (UUID) of the file systems that you recently created, create a temporary folder, add the corresponding entries on /etc/fstab, and mount all the file systems.

This command also iterates on each disk defined on the "in" part of the "for" cycle:

```

for disk in c d e f; do diskuuid=$(blkid -s UUID -o value /dev/sd${disk}); \
mkdir /tempdata${disk}; \
echo "UUID=${diskuuid} /tempdata${disk} ext4 defaults,nofail 0 0" >> /etc/fstab; \
mount -a; \
done

```

### Verify that the disks are mounted properly

```
lsblk
```

```
[root@vmlvmoncrypt ~]# lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
fd0      2:0    1   4K  0 disk 
sda      8:0    0  32G  0 disk 
└─sda1   8:1    0 500M  0 part /boot
└─sda2   8:2    0 31.5G  0 part /
sdb      8:16   0  32G  0 disk 
└─sdb1   8:17   0  32G  0 part /mnt/resource
sdc      8:32   0   5G  0 disk /tempdatac
sdd      8:48   0   5G  0 disk /tempdatad
sde      8:64   0   5G  0 disk /tempdatae
 sdf      8:80   0   5G  0 disk /tempdataf
sr0     11:0   1  628K  0 rom
```

Also verify that the disks are configured:

```
cat /etc/fstab
```

```
[root@vmlvmoncrypt ~]# cat /etc/fstab
#
# /etc/fstab
# Created by anaconda on Thu Jun 20 18:47:49 2019
#
# Accessible filesystems, by reference, are maintained under '/dev/disk'
# See man pages fstab(5), findfs(8), mount(8) and/or blkid(8) for more info
#
UUID=52e42afc-2da4-4391-bbc0-92f2a1b45c62 /          xfs      defaults        0 0
UUID=a8fbef35-ff5e-4515-bb7e-c408c118d4c0 /boot        xfs      defaults        0 0
UUID=e347f00e-02ca-4b9b-9aee-1295c09ed634 /tempdatac ext4 defaults,nofail 0 0
UUID=1ee5221f-201a-4da7-a0df-fb0c906ac323 /tempdatad ext4 defaults,nofail 0 0
UUID=a16ab0a2-0e47-4a04-a5a9-28618e6377ba /tempdatae ext4 defaults,nofail 0 0
UUID=5a98ba0d-9b92-44c8-ac7d-9335e56ab0f3 /tempdataf ext4 defaults,nofail 0 0
```

### Encrypt the data disks

PowerShell using a key encryption key (KEK):

```
$sequenceVersion = [Guid]::NewGuid()
Set-AzVMDiskEncryptionExtension -ResourceGroupName $RGNAME ` 
-VMName ${VMNAME} ` 
-DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl ` 
-DiskEncryptionKeyId $KeyVaultResourceId ` 
-KeyEncryptionKeyUrl $keyEncryptionKeyUrl ` 
-KeyEncryptionKeyVaultId $KeyVaultResourceId ` 
-VolumeType 'DATA' ` 
-EncryptFormatAll ` 
-SequenceVersion $sequenceVersion ` 
-skipVmBackup;
```

Azure CLI using a KEK:

```
az vm encryption enable \
--resource-group ${RGNAME} \
--name ${VMNAME} \
--disk-encryption-keyvault ${KEYVAULTNAME} \
--key-encryption-key ${KEYNAME} \
--key-encryption-keyvault ${KEYVAULTNAME} \
--volume-type "DATA" \
--encrypt-format-all \
-o table
```

## Verify the encryption status

Continue to the next step only when all the disks are encrypted.

PowerShell:

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName ${RGNAME} -VMName ${VMNAME}
```

```
OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : EncryptionInProgress
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage        : Encryption succeeded for data volumes
```

Azure CLI:

```
az vm encryption show -n ${VMNAME} -g ${RGNAME} -o table
```

```
user@Azure>az vm encryption show -n ${VMNAME} -g ${RGNAME} -o table
Status           Message
-----
Provisioning succeeded Encryption succeeded for data volumes
```

Portal:

The extension will add the file systems to /var/lib/azure\_disk\_encryption\_config/azure\_crypt\_mount (an old encryption) or to /etc/crypttab (new encryptions).

#### NOTE

Do not modify any of these files.

This file will take care of activating these disks during the boot process so that LVM or RAID can use them later.

Don't worry about the mount points on this file. Azure Disk Encryption will lose the ability to get the disks mounted as a normal file system after we create a physical volume or a RAID device on top of those encrypted devices. (This will remove the file system format that we used during the preparation process.)

#### Remove the temporary folders and temporary fstab entries

You unmount the file systems on the disks that will be used as part of LVM.

```
for disk in c d e f; do umount /tempdata${disk}; done
```

And remove the /etc/fstab entries:

```
vi /etc/fstab
```

#### Verify that the disks are not mounted and that the entries on /etc/fstab were removed

```
lsblk
```

```
[root@vmlvmoncrypt ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
fd0            2:0    1   4K  0 disk 
sda            8:0    0  32G  0 disk 
└─sda1         8:1    0 500M  0 part /boot
└─sda2         8:2    0 31.5G 0 part /

└─6712ad6f-65ce-487b-aa52-462f381611a1 253:1  0   5G  0 crypt
sdf            8:80   0   5G  0 disk 
└─ea607dfd-c396-48d6-bc54-603cf741bc2a 253:2  0   5G  0 crypt
sdg            8:96   0   5G  0 disk 
└─4159c60a-a546-455b-985f-92865d51158c 253:3  0   5G  0 crypt
sr0           11:0   1 1024M 0 rom
```

And verify that the disks are configured:

```
cat /etc/fstab
```

```
[root@vmlvmoncrypt ~]# cat /etc/fstab
#
# /etc/fstab
# Created by anaconda on Thu Jun 20 18:47:49 2019
#
# Accessible filesystems, by reference, are maintained under '/dev/disk'
# See man pages fstab(5), findfs(8), mount(8) and/or blkid(8) for more info
#
UUID=52e42afc-2da4-4391-bbc0-92f2a1b45c62 /          xfs      defaults        0 0
UUID=a8fbef35-ff5e-4515-bb7e-c408c118d4c0 /boot       xfs      defaults        0 0

/dev/mapper/resourcecrypt /mnt/resource auto defaults,discard,nofail 0 0
```

## Steps for LVM-on-crypt

Now that the underlying disks are encrypted, you can create the LVM structures.

Instead of using the device name, use the /dev/mapper paths for each of the disks to create a physical volume (on the crypt layer on top of the disk, not on the disk itself).

### Configure LVM on top of the encrypted layers

#### Create the physical volumes

You'll get a warning that asks if it's OK to wipe out the file system signature. Continue by entering **y**, or use **echo "y"** as shown:

```
echo "y" | pvcreate /dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052
echo "y" | pvcreate /dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1
echo "y" | pvcreate /dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a
echo "y" | pvcreate /dev/mapper/4159c60a-a546-455b-985f-92865d51158c
```

```
[root@vmlvmoncrypt ~]# echo "y" | pvcreate /dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052
WARNING: ext4 signature detected on /dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052 at offset 1080. Wipe it? [y/n]: t
Physical volume "/dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052" successfully created.
```

#### NOTE

The /dev/mapper/device names here need to be replaced for your actual values based on the output of **lsblk**.

### Verify the information for physical volumes

```
pvs
```

```
[root@vmlvmoncrypt ~]# pvs
PV                                         VG Fmt Attr PSize PFree
/dev/mapper/4159c60a-a546-455b-985f-92865d51158c  lvm2 --- <5.00g <5.00g
/dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1  lvm2 --- <5.00g <5.00g
/dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052  lvm2 --- <5.00g <5.00g
/dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a  lvm2 --- <5.00g <5.00g
```

#### Create the volume group

Create the volume group by using the same devices already initialized:

```
vgcreate vgdata /dev/mapper/
```

#### Check the information for the volume group

```
vgdisplay -v vgdata
```

```
pvs
```

```
[root@vmlvmoncrypt ~]# pvs
PV                                         VG      Fmt  Attr PSize PFree
/dev/mapper/4159c60a-a546-455b-985f-92865d51158c vgdata  lvm2 a-- <5.00g <5.00g
/dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1 vgdata  lvm2 a-- <5.00g <5.00g
/dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052 vgdata  lvm2 a-- <5.00g <5.00g
/dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a vgdata  lvm2 a-- <5.00g <5.00g
```

#### Create logical volumes

```
lvcreate -L 10G -n lvdata1 vgdata
lvcreate -L 7G -n lvdata2 vgdata
```

#### Check the created logical volumes

```
lvdisplay
lvdisplay vgdata/lvdata1
lvdisplay vgdata/lvdata2
```

```
[root@vmlvmoncrypt ~]# lvdisplay
--- Logical volume ---

8d5faa52-282f-4609-9bc3-f3077c910982

On this variation of **lsblk**, we're listing the devices showing the dependencies in reverse order. This option helps to identify the devices grouped by the logical volume instead of the original /dev/sd[disk] device names.

It's important to make sure that the **nofail** option is added to the mount point options of the LVM volumes created on top of a device encrypted through Azure Disk Encryption. It prevents the OS from getting stuck during the boot process (or in maintenance mode).

If you don't use the **nofail** option:

- The OS will never get into the stage where Azure Disk Encryption is started and the data disks are unlocked and mounted.
- The encrypted disks will be unlocked at the end of the boot process. The LVM volumes and file systems will be automatically mounted until Azure Disk Encryption unlocks them.

You can test rebooting the VM and validate that the file systems are also automatically getting mounted after boot time. This process might take several minutes, depending on the number and sizes of file systems.

#### **Reboot the VM and verify after reboot**

```
shutdown -r now
```

```
lsblk
df -h
```

## Steps for RAID-on-crypt

Now that the underlying disks are encrypted, you can continue to create the RAID structures. The process is the same as the one for LVM, but instead of using the device name, use the /dev/mapper paths for each disk.

#### **Configure RAID on top of the encrypted layer of the disks**

```
mdadm --create /dev/md10 \
--level 0 \
--raid-devices=4 \
/dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052 \
/dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1 \
/dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a \
/dev/mapper/4159c60a-a546-455b-985f-92865d51158c
```

```
[root@vmlvmoncrypt ~]# mdadm --create /dev/md10 \
> --level 0 \
> --raid-devices=4 \
> /dev/mapper/c49ff535-1df9-45ad-9dad-f0846509f052 \
> /dev/mapper/6712ad6f-65ce-487b-aa52-462f381611a1 \
> /dev/mapper/ea607dfd-c396-48d6-bc54-603cf741bc2a \
> /dev/mapper/4159c60a-a546-455b-985f-92865d51158c
mdadm: Defaulting to version 1.2 metadata
mdadm: array /dev/md10 started.
```

#### NOTE

The /dev/mapper/device names here need to be replaced with your actual values, based on the output of `lsblk`.

#### Check/monitor RAID creation

```
watch -n1 cat /proc/mdstat  
mdadm --examine /dev/mapper/[]  
mdadm --detail /dev/md10
```

```
[root@vmlvmoncrypt ~]# mdadm --detail /dev/md10  
/dev/md10:  
    Version : 1.2  
Creation Time : Wed Mar 18 02:15:42 2020  
    Raid Level : raid0  
    Array Size : 20942848 (19.97 GiB 21.45 GB)  
    Raid Devices : 4  
    Total Devices : 4  
        Persistence : Superblock is persistent  
  
        Update Time : Wed Mar 18 02:15:42 2020  
            State : clean  
    Active Devices : 4  
Working Devices : 4  
Failed Devices : 0  
Spare Devices : 0  
  
    Chunk Size : 512K  
  
Consistency Policy : none  
  
                Name : vmlvmoncrypt:10 (local to host vmlvmoncrypt)  
                UUID : 62fbf2ff:0dae41b1:96c61bd5:b3119c49  
                Events : 0  
  
      Number  Major  Minor  RaidDevice State  
        0      253       0        0  active sync  /dev/dm-0  
        1      253       1        1  active sync  /dev/dm-1  
        2      253       2        2  active sync  /dev/dm-2  
        3      253       4        3  active sync  /dev/dm-4
```

#### Create a file system on top of the new RAID device

```
mkfs.ext4 /dev/md10
```

Create a new mount point for the file system, add the new file system to /etc/fstab, and mount it:

#### NOTE

This cycle iterates only on one device for this particular example, is built this way to be used for multiple md devices if needed.

```
for device in md10; do diskuuid=$(blkid -s UUID -o value /dev/${device}); \  
mkdir /raiddata; \  
echo "UUID=${diskuuid} /raiddata ext4 defaults,nofail 0 0" >> /etc/fstab; \  
mount -a; \  
done
```

Verify that the new file system is mounted:

```
lsblk -fs  
df -h
```

```
md10  
└─c49ff535-1df9-45ad-9dad-f0846509f052 ext4  
    └─sdd  
        └─sde  
            └─ea607dfd-c396-48d6-bc54-603cf741bc2a  
                └─sdf  
                    └─4159c60a-a546-455b-985f-92865d51158c  
                        └─sda  
                            └─crypto_LUKS  
                                └─vmlvmoncrypt:10  
                                    └─c72438c2-8496-4d5b-aa55-90bf979b080e /raiddata
```

It's important to make sure that the **nofail** option is added to the mount point options of the RAID volumes created on top of a device encrypted through Azure Disk Encryption. It prevents the OS from getting stuck during the boot process (or in maintenance mode).

If you don't use the **nofail** option:

- The OS will never get into the stage where Azure Disk Encryption is started and the data disks are unlocked and mounted.
- The encrypted disks will be unlocked at the end of the boot process. The RAID volumes and file systems will be automatically mounted until Azure Disk Encryption unlocks them.

You can test rebooting the VM and validate that the file systems are also automatically getting mounted after boot time. This process might take several minutes, depending on the number and sizes of file systems.

```
shutdown -r now
```

And when you can log in:

```
lsblk  
df -h
```

# How to resize logical volume management devices that use Azure Disk Encryption

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In this article, you'll learn how to resize data disks that use Azure Disk Encryption. To resize the disks, you'll use logical volume management (LVM) on Linux. The steps apply to multiple scenarios.

You can use this resizing process in the following environments:

- Linux distributions:
  - Red Hat Enterprise Linux (RHEL) 7 or later
  - Ubuntu 16 or later
  - SUSE 12 or later
- Azure Disk Encryption versions:
  - Single-pass extension
  - Dual-pass extension

## Prerequisites

This article assumes that you have:

- An existing LVM configuration. For more information, see [Configure LVM on a Linux VM](#).
- Disks that are already encrypted by Azure Disk Encryption. For more information, see [Configure LVM and RAID on encrypted devices](#).
- Experience using Linux and LVM.
- Experience using `/dev/disk/scsi1/paths` for data disks on Azure. For more information, see [Troubleshoot Linux VM device name problems](#).

## Scenarios

The procedures in this article apply to the following scenarios:

- Traditional LVM and LVM-on-crypt configurations
- Traditional LVM encryption
- LVM-on-crypt

### Traditional LVM and LVM-on-crypt configurations

Traditional LVM and LVM-on-crypt configurations extend a logical volume (LV) when the volume group (VG) has available space.

### Traditional LVM encryption

In traditional LVM encryption, LVs are encrypted. The whole disk isn't encrypted.

By using traditional LVM encryption, you can:

- Extend the LV when you add a new physical volume (PV).
- Extend the LV when you resize an existing PV.

## LVM-on-crypt

The recommended method for disk encryption is LVM-on-encrypt. This method encrypts the entire disk, not just the LV.

By using LVM-on-crypt, you can:

- Extend the LV when you add a new PV.
- Extend the LV when you resize an existing PV.

### NOTE

We don't recommend mixing traditional LVM encryption and LVM-on-crypt on the same VM.

The following sections provide examples of how to use LVM and LVM-on-crypt. The examples use preexisting values for disks, PVs, VGs, LVs, file systems, universally unique identifiers (UUIDs), and mount points. Replace these values with your own values to fit your environment.

### Extend an LV when the VG has available space

The traditional way to resize LVs is to extend an LV when the VG has space available. You can use this method for nonencrypted disks, traditional LVM-encrypted volumes, and LVM-on-crypt configurations.

1. Verify the current size of the file system that you want to increase:

```
df -h /mountpoint
```

```
[root@azurervm]# df -h /datalv02
Filesystem      Size  Used Avail Use% Mounted on
/dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5  974M  958M     0 100% /datalv02
```

2. Verify that the VG has enough space to increase the LV:

```
vgs
```

```
[root@azurervm]# vgs
VG #PV #LV #SN Attr   VSize   VFree
datavg    3    4    0 wz--n- <14.99g <4.99g
```

You can also use `vgdisplay`:

```
vgdisplay vgname
```

```
[root@azurervm]# vgdisplay datavg
--- Volume group ---
VG Name           datavg
System ID
Format          lvm2
Metadata Areas    3
Metadata Sequence No 5
VG Access        read/write
VG Status         resizable
MAX LV            0
Cur LV            4
Open LV           4
Max PV            0
Cur PV            3
Act PV            3
VG Size          <14.99 GiB
PE Size          4.00 MiB
Total PE          3837
Alloc PE / Size  2560 / 10.00 GiB
Free PE / Size   1277 / <4.99 GiB
VG UUID          jvc1Kz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY
```

3. Identify which LV needs to be resized:

```
lsblk
```

```
[root@azurervm]# lsblk
NAME                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                  2:0    1   4K  0 disk
sda                  8:0    0 32G  0 disk
└─sda1                8:1    0 500M 0 part  /boot
└─sda2                8:2    0 31.5G 0 part  /
sdb                  8:16   0 32G  0 disk
└─sdb1                8:17   0 32G  0 part  /mnt/resource
sdc                  8:32   0 48M  0 disk
└─sdc1                8:33   0 46M  0 part  /mnt/azure_bek_disk
sdd                  8:48   0 5G   0 disk
└─datavg-datalv01      253:0  0 1G   0 lvm
  └─55b4af2-a160-426b-9bd7-588af6c46e9b 253:4  0 1022M 0 crypt  /datalv01
└─datavg-datalv02      253:1  0 1G   0 lvm
  └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5 253:5  0 1022M 0 crypt  /datalv02
└─datavg-datalv03      253:2  0 1G   0 lvm
  └─70abfc58-b0fd-441b-8b77-f86c9249af5e 253:6  0 1022M 0 crypt  /datalv03
sde                  8:64   0 5G   0 disk
└─datavg-datalv04      253:3  0 7G   0 lvm
  └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7  0 7G   0 crypt  /datalv04
 sdf                  8:80   0 5G   0 disk
└─datavg-datalv04      253:3  0 7G   0 lvm
  └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7  0 7G   0 crypt  /datalv04
sr0                 11:0   1 1024M 0 rom
```

For LVM-on-crypt, the difference is that this output shows that the encrypted layer is at the disk level.

```
[root@vmresizelv ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
fd0            2:0    1   4K  0 disk 
sda            8:0    0   32G  0 disk 
└─sda1         8:1    0   500M 0 part /boot
      └─sda2         8:2    0   31.5G 0 part /
sdb            8:16   0   32G  0 disk 
└─sdb1         8:17   0   32G  0 part 
  └─resourcecrypt 253:0   0   32G  0 crypt /mnt/resource
sdc            8:32   0   48M  0 disk 
└─sdc1         8:33   0   47M  0 part /mnt/azure_bek_disk
sde            8:64   0     5G  0 disk 
└─e19fcd77-e974-4e5c-a874-e78e4b6d2f48 253:1   0   5G  0 crypt
  ├─datavg-datalv01 253:4   0   1G  0 lvm  /datalv01
  └─datavg-datalv02 253:5   0   6G  0 lvm  /datalv02
    ├─datavg-datalv03 253:6   0   4G  0 lvm  /datalv03
    └─datavg-datalv04 253:7   0   3G  0 lvm  /datalv04
sdf            8:80   0   5G  0 disk 
└─49de5df0-1c65-48bf-809c-588805eda921 253:2   0   5G  0 crypt
  ├─datavg-datalv02 253:5   0   6G  0 lvm  /datalv02
  └─datavg-datalv04 253:7   0   3G  0 lvm  /datalv04
sdg            8:96   0   5G  0 disk 
└─8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 253:3   0   5G  0 crypt
  ├─datavg-datalv03 253:6   0   4G  0 lvm  /datalv03
  └─datavg-datalv04 253:7   0   3G  0 lvm  /datalv04
```

4. Check the LV size:

```
lvdisplay lvname
```

```
[root@azurervm]# lvdisplay /dev/datavg/datalv02
--- Logical volume ---
LV Path           /dev/datavg/datalv02
LV Name          datalv02
VG Name          datavg
LV UUID          Isacy4-ukYq-UKCB-tG48-tjfc-LWlr-kWTyfy
LV Write Access  read/write
LV Creation host, time  vmresizelv, 2020-09-18 20:13:14 +0000
LV Status        available
# open           1
LV Size          1.00 GiB
Current LE       256
Segments         1
Allocation       inherit
Read ahead sectors auto
- currently set to 8192
Block device     253:1
```

5. Increase the LV size by using `-r` to resize the file system online:

```
lvextend -r -L +2G /dev/vgname/lvname
```

```
[root@azurervm]# lvextend -r -L +2G /dev/datavg/datalv02
  size of logical volume datavg/datalv02 changed from 1.00 GiB (256 extents) to 3.00 GiB (768 extents).
Logical volume datavg/datalv02 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5 is mounted on /datalv02; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5 is now 785920 blocks long.
```

6. Verify the new sizes for the LV and the file system:

```
df -h /mountpoint
```

```
[root@azurervm]# df -h /datalv02/
Filesystem      Size  Used Avail Use% Mounted on
/dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5  3.0G  959M  1.9G  34% /datalv02
```

The size output indicates that the LV and file system were successfully resized.

You can check the LV information again to confirm the changes at the level of the LV:

```
lvdisplay lvname
```

```
[root@azurevm]# lvdisplay /dev/datavg/datalv02
--- Logical volume ---
LV Path              /dev/datavg/datalv02
LV Name             datalv02
VG Name              datavg
LV UUID             Isacy4-ukYq-UKCB-tG48-tjfc-LWlr-kWTyfy
LV Write Access     read/write
LV Creation host, time vmresizelv, 2020-09-18 20:13:14 +0000
LV Status            available
# open                1
LV Size              3.00 GiB
Current LE           768
Segments              3
Allocation            inherit
Read ahead sectors   auto
- currently set to    8192
Block device          253:1
```

#### Extend a traditional LVM volume by adding a new PV

When you need to add a new disk to increase the VG size, extend your traditional LVM volume by adding a new PV.

1. Verify the current size of the file system that you want to increase:

```
df -h /mountpoint
```

```
[root@azurevm]# df -h /datalv01
Filesystem      Size  Used Avail Use% Mounted on
/dev/mapper/55b4af2-a160-426b-9bd7-588af6c46e9b  974M  958M      0 100% /datalv01
```

2. Verify the current PV configuration:

```
pvs
```

```
[root@azurevm]# pvs
PV      VG      Fmt  Attr PSize  PFree
/dev/sdd  datavg lvm2 a-- <5.00g    0
/dev/sde  datavg lvm2 a-- <5.00g    0
/dev/sdf  datavg lvm2 a-- <5.00g    0
```

3. Check the current VG information:

```
vgs
```

```
[root@azurevm]# vgs
VG      #PV  #LV  #SN Attr   VSize  VFree
datavg    3    4    0 wz--n- <14.99g    0
```

4. Check the current disk list. Identify data disks by checking the devices in `/dev/disk/azure/scsi1/`.

```
ls -l /dev/disk/azure/scsi1/
```

```
[root@azurervm]# ls -l /dev/disk/azure/scsi1/
total 0
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun0 -> ../../.../sdd
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun1 -> ../../.../sde
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun2 -> ../../.../sdf
```

5. Check the output of `lsblk`:

```
lsblk
```

```
[root@azurervm]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0           2:0    1   4K  0 disk
sda           8:0    0  32G  0 disk
└─sda1        8:1    0 500M  0 part  /boot
   └─sda2        8:2    0 31.5G 0 part  /
sdb           8:16   0  32G  0 disk
└─sdb1        8:17   0 32G  0 part  /mnt/resource
sdc           8:32   0  48M  0 disk
└─sdc1        8:33   0  46M  0 part  /mnt/azure_bek_disk
sdd           8:48   0   5G  0 disk
  ├─datavg-datalv01  253:0   0  1G  0 lvm
  │  ├─55b4af2d-a160-426b-9bd7-588af6c46e9b  253:4   0 1022M 0 crypt /datalv01
  │  ├─datavg-datalv02  253:1   0  6G  0 lvm
  │  └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5  253:5   0  6G  0 crypt /datalv02
  ├─datavg-datalv03  253:2   0  1G  0 lvm
  └─70abfc58-b0fd-441b-8b77-f86c9249af5e  253:6   0 1022M 0 crypt /datalv03
sde           8:64   0   5G  0 disk
  └─datavg-datalv04  253:3   0  7G  0 lvm
    └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c  253:7   0  7G  0 crypt /datalv04
sdf           8:80   0   5G  0 disk
  └─datavg-datalv02  253:1   0  6G  0 lvm
    └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5  253:5   0  6G  0 crypt /datalv02
  └─datavg-datalv04  253:3   0  7G  0 lvm
    └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c  253:7   0  7G  0 crypt /datalv04
sr0          11:0   1 1024M 0 rom
```

6. Attach the new disk to the VM by following the instructions in [Attach a data disk to a Linux VM](#).

7. Check the disk list, and notice the new disk.

```
ls -l /dev/disk/azure/scsi1/
```

```
[root@azurervm]# ls -l /dev/disk/azure/scsi1/
total 0
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun0 -> ../../.../sdd
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun1 -> ../../.../sde
lrwxrwxrwx. 1 root root 12 Sep 18 21:43 lun2 -> ../../.../sdf
lrwxrwxrwx. 1 root root 12 Sep 18 22:20 lun3 -> ../../.../sdg
```

```
lsblk
```

```
[root@azurervm]# lsblk
NAME          MAJ:MIN RM   SIZE RO TYPE MOUNTPOINT
fd0            2:0    1    4K  0 disk

  └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7   0   7G  0 crypt /datalv04
sdg            8:96   0    5G  0 disk 
sr0           11:0   1 1024M 0 rom
```

8. Create a new PV on top of the new data disk:

```
pvcreate /dev/newdisk
```

```
[root@azurervm]# pvcreate /dev/sdg
  Physical volume "/dev/sdg" successfully created.
[root@azurervm]#
```

This method uses the whole disk as a PV without a partition. Alternatively, you can use `fdisk` to create a partition and then use that partition for `pvcreate`.

9. Verify that the PV was added to the PV list:

```
pvs
```

```
[root@azurervm]# pvs
  PV        VG      Fmt  Attr PSize  PFree
  /dev/sdd  datavg lvm2 a-- <5.00g    0
  /dev/sde  datavg lvm2 a-- <5.00g    0
  /dev/sdf  datavg lvm2 a-- <5.00g    0
  /dev/sdg          lvm2 ---  5.00g  5.00g
```

10. Extend the VG by adding the new PV to it:

```
vgextend vgname /dev/newdisk
```

```
[root@azurervm]# vgextend datavg /dev/sdg
  Volume group "datavg" successfully extended
```

11. Check the new VG size:

```
vgs
```

```
[root@azurervm]# vgs
  VG     #PV #LV #SN Attr   VSize  VFree
  datavg    4    4    0 wz--n- 19.98g <5.00g
```

12. Use `lsblk` to identify the LV that needs to be resized:

```
lsblk
```

```
[root@azurervm]# lsblk
NAME                           MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0                            2:0    1   4K  0 disk
sda                            8:0    0  32G  0 disk
└─sda1                          8:1    0 500M  0 part  /boot
    └─sda2                        8:2    0 31.5G 0 part  /
sdb                            8:16   0  32G  0 disk
└─sdb1                          8:17   0 32G  0 part  /mnt/resource
sdc                            8:32   0  48M  0 disk
└─sdc1                          8:33   0  46M  0 part  /mnt/azure_bek_disk
sdd                            8:48   0   5G  0 disk
└─datavg-datalv01              253:0   0   1G  0 lvm
    └─55b4af2-a160-426b-9bd7-588af6c46e9b 253:4   0 1022M 0 crypt /datalv01
datavg-datalv02                253:1   0   6G  0 lvm
    └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5 253:5   0   6G  0 crypt /datalv02
datavg-datalv03                253:2   0   1G  0 lvm
    └─70abfc58-b0fd-441b-8b77-f86c9249af5e 253:6   0 1022M 0 crypt /datalv03
sde                            8:64   0   5G  0 disk
└─datavg-datalv04              253:3   0   7G  0 lvm
    └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7   0   7G  0 crypt /datalv04
sdf                            8:80   0   5G  0 disk
└─datavg-datalv02              253:1   0   6G  0 lvm
    └─78b259a1-956b-4f3a-8e6b-c05bf5040bc5 253:5   0   6G  0 crypt /datalv02
datavg-datalv04                253:3   0   7G  0 lvm
    └─e5dee6bc-0f22-4579-b6c0-6103a9aba86c 253:7   0   7G  0 crypt /datalv04
sdg                            8:96   0   5G  0 disk
```

13. Extend the LV size by using `-r` to increase the file system online:

```
lvextend -r -L +2G /dev/vgname/lvname
```

```
[root@azurervm]# lvextend -r -L +2G /dev/datavg/datalv01
  Size of logical volume datavg/datalv01 changed from 1.00 GiB (256 extents) to 3.00 GiB (768 extents).
Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/55b4af2-a160-426b-9bd7-588af6c46e9b is mounted on /datalv01; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/55b4af2-a160-426b-9bd7-588af6c46e9b is now 785920 blocks long.
```

14. Verify the new sizes of the LV and file system:

```
df -h /mountpoint
```

```
[root@azurervm]# df -h /datalv01
Filesystem      Size  Used Avail Use% Mounted on
/dev/mapper/55b4af2-a160-426b-9bd7-588af6c46e9b  3.0G  959M  1.9G  34% /datalv01
```

#### IMPORTANT

When Azure Data Encryption is used on traditional LVM configurations, the encrypted layer is created at the LV level, not at the disk level.

At this point, the encrypted layer is expanded to the new disk. The actual data disk has no encryption settings at the platform level, so its encryption status isn't updated.

These are some of the reasons why LVM-on-crypt is the recommended approach.

15. Check the encryption information from the portal:

LUN ⓘ	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (Mbps)	Encryption ⓘ
0	vmresizely_datadisk0	Standard HDD	5	500	60	SSE with PMK & ADE
1	vmresizely_datadisk1	Standard HDD	5	500	60	SSE with PMK & ADE
2	vmresizely_datadisk2	Standard HDD	5	500	60	SSE with PMK & ADE
3	vmresizely_datadisk3	Standard HDD	5	500	60	SSE with PMK

To update the encryption settings on the disk, add a new LV and enable the extension on the VM.

16. Add a new LV, create a file system on it, and add it to `/etc/fstab`.
17. Set the encryption extension again. This time you'll stamp the encryption settings on the new data disk at the platform level. Here's a CLI example:

```
az vm encryption enable -g ${RGNAME} --name ${VMNAME} --disk-encryption-keyvault "<your-unique-keyvault-name>"
```

18. Check the encryption information from the portal:

LUN ⓘ	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (Mbps)	Encryption ⓘ
0	vmresizely_datadisk0	Standard HDD	5	500	60	SSE with PMK & ADE
1	vmresizely_datadisk1	Standard HDD	5	500	60	SSE with PMK & ADE
2	vmresizely_datadisk2	Standard HDD	5	500	60	SSE with PMK & ADE
3	vmresizely_datadisk3	Standard HDD	5	500	60	SSE with PMK & ADE

After the encryption settings are updated, you can delete the new LV. Also delete the entry from the `/etc/fstab` and `/etc/crypttab` that you created.

```
[root@azurevm]# cat /etc/fstab
#
# /etc/fstab
# Created by anaconda on Thu Jun 20 18:47:49 2019
#
# Accessible filesystems, by reference, are maintained under '/dev/disk'
# See man pages fstab(5), findfs(8), mount(8) and/or blkid(8) for more info
#
UUID=52e42afc-2da4-4391-bbc0-92f2alb45c62 /          xfs      defaults        0 0
UUID=a8fbef35-f5e4-4515-bb7e-c408c118d4c0 /boot       xfs      defaults        0 0
/dev/mapper/55b4af2-a160-426b-9bd7-588af6c46e9b /data1v01 ext4 defaults,nofail 0 0
/dev/mapper/78b259a1-956b-4f3a-8e6b-c05bf5040bc5 /data1v02 ext4 defaults,nofail 0 0

/dev/mapper/9157c7b5-8bad-4a84-84e2-0ca2bfffce4 /data1v05 ext4 defaults,nofail 0 0
LABEL=BERV040VOLUME /mnt/azure_bek_disk auto defaults,discard,nofail 0 0
[root@azurevm]#
[root@azurevm]#
[root@azurevm]# cat /etc/crypttab
55b4af2-a160-426b-9bd7-588af6c46e9b /dev/mapper/datavg-data1v01 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail
78b259a1-956b-4f3a-8e6b-c05bf5040bc5 /dev/mapper/datavg-data1v02 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail
70abfc58-b0fd-441b-8b77-f86c9249af5e /dev/mapper/datavg-data1v03 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_0 luks,nofail
e5dee6bc-0f22-4579-b6c0-6103a9aba86c /dev/mapper/datavg-data1v04 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_2 luks,nofail
9157c7b5-8bad-4a84-84e2-0ca2bfffce4 /dev/mapper/datavg-data1v05 /mnt/azure_bek_disk/LinuxPassPhraseFileName_1_3 luks,nofail
[root@azurevm]#
```

Follow these steps to finish cleaning up:

1. Unmount the LV:

```
umount /mountpoint
```

2. Close the encrypted layer of the volume:

```
cryptsetup luksClose /dev/vgname/lvname
```

3. Delete the LV:

```
lvremove /dev/vgname/lvname
```

### Extend a traditional LVM volume by resizing an existing PV

In some scenarios, your limitations might require you to resize an existing disk. Here's how:

1. Identify your encrypted disks:

```
ls -l /dev/disk/azure/scsi1/
```

```
[root@vmresizelv ~]# ls -l /dev/disk/azure/scsi1/
total 0
lrwxrwxrwx. 1 root root 12 Sep 19 00:21 lun0 -> ../../../../../sdd
lrwxrwxrwx. 1 root root 12 Sep 19 00:21 lun1 -> ../../../../../sde
lrwxrwxrwx. 1 root root 12 Sep 19 00:21 lun2 -> ../../../../../sdf
lrwxrwxrwx. 1 root root 12 Sep 19 00:21 lun3 -> ../../../../../sdg
```

```
lsblk -fs
```

```
[root@vmresizelv ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0           2:0    1   4K  0 disk
sda           8:0    0 32G  0 disk
└─sda1        8:1    0 500M 0 part  /boot
               8:2    0 31.5G 0 part  /
sdb           8:16   0 32G  0 disk
└─sdb1        8:17   0 32G  0 part  /mnt/resource
sdc           8:32   0 48M  0 disk
└─sdc1        8:33   0 46M  0 part  /mnt/azure_bek_disk
sdd           8:48   0 5G   0 disk
└─datavg-datalv01 253:0  0 20G  0 lvm
  └─bb92534b-47a8-40da-adff-c4e9c0f643f0 253:1  0 20G  0 [crypt] /datalv01
sde           8:64   0 5G   0 disk
└─datavg-datalv01 253:0  0 20G  0 lvm
  └─bb92534b-47a8-40da-adff-c4e9c0f643f0 253:1  0 20G  0 [crypt] /datalv01
sdf           8:80   0 5G   0 disk
└─datavg-datalv01 253:0  0 20G  0 lvm
  └─bb92534b-47a8-40da-adff-c4e9c0f643f0 253:1  0 20G  0 [crypt] /datalv01
sdg           8:96   0 5G   0 disk
└─datavg-datalv01 253:0  0 20G  0 lvm
  └─bb92534b-47a8-40da-adff-c4e9c0f643f0 253:1  0 20G  0 [crypt] /datalv01
sr0          11:0   1 1024M 0 rom
```

2. Check the PV information:

```
pvs
```

```
[root@vmresizelv ~]# pvs
PV          VG      Fmt  Attr PSize  PFree
/dev/sdd    datavg lvm2 a--  <5.00g  0
/dev/sde    datavg lvm2 a--  <5.00g  0
/dev/sdf    datavg lvm2 a--  <5.00g  0
/dev/sdg    datavg lvm2 a--  <5.00g  0
```

The results in the image show that all of the space on all of the PVs is currently used.

3. Check the VG information:

```
vgs
vgdisplay -v vgname
```

```

[root@vmresizelv ~]# vgs
  VG      #PV #LV #SN Attr   VSize  VFree
  datavg    4   1   0 wz--n- 19.98g  0
[root@vmresizelv ~]# vgdisplay datavg
--- Volume group ---
VG Name           datavg
System ID
Format          lvm2
Metadata Areas   4
Metadata Sequence No 16
VG Access        read/write
VG Status        resizable
MAX LV          0
Cur LV          1
Open LV          1
Max PV          0
Cur PV          4
Act PV          4
VG Size         19.98 GiB
PE Size         4.00 MiB
Total PE        5116
Alloc PE / Size 5116 / 19.98 GiB
Free PE / Size  0 / 0
VG UUID         jvc1Kz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY

```

4. Check the disk sizes. You can use `fdisk` or `lsblk` to list the drive sizes.

```

for disk in `ls -l /dev/disk/azure/scsi1/* | awk -F/ '{print $NF}'` ; do echo "fdisk -l /dev/${disk}"
| grep ^Disk "; done | bash

lsblk -o "NAME,SIZE"

```

Disk	<code>/dev/sdd</code> :	5368 MB	, 5368709120 bytes, 10485760 sectors
Disk	<code>/dev/sde</code> :	5368 MB	, 5368709120 bytes, 10485760 sectors
Disk	<code>/dev/sdf</code> :	5368 MB	, 5368709120 bytes, 10485760 sectors
Disk	<code>/dev/sdg</code> :	5368 MB	, 5368709120 bytes, 10485760 sectors

Here we identified which PVs are associated with which LVs by using `lsblk -fs`. You can identify the associations by running `lvdisplay`.

```

lvdisplay --maps VG/LV
lvdisplay --maps datavg/data1v1

```

```
[root@vmresizelv ~]# lvdisplay --maps datavg/datalv01
--- Logical volume ---
LV Path                  /dev/datavg/datalv01
LV Name                 datalv01
VG Name                 datavg
LV UUID                 oiTd6A-PTqY-AbzV-Kd0J-0891-dlMP-jBUJUC
LV Write Access          read/write
LV Creation host, time  vmresizelv, 2020-09-19 00:21:25 +0000
LV Status                available
# open                   1
LV Size                  19.98 GiB
Current LE               5116
Segments                 4
Allocation               inherit
Read ahead sectors       auto
- currently set to      8192
Block device             253:0

--- Segments ---
Logical extents 0 to 1278:
  Type        linear
  Physical volume /dev/sdd
  Physical extents 0 to 1278

Logical extents 1279 to 2557:
  Type        linear
  Physical volume /dev/sde
  Physical extents 0 to 1278

Logical extents 2558 to 3836:
  Type        linear
  Physical volume /dev/sdf
  Physical extents 0 to 1278

Logical extents 3837 to 5115:
  Type        linear
  Physical volume /dev/sdg
  Physical extents 0 to 1278
```

In this case, all four data drives are part of the same VG and a single LV. Your configuration might differ.

#### 5. Check the current file system utilization:

```
df -h /datalvm*
```

Filesystem	Size	Used	Avail	Use%	Mounted on
/dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0	20G	20G	0	100%	/datalv01

#### 6. Resize the data disks by following the instructions in [Expand an Azure managed disk](#). You can use the portal, the CLI, or PowerShell.

##### **IMPORTANT**

You can't resize virtual disks while the VM is running. Deallocate your VM for this step.

#### 7. Start the VM and check the new sizes by using `fdisk`.

```
for disk in `ls -l /dev/disk/azure/scsi1/* | awk -F/ '{print $NF}'` ; do echo "fdisk -l /dev/${disk}" | grep ^Disk ; done | bash
```

```
lsblk -o "NAME,SIZE"
```

```
Disk /dev/sdd: 21.5 GB, 21474836480 bytes, 41943040 sectors  
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors  
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors  
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
```

In this case, `/dev/sdd` was resized from 5 G to 20 G.

8. Check the current PV size:

```
pvdisplay /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvdisplay /dev/sdd  
--- Physical volume ---  
PV Name /dev/sdd  
VG Name datavg  
PV Size 5.00 GiB / not usable 4.00 MiB  
Allocatable yes (but full)  
PE Size 4.00 MiB  
Total PE 1279  
Free PE 0  
Allocated PE 1279  
PV UUID gy2E19-BHhh-1Hy1-MGJg-P6tu-iSeh-vYpO8U
```

Even though the disk was resized, the PV still has the previous size.

9. Resize the PV:

```
pvresize /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvresize /dev/sdd  
Physical volume "/dev/sdd" changed  
1 physical volume(s) resized / 0 physical volume(s) not resized
```

10. Check the PV size:

```
pvdisplay /dev/resizeddisk
```

```
[root@vmresizelv ~]# pvdisplay /dev/sdd  
--- Physical volume ---  
PV Name /dev/sdd  
VG Name datavg  
PV Size <20.00 GiB / not usable 3.00 MiB  
Allocatable yes  
PE Size 4.00 MiB  
Total PE 5119  
Free PE 3840  
Allocated PE 1279  
PV UUID gy2E19-BHhh-1Hy1-MGJg-P6tu-iSeh-vYpO8U
```

Apply the same procedure for all of the disks that you want to resize.

11. Check the VG information.

```
vgdisplay vgname
```

```
[root@vmresizelv ~]# vgdisplay datavg
--- Volume group ---
VG Name          datavg
System ID        lvm2
Format           lvm2
Metadata Areas   4
Metadata Sequence No 17
VG Access        read/write
VG Status        resizable
MAX LV           0
Cur LV           1
Open LV          1
Max PV           0
Cur PV           4
Act PV           4
VG Size          34.98 GiB
PE Size          4.00 MiB
Total PE         8956
Alloc PE / Size  5116 / 19.98 GiB
Free  PE / Size  3840 / 15.00 GiB
VG UUID          jvc1Kz-FXLd-dNjC-14q7-k85I-Pp8z-bMqFLY
```

The VG now has enough space to be allocated to the LVs.

## 12. Resize the LV:

```
lvresize -r -L +5G vgname/lvname
lvresize -r -l +100%FREE /dev/datavg/datalv01
```

```
[root@vmresizelv ~]# lvresize -r -L +5G /dev/datavg/datalv01
Size of logical volume datavg/datalv01 changed from 19.98 GiB (5116 extents) to 24.98 GiB (6396 extents).
Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0 is mounted on /datalv01; on-line resizing required
old_desc_blocks = 3, new_desc_blocks = 4
The filesystem on /dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0 is now 6548992 blocks long.
```

## 13. Check the size of the file system:

```
df -h /datalv01
```

```
[root@vmresizelv ~]# df -h /datalv01/
Filesystem              Size  Used Avail Use% Mounted on
/dev/mapper/bb92534b-47a8-40da-adff-c4e9c0f643f0    35G   20G   14G  60% /datalv01
```

### Extend an LVM-on-crypt volume by adding a new PV

You can also extend an LVM-on-crypt volume by adding a new PV. This method closely follows the steps in [Configure LVM and RAID on encrypted devices](#). See the sections that explain how to add a new disk and set it up in an LVM-on-crypt configuration.

You can use this method to add space to an existing LV. Or you can create new VGs or LVs.

## 1. Verify the current size of your VG:

```
vgdisplay vgname
```

```
[root@vmresizelv ~]# vgdisplay datavg
--- Volume group ---
VG Name           datavg
System ID
Format           lvm2
Metadata Areas   3
Metadata Sequence No 9
VG Access        read/write
VG Status        resizable
MAX LV           0
Cur LV           4
Open LV           4
Max PV           0
Cur PV           3
Act PV           3
VG Size          <14.99 GiB
PE Size          4.00 MiB
Total PE         3837
Alloc PE / Size  3837 / <14.99 GiB
Free  PE / Size  0 / 0
VG UUID          4vKd5r-Q8wn-OVwP-vBiX-c9TH-xWzO-SdUVVM
```

2. Verify the size of the file system and LV that you want to expand:

```
lvdisplay /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvdisplay /dev/datavg/datalv01
--- Logical volume ---
LV Path           /dev/datavg/datalv01
LV Name           datalv01
VG Name           datavg
LV UUID           K8zZjy-brpp-Lx74-atfR-lTVu-h26Q-urRi7z
LV Write Access   read/write
LV Creation host, time vmresizelv, 2020-09-21 14:44:27 +0000
LV Status         available
# open            1
LV Size           1.00 GiB
Current LE        256
Segments          1
Allocation        inherit
Read ahead sectors auto
- currently set to 8192
Block device      253:4
```

```
df -h mountpoint
```

```
[root@vmresizelv ~]# df -h /datalv01
Filesystem           Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv01  976M  960M    0 100% /datalv01
```

3. Add a new data disk to the VM and identify it.

Before you add the new disk, check the disks:

```
fdisk -l | egrep '^Disk /"
```

```
[root@vmresizelv ~]# fdisk -l | egrep '^Disk /"
Disk /dev/sdc: 50 MB, 50331648 bytes, 98304 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdb: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/sda: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/mapper/resourcecrypt: 34.4 GB, 34356527104 bytes, 67102592 sectors
Disk /dev/mapper/e19fcfd77-e974-4e5c-a874-e78e4b6d2f48: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/49de5df0-1c65-48bf-809c-588805eda921: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/datavg-datalv01: 1073 MB, 1073741824 bytes, 2097152 sectors
Disk /dev/mapper/datavg-datalv02: 6442 MB, 6442450944 bytes, 12582912 sectors
Disk /dev/mapper/datavg-datalv03: 4294 MB, 4294967296 bytes, 8388608 sectors
Disk /dev/mapper/datavg-datalv04: 4282 MB, 4282384384 bytes, 8364032 sectors
```

Here's another way to check the disks before you add the new disk:

```
lsblk
```

```
[root@vmresizelv ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
fd0            2:0    1   4K  0 disk
sda            8:0    0 32G  0 disk
└─sda1         8:1    0 500M 0 part  /boot
  └─sda2         8:2    0 31.5G 0 part  /
sdb            8:16   0 32G  0 disk
└─sdb1         8:17   0 32G  0 part
  └─resourcecrypt  253:0  0 32G  0 crypt /mnt/resource
sdc            8:32   0 48M  0 disk
└─sdc1         8:33   0 47M  0 part  /mnt/azure_bek_disk
└─sde          8:64   0 5G  0 disk
  └─e19fcfd77-e974-4e5c-a874-e78e4b6d2f48 253:1  0 5G  0 crypt
    ├─datavg-datalv01  253:4  0 1G  0 lvm   /datalv01
    ├─datavg-datalv02  253:5  0 6G  0 lvm   /datalv02
    ├─datavg-datalv03  253:6  0 4G  0 lvm   /datalv03
    └─datavg-datalv04  253:7  0 3G  0 lvm   /datalv04
└─sdf          8:80   0 5G  0 disk
  └─49de5df0-1c65-48bf-809c-588805eda921 253:2  0 5G  0 crypt
    ├─datavg-datalv02  253:5  0 6G  0 lvm   /datalv02
    └─datavg-datalv04  253:7  0 3G  0 lvm   /datalv04
└─sdg          8:96   0 5G  0 disk
  └─8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 253:3  0 5G  0 crypt
    ├─datavg-datalv03  253:6  0 4G  0 lvm   /datalv03
    └─datavg-datalv04  253:7  0 3G  0 lvm   /datalv04
```

To add the new disk, you can use PowerShell, the Azure CLI, or the Azure portal. For more information, see [Attach a data disk to a Linux VM](#).

The kernel name scheme applies to the newly added device. A new drive is normally assigned the next available letter. In this case, the added disk is `sdd`.

#### 4. Check the disks to make sure the new disk has been added:

```
fdisk -l | egrep '^Disk /"
```

```
[root@vmresizelv ~]# fdisk -l | egrep '^Disk /"
Disk /dev/sdc: 50 MB, 50331648 bytes, 98304 sectors
Disk /dev/sdf: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdg: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sde: 5368 MB, 5368709120 bytes, 10485760 sectors
Disk /dev/sdb: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/sda: 34.4 GB, 34359738368 bytes, 67108864 sectors
Disk /dev/mapper/resourcecrypt: 34.4 GB, 34356527104 bytes, 67102592 sectors
Disk /dev/mapper/e19fcfd77-e974-4e5c-a874-e78e4b6d2f48: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/49de5df0-1c65-48bf-809c-588805eda921: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57: 5366 MB, 5366611968 bytes, 10481664 sectors
Disk /dev/mapper/datavg-datalv01: 1073 MB, 1073741824 bytes, 2097152 sectors
Disk /dev/mapper/datavg-datalv02: 6442 MB, 6442450944 bytes, 12582912 sectors
Disk /dev/mapper/datavg-datalv03: 4294 MB, 4294967296 bytes, 8388608 sectors
Disk /dev/mapper/datavg-datalv04: 4282 MB, 4282384384 bytes, 8364032 sectors
Disk /dev/sdd: 5368 MB, 5368709120 bytes, 10485760 sectors
```

```
lsblk
```

```
[root@vmresizelv ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
fd0           2:0    1   4K  0 disk 
sda           8:0    0  32G  0 disk 
└─sda1        8:1    0 500M  0 part /boot
└─sda2        8:2    0 31.5G 0 part /
sdb           8:16   0   32G  0 disk 
└─sdb1        8:17   0   32G  0 part 
  └─resourcecrypt 253:0   0   32G  0 crypt /mnt/resource
sdc           8:32   0   48M  0 disk 
└─sdc1        8:33   0   47M  0 part /mnt/azure_bek_disk
└─sdd         8:48   0     5G  0 disk 
  └─sde        8:64   0     5G  0 disk 
    └─e19fc77-e974-4e5c-a874-e78e4b6d2f48 253:1   0     5G  0 crypt
      ├─datavg-datalv01 253:4   0     1G  0 lvm   /datalv01
      ├─datavg-datalv02 253:5   0     6G  0 lvm   /datalv02
      ├─datavg-datalv03 253:6   0     4G  0 lvm   /datalv03
      └─datavg-datalv04 253:7   0     4G  0 lvm   /datalv04
sdf           8:80   0     5G  0 disk 
└─49de5df0-1c65-48bf-809c-588805eda921 253:2   0     5G  0 crypt
  ├─datavg-datalv02 253:5   0     6G  0 lvm   /datalv02
  └─datavg-datalv04 253:7   0     4G  0 lvm   /datalv04
sdg           8:96   0     5G  0 disk 
└─8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 253:3   0     5G  0 crypt
  ├─datavg-datalv03 253:6   0     4G  0 lvm   /datalv03
  └─datavg-datalv04 253:7   0     4G  0 lvm   /datalv04
```

5. Create a file system on top of the recently added disk. Match the disk to the linked devices on `/dev/disk/azure/scsi1/`.

```
ls -la /dev/disk/azure/scsi1/
```

```
[root@vmresizelv ~]# ls -la /dev/disk/azure/scsi1/*
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun1 -> ../../../../../../sde
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun2 -> ../../../../../../sdf
lrwxrwxrwx. 1 root root 12 Sep 21 14:32 /dev/disk/azure/scsi1/lun3 -> ../../../../../../sdg
lrwxrwxrwx. 1 root root 12 Sep 21 16:39 /dev/disk/azure/scsi1/lun4 -> ../../../../../../sdd
```

```
mkfs.ext4 /dev/disk/azure/scsi1/${disk}
```

```
[root@vmresizelv ~]# mkfs.ext4 /dev/disk/azure/scsi1/lun4
mke2fs 1.42.9 (28-Dec-2013)
/dev/disk/azure/scsi1/lun4 is entire device, not just one partition!
Proceed anyway? (y,n) y
Discarding device blocks: done
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
Stride=0 blocks, Stripe width=0 blocks
327680 inodes, 1310720 blocks
65536 blocks (5.00%) reserved for the super user
First data block=0
Maximum filesystem blocks=1342177280
40 block groups
32768 blocks per group, 32768 fragments per group
8192 inodes per group
Superblock backups stored on blocks:
      32768, 98304, 163840, 229376, 294912, 819200, 884736

Allocating group tables: done
Writing inode tables: done
Creating journal (32768 blocks): done
Writing superblocks and filesystem accounting information: done
```

6. Create a temporary mount point for the new added disk:

```
newmount=/data4  
mkdir ${newmount}
```

7. Add the recently created file system to `/etc/fstab`.

```
blkid /dev/disk/azure/scsi1/lun4| awk -F\" '{print "UUID=\"$2\" \"$newmount\" \"$4\" defaults,nofail 0  
0\""}' >> /etc/fstab
```

8. Mount the newly created file system:

```
mount -a
```

9. Verify that the new file system is mounted:

```
df -h
```

```
[root@vmresizelv ~]# df -h  
Filesystem           Size  Used Avail Use% Mounted on  
/dev/sda2            32G  2.7G  29G  9% /  
devtmpfs             7.9G   0    7.9G  0% /dev  
tmpfs               7.9G   0    7.9G  0% /dev/shm  
tmpfs               7.9G  18M  7.9G  1% /run  
tmpfs               7.9G   0    7.9G  0% /sys/fs/cgroup  
/dev/sda1            497M 100M  397M 21% /boot

└─49de5df0-1c65-48bf-809c-588805eda921 253:2   0   5G  0 crypt  
    ├─datavg-datalv02   253:5   0   6G  0 lvm  /datalv02  
    └─datavg-datalv04   253:7   0   4G  0 lvm  /datalv04  
sdg        8:96    0   5G  0 disk  
└─8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 253:3   0   5G  0 crypt  
    ├─datavg-datalv03   253:6   0   4G  0 lvm  /datalv03  
    └─datavg-datalv04   253:7   0   4G  0 lvm  /datalv04
```

10. Restart the encryption that you previously started for data drives.

**TIP**

For LVM-on-crypt, we recommend that you use `EncryptFormatAll`. Otherwise, you might see a double encryption while you set additional disks.

For more information, see [Configure LVM and RAID on encrypted devices](#).

Here's an example:

```
az vm encryption enable \
--resource-group ${RGNAME} \
--name ${VMNAME} \
--disk-encryption-keyvault ${KEYVAULTNAME} \
--key-encryption-key ${KEYNAME} \
--key-encryption-keyvault ${KEYVAULTNAME} \
--volume-type "DATA" \
--encrypt-format-all \
-o table
```

When the encryption finishes, you see a crypt layer on the newly added disk:

```
lsblk
```

```
[root@vmresizelv ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
fd0           2:0     1   4K  0 disk 
sda           8:0     0   32G  0 disk 
└─sda1        8:1     0   500M 0 part /boot
      └─sda2        8:2     0   31.5G 0 part /
sdb           8:16    0   32G  0 disk 
└─sdb1        8:17    0   32G  0 part 
      └─resourcecrypt 253:0    0   32G  0 crypt /mnt/resource
sdc           8:32    0   48M  0 disk 
└─sdc1        8:33    0   47M  0 part /mnt/azure_bek_disk
sdd           8:48    0   5G   0 disk 
└─8673c519-c5e4-44af-9b0f-fe286c2375b6 253:8    0   5G   0 crypt /data4
sde           8:64    0   5G   0 disk 
└─e19fc77-e974-4e5c-a874-e78e4b6d2f48 253:1    0   5G   0 crypt

    └─datavg-datalv04 253:7    0   4G   0 lvm   /datalv04
```

11. Unmount the encrypted layer of the new disk:

```
umount ${newmount}
```

12. Check the current PV information:

```
pvs
```

```
[root@vmresizelv ~]# pvs
PV              VG      Fmt  Attr PSize  PFree
/dev/mapper/49de5df0-1c65-48bf-809c-588805eda921 datavg lvm2 a-- <5.00g  0
/dev/mapper/8a33198f-fa7e-491f-a9c6-e9d0a1d25d57 datavg lvm2 a-- <5.00g  0
/dev/mapper/e19fc77-e974-4e5c-a874-e78e4b6d2f48 datavg lvm2 a-- <5.00g  0
```

13. Create a PV on top of the encrypted layer of the disk. Take the device name from the previous `lsblk` command. Add a `/dev/` mapper in front of the device name to create the PV:

```
pvcreate /dev/mapper/mapperdevicename
```

```
[root@vmresizelv ~]# pvcreate /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6
WARNING: ext4 signature detected on /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6 at offset 1080. Wipe it? [y/n]: y
Wiping ext4 signature on /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6.
Physical volume "/dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6" successfully created.
```

You see a warning about wiping the current `ext4 fs` signature. This warning is expected. Answer this question with `y`.

14. Verify that the new PV was added to the LVM configuration:

```
pvs
```

```
[root@vmresizelv ~]# pvs
PV              VG      Fmt  Attr PSize  PFree
/dev/mapper/49de5df0-1c65-48bf-809c-588805eda921  datavg lvm2 a-- <5.00g    0
[redacted]
[redacted]
[redacted]
```

15. Add the new PV to the VG that you need to increase.

```
vgextend vgname /dev/mapper/nameofthenewpv
```

```
[root@vmresizelv ~]# vgextend datavg /dev/mapper/8673c519-c5e4-44af-9b0f-fe286c2375b6
Volume group "datavg" successfully extended
```

16. Verify the new size and free space of the VG:

```
vgdisplay vgname
```

```
[root@vmresizelv ~]# vgdisplay datavg
--- Volume group ---
VG Name          datavg
System ID
Format          lvm2
Metadata Areas   4
Metadata Sequence No 10
VG Access        read/write
VG Status        resizable
MAX LV
Cur LV
Open LV
Max PV
Cur PV
Act PV
VG Size         19.98 GiB
PE Size          4.00 MiB
Total PE         5116
Alloc PE / Size  3837 / <14.99 GiB
Free PE / Size   1279 / <5.00 GiB
VG UUID          4vKd5r-Q8wn-OVwP-vBiX-c9TH-xWzO-SdUVVM
```

Note the increase of the `Total PE` count and the `Free PE / Size`.

17. Increase the size of the LV and the file system. Use the `-r` option on `lvextend`. In this example, we're adding the total available space in the VG to the given LV.

```
lvextend -r -l +100%FREE /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvextend -r -l +100%FREE datavg/datalv01
  Size of logical volume datavg/datalv01 changed from 1.00 GiB (256 extents) to <6.00 GiB (1535 extents).
  Logical volume datavg/datalv01 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/datavg-datalv01 is mounted on /datalv01; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/datavg-datalv01 is now 1571840 blocks long.
```

Follow the next steps to verify your changes.

1. Verify the size of the LV:

```
lvdisplay /dev/vgname/lvname
```

```
[root@vmresizelv ~]# lvdisplay /dev/datavg/datalv01
--- Logical volume ---
LV Path          /dev/datavg/datalv01
LV Name          datalv01
VG Name          datavg
LV UUID          K8zZjy-brpp-Lx74-atfR-lTVu-h26Q-urRi7z
LV Write Access  read/write
LV Creation host, time  vmresizelv, 2020-09-21 14:44:27 +0000
LV Status        available
# open           1
LV Size          <6.00 GiB
Current LE       1535
Segments         2
Allocation       inherit
Read ahead sectors auto
- currently set to 8192
Block device     253:4
```

2. Verify the new size of the file system:

```
df -h mountpoint
```

```
[root@vmresizelv ~]# df -h /datalv01/
Filesystem          Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv01  5.9G  962M  4.7G 17% /datalv01
```

3. Verify that the LVM layer is on top of the encrypted layer:

```
lsblk
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT

└ datavg-datalv04	253:7	0	4G	0	lvm	/datalv04

If you use `lsblk` without options, then you see the mount points multiple times. The command sorts by device and LVs.

You might want to use `lsblk -fs`. In this command, `-fs` reverses the sort order so that the mount points are shown once. The disks are shown multiple times.

```
lsblk -fs
```

NAME	FSTYPE	LABEL	UUID	MOUNTPOINT
fd0				
sda	xfs		a8fbef35-ff5e-4515-bb7e-c408c118d4c0	/boot

#### Extend an LVM on a crypt volume by resizing an existing PV

- Identify your encrypted disks:

```
lsblk
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT
fd0	2:0	1	4K	0	disk	
sda	8:0	0	32G	0	disk	
└─sda1	8:1	0	500M	0	part	/boot
└─sda2	8:2	0	31.5G	0	part	/
sdb	8:16	0	32G	0	disk	
└─sdb1	8:17	0	32G	0	part	
└─resourcecrypt	253:0	0	32G	0	crypt	/mnt/resource
sdc	8:32	0	48M	0	disk	
└─sdc1	8:33	0	47M	0	part	/mnt/azure_bek_disk
sdd	8:48	0	2G	0	disk	
└─2c7d881a-6f89-4ef5-992a-944bdb26f4d8	253:1	0	2G	0	crypt	
└─datavg-datalv1	253:3	0	1.5G	0	lvm	/datalvml
└─datavg-datalv2	253:4	0	2.5G	0	lvm	/datalvml2
sde	8:64	0	2G	0	disk	
└─ba122ca3-1865-43c1-ba96-6d88e3ebcce1	253:2	0	2G	0	crypt	
└─datavg-datalv2	253:4	0	2.5G	0	lvm	/datalvml2

```
lsblk -s
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE	MOUNTPOINT
fd0	2:0	1	4K	0	disk	
sda	8:1	0	500M	0	part	/boot
└─sda1	8:0	0	32G	0	disk	
└─sda2	8:2	0	31.5G	0	part	/
sdb	8:0	0	32G	0	disk	
└─sdb1	8:17	0	32G	0	part	
└─resourcecrypt	253:0	0	32G	0	crypt	/mnt/resource
└─sdb1	8:16	0	32G	0	disk	
└─datavg-datalv1	253:3	0	1.5G	0	lvm	/datalvml
└─2c7d881a-6f89-4ef5-992a-944bdb26f4d8	253:1	0	2G	0	crypt	
└─sdd	8:48	0	2G	0	disk	
└─datavg-datalv2	253:4	0	2.5G	0	lvm	/datalvml2
└─2c7d881a-6f89-4ef5-992a-944bdb26f4d8	253:1	0	2G	0	crypt	
└─sdd	8:48	0	2G	0	disk	
└─ba122ca3-1865-43c1-ba96-6d88e3ebcce1	253:2	0	2G	0	crypt	
└─sde	8:64	0	2G	0	disk	

2. Check your PV information:

```
pvs
```

PV	VG	Fmt	Attr	PSize	PFree
/dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8	datavg	lvm2	a--	<2.00g	0
/dev/mapper/ba122ca3-1865-43c1-ba96-6d88e3ebcce1	datavg	lvm2	a--	<2.00g	0

3. Check your VG information:

```
vgs
```

```
[root@vm ]# vgdisplay datavg
--- Volume group ---
VG Name           datavg
System ID
Format           lvm2
Metadata Areas   2
Metadata Sequence No 3
VG Access        read/write
VG Status         resizable
MAX LV            0
Cur LV            2
Open LV           2
Max PV            0
Cur PV            2
Act PV            2
VG Size          3.99 GiB
PE Size          4.00 MiB
Total PE          1022
Alloc PE / Size  1022 / 3.99 GiB
Free PE / Size   0 / 0
VG UUID          24nwHl-raFN-igfO-0wk9-WTvc-sSTO-cXVYUX
```

4. Check your LV information:

```
lvs
```

```
[root@vm ]# lvs
LV      VG      Attr      LSize Pool Origin Data%  Meta%  Move Log Cpy%Sync Convert
datalv1  datavg -wi-ao---- 1.50g
datalv2  datavg -wi-ao---- 2.49g
```

5. Check the file system utilization:

```
df -h /mountpoint(s)
```

```
[root@vm ]# df -h /datalvm*
Filesystem              Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv1 1.5G  1.5G    0 100% /datalvml
/dev/mapper/datavg-datalv2 2.4G  2.4G    0 100% /datalvm2
```

6. Check the sizes of your disks:

```
fdisk
fdisk -l | egrep ^"Disk /"
lsblk
```

```
[root@vm ]# fdisk -l /dev/sdd
Disk /dev/sdd: 2147 MB, 2147483648 bytes, 4194304 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes

[root@vm ]# fdisk -l /dev/sde
Disk /dev/sde: 2147 MB, 2147483648 bytes, 4194304 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
```

7. Resize the data disk. You can use the portal, CLI, or PowerShell. For more information, see the disk-resize section in [Expand virtual hard disks on a Linux VM](#).

**IMPORTANT**

You can't resize virtual disks while the VM is running. Deallocate your VM for this step.

8. Check your disks sizes:

```
fdisk
fdisk -l | egrep '^Disk /'
lsblk
```

```
[root@vmresizelvm ~]# fdisk -l /dev/sdd
Disk /dev/sdd: 4294 MB, 4294967296 bytes, 8388608 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes

[root@vmresizelvm ~]# fdisk -l /dev/sde
Disk /dev/sde: 4294 MB, 4294967296 bytes, 8388608 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 4096 bytes
I/O size (minimum/optimal): 4096 bytes / 4096 bytes
```

In this case, both disks were resized from 2 GB to 4 GB. But the size of the file system, LV, and PV remain the same.

9. Check the current PV size. Remember that on LVM-on-crypt, the PV is the `/dev/mapper/` device, not the `/dev/sd*` device.

```
pvdisplay /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# pvdisplay /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
--- Physical volume ---
PV Name           /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
VG Name           datavg
PV Size          <2.00 GiB / not usable 2.00 MiB
Allocatable       yes (but full)
PE Size          4.00 MiB
Total PE         511
Free PE          0
Allocated PE     511
PV UUID          30iBnM-fZgv-1sXe-FJo2-052x-wjxu-8Fb6Mw
```

10. Resize the PV:

```
pvresize /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# [pvresize /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
Physical volume "/dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8" changed
[1 physical volume(s) resized] / 0 physical volume(s) not resized
```

11. Check the new PV size:

```
pvdisplay /dev/mapper/devicemappername
```

```
[root@vmresizelvm ~]# pvdisplay /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
--- Physical volume ---
PV Name           /dev/mapper/2c7d881a-6f89-4ef5-992a-944bdb26f4d8
VG Name           datavg
PV Size          <4.00 GiB / not usable 0
Allocatable       yes
PE Size          4.00 MiB
Total PE         1023
Free PE          512
Allocated PE     511
PV UUID          30iBnM-fZgv-1sXe-FJo2-052x-wjxu-8Fb6Mw
```

12. Resize the encrypted layer on the PV:

```
cryptsetup resize /dev/mapper/devicemappername
```

Apply the same procedure for all of the disks that you want to resize.

13. Check your VG information:

```
vgdisplay vgname
```

```
[root@vmresizelvm ~]# vgdisplay datavg
--- Volume group ---
VG Name           datavg
System ID        lvm2
Format           lvm2
Metadata Areas   2
Metadata Sequence No 4
VG Access        read/write
VG Status         resizable
MAX LV            0
Cur LV            2
Open LV            2
Max PV            0
Cur PV            2
Act PV            2
VG Size          5.99 GiB
PE Size          4.00 MiB
Total PE          1534
Alloc PE / Size  1022 / 3.99 GiB
Free  PE / Size  512 / 2.00 GiB
VG UUID          24nwHl-raFN-igfO-0wk9-WTvc-sSTO-cXVYUX
```

The VG now has enough space to be allocated to the LVs.

#### 14. Check the LV information:

```
lvdisplay vgname/lvname
```

```
[root@vmresizelvm ~]# lvdisplay datavg/datalv2
--- Logical volume ---
LV Path           /dev/datavg/datalv2
LV Name           datalv2
VG Name           datavg
LV UUID           iK3HYF-wYPX-XAs0-0WGB-Zite-DlaT-dFae2o
LV Write Access   read/write
LV Creation host, time  vmresizelvm, 2020-05-18 18:33:54 +0000
LV Status         available
# open            1
LV Size           2.49 GiB
Current LE        638
Segments          2
Allocation        inherit
Read ahead sectors auto
- currently set to 8192
Block device      253:3
```

#### 15. Check the file system utilization:

```
df -h /mountpoint
```

```
[root@vmresizelvm ~]# df -h /datalvm2/
Filesystem          Size  Used Avail Use% Mounted on
/dev/mapper/datavg-datalv2  2.4G  2.4G     0 100% /datalvm2
```

#### 16. Resize the LV:

```
lvresize -r -L +2G /dev/vgname/lvname
```

```
[root@vmresizelvm]# lvresize -r -L +2G /dev/datavg/datalv2
  Size of logical volume datavg/datalv2 changed from 2.50 GiB (640 extents) to 4.50 GiB (1152 extents).
  Logical volume datavg/datalv2 successfully resized.
resize2fs 1.42.9 (28-Dec-2013)
Filesystem at /dev/mapper/datavg-datalv2 is mounted on /datalvm2; on-line resizing required
old_desc_blocks = 1, new_desc_blocks = 1
The filesystem on /dev/mapper/datalv2 is now 1179648 blocks long.
```

Here we use the `-r` option to also resize the file system.

17. Check the LV information:

```
lvdisplay vgname/lvname
```

```
[root@vmresizelvm ~]# lvdisplay datavg/datalv2
--- Logical volume ---
  LV Path          /dev/datavg/datalv2
  LV Name          datalv2
  VG Name          datavg
  LV UUID          iK3HYF-wYPX-XAs0-0WGB-Zite-DlaT-dFae2o
  LV Write Access  read/write
  LV Creation host, time  vmresizelvm, 2020-05-18 18:33:54 +0000
  LV Status        available
  # open           1
  LV Size          4.49 GiB
  Current LE       1150
  Segments         3
  Allocation       inherit
  Read ahead sectors  auto
    - currently set to   8192
  Block device     253:3
```

18. Check the file system utilization:

```
df -h /mountpoint
```

```
[root@vmresizelvm ~]# df -h /datalvm2/
  Filesystem      Size  Used Avail Use% Mounted on
  /dev/mapper/datalv2  4.4G  2.4G  1.8G  58% /datalvm2
```

Apply the same resizing procedure to any other LV that requires it.

## Next steps

[Troubleshoot Azure Disk Encryption](#)

# Azure Disk Encryption for Linux VMs troubleshooting guide

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

This guide is for IT professionals, information security analysts, and cloud administrators whose organizations use Azure Disk Encryption. This article is to help with troubleshooting disk-encryption-related problems.

Before taking any of the steps below, first ensure that the VMs you are attempting to encrypt are among the [supported VM sizes and operating systems](#), and that you have met all the prerequisites:

- [Additional requirements for VMs](#)
- [Networking requirements](#)
- [Encryption key storage requirements](#)

## Troubleshooting Linux OS disk encryption

Linux operating system (OS) disk encryption must unmount the OS drive before running it through the full disk encryption process. If it can't unmount the drive, an error message of "failed to unmount after ..." is likely to occur.

This error can occur when OS disk encryption is attempted on a VM with an environment that has been changed from the supported stock gallery image. Deviations from the supported image can interfere with the extension's ability to unmount the OS drive. Examples of deviations can include the following items:

- Customized images no longer match a supported file system or partitioning scheme.
- Large applications such as SAP, MongoDB, Apache Cassandra, and Docker aren't supported when they're installed and running in the OS before encryption. Azure Disk Encryption is unable to shut down these processes safely as required in preparation of the OS drive for disk encryption. If there are still active processes holding open file handles to the OS drive, the OS drive can't be unmounted, resulting in a failure to encrypt the OS drive.
- Custom scripts that run in close time proximity to the encryption being enabled, or if any other changes are being made on the VM during the encryption process. This conflict can happen when an Azure Resource Manager template defines multiple extensions to execute simultaneously, or when a custom script extension or other action runs simultaneously to disk encryption. Serializing and isolating such steps might resolve the issue.
- Security Enhanced Linux (SELinux) hasn't been disabled before enabling encryption, so the unmount step fails. SELinux can be reenabled after encryption is complete.
- The OS disk uses a Logical Volume Manager (LVM) scheme. Although limited LVM data disk support is available, an LVM OS disk isn't.
- Minimum memory requirements aren't met (7 GB is suggested for OS disk encryption).
- Data drives are recursively mounted under the /mnt/ directory, or each other (for example, /mnt/data1, /mnt/data2, /data3 + /data3/data4).

## Update the default kernel for Ubuntu 14.04 LTS

The Ubuntu 14.04 LTS image ships with a default kernel version of 4.4. This kernel version has a known issue in which Out of Memory Killer improperly terminates the dd command during the OS encryption process. This

bug has been fixed in the most recent Azure tuned Linux kernel. To avoid this error, prior to enabling encryption on the image, update to the [Azure tuned kernel 4.15](#) or later using the following commands:

```
sudo apt-get update  
sudo apt-get install linux-azure  
sudo reboot
```

After the VM has restarted into the new kernel, the new kernel version can be confirmed using:

```
uname -a
```

## Update the Azure Virtual Machine Agent and extension versions

Azure Disk Encryption operations may fail on virtual machine images using unsupported versions of the Azure Virtual Machine Agent. Linux images with agent versions earlier than 2.2.38 should be updated prior to enabling encryption. For more information, see [How to update the Azure Linux Agent on a VM](#) and [Minimum version support for virtual machine agents in Azure](#).

The correct version of the Microsoft.Azure.Security.AzureDiskEncryption or Microsoft.Azure.Security.AzureDiskEncryptionForLinux guest agent extension is also required. Extension versions are maintained and updated automatically by the platform when Azure Virtual Machine agent prerequisites are satisfied and a supported version of the virtual machine agent is used.

The Microsoft.OSTCExtensions.AzureDiskEncryptionForLinux extension has been deprecated and is no longer supported.

## Unable to encrypt Linux disks

In some cases, the Linux disk encryption appears to be stuck at "OS disk encryption started" and SSH is disabled. The encryption process can take between 3-16 hours to finish on a stock gallery image. If multi-terabyte-sized data disks are added, the process might take days.

The Linux OS disk encryption sequence unmounts the OS drive temporarily. It then performs block-by-block encryption of the entire OS disk, before it remounts it in its encrypted state. Linux Disk Encryption doesn't allow for concurrent use of the VM while the encryption is in progress. The performance characteristics of the VM can make a significant difference in the time required to complete encryption. These characteristics include the size of the disk and whether the storage account is standard or premium (SSD) storage.

While the OS drive is being encrypted, the VM enters a servicing state and disables SSH to prevent any disruption to the ongoing process. To check the encryption status, use the Azure PowerShell [Get-AzVmDiskEncryptionStatus](#) command, and check the **ProgressMessage** field. **ProgressMessage** will report a series of statuses as the data and OS disks are encrypted:

```

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName "myVM"

OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : EncryptionInProgress
OsVolumeEncryptionSettings :
ProgressMessage         : Transitioning

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName "myVM"

OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : EncryptionInProgress
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage         : Encryption succeeded for data volumes

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName "myVM"

OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : EncryptionInProgress
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage         : Provisioning succeeded

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName "myVM"

OsVolumeEncrypted      : EncryptionInProgress
DataVolumesEncrypted   : EncryptionInProgress
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage         : OS disk encryption started

```

The **ProgressMessage** will remain in **OS disk encryption started** for most of the encryption process. When encryption is complete and successful, **ProgressMessage** will return:

```

PS > Get-AzVMDiskEncryptionStatus -ResourceGroupName "MyResourceGroup" -VMName "myVM"

OsVolumeEncrypted      : Encrypted
DataVolumesEncrypted   : NotMounted
OsVolumeEncryptionSettings : Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage         : Encryption succeeded for all volumes

```

After this message is available, the encrypted OS drive is expected to be ready for use and the VM is ready to be used again.

If the boot information, the progress message, or an error reports that OS encryption has failed in the middle of this process, restore the VM to the snapshot or backup taken immediately before encryption. An example of a message is the "failed to unmount" error that is described in this guide.

Before reattempting encryption, reevaluate the characteristics of the VM and make sure that all of the prerequisites are satisfied.

## Troubleshooting Azure Disk Encryption behind a firewall

See [Disk Encryption on an isolated network](#)

## Troubleshooting encryption status

The portal may display a disk as encrypted even after it has been unencrypted within the VM. This can occur when low-level commands are used to directly unencrypt the disk from within the VM, instead of using the higher level Azure Disk Encryption management commands. The higher level commands not only unencrypt the disk from within the VM, but outside of the VM they also update important platform level encryption settings and extension settings associated with the VM. If these are not kept in alignment, the platform will not be able to

report encryption status or provision the VM properly.

To disable Azure Disk Encryption with PowerShell, use [Disable-AzVMDiskEncryption](#) followed by [Remove-AzVMDiskEncryptionExtension](#). Running Remove-AzVMDiskEncryptionExtension before the encryption is disabled will fail.

To disable Azure Disk Encryption with CLI, use [az vm encryption disable](#).

## Next steps

In this document, you learned more about some common problems in Azure Disk Encryption and how to troubleshoot those problems. For more information about this service and its capabilities, see the following articles:

- [Apply disk encryption in Microsoft Defender for Cloud](#)
- [Azure data encryption at rest](#)

# Upgrading the Azure Disk Encryption version

9/21/2022 • 2 minutes to read • [Edit Online](#)

The first version of Azure Disk Encryption (ADE) relied on Azure Active Directory (AAD) for authentication; the current version does not. We strongly encourage the use of the newest version.

## Determine ADE version

The versions of ADE in scope for migration are:

- **Windows:** 1.1.\* (ADE on the VM must be upgraded to 2.2)
- **Linux:** 0.1.\* (ADE on the VM must be upgraded to 1.2)

You can determine the version of ADE with which a VM was encrypted via Azure CLI, Azure PowerShell, or the Azure portal.

- [CLI](#)
- [PowerShell](#)
- [Portal](#)

To determine the ADE version, run the Azure CLI `az vm get-instance-view` command.

```
az vm get-instance-view --resource-group <ResourceGroupName> --name <VMName>
```

Locate the `AzureDiskEncryption` extension in the output and identify the version number from the "TypeHandlerVersion" field in the output.

## How to migrate

Migration from Azure Disk Encryption (with AAD) to Azure Disk Encryption (without AAD) is only available through Azure PowerShell. Ensure you have the latest version of Azure PowerShell and at least the [Azure PowerShell Az module version 5.9.0](#) installed .

To upgrade from Azure Disk Encryption (with AAD) to Azure Disk Encryption (without AAD), use the [Set-AzVMDiskEncryptionExtension](#) PowerShell cmdlet.

### WARNING

The `Set-AzVMDiskEncryptionExtension` cmdlet must only be used on VMs encrypted with Azure Disk Encryption (with AAD). Attempting to migrate an unencrypted VM, or a VM encrypted with Azure Disk Encryption (without AAD), will result in a terminal error.

```
Set-AzVMDiskEncryptionExtension -ResourceGroupName <resourceGroupName> -VMName <vmName> -Migrate
```

When the cmdlet prompts you for confirmation, enter "Y". The ADE version will be updated and the VM rebooted. The output will look similar to the following:

```

> Set-AzVMDiskEncryptionExtension -ResourceGroupName myResourceGroup -VMName myVM -Migrate

Update AzureDiskEncryption version?
This cmdlet updates Azure Disk Encryption version to single pass (Azure Disk Encryption without AAD). This
may reboot
the machine and takes 10-15 minutes to finish. Are you sure you want to continue?
[Y] Yes [N] No [S] Suspend [?] Help (default is "Y"): Y
Azure Disk Encryption Extension Public Settings

Running ADE extension (without AAD) for -Migrate..
ADE extension (without AAD) is now complete. Clearing VM model..

RequestId IsSuccessStatusCode StatusCode ReasonPhrase
----- -----
True          OK   OK

```

#### **IMPORTANT**

The upgrade will take at least 10 - 15 minutes to complete. Do not cancel the cmdlet while the upgrade is in progress.  
Doing so puts the health of the VM at risk.

## Next steps

- [Azure Disk Encryption troubleshooting](#)

# Azure Disk Encryption with Azure Active Directory (AD) (previous release)

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure Active Directory (Azure AD) application parameter to enable VM disk encryption. With the new release, you're no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters by using the new release. For instructions on how to enable VM disk encryption by using the new release, see [Azure Disk Encryption for Linux VMs](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

This article provides supplements to [Azure Disk Encryption for Linux VMs](#) with additional requirements and prerequisites for Azure Disk Encryption with Azure AD (previous release).

The information in these sections remains the same:

- [Supported VMs and operating systems](#)
- [Additional VM requirements](#)

## Networking and Group Policy

To enable the Azure Disk Encryption feature by using the older AAD parameter syntax, the infrastructure as a service (IaaS) VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the IaaS VM must be able to connect to an Azure AD endpoint, [login.microsoftonline.com].
- To write the encryption keys to your key vault, the IaaS VM must be able to connect to the key vault endpoint.
- The IaaS VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see [Azure Key Vault behind a firewall](#).
- On Windows, if TLS 1.0 is explicitly disabled and the .NET version isn't updated to 4.6 or higher, the following registry change enables Azure Disk Encryption to select the more recent TLS version:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001

[HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001`
```

## Group Policy

- The Azure Disk Encryption solution uses the BitLocker external key protector for Windows IaaS VMs. For domain-joined VMs, don't push any Group Policies that enforce TPM protectors. For information about the Group Policy for the option **Allow BitLocker without a compatible TPM**, see [BitLocker Group](#)

## Policy reference.

- BitLocker policy on domain-joined virtual machines with a custom Group Policy must include the following setting: [Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key](#). Azure Disk Encryption fails when custom Group Policy settings for BitLocker are incompatible. On machines that don't have the correct policy setting, apply the new policy, force the new policy to update (gpupdate.exe /force), and then restart if it's required.

## Encryption key storage requirements

Azure Disk Encryption requires Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For more information, see [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#).

## Next steps

- [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#)
- [Enable Azure Disk Encryption with Azure AD on Linux VMs \(previous release\)](#)
- [Azure Disk Encryption prerequisites CLI script](#)
- [Azure Disk Encryption prerequisites PowerShell script](#)

# Creating and configuring a key vault for Azure Disk Encryption with Azure AD (previous release) for Linux VMs

9/21/2022 • 15 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure AD application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see [Azure Disk Encryption](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#).

Creating and configuring a key vault for use with Azure Disk Encryption with Azure AD (previous release) involves three steps:

1. Create a key vault.
2. Set up an Azure AD application and service principal.
3. Set the key vault access policy for the Azure AD app.
4. Set key vault advanced access policies.

You may also, if you wish, generate or import a key encryption key (KEK).

See the main [Creating and configuring a key vault for Azure Disk Encryption](#) article for steps on how to [Install tools and connect to Azure](#).

## NOTE

The steps in this article are automated in the [Azure Disk Encryption prerequisites CLI script](#) and [Azure Disk Encryption prerequisites PowerShell script](#).

## Create a key vault

Azure Disk Encryption is integrated with [Azure Key Vault](#) to help you control and manage the disk-encryption keys and secrets in your key vault subscription. You can create a key vault or use an existing one for Azure Disk Encryption. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#). You can use a Resource Manager template, Azure PowerShell, or the Azure CLI to create a key vault.

## WARNING

In order to make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the Key Vault and the VMs to be co-located in the same region. Create and use a Key Vault that is in the same region as the VM to be encrypted.

## Create a key vault with PowerShell

You can create a key vault with Azure PowerShell using the [New-AzKeyVault](#) cmdlet. For additional cmdlets for Key Vault, see [Az.KeyVault](#).

1. Create a new resource group, if needed, with [New-AzResourceGroup](#). To list data center locations, use [Get-AzLocation](#).

```
# Get-AzLocation  
New-AzResourceGroup -Name 'MyKeyVaultResourceGroup' -Location 'East US'
```

2. Create a new key vault using [New-AzKeyVault](#)

```
New-AzKeyVault -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -Location  
'East US'
```

3. Note the **Vault Name**, **Resource Group Name**, **Resource ID**, **Vault URI**, and the **Object ID** that are returned for later use when you encrypt the disks.

## Create a key vault with Azure CLI

You can manage your key vault with Azure CLI using the `az keyvault` commands. To create a key vault, use [az keyvault create](#).

1. Create a new resource group, if needed, with [az group create](#). To list locations, use [az account list-locations](#)

```
# To list locations: az account list-locations --output table  
az group create -n "MyKeyVaultResourceGroup" -l "East US"
```

2. Create a new key vault using [az keyvault create](#).

```
az keyvault create --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --location "East  
US"
```

3. Note the **Vault Name** (name), **Resource Group Name**, **Resource ID** (ID), **Vault URI**, and the **Object ID** that are returned for use later.

## Create a key vault with a Resource Manager template

You can create a key vault by using the [Resource Manager template](#).

1. On the Azure quickstart template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then click **Purchase**.

## Set up an Azure AD app and service principal

When you need encryption to be enabled on a running VM in Azure, Azure Disk Encryption generates and writes the encryption keys to your key vault. Managing encryption keys in your key vault requires Azure AD authentication. Create an Azure AD application for this purpose. For authentication purposes, you can use either client secret-based authentication or [client certificate-based Azure AD authentication](#).

### Set up an Azure AD app and service principal with Azure PowerShell

To execute the following commands, get and use the [Azure AD PowerShell module](#).

1. Use the [New-AzADApplication](#) PowerShell cmdlet to create an Azure AD application.

MyApplicationHomePage and the MyApplicationUri can be any values you wish.

```
$aadClientSecret = "My AAD client secret"
$aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -AsPlainText -Force
$azureAdApplication = New-AzADApplication -DisplayName "My Application Display Name" -HomePage
"https://MyApplicationHomePage" -IdentifierUris "https://MyApplicationUri" -Password
$aadClientSecretSec
$servicePrincipal = New-AzADServicePrincipal -ApplicationId $azureAdApplication.ApplicationId -Role
Contributor
```

2. The \$azureAdApplication.ApplicationId is the Azure AD ClientID and the \$aadClientSecret is the client secret that you will use later to enable Azure Disk Encryption. Safeguard the Azure AD client secret appropriately. Running `$azureAdApplication.ApplicationId` will show you the ApplicationID.

### Set up an Azure AD app and service principal with Azure CLI

You can manage your service principals with Azure CLI using the `az ad sp` commands. For more information, see [Create an Azure service principal](#).

1. Create a new service principal.

```
az ad sp create-for-rbac --name "ServicePrincipalName" --password "My-AAD-client-secret" --role
Contributor --scopes /subscriptions/<subscription_id>
```

2. The appId returned is the Azure AD ClientID used in other commands. It's also the SPN you'll use for az keyvault set-policy. The password is the client secret that you should use later to enable Azure Disk Encryption. Safeguard the Azure AD client secret appropriately.

### Set up an Azure AD app and service principal though the Azure portal

Use the steps from the [Use portal to create an Azure Active Directory application and service principal that can access resources](#) article to create an Azure AD application. Each step listed below will take you directly to the article section to complete.

1. [Verify required permissions](#)
2. [Create an Azure Active Directory application](#)
  - You can use any name and sign-on URL you would like when creating the application.
3. [Get the application ID and the authentication key.](#)
  - The authentication key is the client secret and is used as the AadClientSecret for Set-AzVMDiskEncryptionExtension.
    - The authentication key is used by the application as a credential to sign in to Azure AD. In the Azure portal, this secret is called keys, but has no relation to key vaults. Secure this secret appropriately.
  - The application ID will be used later as the AadClientId for Set-AzVMDiskEncryptionExtension and as the ServicePrincipalName for Set-AzKeyVaultAccessPolicy.

## Set the key vault access policy for the Azure AD app

To write encryption secrets to a specified Key Vault, Azure Disk Encryption needs the Client ID and the Client Secret of the Azure Active Directory application that has permissions to write secrets to the Key Vault.

#### NOTE

Azure Disk Encryption requires you to configure the following access policies to your Azure AD client application: *WrapKey* and *Set* permissions.

## Set the key vault access policy for the Azure AD app with Azure PowerShell

Your Azure AD application needs rights to access the keys or secrets in the vault. Use the [Set-AzKeyVaultAccessPolicy](#) cmdlet to grant permissions to the application, using the client ID (which was generated when the application was registered) as the *-ServicePrincipalName* parameter value. To learn more, see the blog post [Azure Key Vault - Step by Step](#).

1. Set the key vault access policy for the AD application with PowerShell.

```
$keyVaultName = 'MySecureVault'  
$aadClientID = 'MyAadAppClientID'  
$KVRGname = 'MyKeyVaultResourceGroup'  
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -  
PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname
```

## Set the key vault access policy for the Azure AD app with Azure CLI

Use [az keyvault set-policy](#) to set the access policy. For more information, see [Manage Key Vault using CLI 2.0](#).

Give the service principal you created via the Azure CLI access to get secrets and wrap keys with the following command:

```
az keyvault set-policy --name "MySecureVault" --spn "<spn created with CLI/the Azure AD ClientID>" --key-permissions wrapKey --secret-permissions set
```

## Set the key vault access policy for the Azure AD app with the portal

1. Open the resource group with your key vault.
2. Select your key vault, go to **Access Policies**, then click **Add new**.
3. Under **Select principal**, search for the Azure AD application you created and select it.
4. For **Key permissions**, check **Wrap Key** under **Cryptographic Operations**.
5. For **Secret permissions**, check **Set** under **Secret Management Operations**.
6. Click **OK** to save the access policy.

# Set key vault advanced access policies

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes. Enable disk encryption on the key vault or deployments will fail.

## Set key vault advanced access policies with Azure PowerShell

Use the key vault PowerShell cmdlet [Set-AzKeyVaultAccessPolicy](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForDiskEncryption
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForTemplateDeployment
```

## Set key vault advanced access policies using the Azure CLI

Use [az keyvault update](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Allow Virtual Machines to retrieve certificates stored as secrets from the vault.

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
deployment "true"
```

- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

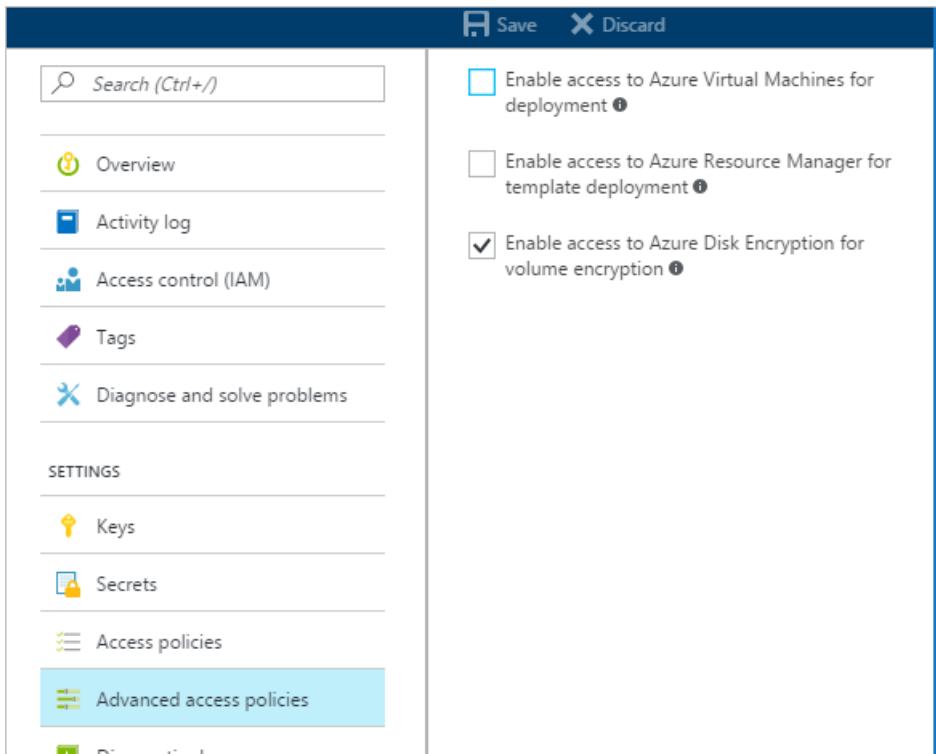

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
template-deployment "true"
```

## Set key vault advanced access policies through the Azure portal

1. Select your keyvault, go to Access Policies, and Click to show advanced access policies.
2. Select the box labeled Enable access to Azure Disk Encryption for volume encryption.

3. Select **Enable access to Azure Virtual Machines for deployment** and/or **Enable Access to Azure Resource Manager for template deployment**, if needed.

4. Click **Save**.

## Set up a key encryption key (optional)

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. Use the [Add-AzKeyVaultKey](#) cmdlet to create a key encryption key in the key vault. You can also import a KEK from your on-premises key management HSM. For more information, see [Key Vault Documentation](#). When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

- When generating keys, use an RSA key type. Azure Disk Encryption does not yet support using Elliptic Curve keys.
- Your key vault secret and KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:
  - Example of a valid secret URL:  
<https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
  - Example of a valid KEK URL:  
<https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
- Azure Disk Encryption doesn't support specifying port numbers as part of key vault secrets and KEK URLs. For examples of non-supported and supported key vault URLs, see the following examples:
  - Unacceptable key vault URL  
<https://contosovault.vault.azure.net:443/secrets/contososecret/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
  - Acceptable key vault URL:  
<https://contosovault.vault.azure.net/secrets/contososecret/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

### Set up a key encryption key with Azure PowerShell

Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment. This script creates all Azure Disk Encryption prerequisites and encrypts an existing IaaS VM, wrapping the disk encryption

key by using a key encryption key.

```
# Step 1: Create a new resource group and key vault in the same location.
# Fill in 'MyLocation', 'MyKeyVaultResourceGroup', and 'MySecureVault' with your values.
# Use Get-AzLocation to get available locations and use the DisplayName.
# To use an existing resource group, comment out the line for New-AzResourceGroup

$Loc = 'MyLocation';
$KVRGname = 'MyKeyVaultResourceGroup';
$keyVaultName = 'MySecureVault';
New-AzResourceGroup -Name $KVRGname -Location $Loc;
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc;
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$keyVaultResourceId = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname).ResourceId;
$diskEncryptionKeyVaultUrl = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname).VaultUri;

# Step 2: Create the AD application and service principal.
# Fill in 'MyAADClientSecret', "<My Application Display Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish.

$aadClientSecret = 'MyAADClientSecret';
$aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -AsPlainText -Force;
$azureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -Password $aadClientSecretSec
$servicePrincipal = New-AzADServicePrincipal -ApplicationId $azureAdApplication.ApplicationId -Role Contributor;
$aadClientID = $azureAdApplication.ApplicationId;

#Step 3: Enable the vault for disk encryption and set the access policy for the Azure AD application.

Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -
EnabledForDiskEncryption;
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -
PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname;

#Step 4: Create a new key in the key vault with the Add-AzKeyVaultKey cmdlet.
# Fill in 'MyKeyEncryptionKey' with your value.

$keyEncryptionKeyName = 'MyKeyEncryptionKey';
Add-AzKeyVaultKey -VaultName $keyVaultName -Name $keyEncryptionKeyName -Destination 'Software';
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name $keyEncryptionKeyName).Key.kid;

#Step 5: Encrypt the disks of an existing IaaS VM
# Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

$VMName = 'MySecureVM';
$VMRGName = 'MyVirtualMachineResourceGroup';
Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID $aadClientID -
AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyId $keyVaultResourceId;
```

## Certificate-based authentication (optional)

If you would like to use certificate authentication, you can upload one to your key vault and deploy it to the client. Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

```
# Fill in "MyKeyVaultResourceGroup", "MySecureVault", and 'MyLocation' ('My location' only if needed)
```

```

$KVRGname = 'MyKeyVaultResourceGroup'
$keyVaultName= 'MySecureVault'

# Create a key vault and set enabledForDiskEncryption property on it.
# Comment out the next three lines if you already have an existing key vault enabled for encryption. No
need to set 'My location' in this case.

$Loc = 'MyLocation'
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDiskEncryption

#Setting some variables with the key vault information
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname
$DiskEncryptionKeyVaultUrl = $keyVault.VaultUri
$keyVaultResourceId = $keyVault.ResourceId

# Create the Azure AD application and associate the certificate with it.
# Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display Name>", "
<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish

$CertPath = "C:\certificates\mycert.pfx"
$CertPassword = "Password"
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

$AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "
<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -CertValue $CertValue
$ServicePrincipal = New-AzADServicePrincipal -ApplicationId $AzureAdApplication.ApplicationId -Role
Contributor

$AADClientID = $AzureAdApplication.ApplicationId
$aadClientCertThumbprint= $cert.Thumbprint

Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -PermissionsToKeys
'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname

# Upload the pfx file to the key vault.
# Fill in "MyAADCert".

$keyVaultSecretName = "MyAADCert"
$fileContentBytes = get-content $CertPath -Encoding Byte
$fileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
$jsonObject = @{
    "data" : "$filecontentencoded",
    "dataType" : "pfx",
    "password" : "$CertPassword"
}
"@

$jsonObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
$jsonEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

#Set the secret and set the key vault policy for -EnabledForDeployment

$secret = ConvertTo-SecureString -String $jsonEncoded -AsPlainText -Force
Set-AzKeyVaultSecret -VaultName $keyVaultName -Name $keyVaultSecretName -SecretValue $secret
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDeployment

# Deploy the certificate to the VM
# Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

$VMName = 'MySecureVM'
$VMRGName = 'MyVirtualMachineResourceGroup'
$CertUrl = (Get-AzKeyVaultSecret -VaultName $keyVaultName -Name $keyVaultSecretName).Id
$SourceVaultId = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname).ResourceId
$VM = Get-AzVM -ResourceGroupName $VMRGName -Name $VMName

```

```
$VM = Add-AzVMSecret -VM $VM -SourceVaultId $SourceVaultId -CertificateStore "My" -CertificateUrl $CertUrl
Update-AzVM -VM $VM -ResourceGroupName $VMRGName

#Enable encryption on the VM using Azure AD client ID and the client certificate thumbprint

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -AadClientID $AADClientID -
AadClientCertThumbprint $AADClientCertThumbprint -DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $KeyVaultResourceId
```

## Certificate-based authentication and a KEK (optional)

If you would like to use certificate authentication and wrap the encryption key with a KEK, you can use the below script as an example. Before using the PowerShell script, you should be familiar with all of the previous Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

### IMPORTANT

Azure AD certificate-based authentication is currently not supported on Linux VMs.

```
# Fill in 'MyKeyVaultResourceGroup', 'MySecureVault', and 'MyLocation' (if needed)

$KVRGname = 'MyKeyVaultResourceGroup'
$keyVaultName= 'MySecureVault'

# Create a key vault and set enabledForDiskEncryption property on it.
# Comment out the next three lines if you already have an existing key vault enabled for encryption.

$Loc = 'MyLocation'
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDiskEncryption

# Create the Azure AD application and associate the certificate with it.
# Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display Name>", "
<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish

$CertPath = "C:\certificates\mycert.pfx"
$CertPassword = "Password"
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

$AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "
<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -CertValue $CertValue
$ServicePrincipal = New-AzADServicePrincipal -ApplicationId $AzureAdApplication.ApplicationId -Role
Contributor

$AADClientID = $AzureAdApplication.ApplicationId
$aadClientCertThumbprint= $cert.Thumbprint

## Give access for setting secrets and wrapping keys
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -PermissionsToKeys
'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname

# Upload the pfx file to the key vault.
# Fill in "MyAADCert".

$keyVaultSecretName = "MyAADCert"
$FileContentBytes = get-content $CertPath -Encoding Byte
$FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
$JSONObject = @"
{
    "name": "MyAADCert",
    "type": "AsymmetricX509Certificate",
    "value": $FileContentEncoded
}"
```

```

        "data" : "$filecontentencoded",
        "dataType" : "pfx",
        "password" : "$CertPassword"
    }
"""

$JSONObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
$JSONEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

```

## Next steps

[Enable Azure Disk Encryption with Azure AD on Linux VMs \(previous release\)](#)

# Enable Azure Disk Encryption with Azure AD on Linux VMs (previous release)

9/21/2022 • 17 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure Active Directory (Azure AD) application parameter to enable VM disk encryption. With the new release, you're no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters by using the new release. For instructions on how to enable VM disk encryption by using the new release, see [Azure Disk Encryption for Linux VMs](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

You can enable many disk-encryption scenarios, and the steps might vary according to the scenario. The following sections cover the scenarios in greater detail for Linux infrastructure as a service (IaaS) VMs. You can only apply disk encryption to virtual machines of [supported VM sizes and operating systems](#). You must also meet the following prerequisites:

- [Additional requirements for VMs](#)
- [Networking and Group Policy](#)
- [Encryption key storage requirements](#)

Take a [snapshot](#), make a backup, or both before you encrypt the disks. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. After a backup is made, you can use the `Set-AzVMDiskEncryptionExtension` cmdlet to encrypt managed disks by specifying the `-skipVmBackup` parameter. For more information about how to back up and restore encrypted VMs, see [Azure Backup](#).

## WARNING

- If you previously used [Azure Disk Encryption with the Azure AD app](#) to encrypt this VM, you must continue to use this option to encrypt your VM. You can't use [Azure Disk Encryption](#) on this encrypted VM because this isn't a supported scenario, which means switching away from the Azure AD application for this encrypted VM isn't supported yet.
- To make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the key vault and the VMs to be co-located in the same region. Create and use a key vault that's in the same region as the VM to be encrypted.
- When you encrypt Linux OS volumes, the process can take a few hours. It's normal for Linux OS volumes to take longer than data volumes to encrypt.
- When you encrypt Linux OS volumes, the VM should be considered unavailable. We strongly recommend that you avoid SSH logins while the encryption is in progress to avoid blocking any open files that need to be accessed during the encryption process. To check progress, use the `Get-AzVMDiskEncryptionStatus` or `vm encryption show` commands. You can expect this process to take a few hours for a 30-GB OS volume, plus additional time for encrypting data volumes. Data volume encryption time is proportional to the size and quantity of the data volumes unless the **encrypt format all** option is used.
- Disabling encryption on Linux VMs is only supported for data volumes. It's not supported on data or OS volumes if the OS volume has been encrypted.

# Enable encryption on an existing or running IaaS Linux VM

In this scenario, you can enable encryption by using the Azure Resource Manager template, PowerShell cmdlets, or Azure CLI commands.

## IMPORTANT

It's mandatory to take a snapshot or back up a managed disk-based VM instance outside of and prior to enabling Azure Disk Encryption. You can take a snapshot of the managed disk from the Azure portal, or you can use [Azure Backup](#).

Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. After a backup is made, use the `Set-AzVMDiskEncryptionExtension` cmdlet to encrypt managed disks by specifying the `-skipVmBackup` parameter. The `Set-AzVMDiskEncryptionExtension` command fails against managed disk-based VMs until a backup is made and this parameter is specified.

Encrypting or disabling encryption might cause the VM to reboot.

## Enable encryption on an existing or running Linux VM by using the Azure CLI

You can enable disk encryption on your encrypted VHD by installing and using the [Azure CLI 2.0](#) command-line tool. You can use it in your browser with [Azure Cloud Shell](#), or you can install it on your local machine and use it in any PowerShell session. To enable encryption on existing or running IaaS Linux VMs in Azure, use the following CLI commands:

Use the `az vm encryption enable` command to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM by using a client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
```

- **Encrypt a running VM by using KEK to wrap the client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI which is the Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
```

## NOTE

The syntax for the value of the `disk-encryption-keyvault` parameter is the full identifier string:  
`/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]`.

The syntax for the value of the `key-encryption-key` parameter is the full URI to the KEK as in: `https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]`.

- **Verify that the disks are encrypted:** To check on the encryption status of an IaaS VM, use the `az vm encryption show` command.

```
az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
```

- **Disable encryption:** To disable encryption, use the `az vm encryption disable` command. Disabling encryption is only allowed on data volumes for Linux VMs.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --volume-type DATA
```

## Enable encryption on an existing or running Linux VM by using PowerShell

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet to enable encryption on a running IaaS virtual machine in Azure. Take a [snapshot](#) or make a backup of the VM with [Azure Backup](#) before the disks are encrypted. The `-skipVmBackup` parameter is already specified in the PowerShell scripts to encrypt a running Linux VM.

- **Encrypt a running VM by using a client secret:** The following script initializes your variables and runs the `Set-AzVMDiskEncryptionExtension` cmdlet. The resource group, VM, key vault, Azure AD app, and client secret should have already been created as prerequisites. Replace `MyVirtualMachineResourceGroup`, `MyKeyVaultResourceGroup`, `MySecureVM`, `MySecureVault`, `My-AAD-client-ID`, and `My-AAD-client-secret` with your values. Modify the `-VolumeType` parameter to specify which disks you're encrypting.

```
$VMRGName = 'MyVirtualMachineResourceGroup';
$KVRGname = 'MyKeyVaultResourceGroup';
$vmName = 'MySecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId -VolumeType '[All|OS|Data]' -SequenceVersion
$sequenceVersion -skipVmBackup;
```

- **Encrypt a running VM by using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to the key vault. Modify the `-VolumeType` parameter to specify which disks you're encrypting.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $keyVaultResourceId -VolumeType '[All|OS|Data]' -SequenceVersion
$sequenceVersion -skipVmBackup;
```

**NOTE**

The syntax for the value of the disk-encryption-keyvault parameter is the full identifier string:  
/subscriptions/[subscription-id-guid]/resourceGroups/[KVresource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name].

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id].

- **Verify that the disks are encrypted:** To check on the encryption status of an IaaS VM, use the [Get-AzVmDiskEncryptionStatus](#) cmdlet.

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName MyVirtualMachineResourceGroup -VMName MySecureVM
```

- **Disable disk encryption:** To disable the encryption, use the [Disable-AzureRmVMDiskEncryption](#) cmdlet. Disabling encryption is only allowed on data volumes for Linux VMs.

```
Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

### Enable encryption on an existing or running IaaS Linux VM with a template

You can enable disk encryption on an existing or running IaaS Linux VM in Azure by using the [Resource Manager template](#).

1. Select **Deploy to Azure** on the Azure quickstart template.
2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Select **Create** to enable encryption on the existing or running IaaS VM.

The following table lists Resource Manager template parameters for existing or running VMs that use an Azure AD client ID:

PARAMETER	DESCRIPTION
AADClientID	Client ID of the Azure AD application that has permissions to write secrets to the key vault.
AADClientSecret	Client secret of the Azure AD application that has permissions to write secrets to your key vault.
keyVaultName	Name of the key vault that the key should be uploaded to. You can get it by using the Azure CLI command <pre>az keyvault show --name "MySecureVault" --query KVresourceGroup</pre>
keyEncryptionKeyURL	URL of the key encryption key that's used to encrypt the generated key. This parameter is optional if you select <b>nokek</b> in the <b>UseExistingKek</b> drop-down list. If you select <b>kek</b> in the <b>UseExistingKek</b> drop-down list, you must enter the <i>keyEncryptionKeyURL</i> value.

PARAMETER	DESCRIPTION
volumeType	Type of volume that the encryption operation is performed on. Valid supported values are <i>OS</i> or <i>All</i> . (See supported Linux distributions and their versions for OS and data disks in the prerequisites section earlier.)
sequenceVersion	Sequence version of the BitLocker operation. Increment this version number every time a disk-encryption operation is performed on the same VM.
vmName	Name of the VM that the encryption operation is to be performed on.
passphrase	Type a strong passphrase as the data encryption key.

## Use the EncryptFormatAll feature for data disks on Linux IaaS VMs

The `EncryptFormatAll` parameter reduces the time for Linux data disks to be encrypted. Partitions that meet certain criteria are formatted (with their current file system). Then they're remounted back to where they were before command execution. If you want to exclude a data disk that meets the criteria, you can unmount it before you run the command.

After you run this command, any drives that were mounted previously are reformatted. Then the encryption layer starts on top of the now empty drive. When this option is selected, the temporary disk attached to the VM is also encrypted. If the ephemeral drive is reset, it's reformatted and re-encrypted for the VM by the Azure Disk Encryption solution at the next opportunity.

### WARNING

`EncryptFormatAll` shouldn't be used when there's needed data on a VM's data volumes. You can exclude disks from encryption by unmounting them. Try out the `EncryptFormatAll` parameter on a test VM first to understand the feature parameter and its implication before you try it on the production VM. The `EncryptFormatAll` option formats the data disk, so all the data on it will be lost. Before you proceed, verify that any disks you want to exclude are properly unmounted.

If you set this parameter while you update encryption settings, it might lead to a reboot before the actual encryption. In this case, you also want to remove the disk you don't want formatted from the `fstab` file. Similarly, you should add the partition you want encrypt-formatted to the `fstab` file before you initiate the encryption operation.

### EncryptFormatAll criteria

The parameter goes through all partitions and encrypts them as long as they meet *all* of the following criteria:

- Is not a root/OS/boot partition
- Is not already encrypted
- Is not a BEK volume
- Is not a RAID volume
- Is not an LVM volume
- Is mounted

Encrypt the disks that compose the RAID or LVM volume rather than the RAID or LVM volume.

### Use the EncryptFormatAll parameter with a template

To use the `EncryptFormatAll` option, use any preexisting Azure Resource Manager template that encrypts a Linux VM and change the `EncryptionOperation` field for the `AzureDiskEncryption` resource.

1. As an example, use the [Resource Manager template to encrypt a running Linux IaaS VM](#).
2. Select **Deploy to Azure** on the Azure quickstart template.
3. Change the **EncryptionOperation** field from **EnableEncryption** to **EnableEncryptionFormatAll**.
4. Select the subscription, resource group, resource group location, other parameters, legal terms, and agreement. Select **Create** to enable encryption on the existing or running IaaS VM.

## Use the **EncryptFormatAll** parameter with a **PowerShell cmdlet**

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet with the **EncryptFormatAll** parameter.

**Encrypt a running VM by using a client secret and **EncryptFormatAll**:** As an example, the following script initializes your variables and runs the [Set-AzVMDiskEncryptionExtension](#) cmdlet with the **EncryptFormatAll** parameter. The resource group, VM, key vault, Azure AD app, and client secret should have already been created as prerequisites. Replace **MyKeyVaultResourceGroup**, **MyVirtualMachineResourceGroup**, **MySecureVM**, **MySecureVault**, **My-AAD-client-ID**, and **My-AAD-client-secret** with your values.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID $aadClientID -
AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $keyVaultResourceId -EncryptFormatAll
```

## Use the **EncryptFormatAll** parameter with Logical Volume Manager (LVM)

We recommend an LVM-on-crypt setup. For all the following examples, replace the device-path and mountpoints with whatever suits your use case. This setup can be done as follows:

- Add the data disks that will compose the VM.
  - Format, mount, and add these disks to the fstab file.
1. Format the newly added disk. We use symlinks generated by Azure here. Using symlinks avoids problems related to device names changing. For more information, see [Troubleshoot device names problems](#).

```
mkfs -t ext4 /dev/disk/azure/scsi1/lun0
```

2. Mount the disks.

```
mount /dev/disk/azure/scsi1/lun0 /mnt/mountpoint
```

3. Add to fstab.

```
echo "/dev/disk/azure/scsi1/lun0 /mnt/mountpoint ext4 defaults,nofail 1 2" >> /etc/fstab
```

4. Run the [Set-AzVMDiskEncryptionExtension](#) PowerShell cmdlet with **-EncryptFormatAll** to encrypt these disks.

```
Set-AzVMDiskEncryptionExtension -ResourceGroupName "MySecureGroup" -VMName "MySecureVM" -  
DiskEncryptionKeyVaultUrl "https://mykeyvault.vault.azure.net/" -EncryptFormatAll
```

5. Set up LVM on top of these new disks. Note the encrypted drives are unlocked after the VM has finished booting. So, the LVM mounting will also have to be subsequently delayed.

## New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using the Resource Manager template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail the Resource Manager template and CLI commands.

Use the instructions in the appendix for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- [Prepare a pre-encrypted Linux VHD](#)

### IMPORTANT

It's mandatory to take a snapshot or back up a managed disk-based VM instance outside of and prior to enabling Azure Disk Encryption. You can take a snapshot of the managed disk from the portal, or you can use [Azure Backup](#). Backups ensure that a recovery option is possible in the case of any unexpected failure during encryption. After a backup is made, use the `Set-AzVMDiskEncryptionExtension` cmdlet to encrypt managed disks by specifying the `-skipVmBackup` parameter. The `Set-AzVMDiskEncryptionExtension` command fails against managed disk-based VMs until a backup is made and this parameter is specified.

Encrypting or disabling encryption might cause the VM to reboot.

### Use Azure PowerShell to encrypt IaaS VMs with pre-encrypted VHDS

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet `Set-AzVMOSDisk`. The following example gives you some common parameters.

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"  
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri "os.vhd" Caching ReadWrite  
-Windows -CreateOption "Attach" -DiskEncryptionKeyUrl  
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaa" -  
DiskEncryptionKeyId "/subscriptions/00000000-0000-0000-0000-  
0000000000/resourceGroups/myresourcegroup/providers/Microsoft.KeyVault/vaults/mytestvault"  
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

## Enable encryption on a newly added data disk

You can add a new data disk by using [az vm disk attach](#) or [through the Azure portal](#). Before you can encrypt, you need to mount the newly attached data disk first. You must request encryption of the data drive because the drive will be unusable while encryption is in progress.

### Enable encryption on a newly added disk with the Azure CLI

If the VM was previously encrypted with "All," then the `--volume-type` parameter should remain All. All includes both OS and data disks. If the VM was previously encrypted with a volume type of "OS," then the `--volume-type` parameter should be changed to All so that both the OS and the new data disk will be included. If the VM was encrypted with only the volume type of "Data," then it can remain Data as demonstrated here. Adding and attaching a new data disk to a VM isn't sufficient preparation for encryption. The newly attached disk must also be formatted and properly mounted within the VM before you enable encryption. On Linux, the disk must be mounted in `/etc/fstab` with a [persistent block device name](#).

In contrast to PowerShell syntax, the CLI doesn't require you to provide a unique sequence version when you enable encryption. The CLI automatically generates and uses its own unique sequence version value.

- **Encrypt a running VM by using a client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --volume-type "Data"
```

- **Encrypt a running VM by using KEK to wrap the client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI which is the Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type "Data"
```

## Enable encryption on a newly added disk with Azure PowerShell

When you use PowerShell to encrypt a new disk for Linux, a new sequence version needs to be specified. The sequence version has to be unique. The following script generates a GUID for the sequence version.

- **Encrypt a running VM by using a client secret:** The following script initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, Azure AD app, and client secret should have already been created as prerequisites. Replace MyVirtualMachineResourceGroup, MyKeyVaultResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values. The -VolumeType parameter is set to data disks and not the OS disk. If the VM was previously encrypted with a volume type of "OS" or "All," then the -VolumeType parameter should be changed to All so that both the OS and the new data disk will be included.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyId $keyVaultResourceId -VolumeType 'data' -SequenceVersion $sequenceVersion;
```

- **Encrypt a running VM by using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to the key vault. The -VolumeType parameter is set to data disks and not the OS disk. If the VM was previously encrypted with a volume type of "OS" or "All," then the -VolumeType parameter should be changed to All so that both the OS and the new data disk will be included.

```

$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$KeyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$KeyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $KeyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $KeyVaultResourceId -VolumeType 'data' -SequenceVersion $sequenceVersion;

```

#### NOTE

The syntax for the value of the disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name].

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id].

## Disable encryption for Linux VMs

You can disable encryption by using Azure PowerShell, the Azure CLI, or a Resource Manager template.

#### IMPORTANT

Disabling encryption with Azure Disk Encryption on Linux VMs is only supported for data volumes. It's not supported on data or OS volumes if the OS volume has been encrypted.

- Disable disk encryption with Azure PowerShell:** To disable encryption, use the [Disable-AzureRmVMDiskEncryption](#) cmdlet.

```
Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName
'MySecureVM' [--volume-type {ALL, DATA, OS}]
```

- Disable encryption with the Azure CLI:** To disable encryption, use the [az vm encryption disable](#) command.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --
volume-type [ALL, DATA, OS]
```

- Disable encryption with a Resource Manager template:** To disable encryption, use the [Disable encryption on a running Linux VM](#) template.

- Select **Deploy to Azure**.
- Select the subscription, resource group, location, VM, legal terms, and agreement.
- Select **Purchase** to disable disk encryption on a running Windows VM.

# Azure Disk Encryption for Windows VMs

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Azure Disk Encryption helps protect and safeguard your data to meet your organizational security and compliance commitments. It uses the [BitLocker](#) feature of Windows to provide volume encryption for the OS and data disks of Azure virtual machines (VMs), and is integrated with [Azure Key Vault](#) to help you control and manage the disk encryption keys and secrets.

Azure Disk Encryption is zone resilient, the same way as Virtual Machines. For details, see [Azure Services that support Availability Zones](#).

If you use [Microsoft Defender for Cloud](#), you're alerted if you have VMs that aren't encrypted. The alerts show as High Severity and the recommendation is to encrypt these VMs.

VIRTUAL MACHINES RECOMMENDATIONS		TOTAL			
Missing disk encryption	2 of 2 VMs	<div style="width: 100%; background-color: red; height: 10px;"></div>			
Virtual machines					
NAME	ONBOARDING	SYSTEM UPDATES	ANTIMALWARE	BASELINE	DISK ENCRYPTION
ASC-VM1	✓	✓	✓	✓	!
ASC-VM2	✓	✓	✓	✓	!

## WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM. See [Azure Disk Encryption with Azure AD \(previous release\)](#) for details.
- Certain recommendations might increase data, network, or compute resource usage, resulting in additional license or subscription costs. You must have a valid active Azure subscription to create resources in Azure in the supported regions.
- Do not use BitLocker to manually decrypt a VM or disk that was encrypted through Azure Disk Encryption.

You can learn the fundamentals of Azure Disk Encryption for Windows in just a few minutes with the [Create and encrypt a Windows VM with Azure CLI quickstart](#) or the [Create and encrypt a Windows VM with Azure PowerShell quickstart](#).

## Supported VMs and operating systems

### Supported VMs

Windows VMs are available in a [range of sizes](#). Azure Disk Encryption is supported on Generation 1 and Generation 2 VMs. Azure Disk Encryption is also available for VMs with premium storage.

Azure Disk Encryption is not available on [Basic, A-series VMs](#), or on virtual machines with a less than 2 GB of memory. For more exceptions, see [Azure Disk Encryption: Unsupported scenarios](#).

## Supported operating systems

- Windows client: Windows 8 and later.
- Windows Server: Windows Server 2008 R2 and later.
- Windows 10 Enterprise multi-session.

### NOTE

Windows Server 2022 does not support an RSA 2048 bit key. For more details, see [FAQ: What size should I use for my key encryption key?](#)

Windows Server 2008 R2 requires the .NET Framework 4.5 to be installed for encryption; install it from Windows Update with the optional update Microsoft .NET Framework 4.5.2 for Windows Server 2008 R2 x64-based systems ([KB2901983](#)).

Windows Server 2012 R2 Core and Windows Server 2016 Core requires the bdehdcfg component to be installed on the VM for encryption.

## Networking requirements

To enable Azure Disk Encryption, the VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the Windows VM must be able to connect to an Azure Active Directory endpoint, [login.microsoftonline.com].
- To write the encryption keys to your key vault, the Windows VM must be able to connect to the key vault endpoint.
- The Windows VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see [Azure Key Vault behind a firewall](#).

## Group Policy requirements

Azure Disk Encryption uses the BitLocker external key protector for Windows VMs. For domain joined VMs, don't push any group policies that enforce TPM protectors. For information about the group policy for "Allow BitLocker without a compatible TPM," see [BitLocker Group Policy Reference](#).

BitLocker policy on domain joined virtual machines with custom group policy must include the following setting: [Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key](#). Azure Disk Encryption will fail when custom group policy settings for BitLocker are incompatible. On machines that didn't have the correct policy setting, apply the new policy, and force the new policy to update (gpupdate.exe /force). Restarting may be required.

Microsoft Bitlocker Administration and Monitoring (MBAM) group policy features are not compatible with Azure Disk Encryption.

### WARNING

Azure Disk Encryption **does not store recovery keys**. If the [Interactive logon: Machine account lockout threshold](#) security setting is enabled, machines can only be recovered by providing a recovery key via the serial console. Instructions for ensuring the appropriate recovery policies are enabled can be found in the [Bitlocker recovery guide plan](#).

Azure Disk Encryption will fail if domain level group policy blocks the AES-CBC algorithm, which is used by BitLocker.

# Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see [Creating and configuring a key vault for Azure Disk Encryption](#).

## Terminology

The following table defines some of the common terms used in Azure disk encryption documentation:

TERMINOLOGY	DEFINITION
Azure Key Vault	Key Vault is a cryptographic, key management service that's based on Federal Information Processing Standards (FIPS) validated hardware security modules. These standards help to safeguard your cryptographic keys and sensitive secrets. For more information, see the <a href="#">Azure Key Vault</a> documentation and <a href="#">Creating and configuring a key vault for Azure Disk Encryption</a> .
Azure CLI	The <a href="#">Azure CLI</a> is optimized for managing and administering Azure resources from the command line.
BitLocker	<a href="#">BitLocker</a> is an industry-recognized Windows volume encryption technology that's used to enable disk encryption on Windows VMs.
Key encryption key (KEK)	The asymmetric key (RSA 2048) that you can use to protect or wrap the secret. You can provide a hardware security module (HSM)-protected key or software-protected key. For more information, see the <a href="#">Azure Key Vault</a> documentation and <a href="#">Creating and configuring a key vault for Azure Disk Encryption</a> .
PowerShell cmdlets	For more information, see <a href="#">Azure PowerShell cmdlets</a> .

## Next steps

- [Quickstart - Create and encrypt a Windows VM with Azure CLI](#)
- [Quickstart - Create and encrypt a Windows VM with Azure PowerShell](#)
- [Azure Disk Encryption scenarios on Windows VMs](#)
- [Azure Disk Encryption prerequisites CLI script](#)
- [Azure Disk Encryption prerequisites PowerShell script](#)
- [Creating and configuring a key vault for Azure Disk Encryption](#)

# Quickstart: Create and encrypt a Windows VM with the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to create and encrypt a Windows Server 2016 virtual machine (VM).

If you don't have an [Azure subscription](#), create an [Azure free account](#) before you begin.

## Prerequisites

You can use either the Azure Cloud Shell or a local Azure CLI.

- [Azure Cloud Shell](#) with the Bash environment. Or launch the Cloud Shell here.

 [Launch Cloud Shell](#)

- Local Azure CLI, see how to [install the Azure CLI](#). If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see [How to run the Azure CLI in a Docker container](#).
  - Sign in to the Azure CLI by using the `az login` command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see [Sign in with the Azure CLI](#).
  - When you first use Azure CLI, install the Azure CLI extension. For more information about extensions, see [Use extensions with the Azure CLI](#).
  - Run `az version` to find the version and dependent libraries that are installed. To upgrade to the latest version, run `az upgrade`.
- This article requires version 2.0.30 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

## Create a resource group

Create a resource group with the `az group create` command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named `myResourceGroup` in the `eastus` location:

```
az group create --name myResourceGroup --location eastus
```

## Create a virtual machine

Create a VM with `az vm create`. The following example creates a VM named `myVM`. This example uses `azureuser` for an administrative user name and `myPassword12` as the password.

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image win2016datacenter \
--admin-username azureuser \
--admin-password myPassword12
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

```
{
  "fqdns": "",
  "id": "/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroup"
}
```

## Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with [az keyvault create](#). To enable the Key Vault to store encryption keys, use the --enabled-for-disk-encryption parameter.

### IMPORTANT

Each Key Vault must have a unique name. The following example creates a Key Vault named *myKV*, but you must name yours something different.

```
az keyvault create --name "myKV" --resource-group "myResourceGroup" --location eastus --enabled-for-disk-encryption
```

## Encrypt the virtual machine

Encrypt your VM with [az vm encryption](#), providing your unique Key Vault name to the --disk-encryption-keyvault parameter.

```
az vm encryption enable -g MyResourceGroup --name MyVM --disk-encryption-keyvault myKV
```

You can verify that encryption is enabled on your VM with [az vm show](#)

```
az vm encryption show --name MyVM -g MyResourceGroup
```

You will see the following in the returned output:

```
"EncryptionOperation": "EnableEncryption"
```

## Clean up resources

When no longer needed, you can use the [az group delete](#) command to remove the resource group, VM, and Key Vault.

```
az group delete --name myResourceGroup
```

## Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enable for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption prerequisites for IaaS VMs.

[Azure Disk Encryption overview](#)

# Quickstart: Create and encrypt a Windows virtual machine in Azure with PowerShell

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to create a Windows virtual machine (VM), create a Key Vault for the storage of encryption keys, and encrypt the VM.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Create a resource group

Create an Azure resource group with [New-AzResourceGroup](#). A resource group is a logical container into which Azure resources are deployed and managed:

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

## Create a virtual machine

Create an Azure virtual machine with [New-AzVM](#). You must supply credentials to the cmdlet.

```
$cred = Get-Credential  
  
New-AzVM -Name MyVm -Credential $cred -ResourceGroupName MyResourceGroup -Image win2016datacenter -Size Standard_D2S_V3
```

It will take a few minutes for your VM to be deployed.

## Create a Key Vault configured for encryption keys

Azure disk encryption stores its encryption key in an Azure Key Vault. Create a Key Vault with [New-AzKeyVault](#). To enable the Key Vault to store encryption keys, use the `-EnabledForDiskEncryption` parameter.

### IMPORTANT

Each Key Vault must have a unique name. The following example creates a Key Vault named *myKV*, but you must name yours something different.

```
New-AzKeyVault -name MyKV -ResourceGroupName myResourceGroup -Location EastUS -EnabledForDiskEncryption
```

## Encrypt the virtual machine

Encrypt your VM with [Set-AzVmDiskEncryptionExtension](#).

`Set-AzVmDiskEncryptionExtension` requires some values from your Key Vault object. You can obtain these values by passing the unique name of your key vault to [Get-AzKeyVault](#).

```
$KeyVault = Get-AzKeyVault -VaultName MyKV -ResourceGroupName MyResourceGroup

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName MyVM -DiskEncryptionKeyVaultUrl
$KeyVault.VaultUri -DiskEncryptionKeyId $KeyVault.ResourceId
```

After a few minutes the process will return the following:

RequestId	IsSuccess	Status	Code	ReasonPhrase
	True	OK	OK	

You can verify the encryption process by running [Get-AzVmDiskEncryptionStatus](#).

```
Get-AzVmDiskEncryptionStatus -VMName MyVM -ResourceGroupName MyResourceGroup
```

When encryption is enabled, you will see the following in the returned output:

OsVolumeEncrypted	:	Encrypted
DataVolumesEncrypted	:	NoDiskFound
OsVolumeEncryptionSettings	:	Microsoft.Azure.Management.Compute.Models.DiskEncryptionSettings
ProgressMessage	:	Provisioning succeeded

## Clean up resources

When no longer needed, you can use the [Remove-AzResourceGroup](#) cmdlet to remove the resource group, VM, and all related resources:

```
Remove-AzResourceGroup -Name "myResourceGroup"
```

## Next steps

In this quickstart, you created a virtual machine, created a Key Vault that was enable for encryption keys, and encrypted the VM. Advance to the next article to learn more about Azure Disk Encryption prerequisites for IaaS VMs.

[Azure Disk Encryption overview](#)

# Quickstart: Create and encrypt a Windows virtual machine with the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create VMs and their associated resources. In this quickstart you will use the Azure portal to deploy a Windows virtual machine, create a key vault for the storage of encryption keys, and encrypt the VM.

If you don't have an Azure subscription, create a [free account](#) before you begin.

## Sign in to Azure

Sign in to the [Azure portal](#).

## Create a virtual machine

1. Choose **Create a resource** in the upper left corner of the Azure portal.
2. In the New page, under Popular, select **Windows Server 2016 Datacenter**.
3. In the Basics tab, under Project details, make sure the correct subscription is selected.
4. For "Resource Group", select **Create new**. Enter *myResourceGroup* as the name and select **Ok**.
5. For **Virtual machine name**, enter *MyVM*.
6. For **Region**, select *(US) East US*.
7. Verify that the **Size** is *Standard D2s v3*.
8. Under **Administrator account**, select **Password**. Enter a user name and a password.

## Create a virtual machine

Complete the Basics tab then Review + create to provision a virtual machine with default customization.

< Previous

Next : Disks >

## WARNING

The "Disks" tab features an "Encryption Type" field under Disk options. This field is used to specify encryption options for **Managed Disks + CMK**, not for Azure Disk Encryption.

To avoid confusion, we suggest you skip the *Disks* tab entirely while completing this tutorial.

9. Select the "Management" tab and verify that you have a Diagnostics Storage Account. If you have no storage accounts, select "Create New", give your new account a name, and select "Ok"

The screenshot shows the 'Create a virtual machine' wizard on the 'Management' tab. A red circle highlights the 'Management' tab. A red arrow points from the 'Management' tab to a separate 'Create storage account' dialog box. The 'Create storage account' dialog has the following fields:

- Name: adestorageaccount (with a green checkmark)
- Account kind: Storage (general purpose v1)
- Performance: Standard (selected)
- Replication: Locally-redundant storage (LRS)

The 'Create storage account' dialog also has a note: "No existing storage accounts in current subscription" and a link "Create new".

10. Click "Review + Create".

11. On the **Create a virtual machine** page, you can see the details about the VM you are about to create.  
When you are ready, select **Create**.

It will take a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

## Encrypt the virtual machine

1. When the VM deployment is complete, select **Go to resource**.
2. On the left-hand sidebar, select **Disks**.
3. On the top bar, select **Additional Settings**.
4. Under **Encryption settings > Disks to encrypt**, select **OS and data disks**.

## Disk settings

Enable Access to:

Azure Virtual Machines for deployment ⓘ

Azure Resource Manager for template deployment ⓘ

Azure Disk Encryption for volume encryption ⓘ

11. Select **Review + create**.
12. After the key vault has passed validation, select **Create**. This will return you to the **Select key from Azure Key Vault** screen.
13. Leave the **Key** field blank and choose **Select**.
14. At the top of the encryption screen, click **Save**. A popup will warn you that the VM will reboot. Click **Yes**.

## Clean up resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources. To do so, select the resource group for the virtual machine, select **Delete**, then confirm the name of the resource group to delete.

## Next steps

In this quickstart, you created a Key Vault that was enable for encryption keys, created a virtual machine, and enabled the virtual machine for encryption.

[Azure Disk Encryption overview](#)

# Azure Disk Encryption scenarios on Windows VMs

9/21/2022 • 13 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Azure Disk Encryption for Windows virtual machines (VMs) uses the BitLocker feature of Windows to provide full disk encryption of the OS disk and data disk. Additionally, it provides encryption of the temporary disk when the VolumeType parameter is All.

Azure Disk Encryption is [integrated with Azure Key Vault](#) to help you control and manage the disk encryption keys and secrets. For an overview of the service, see [Azure Disk Encryption for Windows VMs](#).

You can only apply disk encryption to virtual machines of [supported VM sizes and operating systems](#). You must also meet the following prerequisites:

- [Networking requirements](#)
- [Group Policy requirements](#)
- [Encryption key storage requirements](#)

## IMPORTANT

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM. See [Azure Disk Encryption with Azure AD \(previous release\)](#) for details.
- You should [take a snapshot](#) and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the [Set-AzVMDiskEncryptionExtension cmdlet](#) to encrypt managed disks by specifying the -skipVmBackup parameter. For more information about how to back up and restore encrypted VMs, see [Back up and restore encrypted Azure VM](#).
- Encrypting or disabling encryption may cause a VM to reboot.

## Install tools and connect to Azure

Azure Disk Encryption can be enabled and managed through the [Azure CLI](#) and [Azure PowerShell](#). To do so you must install the tools locally and connect to your Azure subscription.

### Azure CLI

The [Azure CLI 2.0](#) is a command-line tool for managing Azure resources. The CLI is designed to flexibly query data, support long-running operations as non-blocking processes, and make scripting easy. You can install it locally by following the steps in [Install the Azure CLI](#).

To [Sign in to your Azure account with the Azure CLI](#), use the `az login` command.

```
az login
```

If you would like to select a tenant to sign in under, use:

```
az login --tenant <tenant>
```

If you have multiple subscriptions and want to specify a specific one, get your subscription list with [az account](#)

list and specify with [az account set](#).

```
az account list
az account set --subscription "<subscription name or ID>"
```

For more information, see [Get started with Azure CLI 2.0](#).

## Azure PowerShell

The [Azure PowerShell az module](#) provides a set of cmdlets that uses the [Azure Resource Manager](#) model for managing your Azure resources. You can use it in your browser with [Azure Cloud Shell](#), or you can install it on your local machine using the instructions in [Install the Azure PowerShell module](#).

If you already have it installed locally, make sure you use the latest version of Azure PowerShell SDK version to configure Azure Disk Encryption. Download the latest version of [Azure PowerShell release](#).

To [Sign in to your Azure account with Azure PowerShell](#), use the [Connect-AzAccount](#) cmdlet.

```
Connect-AzAccount
```

If you have multiple subscriptions and want to specify one, use the [Get-AzSubscription](#) cmdlet to list them, followed by the [Set-AzContext](#) cmdlet:

```
Set-AzContext -Subscription <SubscriptionId>
```

Running the [Get-AzContext](#) cmdlet will verify that the correct subscription has been selected.

To confirm the Azure Disk Encryption cmdlets are installed, use the [Get-command](#) cmdlet:

```
Get-command *diskencryption*
```

For more information, see [Getting started with Azure PowerShell](#).

## Enable encryption on an existing or running Windows VM

In this scenario, you can enable encryption by using the Resource Manager template, PowerShell cmdlets, or CLI commands. If you need schema information for the virtual machine extension, see the [Azure Disk Encryption for Windows extension](#) article.

### Enable encryption on existing or running VMs with Azure PowerShell

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, and key vault should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values.

```

$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId $keyVaultResourceId;

```

- Encrypt a running VM using KEK:

```

$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId $keyVaultResourceId -
KeyEncryptionKeyUrl $keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $keyVaultResourceId;

```

#### **NOTE**

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- Verify the disks are encrypted: To check on the encryption status of an IaaS VM, use the [Get-AzVmDiskEncryptionStatus](#) cmdlet.

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

#### **Enable encryption on existing or running VMs with the Azure CLI**

Use the [az vm encryption enable](#) command to enable encryption on a running IaaS virtual machine in Azure.

- Encrypt a running VM:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
```

- Encrypt a running VM using KEK:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
```

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

```
/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
```

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: [https://\[keyvault-name\].vault.azure.net/keys/\[kekname\]/\[kek-unique-id\]](https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id])

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the [az vm encryption show](#) command.

```
az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
```

To disable the encryption, see [Disable encryption and remove the encryption extension](#).

#### Using the Resource Manager template

You can enable disk encryption on existing or running IaaS Windows VMs in Azure by using the [Resource Manager template to encrypt a running Windows VM](#).

1. On the Azure quickstart template, click **Deploy to Azure**.
2. Select the subscription, resource group, location, settings, legal terms, and agreement. Click **Purchase** to enable encryption on the existing or running IaaS VM.

The following table lists the Resource Manager template parameters for existing or running VMs:

PARAMETER	DESCRIPTION
vmName	Name of the VM to run the encryption operation.
keyVaultName	Name of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet <pre>(Get-AzKeyVault -ResourceGroupName &lt;MyKeyVaultResourceGroupName&gt;).Vaultname</pre> or the Azure CLI command <pre>az keyvault list --resource-group "MyKeyVaultResourceGroup"</pre>
keyVaultResourceGroup	Name of the resource group that contains the key vault
keyEncryptionKeyURL	The URL of the key encryption key, in the format <a href="https://&lt;keyvault-name&gt;.vault.azure.net/key/&lt;key-name&gt;">https://&lt;keyvault-name&gt;.vault.azure.net/key/&lt;key-name&gt;</a> . If you do not wish to use a KEK, leave this field blank.
volumeType	Type of volume that the encryption operation is performed on. Valid values are <i>OS</i> , <i>Data</i> , and <i>All</i> .
forceUpdateTag	Pass in a unique value like a GUID every time the operation needs to be force run.

PARAMETER	DESCRIPTION
resizeOSDisk	Should the OS partition be resized to occupy full OS VHD before splitting system volume.
location	Location for all resources.

## Enable encryption on NVMe disks for Lsv2 VMs

This scenario describes enabling Azure Disk Encryption on NVMe disks for Lsv2 series VMs. The Lsv2-series features local NVMe storage. Local NVMe Disks are temporary, and data will be lost on these disks if you stop/deallocate your VM (See: [Lsv2-series](#)).

To enable encryption on NVMe disks:

1. Initialize the NVMe disks and create NTFS volumes.
2. Enable encryption on the VM with the VolumeType parameter set to All. This will enable encryption for all OS and data disks, including volumes backed by NVMe disks. For information, see [Enable encryption on an existing or running Windows VM](#).

Encryption will persist on the NVMe disks in the following scenarios:

- VM reboot
- Virtual machine scale set reimage
- Swap OS

NVMe disks will be uninitialized the following scenarios:

- Start VM after deallocation
- Service healing
- Backup

In these scenarios, the NVMe disks need to be initialized after the VM starts. To enable encryption on the NVMe disks, run command to enable Azure Disk Encryption again after the NVMe disks are initialized.

In addition to the scenarios listed in the [Unsupported Scenarios](#) section, encryption of NVMe disks is not supported for:

- VMs encrypted with Azure Disk Encryption with AAD (previous release)
- NVMe disks with storage spaces
- Azure Site Recovery of SKUs with NVMe disks (see [Support matrix for Azure VM disaster recovery between Azure regions: Replicated machines - storage](#)).

## New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can create a new VM from a pre-encrypted VHD and the associated encryption keys using PowerShell cmdlets or CLI commands.

Use the instructions in [Prepare a pre-encrypted Windows VHD](#). After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

### Encrypt VMs with pre-encrypted VHDS with Azure PowerShell

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet [Set-AzVMOSDisk](#). The example below gives you some common parameters.

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri "os.vhd" Caching ReadWrite
-Windows -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.vault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaa" -
DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-
000000000000/resourceGroups/myKvresourcegroup/providers/Microsoft.KeyVault/vaults/mytestvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

## Enable encryption on a newly added data disk

You can [add a new disk to a Windows VM using PowerShell](#), or [through the Azure portal](#).

### Enable encryption on a newly added disk with Azure PowerShell

When using PowerShell to encrypt a new disk for Windows VMs, a new sequence version should be specified. The sequence version has to be unique. The script below generates a GUID for the sequence version. In some cases, a newly added data disk might be encrypted automatically by the Azure Disk Encryption extension. Auto encryption usually occurs when the VM reboots after the new disk comes online. This is typically caused because "All" was specified for the volume type when disk encryption previously ran on the VM. If auto encryption occurs on a newly added data disk, we recommend running the Set-AzVmDiskEncryptionExtension cmdlet again with new sequence version. If your new data disk is auto encrypted and you do not wish to be encrypted, decrypt all drives first then re-encrypt with a new sequence version specifying OS for the volume type.

- Encrypt a running VM:** The script below initializes your variables and runs the Set-AzVmDiskEncryptionExtension cmdlet. The resource group, VM, and key vault should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, and MySecureVault with your values. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVmDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyVaultId $keyVaultResourceId -
VolumeType "All" -SequenceVersion $sequenceVersion;
```

- Encrypt a running VM using KEK:** This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

```

$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$KeyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$keyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;
$sequenceVersion = [Guid]::NewGuid();

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGname -VMName $vmName -
DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -DiskEncryptionKeyId $keyVaultResourceId -
KeyEncryptionKeyUrl $keyEncryptionKeyUrl -KeyEncryptionKeyVaultId $keyVaultResourceId -VolumeType
"All" -SequenceVersion $sequenceVersion;

```

#### **NOTE**

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

```
/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-
name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
```

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: [https://\[keyvault-name\].vault.azure.net/keys/\[kekname\]/\[kek-unique-id\]](https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id])

### **Enable encryption on a newly added disk with Azure CLI**

The Azure CLI command will automatically provide a new sequence version for you when you run the command to enable encryption. The example uses "All" for the volume-type parameter. You may need to change the volume-type parameter to OS if you're only encrypting the OS disk. In contrast to PowerShell syntax, the CLI does not require the user to provide a unique sequence version when enabling encryption. The CLI automatically generates and uses its own unique sequence version value.

- **Encrypt a running VM:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-
encryption-keyvault "MySecureVault" --volume-type "All"
```

- **Encrypt a running VM using KEK:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --disk-
encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault
"MySecureVaultContainingTheKEK" --volume-type "All"
```

### **Disable encryption and remove the encryption extension**

You can disable the Azure disk encryption extension, and you can remove the Azure disk encryption extension. These are two distinct operations.

To remove ADE, it is recommended that you first disable encryption and then remove the extension. If you remove the encryption extension without disabling it, the disks will still be encrypted. If you disable encryption after removing the extension, the extension will be reinstalled (to perform the decrypt operation) and will need to be removed a second time.

#### **Disable encryption**

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template. Disabling encryption does **not** remove the extension (see [Remove the encryption extension](#)).

#### WARNING

Disabling data disk encryption when both the OS and data disks have been encrypted can have unexpected results. Disable encryption on all disks instead.

Disabling encryption will start a background process of BitLocker to decrypt the disks. This process should be given sufficient time to complete before attempting to any re-enable encryption.

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the [Disable-AzVMDiskEncryption](#) cmdlet.

```
Disable-AzVMDiskEncryption -ResourceGroupName "MyVirtualMachineResourceGroup" -VMName "MySecureVM" -VolumeType "all"
```

- **Disable encryption with the Azure CLI:** To disable encryption, use the [az vm encryption disable](#) command.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --volume-type "all"
```

- **Disable encryption with a Resource Manager template:**

1. Click **Deploy to Azure** from the [Disable disk encryption on running Windows VM](#) template.
2. Select the subscription, resource group, location, VM, volume type, legal terms, and agreement.
3. Click **Purchase** to disable disk encryption on a running Windows VM.

#### Remove the encryption extension

If you want to decrypt your disks and remove the encryption extension, you must disable encryption **before** removing the extension; see [disable encryption](#).

You can remove the encryption extension using Azure PowerShell or the Azure CLI.

- **Disable disk encryption with Azure PowerShell:** To remove the encryption, use the [Remove-AzVMDiskEncryptionExtension](#) cmdlet.

```
Remove-AzVMDiskEncryptionExtension -ResourceGroupName "MyVirtualMachineResourceGroup" -VMName "MySecureVM"
```

- **Disable encryption with the Azure CLI:** To remove encryption, use the [az vm extension delete](#) command.

```
az vm extension delete -g "MyVirtualMachineResourceGroup" --vm-name "MySecureVM" -n "AzureDiskEncryptionForWindows"
```

## Unsupported scenarios

Azure Disk Encryption does not work for the following scenarios, features, and technology:

- Encrypting basic tier VM or VMs created through the classic VM creation method.
- Encrypting VMs configured with software-based RAID systems.

- Encrypting VMs configured with Storage Spaces Direct (S2D), or Windows Server versions before 2016 configured with Windows Storage Spaces.
- Integration with an on-premises key management system.
- Azure Files (shared file system).
- Network File System (NFS).
- Dynamic volumes.
- Windows Server containers, which create dynamic volumes for each container.
- Ephemeral OS disks.
- Encryption of shared/distributed file systems like (but not limited to) DFS, GFS, DRDB, and CephFS.
- Moving an encrypted VM to another subscription or region.
- Creating an image or snapshot of an encrypted VM and using it to deploy additional VMs.
- M-series VMs with Write Accelerator disks.
- Applying ADE to a VM that has disks encrypted with [server-side encryption with customer-managed keys](#) (SSE + CMK). Applying SSE + CMK to a data disk on a VM encrypted with ADE is an unsupported scenario as well.
- Migrating a VM that is encrypted with ADE, or has **ever** been encrypted with ADE, to [server-side encryption with customer-managed keys](#).
- Encrypting VMs in failover clusters.
- Encryption of [Azure ultra disks](#).

- [Azure Disk Encryption troubleshooting](#)

# Create and configure a key vault for Azure Disk Encryption on a Windows VM

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#).

## WARNING

- If you have previously used Azure Disk Encryption with Azure AD to encrypt a VM, you must continue use this option to encrypt your VM. See [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#) for details.

Creating and configuring a key vault for use with Azure Disk Encryption involves three steps:

## NOTE

You must select the option in the Azure Key Vault access policy settings to enable access to Azure Disk Encryption for volume encryption. If you have enabled the firewall on the key vault, you must go to the Networking tab on the key vault and enable access to Microsoft Trusted Services.

1. Creating a resource group, if needed.
2. Creating a key vault.
3. Setting key vault advanced access policies.

These steps are illustrated in the following quickstarts:

- [Create and encrypt a Windows VM with Azure CLI](#)
- [Create and encrypt a Windows VM with Azure PowerShell](#)

You may also, if you wish, generate or import a key encryption key (KEK).

## NOTE

The steps in this article are automated in the [Azure Disk Encryption prerequisites CLI script](#) and [Azure Disk Encryption prerequisites PowerShell script](#).

## Install tools and connect to Azure

The steps in this article can be completed with the [Azure CLI](#), the [Azure PowerShell Az module](#), or the [Azure portal](#).

While the portal is accessible through your browser, Azure CLI and Azure PowerShell require local installation; see [Azure Disk Encryption for Windows: Install tools](#) for details.

### Connect to your Azure account

Before using the Azure CLI or Azure PowerShell, you must first connect to your Azure subscription. You do so by

[Signing in with Azure CLI](#), [Signing in with Azure PowerShell](#), or supplying your credentials to the Azure portal when prompted.

```
az login
```

```
Connect-AzAccount
```

## Create a resource group

*If you already have a resource group, you can skip to [Create a key vault](#).*

A resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group using the [az group create](#) Azure CLI command, the [New-AzResourceGroup](#) Azure PowerShell command, or from the [Azure portal](#).

- [Azure portal](#)

### Azure CLI

```
az group create --name "myResourceGroup" --location eastus
```

### Azure PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

## Create a key vault

*If you already have a key vault, you can skip to [Set key vault advanced access policies](#).*

Create a key vault using the [az keyvault create](#) Azure CLI command, the [New-AzKeyVault](#) Azure PowerShell command, the [Azure portal](#), or a [Resource Manager template](#).

#### WARNING

To ensure that encryption secrets don't cross regional boundaries, you must create and use a key vault that's in the **same region and tenant** as the VMs to be encrypted.

Each Key Vault must have a unique name. Replace <your-unique-keyvault-name> with the name of your key vault in the following examples.

### Azure CLI

When creating a key vault by using the Azure CLI, add the "--enabled-for-disk-encryption" flag.

```
az keyvault create --name "<your-unique-keyvault-name>" --resource-group "myResourceGroup" --location "eastus" --enabled-for-disk-encryption
```

### Azure PowerShell

When creating a key vault using Azure PowerShell, add the "-EnabledForDiskEncryption" flag.

```
New-AzKeyVault -name "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup" -Location "eastus" -EnabledForDiskEncryption
```

## Resource Manager template

You can also create a key vault by using the [Resource Manager template](#).

1. On the Azure Quickstart Template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then click **Purchase**.

## Set key vault advanced access policies

### IMPORTANT

Newly-created key vaults have soft-delete on by default. If you are using a pre-existing key vault, you **must** enable soft-delete. See [Azure Key Vault soft-delete overview](#).

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes.

If you didn't enable your key vault for disk encryption, deployment, or template deployment at the time of creation (as demonstrated in the previous step), you must update its advanced access policies.

### Azure CLI

Use [az keyvault update](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-deployment "true"
```

- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

```
az keyvault update --name "<your-unique-keyvault-name>" --resource-group "MyResourceGroup" --enabled-for-template-deployment "true"
```

### Azure PowerShell

Use the key vault PowerShell cmdlet [Set-AzKeyVaultAccessPolicy](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForDiskEncryption
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

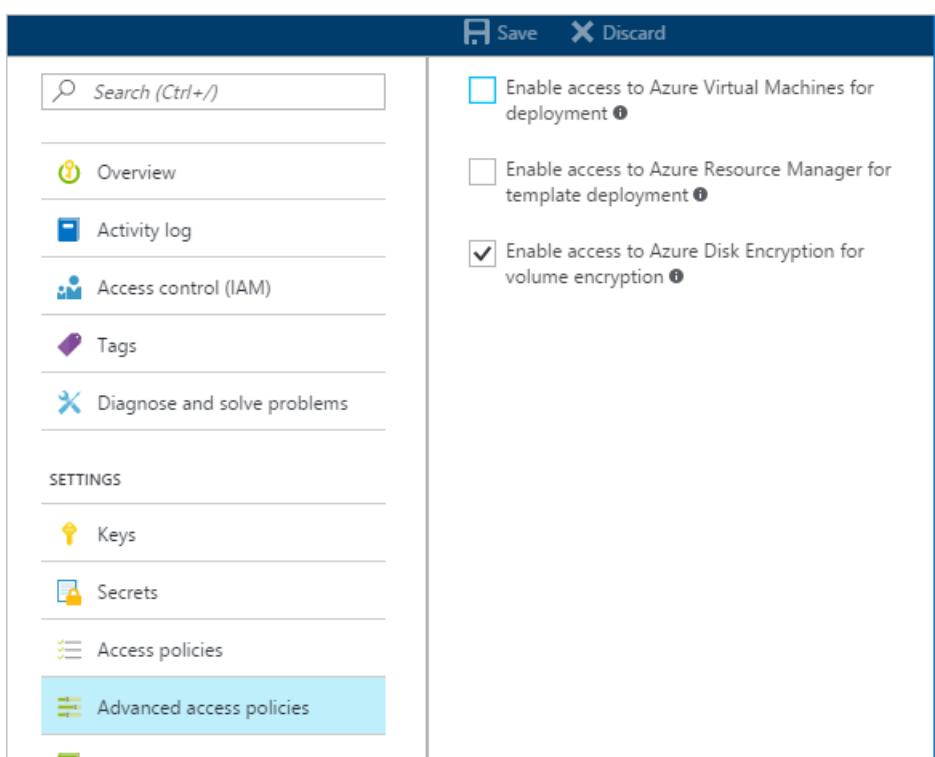

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

```
Set-AzKeyVaultAccessPolicy -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "MyResourceGroup" -EnabledForTemplateDeployment
```

## Azure portal

1. Select your key vault and go to **Access Policies**.
2. Under "Enable Access to", select the box labeled **Azure Disk Encryption for volume encryption**.
3. Select **Azure Virtual Machines for deployment** and/or **Azure Resource Manager for template deployment**, if needed.
4. Click **Save**.

## Azure Disk Encryption and auto-rotation

Although Azure Key Vault now has [key auto-rotation](#), it isn't currently compatible with Azure Disk Encryption. Specifically, Azure Disk Encryption will continue to use the original encryption key, even after it has been auto-rotated.

Rotating an encryption key won't break Azure Disk Encryption, but disabling the "old" encryption key (in other

words, the key Azure Disk Encryption is still using) will.

## Set up a key encryption key (KEK)

### IMPORTANT

The account running to enable disk encryption over the key vault must have "reader" permissions.

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

You can generate a new KEK by using the Azure CLI `az keyvault key create` command, the Azure PowerShell `Add-AzKeyVaultKey` cmdlet, or the [Azure portal](#). You must generate an RSA key type; Azure Disk Encryption doesn't currently support using Elliptic Curve keys.

You can instead import a KEK from your on-premises key management HSM. For more information, see [Key Vault Documentation](#).

Your key vault KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:

- Example of a valid secret URL:

<https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

- Example of a valid KEK URL:

<https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

### Azure CLI

Use the Azure CLI `az keyvault key create` command to generate a new KEK and store it in your key vault.

```
az keyvault key create --name "myKEK" --vault-name "<your-unique-keyvault-name>" --kty RSA --size 4096
```

You may instead import a private key by using the Azure CLI `az keyvault key import` command:

In either case, you supply the name of your KEK to the Azure CLI `az vm encryption enable` `--key-encryption-key` parameter.

```
az vm encryption enable -g "MyResourceGroup" --name "myVM" --disk-encryption-keyvault "<your-unique-keyvault-name>" --key-encryption-key "myKEK"
```

### Azure PowerShell

Use the Azure PowerShell `Add-AzKeyVaultKey` cmdlet to generate a new KEK and store it in your key vault.

```
Add-AzKeyVaultKey -Name "myKEK" -VaultName "<your-unique-keyvault-name>" -Destination "HSM" -Size 4096
```

You may instead import a private key using the Azure PowerShell `az keyvault key import` command.

In either case, you will supply the ID of your KEK key Vault and the URL of your KEK to the Azure PowerShell `Set-AzVMDiskEncryptionExtension` `-KeyEncryptionKeyVaultId` and `-KeyEncryptionKeyUrl` parameters. This example assumes that you are using the same key vault for both the disk encryption key and the KEK.

```
$KeyVault = Get-AzKeyVault -VaultName "<your-unique-keyvault-name>" -ResourceGroupName "myResourceGroup"
$KEK = Get-AzKeyVaultKey -VaultName "<your-unique-keyvault-name>" -Name "myKEK"

Set-AzVMDiskEncryptionExtension -ResourceGroupName MyResourceGroup -VMName "MyVM" -DiskEncryptionKeyVaultUrl
$KeyVault.VaultUri -DiskEncryptionKeyId $KeyVault.ResourceId -KeyEncryptionKeyId $KeyVault.ResourceId
$KeyVault.ResourceId -KeyEncryptionKeyUrl $KEK.Id -SkipVmBackup -VolumeType All
```

## Next steps

- [Azure Disk Encryption prerequisites CLI script](#)
- [Azure Disk Encryption prerequisites PowerShell script](#)
- Learn [Azure Disk Encryption scenarios on Windows VMs](#)
- Learn how to [troubleshoot Azure Disk Encryption](#)
- Read the [Azure Disk Encryption sample scripts](#)

# Azure Disk Encryption sample scripts

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article provides sample scripts for preparing pre-encrypted VHDs and other tasks.

## NOTE

All scripts refer to the latest, non-AAD version of ADE, except where noted.

## Sample PowerShell scripts for Azure Disk Encryption

- **List all encrypted VMs in your subscription**

You can find all ADE-encrypted VMs and the extension version, in all resource groups present in a subscription, using [this PowerShell script](#).

Alternatively, these cmdlets will show all ADE-encrypted VMs (but not the extension version):

```
$osVolEncrypted = {(Get-AzVMDiskEncryptionStatus -ResourceGroupName $_.ResourceGroupName -VMName
$_.Name).OsVolumeEncrypted}
$dataVolEncrypted= {(Get-AzVMDiskEncryptionStatus -ResourceGroupName $_.ResourceGroupName -VMName
$_.Name).DataVolumesEncrypted}
Get-AzVm | Format-Table @{Label="MachineName"; Expression={$.Name}}, @{Label="OsVolumeEncrypted";
Expression=$osVolEncrypted}, @{Label="DataVolumesEncrypted"; Expression=$dataVolEncrypted}
```

- **List all encrypted VMSS instances in your subscription**

You can find all ADE-encrypted VMSS instances and the extension version, in all resource groups present in a subscription, using [this PowerShell script](#).

- **List all disk encryption secrets used for encrypting VMs in a key vault**

```
Get-AzKeyVaultSecret -VaultName $KeyVaultName | where {$_.Tags.ContainsKey('DiskEncryptionKeyFileName')} |
format-table @{Label="MachineName"; Expression={$_.Tags['MachineName']}}, @{Label="VolumeLetter";
Expression={$_.Tags['VolumeLetter']}}, @{Label="EncryptionKeyURL"; Expression={$_.Id}}
```

## Using the Azure Disk Encryption prerequisites PowerShell script

If you're already familiar with the prerequisites for Azure Disk Encryption, you can use the [Azure Disk Encryption prerequisites PowerShell script](#). For an example of using this PowerShell script, see the [Encrypt a VM Quickstart](#). You can remove the comments from a section of the script, starting at line 211, to encrypt all disks for existing VMs in an existing resource group.

The following table shows which parameters can be used in the PowerShell script:

PARAMETER	DESCRIPTION	MANDATORY?
\$resourceGroupName	Name of the resource group to which the KeyVault belongs to. A new resource group with this name will be created if one doesn't exist.	True

PARAMETER	DESCRIPTION	MANDATORY?
\$keyVaultName	Name of the KeyVault in which encryption keys are to be placed. A new vault with this name will be created if one doesn't exist.	True
\$location	Location of the KeyVault. Make sure the KeyVault and VMs to be encrypted are in the same location. Get a location list with <code>Get-AzLocation</code> .	True
\$subscriptionId	Identifier of the Azure subscription to be used. You can get your Subscription ID with <code>Get-AzSubscription</code> .	True
\$aadAppName	Name of the Azure AD application that will be used to write secrets to KeyVault. A new application with this name will be created if one doesn't exist. If this app already exists, pass <code>aadClientSecret</code> parameter to the script.	False
\$aadClientSecret	Client secret of the Azure AD application that was created earlier.	False
\$keyEncryptionKeyName	Name of optional key encryption key in KeyVault. A new key with this name will be created if one doesn't exist.	False

## Resource Manager templates

### Encrypt or decrypt VMs without an Azure AD app

- [Enable disk encryption on an existing or running Windows VM](#)
- [Disable encryption on a running Windows VM](#)

### Encrypt or decrypt VMs with an Azure AD app (previous release)

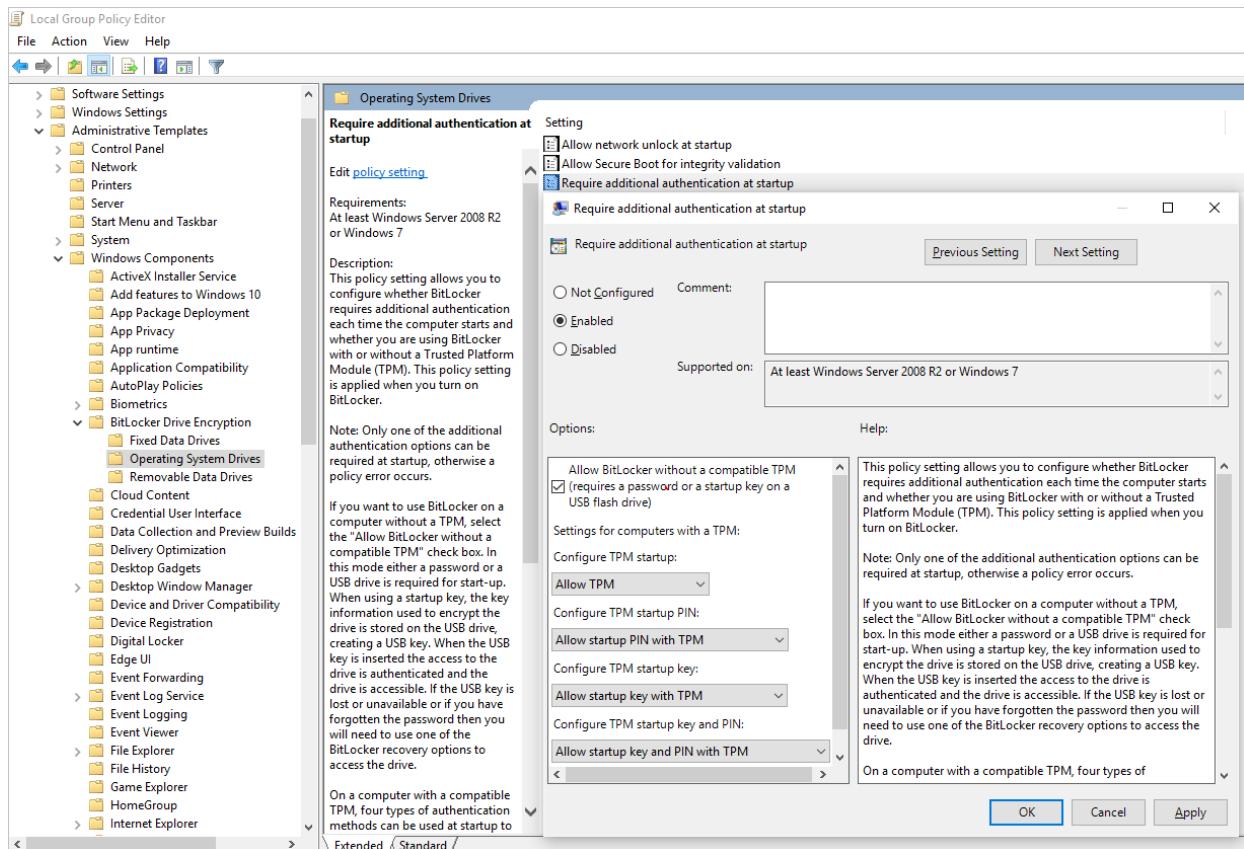

- [Enable disk encryption on an existing or running Windows VM](#)
- [Disable encryption on a running Windows VM](#)
- [Create a new encrypted managed disk from a pre-encrypted VHD/storage blob](#)
  - Creates a new encrypted managed disk provided a pre-encrypted VHD and its corresponding encryption settings

## Prepare a pre-encrypted Windows VHD

The sections that follow are necessary to prepare a pre-encrypted Windows VHD for deployment as an encrypted VHD in Azure IaaS. Use the information to prepare and boot a fresh Windows VM (VHD) on Azure Site Recovery or Azure. For more information on how to prepare and upload a VHD, see [Upload a generalized VHD and use it to create new VMs in Azure](#).

## Update group policy to allow non-TPM for OS protection

Configure the BitLocker Group Policy setting **BitLocker Drive Encryption**, which you'll find under **Local Computer Policy > Computer Configuration > Administrative Templates > Windows Components**. Change this setting to **Operating System Drives > Require additional authentication at startup > Allow BitLocker without a compatible TPM**, as shown in the following figure:

## Install BitLocker feature components

For Windows Server 2012 and later, use the following command:

```
dism /online /Enable-Feature /all /FeatureName:BitLocker /quiet /norestart
```

For Windows Server 2008 R2, use the following command:

```
ServerManagerCmd -install BitLockers
```

## Prepare the OS volume for BitLocker by using `bdehdcfg`

To compress the OS partition and prepare the machine for BitLocker, execute the `bdehdcfg` if needed:

```
bdehdcfg -target c: shrink -quiet
```

## Protect the OS volume by using BitLocker

Use the `manage-bde` command to enable encryption on the boot volume using an external key protector. Also place the external key (.bek file) on the external drive or volume. Encryption is enabled on the system/boot volume after the next reboot.

```
manage-bde -on %systemdrive% -sk [ExternalDriveOrVolume]  
reboot
```

#### NOTE

Prepare the VM with a separate data/resource VHD for getting the external key by using BitLocker.

## Upload encrypted VHD to an Azure storage account

After BitLocker encryption is enabled, the local encrypted VHD needs to be uploaded to your storage account.

```
Add-AzVhd [-Destination] <Uri> [-LocalFilePath] <FileInfo> [[-NumberOfUploaderThreads] <Int32> ] [[-BaseImageUriToPatch] <Uri> ] [[-OverWrite]] [ <CommonParameters>]
```

## Upload the secret for the pre-encrypted VM to your key vault

The disk encryption secret that you obtained previously must be uploaded as a secret in your key vault. This requires granting the set secret permission and the wrapkey permission to the account that will upload the secrets.

```
# Typically, account Id is the user principal name (in user@domain.com format)
$upn = (Get-AzureRmContext).Account.Id
Set-AzKeyVaultAccessPolicy -VaultName $kvname -UserPrincipalName $acctid -PermissionsToKeys wrapKey -
PermissionsToSecrets set

# In cloud shell, the account ID is a managed service identity, so specify the username directly
# $upn = "user@domain.com"
# Set-AzKeyVaultAccessPolicy -VaultName $kvname -UserPrincipalName $acctid -PermissionsToKeys wrapKey -
PermissionsToSecrets set

# When running as a service principal, retrieve the service principal ID from the account ID, and set access
policy to that
# $acctid = (Get-AzureRmContext).Account.Id
# $spoid = (Get-AzureRmADServicePrincipal -ServicePrincipalName $acctid).Id
# Set-AzKeyVaultAccessPolicy -VaultName $kvname -ObjectId $spoid -BypassObjectIdValidation -
PermissionsToKeys wrapKey -PermissionsToSecrets set
```

### Disk encryption secret not encrypted with a KEK

To set up the secret in your key vault, use [Set-AzKeyVaultSecret](#). The passphrase is encoded as a base64 string and then uploaded to the key vault. In addition, make sure that the following tags are set when you create the secret in the key vault.

```
# This is the passphrase that was provided for encryption during the distribution installation
$passphrase = "contoso-password"

$tags = @{
    "DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP";
    "DiskEncryptionKeyFileName" =
    "LinuxPassPhraseFileName"
}
$secretName = [guid]::NewGuid().ToString()
$secretValue = [Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($passphrase))
$secureSecretValue = ConvertTo-SecureString $secretValue -AsPlainText -Force

$secret = Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $secretName -SecretValue $secureSecretValue -
tags $tags
$secretUrl = $secret.Id
```

Use the `$secretUrl` in the next step for [attaching the OS disk without using KEK](#).

### Disk encryption secret encrypted with a KEK

Before you upload the secret to the key vault, you can optionally encrypt it by using a key encryption key. Use the wrap API to first encrypt the secret using the key encryption key. The output of this wrap operation is a base64 URL encoded string, which you can then upload as a secret by using the [Set-AzKeyVaultSecret](#) cmdlet.

```
# This is the passphrase that was provided for encryption during the distribution installation
$passphrase = "contoso-password"

Add-AzKeyVaultKey -VaultName $KeyVaultName -Name "keyencryptionkey" -Destination Software
$keyEncryptionKey = Get-AzKeyVaultKey -VaultName $KeyVault.OriginalVault.Name -Name "keyencryptionkey"

$apiversion = "2015-06-01"

#####
# Get Auth URI
#####

$uri = $KeyVault.VaultUri + "/keys"
$headers = @{}

$response = try { Invoke-RestMethod -Method GET -Uri $uri -Headers $headers } catch {
$_.Exception.Response }

$authHeader = $response.Headers["www-authenticate"]
$authUri = [regex]::match($authHeader, 'authorization="(.*)"').Groups[1].Value

Write-Host "Got Auth URI successfully"

#####
# Get Auth Token
#####

$uri = $authUri + "/oauth2/token"
$body = "grant_type=client_credentials"
$body += "&client_id=" + $AadClientId
$body += "&client_secret=" + [Uri]::EscapeDataString($AadClientSecret)
$body += "&resource=" + [Uri]::EscapeDataString("https://vault.azure.net")
$headers = @{}

$response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body $body

$access_token = $response.access_token

Write-Host "Got Auth Token successfully"

#####
# Get KEK info
#####

$uri = $KeyEncryptionKey.Id + "?api-version=" + $apiversion
$headers = @{"Authorization" = "Bearer " + $access_token}

$response = Invoke-RestMethod -Method GET -Uri $uri -Headers $headers

$keyid = $response.key.kid

Write-Host "Got KEK info successfully"

#####
# Encrypt passphrase using KEK
#####

$passphraseB64 = [Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Passphrase))
$uri = $keyid + "/encrypt?api-version=" + $apiversion
$headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" = "application/json"}
$bodyObj = @{"alg" = "RSA-OAEP"; "value" = $passphraseB64}
$body = $bodyObj | ConvertTo-Json
```

```

$response = Invoke-RestMethod -Method POST -Uri $uri -Headers $headers -Body $body

$wrappedSecret = $response.value

Write-Host "Encrypted passphrase successfully"

#####
# Store secret
#####

$secretName = [guid]::NewGuid().ToString()
$uri = $KeyVault.VaultUri + "/secrets/" + $secretName + "?api-version=" + $apiversion
$secretAttributes = @{"enabled" = $true}
$secretTags = @{"DiskEncryptionKeyEncryptionAlgorithm" = "RSA-OAEP"; "DiskEncryptionKeyFileName" =
"LinuxPassPhraseFileName"}
$headers = @{"Authorization" = "Bearer " + $access_token; "Content-Type" = "application/json"}
$bodyObj = @{"value" = $wrappedSecret; "attributes" = $secretAttributes; "tags" = $secretTags}
$body = $bodyObj | ConvertTo-Json

$response = Invoke-RestMethod -Method PUT -Uri $uri -Headers $headers -Body $body

Write-Host "Stored secret successfully"

$secretUrl = $response.id

```

Use `$KeyEncryptionKey` and `$secretUrl` in the next step for [attaching the OS disk using KEK](#).

## Specify a secret URL when you attach an OS disk

### Without using a KEK

While you're attaching the OS disk, you need to pass `$secretUrl`. The URL was generated in the "Disk-encryption secret not encrypted with a KEK" section.

```

Set-AzVMOSDisk ` 
    -VM $VirtualMachine ` 
    -Name $OSDiskName ` 
    -SourceImageUri $VhdUri ` 
    -VhdUri $OSDiskUri ` 
    -Windows ` 
    -CreateOption FromImage ` 
    -DiskEncryptionKeyVaultId $KeyVault.ResourceId ` 
    -DiskEncryptionKeyUrl $SecretUrl

```

### Using a KEK

When you attach the OS disk, pass `$KeyEncryptionKey` and `$secretUrl`. The URL was generated in the "Disk encryption secret encrypted with a KEK" section.

```

Set-AzVMOSDisk ` 
    -VM $VirtualMachine ` 
    -Name $OSDiskName ` 
    -SourceImageUri $CopiedTemplateBlobUri ` 
    -VhdUri $OSDiskUri ` 
    -Windows ` 
    -CreateOption FromImage ` 
    -DiskEncryptionKeyVaultId $KeyVault.ResourceId ` 
    -DiskEncryptionKeyUrl $SecretUrl ` 
    -KeyEncryptionKeyVaultId $KeyVault.ResourceId ` 
    -KeyEncryptionKeyURL $KeyEncryptionKey.Id

```

# Azure Disk Encryption troubleshooting guide

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs ✓ Flexible scale sets

This guide is for IT professionals, information security analysts, and cloud administrators whose organizations use Azure Disk Encryption. This article is to help with troubleshooting disk-encryption-related problems.

Before taking any of the steps below, first ensure that the VMs you are attempting to encrypt are among the [supported VM sizes and operating systems](#), and that you have met all the prerequisites:

- [Networking requirements](#)
- [Group policy requirements](#)
- [Encryption key storage requirements](#)

## Troubleshooting 'Failed to send DiskEncryptionData'

When encrypting a VM fails with the error message "Failed to send DiskEncryptionData...", it is usually caused by one of the following situations:

- Having the Key Vault existing in a different region and/or subscription than the Virtual Machine
- Advanced access policies in the Key Vault are not set to allow Azure Disk Encryption
- Key Encryption Key, when in use, has been disabled or deleted in the Key Vault
- Typo in the Resource ID or URL for the Key Vault or Key Encryption Key (KEK)
- Special characters used while naming the VM, data disks, or keys. i.e \_VMName, élite, etc
- Unsupported encryption scenarios
- Network issues that prevent the VM/Host from accessing the required resources

### Suggestions

- Make sure the Key Vault exists in the same region and subscription as the Virtual Machine
- Ensure that you have [set key vault advanced access policies](#) properly
- If you are using KEK, ensure the key exists and is enabled in Key Vault
- Check VM name, data disks, and keys follow [key vault resource naming restrictions](#)
- Check for any typos in the Key Vault name or KEK name in your PowerShell or CLI command

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string: /subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- Ensure you are not following any [unsupported scenario](#)
- Ensure you are meeting [network requirements](#) and try again

## Troubleshooting Azure Disk Encryption behind a firewall

When connectivity is restricted by a firewall, proxy requirement, or network security group (NSG) settings, the ability of the extension to perform needed tasks might be disrupted. This disruption can result in status

messages such as "Extension status not available on the VM." In expected scenarios, the encryption fails to finish. The sections that follow have some common firewall problems that you might investigate.

## Network security groups

Any network security group settings that are applied must still allow the endpoint to meet the documented network configuration [prerequisites](#) for disk encryption.

## Azure Key Vault behind a firewall

When encryption is being enabled with [Azure AD credentials](#), the target VM must allow connectivity to both Azure Active Directory endpoints and Key Vault endpoints. Current Azure Active Directory authentication endpoints are maintained in sections 56 and 59 of the [Microsoft 365 URLs and IP address ranges](#) documentation. Key Vault instructions are provided in the documentation on how to [Access Azure Key Vault behind a firewall](#).

## Azure Instance Metadata Service

The VM must be able to access the [Azure Instance Metadata service](#) endpoint ( `169.254.169.254` ) and the [virtual public IP address](#) ( `168.63.129.16` ) used for communication with Azure platform resources. Proxy configurations that alter local HTTP traffic to these addresses (for example, adding an X-Forwarded-For header) are not supported.

# Troubleshooting Windows Server 2016 Server Core

On Windows Server 2016 Server Core, the bdehdcfg component isn't available by default. This component is required by Azure Disk Encryption. It's used to split the system volume from OS volume, which is done only once for the life time of the VM. These binaries aren't required during later encryption operations.

To work around this issue, copy the following four files from a Windows Server 2016 Data Center VM to the same location on Server Core:

```
\windows\system32\bdehdcfg.exe  
\windows\system32\bdehdcfglib.dll  
\windows\system32\en-US\bdehdcfglib.dll.mui  
\windows\system32\en-US\bdehdcfg.exe.mui
```

1. Enter the following command:

```
bdehdcfg.exe -target default
```

2. This command creates a 550-MB system partition. Reboot the system.

3. Use DiskPart to check the volumes, and then proceed.

For example:

```
DISKPART> list vol

Volume ### Ltr Label Fs Type Size Status Info
----- -- -----
Volume 0 C NTFS Partition 126 GB Healthy Boot
Volume 1 NTFS Partition 550 MB Healthy System
Volume 2 D Temporary S NTFS Partition 13 GB Healthy Pagefile
```

## Troubleshooting encryption status

The portal may display a disk as encrypted even after it has been unencrypted within the VM. This can occur

when low-level commands are used to directly unencrypt the disk from within the VM, instead of using the higher level Azure Disk Encryption management commands. The higher level commands not only unencrypt the disk from within the VM, but outside of the VM they also update important platform level encryption settings and extension settings associated with the VM. If these are not kept in alignment, the platform will not be able to report encryption status or provision the VM properly.

To disable Azure Disk Encryption with PowerShell, use [Disable-AzVMDiskEncryption](#) followed by [Remove-AzVMDiskEncryptionExtension](#). Running Remove-AzVMDiskEncryptionExtension before the encryption is disabled will fail.

To disable Azure Disk Encryption with CLI, use `az vm encryption disable`.

## Next steps

In this document, you learned more about some common problems in Azure Disk Encryption and how to troubleshoot those problems. For more information about this service and its capabilities, see the following articles:

- [Apply disk encryption in Microsoft Defender for Cloud](#)
- [Azure data encryption at rest](#)

# Azure Disk Encryption with Azure AD (previous release)

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure AD application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see [Azure Disk Encryption for Windows VMs](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

This article supplements [Azure Disk Encryption for Windows VMs](#) with additional requirements and prerequisites for Azure Disk Encryption with Azure AD (previous release). The [Supported VMs and operating systems](#) section remains the same.

## Networking and Group Policy

To enable the Azure Disk Encryption feature using the older AAD parameter syntax, the IaaS VMs must meet the following network endpoint configuration requirements:

- To get a token to connect to your key vault, the IaaS VM must be able to connect to an Azure Active Directory endpoint, [login.microsoftonline.com].
- To write the encryption keys to your key vault, the IaaS VM must be able to connect to the key vault endpoint.
- The IaaS VM must be able to connect to an Azure storage endpoint that hosts the Azure extension repository and an Azure storage account that hosts the VHD files.
- If your security policy limits access from Azure VMs to the Internet, you can resolve the preceding URI and configure a specific rule to allow outbound connectivity to the IPs. For more information, see [Azure Key Vault behind a firewall](#).
- The VM to be encrypted must be configured to use TLS 1.2 as the default protocol. If TLS 1.0 has been explicitly disabled and the .NET version has not been updated to 4.6 or higher, the following registry change will enable ADE to select the more recent TLS version:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001

[HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\.NETFramework\v4.0.30319]
"SystemDefaultTlsVersions"=dword:00000001
"SchUseStrongCrypto"=dword:00000001`
```

### Group Policy:

- The Azure Disk Encryption solution uses the BitLocker external key protector for Windows IaaS VMs. For domain joined VMs, don't push any group policies that enforce TPM protectors. For information about the group policy for "Allow BitLocker without a compatible TPM," see [BitLocker Group Policy Reference](#).
- BitLocker policy on domain joined virtual machines with custom group policy must include the following

setting: [Configure user storage of BitLocker recovery information -> Allow 256-bit recovery key](#). Azure Disk Encryption will fail when custom group policy settings for BitLocker are incompatible. On machines that didn't have the correct policy setting, apply the new policy, force the new policy to update (gpupdate.exe /force), and then restarting may be required.

## Encryption key storage requirements

Azure Disk Encryption requires an Azure Key Vault to control and manage disk encryption keys and secrets. Your key vault and VMs must reside in the same Azure region and subscription.

For details, see [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#).

## Next steps

- [Creating and configuring a key vault for Azure Disk Encryption with Azure AD \(previous release\)](#)
- [Enable Azure Disk Encryption with Azure AD on Windows VMs \(previous release\)](#)
- [Azure Disk Encryption prerequisites CLI script](#)
- [Azure Disk Encryption prerequisites PowerShell script](#)

# Creating and configuring a key vault for Azure Disk Encryption with Azure AD (previous release)

9/21/2022 • 15 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure AD application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see [Azure Disk Encryption](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

Azure Disk Encryption uses Azure Key Vault to control and manage disk encryption keys and secrets. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#).

Creating and configuring a key vault for use with Azure Disk Encryption with Azure AD (previous release) involves three steps:

1. Create a key vault.
2. Set up an Azure AD application and service principal.
3. Set the key vault access policy for the Azure AD app.
4. Set key vault advanced access policies.

You may also, if you wish, generate or import a key encryption key (KEK).

See the main [Creating and configuring a key vault for Azure Disk Encryption](#) article for steps on how to [Install tools and connect to Azure](#).

## NOTE

The steps in this article are automated in the [Azure Disk Encryption prerequisites CLI script](#) and [Azure Disk Encryption prerequisites PowerShell script](#).

## Create a key vault

Azure Disk Encryption is integrated with [Azure Key Vault](#) to help you control and manage the disk-encryption keys and secrets in your key vault subscription. You can create a key vault or use an existing one for Azure Disk Encryption. For more information about key vaults, see [Get started with Azure Key Vault](#) and [Secure your key vault](#). You can use a Resource Manager template, Azure PowerShell, or the Azure CLI to create a key vault.

## WARNING

In order to make sure the encryption secrets don't cross regional boundaries, Azure Disk Encryption needs the Key Vault and the VMs to be co-located in the same region. Create and use a Key Vault that is in the same region as the VM to be encrypted.

## Create a key vault with PowerShell

You can create a key vault with Azure PowerShell using the [New-AzKeyVault](#) cmdlet. For additional cmdlets for Key Vault, see [Az.KeyVault](#).

1. Create a new resource group, if needed, with [New-AzResourceGroup](#). To list data center locations, use [Get-AzLocation](#).

```
# Get-AzLocation  
New-AzResourceGroup -Name 'MyKeyVaultResourceGroup' -Location 'East US'
```

2. Create a new key vault using [New-AzKeyVault](#)

```
New-AzKeyVault -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -Location 'East US'
```

3. Note the **Vault Name**, **Resource Group Name**, **Resource ID**, **Vault URI**, and the **Object ID** that are returned for later use when you encrypt the disks.

### Create a key vault with Azure CLI

You can manage your key vault with Azure CLI using the [az keyvault](#) commands. To create a key vault, use [az keyvault create](#).

1. Create a new resource group, if needed, with [az group create](#). To list locations, use [az account list-locations](#)

```
# To list locations: az account list-locations --output table  
az group create -n "MyKeyVaultResourceGroup" -l "East US"
```

2. Create a new key vault using [az keyvault create](#).

```
az keyvault create --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --location "East US"
```

3. Note the **Vault Name** (name), **Resource Group Name**, **Resource ID** (ID), **Vault URI**, and the **Object ID** that are returned for use later.

### Create a key vault with a Resource Manager template

You can create a key vault by using the [Resource Manager template](#).

1. On the Azure quickstart template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, Key Vault name, Object ID, legal terms, and agreement, and then click **Purchase**.

## Set up an Azure AD app and service principal

When you need encryption to be enabled on a running VM in Azure, Azure Disk Encryption generates and writes the encryption keys to your key vault. Managing encryption keys in your key vault requires Azure AD authentication. Create an Azure AD application for this purpose. For authentication purposes, you can use either client secret-based authentication or [client certificate-based Azure AD authentication](#).

### Set up an Azure AD app and service principal with Azure PowerShell

To execute the following commands, get and use the [Azure AD PowerShell module](#).

1. Use the [New-AzADApplication](#) PowerShell cmdlet to create an Azure AD application. MyApplicationHomePage and the MyApplicationUri can be any values you wish.

```

$aadClientSecret = "My AAD client secret"
$aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -AsPlainText -Force
$azureAdApplication = New-AzADApplication -DisplayName "My Application Display Name" -HomePage
"https://MyApplicationHomePage" -IdentifierUris "https://MyApplicationUri" -Password
$aadClientSecretSec
$servicePrincipal = New-AzADServicePrincipal -ApplicationId $azureAdApplication.ApplicationId -Role
Contributor

```

- The \$azureAdApplication.ApplicationId is the Azure AD ClientID and the \$aadClientSecret is the client secret that you will use later to enable Azure Disk Encryption. Safeguard the Azure AD client secret appropriately. Running `$azureAdApplication.ApplicationId` will show you the ApplicationID.

## Set up an Azure AD app and service principal with Azure CLI

You can manage your service principals with Azure CLI using the [az ad sp](#) commands. For more information, see [Create an Azure service principal](#).

- Create a new service principal.

```

az ad sp create-for-rbac --name "ServicePrincipalName" --password "My-AAD-client-secret" --role
Contributor --scopes /subscriptions/<subscription_id>

```

- The appId returned is the Azure AD ClientID used in other commands. It's also the SPN you'll use for az keyvault set-policy. The password is the client secret that you should use later to enable Azure Disk Encryption. Safeguard the Azure AD client secret appropriately.

## Set up an Azure AD app and service principal through the Azure portal

Use the steps from the [Use portal to create an Azure Active Directory application and service principal that can access resources](#) article to create an Azure AD application. Each step listed below will take you directly to the article section to complete.

- [Verify required permissions](#)
- [Create an Azure Active Directory application](#)
  - You can use any name and sign-on URL you would like when creating the application.
- [Get the application ID and the authentication key](#).
  - The authentication key is the client secret and is used as the AadClientSecret for Set-AzVMDiskEncryptionExtension.
    - The authentication key is used by the application as a credential to sign in to Azure AD. In the Azure portal, this secret is called keys, but has no relation to key vaults. Secure this secret appropriately.
  - The application ID will be used later as the AadClientId for Set-AzVMDiskEncryptionExtension and as the ServicePrincipalName for Set-AzKeyVaultAccessPolicy.

## Set the key vault access policy for the Azure AD app

To write encryption secrets to a specified Key Vault, Azure Disk Encryption needs the Client ID and the Client Secret of the Azure Active Directory application that has permissions to write secrets to the Key Vault.

### NOTE

Azure Disk Encryption requires you to configure the following access policies to your Azure AD client application: *WrapKey* and *Set* permissions.

## Set the key vault access policy for the Azure AD app with Azure PowerShell

Your Azure AD application needs rights to access the keys or secrets in the vault. Use the [Set-AzKeyVaultAccessPolicy](#) cmdlet to grant permissions to the application, using the client ID (which was generated when the application was registered) as the *-ServicePrincipalName* parameter value. To learn more, see the blog post [Azure Key Vault - Step by Step](#).

1. Set the key vault access policy for the AD application with PowerShell.

```
$keyVaultName = 'MySecureVault'  
$aadClientID = 'MyAadAppClientID'  
$KVRGname = 'MyKeyVaultResourceGroup'  
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -  
PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname
```

### Set the key vault access policy for the Azure AD app with Azure CLI

Use [az keyvault set-policy](#) to set the access policy. For more information, see [Manage Key Vault using CLI 2.0](#).

Give the service principal you created via the Azure CLI access to get secrets and wrap keys with the following command:

```
az keyvault set-policy --name "MySecureVault" --spn "<spn created with CLI/the Azure AD ClientID>" --key-  
permissions wrapKey --secret-permissions set
```

### Set the key vault access policy for the Azure AD app with the portal

1. Open the resource group with your key vault.
2. Select your key vault, go to **Access Policies**, then click **Add new**.
3. Under **Select principal**, search for the Azure AD application you created and select it.
4. For **Key permissions**, check **Wrap Key** under **Cryptographic Operations**.
5. For **Secret permissions**, check **Set** under **Secret Management Operations**.
6. Click **OK** to save the access policy.

# Set key vault advanced access policies

The Azure platform needs access to the encryption keys or secrets in your key vault to make them available to the VM for booting and decrypting the volumes. Enable disk encryption on the key vault or deployments will fail.

## Set key vault advanced access policies with Azure PowerShell

Use the key vault PowerShell cmdlet [Set-AzKeyVaultAccessPolicy](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** EnabledForDiskEncryption is required for Azure Disk encryption.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForDiskEncryption
```

- **Enable Key Vault for deployment, if needed:** Enables the Microsoft.Compute resource provider to retrieve secrets from this key vault when this key vault is referenced in resource creation, for example when creating a virtual machine.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForDeployment
```

- **Enable Key Vault for template deployment, if needed:** Enables Azure Resource Manager to get secrets from this key vault when this key vault is referenced in a template deployment.

```
Set-AzKeyVaultAccessPolicy -VaultName 'MySecureVault' -ResourceGroupName 'MyKeyVaultResourceGroup' -  
EnabledForTemplateDeployment
```

## Set key vault advanced access policies using the Azure CLI

Use [az keyvault update](#) to enable disk encryption for the key vault.

- **Enable Key Vault for disk encryption:** Enabled-for-disk-encryption is required.

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
disk-encryption "true"
```

- **Enable Key Vault for deployment, if needed:** Allow Virtual Machines to retrieve certificates stored as secrets from the vault.

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
deployment "true"
```

- **Enable Key Vault for template deployment, if needed:** Allow Resource Manager to retrieve secrets from the vault.

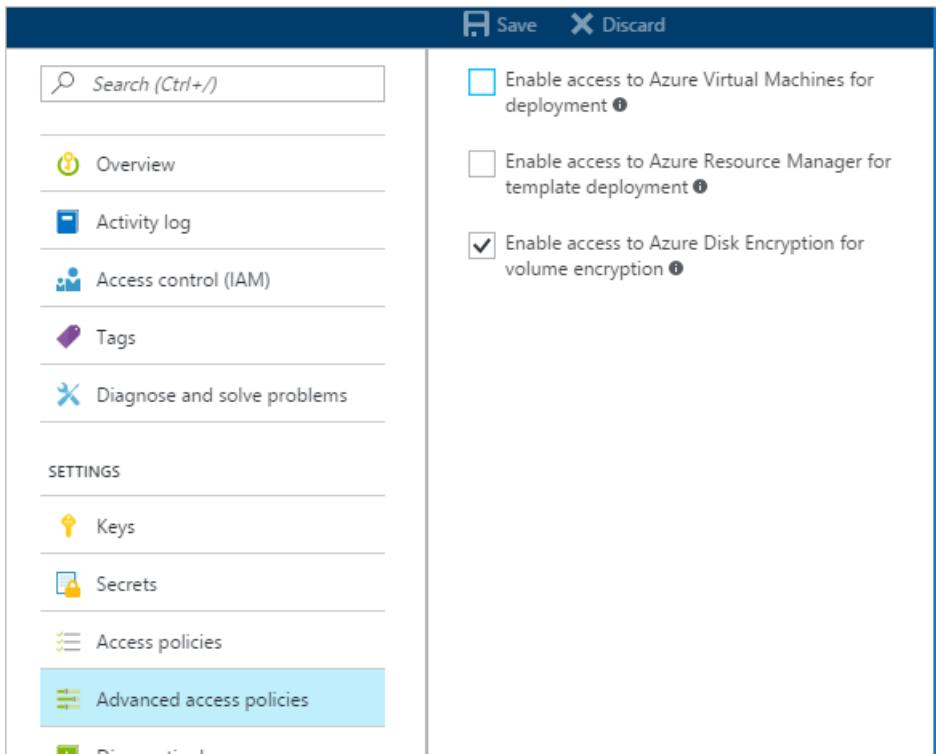

```
az keyvault update --name "MySecureVault" --resource-group "MyKeyVaultResourceGroup" --enabled-for-  
template-deployment "true"
```

## Set key vault advanced access policies through the Azure portal

1. Select your keyvault, go to Access Policies, and Click to show advanced access policies.
2. Select the box labeled Enable access to Azure Disk Encryption for volume encryption.

3. Select **Enable access to Azure Virtual Machines for deployment** and/or **Enable Access to Azure Resource Manager for template deployment**, if needed.

4. Click **Save**.

## Set up a key encryption key (optional)

If you want to use a key encryption key (KEK) for an additional layer of security for encryption keys, add a KEK to your key vault. Use the [Add-AzKeyVaultKey](#) cmdlet to create a key encryption key in the key vault. You can also import a KEK from your on-premises key management HSM. For more information, see [Key Vault Documentation](#). When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

- When generating keys, use an RSA key type. Azure Disk Encryption does not yet support using Elliptic Curve keys.
- Your key vault secret and KEK URLs must be versioned. Azure enforces this restriction of versioning. For valid secret and KEK URLs, see the following examples:
  - Example of a valid secret URL:  
<https://contosovault.vault.azure.net/secrets/EncryptionSecretWithKek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
  - Example of a valid KEK URL:  
<https://contosovault.vault.azure.net/keys/diskencryptionkek/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
- Azure Disk Encryption doesn't support specifying port numbers as part of key vault secrets and KEK URLs. For examples of non-supported and supported key vault URLs, see the following examples:
  - Unacceptable key vault URL  
<https://contosovault.vault.azure.net:443/secrets/contososecret/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>
  - Acceptable key vault URL:  
<https://contosovault.vault.azure.net/secrets/contososecret/xxxxxxxxxxxxxxxxxxxxxxxxxxxx>

### Set up a key encryption key with Azure PowerShell

Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment. This script creates all Azure Disk Encryption prerequisites and encrypts an existing IaaS VM, wrapping the disk encryption

key by using a key encryption key.

```
# Step 1: Create a new resource group and key vault in the same location.
# Fill in 'MyLocation', 'MyKeyVaultResourceGroup', and 'MySecureVault' with your values.
# Use Get-AzLocation to get available locations and use the DisplayName.
# To use an existing resource group, comment out the line for New-AzResourceGroup

$Loc = 'MyLocation';
$KVRGname = 'MyKeyVaultResourceGroup';
$keyVaultName = 'MySecureVault';
New-AzResourceGroup -Name $KVRGname -Location $Loc;
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc;
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$keyVaultResourceId = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName
$KVRGname).ResourceId;
$diskEncryptionKeyVaultUrl = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName
$KVRGname).VaultUri;

# Step 2: Create the AD application and service principal.
# Fill in 'MyAADClientSecret', "<My Application Display Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish.

$aadClientSecret = 'MyAADClientSecret';
$aadClientSecretSec = ConvertTo-SecureString -String $aadClientSecret -AsPlainText -Force;
$azureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "
<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -Password $aadClientSecretSec
$servicePrincipal = New-AzADServicePrincipal -ApplicationId $azureAdApplication.ApplicationId -Role
Contributor;
$aadClientID = $azureAdApplication.ApplicationId;

#Step 3: Enable the vault for disk encryption and set the access policy for the Azure AD application.

Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -
EnabledForDiskEncryption;
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -
PermissionsToKeys 'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname;

#Step 4: Create a new key in the key vault with the Add-AzKeyVaultKey cmdlet.
# Fill in 'MyKeyEncryptionKey' with your value.

$keyEncryptionKeyName = 'MyKeyEncryptionKey';
Add-AzKeyVaultKey -VaultName $keyVaultName -Name $keyEncryptionKeyName -Destination 'Software';
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name $keyEncryptionKeyName).Key.kid;

#Step 5: Encrypt the disks of an existing IaaS VM
# Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

$VMName = 'MySecureVM';
$VMRGName = 'MyVirtualMachineResourceGroup';
Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID $aadClientID -
AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $keyVaultResourceId;
```

## Certificate-based authentication (optional)

If you would like to use certificate authentication, you can upload one to your key vault and deploy it to the client. Before using the PowerShell script, you should be familiar with the Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

```
# Fill in "MyKeyVaultResourceGroup", "MySecureVault", and 'MyLocation' ('My location' only if needed)
```

```

$KVRGname = 'MyKeyVaultResourceGroup'
$keyVaultName= 'MySecureVault'

# Create a key vault and set enabledForDiskEncryption property on it.
# Comment out the next three lines if you already have an existing key vault enabled for encryption. No
need to set 'My location' in this case.

$Loc = 'MyLocation'
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDiskEncryption

#Setting some variables with the key vault information
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname
$DiskEncryptionKeyVaultUrl = $keyVault.VaultUri
$keyVaultResourceId = $keyVault.ResourceId

# Create the Azure AD application and associate the certificate with it.
# Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display Name>", "
<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish

$CertPath = "C:\certificates\mycert.pfx"
$CertPassword = "Password"
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

$AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "
<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -CertValue $CertValue
$ServicePrincipal = New-AzADServicePrincipal -ApplicationId $AzureAdApplication.ApplicationId -Role
Contributor

$AADClientID = $AzureAdApplication.ApplicationId
$aadClientCertThumbprint= $cert.Thumbprint

Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -PermissionsToKeys
'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname

# Upload the pfx file to the key vault.
# Fill in "MyAADCert".

$keyVaultSecretName = "MyAADCert"
$fileContentBytes = get-content $CertPath -Encoding Byte
$fileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
$jsonObject = @{
    "data" : "$filecontentencoded",
    "dataType" : "pfx",
    "password" : "$CertPassword"
}
"@

$jsonObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
$jsonEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

#Set the secret and set the key vault policy for -EnabledForDeployment

$secret = ConvertTo-SecureString -String $jsonEncoded -AsPlainText -Force
Set-AzKeyVaultSecret -VaultName $keyVaultName -Name $keyVaultSecretName -SecretValue $secret
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDeployment

# Deploy the certificate to the VM
# Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

$VMName = 'MySecureVM'
$VMRGName = 'MyVirtualMachineResourceGroup'
$CertUrl = (Get-AzKeyVaultSecret -VaultName $keyVaultName -Name $keyVaultSecretName).Id
$SourceVaultId = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname).ResourceId
$VM = Get-AzVM -ResourceGroupName $VMRGName -Name $VMName

```

```
$VM = Add-AzVMSecret -VM $VM -SourceVaultId $SourceVaultId -CertificateStore "My" -CertificateUrl $CertUrl  
Update-AzVM -VM $VM -ResourceGroupName $VMRGName  
  
#Enable encryption on the VM using Azure AD client ID and the client certificate thumbprint  
  
Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -AadClientID $AADClientID -  
aadClientCertThumbprint $AADClientCertThumbprint -DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -  
diskEncryptionKeyVaultId $KeyVaultResourceId
```

Certificate-based authentication and a KEK (optional)

If you would like to use certificate authentication and wrap the encryption key with a KEK, you can use the below script as an example. Before using the PowerShell script, you should be familiar with all of the previous Azure Disk Encryption prerequisites to understand the steps in the script. The sample script might need changes for your environment.

```

# Fill in 'MyKeyVaultResourceGroup', 'MySecureVault', and 'MyLocation' (if needed)

$KVRGname = 'MyKeyVaultResourceGroup'
$keyVaultName= 'MySecureVault'

# Create a key vault and set enabledForDiskEncryption property on it.
# Comment out the next three lines if you already have an existing key vault enabled for encryption.

$Loc = 'MyLocation'
New-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname -Location $Loc
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ResourceGroupName $KVRGname -EnabledForDiskEncryption

# Create the Azure AD application and associate the certificate with it.
# Fill in "C:\certificates\mycert.pfx", "Password", "<My Application Display Name>", "<https://MyApplicationHomePage>", and "<https://MyApplicationUri>" with your values.
# MyApplicationHomePage and the MyApplicationUri can be any values you wish

$CertPath = "C:\certificates\mycert.pfx"
$CertPassword = "Password"
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath,
$CertPassword)
$CertValue = [System.Convert]::ToBase64String($cert.GetRawCertData())

$AzureAdApplication = New-AzADApplication -DisplayName "<My Application Display Name>" -HomePage "<https://MyApplicationHomePage>" -IdentifierUris "<https://MyApplicationUri>" -CertValue $CertValue
$ServicePrincipal = New-AzADServicePrincipal -ApplicationId $AzureAdApplication.ApplicationId -Role
Contributor

$AADClientID = $AzureAdApplication.ApplicationId
$aadClientCertThumbprint= $cert.Thumbprint

## Give access for setting secrets and wrapping keys
Set-AzKeyVaultAccessPolicy -VaultName $keyVaultName -ServicePrincipalName $aadClientID -PermissionsToKeys
'WrapKey' -PermissionsToSecrets 'Set' -ResourceGroupName $KVRGname

# Upload the pfx file to the key vault.
# Fill in "MyAADCert".

$keyVaultSecretName = "MyAADCert"
$FileContentBytes = get-content $CertPath -Encoding Byte
$FileContentEncoded = [System.Convert]::ToBase64String($fileContentBytes)
    $JSONObject = @"
{
    "data" : "$filecontentencoded",
    "dataType" : "pfx",
    "password" : "$CertPassword"
}
"@
```

```

$JSONObjectBytes = [System.Text.Encoding]::UTF8.GetBytes($jsonObject)
$JSONEncoded = [System.Convert]::ToBase64String($jsonObjectBytes)

#Set the secret and set the key vault policy for deployment

$Secret = ConvertTo-SecureString -String $JSONEncoded -AsPlainText -Force
Set-AzKeyVaultSecret -VaultName $KeyVaultName -Name $KeyVaultSecretName -SecretValue $Secret
Set-AzKeyVaultAccessPolicy -VaultName $KeyVaultName -ResourceGroupName $KVRGname -EnabledForDeployment

#Setting some variables with the key vault information and generating a KEK
# Fill in 'KEKName'

$KEKName ='KEKName'
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname
$DiskEncryptionKeyVaultUrl = $keyVault.VaultUri
$keyVaultResourceId = $keyVault.ResourceId
$KEK = Add-AzKeyVaultKey -VaultName $keyVaultName -Name $KEKName -Destination "Software"
$keyEncryptionKeyUrl = $KEK.Key.kid

# Deploy the certificate to the VM
# Fill in 'MySecureVM' and 'MyVirtualMachineResourceGroup' with your values.

$VMName = 'MySecureVM';
$VMRGName = 'MyVirtualMachineResourceGroup';
$CertUrl = (Get-AzKeyVaultSecret -VaultName $keyVaultName -Name $keyVaultSecretName).Id
$SourceVaultId = (Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGName).ResourceId
$VM = Get-AzVM -ResourceGroupName $VMRGName -Name $VMName
$VM = Add-AzVMSecret -VM $VM -SourceVaultId $SourceVaultId -CertificateStore "My" -CertificateUrl $CertUrl
Update-AzVM -VM $VM -ResourceGroupName $VMRGName

#Enable encryption on the VM using Azure AD client ID and the client certificate thumbprint

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -AadClientID $AADClientID -
AadClientCertThumbprint $AADClientCertThumbprint -DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -
DiskEncryptionKeyId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyId $keyVaultResourceId

```

## Next steps

[Enable Azure Disk Encryption with Azure AD on Windows VMs \(previous release\)](#)

# Azure Disk Encryption with Azure AD for Windows VMs (previous release)

9/21/2022 • 13 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

The new release of Azure Disk Encryption eliminates the requirement for providing an Azure AD application parameter to enable VM disk encryption. With the new release, you are no longer required to provide Azure AD credentials during the enable encryption step. All new VMs must be encrypted without the Azure AD application parameters using the new release. To view instructions to enable VM disk encryption using the new release, see [Azure Disk Encryption for Windows VMs](#). VMs that were already encrypted with Azure AD application parameters are still supported and should continue to be maintained with the AAD syntax.

You can enable many disk-encryption scenarios, and the steps may vary according to the scenario. The following sections cover the scenarios in greater detail for Windows IaaS VMs. Before you can use disk encryption, the [Azure Disk Encryption prerequisites](#) need to be completed.

## IMPORTANT

- You should [take a snapshot](#) and/or create a backup before disks are encrypted. Backups ensure that a recovery option is possible if an unexpected failure occurs during encryption. VMs with managed disks require a backup before encryption occurs. Once a backup is made, you can use the [Set-AzVMDiskEncryptionExtension cmdlet](#) to encrypt managed disks by specifying the `-skipVmBackup` parameter. For more information about how to back up and restore encrypted VMs, see [Back up and restore encrypted Azure VM](#).
- Encrypting or disabling encryption may cause a VM to reboot.

## Enable encryption on new IaaS VMs created from the Marketplace

You can enable disk encryption on new IaaS Windows VM from the Marketplace in Azure using a Resource Manager template. The template creates a new encrypted Windows VM using the Windows Server 2012 gallery image.

1. On the [Resource Manager template](#), click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Click **Purchase** to deploy a new IaaS VM where encryption is enabled.
3. After you deploy the template, verify the VM encryption status using your preferred method:
  - Verify with the Azure CLI by using the [az vm encryption show](#) command.

```
az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
```

- Verify with Azure PowerShell by using the [Get-AzVmDiskEncryptionStatus cmdlet](#).

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

- Select the VM, then click on **Disks** under the **Settings** heading to verify encryption status in the portal. In the chart under **Encryption**, you'll see if it's enabled.

NAME	STATUS	LOCATION	SIZE	DISK ENCRYPTION
ADEDemoCAT	Running	Australia East	Standard_D1	Enabled
ADEPreDemoCAT	Running	Australia East	Standard_D1	Enabled
at-east	Running	East US	Standard_A1	Enabled
at-prevm10	Running	Australia East	Standard_D2	Enabled

The following table lists the Resource Manager template parameters for new VMs from the Marketplace scenario using Azure AD client ID:

PARAMETER	DESCRIPTION
adminUserName	Admin user name for the virtual machine.
adminPassword	Admin user password for the virtual machine.
newStorageAccountName	Name of the storage account to store OS and data VHDs.
vmSize	Size of the VM. Currently, only Standard A, D, and G series are supported.
virtualNetworkName	Name of the VNet that the VM NIC should belong to.
subnetName	Name of the subnet in the VNet that the VM NIC should belong to.
AADClientID	Client ID of the Azure AD application that has permissions to write secrets to your key vault.
AADClientSecret	Client secret of the Azure AD application that has permissions to write secrets to your key vault.
keyVaultURL	<p>URL of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet</p> <pre>(Get-AzKeyVault -VaultName "MyKeyVault" -ResourceGroupName "MyKeyVaultResourceGroupName").VaultURI</pre> <p>or the Azure CLI</p> <pre>az keyvault show --name "MySecureVault" --query properties.vaultUri</pre>
keyEncryptionKeyURL	<p>URL of the key encryption key that's used to encrypt the generated BitLocker key (optional).</p> <p>KeyEncryptionKeyURL is an optional parameter. You can bring your own KEK to further safeguard the data encryption key (Passphrase secret) in your key vault.</p>
keyVaultResourceGroup	Resource group of the key vault.

PARAMETER	DESCRIPTION
vmName	Name of the VM that the encryption operation is to be performed on.

## Enable encryption on existing or running IaaS Windows VMs

In this scenario, you can enable encryption by using a template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail how to enable Azure Disk Encryption.

### Enable encryption on existing or running VMs with Azure PowerShell

Use the [Set-AzVMDiskEncryptionExtension](#) cmdlet to enable encryption on a running IaaS virtual machine in Azure. For information about enabling encryption with Azure Disk Encryption by using PowerShell cmdlets, see the blog posts [Explore Azure Disk Encryption with Azure PowerShell - Part 1](#) and [Explore Azure Disk Encryption with Azure PowerShell - Part 2](#).

- **Encrypt a running VM using a client secret:** The script below initializes your variables and runs the Set-AzVMDiskEncryptionExtension cmdlet. The resource group, VM, key vault, AAD app, and client secret should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values.

```
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId;
```

- **Encrypt a running VM using KEK to wrap the client secret:** Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault.

```

$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $keyVaultResourceId;

```

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

```
/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-
name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
```

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-
name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the [Get-AzVmDiskEncryptionStatus](#) cmdlet.

```
Get-AzVmDiskEncryptionStatus -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

- **Disable disk encryption:** To disable the encryption, use the [Disable-AzureRmVMDiskEncryption](#) cmdlet.

```
Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

### Enable encryption on existing or running VMs with Azure CLI

Use the [az vm encryption enable](#) command to enable encryption on a running IaaS virtual machine in Azure.

- **Encrypt a running VM using a client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-
client-id "<my spn created with CLI/my Azure AD ClientID>" --aad-client-secret "My-AAD-client-
secret" --disk-encryption-keyvault "MySecureVault" --volume-type [All|OS|Data]
```

- **Encrypt a running VM using KEK to wrap the client secret:**

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-
client-id "<my spn created with CLI which is the Azure AD ClientID>" --aad-client-secret "My-AAD-
client-secret" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-
encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type [All|OS|Data]
```

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:

```
/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]
```

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]

- **Verify the disks are encrypted:** To check on the encryption status of an IaaS VM, use the [az vm encryption show](#) command.

```
az vm encryption show --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup"
```

- **Disable encryption:** To disable encryption, use the [az vm encryption disable](#) command.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --volume-type [ALL, DATA, OS]
```

## Using the Resource Manager template

You can enable disk encryption on existing or running IaaS Windows VMs in Azure by using the [Resource Manager template to encrypt a running Windows VM](#).

1. On the Azure quickstart template, click **Deploy to Azure**.
2. Select the subscription, resource group, resource group location, parameters, legal terms, and agreement. Click **Purchase** to enable encryption on the existing or running IaaS VM.

The following table lists the Resource Manager template parameters for existing or running VMs that use an Azure AD client ID:

PARAMETER	DESCRIPTION
AADClientID	Client ID of the Azure AD application that has permissions to write secrets to the key vault.
AADClientSecret	Client secret of the Azure AD application that has permissions to write secrets to the key vault.
keyVaultName	Name of the key vault that the BitLocker key should be uploaded to. You can get it by using the cmdlet <pre>(Get-AzKeyVault -ResourceGroupName &lt;MyKeyVaultResourceGroupName&gt;).Vaultname</pre> or the Azure CLI command <pre>az keyvault list --resource-group "MySecureGroup"</pre>
keyEncryptionKeyURL	URL of the key encryption key that's used to encrypt the generated BitLocker key. This parameter is optional if you select <b>nokek</b> in the UseExistingKek drop-down list. If you select <b>kek</b> in the UseExistingKek drop-down list, you must enter the <i>keyEncryptionKeyURL</i> value.
volumeType	Type of volume that the encryption operation is performed on. Valid values are <i>OS</i> , <i>Data</i> , and <i>All</i> .

PARAMETER	DESCRIPTION
sequenceVersion	Sequence version of the BitLocker operation. Increment this version number every time a disk-encryption operation is performed on the same VM.
vmName	Name of the VM that the encryption operation is to be performed on.

## New IaaS VMs created from customer-encrypted VHD and encryption keys

In this scenario, you can enable encrypting by using the Resource Manager template, PowerShell cmdlets, or CLI commands. The following sections explain in greater detail the Resource Manager template and CLI commands.

Use the instructions in the appendix for preparing pre-encrypted images that can be used in Azure. After the image is created, you can use the steps in the next section to create an encrypted Azure VM.

- [Prepare a pre-encrypted Windows VHD](#)

### Encrypt VMs with pre-encrypted VHDS with Azure PowerShell

You can enable disk encryption on your encrypted VHD by using the PowerShell cmdlet [Set-AzVMOSDisk](#). The example below gives you some common parameters.

```
$VirtualMachine = New-AzVMConfig -VMName "MySecureVM" -VMSize "Standard_A1"
$VirtualMachine = Set-AzVMOSDisk -VM $VirtualMachine -Name "SecureOSDisk" -VhdUri "os.vhd" Caching ReadWrite
-Windows -CreateOption "Attach" -DiskEncryptionKeyUrl
"https://mytestvault.azure.net/secrets/Test1/514ceb769c984379a7e0230bddaaaaaa" -
DiskEncryptionKeyVaultId "/subscriptions/00000000-0000-0000-0000-
0000000000/resourceGroups/myKvresourcegroup/providers/Microsoft.KeyVault/vaults/mytestvault"
New-AzVM -VM $VirtualMachine -ResourceGroupName "MyVirtualMachineResourceGroup"
```

## Enable encryption on a newly added data disk

You can [add a new disk to a Windows VM using PowerShell](#), or [through the Azure portal](#).

### Enable encryption on a newly added disk with Azure PowerShell

When using PowerShell to encrypt a new disk for Windows VMs, a new sequence version should be specified. The sequence version has to be unique. The script below generates a GUID for the sequence version. In some cases, a newly added data disk might be encrypted automatically by the Azure Disk Encryption extension. Auto encryption usually occurs when the VM reboots after the new disk comes online. This is typically caused because "All" was specified for the volume type when disk encryption previously ran on the VM. If auto encryption occurs on a newly added data disk, we recommend running the [Set-AzVmDiskEncryptionExtension](#) cmdlet again with new sequence version. If your new data disk is auto encrypted and you do not wish to be encrypted, decrypt all drives first then re-encrypt with a new sequence version specifying OS for the volume type.

- **Encrypt a running VM using a client secret:** The script below initializes your variables and runs the [Set-AzVMDiskEncryptionExtension](#) cmdlet. The resource group, VM, key vault, AAD app, and client secret should have already been created as prerequisites. Replace MyKeyVaultResourceGroup, MyVirtualMachineResourceGroup, MySecureVM, MySecureVault, My-AAD-client-ID, and My-AAD-client-secret with your values. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

```

$sequenceVersion = [Guid]::.NewGuid();
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MySecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId -VolumeType 'all' -SequenceVersion $sequenceVersion;

```

- Encrypt a running VM using KEK to wrap the client secret: Azure Disk Encryption lets you specify an existing key in your key vault to wrap disk encryption secrets that were generated while enabling encryption. When a key encryption key is specified, Azure Disk Encryption uses that key to wrap the encryption secrets before writing to Key Vault. This example uses "All" for the -VolumeType parameter, which includes both OS and Data volumes. If you only want to encrypt the OS volume, use "OS" for the -VolumeType parameter.

```

$sequenceVersion = [Guid]::.NewGuid();
$KVRGname = 'MyKeyVaultResourceGroup';
$VMRGName = 'MyVirtualMachineResourceGroup';
$vmName = 'MyExtraSecureVM';
$aadClientID = 'My-AAD-client-ID';
$aadClientSecret = 'My-AAD-client-secret';
$keyVaultName = 'MySecureVault';
$keyEncryptionKeyName = 'MyKeyEncryptionKey';
$keyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $keyVault.VaultUri;
$keyVaultResourceId = $keyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name
$keyEncryptionKeyName).Key.kid;

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $vmName -AadClientID
$aadClientID -AadClientSecret $aadClientSecret -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl
-DiskEncryptionKeyVaultId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $keyVaultResourceId -VolumeType 'all' -SequenceVersion $sequenceVersion;

```

#### NOTE

The syntax for the value of disk-encryption-keyvault parameter is the full identifier string:  
`/subscriptions/[subscription-id-guid]/resourceGroups/[resource-group-name]/providers/Microsoft.KeyVault/vaults/[keyvault-name]`

The syntax for the value of the key-encryption-key parameter is the full URI to the KEK as in: `https://[keyvault-name].vault.azure.net/keys/[kekname]/[kek-unique-id]`

## Enable encryption on a newly added disk with Azure CLI

The Azure CLI command will automatically provide a new sequence version for you when you run the command to enable encryption. Acceptable values for the volume-type parameter are All, OS, and Data. You may need to change the volume-type parameter to OS or Data if you're only encrypting one type of disk for the VM. The examples use "All" for the volume-type parameter.

- Encrypt a running VM using a client secret:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI/my Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --volume-type "All"
```

- Encrypt a running VM using KEK to wrap the client secret:

```
az vm encryption enable --resource-group "MyVirtualMachineResourceGroup" --name "MySecureVM" --aad-client-id "<my spn created with CLI which is the Azure AD ClientID>" --aad-client-secret "My-AAD-client-secret" --disk-encryption-keyvault "MySecureVault" --key-encryption-key "MyKEK_URI" --key-encryption-keyvault "MySecureVaultContainingTheKEK" --volume-type "all"
```

## Enable encryption using Azure AD client certificate-based authentication.

You can use client certificate authentication with or without KEK. Before using the PowerShell scripts, you should already have the certificate uploaded to the key vault and deployed to the VM. If you're using KEK too, the KEK should already exist. For more information, see the [Certificate-based authentication for Azure AD](#) section of the prerequisites article.

### Enable encryption using certificate-based authentication with Azure PowerShell

```
## Fill in 'MyVirtualMachineResourceGroup', 'MyKeyVaultResourceGroup', 'My-AAD-client-ID', 'MySecureVault', and 'MySecureVM'.
```

```
$VMRGName = 'MyVirtualMachineResourceGroup'
$KVRGname = 'MyKeyVaultResourceGroup';
$AADClientID ='My-AAD-client-ID';
$keyVaultName = 'MySecureVault';
$VMName = 'MySecureVM';
$KeyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$keyVaultResourceId = $KeyVault.ResourceId;

# Fill in the certificate path and the password so the thumbprint can be set as a variable.

$certPath = '$CertPath = "C:\certificates\mycert.pfx";
$CertPassword ='Password'
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath, $CertPassword)
$aadClientCertThumbprint = $cert.Thumbprint;

# Enable disk encryption using the client certificate thumbprint

Set-AzMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -AadClientID $AADClientID -
AadClientCertThumbprint $aadClientCertThumbprint -DiskEncryptionKeyVaultUrl $DiskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $keyVaultResourceId
```

### Enable encryption using certificate-based authentication and a KEK with Azure PowerShell

```

# Fill in 'MyVirtualMachineResourceGroup', 'MyKeyVaultResourceGroup', 'My-AAD-client-ID', 'MySecureVault,,,'
'MySecureVM', and "KEKName.

$VMRGName = 'MyVirtualMachineResourceGroup';
$KVRGname = 'MyKeyVaultResourceGroup';
$AADClientID ='My-AAD-client-ID';
$keyVaultName = 'MySecureVault';
$VMName = 'MySecureVM';
$keyEncryptionKeyName = 'KEKName';
$KeyVault = Get-AzKeyVault -VaultName $keyVaultName -ResourceGroupName $KVRGname;
$diskEncryptionKeyVaultUrl = $KeyVault.VaultUri;
$keyVaultResourceId = $KeyVault.ResourceId;
$keyEncryptionKeyUrl = (Get-AzKeyVaultKey -VaultName $keyVaultName -Name $keyEncryptionKeyName).Key.kid;

## Fill in the certificate path and the password so the thumbprint can be read and set as a variable.

$certPath = '$CertPath = "C:\certificates\mycert.pfx";
$CertPassword ='Password'
$Cert = New-Object System.Security.Cryptography.X509Certificates.X509Certificate2($CertPath, $CertPassword)
$aadClientCertThumbprint = $cert.Thumbprint;

# Enable disk encryption using the client certificate thumbprint and a KEK

Set-AzVMDiskEncryptionExtension -ResourceGroupName $VMRGName -VMName $VMName -AadClientID $AADClientID -
AadClientCertThumbprint $aadClientCertThumbprint -DiskEncryptionKeyVaultUrl $diskEncryptionKeyVaultUrl -
DiskEncryptionKeyVaultId $keyVaultResourceId -KeyEncryptionKeyUrl $keyEncryptionKeyUrl -
KeyEncryptionKeyVaultId $keyVaultResourceId

```

## Disable encryption

You can disable encryption using Azure PowerShell, the Azure CLI, or with a Resource Manager template.

- **Disable disk encryption with Azure PowerShell:** To disable the encryption, use the [Disable-AzureRmVMDiskEncryption](#) cmdlet.

```
Disable-AzVMDiskEncryption -ResourceGroupName 'MyVirtualMachineResourceGroup' -VMName 'MySecureVM'
```

- **Disable encryption with the Azure CLI:** To disable encryption, use the [az vm encryption disable](#) command.

```
az vm encryption disable --name "MySecureVM" --resource-group "MyVirtualMachineResourceGroup" --
volume-type [ALL, DATA, OS]
```

- **Disable encryption with a Resource Manager Template:**

1. Click **Deploy to Azure** from the [Disable disk encryption on running Windows VM](#) template.
2. Select the subscription, resource group, location, VM, legal terms, and agreement.
3. Click **Purchase** to disable disk encryption on a running Windows VM.

## Next steps

[Azure Disk Encryption overview](#)

# Using Azure ultra disks

9/21/2022 • 14 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article explains how to deploy and use an ultra disk, for conceptual information about ultra disks, refer to [What disk types are available in Azure?](#).

Azure ultra disks offer high throughput, high IOPS, and consistent low latency disk storage for Azure IaaS virtual machines (VMs). This new offering provides top of the line performance at the same availability levels as our existing disks offerings. One major benefit of ultra disks is the ability to dynamically change the performance of the SSD along with your workloads without the need to restart your VMs. Ultra disks are suited for data-intensive workloads such as SAP HANA, top tier databases, and transaction-heavy workloads.

## GA scope and limitations

Ultra disks can't be used as OS disks, they can only be created as empty data disks. Ultra disks also can't be used with some features and functionality, including disk snapshots, disk export, changing disk type, VM images, availability sets, Azure Dedicated Hosts, or Azure disk encryption. Azure Backup and Azure Site Recovery do not support ultra disks. In addition, only un-cached reads and un-cached writes are supported.

Ultra disks support a 4k physical sector size by default. A 512E sector size is available as a generally available offering with no sign-up required. While most applications are compatible with 4k sector sizes, some require 512 byte sector sizes. Oracle Database, for example, requires release 12.2 or later in order to support 4k native disks. For older versions of Oracle DB, 512 byte sector size is required.

The only infrastructure redundancy options currently available to ultra disks are availability zones. VMs using any other redundancy options cannot attach an ultra disk.

The following table outlines the regions ultra disks are available in, as well as their corresponding availability options.

### NOTE

If a region in the following list lacks availability zones that support ultra disks, then a VM in that region must be deployed without infrastructure redundancy in order to attach an ultra disk.

REDUNDANCY OPTIONS	REGIONS
Single VMs	Australia Central Brazil South Central India East Asia Germany West Central Korea Central North Central US, South Central US, West US US Gov Arizona, US Gov Texas, US Gov Virginia
One availability zone	China North 3 Qatar Central
Two availability zones	France Central

REDUNDANCY OPTIONS	REGIONS
Three availability zones	Australia East Canada Central North Europe, West Europe Japan East Southeast Asia Sweden Central UK South Central US, East US, East US 2, West US 2, West US 3

Not every VM size is available in every supported region with ultra disks. The following table lists VM series which are compatible with ultra disks.

VM TYPE	SIZES	DESCRIPTION
General purpose	<a href="#">DSv3-series</a> , <a href="#">Ddsv4-series</a> , <a href="#">Dsv4-series</a> , <a href="#">Dasv4-series</a> , <a href="#">Dsv5-series</a> , <a href="#">Ddsv5-series</a> , <a href="#">Dasv5-series</a>	Balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.
Compute optimized	<a href="#">FSv2-series</a>	High CPU-to-memory ratio. Good for medium traffic web servers, network appliances, batch processes, and application servers.
Memory optimized	<a href="#">ESv3-series</a> , <a href="#">Easv4-series</a> , <a href="#">Edsv4-series</a> , <a href="#">Esv4-series</a> , <a href="#">Esv5-series</a> , <a href="#">Edsv5-series</a> , <a href="#">Easv5-series</a> , <a href="#">Ebsv5 series</a> , <a href="#">Ebdsv5 series</a> , <a href="#">M-series</a> , <a href="#">Mv2-series</a> , <a href="#">Msv2/Mdsv2-series</a>	High memory-to-CPU ratio. Great for relational database servers, medium to large caches, and in-memory analytics.
Storage optimized	<a href="#">LSv2-series</a>	High disk throughput and IO ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases.
GPU optimized	<a href="#">NCv2-series</a> , <a href="#">NCv3-series</a> , <a href="#">NCasT4_v3-series</a> , <a href="#">ND-series</a> , <a href="#">NDv2-series</a> , <a href="#">NVv3-series</a> , <a href="#">NVv4-series</a> , <a href="#">NVadsA10 v5-series</a>	Specialized virtual machines targeted for heavy graphic rendering and video editing, as well as model training and inferencing (ND) with deep learning. Available with single or multiple GPUs.
Performance optimized	<a href="#">HB-series</a> , <a href="#">HC-series</a> , <a href="#">HBv2-series</a>	The fastest and most powerful CPU virtual machines with optional high-throughput network interfaces (RDMA).

## Determine VM size and region availability

### VMs using availability zones

To leverage ultra disks, you need to determine which availability zone you are in. Not every region supports every VM size with ultra disks. To determine if your region, zone, and VM size support ultra disks, run either of the following commands, make sure to replace the `region`, `vmSize`, and `subscription` values first:

**CLI**

```

subscription=<yourSubID>
# example value is southeastasia
region=<yourLocation>
# example value is Standard_E64s_v3
vmSize=<yourVMSize>

az vm list-skus --resource-type virtualMachines --location $region --query "[?name=='$vmSize'].locationInfo[0].zoneDetails[0].Name" --subscription $subscription

```

## PowerShell

```

$region = "southeastasia"
$vmSize = "Standard_E64s_v3"
$sku = (Get-AzComputeResourceSku | where {$_.Locations.Contains($region) -and ($_.Name -eq $vmSize) -and $_.LocationInfo[0].ZoneDetails.Count -gt 0})
if($sku){$sku[0].LocationInfo[0].ZoneDetails} Else {Write-host "$vmSize is not supported with Ultra Disk in $region region"}

```

The response will be similar to the form below, where X is the zone to use for deploying in your chosen region. X could be either 1, 2, or 3.

Preserve the **Zones** value, it represents your availability zone and you will need it in order to deploy an Ultra disk.

RESOURCE TYPE	NAME	LOCATION	ZONES	RESTRICTION	CAPABILITY	VALUE
disks	UltraSSD_LRS	eastus2	X			

### NOTE

If there was no response from the command, then the selected VM size is not supported with ultra disks in the selected region.

Now that you know which zone to deploy to, follow the deployment steps in this article to either deploy a VM with an ultra disk attached or attach an ultra disk to an existing VM.

### VMs with no redundancy options

Ultra disks deployed in select regions must be deployed without any redundancy options, for now. However, not every disk size that supports ultra disks may be in these region. To determine which disk sizes support ultra disks, you can use either of the following code snippets. Make sure to replace the `vmSize` and `subscription` values first:

```

subscription=<yourSubID>
region="westus"
# example value is Standard_E64s_v3
vmSize=<yourVMSize>

az vm list-skus --resource-type virtualMachines --location $region --query "[?name=='$vmSize'].capabilities" --subscription $subscription

```

```

$region = "westus"
$vmSize = "Standard_E64s_v3"
(Get-AzComputeResourceSku | where {$_.Locations.Contains($region) -and ($_.Name -eq $vmSize) })[0].Capabilities

```

The response will be similar to the following form, `UltraSSDAvailable True` indicates whether the VM size supports ultra disks in this region.

Name	Value
---	----
MaxResourceVolumeMB	884736
OSVhdSizeMB	1047552
vCPUs	64
HyperVGenerations	V1, V2
MemoryGB	432
MaxDataDiskCount	32
LowPriorityCapable	True
PremiumIO	True
VMDeploymentTypes	IaaS
vCPUsAvailable	64
ACUs	160
vCPUsPerCore	2
CombinedTempDiskAndCachedIOPS	128000
CombinedTempDiskAndCachedReadBytesPerSecond	1073741824
CombinedTempDiskAndCachedWriteBytesPerSecond	1073741824
CachedDiskBytes	1717986918400
UncachedDiskIOPS	80000
UncachedDiskBytesPerSecond	1258291200
EphemeralOSDiskSupported	True
AcceleratedNetworkingEnabled	True
RdmaEnabled	False
MaxNetworkInterfaces	8
UltraSSDAvailable	True

## Deploy an ultra disk using Azure Resource Manager

First, determine the VM size to deploy. For a list of supported VM sizes, see the [GA scope and limitations](#) section.

If you would like to create a VM with multiple ultra disks, refer to the sample [Create a VM with multiple ultra disks](#).

If you intend to use your own template, make sure that `apiVersion` for `Microsoft.Compute/virtualMachines` and `Microsoft.Compute/Disks` is set as `2018-06-01` (or later).

Set the disk sku to `UltraSSD_LRS`, then set the disk capacity, IOPS, availability zone, and throughput in MBps to create an ultra disk.

Once the VM is provisioned, you can partition and format the data disks and configure them for your workloads.

## Deploy an ultra disk

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)

This section covers deploying a virtual machine equipped with an ultra disk as a data disk. It assumes you have familiarity with deploying a virtual machine, if you do not, see our [Quickstart: Create a Windows virtual machine in the Azure portal](#).

1. Sign in to the [Azure portal](#) and navigate to deploy a virtual machine (VM).
2. Make sure to choose a [supported VM size and region](#).
3. Select **Availability zone** in **Availability options**.

4. Fill in the remaining entries with selections of your choice.

5. Select Disks.

The screenshot shows the 'Create a virtual machine' wizard in the Microsoft Azure portal. The 'Basics' tab is selected. The 'Instance details' section is filled out with the following values:

- Virtual machine name: myVMName
- Region: (US) West US 2
- Availability options: Availability zone
- Availability zone: 1
- Image: Ubuntu Server 18.04 LTS - Gen1
- Size: Standard\_D2s\_v3 - 2 vcpus, 8 GiB memory (\$24.50/month)

The 'Disks' tab is highlighted with a red border. Below it, the 'Review + create' button is visible.

6. On the Disks blade, select Yes for Enable Ultra Disk compatibility.

7. Select Create and attach a new disk to attach an ultra disk now.

The screenshot shows the 'Disks' blade in the Microsoft Azure portal. The 'Disk options' section includes:

- OS disk type: Premium SSD
- Enable Ultra Disk compatibility:

The 'Data disks' section displays a table with the following columns: LUN, Name, Size (GiB), Disk type, and Host caching. At the bottom of the blade, there are two buttons: 'Create and attach a new disk' and 'Attach an existing disk'.

8. On the Create a new disk blade, enter a name, then select Change size.

## Create a new disk ...

Create a new disk to store applications and data on your VM. Disk pricing varies based on factors including disk size, storage type, and number of transactions. [Learn more ↗](#)

Name *	myVMName_DataDisk_0
Source type *	None (empty disk)
Size *	<b>1024 GiB</b> Premium SSD LRS <a href="#">Change size</a>
Encryption type *	(Default) Encryption at-rest with a platform-managed key
Enable shared disk	<input type="radio"/> Yes <input checked="" type="radio"/> No

9. Change the Disk SKU to Ultra Disk.

10. Change the values of Custom disk size (GiB), Disk IOPS, and Disk throughput to ones of your choice.

11. Select OK in both blades.

### Select a disk size ...

Browse available disk sizes and their features.

Disk SKU	Max size	Performance tier	Provisioned IOPS	Provisioned through...	Max Shares	Max burst IOPS	Max burst throughput
Ultra Disk (locally-redundant storage)	65536 GiB	U	160000	2000	5	-	-

Custom disk size (GiB) \* 1024

Disk IOPS \* 2048

Disk throughput (MB/s) \* 8

12. Continue with the VM deployment, it will be the same as you would deploy any other VM.

## Deploy an ultra disk - 512 byte sector size

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)

1. Sign in to the [Azure portal](#), then search for and select Disks.

2. Select + New to create a new disk.

3. Select a region that supports ultra disks and select an availability zone, fill in the rest of the values as you desire.

4. Select **Change size**.

## Create a managed disk

Basics    Encryption    Networking    Advanced    Tags    Review + create

Select the disk type and size needed for your workload. Azure disks are designed for 99.999% availability. Azure managed disks encrypt your data at rest, by default, using Storage Service Encryption. [Learn more about disks.](#)

### Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	<input type="text" value="My Example Subscription"/>
Resource group *	<input type="text"/> <a href="#">Create new</a>

### Disk details

Disk name *	<input type="text"/>
Region *	<input type="text" value="(US) West US 2"/>
Availability zone	<input type="text" value="1"/>
Source type	<input type="text" value="None"/>
Size *	<b>1024 GiB</b> Premium SSD LRS <a href="#">Change size</a>

5. For Disk SKU select Ultra disk, then fill in the values for the desired performance and select OK.

## Select a disk size

Browse available disk sizes and their features.

Disk SKU	<input type="text" value="Ultra Disk (locally-redundant storage)"/>
Max size	Performance tier
65536 GiB	U
Custom disk size (GiB) *	<input type="text" value="1024"/>
Disk IOPS *	<input type="text" value="2048"/>
Disk throughput (MB/s) *	<input type="text" value="8"/>

6. On the Basics blade, select the Advanced tab.

7. Select 512 for Logical sector size, then select Review + Create.

## Create a managed disk

Basics   Encryption   Networking   **Advanced**   Tags   Review + create

Add additional configurations for your managed disk

### Shared disk

Allow this disk to be attached to two or more virtual machines, depending on storage type and disk size. When shared disk is enabled host caching is unavailable. [Learn more about shared disks](#)

Enable shared disk    Yes    No

### Ultra disk

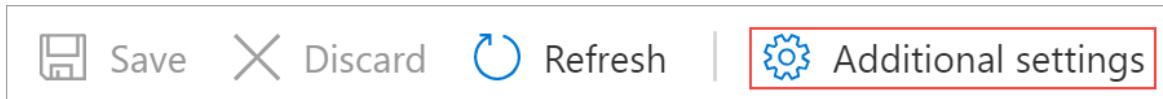

Logical sector size (bytes)    4096    512

## Attach an ultra disk

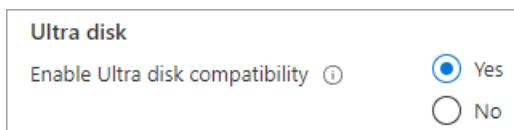

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)

Alternatively, if your existing VM is in a region/availability zone that is capable of using ultra disks, you can make use of ultra disks without having to create a new VM. By enabling ultra disks on your existing VM, then attaching them as data disks. To enable ultra disk compatibility, you must stop the VM. After you stop the VM, you may enable compatibility, then restart the VM. Once compatibility is enabled you can attach an ultra disk:

1. Navigate to your VM and stop it, wait for it to deallocate.
2. Once your VM has been deallocated, select **Disks**.
3. Select **Additional settings**.

4. Select **Yes** for **Enable Ultra Disk compatibility**.

5. Select **Save**.
6. Select **Create and attach a new disk** and fill in a name for your new disk.
7. For **Storage type** select **Ultra Disk**.
8. Change the values of **Size (GiB)**, **Max IOPS**, and **Max throughput** to ones of your choice.
9. After you are returned to your disk's blade, select **Save**.

LUN	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (MBps)	Encryption	Host caching
0	my-ultra-disk	Ultra Disk	4	120	25	Platform-managed key	None

10. Start your VM again.

## Adjust the performance of an ultra disk

- [Portal](#)
- [Azure CLI](#)
- [PowerShell](#)

Ultra disks offer a unique capability that allows you to adjust their performance. You can make these adjustments from the Azure portal, on the disks themselves.

1. Navigate to your VM and select Disks.
2. Select the ultra disk you'd like to modify the performance of.

LUN	Disk name	Storage type
0	ultra-disk-name	Ultra disk LRS

**Create and attach a new disk**   **Attach existing disks**

3. Select **Size + performance** and then make your modifications.

4. Select **Save**.

## Next steps

- [Use Azure ultra disks on Azure Kubernetes Service \(preview\).](#)
- [Migrate log disk to an ultra disk.](#)

# Deploy a Premium SSD v2 (preview)

9/21/2022 • 4 minutes to read • [Edit Online](#)

Azure Premium SSD v2 (preview) is designed for IO-intense enterprise workloads that require sub-millisecond disk latencies and high IOPS and throughput at a low cost. Premium SSD v2 is suited for a broad range of workloads such as SQL server, Oracle, MariaDB, SAP, Cassandra, Mongo DB, big data/analytics, gaming, on virtual machines or stateful containers. For conceptual information on Premium SSD v2, see [Premium SSD v2 \(preview\)](#).

## Limitations

- Premium SSD v2 disks can't be used as an OS disk.
- Currently, Premium SSD v2 disks can only be attached to zonal VMs.
- Currently, Premium SSD v2 disks can't be attached to VMs in virtual machine scale sets.
- Currently, taking snapshots aren't supported, and you can't create a Premium SSD v2 from the snapshot of another disk type.
- Currently, Premium SSD v2 disks can't be attached to VMs with encryption at host enabled.
- Currently, Premium SSD v2 disks can't be attached to VMs in Availability Sets.
- Azure Disk Encryption isn't supported for VMs with Premium SSD v2 disks.
- Azure Backup and Azure Site Recovery aren't supported for VMs with Premium SSD v2 disks.

## Regional availability

Currently only available in the following regions:

- US East
- West Europe

## Prerequisites

- [Sign-up](#) for the public preview.
- Install either the latest [Azure CLI](#) or the latest [Azure PowerShell module](#).

## Determine region availability programmatically

To use a Premium SSD v2, you need to determine the regions and zones where it's supported. Not every region and zones support Premium SSD v2. To determine regions, and zones support premium SSD v2, replace

`yourSubscriptionId` then run the following command:

- [Azure CLI](#)
- [PowerShell](#)
- [Azure portal](#)

```

az login

subscriptionId=<yourSubscriptionId>

az account set --subscription $subscriptionId

az vm list-skus --resource-type disks --query "[?name=='PremiumV2_LRS'].{Region:locationInfo[0].location,
Zones:locationInfo[0].zones}"

```

Now that you know the region and zone to deploy to, follow the deployment steps in this article to create a Premium SSD v2 disk and attach it to a VM.

## Use a Premium SSD v2

- [Azure CLI](#)
- [PowerShell](#)
- [Azure portal](#)

Create a Premium SSD v2 disk in an availability zone. Then create a VM in the same region and availability zone that supports Premium Storage and attach the disk to it. Replace the values of all the variables with your own, then run the following script:

```

## Initialize variables
diskName="yourDiskName"
resourceGroupName="yourResourceGroupName"
region="yourRegionName"
zone="yourZoneNumber"
logicalSectorSize=4096
vmName="yourVMName"
vmImage="Win2016Datacenter"
adminPassword="yourAdminPassword"
adminUserName="yourAdminUserName"
vmSize="Standard_D4s_v3"

## Create a Premium SSD v2 disk
az disk create -n $diskName -g $resourceGroupName \
--size-gb 100 \
--disk-iops-read-write 5000 \
--disk-mbps-read-write 150 \
--location $region \
--zone $zone \
--sku PremiumV2_LRS \
--logical-sector-size $logicalSectorSize

## Create the VM
az vm create -n $vmName -g $resourceGroupName \
--image $vmImage \
--zone $zone \
--authentication-type password --admin-password $adminPassword --admin-username $adminUserName \
--size $vmSize \
--location $region \
--attach-data-disks $diskName

```

## Adjust disk performance

Unlike other managed disks, the performance of a Premium SSD v2 can be configured independently of its size. For conceptual information on this, see [Premium SSD v2 performance](#).

- [Azure CLI](#)

- [PowerShell](#)
- [Azure portal](#)

The following command changes the performance of your disk, update the values as you like, then run the command:

```
az disk update `  
--subscription $subscription `  
--resource-group $rgname `  
--name $diskName `  
--set diskIopsReadWrite=5000 `  
--set diskMbpsReadWrite=200
```

## Next steps

# Virtual machine and disk performance

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article helps clarify disk performance and how it works when you combine Azure Virtual Machines and Azure disks. It also describes how you can diagnose bottlenecks for your disk IO and the changes you can make to optimize for performance.

## How does disk performance work?

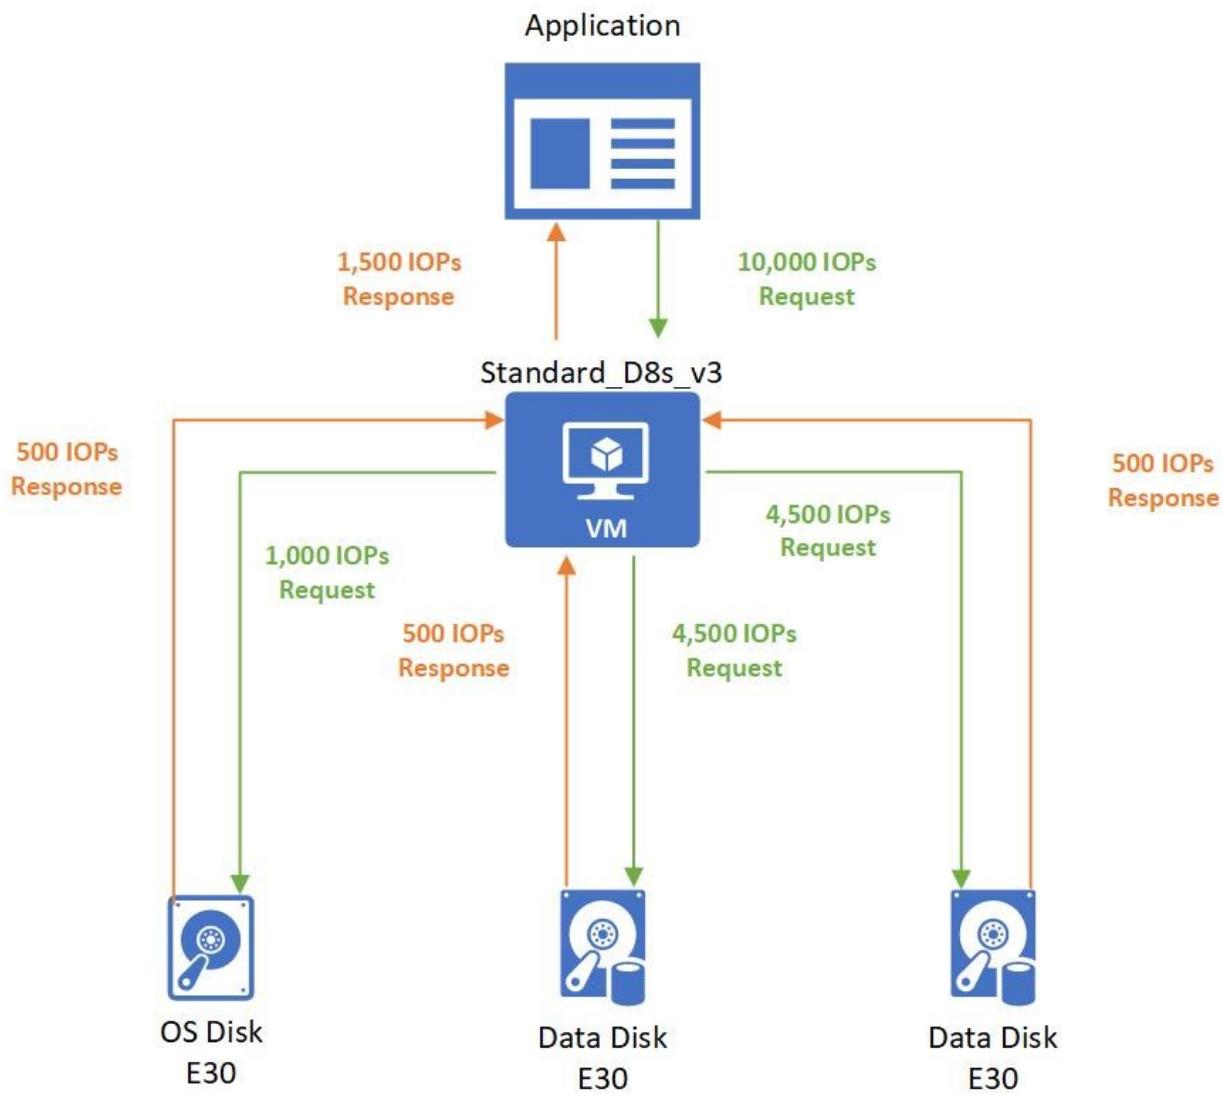

Azure virtual machines have input/output operations per second (IOPS) and throughput performance limits based on the virtual machine type and size. OS disks and data disks can be attached to virtual machines. The disks have their own IOPS and throughput limits.

Your application's performance gets capped when it requests more IOPS or throughput than what is allotted for the virtual machines or attached disks. When capped, the application experiences suboptimal performance. This can lead to negative consequences like increased latency. Let's run through a couple of examples to clarify this concept. To make these examples easy to follow, we'll only look at IOPS. But, the same logic applies to throughput.

## Disk IO capping

Setup:

- Standard\_D8s\_v3
  - Uncached IOPS: 12,800
- E30 OS disk
  - IOPS: 500
- Two E30 data disks × 2
  - IOPS: 500

The application running on the virtual machine makes a request that requires 10,000 IOPS to the virtual machine. All of which are allowed by the VM because the Standard\_D8s\_v3 virtual machine can execute up to 12,800 IOPS.

The 10,000 IOPS requests are broken down into three different requests to the different disks:

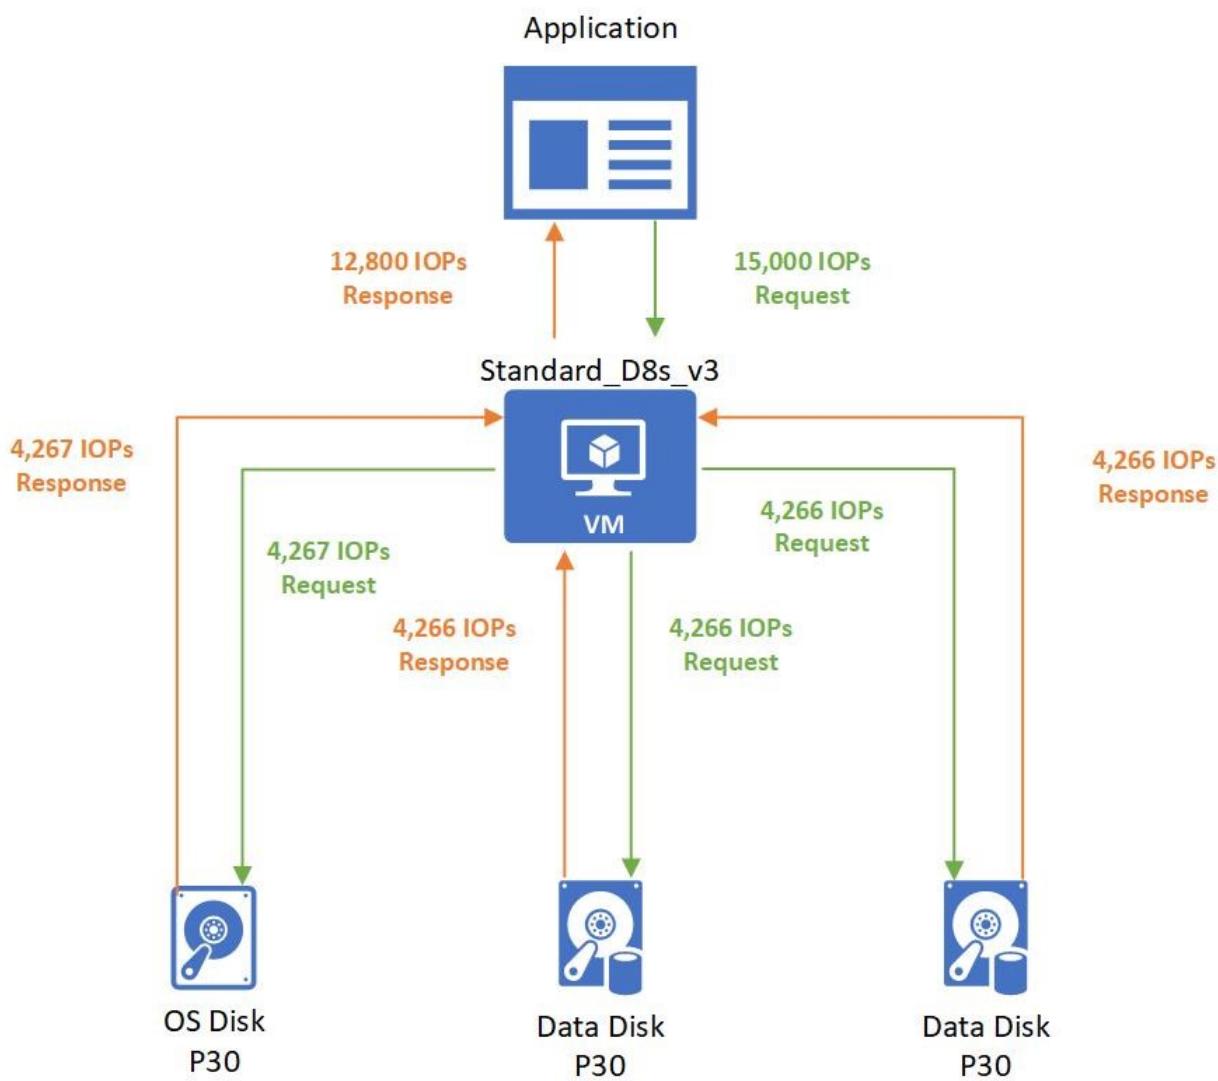

- 1,000 IOPS are requested to the operating system disk.
- 4,500 IOPS are requested to each data disk.

All attached disks are E30 disks and can only handle 500 IOPS. So, they respond back with 500 IOPS each. The application's performance is capped by the attached disks, and it can only process 1,500 IOPS. The application could work at peak performance at 10,000 IOPS if better-performing disks are used, such as Premium SSD P30 disks.

## Virtual machine IO capping

### Setup:

- Standard\_D8s\_v3
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
- Two P30 data disks × 2
  - IOPS: 5,000

The application running on the virtual machine makes a request that requires 15,000 IOPS. Unfortunately, the Standard\_D8s\_v3 virtual machine is only provisioned to handle 12,800 IOPS. The application is capped by the virtual machine limits and must allocate the allotted 12,800 IOPS.

Those 12,800 IOPS requested are broken down into three different requests to the different disks:

- 4,267 IOPS are requested to the operating system disk.
- 4,266 IOPS are requested to each data disk.

All attached disks are P30 disks that can handle 5,000 IOPS. So, they respond back with their requested amounts.

## Virtual machine uncached vs cached limits

Virtual machines that are enabled for both premium storage and premium storage caching have two different storage bandwidth limits. Let's look at the Standard\_D8s\_v3 virtual machine as an example. Here is the documentation on the [Dsv3-series](#) and the [Standard\\_D8s\\_v3](#):

Size	vCPU	Memory: GiB	Temp storage (SSD) GiB	Max data disks	<b>Max cached and temp storage throughput: IOPS/MBps</b>	<b>Max uncached disk throughput: IOPS/MBps</b>	<b>Max NICs/Expected network bandwidth (Mbps)</b>
					(cache size in GiB)		
Standard_D2s_v3	2	8	16	4	4000/32 (50)	3200/48	2/1000
Standard_D4s_v3	4	16	32	8	8000/64 (100)	6400/96	2/2000
Standard_D8s_v3	8	32	64	16	16000/128 (200)	12800/192	4/4000
Standard_D16s_v3	16	64	128	32	32000/256 (400)	25600/384	8/8000
Standard_D32s_v3	32	128	256	32	64000/512 (800)	51200/768	8/16000
Standard_D48s_v3	48	192	384	32	96000/768 (1200)	76800/1152	8/24000
Standard_D64s_v3	64	256	512	32	128000/1024 (1600)	80000/1200	8/30000

- The max *uncached* disk throughput is the default storage maximum limit that the virtual machine can handle.
- The max *cached* storage throughput limit is a separate limit when you enable host caching.

Host caching works by bringing storage closer to the VM that can be written or read to quickly. The amount of storage that is available to the VM for host caching is in the documentation. For example, you can see the Standard\_D8s\_v3 comes with 200 GiB of cache storage.

You can enable host caching when you create your virtual machine and attach disks. You can also turn on and off host caching on your disks on an existing VM.

#### OS disk

Swap OS disk						
Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (MBps)	Encryption ⓘ	Host caching ⓘ
throttling-vm-tes	Premium SSD	-	-	-	SSE with PMK	<input checked="" type="checkbox"/> Read/write

#### Data disks

Filter by name

Showing 2 of 2 attached data disks

Create and attach a new disk  Attach existing disks							
LUN ⓘ	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (MBps)	Encryption ⓘ	Host caching ⓘ
0	throttling-vm-test_DataDisk_0	Premium SSD	-	-	-	SSE with PMK	<input checked="" type="checkbox"/> Read-only
1	throttling-vm-test_DataDisk_1	Premium SSD	-	-	-	SSE with PMK	<input checked="" type="checkbox"/> Read/write

You can adjust the host caching to match your workload requirements for each disk. You can set your host caching to be:

- Read-only:** For workloads that only do read operations
- Read/write:** For workloads that do a balance of read and write operations

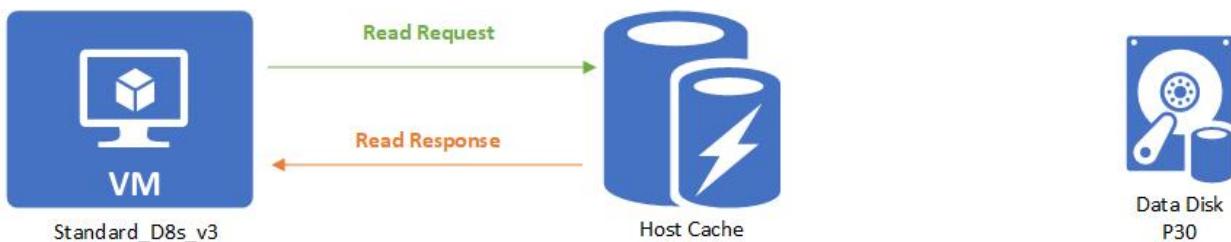

If your workload doesn't follow either of these patterns, we don't recommend that you use host caching.

Let's run through a couple examples of different host cache settings to see how it affects the data flow and performance. In this first example, we'll look at what happens with IO requests when the host caching setting is set to **Read-only**.

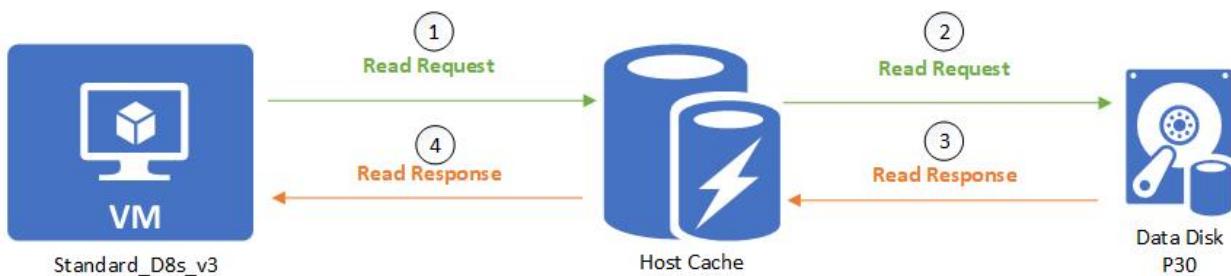

## Setup:

- Standard\_D8s\_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 data disk
  - IOPS: 5,000
  - Host caching: **Read-only**

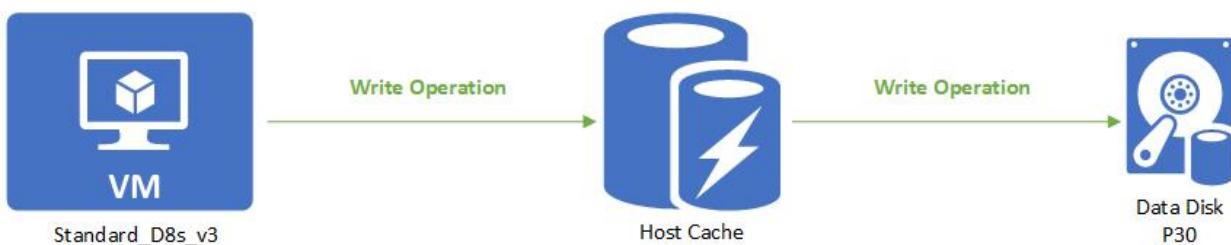

When a read is performed and the desired data is available on the cache, the cache returns the requested data. There is no need to read from the disk. This read is counted toward the VM's cached limits.

When a read is performed and the desired data is *not* available on the cache, the read request is relayed to the disk. Then the disk surfaces it to both the cache and the VM. This read is counted toward both the VM's uncached limit and the VM's cached limit.

When a write is performed, the write has to be written to both the cache and the disk before it is considered complete. This write is counted toward the VM's uncached limit and the VM's cached limit.

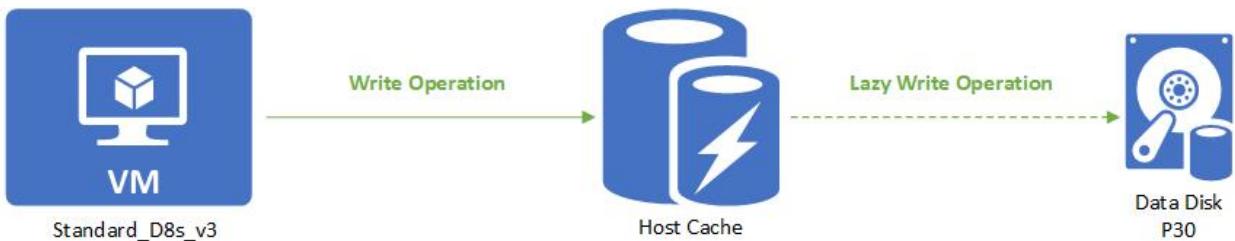

Next let's look at what happens with IO requests when the host cache setting is set to **Read/write**.

## Setup:

- Standard\_D8s\_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 data disk
  - IOPS: 5,000
  - Host caching: **Read/write**

A read is handled the same way as a read-only. Writes are the only thing that's different with read/write caching. When writing with host caching is set to **Read/write**, the write only needs to be written to the host cache to be

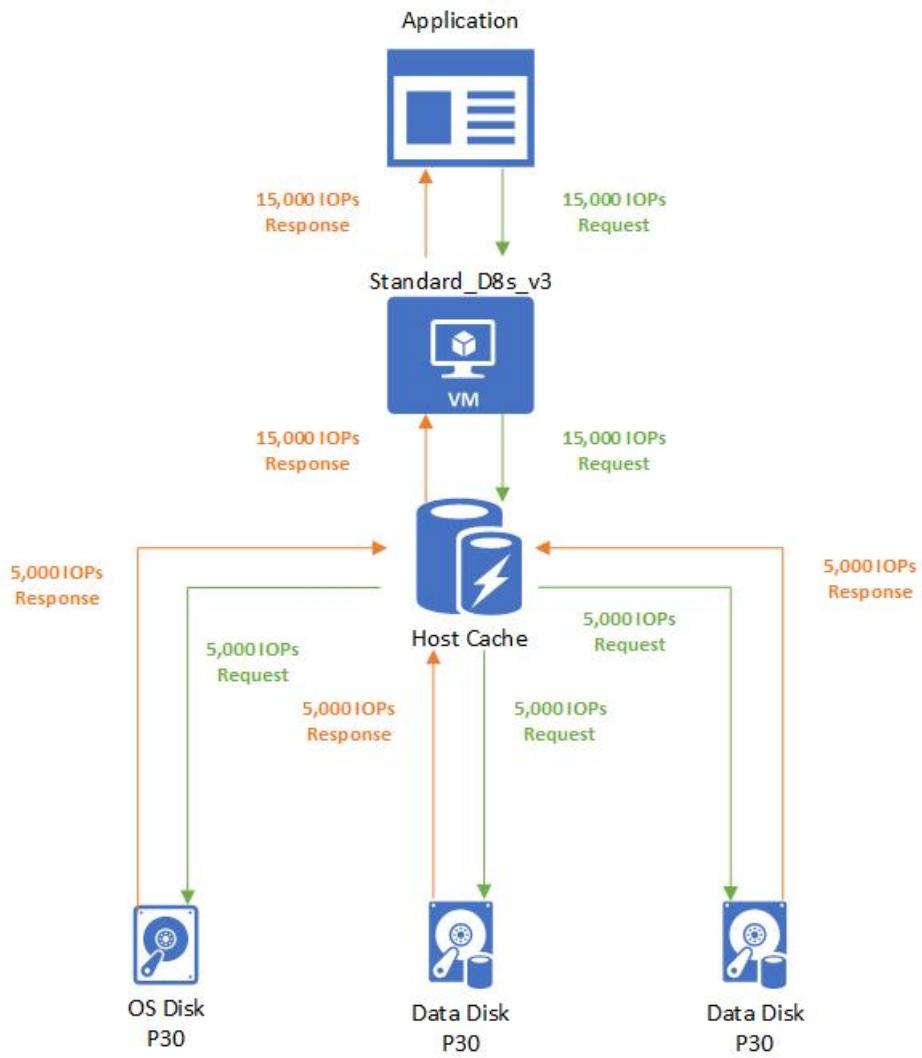

considered complete. The write is then lazily written to the disk as a background process. This means that a write is counted toward cached IO when it is written to the cache. When it is lazily written to the disk, it counts toward the uncached IO.

Let's continue with our Standard\_D8s\_v3 virtual machine. Except this time, we'll enable host caching on the disks. Also, now the VM's IOPS limit is 16,000 IOPS. Attached to the VM are three underlying P30 disks that can each handle 5,000 IOPS.

#### Setup:

- Standard\_D8s\_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**

The application uses a Standard\_D8s\_v3 virtual machine with caching enabled. It makes a request for 15,000 IOPS. The requests are broken down as 5,000 IOPS to each underlying disk attached. No performance capping occurs.

## Combined uncached and cached limits

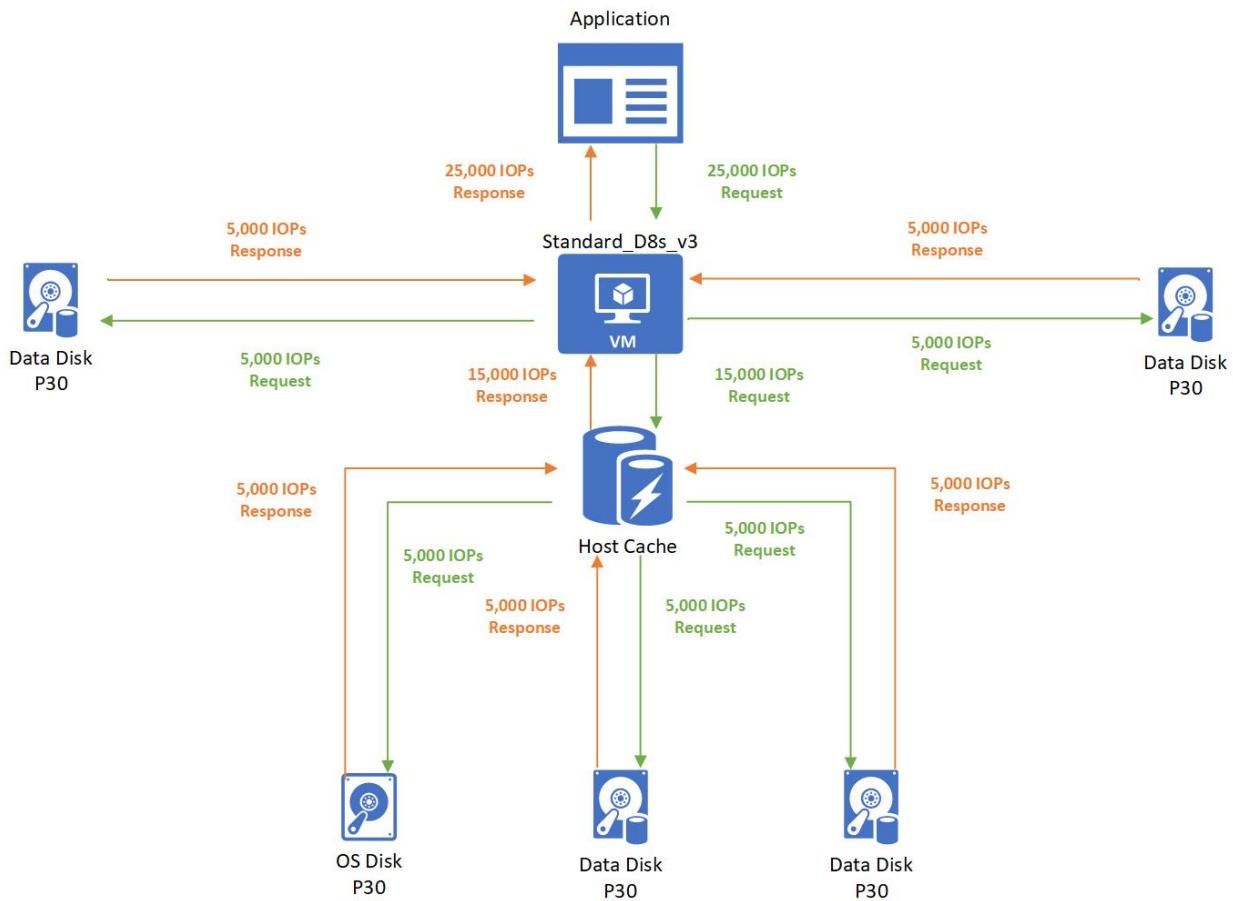

A virtual machine's cached limits are separate from its uncached limits. This means you can enable host caching on disks attached to a VM while not enabling host caching on other disks. This configuration allows your virtual machines to get a total storage IO of the cached limit plus the uncached limit.

Let's run through an example to help you understand how these limits work together. We'll continue with the Standard\_D8s\_v3 virtual machine and premium disks attached configuration.

### Setup:

- Standard\_D8s\_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2

- IOPS: 5,000
- Host caching: **Disabled**

In this case, the application running on a Standard\_D8s\_v3 virtual machine makes a request for 25,000 IOPS. The request is broken down as 5,000 IOPS to each of the attached disks. Three disks use host caching and two disks don't use host caching.

- Since the three disks that use host caching are within the cached limits of 16,000, those requests are successfully completed. No storage performance capping occurs.
- Since the two disks that don't use host caching are within the uncached limits of 12,800, those requests are also successfully completed. No capping occurs.

# Understand how your reservation discount is applied to Azure disk storage

9/21/2022 • 2 minutes to read • [Edit Online](#)

After you purchase Azure disk reserved capacity, a reservation discount is automatically applied to disk resources that match the terms of your reservation. The reservation discount applies to disk SKUs only. Disk snapshots are charged at pay-as-you-go rates.

For more information about Azure disk reservation, see [Save costs with Azure disk reservation](#). For information about pricing for Azure disk reservation, see [Azure Managed Disks pricing](#).

## How the reservation discount is applied

The Azure disk reservation discount is a use-it-or-lose-it discount. It's applied to managed disk resources hourly. For a given hour, if you have no managed disk resources that meet the reservation terms, you lose a reservation quantity for that hour. Unused hours don't carry forward.

When you delete a resource, the reservation discount automatically applies to another matching resource in the specified scope. If no matching resource is found, the reserved hours are lost.

## Discount examples

The following examples show how the Azure disk reservation discount applies depending on your deployment.

Suppose you purchase and reserve 100 P30 disks in the US West 2 region for a one-year term. Each disk has approximately 1 TiB of storage. Assume the cost of this sample reservation is \$140,100. You can choose to pay either the full amount up front or fixed monthly installments of \$11,675 for the next 12 months.

The following scenarios describe what happens if you underuse, overuse, or tier your reserved capacity. For these examples, assume you've signed up for a monthly reservation-payment plan.

### **Underusing your capacity**

Suppose you deploy only 99 of your 100 reserved Azure premium solid-state drive (SSD) P30 disks for an hour within the reservation period. The remaining P30 disk isn't applied during that hour. It also doesn't carry over.

### **Overusing your capacity**

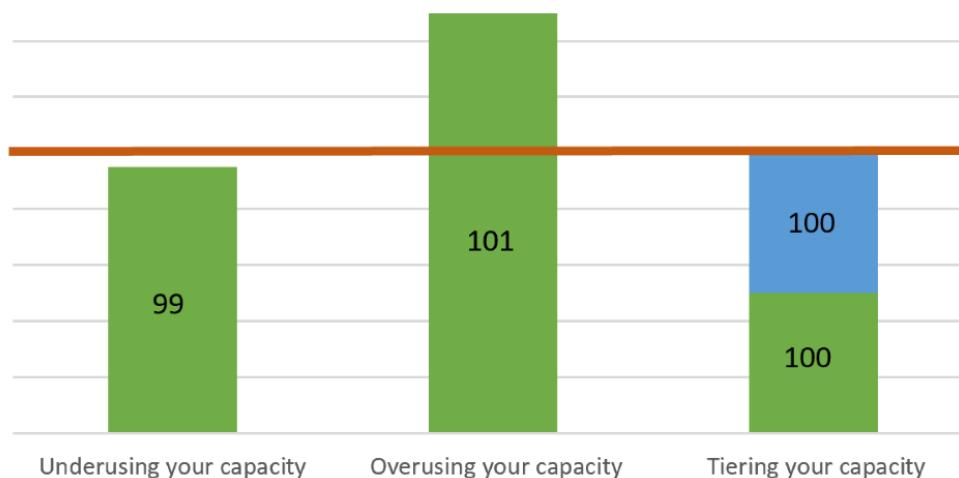

Suppose that for an hour within the reservation period, you use 101 premium SSD P30 disks. The reservation discount applies only to 100 P30 disks. The remaining P30 disk is charged at pay-as-you-go rates for that hour. For the next hour, if your usage goes down to 100 P30 disks, all usage is covered by the reservation.

### **Tiering your capacity**

Suppose that in a given hour within your reservation period, you want to use a total of 200 P30 premium SSDs. Also suppose you use only 100 for the first 30 minutes. During this period, your use is fully covered because you made a reservation for 100 P30 disks. If you then discontinue the use of the first 100 (so that you're using zero) and then begin to use the other 100 for the remaining 30 minutes, that usage is also covered under your reservation.

## Reserved disks example scenarios

# Reduce costs with Azure Disks Reservation

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Save on your Azure Disk Storage usage with reserved capacity. Azure Disk Storage reservations combined with Azure Reserved Virtual Machine Instances let you lower your total virtual machine (VM) costs. The reservation discount is applied automatically to the matching disks in the selected reservation scope. Because of this automatic application, you don't need to assign a reservation to a managed disk to get the discounts.

Discounts are applied hourly depending on the disk usage. Unused reserved capacity doesn't carry over. Azure Disk Storage reservation discounts don't apply to unmanaged disks, ultra disks, or page blob consumption.

## Determine your storage needs

Before you purchase a reservation, determine your storage needs. Currently, Azure Disk Storage reservations are available only for select Azure premium SSD SKUs. The SKU of a premium SSD determines the disk's size and performance.

When determining your storage needs, don't think of disks based on just capacity. For example, you can't have a reservation for a P40 disk and use that to pay for two smaller P30 disks. When purchasing a reservation, you're only purchasing a reservation for the total number of disks per SKU.

A disk reservation is made per disk SKU. As a result, the reservation consumption is based on the unit of the disk SKUs instead of the provided size.

For example, assume you reserve one P40 disk that has 2 TiB of provisioned storage capacity. Also assume you allocate only two P30 disks. The P40 reservation in that case doesn't account for P30 consumption, and you pay the pay-as-you-go rate on the P30 disks.

## Purchase considerations

We recommend the following practices when considering disk reservation purchase:

- Analyze your usage information to help determine which reservations you should purchase. Make sure you track the usage in disk SKUs instead of provisioned or used disk capacity.

- Examine your disk reservation along with your VM reservation. We highly recommend making reservations for both VM usage and disk usage for maximum savings. You can start with determining the right VM reservation and then evaluate the disk reservation. Generally, you'll have a standard configuration for each of your workloads. For example, a SQL Server server might have two P40 data disks and one P30 operating system disk.

This kind of pattern can help you determine the reserved amount you might purchase. This approach can simplify the evaluation process and ensure that you have an aligned plan for both your VM and disks. The plan contains considerations like subscriptions or regions.

## Purchase restrictions

Reservation discounts are currently unavailable for the following:

- Unmanaged disks or page blobs.
- Standard SSDs or standard hard-disk drives (HDDs).
- Premium SSD SKUs smaller than P30: P1, P2, P3, P4, P6, P10, P15, and P20 SSD SKUs.
- Disks in Azure Government, Azure Germany, or Azure China regions.

In rare circumstances, Azure limits the purchase of new reservations to a subset of disk SKUs because of low capacity in a region.

## Buy a disk reservation

You can purchase Azure Disk Storage reservations through the [Azure portal](#). You can pay for the reservation either up front or with monthly payments. For more information about purchasing with monthly payments, see [Purchase reservations with monthly payments](#).

Follow these steps to purchase reserved capacity:

- Go to the [Purchase reservations](#) pane in the Azure portal.
- Select **Azure Managed Disks** to purchase a reservation.

The screenshot shows the 'Purchase reservations' pane in the Azure portal. It displays various service options with their descriptions and 'Buy' buttons. The 'Azure Managed Disks' option is highlighted with a red border.

Service	Description	Action
<b>Virtual machine</b> By Microsoft Corp.	Save on virtual machine costs by buying reserved instances for 1 or 3 years	Buy
<b>SQL Database</b> By Microsoft Corp.	Save on SQL Database compute costs by buying reserved vCores for 1 or 3 years	Buy
<b>Azure SQL Data Warehouse</b> By Microsoft Corp.	Save up to 65% on SQL Data Warehouse costs by buying reserved capacity for 1 or 3 years	Buy

Select Cancel

- After you specify the values for your reservation, the Azure portal displays the cost. The portal also shows the discount percentage over pay-as-you-go billing. Select **Next** to continue to the **Purchase reservations** pane.
- On the **Purchase reservations** pane, you can name your reservation and select the total quantity of reservations you want to make. The number of reservations maps to the number of disks. For example, if you want to reserve a hundred disks, enter the **Quantity** value 100.
- Review the total cost of the reservation.

Reservation name	Product	Scope	Unit price	Quantity	Subtotal (% Discount)	Billing frequency
Disk_RI_01-14-2020_10-31	Premium SSD Managed Disks   P30   West Europe   One Year	Shared	<price>	1	<subtotal>	Upfront

Next: Review + buy Total reservation cost <total-cost>

After you purchase a reservation, it's automatically applied to any existing Disk Storage resources that match the reservation terms. If you haven't created any Disk Storage resources yet, the reservation applies whenever you create a resource that matches the reservation terms. In either case, the reservation term begins immediately after a successful purchase.

## Cancel, exchange, or refund reservations

You can cancel, exchange, or refund reservations within certain limitations. For more information, see [Self-service exchanges and refunds for Azure Reservations](#).

## Expiration of a reservation

When a reservation expires, any Azure Disk Storage capacity that you use under that reservation is billed at the pay-as-you-go rate. Reservations don't renew automatically.

You'll receive an email notification 30 days before the expiration of the reservation and again on the expiration date. To continue taking advantage of the cost savings that a reservation provides, renew it no later than the expiration date.

# Azure premium storage: design for high performance

9/21/2022 • 36 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article provides guidelines for building high performance applications using Azure Premium Storage. You can use the instructions provided in this document combined with performance best practices applicable to technologies used by your application. To illustrate the guidelines, we have used SQL Server running on Premium Storage as an example throughout this document.

While we address performance scenarios for the Storage layer in this article, you will need to optimize the application layer. For example, if you are hosting a SharePoint Farm on Azure Premium Storage, you can use the SQL Server examples from this article to optimize the database server. Additionally, optimize the SharePoint Farm's Web server and Application server to get the most performance.

This article will help answer following common questions about optimizing application performance on Azure Premium Storage,

- How to measure your application performance?
- Why are you not seeing expected high performance?
- Which factors influence your application performance on Premium Storage?
- How do these factors influence performance of your application on Premium Storage?
- How can you optimize for IOPS, Bandwidth and Latency?

We have provided these guidelines specifically for Premium Storage because workloads running on Premium Storage are highly performance sensitive. We have provided examples where appropriate. You can also apply some of these guidelines to applications running on IaaS VMs with Standard Storage disks.

## NOTE

Sometimes, what appears to be a disk performance issue is actually a network bottleneck. In these situations, you should optimize your [network performance](#).

If you are looking to benchmark your disk, see our articles on benchmarking a disk:

- For Linux: [Benchmark your application on Azure Disk Storage](#)
- For Windows: [Benchmarking a disk](#).

If your VM supports accelerated networking, you should make sure it is enabled. If it is not enabled, you can enable it on already deployed VMs on both [Windows](#) and [Linux](#).

Before you begin, if you are new to Premium Storage, first read the [Select an Azure disk type for IaaS VMs](#) and [Scalability targets for premium page blob storage accounts](#).

## Application performance indicators

We assess whether an application is performing well or not using performance indicators like, how fast an application is processing a user request, how much data an application is processing per request, how many requests an application is processing in a specific period of time, how long a user has to wait to get a response after submitting their request. The technical terms for these performance indicators are, IOPS, Throughput or

Bandwidth, and Latency.

In this section, we will discuss the common performance indicators in the context of Premium Storage. In the following section, Gathering Application Requirements, you will learn how to measure these performance indicators for your application. Later in [Optimize application performance](#), you will learn about the factors affecting these performance indicators and recommendations to optimize them.

## IOPS

IOPS, or Input/output Operations Per Second, is the number of requests that your application is sending to the storage disks in one second. An input/output operation could be read or write, sequential, or random. Online Transaction Processing (OLTP) applications like an online retail website need to process many concurrent user requests immediately. The user requests are insert and update intensive database transactions, which the application must process quickly. Therefore, OLTP applications require very high IOPS. Such applications handle millions of small and random IO requests. If you have such an application, you must design the application infrastructure to optimize for IOPS. In [Optimize application performance](#), we discuss in detail all the factors that you must consider to get high IOPS.

When you attach a premium storage disk to your high scale VM, Azure provisions for you a guaranteed number of IOPS as per the disk specification. For example, a P50 disk provisions 7500 IOPS. Each high scale VM size also has a specific IOPS limit that it can sustain. For example, a Standard GS5 VM has 80,000 IOPS limit.

## Throughput

Throughput, or bandwidth is the amount of data that your application is sending to the storage disks in a specified interval. If your application is performing input/output operations with large IO unit sizes, it requires high throughput. Data warehouse applications tend to issue scan intensive operations that access large portions of data at a time and commonly perform bulk operations. In other words, such applications require higher throughput. If you have such an application, you must design its infrastructure to optimize for throughput. In the next section, we discuss in detail the factors you must tune to achieve this.

When you attach a premium storage disk to a high scale VM, Azure provisions throughput as per that disk specification. For example, a P50 disk provisions 250 MB per second disk throughput. Each high scale VM size also has a specific throughput limit that it can sustain. For example, Standard GS5 VM has a maximum throughput of 2,000 MB per second.

There is a relation between throughput and IOPS as shown in the formula below.

$$\text{IOPS} \times \text{IO Size} = \text{Throughput}$$

Therefore, it is important to determine the optimal throughput and IOPS values that your application requires. As you try to optimize one, the other also gets affected. In [Optimize application performance](#), we will discuss in more details about optimizing IOPS and Throughput.

## Latency

Latency is the time it takes an application to receive a single request, send it to the storage disks and send the response to the client. This is a critical measure of an application's performance in addition to IOPS and Throughput. The Latency of a premium storage disk is the time it takes to retrieve the information for a request and communicate it back to your application. Premium Storage provides consistent low latencies. Premium Disks are designed to provide single-digit millisecond latencies for most IO operations. If you enable `ReadOnly` host caching on premium storage disks, you can get much lower read latency. We discuss Disk Caching in more detail in [Disk caching](#).

When you are optimizing your application to get higher IOPS and Throughput, it will affect the latency of your application. After tuning the application performance, always evaluate the latency of the application to avoid unexpected high latency behavior.

The following control plane operations on Managed Disks may involve movement of the Disk from one Storage location to another. This is orchestrated via background copy of data that can take several hours to complete, typically less than 24 hours depending on the amount of data in the disks. During that time your application can experience higher than usual read latency as some reads can get redirected to the original location and can take longer to complete. There is no impact on write latency during this period.

- Update the storage type.
- Detach and attach a disk from one VM to another.
- Create a managed disk from a VHD.
- Create a managed disk from a snapshot.
- Convert unmanaged disks to managed disks.

## Performance Application Checklist for disks

The first step in designing high-performance applications running on Azure Premium Storage is understanding the performance requirements of your application. After you have gathered performance requirements, you can optimize your application to achieve the most optimal performance.

In the previous section, we explained the common performance indicators, IOPS, Throughput, and Latency. You must identify which of these performance indicators are critical to your application to deliver the desired user experience. For example, high IOPS matters most to OLTP applications processing millions of transactions in a second. Whereas, high Throughput is critical for Data Warehouse applications processing large amounts of data in a second. Extremely low Latency is crucial for real-time applications like live video streaming websites.

Next, measure the maximum performance requirements of your application throughout its lifetime. Use the sample checklist below as a start. Record the maximum performance requirements during normal, peak, and off-hours workload periods. By identifying requirements for all workloads levels, you will be able to determine the overall performance requirement of your application. For example, the normal workload of an e-commerce website will be the transactions it serves during most days in a year. The peak workload of the website will be the transactions it serves during holiday season or special sale events. The peak workload is typically experienced for a limited period, but can require your application to scale two or more times its normal operation. Find out the 50 percentile, 90 percentile, and 99 percentile requirements. This helps filter out any outliers in the performance requirements and you can focus your efforts on optimizing for the right values.

## Application performance requirements checklist

PERFORMANCE REQUIREMENTS	50 PERCENTILE	90 PERCENTILE	99 PERCENTILE
Max. Transactions per second			
% Read operations			
% Write operations			
% Random operations			
% Sequential operations			

PERFORMANCE REQUIREMENTS	50 PERCENTILE	90 PERCENTILE	99 PERCENTILE
IO request size			
Average Throughput			
Max. Throughput			
Min. Latency			
Average Latency			
Max. CPU			
Average CPU			
Max. Memory			
Average Memory			
Queue Depth			

#### NOTE

You should consider scaling these numbers based on expected future growth of your application. It is a good idea to plan for growth ahead of time, because it could be harder to change the infrastructure for improving performance later.

If you have an existing application and want to move to Premium Storage, first build the checklist above for the existing application. Then, build a prototype of your application on Premium Storage and design the application based on guidelines described in [Optimize application performance](#). The next article describes the tools you can use to gather the performance measurements.

#### Counters to measure application performance requirements

The best way to measure performance requirements of your application, is to use performance-monitoring tools provided by the operating system of the server. You can use PerfMon for Windows and iostat for Linux. These tools capture counters corresponding to each measure explained in the above section. You must capture the values of these counters when your application is running its normal, peak, and off-hours workloads.

The PerfMon counters are available for processor, memory and, each logical disk and physical disk of your server. When you use premium storage disks with a VM, the physical disk counters are for each premium storage disk, and logical disk counters are for each volume created on the premium storage disks. You must capture the values for the disks that host your application workload. If there is a one to one mapping between logical and physical disks, you can refer to physical disk counters; otherwise refer to the logical disk counters. On Linux, the iostat command generates a CPU and disk utilization report. The disk utilization report provides statistics per physical device or partition. If you have a database server with its data and logs on separate disks, collect this data for both disks. Below table describes counters for disks, processors, and memory:

COUNTER	DESCRIPTION	PERFMON	IOSTAT
IOPS or Transactions per second	Number of I/O requests issued to the storage disk per second.	Disk Reads/sec Disk Writes/sec	tps r/s w/s

COUNTER	DESCRIPTION	PERFMON	IOSTAT
Disk Reads and Writes	% of Reads and Write operations performed on the disk.	% Disk Read Time % Disk Write Time	r/s w/s
Throughput	Amount of data read from or written to the disk per second.	Disk Read Bytes/sec Disk Write Bytes/sec	kB_read/s kB_wrtn/s
Latency	Total time to complete a disk IO request.	Average Disk sec/Read Average disk sec/Write	await svctm
IO size	The size of I/O requests issued to the storage disks.	Average Disk Bytes/Read Average Disk Bytes/Write	avgrq-sz
Queue Depth	Number of outstanding I/O requests waiting to be read from or written to the storage disk.	Current Disk Queue Length	avgqu-sz
Max. Memory	Amount of memory required to run application smoothly	% Committed Bytes in Use	Use vmstat
Max. CPU	Amount CPU required to run application smoothly	% Processor time	%util

Learn more about [iostat](#) and [PerfMon](#).

## Optimize application performance

The main factors that influence performance of an application running on Premium Storage are Nature of IO requests, VM size, Disk size, Number of disks, disk caching, multithreading, and queue depth. You can control some of these factors with knobs provided by the system. Most applications may not give you an option to alter the IO size and Queue Depth directly. For example, if you are using SQL Server, you cannot choose the IO size and queue depth. SQL Server chooses the optimal IO size and queue depth values to get the most performance. It is important to understand the effects of both types of factors on your application performance, so that you can provision appropriate resources to meet performance needs.

Throughout this section, refer to the application requirements checklist that you created, to identify how much you need to optimize your application performance. Based on that, you will be able to determine which factors from this section you will need to tune. To witness the effects of each factor on your application performance, run benchmarking tools on your application setup. Refer to the Benchmarking article, linked at the end, for steps to run common benchmarking tools on Windows and Linux VMs.

### Optimize IOPS, throughput, and latency at a glance

The table below summarizes performance factors and the steps necessary to optimize IOPS, throughput, and latency. The sections following this summary will describe each factor in much more depth.

For more information on VM sizes and on the IOPS, throughput, and latency available for each type of VM, see [Sizes for virtual machines in Azure](#).

	IOPS	Throughput	Latency
<b>Example Scenario</b>	Enterprise OLTP application requiring very high transactions per second rate.	Enterprise Data warehousing application processing large amounts of data.	Near real-time applications requiring instant responses to user requests, like online gaming.
<b>Performance factors</b>			
<b>IO size</b>	Smaller IO size yields higher IOPS.	Larger IO size to yields higher Throughput.	
<b>VM size</b>	Use a VM size that offers IOPS greater than your application requirement.	Use a VM size with throughput limit greater than your application requirement.	Use a VM size that offers scale limits greater than your application requirement.
<b>Disk size</b>	Use a disk size that offers IOPS greater than your application requirement.	Use a disk size with Throughput limit greater than your application requirement.	Use a disk size that offers scale limits greater than your application requirement.
<b>VM and Disk Scale Limits</b>	IOPS limit of the VM size chosen should be greater than total IOPS driven by storage disks attached to it.	Throughput limit of the VM size chosen should be greater than total Throughput driven by premium storage disks attached to it.	Scale limits of the VM size chosen must be greater than total scale limits of attached premium storage disks.
<b>Disk Caching</b>	Enable ReadOnly Cache on premium storage disks with Read heavy operations to get higher Read IOPS.		Enable ReadOnly Cache on premium storage disks with Read heavy operations to get very low Read latencies.
<b>Disk Striping</b>	Use multiple disks and stripe them together to get a combined higher IOPS and Throughput limit. The combined limit per VM should be higher than the combined limits of attached premium disks.		
<b>Stripe Size</b>	Smaller stripe size for random small IO pattern seen in OLTP applications. For example, use stripe size of 64 KB for SQL Server OLTP application.	Larger stripe size for sequential large IO pattern seen in Data Warehouse applications. For example, use 256 KB stripe size for SQL Server Data warehouse application.	
<b>Multithreading</b>	Use multithreading to push higher number of requests to Premium Storage that will lead to higher IOPS and Throughput. For example, on SQL Server set a high MAXDOP value to allocate more CPUs to SQL Server.		

	IOPS	THROUGHPUT	LATENCY
Queue Depth	Larger Queue Depth yields higher IOPS.	Larger Queue Depth yields higher Throughput.	Smaller Queue Depth yields lower latencies.

## Nature of IO requests

An IO request is a unit of input/output operation that your application will be performing. Identifying the nature of IO requests, random or sequential, read or write, small or large, will help you determine the performance requirements of your application. It is important to understand the nature of IO requests, to make the right decisions when designing your application infrastructure. IOs must be distributed evenly to achieve the best performance possible.

IO size is one of the more important factors. The IO size is the size of the input/output operation request generated by your application. The IO size has a significant impact on performance especially on the IOPS and Bandwidth that the application is able to achieve. The following formula shows the relationship between IOPS, IO size, and Bandwidth/Throughput.

$$\text{IOPS} \times \text{IO Size} = \text{Throughput}$$

Some applications allow you to alter their IO size, while some applications do not. For example, SQL Server determines the optimal IO size itself, and does not provide users with any knobs to change it. On the other hand, Oracle provides a parameter called [DB\\_BLOCK\\_SIZE](#) using which you can configure the I/O request size of the database.

If you are using an application, which does not allow you to change the IO size, use the guidelines in this article to optimize the performance KPI that is most relevant to your application. For example,

- An OLTP application generates millions of small and random IO requests. To handle these types of IO requests, you must design your application infrastructure to get higher IOPS.
- A data warehousing application generates large and sequential IO requests. To handle these types of IO requests, you must design your application infrastructure to get higher Bandwidth or Throughput.

If you are using an application, which allows you to change the IO size, use this rule of thumb for the IO size in addition to other performance guidelines,

- Smaller IO size to get higher IOPS. For example, 8 KB for an OLTP application.
- Larger IO size to get higher Bandwidth/Throughput. For example, 1024 KB for a data warehouse application.

Here is an example on how you can calculate the IOPS and Throughput/Bandwidth for your application.

Consider an application using a P30 disk. The maximum IOPS and Throughput/Bandwidth a P30 disk can achieve is 5000 IOPS and 200 MB per second respectively. Now, if your application requires the maximum IOPS from the P30 disk and you use a smaller IO size like 8 KB, the resulting Bandwidth you will be able to get is 40 MB per second. However, if your application requires the maximum Throughput/Bandwidth from P30 disk, and you use a larger IO size like 1024 KB, the resulting IOPS will be less, 200 IOPS. Therefore, tune the IO size such that it meets both your application's IOPS and Throughput/Bandwidth requirement. The following table summarizes the different IO sizes and their corresponding IOPS and Throughput for a P30 disk.

APPLICATION REQUIREMENT	I/O SIZE	IOPS	THROUGHPUT/BANDWIDTH
Max IOPS	8 KB	5,000	40 MB per second

APPLICATION REQUIREMENT	I/O SIZE	IOPS	THROUGHPUT/BANDWIDTH
Max Throughput	1024 KB	200	200 MB per second
Max Throughput + high IOPS	64 KB	3,200	200 MB per second
Max IOPS + high Throughput	32 KB	5,000	160 MB per second

To get IOPS and Bandwidth higher than the maximum value of a single premium storage disk, use multiple premium disks striped together. For example, stripe two P30 disks to get a combined IOPS of 10,000 IOPS or a combined Throughput of 400 MB per second. As explained in the next section, you must use a VM size that supports the combined disk IOPS and Throughput.

#### NOTE

As you increase either IOPS or Throughput the other also increases, make sure you do not hit throughput or IOPS limits of the disk or VM when increasing either one.

To witness the effects of IO size on application performance, you can run benchmarking tools on your VM and disks. Create multiple test runs and use different IO size for each run to see the impact. Refer to the Benchmarking article, linked at the end, for more details.

## High scale VM sizes

When you start designing an application, one of the first things to do is, choose a VM to host your application. Premium Storage comes with High Scale VM sizes that can run applications requiring higher compute power and a high local disk I/O performance. These VMs provide faster processors, a higher memory-to-core ratio, and a Solid-State Drive (SSD) for the local disk. Examples of High Scale VMs supporting Premium Storage are the DS and GS series VMs.

High Scale VMs are available in different sizes with a different number of CPU cores, memory, OS, and temporary disk size. Each VM size also has maximum number of data disks that you can attach to the VM. Therefore, the chosen VM size will affect how much processing, memory, and storage capacity is available for your application. It also affects the Compute and Storage cost. For example, below are the specifications of the largest VM size in a DS series and a GS series:

VM SIZE	CPU CORES	MEMORY	VM DISK SIZES	MAX. DATA DISKS	CACHE SIZE	IOPS	BANDWIDTH CACHE IO LIMITS
Standard_DS14	16	112 GB	OS = 1023 GB Local SSD = 224 GB	32	576 GB	50,000 IOPS 512 MB per second	4,000 IOPS and 33 MB per second
Standard_GS5	32	448 GB	OS = 1023 GB Local SSD = 896 GB	64	4224 GB	80,000 IOPS 2,000 MB per second	5,000 IOPS and 50 MB per second

To view a complete list of all available Azure VM sizes, refer to [Sizes for virtual machines in Azure](#). Choose a VM size that can meet and scale to your desired application performance requirements. In addition to this, take into

account following important considerations when choosing VM sizes.

#### *Scale Limits*

The maximum IOPS limits per VM and per disk are different and independent of each other. Make sure that the application is driving IOPS within the limits of the VM as well as the premium disks attached to it. Otherwise, application performance will experience throttling.

As an example, suppose an application requirement is a maximum of 4,000 IOPS. To achieve this, you provision a P30 disk on a DS1 VM. The P30 disk can deliver up to 5,000 IOPS. However, the DS1 VM is limited to 3,200 IOPS. Consequently, the application performance will be constrained by the VM limit at 3,200 IOPS and there will be degraded performance. To prevent this situation, choose a VM and disk size that will both meet application requirements.

#### *Cost of Operation*

In many cases, it is possible that your overall cost of operation using Premium Storage is lower than using Standard Storage.

For example, consider an application requiring 16,000 IOPS. To achieve this performance, you will need a Standard\_D14 Azure IaaS VM, which can give a maximum IOPS of 16,000 using 32 standard storage 1 TB disks. Each 1-TB standard storage disk can achieve a maximum of 500 IOPS. The estimated cost of this VM per month will be \$1,570. The monthly cost of 32 standard storage disks will be \$1,638. The estimated total monthly cost will be \$3,208.

However, if you hosted the same application on Premium Storage, you will need a smaller VM size and fewer premium storage disks, thus reducing the overall cost. A Standard\_DS13 VM can meet the 16,000 IOPS requirement using four P30 disks. The DS13 VM has a maximum IOPS of 25,600 and each P30 disk has a maximum IOPS of 5,000. Overall, this configuration can achieve  $5,000 \times 4 = 20,000$  IOPS. The estimated cost of this VM per month will be \$1,003. The monthly cost of four P30 premium storage disks will be \$544.34. The estimated total monthly cost will be \$1,544.

Table below summarizes the cost breakdown of this scenario for Standard and Premium Storage.

	STANDARD	PREMIUM
Cost of VM per month	\$1,570.58 (Standard_D14)	\$1,003.66 (Standard_DS13)
Cost of Disks per month	\$1,638.40 (32 x 1-TB disks)	\$544.34 (4 x P30 disks)
Overall Cost per month	\$3,208.98	\$1,544.34

#### *Linux Distros*

With Azure Premium Storage, you get the same level of Performance for VMs running Windows and Linux. We support many flavors of Linux distros. For more information, see [Linux distributions endorsed on Azure](#). It is important to note that different distros are better suited for different types of workloads. You will see different levels of performance depending on the distro your workload is running on. Test the Linux distros with your application and choose the one that works best.

When running Linux with Premium Storage, check the latest updates about required drivers to ensure high performance.

## Premium storage disk sizes

Azure Premium Storage offers a variety of sizes so you can choose one that best suits your needs. Each disk size has a different scale limit for IOPS, bandwidth, and storage. Choose the right Premium Storage Disk size depending on the application requirements and the high scale VM size. The table below shows the disks sizes

and their capabilities. P4, P6, P15, P60, P70, and P80 sizes are currently only supported for Managed Disks.

PRE MIU M SSD SIZ ES	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
Eligi ble for rese rvat ion	No	No	No	No	No	No	No	No	Yes, up to one yea r	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year

\*Applies only to disks with on-demand bursting enabled.

How many disks you choose depends on the disk size chosen. You could use a single P50 disk or multiple P10 disks to meet your application requirement. Take into account considerations listed below when making the choice.

#### *Scale Limits (IOPS and Throughput)*

The IOPS and Throughput limits of each Premium disk size is different and independent from the VM scale limits. Make sure that the total IOPS and Throughput from the disks are within scale limits of the chosen VM size.

For example, if an application requirement is a maximum of 250 MB/sec Throughput and you are using a DS4 VM with a single P30 disk. The DS4 VM can give up to 256 MB/sec Throughput. However, a single P30 disk has Throughput limit of 200 MB/sec. Consequently, the application will be constrained at 200 MB/sec due to the disk limit. To overcome this limit, provision more than one data disks to the VM or resize your disks to P40 or P50.

#### **NOTE**

Reads served by the cache are not included in the disk IOPS and Throughput, hence not subject to disk limits. Cache has its separate IOPS and Throughput limit per VM.

For example, initially your reads and writes are 60MB/sec and 40MB/sec respectively. Over time, the cache warms up and serves more and more of the reads from the cache. Then, you can get higher write Throughput from the disk.

#### *Number of Disks*

Determine the number of disks you will need by assessing application requirements. Each VM size also has a limit on the number of disks that you can attach to the VM. Typically, this is twice the number of cores. Ensure that the VM size you choose can support the number of disks needed.

Remember, the Premium Storage disks have higher performance capabilities compared to Standard Storage disks. Therefore, if you are migrating your application from Azure IaaS VM using Standard Storage to Premium Storage, you will likely need fewer premium disks to achieve the same or higher performance for your application.

## Disk caching

High Scale VMs that leverage Azure Premium Storage have a multi-tier caching technology called BlobCache. BlobCache uses a combination of the host RAM and local SSD for caching. This cache is available for the Premium Storage persistent disks and the VM local disks. By default, this cache setting is set to Read/Write for OS disks and ReadOnly for data disks hosted on Premium Storage. With disk caching enabled on the Premium Storage disks, the high scale VMs can achieve extremely high levels of performance that exceed the underlying disk performance.

### WARNING

Disk Caching is not supported for disks 4 TiB and larger. If multiple disks are attached to your VM, each disk that is smaller than 4 TiB will support caching.

Changing the cache setting of an Azure disk detaches and re-attaches the target disk. If it is the operating system disk, the VM is restarted. Stop all applications/services that might be affected by this disruption before changing the disk cache setting. Not following those recommendations could lead to data corruption.

To learn more about how BlobCache works, refer to the [Inside Azure Premium Storage](#) blog post.

It is important to enable cache on the right set of disks. Whether you should enable disk caching on a premium disk or not will depend on the workload pattern that disk will be handling. Table below shows the default cache settings for OS and Data disks.

DISK TYPE	DEFAULT CACHE SETTING
OS disk	ReadWrite
Data disk	ReadOnly

Following are the recommended disk cache settings for data disks,

DISK CACHING SETTING	RECOMMENDATION ON WHEN TO USE THIS SETTING
None	Configure host-cache as None for write-only and write-heavy disks.
ReadOnly	Configure host-cache as ReadOnly for read-only and read-write disks.
ReadWrite	Configure host-cache as ReadWrite only if your application properly handles writing cached data to persistent disks when needed.

### *ReadOnly*

By configuring ReadOnly caching on Premium Storage data disks, you can achieve low Read latency and get very high Read IOPS and Throughput for your application. This is due two reasons,

1. Reads performed from cache, which is on the VM memory and local SSD, are much faster than reads from the data disk, which is on the Azure blob storage.
2. Premium Storage does not count the Reads served from cache, towards the disk IOPS and Throughput. Therefore, your application is able to achieve higher total IOPS and Throughput.

### *ReadWrite*

By default, the OS disks have ReadWrite caching enabled. We have recently added support for ReadWrite caching on data disks as well. If you are using ReadWrite caching, you must have a proper way to write the data from cache to persistent disks. For example, SQL Server handles writing cached data to the persistent storage disks on its own. Using ReadWrite cache with an application that does not handle persisting the required data can lead to data loss, if the VM crashes.

### *None*

Currently, **None** is only supported on data disks. It is not supported on OS disks. If you set **None** on an OS disk it will override this internally and set it to **ReadOnly**.

As an example, you can apply these guidelines to SQL Server running on Premium Storage by doing the

following,

1. Configure "ReadOnly" cache on premium storage disks hosting data files.
  - a. The fast reads from cache lower the SQL Server query time since data pages are retrieved much faster from the cache compared to directly from the data disks.
  - b. Serving reads from cache, means there is additional Throughput available from premium data disks. SQL Server can use this additional Throughput towards retrieving more data pages and other operations like backup/restore, batch loads, and index rebuilds.
2. Configure "None" cache on premium storage disks hosting the log files.
  - a. Log files have primarily write-heavy operations. Therefore, they do not benefit from the ReadOnly cache.

## Optimize performance on Linux VMs

For all premium SSDs or ultra disks, you may be able to disable "barriers" for file systems on the disk in order to improve performance when it is known that there are no caches that could lose data. If Azure disk caching is set to ReadOnly or None, you can disable barriers. But if caching is set to ReadWrite, barriers should remain enabled to ensure write durability. Barriers are typically enabled by default, but you can disable barriers using one of the following methods depending on the file system type:

- For `reiserFS`, use the `barrier=none` mount option to disable barriers. To explicitly enable barriers, use `barrier=flush`.
- For `ext3/ext4`, use the `barrier=0` mount option to disable barriers. To explicitly enable barriers, use `barrier=1`.
- For `XFS`, use the `nobarrier` mount option to disable barriers. To explicitly enable barriers, use `barrier`. As of version 4.10 of the mainline Linux kernel, the design of XFS file system always ensures durability. Disabling barriers has no effect and the "nobarrier" option is deprecated. However, some Linux distributions may have backported the changes to a distribution release with an earlier kernel version, check with your distribution vendor for the status in the distribution and version you are running.

## Disk striping

When a high scale VM is attached with several premium storage persistent disks, the disks can be striped together to aggregate their IOPs, bandwidth, and storage capacity.

On Windows, you can use Storage Spaces to stripe disks together. You must configure one column for each disk in a pool. Otherwise, the overall performance of striped volume can be lower than expected, due to uneven distribution of traffic across the disks.

Important: Using Server Manager UI, you can set the total number of columns up to 8 for a striped volume. When attaching more than eight disks, use PowerShell to create the volume. Using PowerShell, you can set the number of columns equal to the number of disks. For example, if there are 16 disks in a single stripe set; specify 16 columns in the `NumberOfColumns` parameter of the `New-VirtualDisk` PowerShell cmdlet.

On Linux, use the MDADM utility to stripe disks together. For detailed steps on striping disks on Linux refer to [Configure Software RAID on Linux](#).

### Stripe Size

An important configuration in disk striping is the stripe size. The stripe size or block size is the smallest chunk of data that application can address on a striped volume. The stripe size you configure depends on the type of application and its request pattern. If you choose the wrong stripe size, it could lead to IO misalignment, which leads to degraded performance of your application.

For example, if an IO request generated by your application is bigger than the disk stripe size, the storage system writes it across stripe unit boundaries on more than one disk. When it is time to access that data, it will have to seek across more than one stripe units to complete the request. The cumulative effect of such behavior

can lead to substantial performance degradation. On the other hand, if the IO request size is smaller than stripe size, and if it is random in nature, the IO requests may add up on the same disk causing a bottleneck and ultimately degrading the IO performance.

Depending on the type of workload your application is running, choose an appropriate stripe size. For random small IO requests, use a smaller stripe size. Whereas for large sequential IO requests use a larger stripe size. Find out the stripe size recommendations for the application you will be running on Premium Storage. For SQL Server, configure stripe size of 64 KB for OLTP workloads and 256 KB for data warehousing workloads. See [Performance best practices for SQL Server on Azure VMs](#) to learn more.

#### NOTE

You can stripe together a maximum of 32 premium storage disks on a DS series VM and 64 premium storage disks on a GS series VM.

## Multi-threading

Azure has designed Premium Storage platform to be massively parallel. Therefore, a multi-threaded application achieves much higher performance than a single-threaded application. A multi-threaded application splits up its tasks across multiple threads and increases efficiency of its execution by utilizing the VM and disk resources to the maximum.

For example, if your application is running on a single core VM using two threads, the CPU can switch between the two threads to achieve efficiency. While one thread is waiting on a disk IO to complete, the CPU can switch to the other thread. In this way, two threads can accomplish more than a single thread would. If the VM has more than one core, it further decreases running time since each core can execute tasks in parallel.

You may not be able to change the way an off-the-shelf application implements single threading or multi-threading. For example, SQL Server is capable of handling multi-CPU and multi-core. However, SQL Server decides under what conditions it will leverage one or more threads to process a query. It can run queries and build indexes using multi-threading. For a query that involves joining large tables and sorting data before returning to the user, SQL Server will likely use multiple threads. However, a user cannot control whether SQL Server executes a query using a single thread or multiple threads.

There are configuration settings that you can alter to influence this multi-threading or parallel processing of an application. For example, in case of SQL Server it is the maximum Degree of Parallelism configuration. This setting called MAXDOP, allows you to configure the maximum number of processors SQL Server can use when parallel processing. You can configure MAXDOP for individual queries or index operations. This is beneficial when you want to balance resources of your system for a performance critical application.

For example, say your application using SQL Server is executing a large query and an index operation at the same time. Let us assume that you wanted the index operation to be more performant compared to the large query. In such a case, you can set MAXDOP value of the index operation to be higher than the MAXDOP value for the query. This way, SQL Server has more number of processors that it can leverage for the index operation compared to the number of processors it can dedicate to the large query. Remember, you do not control the number of threads SQL Server will use for each operation. You can control the maximum number of processors being dedicated for multi-threading.

Learn more about [Degrees of Parallelism](#) in SQL Server. Find out such settings that influence multi-threading in your application and their configurations to optimize performance.

## Queue depth

The queue depth or queue length or queue size is the number of pending IO requests in the system. The value of queue depth determines how many IO operations your application can line up, which the storage disks will be

processing. It affects all the three application performance indicators that we discussed in this article viz., IOPS, throughput, and latency.

Queue Depth and multi-threading are closely related. The Queue Depth value indicates how much multi-threading can be achieved by the application. If the Queue Depth is large, application can execute more operations concurrently, in other words, more multi-threading. If the Queue Depth is small, even though application is multi-threaded, it will not have enough requests lined up for concurrent execution.

Typically, off the shelf applications do not allow you to change the queue depth, because if set incorrectly it will do more harm than good. Applications will set the right value of queue depth to get the optimal performance. However, it is important to understand this concept so that you can troubleshoot performance issues with your application. You can also observe the effects of queue depth by running benchmarking tools on your system.

Some applications provide settings to influence the Queue Depth. For example, the MAXDOP (maximum degree of parallelism) setting in SQL Server explained in previous section. MAXDOP is a way to influence Queue Depth and multi-threading, although it does not directly change the Queue Depth value of SQL Server.

#### *High queue depth*

A high queue depth lines up more operations on the disk. The disk knows the next request in its queue ahead of time. Consequently, the disk can schedule operations ahead of time and process them in an optimal sequence. Since the application is sending more requests to the disk, the disk can process more parallel IOs. Ultimately, the application will be able to achieve higher IOPS. Since application is processing more requests, the total Throughput of the application also increases.

Typically, an application can achieve maximum Throughput with 8-16+ outstanding IOs per attached disk. If a queue depth is one, application is not pushing enough IOs to the system, and it will process less amount of in a given period. In other words, less Throughput.

For example, in SQL Server, setting the MAXDOP value for a query to "4" informs SQL Server that it can use up to four cores to execute the query. SQL Server will determine what is best queue depth value and the number of cores for the query execution.

#### *Optimal queue depth*

Very high queue depth value also has its drawbacks. If queue depth value is too high, the application will try to drive very high IOPS. Unless application has persistent disks with sufficient provisioned IOPS, this can negatively affect application latencies. Following formula shows the relationship between IOPS, latency, and queue depth.

$$\text{IOPS} \times \text{Latency} = \text{Queue Depth}$$

You should not configure Queue Depth to any high value, but to an optimal value, which can deliver enough IOPS for the application without affecting latencies. For example, if the application latency needs to be 1 millisecond, the Queue Depth required to achieve 5,000 IOPS is,  $QD = 5000 \times 0.001 = 5$ .

#### *Queue Depth for Striped Volume*

For a striped volume, maintain a high enough queue depth such that, every disk has a peak queue depth individually. For example, consider an application that pushes a queue depth of 2 and there are four disks in the stripe. The two IO requests will go to two disks and remaining two disks will be idle. Therefore, configure the queue depth such that all the disks can be busy. Formula below shows how to determine the queue depth of striped volumes.

$$\text{QD per Disk} \times \text{No. of Columns per Volume} = \text{QD of Striped Volume}$$

## Throttling

Azure Premium Storage provisions specified number of IOPS and Throughput depending on the VM sizes and disk sizes you choose. Anytime your application tries to drive IOPS or Throughput above these limits of what the VM or disk can handle, Premium Storage will throttle it. This manifests in the form of degraded performance in your application. This can mean higher latency, lower Throughput, or lower IOPS. If Premium Storage does not throttle, your application could completely fail by exceeding what its resources are capable of achieving. So, to avoid performance issues due to throttling, always provision sufficient resources for your application. Take into consideration what we discussed in the VM sizes and Disk sizes sections above. Benchmarking is the best way to figure out what resources you will need to host your application.

## Next steps

If you are looking to benchmark your disk, see our articles on benchmarking a disk:

# Disk performance metrics

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure offers metrics in the Azure portal that provide insight on how your virtual machines (VM) and disks perform. The metrics can also be retrieved through an API call. This article is broken into 3 subsections:

- **Disk IO, throughput and queue depth metrics** - These metrics allow you to see the storage performance from the perspective of a disk and a virtual machine.
- **Disk bursting metrics** - These are the metrics provide observability into our [bursting](#) feature on our premium disks.
- **Storage IO utilization metrics** - These metrics help diagnose bottlenecks in your storage performance with disks.

All metrics are emitted every minute, except for the bursting credit percentage metric, which is emitted every 5 minutes.

## Disk IO, throughput and queue depth metrics

The following metrics are available to get insight on VM and Disk IO, throughput, and queue depth performance:

- **OS Disk Queue Depth**: The number of current outstanding IO requests that are waiting to be read from or written to the OS disk.
- **OS Disk Read Bytes/Sec**: The number of bytes that are read in a second from the OS disk.
- **OS Disk Read Operations/Sec**: The number of input operations that are read in a second from the OS disk.
- **OS Disk Write Bytes/Sec**: The number of bytes that are written in a second from the OS disk.
- **OS Disk Write Operations/Sec**: The number of output operations that are written in a second from the OS disk.
- **Data Disk Queue Depth**: The number of current outstanding IO requests that are waiting to be read from or written to the data disk(s).
- **Data Disk Read Bytes/Sec**: The number of bytes that are read in a second from the data disk(s).
- **Data Disk Read Operations/Sec**: The number of input operations that are read in a second from data disk(s).
- **Data Disk Write Bytes/Sec**: The number of bytes that are written in a second from the data disk(s).
- **Data Disk Write Operations/Sec**: The number of output operations that are written in a second from data disk(s).
- **Disk Read Bytes/Sec**: The number of total bytes that are read in a second from all disks attached to a VM.
- **Disk Read Operations/Sec**: The number of input operations that are read in a second from all disks attached to a VM.
- **Disk Write Bytes/Sec**: The number of bytes that are written in a second from all disks attached to a VM.
- **Disk Write Operations/Sec**: The number of output operations that are written in a second from all disks attached to a VM.

## Bursting metrics

The following metrics help with observability into our [bursting](#) feature on our premium disks:

- **Data Disk Max Burst Bandwidth:** The throughput limit that the data disk(s) can burst up to.
- **OS Disk Max Burst Bandwidth:** The throughput limit that the OS disk can burst up to.
- **Data Disk Max Burst IOPS:** the IOPS limit that the data disk(s) can burst up to.
- **OS Disk Max Burst IOPS:** The IOPS limit that the OS disk can burst up to.
- **Data Disk Target Bandwidth:** The throughput limit that the data(s) disk can achieve without bursting.
- **OS Disk Target Bandwidth:** The throughput limit that the OS disk can achieve without bursting.
- **Data Disk Target IOPS:** The IOPS limit that the data disk(s) can achieve without bursting.
- **OS Disk Target IOPS:** The IOPS limit that the data disk(s) can achieve without bursting.
- **Data Disk Used Burst BPS Credits Percentage:** The accumulated percentage of the throughput burst used for the data disk(s). Emitted on a 5 minute interval.
- **OS Disk Used Burst BPS Credits Percentage:** The accumulated percentage of the throughput burst used for the OS disk. Emitted on a 5 minute interval.
- **Data Disk Used Burst IO Credits Percentage:** The accumulated percentage of the IOPS burst used for the data disk(s). Emitted on a 5 minute interval.
- **OS Disk Used Burst IO Credits Percentage:** The accumulated percentage of the IOPS burst used for the OS disk. Emitted on a 5 minute interval.

## Storage IO utilization metrics

The following metrics help diagnose bottleneck in your Virtual Machine and Disk combination. These metrics are only available with the following configuration:

- Only available on VM series that support premium storage.
- Not available for ultra disks, all other disk types on these VM series can utilize these metrics.

Metrics that help diagnose disk IO capping:

- **Data Disk IOPS Consumed Percentage:** The percentage calculated by the data disk IOPS completed over the provisioned data disk IOPS. If this amount is at 100%, your application running is IO capped from your data disk's IOPS limit.
- **Data Disk Bandwidth Consumed Percentage:** The percentage calculated by the data disk throughput completed over the provisioned data disk throughput. If this amount is at 100%, your application running is IO capped from your data disk's bandwidth limit.
- **OS Disk IOPS Consumed Percentage:** The percentage calculated by the OS disk IOPS completed over the provisioned OS disk IOPS. If this amount is at 100%, your application running is IO capped from your OS disk's IOPS limit.
- **OS Disk Bandwidth Consumed Percentage:** The percentage calculated by the OS disk throughput completed over the provisioned OS disk throughput. If this amount is at 100%, your application running is IO capped from your OS disk's bandwidth limit.

Metrics that help diagnose VM IO capping:

- **VM Cached IOPS Consumed Percentage:** The percentage calculated by the total IOPS completed over the max cached virtual machine IOPS limit. If this amount is at 100%, your application running is IO capped from your VM's cached IOPS limit.
- **VM Cached Bandwidth Consumed Percentage:** The percentage calculated by the total disk throughput completed over the max cached virtual machine throughput. If this amount is at 100%, your application running is IO capped from your VM's cached bandwidth limit.
- **VM uncached IOPS Consumed Percentage:** The percentage calculated by the total IOPS on a virtual machine completed over the max uncached virtual machine IOPS limit. If this amount is at 100%, your application running is IO capped from your VM's uncached IOPS limit.
- **VM Uncached Bandwidth Consumed Percentage:** The percentage calculated by the total disk

throughput on a virtual machine completed over the max provisioned virtual machine throughput. If this amount is at 100%, your application running is IO capped from your VM's uncached bandwidth limit.

## Storage IO metrics example

Let's run through an example of how to use these new Storage IO utilization metrics to help us debug where a bottleneck is in our system. The system setup is the same as the previous example, except this time the attached OS disk is *not* cached.

### Setup:

- Standard\_D8s\_v3
  - Cached IOPS: 16,000
  - Uncached IOPS: 12,800
- P30 OS disk
  - IOPS: 5,000
  - Host caching: **Disabled**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Read/write**
- Two P30 data disks × 2
  - IOPS: 5,000
  - Host caching: **Disabled**

Let's run a benchmarking test on this virtual machine and disk combination that creates IO activity. To learn how to benchmark storage IO on Azure, see [Benchmark your application on Azure Disk Storage](#). From the benchmarking tool, you can see that the VM and disk combination can achieve 22,800 IOPS:

```
demouser@IO-Utilization-Demo:~$ sudo fio fioread.ini
reader1: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader3: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader5: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader10: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
reader12: (g=0): rw=randread, bs=(R) 8192B-8192B, (W) 8192B-8192B, (T) 8192B-8192B, ioengine=libaio, iodepth=256
fio-3.1
Starting 5 processes
Jobs: 5 (f=5), 0-22800 IOPS: [r(5)][0.4%][r=178MiB/s,w=0KiB/s] r=22.8k, v=0 IOPS][eta 27m:06s]
```

The Standard\_D8s\_v3 can achieve a total of 28,600 IOPS. Using the metrics, let's investigate what's going on and identify our storage IO bottleneck. On the left pane, select **Metrics**:

The screenshot shows the Azure portal interface for a virtual machine named "IO-Utilization-Demo". The left sidebar has a "Metrics" icon highlighted with a red box. The main content area shows the "Metrics" blade with the following details:

- Monitoring**: Shows an advisor message: "Adviser (1 of 6): All network ports should be restricted on network security groups associated to [redacted]."
- Essentials**:
  - Resource group: (change)
  - Status: Running
  - Location: East US 2
  - Subscription: (change)
  - Subscription ID: [redacted]
  - Tags: (change) Click here to add tags
- Metrics**: A list of metrics including:
  - Cached IOPS Consumed Percentage
  - Uncached IOPS Consumed Percentage
  - Latency
  - Throughput
  - Throughput Latency
  - Throughput Throughput
- Diagnostic settings**
- Logs**
- Connection monitor**
- Automation**

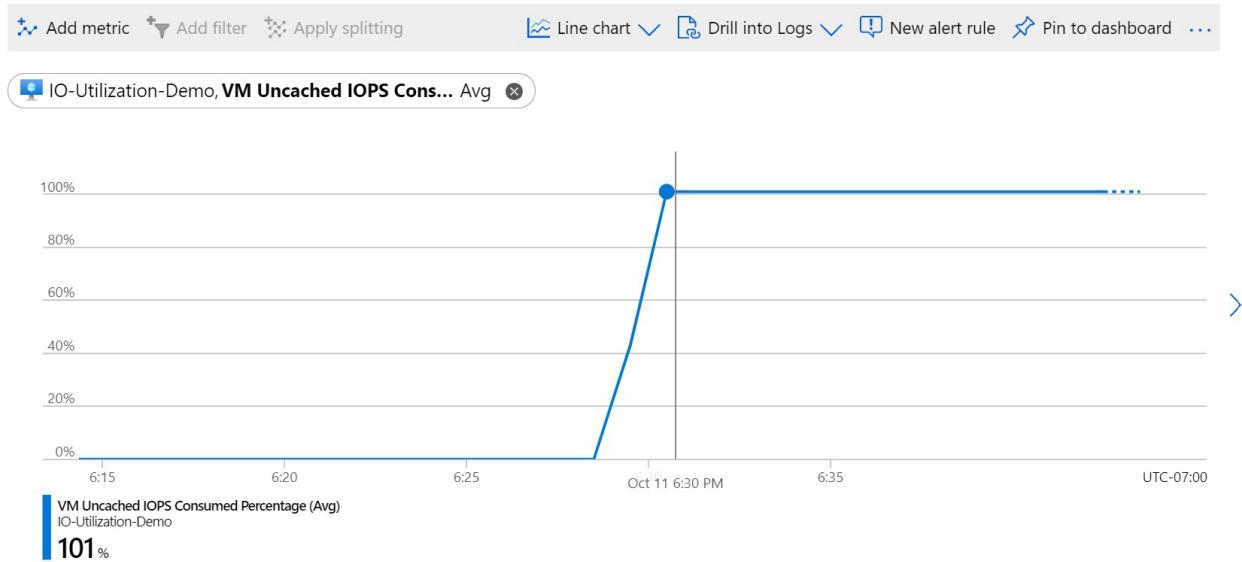

Let's first take a look at our **VM Cached IOPS Consumed Percentage** metric:

### Avg VM Cached IOPS Consumed Percentage for IO-Utilization-Demo

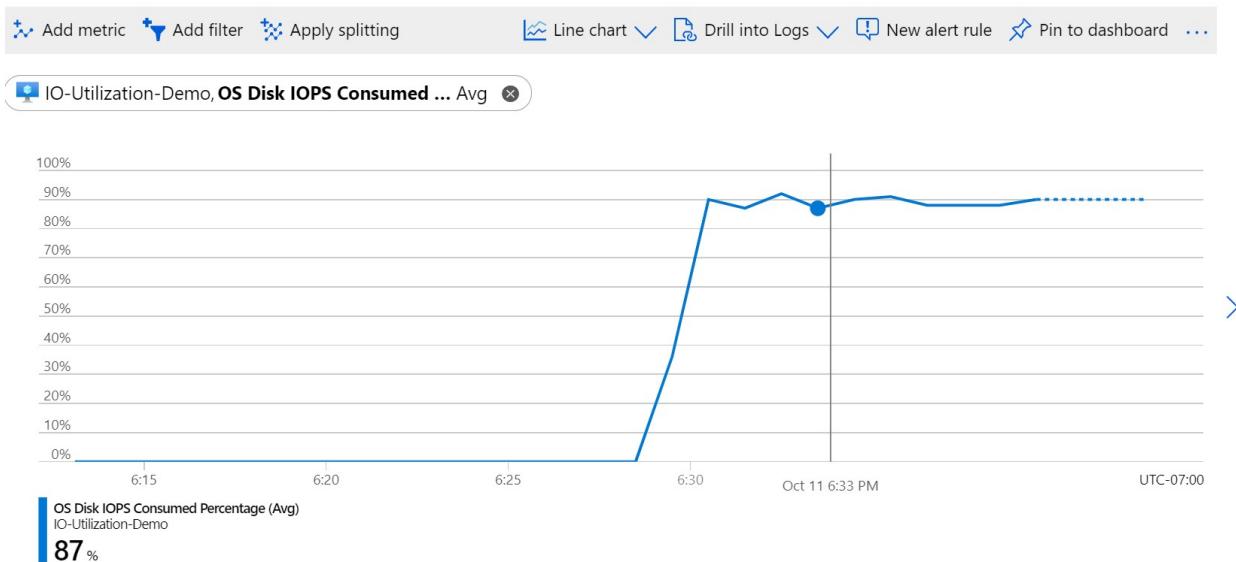

This metric tells us that 61% of the 16,000 IOPS allotted to the cached IOPS on the VM is being used. This percentage means that the storage IO bottleneck isn't with the disks that are cached because it isn't at 100%. Now let's look at our **VM Uncached IOPS Consumed Percentage** metric:

### Avg VM Uncached IOPS Consumed Percentage for IO-Utilization-Demo

This metric is at 100%. It tells us that all of the 12,800 IOPS allotted to the uncached IOPS on the VM are being used. One way we can remediate this issue is to change the size of our VM to a larger size that can handle the additional IO. But before we do that, let's look at the attached disk to find out how many IOPS they are seeing. Check the OS Disk by looking at the **OS Disk IOPS Consumed Percentage**:

### Avg OS Disk IOPS Consumed Percentage for IO-Utilization-Demo

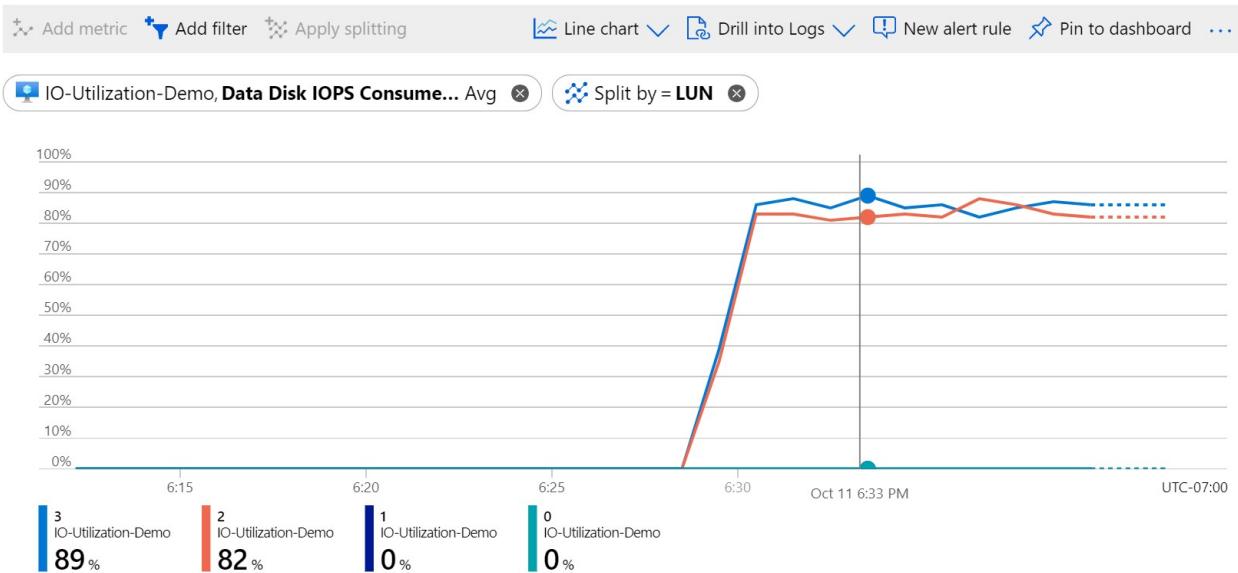

This metric tells us that around 90% of the 5,000 IOPS provisioned for this P30 OS disk is being used. This percentage means there's no bottleneck at the OS disk. Now let's check the data disks that are attached to the VM by looking at the **Data Disk IOPS Consumed Percentage**:

### Avg Data Disk IOPS Consumed Percentage for IO-Utilization-Demo

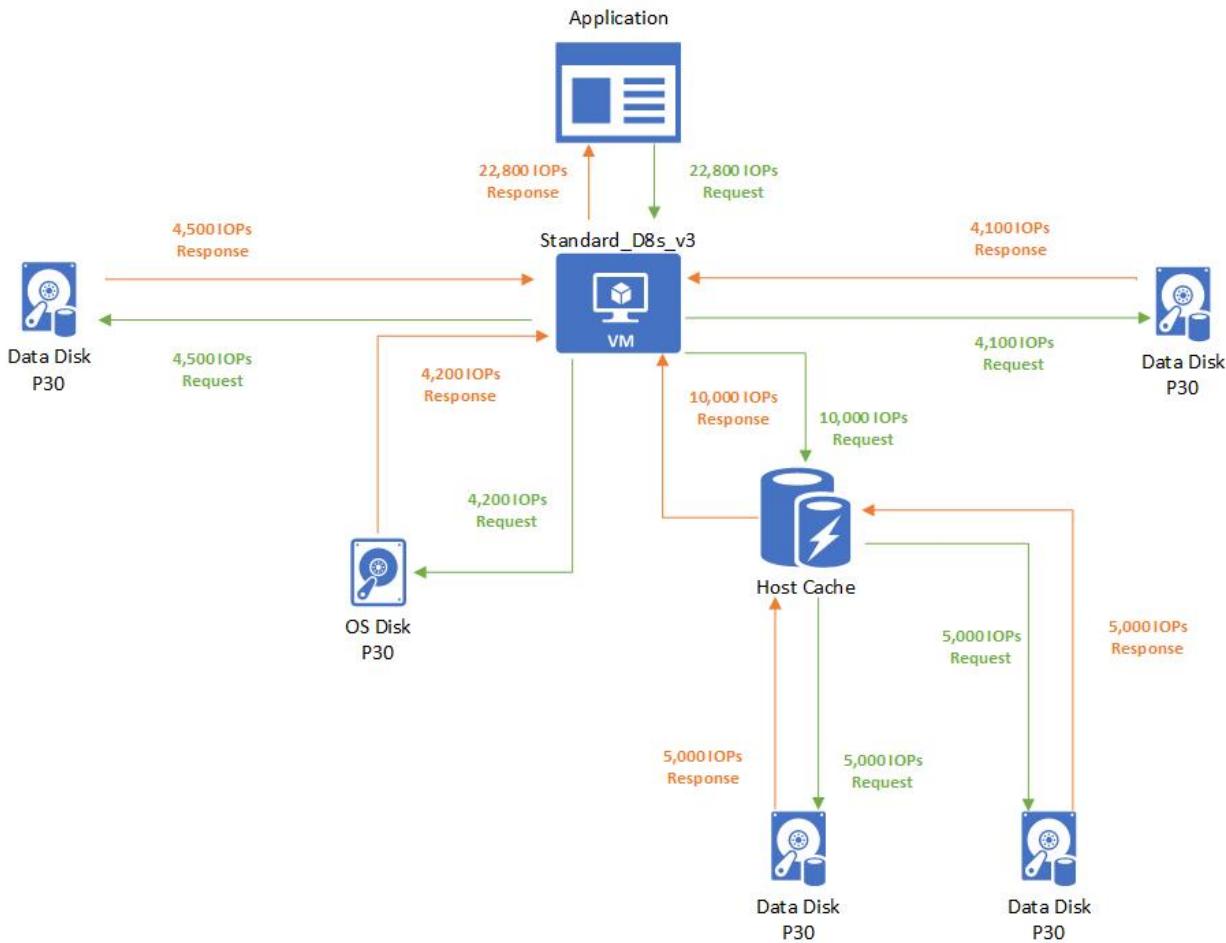

This metric tells us that the average IOPS consumed percentage across all the disks attached is around 42%. This percentage is calculated based on the IOPS that are used by the disks, and aren't being served from the host cache. Let's drill deeper into this metric by applying *splitting* on these metrics and splitting by the LUN value:

## Avg Data Disk IOPS Consumed Percentage for IO-Utilization-Demo by LUN

This metric tells us the data disks attached on LUN 3 and 2 are using around 85% of their provisioned IOPS. Here is a diagram of what the IO looks like from the VM and disks architecture:

# Managed disk bursting

9/21/2022 • 10 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Azure offers the ability to boost disk storage IOPS and MB/s performance, this is referred to as bursting for both virtual machines (VM) and disks. You can effectively use VM and disk bursting to achieve better bursting performance on both your VMs and disk.

Bursting for Azure VMs and disk resources aren't dependent on each other. You don't need to have a burst-capable VM for an attached burst-capable disk to burst. Similarly, you don't need to have a burst-capable disk attached to your burst-capable VM for the VM to burst.

## Common scenarios

The following scenarios can benefit greatly from bursting:

- **Improve startup times** – With bursting, your instance will startup at a faster rate. For example, the default OS disk for premium enabled VMs is the P4 disk, which is a provisioned performance of up to 120 IOPS and 25 MB/s. With bursting, the P4 can go up to 3500 IOPS and 170 MB/s allowing for startup to accelerate by up to 6X.
- **Handle batch jobs** – Some application workloads are cyclical in nature. They require a baseline performance most of the time, and higher performance for short periods of time. An example of this is an accounting program that processes daily transactions that require a small amount of disk traffic. At the end of the month this program would complete reconciling reports that need a much higher amount of disk traffic.
- **Traffic spikes** – Web servers and their applications can experience traffic surges at any time. If your web server is backed by VMs or disks that use bursting, the servers would be better equipped to handle traffic spikes.

## Disk-level bursting

Currently, there are two managed disk types that can burst, [premium SSDs](#), and [standard SSDs](#). Other disk types cannot currently burst. There are two models of bursting for disks:

- An on-demand bursting model, where the disk bursts whenever its needs exceed its current capacity. This model incurs additional charges anytime the disk bursts. On-demand bursting is only available for premium SSDs larger than 512 GiB.
- A credit-based model, where the disk will burst only if it has burst credits accumulated in its credit bucket. This model does not incur additional charges when the disk bursts. Credit-based bursting is only available for premium SSDs 512 GiB and smaller, and standard SSDs 1024 GiB and smaller.

Azure [premium SSDs](#) can use either bursting model, but [standard SSDs](#) currently only offer credit-based bursting.

Additionally, the [performance tier of managed disks can be changed](#), which could be ideal if your workload would otherwise be running in burst.

	CREDIT-BASED BURSTING	ON-DEMAND BURSTING	CHANGING PERFORMANCE TIER
Scenarios	Ideal for short-term scaling (30 minutes or less).	Ideal for short-term scaling(Not time restricted).	Ideal if your workload would otherwise continually be running in burst.
Cost	Free	Cost is variable, see the <a href="#">Billing</a> section for details.	The cost of each performance tier is fixed, see <a href="#">Managed Disks pricing</a> for details.
Availability	Only available for premium SSDs 512 GiB and smaller, and standard SSDs 1024 GiB and smaller.	Only available for premium SSDs larger than 512 GiB.	Available to all premium SSD sizes.
Enablement	Enabled by default on eligible disks.	Must be enabled by user.	User must manually change their tier.

## On-demand bursting

Premium SSDs using the on-demand bursting model of disk bursting can burst beyond original provisioned targets, as often as needed by their workload, up to the max burst target. For example, on a 1-TiB P30 disk, the provisioned IOPS is 5000 IOPS. When disk bursting is enabled on this disk, your workloads can issue IOs to this disk up to the max burst performance of 30,000 IOPS and 1,000 MBps. For the max burst targets on each supported disk, see [Scalability and performance targets for VM disks](#).

If you expect your workloads to frequently run beyond the provisioned perf target, disk bursting won't be cost-effective. In this case, we recommend that you change your disk's performance tier to a [higher tier](#) instead, for better baseline performance. Review your billing details and assess that against the traffic pattern of your workloads.

Before you enable on-demand bursting, understand the following:

- On-demand bursting cannot be enabled on a premium SSD that has less than or equal to 512 GiB. Premium SSDs less than or equal to 512 GiB will always use credit-based bursting.
- On-demand bursting is only supported on premium SSDs. If a premium SSD with on-demand bursting enabled is switched to another disk type, then disk bursting is disabled.
- On-demand bursting doesn't automatically disable itself when the performance tier is changed. If you want to change your performance tier but do not want to keep disk bursting, you must disable it.
- On-demand bursting can only be enabled when the disk is detached from a VM or when the VM is stopped. On-demand bursting can be disabled 12 hours after it has been enabled.

## Regional availability

Currently, the on-demand model for disk bursting is available in all public Azure regions.

## Billing

Premium SSDs using the on-demand bursting model are charged an hourly burst enablement flat fee and transaction costs apply to any burst transactions beyond the provisioned target. Transaction costs are charged using the pay-as-you go model, based on uncached disk IOs, including both reads and writes that exceed provisioned targets. The following is an example of disk traffic patterns over a billing hour:

Disk configuration: Premium SSD – 1 TiB (P30), Disk bursting enabled.

- 00:00:00 – 00:10:00 Disk IOPS below provisioned target of 5,000 IOPS
- 00:10:01 – 00:10:10 Application issued a batch job causing the disk IOPS to burst at 6,000 IOPS for 10 seconds.

seconds

- 00:10:11 – 00:59:00 Disk IOPS below provisioned target of 5,000 IOPS
- 00:59:01 – 01:00:00 Application issued another batch job causing the disk IOPS to burst at 7,000 IOPS for 60 seconds

In this billing hour, the cost of bursting consists of two charges:

The first charge is the burst enablement flat fee of \$X (determined by your region). This flat fee is always charged on the disk regardless of the attach status until it is disabled.

Second is the burst transaction cost. Disk bursting occurred in two time slots. From 00:10:01 – 00:10:10, the accumulated burst transaction is  $(6,000 - 5,000) \times 10 = 10,000$ . From 00:59:01 – 01:00:00, the accumulated burst transaction is  $(7,000 - 5,000) \times 60 = 120,000$ . The total burst transactions are  $10,000 + 120,000 = 130,000$ . Burst transaction cost will be charged at \$Y based on 13 units of 10,000 transactions (based on regional pricing).

With that, the total cost on disk bursting of this billing hour equals to  $\$X + \$Y$ . The same calculation would apply for bursting over provisioned target of MBps. We translate the usage of MB to transactions with IO size of 256KB. If your disk traffic exceed both provisioned IOPS and MBps target, you can refer to the example below to calculate the burst transactions.

Disk configuration: Premium SSD – 1 TB (P30), Disk bursting enabled.

- 00:00:01 – 00:00:05 Application issued a batch job causing the disk IOPS to burst at 10,000 IOPS and 300 MBps for five seconds.
- 00:00:06 – 00:00:10 Application issued a recovery job causing the disk IOPS to burst at 6,000 IOPS and 600 MBps for five seconds.

The burst transaction is accounted as the max number of transactions from either IOPS or MBps bursting. From 00:00:01 – 00:00:05, the accumulated burst transaction is  $\max((10,000 - 5,000), (300 - 200) * 1024 / 256) * 5 = 25,000$  transactions. From 00:00:06 – 00:00:10, the accumulated burst transaction is  $\max((6,000 - 5,000), (600 - 200) * 1024 / 256) * 5 = 8,000$  transactions. On top of that, you include the burst enablement flat fee to get the total cost for enabling on-demand based disk bursting.

You can refer to the [Managed Disks pricing page](#) for details on pricing and use [Azure Pricing Calculator](#) to make the assessment for your workload.

To enable on-demand bursting, see [Enable on-demand bursting](#).

### Credit-based bursting

For premium SSDs, credit-based bursting is available for disk sizes P20 and smaller. For standard SSDs, credit-based bursting is available for disk sizes E30 and smaller. For both standard and premium SSDs, credit-based bursting is available in all regions in Azure Public, Government, and China Clouds. By default, disk bursting is enabled on all new and existing deployments of supported disk sizes. VM-level bursting only uses credit-based bursting.

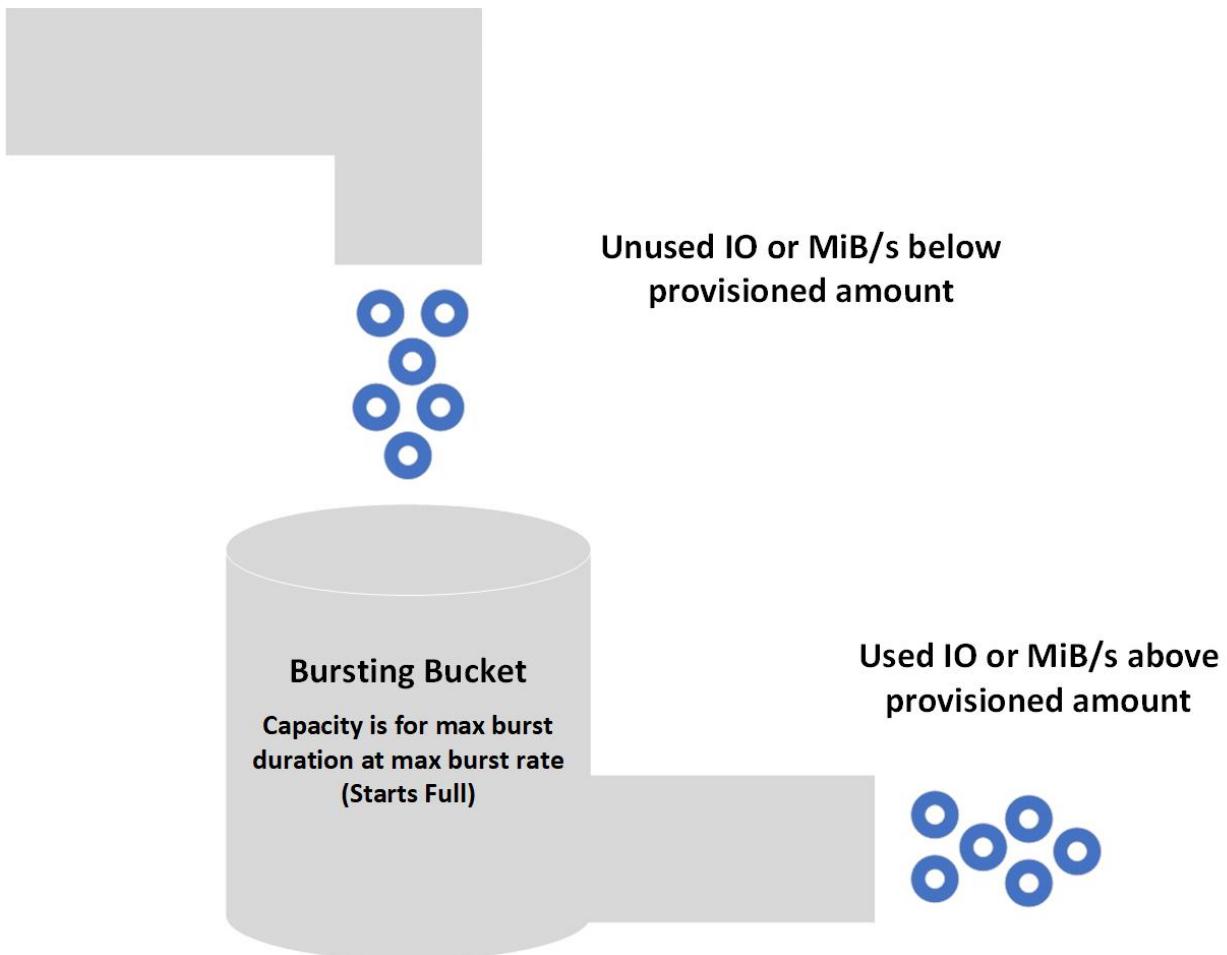

## Virtual machine-level bursting

VM-level bursting only uses the credit-based model for bursting, it is enabled by default for most Premium Storage supported VMs.

## Bursting flow

The bursting credit system applies in the same manner at both the VM level and disk level. Your resource, either a VM or disk, will start with fully stocked credits in its own burst bucket. These credits allow you to burst for up to 30 minutes at the maximum burst rate. You accumulate credits whenever the resource's IOPS or MB/s are

being utilized below the resource's performance target. If your resource has accrued bursting credits and your workload needs the extra performance, your resource can use those credits to go above its performance limits and increase its performance to meet the workload demands.

How you spend your available credits is up to you. You can use your 30 minutes of burst credits consecutively or sporadically throughout the day. When resources are deployed they come with a full allocation of credits. When those deplete, it takes less than a day to restock. Credits can be spent at your discretion, the burst bucket does not need to be full in order for resources to burst. Burst accumulation varies depending on each resource, since it is based on unused IOPS and MB/s below their performance targets. Higher baseline performance resources can accrue their bursting credits faster than lower baseline performing resources. For example, a P1 disk idling will accrue 120 IOPS per second, whereas an idling P20 disk would accrue 2,300 IOPS per second.

## Bursting states

There are three states your resource can be in with bursting enabled:

- **Accruing** – The resource's IO traffic is using less than the performance target. Accumulating bursting credits for IOPS and MB/s are done separate from one another. Your resource can be accruing IOPS credits and spending MB/s credits or vice versa.
- **Bursting** – The resource's traffic is using more than the performance target. The burst traffic will independently consume credits from IOPS or bandwidth.
- **Constant** – The resource's traffic is exactly at the performance target.

## Bursting examples

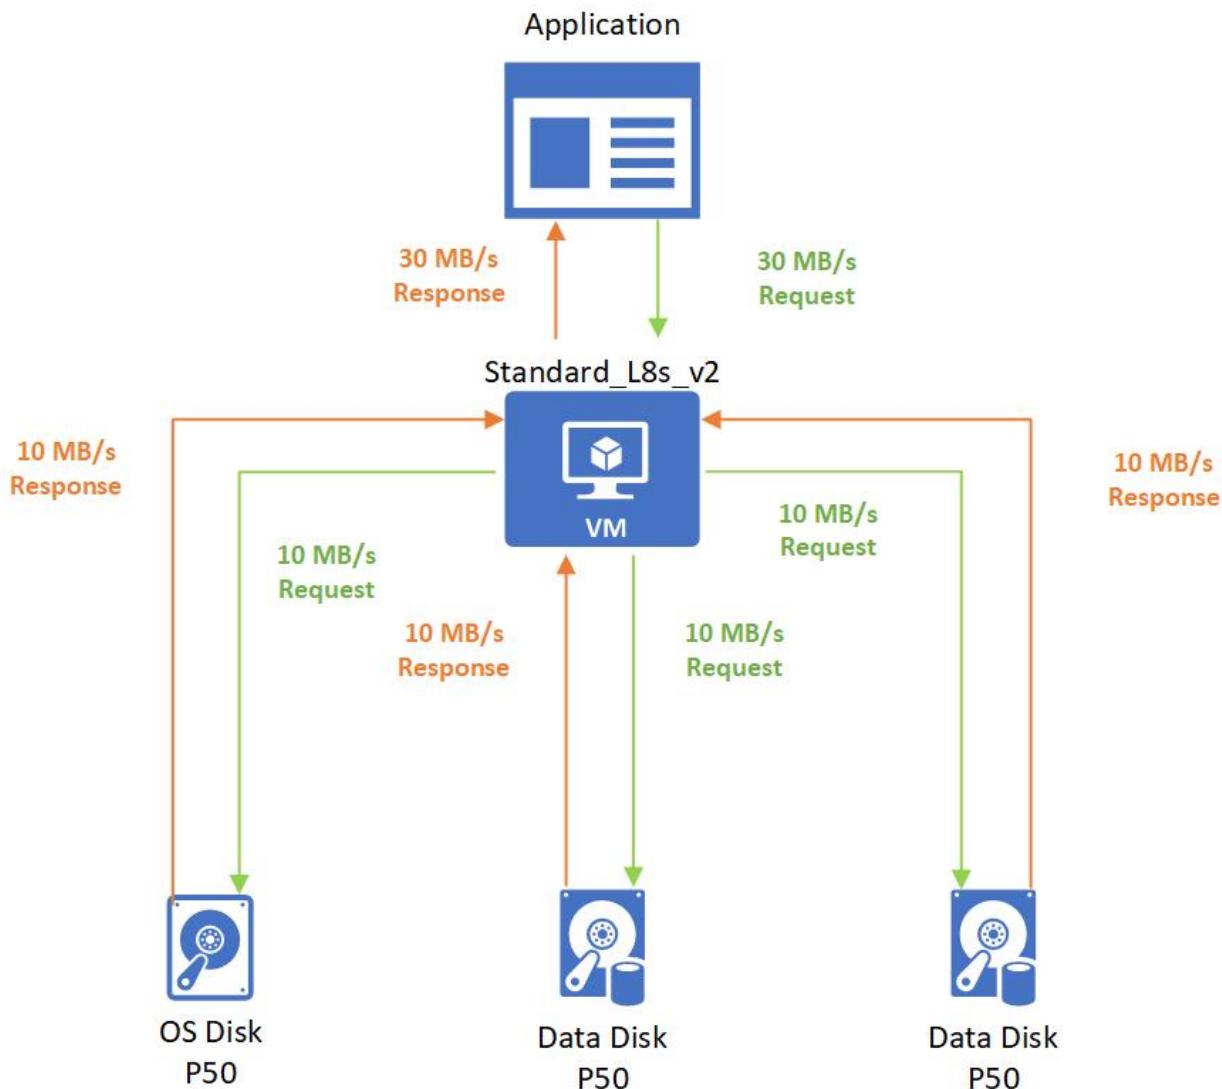

The following examples show how bursting works with various VM and disk combinations. To make the examples easy to follow, we will focus on MB/s, but the same logic is applied independently to IOPS.

### Burstable virtual machine with non-burstable disks

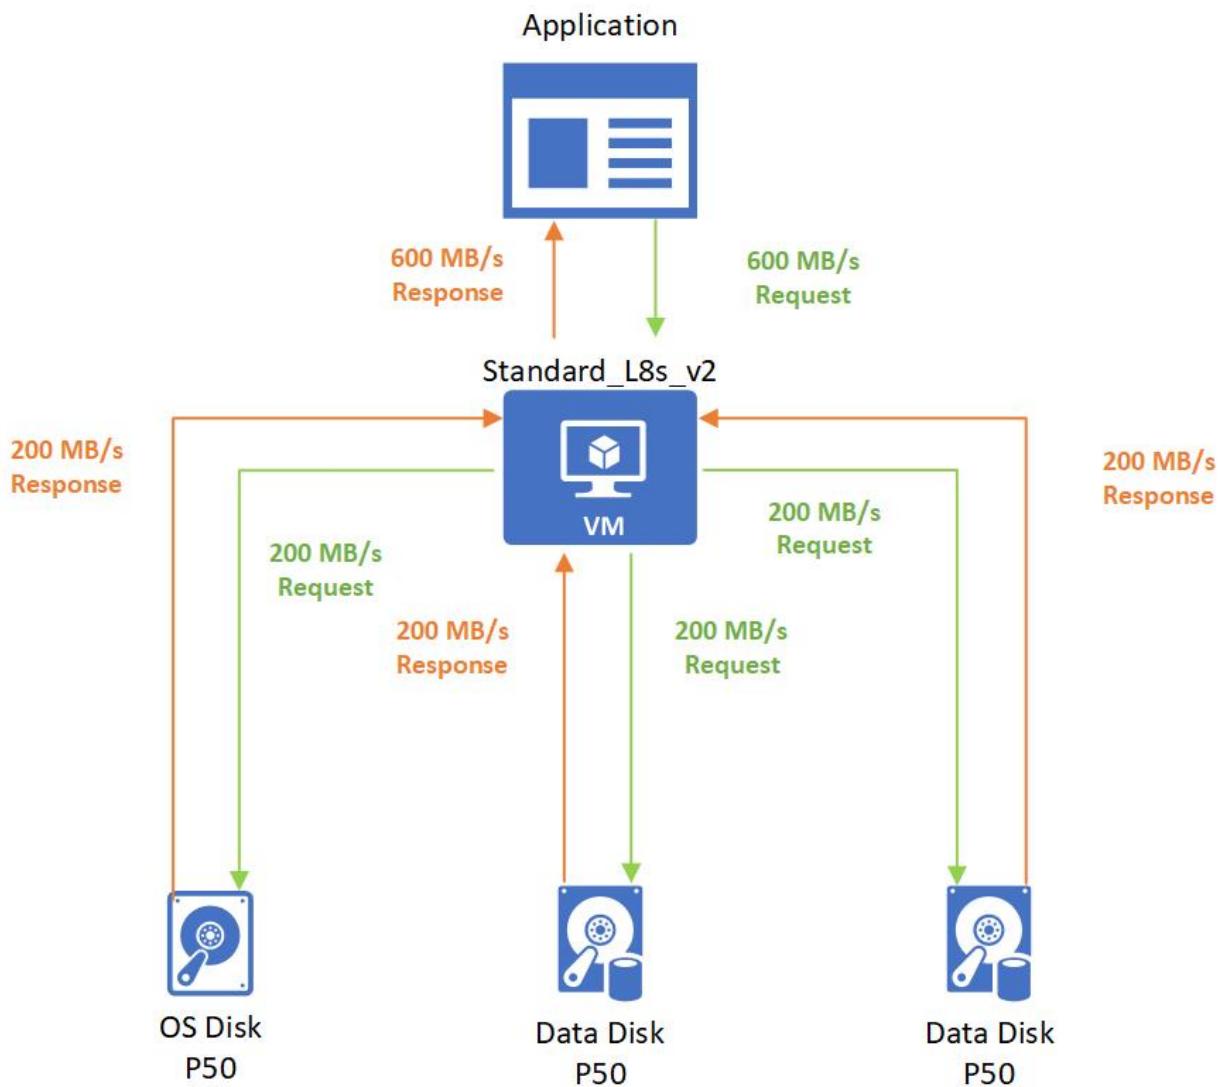

## VM and disk combination:

- Standard\_L8s\_v2
  - Uncached MB/s: 160
  - Max burst MB/s: 1,280
- P50 OS Disk
  - Provisioned MB/s: 250
  - On-Demand Bursting: **not enabled**
- 2 P50 Data Disks
  - Provisioned MB/s: 250
  - On-Demand Bursting: **not enabled**

After the initial boot up, an application is run on the VM and has a non-critical workload. This workload requires 30 MB/s that gets spread evenly across all the disks.

Then the application needs to process a batched job that requires 600 MB/s. The Standard\_L8s\_v2 bursts to meet this demand and then requests to the disks get evenly spread out to P50 disks.

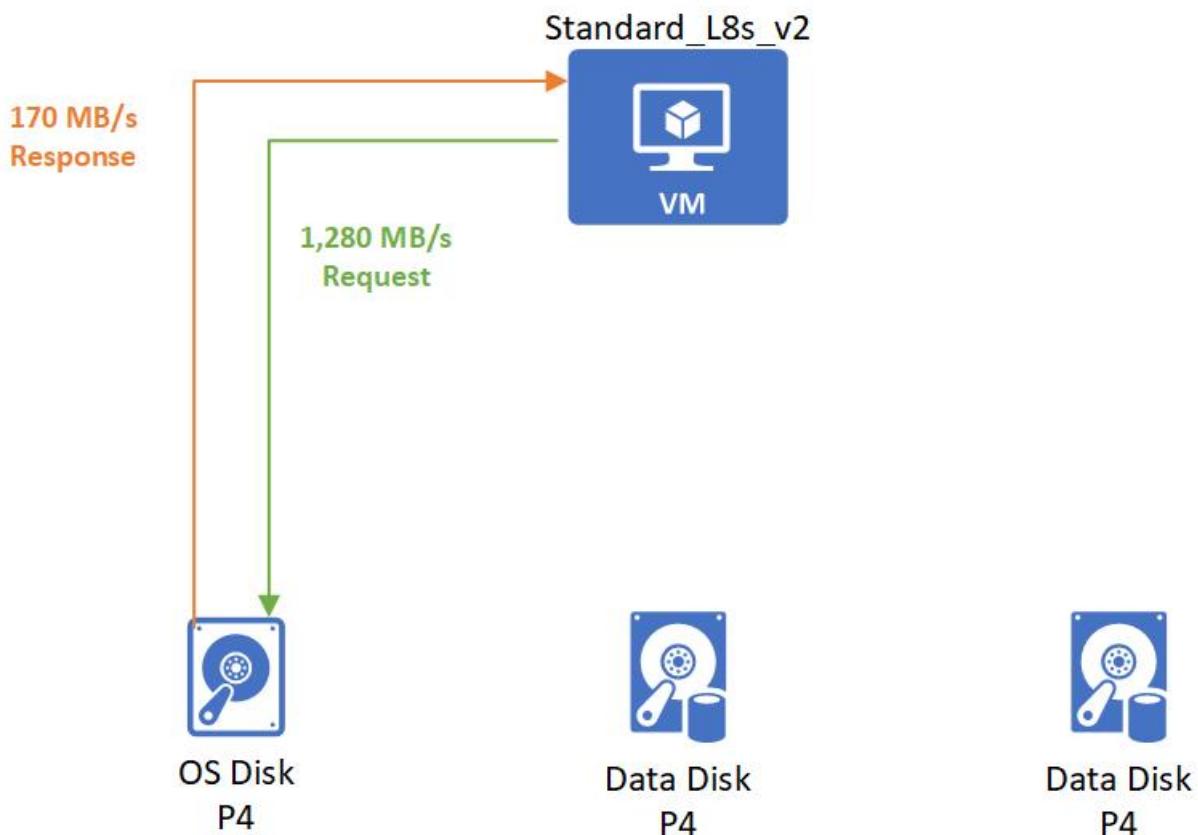

### Burstable virtual machine with burstable disks

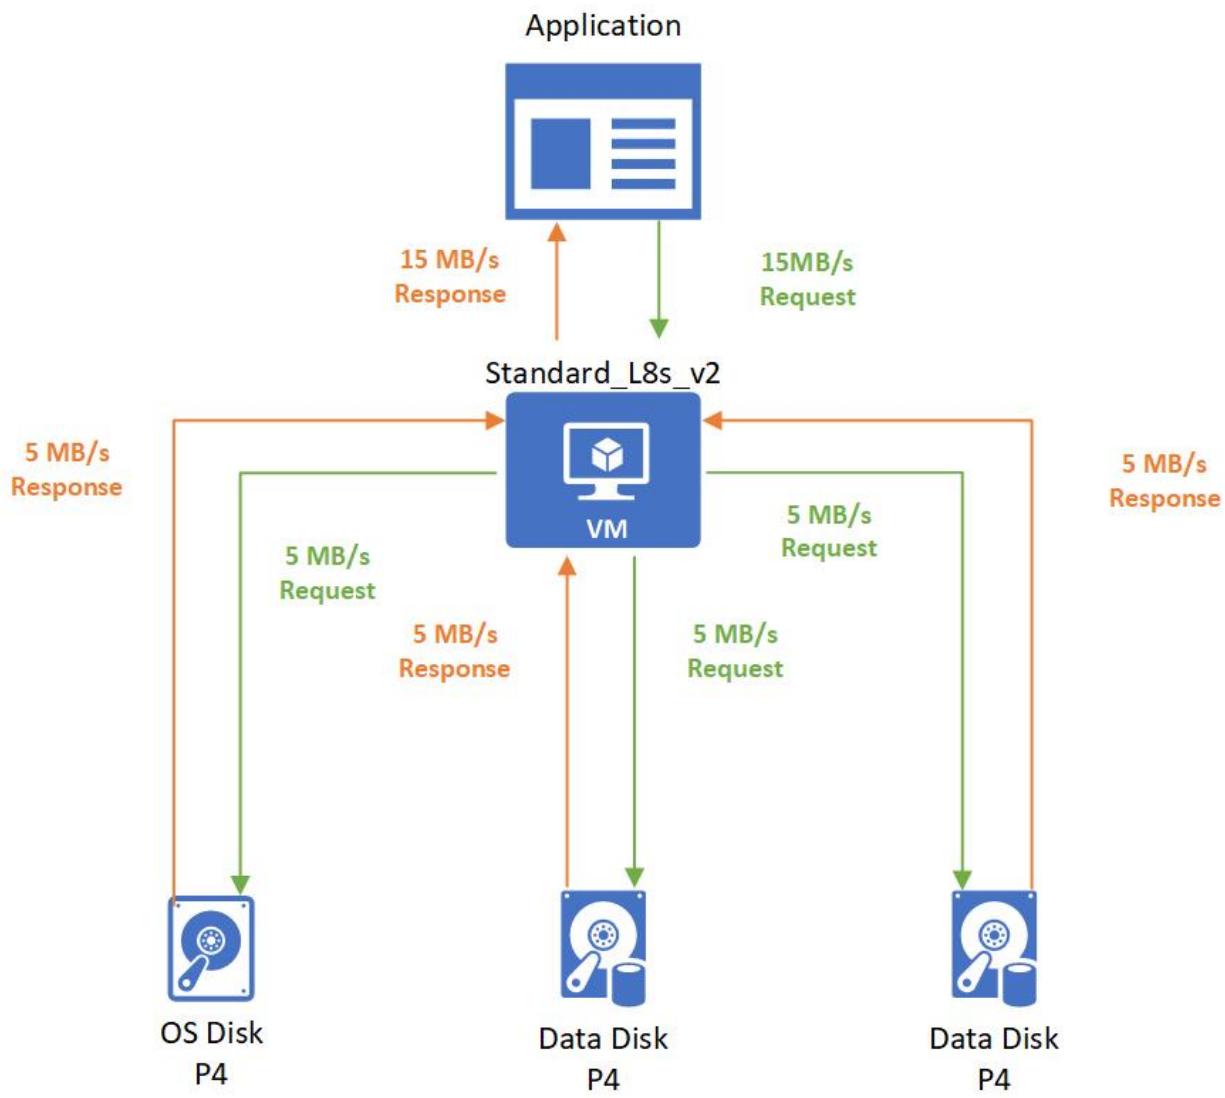

VM and disk combination:

- Standard\_L8s\_v2
  - Uncached MB/s: 160
  - Max burst MB/s: 1,280
- P4 OS Disk
  - Provisioned MB/s: 25
  - Max burst MB/s: 170
- 2 P4 Data Disks
  - Provisioned MB/s: 25
  - Max burst MB/s: 170

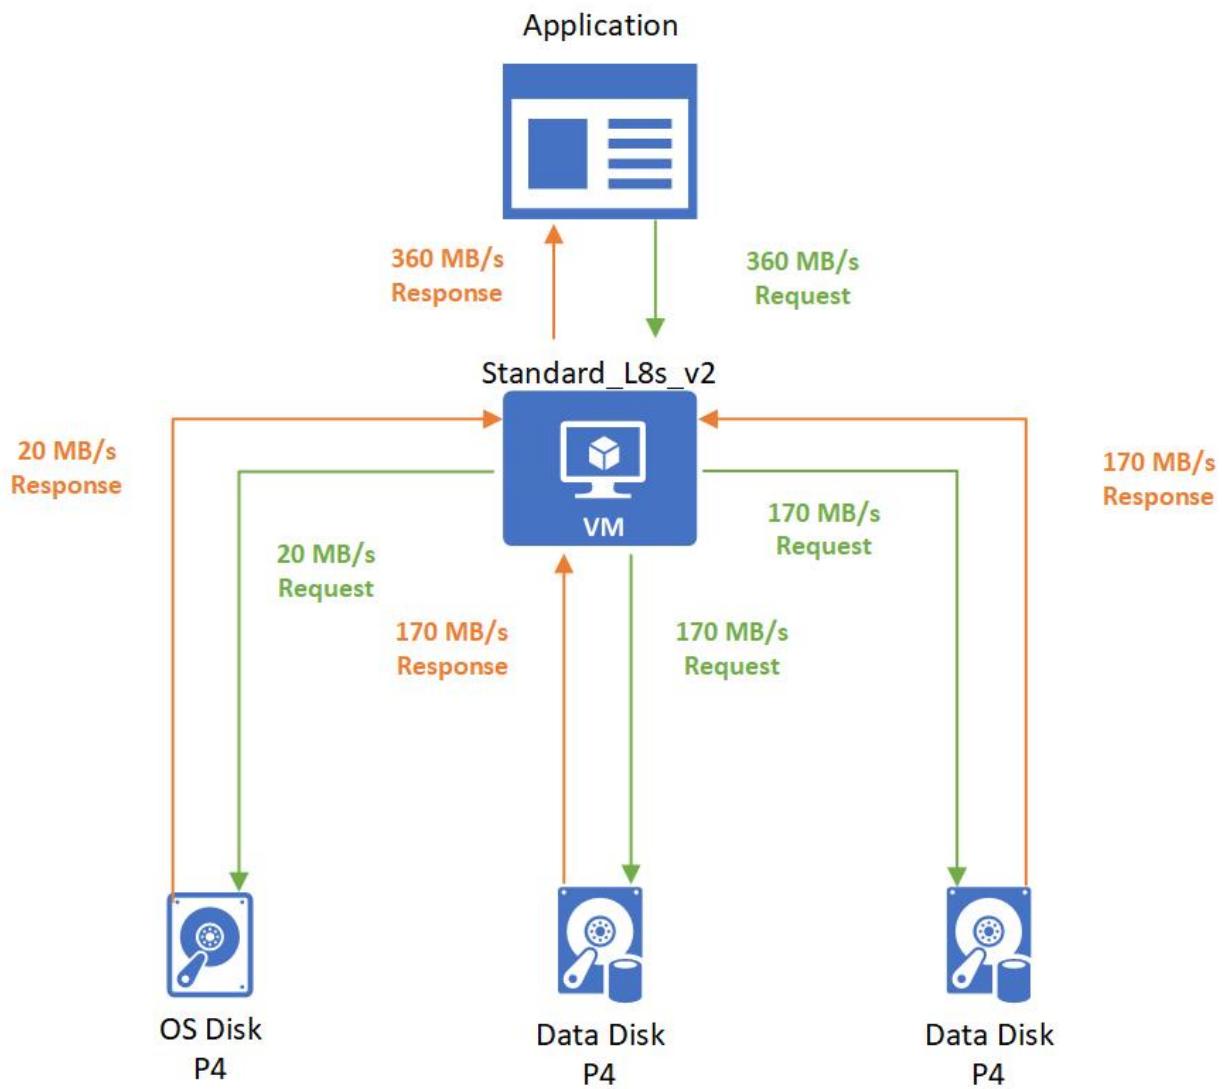

When the VM starts, it will burst to request its burst limit of 1,280 MB/s from the OS disk and the OS disk will respond with its burst performance of 170 MB/s.

After startup, you start an application that has a non-critical workload. This application requires 15 MB/s that gets spread evenly across all the disks.

Then the application needs to process a batched job that requires 360 MB/s. The Standard\_L8s\_v2 bursts to meet this demand and then requests. Only 20 MB/s are needed by the OS disk. The remaining 340 MB/s are handled by the bursting P4 data disks.

## Next steps

- To enable on-demand bursting, see [Enable on-demand bursting](#).
- To learn how to gain insight into your bursting resources, see [Disk bursting metrics](#).
- To see exactly how much each applicable disk size can burst, see [Scalability and performance targets for VM disks](#).

# Enable on-demand bursting

9/21/2022 • 3 minutes to read • [Edit Online](#)

Premium solid-state drives (SSD) have two available bursting models; credit-based bursting and on-demand bursting. This article covers how to switch to on-demand bursting. Disks that use the on-demand model can burst beyond their original provisioned targets. On-demand bursting occurs as often as needed by the workload, up to the maximum burst target. On-demand bursting incurs additional charges.

For details on disk bursting, see [Managed disk bursting](#).

For the max burst targets on each supported disk, see [Scalability and performance targets for VM disks](#).

## IMPORTANT

You don't need to follow the steps in this article to use credit-based bursting. By default, credit-based bursting is enabled on all eligible disks.

Before you enable on-demand bursting, understand the following:

- On-demand bursting cannot be enabled on a premium SSD that has less than or equal to 512 GiB. Premium SSDs less than or equal to 512 GiB will always use credit-based bursting.
- On-demand bursting is only supported on premium SSDs. If a premium SSD with on-demand bursting enabled is switched to another disk type, then disk bursting is disabled.
- On-demand bursting doesn't automatically disable itself when the performance tier is changed. If you want to change your performance tier but do not want to keep disk bursting, you must disable it.
- On-demand bursting can only be enabled when the disk is detached from a VM or when the VM is stopped. On-demand bursting can be disabled 12 hours after it has been enabled.

## Regional availability

Currently, the on-demand model for disk bursting is available in all public Azure regions.

## Get started

On-demand bursting can be enabled with either the Azure PowerShell module, the Azure CLI, or Azure Resource Manager templates. The following examples cover how to create a new disk with on-demand bursting enabled and enabling on-demand bursting on existing disks.

- [PowerShell](#)
- [Azure CLI](#)
- [Azure Resource Manager](#)

On-demand bursting cmdlets are available in version 5.5.0 and newer of the Az module. Alternatively, you may use the [Azure Cloud Shell](#).

### Create an empty data disk with on-demand bursting

A managed disk must be larger than 512 GiB to enable on-demand bursting. Replace the `<myResourceGroupDisk>` and `<myDataDisk>` parameters then run the following script to create a premium SSD with on-demand bursting:

```
Set-AzContext -SubscriptionName <yourSubscriptionName>

$diskConfig = New-AzDiskConfig -Location 'WestCentralUS' -CreateOption Empty -DiskSizeGB 1024 -SkuName Premium_LRS -BurstingEnabled $true

$dataDisk = New-AzDisk -ResourceGroupName <myResourceGroupDisk> -DiskName <myDataDisk> -Disk $diskConfig
```

## Enable on-demand bursting on an existing disk

A managed disk must be larger than 512 GiB to enable on-demand bursting. Replace the `<myResourceGroupDisk>`, `<myDataDisk>` parameters and run this command to enable on-demand bursting on an existing disk:

```
New-AzDiskUpdateConfig -BurstingEnabled $true | Update-AzDisk -ResourceGroupName <myResourceGroupDisk> -DiskName <myDataDisk> //Set the flag to $false to disable on-demand bursting
```

## Next steps

To learn how to gain insight into your bursting resources, see [Disk bursting metrics](#).

# Performance tiers for managed disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The performance of your Azure managed disk is set when you create your disk, in the form of its performance tier. When you set the provisioned size of your disk, a performance tier is automatically selected. The performance tier determines the IOPS and throughput your managed disk has. The performance tier can be changed at deployment or afterwards, without changing the size of the disk and without downtime.

Changing the performance tier allows you to prepare for and meet higher demand without using your disk's bursting capability. It can be more cost-effective to change your performance tier rather than rely on bursting, depending on how long the additional performance is necessary. This is ideal for events that temporarily require a consistently higher level of performance, like holiday shopping, performance testing, or running a training environment. To handle these events, you can switch a disk to a higher performance tier without downtime, for as long as you need the additional performance. You can then return to the original tier without downtime when the additional performance is no longer necessary.

## Restrictions

- This feature is currently supported only for premium SSDs.
- This feature isn't currently supported with shared disks.
- The P60, P70, and P80 performance tiers can only be used by disks that are larger than 4,096 GiB.
- A disk's performance tier can be downgraded only once every 12 hours.
- The system does not return Performance Tier for disks created before June 2020. You can take advantage of Performance Tier for an older disk by updating it with the baseline Tier.

## How it works

When you first deploy or provision a disk, the baseline performance tier for that disk is set based on the provisioned disk size. You can use a performance tier higher than the original baseline to meet higher demand. When you no longer need that performance level, you can return to the initial baseline performance tier.

### Billing impact

Your billing changes as your performance tier changes. For example, if you provision a P10 disk (128 GiB), your baseline performance tier is set as P10 (500 IOPS and 100 MBps). You'll be billed at the P10 rate. You can upgrade the tier to match the performance of P50 (7,500 IOPS and 250 MBps) without increasing the disk size. During the time of the upgrade, you'll be billed at the P50 rate. When you no longer need the higher performance, you can return to the P10 tier. The disk will once again be billed at the P10 rate.

For billing information, see [Managed disk pricing](#).

## What tiers can be changed

The following table depicts which tiers each baseline performance tier can upgrade to.

DISK SIZE	BASELINE PERFORMANCE TIER	CAN BE UPGRADED TO
4 GiB	P1	P2, P3, P4, P6, P10, P15, P20, P30, P40, P50

DISK SIZE	BASELINE PERFORMANCE TIER	CAN BE UPGRADED TO
8 GiB	P2	P3, P4, P6, P10, P15, P20, P30, P40, P50
16 GiB	P3	P4, P6, P10, P15, P20, P30, P40, P50
32 GiB	P4	P6, P10, P15, P20, P30, P40, P50
64 GiB	P6	P10, P15, P20, P30, P40, P50
128 GiB	P10	P15, P20, P30, P40, P50
256 GiB	P15	P20, P30, P40, P50
512 GiB	P20	P30, P40, P50
1 TiB	P30	P40, P50
2 TiB	P40	P50
4 TiB	P50	None
8 TiB	P60	P70, P80
16 TiB	P70	P80
32 TiB	P80	None

## Next steps

To learn how to change your performance tier, see [portal](#) or [PowerShell/CLI](#) articles.

# Change your performance tier without downtime using the Azure PowerShell module or the Azure CLI

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

The performance of your Azure managed disk is set when you create your disk, in the form of its performance tier. The performance tier determines the IOPS and throughput your managed disk has. When you set the provisioned size of your disk, a performance tier is automatically selected. The performance tier can be changed at deployment or afterwards, without changing the size of the disk and without downtime. To learn more about performance tiers, see [Performance tiers for managed disks](#).

Changing your performance tier has billing implications. See [Billing impact](#) for details.

## Restrictions

- This feature is currently supported only for premium SSDs.
- This feature isn't currently supported with shared disks.
- The P60, P70, and P80 performance tiers can only be used by disks that are larger than 4,096 GiB.
- A disk's performance tier can be downgraded only once every 12 hours.
- The system does not return Performance Tier for disks created before June 2020. You can take advantage of Performance Tier for an older disk by updating it with the baseline Tier.

## Prerequisites

- [Azure CLI](#)
- [PowerShell](#)

Install the latest [Azure CLI](#) and sign in to an Azure account with [az login](#).

## Create an empty data disk with a tier higher than the baseline tier

- [Azure CLI](#)
- [PowerShell](#)

```
subscriptionId=<yourSubscriptionIDHere>
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
diskSize=<yourDiskSizeHere>
performanceTier=<yourDesiredPerformanceTier>
region=westcentralus

az account set --subscription $subscriptionId

az disk create -n $diskName -g $resourceGroupName -l $region --sku Premium_LRS --size-gb $diskSize --tier
$performanceTier
```

## Create an OS disk with a tier higher than the baseline tier from an Azure Marketplace image

```
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
performanceTier=<yourDesiredPerformanceTier>
region=westcentralus
image=Canonical:UbuntuServer:18.04-LTS:18.04.202002180

az disk create -n $diskName -g $resourceGroupName -l $region --image-reference $image --sku Premium_LRS --
tier $performanceTier
```

## Update the tier of a disk without downtime

- [Azure CLI](#)
- [PowerShell](#)

1. Update the tier of a disk even when it is attached to a running VM

```
resourceGroupName=<yourResourceGroupNameHere>
diskName=<yourDiskNameHere>
performanceTier=<yourDesiredPerformanceTier>

az disk update -n $diskName -g $resourceGroupName --set tier=$performanceTier
```

## Show the tier of a disk

- [Azure CLI](#)
- [PowerShell](#)

```
az disk show -n $diskName -g $resourceGroupName --query [tier] -o tsv
```

## Next steps

If you need to resize a disk to take advantage of the higher performance tiers, see these articles:

- [Expand virtual hard disks on a Linux VM with the Azure CLI](#)
- [Expand a managed disk attached to a Windows virtual machine](#)

# Change your performance tier using the Azure portal

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

The performance of your Azure managed disk is set when you create your disk, in the form of its performance tier. The performance tier determines the IOPS and throughput your managed disk has. When you set the provisioned size of your disk, a performance tier is automatically selected. The performance tier can be changed at deployment or afterwards, without changing the size of the disk and without downtime. To learn more about performance tiers, see [Performance tiers for managed disks](#).

Changing your performance tier has billing implications. See [Billing impact](#) for details.

## Restrictions

- This feature is currently supported only for premium SSDs.
- This feature isn't currently supported with shared disks.
- The P60, P70, and P80 performance tiers can only be used by disks that are larger than 4,096 GiB.
- A disk's performance tier can be downgraded only once every 12 hours.
- The system does not return Performance Tier for disks created before June 2020. You can take advantage of Performance Tier for an older disk by updating it with the baseline Tier.

## Getting started

### New disks

The following steps show how to change the performance tier of your disk when you first create the disk:

1. Sign in to the [Azure portal](#).
2. Navigate to the VM you'd like to create a new disk for.
3. When selecting the new disk, first choose the size, of disk you need.
4. Once you've selected a size, then select a different performance tier, to change its performance.
5. Select **OK** to create the disk.

Size	Disk tier	Provisioned IOPS	Provisioned throughput	Max Shares	Max burst IOPS	Max burst throughput
4 GiB	P1	120	25	-	3500	170
8 GiB	P2	120	25	-	3500	170
16 GiB	P3	120	25	-	3500	170
32 GiB	P4	120	25	-	3500	170
64 GiB	P6	240	50	-	3500	170
128 GiB	P10	500	100	-	3500	170
256 GiB	P15	1100	125	2	3500	170
512 GiB	P20	2300	150	2	3500	170
1024 GiB	P30	5000	200	5	-	-
2048 GiB	P40	7500	250	5	-	-
4096 GiB	P50	7500	250	5	-	-
8192 GiB	P60	16000	500	10	-	-
16384 GiB	P70	18000	750	10	-	-
32767 GiB	P80	20000	900	10	-	-

## Change the performance tier of an existing disk

A disk's performance tier can be changed without downtime, so you don't have to deallocate your VM or detach your disk to change the tier.

### Change performance tier

1. Navigate to the VM containing the disk you'd like to change.
2. Select your disk
3. Select **Size + Performance**.
4. In the **Performance tier** dropdown, select a tier other than the disk's current performance tier.
5. Select **Resize**.

 **performance-tier-upgrade** | Size + performance 

Disk

Search (Ctrl+/)

Premium SSD

Size	Disk tier	Provisioned IOPS
4 GiB	P1	120
8 GiB	P2	120
16 GiB	P3	120
32 GiB	P4	120
64 GiB	P6	240
128 GiB	P10	500
256 GiB	P15	1100
512 GiB	P20	2300
1024 GiB	P30	5000
2048 GiB	P40	7500
4096 GiB	P50	7500
8192 GiB	P60	16000

- [Expand a managed disk attached to a Windows virtual machine](#)

# Enable Write Accelerator

9/21/2022 • 9 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Write Accelerator is a disk capability for M-Series Virtual Machines (VMs) on Premium Storage with Azure Managed Disks exclusively. As the name states, the purpose of the functionality is to improve the I/O latency of writes against Azure Premium Storage. Write Accelerator is ideally suited where log file updates are required to persist to disk in a highly performant manner for modern databases.

Write Accelerator is generally available for M-series VMs in the Public Cloud.

## Planning for using Write Accelerator

Write Accelerator should be used for the volumes that contain the transaction log or redo logs of a DBMS. It is not recommended to use Write Accelerator for the data volumes of a DBMS as the feature has been optimized to be used against log disks.

Write Accelerator only works in conjunction with [Azure managed disks](#).

### IMPORTANT

Enabling Write Accelerator for the operating system disk of the VM will reboot the VM.

To enable Write Accelerator to an existing Azure disk that is NOT part of a volume build out of multiple disks with Windows disk or volume managers, Windows Storage Spaces, Windows Scale-out file server (SOFS), Linux LVM, or MDADM, the workload accessing the Azure disk needs to be shut down. Database applications using the Azure disk MUST be shut down.

If you want to enable or disable Write Accelerator for an existing volume that is built out of multiple Azure Premium Storage disks and striped using Windows disk or volume managers, Windows Storage Spaces, Windows Scale-out file server (SOFS), Linux LVM or MDADM, all disks building the volume must be enabled or disabled for Write Accelerator in separate steps. Before enabling or disabling Write Accelerator in such a configuration, shut down the Azure VM.

Enabling Write Accelerator for OS disks should not be necessary for SAP-related VM configurations.

### Restrictions when using Write Accelerator

When using Write Accelerator for an Azure disk/VHD, these restrictions apply:

- The Premium disk caching must be set to 'None' or 'Read Only'. All other caching modes are not supported.
- Snapshots are currently supported for only Write Accelerator-enabled data disks, and not the OS disk.  
During backup, the Azure Backup service automatically backs up and protects Write Accelerator-enabled data disks attached to the VM.
- Only smaller I/O sizes (<=64 KiB) are taking the accelerated path. In workload situations where data is getting bulk loaded or where the transaction log buffers of the different DBMS are filled to a larger degree before getting persisted to the storage, chances are that the I/O written to disk is not taking the accelerated path.

There are limits of Azure Premium Storage VHDs per VM that can be supported by Write Accelerator. The current limits are:

VM SKU	NUMBER OF WRITE ACCELERATOR DISKS	WRITE ACCELERATOR DISK IOPS PER VM
M416ms_v2, M416s_v2	16	20000
M208ms_v2, M208s_v2	8	10000
M192ids_v2, M192idms_v2, M192is_v2, M192ims_v2,	16	20000
M128ms, M128s, M128ds_v2, M128dms_v2, M128s_v2, M128ms_v2	16	20000
M64ms, M64ls, M64s, M64ds_v2, M64dms_v2, M64s_v2, M64ms_v2	8	10000
M32ms, M32ls, M32ts, M32s, M32dms_v2, M32ms_v2	4	5000
M16ms, M16s	2	2500
M8ms, M8s	1	1250

The IOPS limits are per VM and *not* per disk. All Write Accelerator disks share the same IOPS limit per VM. Attached disks cannot exceed the write accelerator IOPS limit for a VM. For an example, even though the attached disks can do 30,000 IOPS, the system does not allow the disks to go above 20,000 IOPS for M416ms\_v2.

## Enabling Write Accelerator on a specific disk

The next few sections will describe how Write Accelerator can be enabled on Azure Premium Storage VHDs.

### Prerequisites

The following prerequisites apply to the usage of Write Accelerator at this point in time:

- The disks you want to apply Azure Write Accelerator against need to be [Azure managed disks](#) on Premium Storage.
- You must be using an M-series VM

## Enabling Azure Write Accelerator using Azure PowerShell

The Azure Power Shell module from version 5.5.0 include the changes to the relevant cmdlets to enable or disable Write Accelerator for specific Azure Premium Storage disks. In order to enable or deploy disks supported by Write Accelerator, the following Power Shell commands got changed, and extended to accept a parameter for Write Accelerator.

A new switch parameter, **-WriteAccelerator** has been added to the following cmdlets:

- [Set-AzVMOSDisk](#)
- [Add-AzVMDataDisk](#)
- [Set-AzVMDataDisk](#)
- [Add-AzVmssDataDisk](#)

Not giving the parameter sets the property to false and will deploy disks that have no support by Write Accelerator.

A new switch parameter, **-OsDiskWriteAccelerator** was added to the following cmdlets:

- [Set-AzVmssStorageProfile](#)

Not specifying the parameter sets the property to false by default, returning disks that don't leverage Write Accelerator.

A new optional Boolean (non-nullable) parameter, **-OsDiskWriteAccelerator** was added to the following cmdlets:

- [Update-AzVM](#)
- [Update-AzVmss](#)

Specify either \$true or \$false to control support of Azure Write Accelerator with the disks.

Examples of commands could look like:

```
New-AzVMConfig | Set-AzVMOsDisk | Add-AzVMDataDisk -Name "datadisk1" | Add-AzVMDataDisk -Name "logdisk1" -WriteAccelerator | New-AzVM

Get-AzVM | Update-AzVM -OsDiskWriteAccelerator $true

New-AzVmssConfig | Set-AzVmssStorageProfile -OsDiskWriteAccelerator | Add-AzVmssDataDisk -Name "datadisk1" -WriteAccelerator:$false | Add-AzVmssDataDisk -Name "logdisk1" -WriteAccelerator | New-AzVmss

Get-AzVmss | Update-AzVmss -OsDiskWriteAccelerator:$false
```

Two main scenarios can be scripted as shown in the following sections.

### Adding a new disk supported by Write Accelerator using PowerShell

You can use this script to add a new disk to your VM. The disk created with this script uses Write Accelerator.

Replace `myVM`, `myWAVMs`, `log001`, size of the disk, and LunID of the disk with values appropriate for your specific deployment.

```
# Specify your VM Name
$vmName="myVM"
#Specify your Resource Group
$rgName = "myWAVMs"
#data disk name
$datadiskname = "log001"
#LUN Id
$lunid=8
#size
$size=1023
#Pulls the VM info for later
$vm=Get-AzVM -ResourceGroupName $rgname -Name $vmname
#add a new VM data disk
Add-AzVMDataDisk -CreateOption empty -DiskSizeInGB $size -Name $vmname-$datadiskname -VM $vm -Caching None -WriteAccelerator:$true -lun $lunid
#Updates the VM with the disk config - does not require a reboot
Update-AzVM -ResourceGroupName $rgname -VM $vm
```

### Enabling Write Accelerator on an existing Azure disk using PowerShell

You can use this script to enable Write Accelerator on an existing disk. Replace `myVM`, `myWAVMs`, and `test-log001` with values appropriate for your specific deployment. The script adds Write Accelerator to an existing disk where the value for `$newstatus` is set to '\$true'. Using the value '\$false' will disable Write Accelerator on a given disk.

```

#Specify your VM Name
$vmName="myVM"
#Specify your Resource Group
$rgName = "myWAVMs"
#data disk name
$datadiskname = "test-log001"
#new Write Accelerator status ($true for enabled, $false for disabled)
$newstatus = $true
#Pulls the VM info for later
$vm=Get-AzVM -ResourceGroupName $rgname -Name $vmname
#add a new VM data disk
Set-AzVMDataDisk -VM $vm -Name $datadiskname -Caching None -WriteAccelerator:$newstatus
#Updates the VM with the disk config - does not require a reboot
Update-AzVM -ResourceGroupName $rgname -VM $vm

```

#### NOTE

Executing the script above will detach the disk specified, enable Write Accelerator against the disk, and then attach the disk again

## Enabling Write Accelerator using the Azure portal

You can enable Write Accelerator via the portal where you specify your disk caching settings:

LUN	NAME	SIZE	STORAGE ACCOUNT TYPE	ENCRYPTION	HOST CACHING
0	WADisk1	1023 GiB	Premium_LRS	Not enabled	Read-only + Write Accelerator
1	WADisk2	1023 GiB	Premium_LRS	Not enabled	None + Write Accelerator

## Enabling Write Accelerator using the Azure CLI

You can use the [Azure CLI](#) to enable Write Accelerator.

To enable Write Accelerator on an existing disk, use [az vm update](#), you may use the following examples if you replace the `diskName`, `VMName`, and `ResourceGroup` with your own values:

```
az vm update -g group1 -n vm1 -write-accelerator 1=true
```

To attach a disk with Write Accelerator enabled use [az vm disk attach](#), you may use the following example if you substitute in your own values: `az vm disk attach -g group1 -vm-name vm1 -disk d1 --enable-write-accelerator`

To disable Write Accelerator, use [az vm update](#), setting the properties to false:

```
az vm update -g group1 -n vm1 -write-accelerator 0=false 1=false
```

# Enabling Write Accelerator using REST APIs

To deploy through Azure REST API, you need to install the Azure armclient.

## Install armclient

To run armclient, you need to install it through Chocolatey. You can install it through cmd.exe or PowerShell. Use elevated rights for these commands ("Run as Administrator").

Using cmd.exe, run the following command:

```
@%SystemRoot%\System32\WindowsPowerShell\v1.0\powershell.exe" -NoProfile -InputFormat None -ExecutionPolicy Bypass -Command "iex ((New-Object System.Net.WebClient).DownloadString('https://chocolatey.org/install.ps1'))" && SET "PATH=%PATH%;%ALLUSERSPROFILE%\chocolatey\bin"
```

Using Power Shell, run the following command:

```
Set-ExecutionPolicy Bypass -Scope Process -Force; iex ((New-Object System.Net.WebClient).DownloadString('https://chocolatey.org/install.ps1'))
```

Now you can install the armclient by using the following command in either cmd.exe or PowerShell

```
choco install armclient
```

## Getting your current VM configuration

To change the attributes of your disk configuration, you first need to get the current configuration in a JSON file. You can get the current configuration by executing the following command:

```
armclient GET /subscriptions/<<subscription-ID>>/resourceGroups/<<ResourceGroup>>/providers/Microsoft.Compute/virtualMachines/<<virtualmachinename>>?api-version=2017-12-01 > <<filename.json>>
```

Replace the terms within '<< >>' with your data, including the file name the JSON file should have.

The output could look like:

```
{
  "properties": {
    "vmId": "2444c93e-f8bb-4a20-af2d-1658d9dbbbcb",
    "hardwareProfile": {
      "vmSize": "Standard_M64s"
    },
    "storageProfile": {
      "imageReference": {
        "publisher": "SUSE",
        "offer": "SLES-SAP",
        "sku": "12-SP3",
        "version": "latest"
      },
      "osDisk": {
        "osType": "Linux",
        "name": "mylittlesap_OsDisk_1_754a1b8bb390468e9b4c429b81cc5f5a",
        "createOption": "FromImage",
        "caching": "ReadWrite",
        "managedDisk": {
          "storageAccountType": "Premium_LRS",
          "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/mylittlesap_OsDisk_1_754a1b8bb390468e9b4c429b81cc5f5a"
        },
        "diskSizeGB": 30
      },
      "dataDisks": [
        {
          "lun": 0,
          "name": "data1",
          "createOption": "Attach",
          "caching": "None",
          "managedDisk": {
            "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data1"
          }
        }
      ]
  }
}
```

```

        "storageAccountType": "Premium_LRS",
        "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data1"
    },
    "diskSizeGB": 1023
},
{
    "lun": 1,
    "name": "log1",
    "createOption": "Attach",
    "caching": "None",
    "managedDisk": {
        "storageAccountType": "Premium_LRS",
        "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data2"
    },
    "diskSizeGB": 1023
}
],
},
"osProfile": {
    "computerName": "mylittlesapVM",
    "adminUsername": "pl",
    "linuxConfiguration": {
        "disablePasswordAuthentication": false
    },
    "secrets": []
},
"networkProfile": {
    "networkInterfaces": [
        {
            "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Network/networkInterfaces/mylittlesap518"
        }
    ]
},
"diagnosticsProfile": {
    "bootDiagnostics": {
        "enabled": true,
        "storageUri": "https://mylittlesapdiag895.blob.core.windows.net/"
    }
},
"provisioningState": "Succeeded"
},
"type": "Microsoft.Compute/virtualMachines",
"location": "westeurope",
"id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/virtualMachines/mylittlesapVM",
"name": "mylittlesapVM"

```

Next, update the JSON file and to enable Write Accelerator on the disk called 'log1'. This can be accomplished by adding this attribute into the JSON file after the cache entry of the disk.

```
{
    "lun": 1,
    "name": "log1",
    "createOption": "Attach",
    "caching": "None",
    "writeAcceleratorEnabled": true,
    "managedDisk": {
        "storageAccountType": "Premium_LRS",
        "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data2"
    },
    "diskSizeGB": 1023
}
```

Then update the existing deployment with this command:

```
armclient PUT /subscriptions/<<subscription-ID>>/resourceGroups/<<ResourceGroup>>/providers/Microsoft.Compute/virtualMachines/<<virtualmachinename>>?api-version=2017-12-01 @<<filename.json>>
```

The output should look like the one below. You can see that Write Accelerator enabled for one disk.

```
{
    "properties": {
        "vmId": "2444c93e-f8bb-4a20-af2d-1658d9dbbbc",
        "hardwareProfile": {
            "vmSize": "Standard_M64s"
        },
        "storageProfile": {
            "imageReference": {
                "publisher": "SUSE",
                "offer": "SLES-SAP",
                "sku": "12-SP3",
                "version": "latest"
            },
            "osDisk": {
                "osType": "Linux",
                "name": "mylittlesap_OsDisk_1_754a1b8bb390468e9b4c429b81cc5f5a",
                "createOption": "FromImage",
                "caching": "ReadWrite",
                "managedDisk": {
                    "storageAccountType": "Premium_LRS",
                    "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/mylittlesap_OsDisk_1_754a1b8bb390468e9b4c429b81cc5f5a"
                },
                "diskSizeGB": 30
            },
            "dataDisks": [
                {
                    "lun": 0,
                    "name": "data1",
                    "createOption": "Attach",
                    "caching": "None",
                    "managedDisk": {
                        "storageAccountType": "Premium_LRS",
                        "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data1"
                    },
                    "diskSizeGB": 1023
                },
                {
                    "lun": 1,
                    "name": "log1",
                    "createOption": "Attach",
                    "caching": "None"
                }
            ]
        }
    }
}
```

```

    "caching": "None",
    "writeAcceleratorEnabled": true,
    "managedDisk": {
        "storageAccountType": "Premium_LRS",
        "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/disks/data2"
    },
    "diskSizeGB": 1023
}
],
},
"osProfile": {
    "computerName": "mylittlesapVM",
    "adminUsername": "pl",
    "linuxConfiguration": {
        "disablePasswordAuthentication": false
    },
    "secrets": []
},
"networkProfile": {
    "networkInterfaces": [
        {
            "id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Network/networkInterfaces/mylittlesap518"
        }
    ]
},
"diagnosticsProfile": {
    "bootDiagnostics": {
        "enabled": true,
        "storageUri": "https://mylittlesapdiag895.blob.core.windows.net/"
    }
},
"provisioningState": "Succeeded"
},
"type": "Microsoft.Compute/virtualMachines",
"location": "westeurope",
"id": "/subscriptions/XXXXXXXXXXXXXXXXXXXXXX/resourceGroups/mylittlesap/providers/Microsoft.Compute/virtualMachines/mylittlesapVM",
"name": "mylittlesapVM"

```

Once you've made this change, the drive should be supported by Write Accelerator.

# Benchmark a disk

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Benchmarking is the process of simulating different workloads on your application and measuring the application performance for each workload. Using the steps described in the [designing for high performance article](#), you have gathered the application performance requirements. By running benchmarking tools on the VMs hosting the application, you can determine the performance levels that your application can achieve with premium SSDs. In this article, we provide you examples of benchmarking a Standard\_D8ds\_v4 VM provisioned with Azure premium SSDs.

We have used common benchmarking tools DiskSpd and FIO, for Windows and Linux respectively. These tools spawn multiple threads simulating a production like workload, and measure the system performance. Using the tools you can also configure parameters like block size and queue depth, which you normally cannot change for an application. This gives you more flexibility to drive the maximum performance on a high scale VM provisioned with premium SSDs for different types of application workloads. To learn more about each benchmarking tool visit [DiskSpd](#) and [FIO](#).

To follow the examples below, create a Standard\_D8ds\_v4 and attach four premium SSDs to the VM. Of the four disks, configure three with host caching as "None" and stripe them into a volume called NoCacheWrites. Configure host caching as "ReadOnly" on the remaining disk and create a volume called CacheReads with this disk. Using this setup, you are able to see the maximum Read and Write performance from a Standard\_D8ds\_v4 VM. For detailed steps about creating a Standard\_D8ds\_v4 with premium SSDs, see [Designing for high performance](#).

## Warm up the Cache

The disk with ReadOnly host caching is able to give higher IOPS than the disk limit. To get this maximum read performance from the host cache, first you must warm up the cache of this disk. This ensures that the Read IOs that the benchmarking tool will drive on CacheReads volume, actually hits the cache, and not the disk directly. The cache hits result in more IOPS from the single cache enabled disk.

### IMPORTANT

You must warm up the cache before running benchmarks every time VM is rebooted.

## DISKSPD

[Download the DISKSPD tool](#) on the VM. DISKSPD is a tool that you can customize to create your own synthetic workloads. We will use the same setup described above to run benchmarking tests. You can change the specifications to test different workloads.

In this example, we use the following set of baseline parameters:

- -c200G: Creates (or recreates) the sample file used in the test. It can be set in bytes, KiB, MiB, GiB, or blocks. In this case, a large file of 200-GiB target file is used to minimize memory caching.
- -w100: Specifies the percentage of operations that are write requests (-w0 is equivalent to 100% read).
- -b4K: Indicates the block size in bytes, KiB, MiB, or GiB. In this case, 4K block size is used to simulate a random I/O test.

- -F4: Sets a total of four threads.
- -r: Indicates the random I/O test (overrides the -s parameter).
- -o128: Indicates the number of outstanding I/O requests per target per thread. This is also known as the queue depth. In this case, 128 is used to stress the CPU.
- -W7200: Specifies the duration of the warm-up time before measurements start.
- -d30: Specifies the duration of the test, not including warm-up.
- -Sh: Disable software and hardware write caching (equivalent to -Suw).

For a complete list of parameters, see the [GitHub repository](#).

## Maximum write IOPS

We use a high queue depth of 128, a small block size of 8 KB, and four worker threads for driving Write operations. The write workers are driving traffic on the “NoCacheWrites” volume, which has three disks with cache set to “None”.

Run the following command for 30 seconds of warm-up and 30 seconds of measurement:

```
diskspd -c200G -w100 -b8K -F4 -r -o128 -W30 -d30 -Sh testfile.dat
```

Results show that the Standard\_D8ds\_v4 VM is delivering its maximum write IOPS limit of 12,800.

Total IO						
thread	bytes	I/Os	MiB/s	I/O per s	file	
0	802029568	97904	25.49	3262.63	G:\testfile.dat (200GiB)

total:	3208642560	391680	101.97	13052.65		

## Maximum read IOPS

We use a high queue depth of 128, a small block size of four KB, and four worker threads for driving Read operations. The read workers are driving traffic on the “CacheReads” volume, which has one disk with cache set to “ReadOnly”.

Run the following command for two hours of warm-up and 30 seconds of measurement:

```
diskspd -c200G -b4K -F4 -r -o128 -W7200 -d30 -Sh testfile.dat
```

Results show that the Standard\_D8ds\_v4 VM is delivering its maximum read IOPS limit of 77,000.

Total IO	thread	bytes	I/Os	MiB/s	I/O per s	file
	0	2632953856	642811	83.66	21417.94	F:\testfile.dat (200GiB)
	1	2468286464	602609	78.43	20078.44	F:\testfile.dat (200GiB)
	2	2044755968	499208	64.97	16633.21	F:\testfile.dat (200GiB)

	total:	0	0	0.00	0.00	

### Maximum throughput

To get the maximum read and write throughput, you can change to a larger block size of 64 KB.

## FIO

FIO is a popular tool to benchmark storage on the Linux VMs. It has the flexibility to select different IO sizes, sequential or random reads and writes. It spawns worker threads or processes to perform the specified I/O operations. You can specify the type of I/O operations each worker thread must perform using job files. We created one job file per scenario illustrated in the examples below. You can change the specifications in these job files to benchmark different workloads running on Premium Storage. In the examples, we are using a Standard\_D8ds\_v4 running **Ubuntu**. Use the same setup described in the beginning of the benchmark section and warm up the cache before running the benchmark tests.

Before you begin, [download FIO](#) and install it on your virtual machine.

Run the following command for Ubuntu,

```
apt-get install fio
```

We use four worker threads for driving Write operations and four worker threads for driving Read operations on the disks. The write workers are driving traffic on the "nocache" volume, which has three disks with cache set to "None". The read workers are driving traffic on the "readcache" volume, which has one disk with cache set to "ReadOnly".

### Maximum write IOPS

Create the job file with following specifications to get maximum Write IOPS. Name it "fiowrite.ini".

```

[global]
size=30g
direct=1
iodepth=256
ioengine=libaio
bs=4k
numjobs=4

[writer1]
rw=randwrite
directory=/mnt/nocache

```

Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

- A high queue depth of 256.
- A small block size of 4 KB.
- Multiple threads performing random writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fiowrite.ini
```

While the test runs, you are able to see the number of write IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard\_D8ds\_v4 VM is delivering its maximum write IOPS limit of 12,800 IOPS.

```

:~$ sudo fio fiowriteuncached.ini
writer1: (g=0): rw=randwrite, bs=(R) 4096B-4096B, (W) 4096B-4096B, (T) 4096B-4096B, ioengine=libaio, iodepth=256
...
fio-3.1
Starting 4 processes
Jobs: 4 (f=4): [w(4)][0.2%][r=0KiB/s,w=51.1MiB/s][r=0, w=13.1k IOPS][eta 54m:23s]

```

## Maximum read IOPS

Create the job file with following specifications to get maximum Read IOPS. Name it "fioread.ini".

```

[global]
size=30g
direct=1
iodepth=256
ioengine=libaio
bs=4k
numjobs=4

[reader1]
rw=randread
directory=/mnt/readcache

```

Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

- A high queue depth of 256.
- A small block size of 4 KB.
- Multiple threads performing random writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fioread.ini
```

While the test runs, you are able to see the number of read IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard\_D8ds\_v4 VM is delivering more than 77,000 Read IOPS. This is a combination of the disk and the cache performance.

```
:~$ sudo fio fioreadcache.ini
reader1: (g=0): rw=randread, bs=(R) 4096B-4096B, (W) 4096B-4096B, (T) 4096B-4096B, ioengine=libaio, iodepth=256
...
fio-3.1
Starting 4 processes
Jobs: 4 (f=4): [r(4)][2.0%][r=307MiB/s,w=0KiB/s] [r=78.6k,w=0 IOPS][eta 08m:59s]
```

## Maximum read and write IOPS

Create the job file with following specifications to get maximum combined Read and Write IOPS. Name it "fioreadwrite.ini".

```
[global]
size=30g
direct=1
iodepth=128
ioengine=libaio
bs=4k
numjobs=4

[reader1]
rw=randread
directory=/mnt/readcache

[writer1]
rw=randwrite
directory=/mnt/nocache
rate_iops=3200
```

Note the follow key things that are in line with the design guidelines discussed in previous sections. These specifications are essential to drive maximum IOPS,

- A high queue depth of 128.
- A small block size of 4 KB.
- Multiple threads performing random reads and writes.

Run the following command to kick off the FIO test for 30 seconds,

```
sudo fio --runtime 30 fioreadwrite.ini
```

While the test runs, you are able to see the number of combined read and write IOPS the VM and Premium disks are delivering. As shown in the sample below, the Standard\_D8ds\_v4 VM is delivering more than 90,000 combined Read and Write IOPS. This is a combination of the disk and the cache performance.

```
:~$ sudo fio fioboth.ini
reader1: (g=0): rw=randread, bs=(R) 4096B-4096B, (W) 4096B-4096B, (T) 4096B-4096B, ioengine=libaio, iodepth=256
...
writer1: (g=0): rw=randwrite, bs=(R) 4096B-4096B, (W) 4096B-4096B, (T) 4096B-4096B, ioengine=libaio, iodepth=256
...
fio-3.1
Starting 8 processes
Jobs: 8 (f=8), 0-12800 IOPS: [r(4),w(4)][0.7%][r=306MiB/s,w=49.4MiB/s] [r=78.3k,w=12.6k IOPS][eta 54m:36s]]
```

## Maximum combined throughput

To get the maximum combined Read and Write Throughput, use a larger block size and large queue depth with multiple threads performing reads and writes. You can use a block size of 64 KB and queue depth of 128.

## Next steps

Proceed to our article on [designing for high performance](#).

In that article, you create a checklist similar to your existing application for the prototype. Using Benchmarking tools you can simulate the workloads and measure performance on the prototype application. By doing so, you can determine which disk offering can match or surpass your application performance requirements. Then you can implement the same guidelines for your production application.

# Scalability and performance targets for VM disks

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can attach a number of data disks to an Azure virtual machine (VM). Based on the scalability and performance targets for a VM's data disks, you can determine the number and type of disk that you need to meet your performance and capacity requirements.

## IMPORTANT

For optimal performance, limit the number of highly utilized disks attached to the virtual machine to avoid possible throttling. If all attached disks aren't highly utilized at the same time, the virtual machine can support a larger number of disks.

### For Azure managed disks:

The following table illustrates the default and maximum limits of the number of resources per region per subscription. The limits remain the same irrespective of disks encrypted with either platform-managed keys or customer-managed keys. There is no limit for the number of Managed Disks, snapshots and images per resource group.

RESOURCE	LIMIT
Standard managed disks	50,000
Standard SSD managed disks	50,000
Premium managed disks	50,000
Standard_LRS snapshots <sup>1</sup>	75,000
Standard_ZRS snapshots <sup>1</sup>	75,000
Managed image	50,000

<sup>1</sup>An individual disk can have 500 incremental snapshots.

### For standard storage accounts:

A Standard storage account has a maximum total request rate of 20,000 IOPS. The total IOPS across all of your virtual machine disks in a Standard storage account should not exceed this limit.

For unmanaged disks, you can roughly calculate the number of highly utilized disks supported by a single standard storage account based on the request rate limit. For example, for a Basic tier VM, the maximum number of highly utilized disks is about 66, which is 20,000/300 IOPS per disk. The maximum number of highly utilized disks for a Standard tier VM is about 40, which is 20,000/500 IOPS per disk.

### For premium storage accounts:

A premium storage account has a maximum total throughput rate of 50 Gbps. The total throughput across all of

your VM disks should not exceed this limit.

See [VM sizes](#) for additional details.

## Managed virtual machine disks

Sizes denoted with an asterisk are currently in preview. See our [FAQ](#) to learn what regions they are available in.

### Standard HDD managed disks

STANDARD DISK TYPE	S4	S6	S10	S15	S20	S30	S40	S50	S60	S70	S80

# Create an incremental snapshot for managed disks

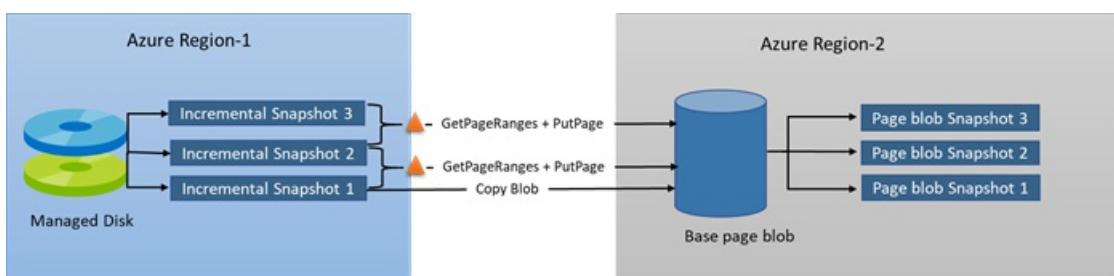

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Incremental snapshots are point in time backups for managed disks that, when taken, consist only of the changes since the last snapshot. When you restore a disk from an incremental snapshot, the system reconstructs the full disk which represents the point in time backup of the disk when the incremental snapshot was taken. This capability for managed disk snapshots potentially allows them to be more cost effective, since, unless you choose to, you do not have to store the entire disk with each individual snapshot. Just like full snapshots, incremental snapshots can be used to either create a full managed disk or a full snapshot. Both full snapshots and incremental snapshots can be used immediately after being taken. In other words, once you take either snapshot, you can immediately read the underlying VHD and use it to restore disks.

There are a few differences between an incremental snapshot and a full snapshot. Incremental snapshots will always use standard HDD storage, irrespective of the storage type of the disk, whereas full snapshots can use premium SSDs. If you are using full snapshots on Premium Storage to scale up VM deployments, we recommend you use custom images on standard storage in the [Shared Image Gallery](#). It will help you achieve a more massive scale with lower cost. Additionally, incremental snapshots potentially offer better reliability with [zone-redundant storage](#) (ZRS). If ZRS is available in the selected region, an incremental snapshot will use ZRS automatically. If ZRS is not available in the region, then the snapshot will default to [locally-redundant storage](#) (LRS). You can override this behavior and select one manually but, we do not recommend that.

Incremental snapshots offer a differential capability. They enable you to get the changes between two incremental snapshots of the same managed disk, down to the block level. You can use this to reduce your data footprint when copying snapshots across regions. For example, you can download the first incremental snapshot as a base blob in another region. For the subsequent incremental snapshots, you can copy only the changes since the last snapshot to the base blob. After copying the changes, you can take snapshots on the base blob that represent your point in time backup of the disk in another region. You can restore your disk either from the base blob or from a snapshot on the base blob in another region.

Incremental snapshots are billed for the used size only. You can find the used size of your snapshots by looking at the [Azure usage report](#). For example, if the used data size of a snapshot is 10 GiB, the [daily usage report](#) will show  $10 \text{ GiB}/(31 \text{ days}) = 0.3226$  as the consumed quantity.

## Restrictions

- Incremental snapshots currently can't be moved between subscriptions.
- You can currently only generate SAS URLs of up to five snapshots of a particular snapshot family at any given time.
- You can't create an incremental snapshot for a particular disk outside of that disk's subscription.
- Incremental snapshots can't be moved to another resource group. But, they can be copied to another resource group or region.

- Up to seven incremental snapshots per disk can be created every five minutes.
- A total of 500 incremental snapshots can be created for a single disk.
- You can't get the changes between snapshots taken before and after you changed the size of the parent disk across 4 TB boundary. For example, You took an incremental snapshot `snapshot-a` when the size of a disk was 2 TB. Now you increased the size of the disk to 6 TB and then took another incremental snapshot `snapshot-b`. You can't get the changes between `snapshot-a` and `snapshot-b`. You have to again download the full copy of `snapshot-b` created after the resize. Subsequently, you can get the changes between `snapshot-b` and snapshots created after `snapshot-b`.

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)
- [Resource Manager Template](#)

You can use the Azure CLI to create an incremental snapshot. You will need the latest version of the Azure CLI. See the following articles to learn how to either [install](#) or [update](#) the Azure CLI.

The following script will create an incremental snapshot of a particular disk:

```
# Declare variables
diskName="yourDiskNameHere"
resourceGroupName="yourResourceGroupNameHere"
snapshotName="desiredSnapshotNameHere"

# Get the disk you need to backup
yourDiskID=$(az disk show -n $diskName -g $resourceGroupName --query "id" --output tsv)

# Create the snapshot
az snapshot create -g $resourceGroupName -n $snapshotName --source $yourDiskID --incremental true
```

You can identify incremental snapshots from the same disk with the `SourceResourceId` property of snapshots. `SourceResourceId` is the Azure Resource Manager resource ID of the parent disk.

You can use `SourceResourceId` to create a list of all snapshots associated with a particular disk. Replace `yourResourceGroupNameHere` with your value and then you can use the following example to list your existing incremental snapshots:

```
# Declare variables and create snapshot list
subscriptionId="yourSubscriptionId"
resourceGroupName="yourResourceGroupNameHere"
diskName="yourDiskNameHere"

az account set --subscription $subscriptionId

diskId=$(az disk show -n $diskName -g $resourceGroupName --query [id] -o tsv)

az snapshot list --query "[?creationData.sourceResourceId=='$diskId' && incremental]" -g $resourceGroupName
--output table
```

## Next steps

See [Copy an incremental snapshot to a new region](#) to learn how to copy an incremental snapshot across regions.

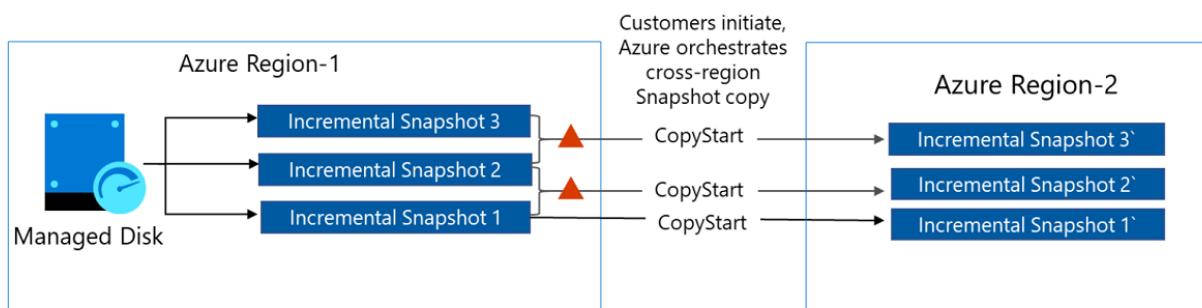

If you'd like to see sample code demonstrating the differential capability of incremental snapshots, using .NET, see [Copy Azure Managed Disks backups to another region with differential capability of incremental snapshots](#).

# Copy an incremental snapshot to a new region

9/21/2022 • 2 minutes to read • [Edit Online](#)

Incremental snapshots can be copied to any region. The process is managed by Azure, removing the maintenance overhead of managing the copy process by staging a storage account in the target region. Azure ensures that only changes since the last snapshot in the target region are copied to the target region to reduce the data footprint, reducing the recovery point objective. You can check the progress of the copy so you know when a target snapshot is ready to restore disks in the target region. You're only charged for the bandwidth cost of the data transfer across the region and the read transactions on the source snapshots.

This article covers copying an incremental snapshot from one region to another. See [Create an incremental snapshot for managed disks](#) for conceptual details on incremental snapshots.

## Restrictions

- You can copy 100 incremental snapshots in parallel at the same time per subscription per region.
- If you use the REST API, you must use version 2020-12-01 or newer of the Azure Compute REST API.

## Get started

- [Azure CLI](#)
- [Azure PowerShell](#)
- [Portal](#)
- [Resource Manager Template](#)

You can use the Azure CLI to copy an incremental snapshot. You need the latest version of the Azure CLI. See the following articles to learn how to either [install](#) or [update](#) the Azure CLI.

The following script copies an incremental snapshot from one region to another:

```
subscriptionId=<yourSubscriptionID>
resourceGroupName=<yourResourceGroupName>
targetSnapshotName=<name>
sourceSnapshotResourceId=<sourceSnapshotResourceId>
targetRegion=<validRegion>

sourceSnapshotId=$(az snapshot show -n $sourceSnapshotName -g $resourceGroupName --query [id] -o tsv)

az snapshot create -g $resourceGroupName -n $targetSnapshotName -l $targetRegion --source $sourceSnapshotId
--incremental --copy-start

az snapshot show -n $sourceSnapshotName -g $resourceGroupName --query [completionPercent] -o tsv
```

## Next steps

If you'd like to see sample code demonstrating the differential capability of incremental snapshots, using .NET, see [Copy Azure Managed Disks backups to another region with differential capability of incremental snapshots](#).

# Overview of Azure Disk Backup

9/21/2022 • 7 minutes to read • [Edit Online](#)

Azure Disk Backup is a native, cloud-based backup solution that protects your data in managed disks. It's a simple, secure, and cost-effective solution that enables you to configure protection for managed disks in a few steps. It assures that you can recover your data in a disaster scenario.

Azure Disk Backup offers a turnkey solution that provides snapshot lifecycle management for managed disks by automating periodic creation of snapshots and retaining it for configured duration using backup policy. You can manage the disk snapshots with zero infrastructure cost and without the need for custom scripting or any management overhead. This is a crash-consistent backup solution that takes point-in-time backup of a managed disk using [incremental snapshots](#) with support for multiple backups per day. It's also an agent-less solution and doesn't impact production application performance. It supports backup and restore of both OS and data disks (including shared disks), whether or not they're currently attached to a running Azure virtual machine.

If you require application-consistent backup of virtual machine including the data disks, or an option to restore an entire virtual machine from backup, restore a file or folder, or restore to a secondary region, then use the [Azure VM backup](#) solution. Azure Backup offers side-by-side support for backup of managed disks using Disk Backup in addition to [Azure VM backup](#) solutions. This is useful when you need once-a-day application consistent backups of virtual machines and also more frequent backups of OS disks or a specific data disk that are crash consistent, and don't impact the production application performance.

Azure Disk Backup is integrated into Backup Center, which provides a **single unified management experience** in Azure for enterprises to govern, monitor, operate, and analyze backups at scale.

## Key benefits of Disk Backup

Azure Disk backup is an agentless and crash consistent solution that uses [incremental snapshots](#) and offers the following advantages:

- More frequent and quick backups without interrupting the virtual machine.
- Doesn't affect the performance of the production application.
- No security concerns since it doesn't require running custom scripts or installing agents.
- A cost-effective solution to back up specific disks when compared to backing up entire virtual machine.

Azure Disk backup solution is useful in the following scenarios:

- Need for frequent backups per day without application being quiescent.
- Apps running in a cluster scenario: both Windows Server Failover Cluster and Linux clusters are writing to shared disks.
- Specific need for agentless backup because of security or performance concerns on the application.
- Application consistent backup of VM isn't feasible since line-of-business apps don't support Volume Shadow Copy Service (VSS).

Consider Azure Disk Backup in scenarios where:

- A mission-critical application is running on an Azure Virtual machine that demands multiple backups per day to meet the recovery point objective, but without impacting the production environment or application performance.
- Your organization or industry regulation restricts installing agents because of security concerns.
- Executing custom pre or post scripts and invoking freeze and thaw on Linux virtual machines to get

application-consistent backup puts undue overhead on production workload availability.

- Containerized applications running on Azure Kubernetes Service (AKS cluster) are using managed disks as persistent storage. Today, you must back up the managed disk via automation scripts that are hard to manage.
- A managed disk is holding critical business data, used as a file-share, or contains database backup files, and you want to optimize backup cost by not investing in Azure VM backup.
- You have many Linux and Windows single-disk virtual machines (that is, a virtual machine with just an OS disk and no data disks attached) that host web server, state-less machines, or serves as a staging environment with application configuration settings, and you need a cost efficient backup solution to protect the OS disk. For example, to trigger a quick on-demand backup before upgrading or patching the virtual machine.
- A virtual machine is running an OS configuration that is unsupported by Azure VM backup solution (for example, Windows 2008 32-bit Server).

## How the backup and restore process works

- The first step in configuring backup for Azure Managed Disks is creating a [Backup vault](#). The vault gives you a consolidated view of the backups configured across different workloads. Azure Disk backup supports only Operational Tier backup. Copying of backups to the vault storage tier is not supported. So, the Backup vault storage redundancy setting (LRS/GRS) doesn't apply to the backups stored in Operational Tier.
- Then create a Backup policy that allows you to configure backup frequency and retention duration.
- To configure backup, go to the Backup vault, assign a backup policy, select the managed disk that needs to be backed up and provide a resource group where the snapshots are to be stored and managed. Azure Backup automatically triggers scheduled backup jobs that create an incremental snapshot of the disk according to the backup frequency. Older snapshots are deleted according to the retention duration specified by the backup policy.
- Azure Backup uses [incremental snapshots](#) of the managed disk. Incremental snapshots are a cost-effective, point-in-time backup of managed disks that are billed for the delta changes to the disk since the last snapshot. These are always stored on the most cost-effective storage, standard HDD storage regardless of the storage type of the parent disks. The first snapshot of the disk will occupy the used size of the disk, and consecutive incremental snapshots store delta changes to the disk since the last snapshot. Azure Backup automatically assigns tag to the snapshots it creates to uniquely identify them.
- Once you configure the backup of a managed disk, a backup instance will be created within the backup vault. Using the backup instance, you can find health of backup operations, trigger on-demand backups, and perform restore operations. You can also view health of backups across multiple vaults and backup instances using Backup Center, which provides a single pane of glass view.
- To restore, just select the recovery point from which you want to restore the disk. Provide the resource group where the restored disk is to be created from the snapshot. Azure Backup provides an instant restore experience since the snapshots are stored locally in your subscription.
- Backup Vault uses Managed Identity to access other Azure resources. To configure backup of a managed disk and to restore from past backup, Backup Vault's managed identity requires a set of permissions on the source disk, the snapshot resource group where snapshots are created and managed, and the target resource group where you want to restore the backup. You can grant permissions to the managed identity by using Azure role-based access control (Azure RBAC). Managed identity is a service principal of a special type that may only be used with Azure resources. Learn more about [Managed Identities](#).
- Currently Azure Disk Backup supports operational backup of managed disks and doesn't copy the backups to Backup Vault storage. Refer to the [support matrix](#) for a detailed list of supported and

unsupported scenarios, and region availability.

## Pricing

Azure Backup uses [incremental snapshots](#) of the managed disk. Incremental snapshots are charged per GiB of the storage occupied by the delta changes since the last snapshot. For example, if you're using a managed disk with a provisioned size of 128 GiB, with 100 GiB used, the first incremental snapshot is billed only for the used size of 100 GiB. 20 GiB of data is added on the disk before you create the second snapshot. Now, the second incremental snapshot is billed for only 20 GiB.

Incremental snapshots are always stored on standard storage, irrespective of the storage type of parent-managed disks, and are charged based on the pricing of standard storage. For example, incremental snapshots of a Premium SSD-Managed Disk are stored on standard storage. By default, they are stored on ZRS in regions that support ZRS. Otherwise, they are stored on locally redundant storage (LRS). The per GiB pricing of both the options, LRS and ZRS, is the same.

The snapshots created by Azure Backup are stored in the resource group within your Azure subscription and incur Snapshot Storage charges. For more details about the snapshot pricing, see [Managed Disk Pricing](#). Because the snapshots aren't copied to the Backup Vault, Azure Backup doesn't charge a Protected Instance fee and Backup Storage cost doesn't apply.

The number of recovery points is determined by the Backup policy used to configure backups of the disk backup instances. Older block blobs are deleted according to the garbage collection process as the corresponding older recovery points are pruned.

[Azure Disk Backup support matrix](#)

# Back up Azure Managed Disks

9/21/2022 • 9 minutes to read • [Edit Online](#)

This article explains how to back up [Azure Managed Disk](#) from the Azure portal.

In this article, you'll learn how to:

- Create a Backup vault
- Create a backup policy
- Configure a backup of an Azure Disk
- Run an on-demand backup job

For information on the Azure Disk backup region availability, supported scenarios and limitations, see the [support matrix](#).

## Create a Backup vault

A Backup vault is a storage entity in Azure that holds backup data for various newer workloads that Azure Backup supports, such as Azure Database for PostgreSQL servers and Azure Disks. Backup vaults make it easy to organize your backup data, while minimizing management overhead. Backup vaults are based on the Azure Resource Manager model of Azure, which provides enhanced capabilities to help secure backup data.

1. Sign in to the Azure portal at <https://portal.azure.com>.
2. Type **Backup center** in the search box.
3. Under **Services**, select **Backup center**.
4. In the **Backup center** page, select **Vault**.

5. In the **Initiate: Create Vault** screen, select **Backup vault**, and **Proceed**.

A vault is an entity that stores the backups and recovery points created over time. The vault also contains the backup policies that are associated with the protected virtual machines. Proceed to vault creation by selecting vault type.

Vault Type

Recovery Services vault

Backup vault

Supported datasources

- Azure Virtual machines
- SQL in Azure VM
- Azure Storage (Azure Files)
- SAP HANA in Azure VM
- Azure Backup Server
- Azure Backup Agent
- DPM

Backup storage redundancy	Globally-redundant

Review + create Next: Backup policy >

3. In the **Backup policy** tab, select the backup schedule frequency.

The screenshot shows the 'Create Backup Policy' page in the Microsoft Azure portal. The 'Backup policy' tab is selected. Under 'Backup schedule', 'Hourly' is chosen as the backup frequency with a time interval of 'Every 4 hours'. In the 'Retention settings' section, there is a single retention rule named 'Default' set to '7 Days'. At the bottom, there are 'Review + create', 'Previous', and 'Next: Review + create >' buttons.

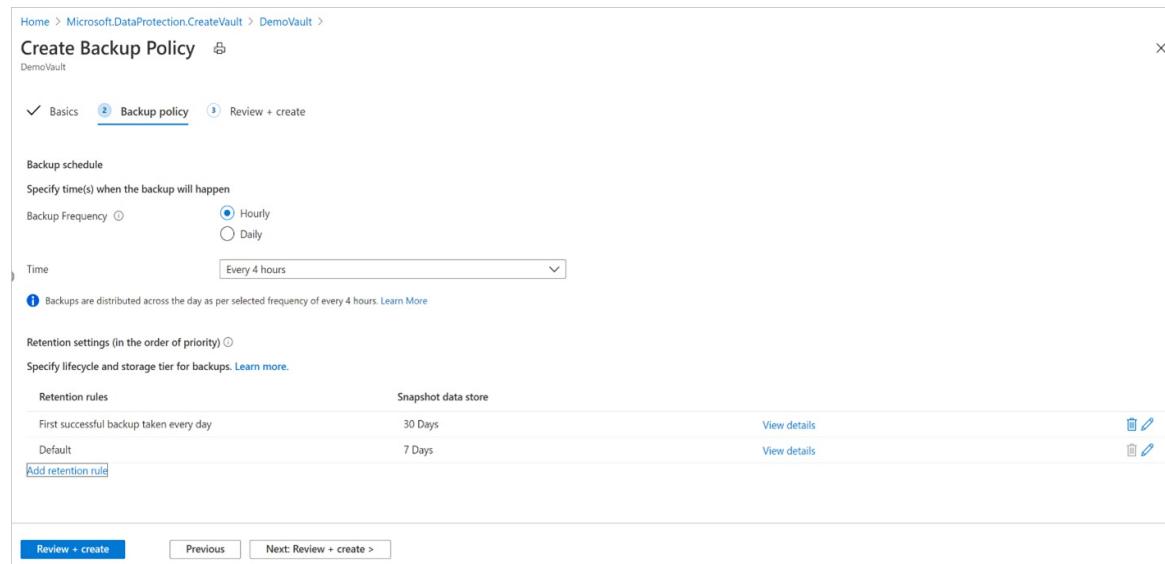

Azure Disk Backup offers multiple backups per day. If you require more frequent backups, choose the **Hourly** backup frequency with the ability to take backups with intervals of every 1, 2, 4, 6, 8, or 12 hours. The backups are scheduled based on the **Time** interval selected. For example, if you select **Every 4 hours**, then the backups are taken at approximately in the interval of every 4 hours so the backups are distributed equally across the day. If a once a day backup is sufficient, then choose the **Daily** backup frequency. In the daily backup frequency, you can specify the time of the day when your backups are taken. It's important to note that the time of the day indicates the backup start time and not the time when the backup completes. The time required for completing the backup operation is dependent on various factors including size of the disk, and churn rate between consecutive backups. However, Azure Disk backup is an agentless backup that uses [incremental snapshots](#), which doesn't impact the production application performance.

4. In the **Backup policy** tab, select retention settings that meet the recovery point objective (RPO) requirement.

The default retention rule applies if no other retention rule is specified. The default retention rule can be modified to change the retention duration, but it cannot be deleted. You can add a new retention rule by selecting **Add retention rule**.

The screenshot shows the 'Add retention' dialog box overlaid on the 'Create Backup Policy' page. The dialog box contains fields for 'Retention rules' (set to 'Backup taken every day') and 'Data store' (set to 'Snapshot data store' with a duration of '30 Day(s)'). A 'Cancel' button is located at the bottom right of the dialog.

You can pick first successful backup taken daily or weekly, and provide the retention duration that the specific backups are to be retained before they're deleted. This option is useful to retain specific backups of the day or week for a longer duration of time. All other frequent backups can be retained for a shorter duration.

The screenshot shows the 'Create Backup Policy' wizard in progress. The current step is 'Backup policy'. The 'Backup schedule' section shows 'Backup Frequency' set to 'Hourly' with 'Every 4 hours' selected. The 'Retention settings (in the order of priority)' section lists two rules: 'First successful backup taken every day' with a 'Snapshot data store' of '30 Days', and a 'Default' rule with a 'Snapshot data store' of '7 Days'. At the bottom, there are buttons for 'Review + create', 'Previous', and 'Next: Review + create >'.

#### NOTE

Azure Backup for Managed Disks uses incremental snapshots which are limited to 200 snapshots per disk. To allow you to take on-demand backups aside from scheduled backups, backup policy limits the total backups to 180. Learn more about [incremental snapshots for managed disk](#).

5. Complete the backup policy creation by selecting **Review + create**.

## Configure backup

- Azure Disk backup supports only the operational tier backup. Copying of backups to the vault storage tier is currently not supported. The Backup vault storage redundancy setting (LRS/GRS) doesn't apply to the backups stored in the operational tier.  
Incremental snapshots are stored in a Standard HDD storage, irrespective of the selected storage type of the parent disk. For additional reliability, incremental snapshots are stored on **Zone Redundant Storage (ZRS)** by default in ZRS supported regions.
- Azure Disk backup supports cross-subscription (backup vault in one subscription and the source disk in another) backup and restore. Currently, cross-region backup and restore aren't supported by Azure Disk backup, that is, the backup vault and disk to back up are in different regions.  
So, to use Azure Disk backup, ensure that the backup vault and disk to back up are in the same region.
- Once you configure the disk backup, you can't change the Snapshot Resource Group that's assigned to a backup instance.

To configure disk backup, follow these steps:

1. Go to **Backup center** -> **Overview** and click **+ Backup** to start configuring backup of the disk.

The screenshot shows the Microsoft Azure Backup center interface. On the left, there's a navigation sidebar with sections like Overview, Getting started, Community, Manage (Backup instances, Backup policies, Vaults, Monitoring + reporting, Backup jobs, Alerts, Backup reports), Policy and compliance (Backup compliance, Azure policies for backup, Protectable datasources), and Support + troubleshooting (New support request). The main area displays the following information:

- Datasource type: Azure Disks**
- Jobs (last 24 Hours)**: Shows 97 Failed, 5 In progress, and 436 Completed scheduled backups.
- Backup instances**: Shows 122 total instances, with 99 Protection configured, 16 Protection error, and 0 Configuring protection failed. It also indicates 10 instances out of 122 have underlying datasource issues.
- Active Alerts (last 24 Hours)**: Shows 0 Security alerts and 98 Configured alerts. A legend indicates 0 Sev0, 98/98 Sev1, and 0 Sev2.
- Global alerts**: Shows 140 Security alerts and 0 Configured alerts. A legend indicates 140/140 Sev0, 0/140 Sev1, and 0/140 Sev2.

2. Select Azure Disks in the Datasource type drop-down list, and then click Continue.

The screenshot shows the 'Start: Configure Backup' step of the Azure Backup wizard. It has two dropdown menus: 'Datasource type' set to 'Azure Disks' and 'Vault type' set to 'Backup vault'. At the bottom are 'Continue' and 'Cancel' buttons.

3. Select a Backup vault and click Next to proceed.

#### NOTE

- Ensure that both the backup vault and the disk to be backed up are in same location.
- Azure Backup uses *incremental snapshots* of managed disks, which store only the delta changes to the disk as the last snapshot on Standard HDD storage, regardless of the storage type of the parent disk. For additional reliability, incremental snapshots are stored on Zone Redundant Storage (ZRS) by default in the ZRS supported regions. Currently, Azure Disk Backup supports operational backup of managed disks that doesn't copy backups to the Backup vault storage. So, the backup storage redundancy setting of the Backup vault doesn't apply to the recovery points.

Default	7 Days	<a href="#">View details</a>

Previous Next

5. On the **Datasources** tab, click + Add/Edit to choose one or more Azure Managed Disks for which you want to configure backup.

The screenshot shows the 'Configure Backup' wizard in the Azure portal. The current step is 'Select resources to backup'. A table lists a single disk named 'DemoDataDisk' under the 'Subscription' column. Below the table, a note says 'Please ensure the pre-requisites are met before proceeding - Learn More'. Under 'Snapshot resource group', it shows a tree structure with 'Subscription' and 'Snapshot resource group' selected. A 'Validate' button is present. At the bottom, there are 'Previous' and 'Next' buttons, and a 'Select (0 items)' link.

#### NOTE

While the portal allows you to select multiple disks and configure backup, each disk is an individual backup instance. Currently, Azure Disk Backup only supports backup of individual disks. Point-in-time backup of multiple disks attached to a virtual machine isn't supported.

In the Azure portal, you can only select disks within the same subscription. If you have several disks to be backed up or if the disks reside in different subscriptions, you can use scripts ([PowerShell/CLI](#)) to automate.

See the [support matrix](#) for more information on the Azure Disk backup region availability, supported scenarios, and limitations.

## 6. Select Snapshot resource group and click Validate to initiate prerequisites checks.

Choosing resource group for storing and managing snapshots:

- Don't select the same resource group as that of the source disk.
- As a guideline, it's recommended to create a dedicated resource group as a snapshot datastore to be used by the Azure Backup service. Having a dedicated resource group allows restricting access permissions on the resource group, providing safety and ease of management of the backup data.
- You can use this resource group for storing snapshots across multiple disks that are being (or planned to be) backed up.
- You can't create an incremental snapshot for a particular disk outside of that disk's subscription. So, choose the resource group within the same subscription where the disk needs to be backed up. [Learn more](#) about incremental snapshot for managed disks.
- Once you configure the backup of a disk, you can't change the Snapshot Resource Group that's assigned to a backup instance.

7. Once the validation is complete, check if there are any errors reported in the Backup readiness column.

### NOTE

Validation might take few minutes to complete. Validation may fail if:

- A disk is unsupported. See the [support matrix](#) for unsupported scenarios.
- The Backup vault managed identity does not have valid role assignments on the *disk* to be backed up or on the *snapshot resource group* where incremental snapshots are stored.

If the *Role assignment not done* error message displays in the **Backup readiness** column, the Backup vault managed identity needs role permissions on the selected disk(s) and/or on the Snapshot resource group.

To configure backup of managed disks, the following prerequisites are required:

#### NOTE

Backup vault uses managed identity to access other Azure resources. To configure a backup of managed disks, Backup Vault's managed identity requires a set of permissions on the source disks and resource groups where snapshots are created and managed.

A system-assigned managed identity is restricted to one per resource and is tied to the lifecycle of this resource. To grant permissions to the managed identity, use Azure role-based access control (Azure RBAC). Managed identity is a service principal of a special type that may only be used with Azure resources. Learn more about [managed identities](#).

- Assign the **Disk Backup Reader** role to Backup Vault's managed identity on the Source disk that needs to be backed up.
- Assign the **Disk Snapshot Contributor** role to the Backup vault's managed identity on the Resource group where backups are created and managed by the Azure Backup service. The disk snapshots are stored in a resource group within your subscription. To allow Azure Backup service to create, store, and manage snapshots, you need to provide permissions to the backup vault.

#### NOTE

The Configure Backup flow using Azure portal helps you in granting required role permissions to the above resources.

8. Select the checkbox next to each row with the *Role assignment not done* error message status in the Backup readiness column and click **Add missing roles** to automatically grant required role permissions for the Backup vault managed identity on selected resources.

## Next steps

- [Restore Azure Managed Disks](#)

# Restore Azure Managed Disks

9/21/2022 • 5 minutes to read • [Edit Online](#)

This article explains how to restore [Azure Managed Disks](#) from a restore point created by Azure Backup.

Currently, the Original-Location Recovery (OLR) option of restoring by replacing existing the source disk from where the backups were taken isn't supported. You can restore from a recovery point to create a new disk either in the same resource group as that of the source disk from where the backups were taken or in any other resource group. This is known as Alternate-Location Recovery (ALR) and this helps to keep both the source disk and the restored (new) disk.

In this article, you'll learn how to:

- Restore to create a new disk
- Track the restore operation status

## Restore to create a new disk

Backup Vault uses Managed Identity to access other Azure resources. To restore from backup, Backup vault's managed identity requires a set of permissions on the resource group where the disk is to be restored.

Backup vault uses a system assigned managed identity, which is restricted to one per resource and is tied to the lifecycle of this resource. You can grant permissions to the managed identity by using Azure role-based access control (Azure RBAC). Managed identity is a service principal of a special type that may only be used with Azure resources. Learn more about [Managed Identities](#).

The following pre-requisites are required to perform a restore operation:

1. Assign the **Disk Restore Operator** role to the Backup Vault's managed identity on the Resource group where the disk will be restored by the Azure Backup service.

### NOTE

You can choose the same resource group as that of the source disk from where backups are taken or to any other resource group within the same or a different subscription.

- a. Go to the resource group where the disk is to be restored to. For example, the resource group is *TargetRG*.
- b. Go to **Access control (IAM)** and select **Add role assignments**
- c. On the right context pane, select **Disk Restore Operator** in the **Role** dropdown list. Select the backup vault's managed identity and **Save**.

### TIP

Type the backup vault's name to select the vault's managed identity.

The screenshot shows the 'Access control (IAM)' blade for a resource group named 'TargetRG'. The left sidebar includes sections like Overview, Activity log, Access control (IAM), Tags, Events, Settings, Deployments, Security, Policies, Properties, Locks, Cost Management, Cost analysis, Cost alerts (preview), Budgets, Advisor recommendations, and Monitoring. The main area has tabs for Check access, Role assignments, Roles, Deny assignments, and Classic administrators. Under 'Check access', there's a 'My access' section with a 'View my access' button, and a 'Check access' section with a 'Find' dropdown set to 'User, group, or service principal' and a search bar. On the right, there are three cards: 'Grant access to this resource', 'View access to this resource', and 'View deny assignments'. A modal window titled 'Add role assignment' is overlaid, showing the 'Role' dropdown set to 'Disk Restore Operator', the 'Assign access to' dropdown set to 'User, group, or service principal', and the 'Select' dropdown showing 'DemoVault'. The 'Selected members' list contains 'DemoVault'. At the bottom of the modal are 'Save' and 'Discard' buttons.

2. Verify that the backup vault's managed identity has the right set of role assignments on the resource group where the disk will be restored.

a. Go to **Backup vault** - > **Identity** and select **Azure role assignments**

The screenshot shows the 'Identity' blade for a backup vault named 'DemoVault'. The left sidebar includes sections like Overview, Activity log, Tags, Manage (Properties, Identity, Backup policies, Backup instances, Locks), Monitoring + reporting (Alerts, Backup jobs), Automation, and Tasks (preview). The main area shows a 'System assigned (preview)' section with a status of 'On', an object ID of '670ea13c-1dbc-45f0-a019-02b8dc01f7e3', and a 'Permissions' section with a 'Azure role assignments' button highlighted with a red box. A note at the bottom states: 'This resource is registered with Azure Active Directory. The managed identity can be configured to allow access to other resources. Be careful when making changes to the account as it can result in failures.' At the top, there are 'Save', 'Discard', 'Refresh', and 'Get feedback?' buttons.

b. Verify that the role, resource name, and resource type appear correctly.

The screenshot shows the 'Azure role assignments' blade for the 'DemoVault' backup vault. The left sidebar includes sections like Home, Azure role assignments, Add role assignment (Preview), Refresh, and a note about permissions. The main area lists role assignments with columns for Subscription, Role, Resource Name, Resource Type, and Assigned To. Two entries are shown: 'Disk Snapshot Contributor' assigned to 'SnapshotsRG' as a Resource Group, and 'Disk Restore Operator' assigned to 'TargetRG' as a Resource Group. Both entries are highlighted with a red box. At the bottom, there are 'Save' and 'Discard' buttons.

Subscription *	Role	Resource Name	Resource Type	Assigned To
AzureBackup_Functional_Testing	Disk Snapshot Contributor	SnapshotsRG	Resource Group	DemoVault
	Disk Restore Operator	TargetRG	Resource Group	DemoVault
	Disk Backup Reader	ContosoDemoVM_DataDisk_0	Disks	DemoVault

#### NOTE

While the role assignments are reflected correctly on the portal, it may take approximately 15 minutes for the permission to be applied on the backup vault's managed identity.

During scheduled backups or an on-demand backup operation, Azure Backup stores the disk incremental snapshots in the Snapshot Resource Group provided during configuring backup of the disk. Azure Backup uses these incremental snapshots during the restore operation. If the snapshots are deleted or moved from the Snapshot Resource Group or if the Backup vault role assignments are revoked on the Snapshot Resource Group, the restore operation will fail.

3. If the disk to be restored is encrypted with [customer-managed keys \(CMK\)](#) or using [double encryption using platform-managed keys and customer-managed keys](#), then assign the **Reader** role permission to the Backup Vault's managed identity on the **Disk Encryption Set** resource.

Once the prerequisites are met, follow these steps to perform the restore operation.

1. In the [Azure portal](#), go to **Backup center**. Select **Backup instances** under the **Manage** section. From the list of backup instances, select the disk backup instance for which you want to perform the restore operation.

Name	Datasource subscription	Datasource resource group	Datasource location	Vault
ContosoDemoVM_DataDisk_0	AzureBackup_Functional_Testing	CortosoRG	Southeast Asia	DemoVault

Alternately, you can perform this operation from the Backup vault you used to configure backup for the disk.

2. In the **Backup instance** screen, select the restore point that you want to use to perform the restore operation and select **Restore**.

The screenshot shows the Microsoft Azure Backup center interface. At the top, there are navigation links: Home > Backup center (Preview) > ContosoDemoVM\_DataDisk\_0. Below this, a 'Backup instance' header includes options: Backup Now, Restore, Change policy, Delete, and Refresh. A 'Jobs (last 7 days)' table provides a summary of recent operations:

Operation	Failed	In progress	Completed
Scheduled backup	1	0	4
On-demand backup	2	0	0
Restore	0	0	0

Below the jobs table is a 'RESTORE POINTS' section. It shows a table of restore points from the last 30 days:

Time	Backup type	Data store	Action
1/5/2021, 5:02:15 AM	Incremental	Snapshot	Restore
1/5/2021, 1:02:21 AM	Incremental	Snapshot	...
1/4/2021, 9:01:58 PM	Incremental	Snapshot	...
1/4/2021, 5:12:31 PM	Incremental	Snapshot	...

3. In the **Restore** workflow, review the **Basics** and **Select recovery point** tab information, and select **Next: Restore parameters**.

The screenshot shows the 'Select recovery point' step of the restore workflow. The navigation bar at the top indicates the current step: ② Select recovery point. The main area displays the selected recovery point details:

Recovery Point \*: 1/5/2021, 5:02:15 AM  
Select recovery point

Data store: Snapshot

At the bottom, there are 'Previous' and 'Next: Restore parameters >' buttons.

4. In the **Restore parameters** tab, select the **Target subscription** and **Target resource group** where you want to restore the backup to. Provide the name of the disk to be restored. Select **Next: Review + restore**.

Microsoft Azure (Preview) Search resources, services, and docs (G+)

Home > Backup center (Preview) > ContosoDemoVM\_DataDisk\_0 >

## Restore

Basics Select recovery point Restore parameters Review + restore

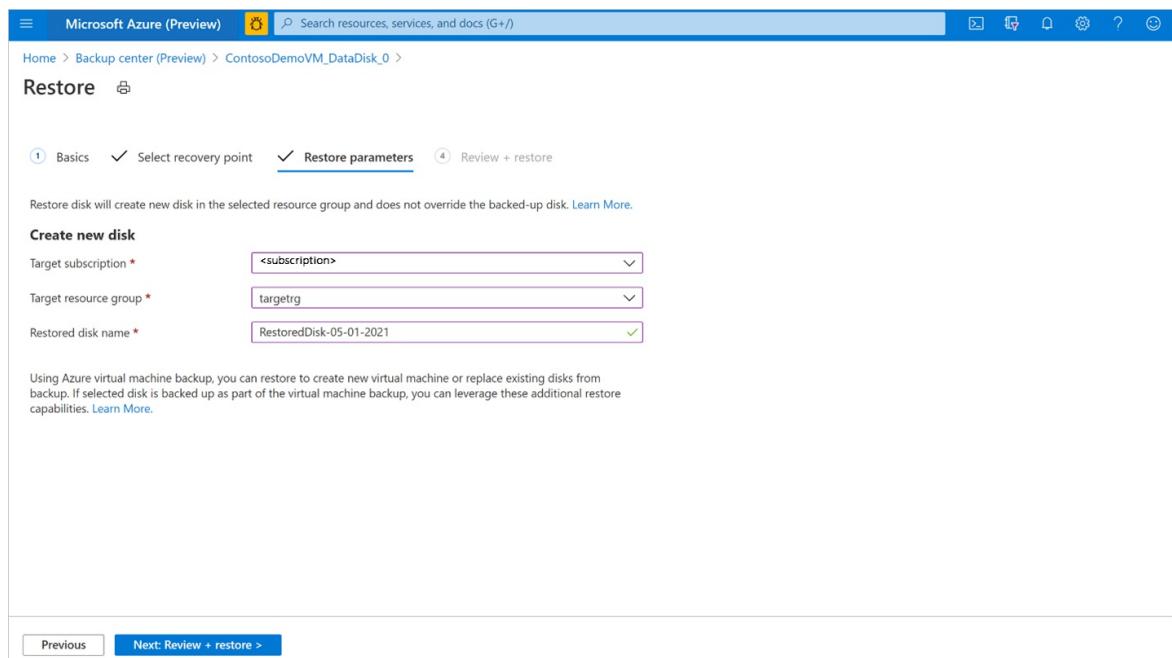

Restore disk will create new disk in the selected resource group and does not override the backed-up disk. [Learn More](#).

Create new disk

Target subscription \* <subscription>  
Target resource group \* targetrg  
Restored disk name \* RestoredDisk-05-01-2021

Using Azure virtual machine backup, you can restore to create new virtual machine or replace existing disks from backup. If selected disk is backed up as part of the virtual machine backup, you can leverage these additional restore capabilities. [Learn More](#).

Previous Next: Review + restore >

**TIP**

Disks being backed up by Azure Backup using the Disk Backup solution can also be backed up by Azure Backup using the Azure VM backup solution with the Recovery Services vault. If you have configured protection of the Azure VM to which this disk is attached, you can also use the Azure VM restore operation. You can choose to restore the VM, or disks and files or folders from the recovery point of the corresponding Azure VM backup instance. For more information, see [Azure VM backup](#).

- Once the validation is successful, select **Restore** to start the restore operation.

Microsoft Azure (Preview) Search resources, services, and docs (G+)

Home > Backup center (Preview) > ContosoDemoVM\_DataDisk\_0 >

## Restore

Validation succeeded.

Basics Select recovery point Restore parameters Review + restore

Basics

Data source type Azure Disk  
Backup instance ContosoDemoVM\_DataDisk\_0

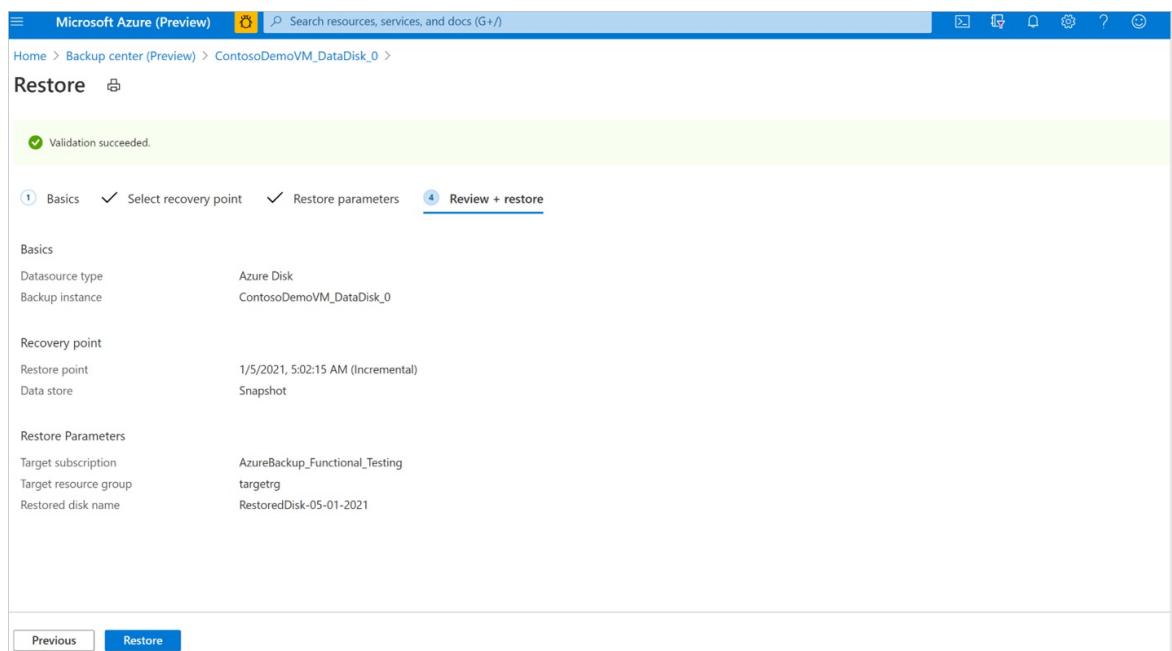

Recovery point

Restore point 1/5/2021, 5:02:15 AM (Incremental)  
Data store Snapshot

Restore Parameters

Target subscription AzureBackup\_Functional\_Testing  
Target resource group targetrg  
Restored disk name RestoredDisk-05-01-2021

Previous Restore

## NOTE

Validation might take few minutes to complete before you can trigger restore operation. Validation may fail if:

- a disk with the same name provided in **Restored disk name** already exists in the **Target resource group**
- the Backup vault's managed identity doesn't have valid role assignments on the **Target resource group**
- the Backup vault's managed identity role assignments are revoked on the **Snapshot resource group** where incremental snapshots are stored
- If incremental snapshots are deleted or moved from the snapshot resource group

Restore will create a new disk from the selected recovery point in the target resource group that was provided during the restore operation. To use the restored disk on an existing virtual machine, you'll need to perform more steps:

- If the restored disk is a data disk, you can attach an existing disk to a virtual machine. If the restored disk is OS disk, you can swap the OS disk of a virtual machine from the Azure portal under the **Virtual machine** pane - > **Disk**s menu in the **Settings** section.

Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (...)	Encryption
ContosoDemoVM_OsDisk_1_84b542ec3	Premium SSD	127	500	100	SSE with PMK

LUN	Disk name	Storage type	Size (GiB)	Max IOPS	Max throughput (...)	Encryption
0	ContosoDemoVM_DataDisk_0	Premium SSD	1024	5000	200	SSE with PMK

- For Windows virtual machines, if the restored disk is a data disk, follow the instructions to [detach the original data disk](#) from the virtual machine. Then [attach the restored disk](#) to the virtual machine. Follow the instructions to [swap the OS disk](#) of the virtual machine with the restored disk.
- For Linux virtual machines, if the restored disk is a data disk, follow the instructions to [detach the original data disk](#) from the virtual machine. Then [attach the restored disk](#) to the virtual machine. Follow the instructions to [swap the OS disk](#) of the virtual machine with the restored disk.

It's recommended that you revoke the **Disk Restore Operator** role assignment from the Backup vault's managed identity on the **Target resource group** after the successful completion of restore operation.

## Track a restore operation

After you trigger the restore operation, the backup service creates a job for tracking. Azure Backup displays notifications about the job in the portal. To view the restore job progress:

1. Go to the **Backup instance** screen. It shows the jobs dashboard with operation and status for the past seven days.

Microsoft Azure (Preview) Search resources, services, and docs (G+)

Home > Backup center (Preview) > ContosoDemoVM\_DataDisk\_0

# Backup and disaster recovery for Azure managed disks

9/21/2022 • 11 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article explains how to plan for backup and disaster recovery for Azure managed disks.

First, we cover the built-in fault tolerance capabilities in the Azure platform that guard against local failures. We then discuss the disaster scenarios not fully covered by the built-in capabilities. We also show several examples of workload scenarios where different backup and disaster recovery considerations can apply. We also cover some disaster recovery solutions for managed disks.

## Introduction

Azure uses various methods for redundancy and fault tolerance to protect customers from localized hardware failures. Local failures can include problems with an Azure Storage server machine that stores part of the data for a virtual disk or failures of solid-state drives (SSDs) or hard disk drives (HDDs) on that server. Isolated hardware component failures can happen during normal operations.

Azure is designed to be resilient to these failures. Major disasters can result in failures or the inaccessibility of many storage servers or even a whole data center. Although your virtual machines (VMs) and disks are normally protected from localized failures, additional steps are necessary to protect your workload from region-wide catastrophic failures, such as a major disaster, that can affect your VMs and disks.

In addition to the possibility of platform failures, problems with a customer application or data can occur. For example, a new version of your application might inadvertently make a change to the data that causes it to break. In that case, you might want to revert the application and the data to a prior version that contains the last known good state. This requires maintaining regular backups.

For regional disaster recovery, you must back up your infrastructure as a service (IaaS) VM disks to a different region.

Before we look at backup and disaster recovery options, let's recap a few methods available for handling localized failures.

### Azure IaaS resiliency

Resiliency refers to the tolerance for normal failures that occur in hardware components. Resiliency is the ability to recover from failures and continue to function. It's not about avoiding failures, but responding to failures in a way that avoids downtime or data loss. The goal of resiliency is to return the application to a fully functioning state following a failure. Azure VMs and managed disks are designed to be resilient to common hardware faults. Let's look at how the Azure IaaS platform provides this resiliency.

A VM consists mainly of two parts: a compute server and the persistent disks. Both affect the fault tolerance of a VM.

If the Azure compute host server that houses your VM experiences a hardware failure, which is rare, Azure is designed to automatically restore the VM on another server. In this scenario, your computer reboots, and the VM comes back up after some time. Azure automatically detects such hardware failures and begins recovery to help ensure the customer VM is available as soon as possible.

Regarding your managed disk, the durability of data is critical for a persistent storage platform. Azure customers

have important business applications running on IaaS, and they depend on the persistence of the data. Azure designs protection for these IaaS disks, with three redundant copies of the data that is stored locally. These copies provide for high durability against local failures. If one of the hardware components that holds your disk fails, your VM is not affected, because there are two additional copies to support disk requests. It works fine, even if two different hardware components that support a disk fail at the same time (which is rare).

To ensure that you always maintain three replicas, Azure automatically creates a new copy of the data in the background if one of the three copies becomes unavailable. Therefore, it should not be necessary to use RAID with Azure disks for fault tolerance. A simple RAID 0 configuration should be sufficient for striping the disks, if necessary, to create larger volumes.

Because of this architecture, Azure has consistently delivered enterprise-grade durability for IaaS disks, with an industry-leading zero percent [annualized failure rate](#).

Localized hardware faults on the compute host or in the storage platform can sometimes result in the temporary unavailability of the VM that is covered by the [Azure SLA](#) for VM availability. Azure also provides an industry-leading SLA for single VM instances that use Azure premium SSDs.

To safeguard application workloads from downtime due to the temporary unavailability of a disk or VM, customers can use [availability sets](#). Two or more virtual machines in an availability set provide redundancy for the application. Azure then creates these VMs and disks in separate fault domains with different power, network, and server components.

Because of these separate fault domains, localized hardware failures typically don't affect multiple VMs in the set at the same time. Having separate fault domains provides high availability for your application. It's considered a good practice to use availability sets when high availability is required.

### **Backup and disaster recovery**

Disaster recovery is the ability to recover from rare, but major, incidents. These incidents include non-transient, wide-scale failures, such as a service disruption that affects an entire region. Disaster recovery includes data backup and archiving, and might include manual intervention, such as restoring a database from a backup.

The Azure platform's built-in protection against localized failures might not fully protect the VMs/disks if a major disaster causes large-scale outages. These large-scale outages include catastrophic events, such as if a data center is hit by a hurricane, earthquake, fire, or if there is a large-scale hardware unit failure. In addition, you might encounter failures due to application or data issues.

To help protect your IaaS workloads from outages, you should plan for redundancy and have backups to enable recovery. For disaster recovery, you should back up in a different geographic location away from the primary site. This approach helps ensure your backup is not affected by the same event that originally affected the VM or disks. For more information, see [Disaster recovery for Azure applications](#).

Your disaster recovery considerations might include the following aspects:

- **High availability:** The ability of the application to continue running in a healthy state, without significant downtime. By healthy state, this state means that the application is responsive, and users can connect to the application and interact with it. Certain mission-critical applications and databases might be required to always be available, even when there are failures in the platform. For these workloads, you might need to plan redundancy for the application, as well as the data.
- **Data durability:** In some cases, the main consideration is ensuring that the data is preserved if a disaster happens. Therefore, you might need a backup of your data in a different site. For such workloads, you might not need full redundancy for the application, but only a regular backup of the disks.

## **Backup and disaster recovery scenarios**

Let's look at a few typical examples of application workload scenarios and the considerations for planning for

disaster recovery.

### **Scenario 1: Major database solutions**

Consider a production database server, like SQL Server or Oracle, that can support high availability. Critical production applications and users depend on this database. The disaster recovery plan for this system might need to support the following requirements:

- The data must be protected and recoverable.
- The server must be available for use.

The disaster recovery plan might require maintaining a replica of the database in a different region as a backup. Depending on the requirements for server availability and data recovery, the solution might range from an active-active or active-passive replica site to periodic offline backups of the data. Relational databases, such as SQL Server and Oracle, provide various options for replication. For SQL Server, use [SQL Server Always On Availability Groups](#) for high availability.

NoSQL databases, like MongoDB, also support [replicas](#) for redundancy. The replicas for high availability are used.

### **Scenario 2: A cluster of redundant VMs**

Consider a workload handled by a cluster of VMs that provide redundancy and load balancing. One example is a Cassandra cluster deployed in a region. This type of architecture already provides a high level of redundancy within that region. However, to protect the workload from a regional-level failure, you should consider spreading the cluster across two regions or making periodic backups to another region.

### **Scenario 3: IaaS application workload**

Let's look at the IaaS application workload. For example, this application might be a typical production workload running on an Azure VM. It might be a web server or file server holding the content and other resources of a site. It might also be a custom-built business application running on a VM that stored its data, resources, and application state on the VM disks. In this case, it's important to make sure you take backups on a regular basis. Backup frequency should be based on the nature of the VM workload. For example, if the application runs every day and modifies data, then the backup should be taken every hour.

Another example is a reporting server that pulls data from other sources and generates aggregated reports. The loss of this VM or disks might lead to the loss of the reports. However, it might be possible to rerun the reporting process and regenerate the output. In that case, you don't really have a loss of data, even if the reporting server is hit with a disaster. As a result, you might have a higher level of tolerance for losing part of the data on the reporting server. In that case, less frequent backups are an option to reduce costs.

### **Scenario 4: IaaS application data issues**

IaaS application data issues are another possibility. Consider an application that computes, maintains, and serves critical commercial data, such as pricing information. A new version of your application had a software bug that incorrectly computed the pricing and corrupted the existing commerce data served by the platform. Here, the best course of action is to revert to the earlier version of the application and the data. To enable this, take periodic backups of your system.

## **Disaster recovery solution: Azure Disk Backup**

Azure Disk Backup is a native, cloud-based backup solution that protects your data in managed disks. It's a simple, secure, and cost-effective solution that enables you to configure protection for managed disks in a few steps. It assures that you can recover your data in a disaster scenario.

Azure Disk Backup offers a turnkey solution that provides snapshot lifecycle management for managed disks by automating periodic creation of snapshots and retaining it for configured duration using backup policy. You can manage the disk snapshots with zero infrastructure cost and without the need for custom scripting or any

management overhead. This is a crash-consistent backup solution that takes point-in-time backup of a managed disk using incremental snapshots with support for multiple backups per day. It's also an agent-less solution and doesn't impact production application performance. It supports backup and restore of both OS and data disks (including shared disks), whether or not they're currently attached to a running Azure VM.

For more details on Azure Disk Backup, see [Overview of Azure Disk Backup](#).

## Alternative solution: Consistent snapshots

If you are unable to use Azure Backup, you can implement your own backup mechanism by using snapshots. Creating consistent snapshots for all the disks used by a VM and then replicating those snapshots to another region is complicated. For this reason, Azure considers using the Backup service as a better option than building a custom solution.

If you use locally redundant storage for disks, you need to replicate the data yourself.

A snapshot is a representation of an object at a specific point in time. A snapshot incurs billing for the incremental size of the data it holds. For more information, see [Create an incremental snapshot for managed disks](#).

### Create snapshots while the VM is running

Although you can take a snapshot at any time, if the VM is running, there is still data being streamed to the disks. The snapshots might contain partial operations that were in flight. Also, if there are several disks involved, the snapshots of different disks might have occurred at different times. These scenarios may cause the snapshots to be uncoordinated. This lack of coordination is especially problematic for striped volumes whose files might be corrupted if changes were being made during backup.

To avoid this situation, the backup process must implement the following steps:

1. Freeze all the disks.
2. Flush all the pending writes.
3. [Create an incremental snapshot for managed disks](#) for all the disks.

Some Windows applications, like SQL Server, provide a coordinated backup mechanism via a volume shadow service to create application-consistent backups. On Linux, you can use a tool like `fsfreeze` for coordinating the disks. This tool provides file-consistent backups, but not application-consistent snapshots. This process is complex, so you should consider using [Azure Disk Backup](#) or a third-party backup solution that already implements this procedure.

The previous process results in a collection of coordinated snapshots for all of the VM disks, representing a specific point-in-time view of the VM. This is a backup restore point for the VM. You can repeat the process at scheduled intervals to create periodic backups. See [Copy the backups to another region](#) for steps to copy the snapshots to another region for disaster recovery.

### Create snapshots while the VM is offline

Another option to create consistent backups is to shut down the VM and take snapshots of each disk. Taking offline snapshots is easier than coordinating snapshots of a running VM, but it requires a few minutes of downtime.

### Copy the snapshots to another region

Creation of the snapshots alone might not be sufficient for disaster recovery. You must also copy the snapshots to another region. See [Copy an incremental snapshot to a new region](#).

## Other options

## **SQL Server**

SQL Server running in a VM has its own built-in capabilities to back up your SQL Server database to Azure Blob storage or a file share. For more information, see [Back up and restore for SQL Server in Azure virtual machines](#). In addition to back up and restore, [SQL Server Always On availability groups](#) can maintain secondary replicas of databases. This ability greatly reduces the disaster recovery time.

## Next steps

See [Back up Azure unmanaged Virtual Machine disks with incremental snapshots](#).

# Create a snapshot of a virtual hard disk

9/21/2022 • 4 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

A snapshot is a full, read-only copy of a virtual hard disk (VHD). You can use a snapshot as a point-in-time backup, or to help troubleshoot virtual machine (VM) issues. You can take a snapshot of both operating system (OS) or data disk VHDs.

## Create a snapshot of a VHD

If you want to use a snapshot to create a new VM, ensure that you first cleanly shut down the VM. This action clears any processes that are in progress.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

To create a snapshot using the Azure portal, complete these steps.

1. In the [Azure portal](#), select **Create a resource**.
2. Search for and select **Snapshot**.
3. In the **Snapshot** window, select **Create**. The **Create snapshot** window appears.
4. For **Resource group**, select an existing [resource group](#) or enter the name of a new one.
5. Enter a **Name**, then select a **Region** and **Snapshot type** for the new snapshot. If you would like to store your snapshot in zone-resilient storage, you need to select a region that supports [availability zones](#). For a list of supporting regions, see [Azure regions with availability zones](#).
6. For **Source subscription**, select the subscription that contains the managed disk to be backed up.
7. For **Source disk**, select the managed disk to snapshot.
8. For **Storage type**, select **Standard HDD**, unless you require zone-redundant storage or high-performance storage for your snapshot.
9. If needed, configure settings on the **Encryption**, **Networking**, and **Tags** tabs. Otherwise, default settings are used for your snapshot.
10. Select **Review + create**.

## Next steps

To recover using a snapshot, you must create a new disk from the snapshot, then either deploy a new VM, and use the managed disk as the OS disk, or attach the disk as a data disk to an existing VM.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

For more information, see the example in [Create a VM from a VHD by using the Azure portal](#).

# Back up Azure unmanaged Virtual Machine disks with incremental snapshots

9/21/2022 • 7 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs

## Overview

Azure Storage provides the capability to take snapshots of blobs. Snapshots capture the blob state at that point in time. In this article, we describe a scenario in which you can maintain backups of virtual machine disks using snapshots. You can use this methodology when you choose not to use Azure Backup and Recovery Service, and wish to create a custom backup strategy for your virtual machine disks. For virtual machines running business or mission critical workloads, it's recommended to use [Azure Backup](#) as part of the backup strategy.

Azure virtual machine disks are stored as page blobs in Azure Storage. Since we are describing a backup strategy for virtual machine disks in this article, we refer to snapshots in the context of page blobs. To learn more about snapshots, refer to [Creating a Snapshot of a Blob](#).

## What is a snapshot?

A blob snapshot is a read-only version of a blob that is captured at a point in time. Once a snapshot has been created, it can be read, copied, or deleted, but not modified. Snapshots provide a way to back up a blob as it appears at a moment in time. Until REST version 2015-04-05, you had the ability to copy full snapshots. With the REST version 2015-07-08 and above, you can also copy incremental snapshots.

## Full snapshot copy

Snapshots can be copied to another storage account as a blob to keep backups of the base blob. You can also copy a snapshot over its base blob, which is like restoring the blob to an earlier version. When a snapshot is copied from one storage account to another, it occupies the same space as the base page blob. Therefore, copying whole snapshots from one storage account to another is slow and consumes much space in the target storage account.

### NOTE

If you copy the base blob to another destination, the snapshots of the blob are not copied along with it. Similarly, if you overwrite a base blob with a copy, snapshots associated with the base blob are not affected and stay intact under the base blob name.

## Back up disks using snapshots

As a backup strategy for your virtual machine disks, you can take periodic snapshots of the disk or page blob, and copy them to another storage account using tools like [Copy Blob](#) operation or [AzCopy](#). You can copy a snapshot to a destination page blob with a different name. The resulting destination page blob is a writeable page blob and not a snapshot. Later in this article, we describe steps to take backups of virtual machine disks using snapshots.

## Restore disks using snapshots

When it is time to restore your disk to a stable version that was previously captured in one of the backup snapshots, you can copy a snapshot over the base page blob. After the snapshot is promoted to the base page

blob, the snapshot remains, but its source is overwritten with a copy that can be both read and written. Later in this article we describe steps to restore a previous version of your disk from its snapshot.

## Implementing full snapshot copy

You can implement a full snapshot copy by doing the following,

- First, take a snapshot of the base blob using the [Snapshot Blob](#) operation.
- Then, copy the snapshot to a target storage account using [Copy Blob](#).
- Repeat this process to maintain backup copies of your base blob.

## Incremental snapshot copy

The new feature in the [GetPageRanges](#) API provides a much better way to back up the snapshots of your page blobs or disks. The API returns the list of changes between the base blob and the snapshots, which reduces the amount of storage space used on the backup account. The API supports page blobs on Premium Storage as well as Standard Storage. Using this API, you can build faster and more efficient backup solutions for Azure VMs. This API will be available with the REST version 2015-07-08 and higher.

Incremental Snapshot Copy allows you to copy from one storage account to another the difference between,

- Base blob and its Snapshot OR
- Any two snapshots of the base blob

Provided the following conditions are met,

- The blob was created on Jan-1-2016 or later.
- The blob was not overwritten with [PutPage](#) or [Copy Blob](#) between two snapshots.

### NOTE

This feature is available for Premium and Standard Azure Page Blobs.

When you have a custom backup strategy using snapshots, copying the snapshots from one storage account to another can be slow and can consume much storage space. Instead of copying the entire snapshot to a backup storage account, you can write the difference between consecutive snapshots to a backup page blob. This way, the time to copy and the space to store backups is substantially reduced.

## Implementing Incremental Snapshot Copy

You can implement incremental snapshot copy by doing the following,

- Take a snapshot of the base blob using [Snapshot Blob](#).
- Copy the snapshot to the target backup storage account in same or any other Azure region using [Copy Blob](#). This is the backup page blob. Take a snapshot of the backup page blob and store it in the backup account.
- Take another snapshot of the base blob using [Snapshot Blob](#).
- Get the difference between the first and second snapshots of the base blob using [GetPageRanges](#). Use the new parameter `prevsnapshot`, to specify the `DateTime` value of the snapshot you want to get the difference with. When this parameter is present, the REST response includes only the pages that were changed between target snapshot and previous snapshot including clear pages.
- Use [PutPage](#) to apply these changes to the backup page blob.
- Finally, take a snapshot of the backup page blob and store it in the backup storage account.

In the next section, we will describe in more detail how you can maintain backups of disks using Incremental Snapshot Copy

## Scenario

In this section, we describe a scenario that involves a custom backup strategy for virtual machine disks using snapshots.

Consider a DS-series Azure VM with a premium storage P30 disk attached. The P30 disk called *mypremiumdisk* is stored in a premium storage account called *mypremiumaccount*. A standard storage account called *mybackupsstdaccount* is used for storing the backup of *mypremiumdisk*. We would like to keep a snapshot of *mypremiumdisk* every 12 hours.

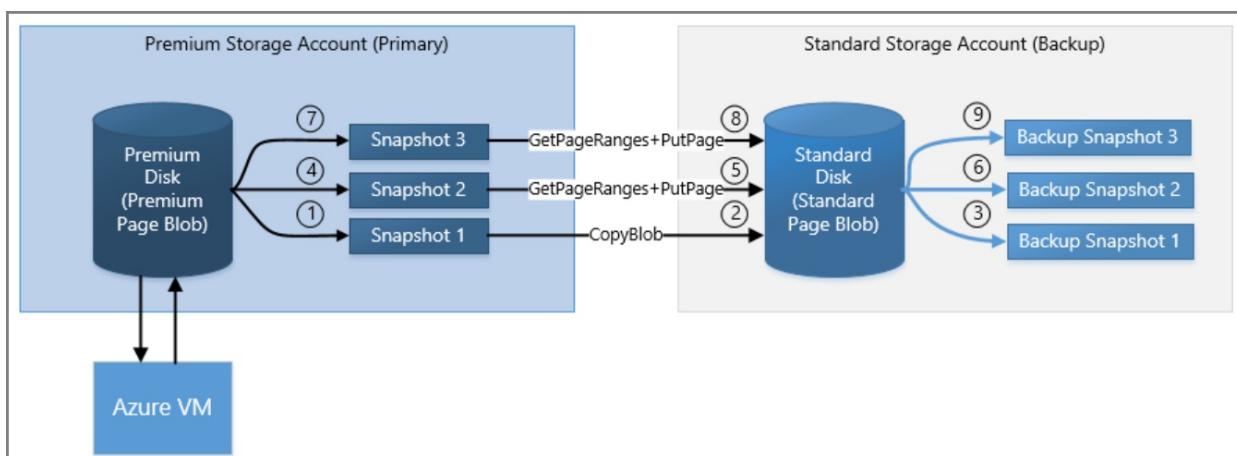

To learn about creating a storage account, see [Create a storage account](#).

To learn about backing up Azure VMs, refer to [Plan Azure VM backups](#).

## Steps to maintain backups of a disk using incremental snapshots

The following steps describe how to take snapshots of *mypremiumdisk* and maintain the backups in *mybackupsstdaccount*. The backup is a standard page blob called *mybackupsstdpageblob*. The backup page blob always reflects the same state as the last snapshot of *mypremiumdisk*.

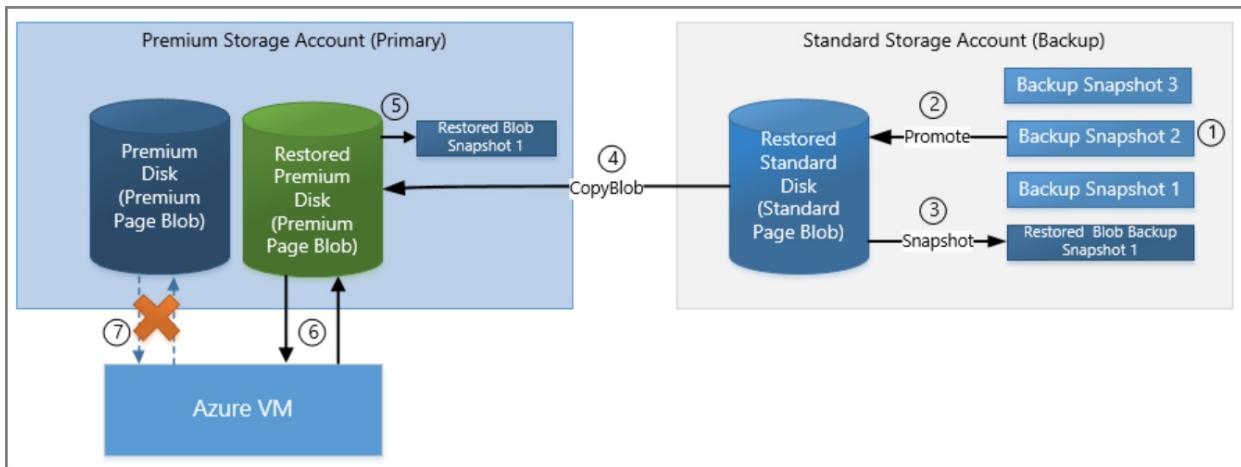

1. Create the backup page blob for your premium storage disk, by taking a snapshot of *mypremiumdisk* called *mypremiumdisk\_ss1*.
2. Copy this snapshot to *mybackupsstdaccount* as a page blob called *mybackupsstdpageblob*.
3. Take a snapshot of *mybackupsstdpageblob* called *mybackupsstdpageblob\_ss1*, using [Snapshot Blob](#) and store it in *mybackupsstdaccount*.
4. During the backup window, create another snapshot of *mypremiumdisk*, say *mypremiumdisk\_ss2*, and store it in *mypremiumaccount*.
5. Get the incremental changes between the two snapshots, *mypremiumdisk\_ss2* and *mypremiumdisk\_ss1*, using [GetPageRanges](#) on *mypremiumdisk\_ss2* with the **prevsnapshot** parameter set to the timestamp of *mypremiumdisk\_ss1*. Write these incremental changes to the backup page blob *mybackupsstdpageblob* in *mybackupsstdaccount*. If there are deleted ranges in the incremental changes, they must be cleared from the backup page blob. Use [PutPage](#) to write incremental changes to the backup page blob.
6. Take a snapshot of the backup page blob *mybackupsstdpageblob*, called *mybackupsstdpageblob\_ss2*. Delete the previous snapshot *mypremiumdisk\_ss1* from premium storage account.
7. Repeat steps 4-6 every backup window. In this way, you can maintain backups of *mypremiumdisk* in a standard storage account.

## Steps to restore a disk from snapshots

The following steps, describe how to restore the premium disk, *mypremiumdisk* to an earlier snapshot from the backup storage account *mybackupsstdaccount*.

1. Identify the point in time that you wish to restore the premium disk to. Let's say that it is snapshot *mybackupstdpageblob\_ss2*, which is stored in the backup storage account *mybackupstdaccount*.
2. In *mybackupstdaccount*, promote the snapshot *mybackupstdpageblob\_ss2* as the new backup base page blob *mybackupstdpageblobrestored*.
3. Take a snapshot of this restored backup page blob, called *mybackupstdpageblobrestored\_ss1*.
4. Copy the restored page blob *mybackupstdpageblobrestored* from *mybackupstdaccount* to *mypremiumaccount* as the new premium disk *mypremiumdiskrestored*.
5. Take a snapshot of *mypremiumdiskrestored*, called *mypremiumdiskrestored\_ss1* for making future incremental backups.
6. Point the DS series VM to the restored disk *mypremiumdiskrestored* and detach the old *mypremiumdisk* from the VM.
7. Begin the Backup process described in previous section for the restored disk *mypremiumdiskrestored*, using the *mybackupstdpageblobrestored* as the backup page blob.

## Next Steps

# Backup and disaster recovery for Azure unmanaged disks

9/21/2022 • 21 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article explains how to plan for backup and disaster recovery (DR) of IaaS virtual machines (VMs) and disks in Azure. This document covers unmanaged disks, or page blobs.

First, we cover the built-in fault tolerance capabilities in the Azure platform that helps guard against local failures. We then discuss the disaster scenarios not fully covered by the built-in capabilities. We also show several examples of workload scenarios where different backup and DR considerations can apply. We then review possible solutions for the DR of IaaS disks.

## Introduction

The Azure platform uses various methods for redundancy and fault tolerance to help protect customers from localized hardware failures. Local failures can include problems with an Azure Storage server machine that stores part of the data for a virtual disk or failures of an SSD or HDD on that server. Such isolated hardware component failures can happen during normal operations.

The Azure platform is designed to be resilient to these failures. Major disasters can result in failures or the inaccessibility of many storage servers or even a whole datacenter. Although your VMs and disks are normally protected from localized failures, additional steps are necessary to protect your workload from region-wide catastrophic failures, such as a major disaster, that can affect your VM and disks.

In addition to the possibility of platform failures, problems with a customer application or data can occur. For example, a new version of your application might inadvertently make a change to the data that causes it to break. In that case, you might want to revert the application and the data to a prior version that contains the last known good state. This requires maintaining regular backups.

For regional disaster recovery, you must back up your IaaS VM disks to a different region.

Before we look at backup and DR options, let's recap a few methods available for handling localized failures.

### Azure IaaS resiliency

*Resiliency* refers to the tolerance for normal failures that occur in hardware components. Resiliency is the ability to recover from failures and continue to function. It's not about avoiding failures, but responding to failures in a way that avoids downtime or data loss. The goal of resiliency is to return the application to a fully functioning state following a failure. Azure virtual machines and disks are designed to be resilient to common hardware faults. Let's look at how the Azure IaaS platform provides this resiliency.

A virtual machine consists mainly of two parts: a compute server and the persistent disks. Both affect the fault tolerance of a virtual machine.

If the Azure compute host server that houses your VM experiences a hardware failure, which is rare, Azure is designed to automatically restore the VM on another server. If this scenario, your computer reboots, and the VM comes back up after some time. Azure automatically detects such hardware failures and executes recoveries to help ensure the customer VM is available as soon as possible.

Regarding IaaS disks, the durability of data is critical for a persistent storage platform. Azure customers have important business applications running on IaaS, and they depend on the persistence of the data. Azure designs

protection for these IaaS disks, with three redundant copies of the data that is stored locally. These copies provide for high durability against local failures. If one of the hardware components that holds your disk fails, your VM is not affected, because there are two additional copies to support disk requests. It works fine, even if two different hardware components that support a disk fail at the same time (which is rare).

To ensure that you always maintain three replicas, Azure Storage automatically spawns a new copy of the data in the background if one of the three copies becomes unavailable. Therefore, it should not be necessary to use RAID with Azure disks for fault tolerance. A simple RAID 0 configuration should be sufficient for striping the disks, if necessary, to create larger volumes.

Because of this architecture, Azure has consistently delivered enterprise-grade durability for IaaS disks, with an industry-leading zero percent [annualized failure rate](#).

Localized hardware faults on the compute host or in the Storage platform can sometimes result in the temporary unavailability of the VM that is covered by the [Azure SLA](#) for VM availability. Azure also provides an industry-leading SLA for single VM instances that use Azure premium SSDs.

To safeguard application workloads from downtime due to the temporary unavailability of a disk or VM, customers can use [availability sets](#). Two or more virtual machines in an availability set provide redundancy for the application. Azure then creates these VMs and disks in separate fault domains with different power, network, and server components.

Because of these separate fault domains, localized hardware failures typically do not affect multiple VMs in the set at the same time. Having separate fault domains provides high availability for your application. It's considered a good practice to use availability sets when high availability is required. The next section covers the disaster recovery aspect.

### **Backup and disaster recovery**

Disaster recovery is the ability to recover from rare, but major, incidents. These incidents include non-transient, wide-scale failures, such as service disruption that affects an entire region. Disaster recovery includes data backup and archiving, and might include manual intervention, such as restoring a database from a backup.

The Azure platform's built-in protection against localized failures might not fully protect the VMs/disks if a major disaster causes large-scale outages. These large-scale outages include catastrophic events, such as if a datacenter is hit by a hurricane, earthquake, fire, or if there is a large-scale hardware unit failure. In addition, you might encounter failures due to application or data issues.

To help protect your IaaS workloads from outages, you should plan for redundancy and have backups to enable recovery. For disaster recovery, you should back up in a different geographic location away from the primary site. This approach helps ensure your backup is not affected by the same event that originally affected the VM or disks. For more information, see [Disaster recovery for Azure applications](#).

Your DR considerations might include the following aspects:

- High availability: The ability of the application to continue running in a healthy state, without significant downtime. By *healthy state*, this state means that the application is responsive, and users can connect to the application and interact with it. Certain mission-critical applications and databases might be required to always be available, even when there are failures in the platform. For these workloads, you might need to plan redundancy for the application, as well as the data.
- Data durability: In some cases, the main consideration is ensuring that the data is preserved if a disaster happens. Therefore, you might need a backup of your data in a different site. For such workloads, you might not need full redundancy for the application, but only a regular backup of the disks.

## **Backup and DR scenarios**

Let's look at a few typical examples of application workload scenarios and the considerations for planning for

disaster recovery.

### Scenario 1: Major database solutions

Consider a production database server, like SQL Server or Oracle, that can support high availability. Critical production applications and users depend on this database. The disaster recovery plan for this system might need to support the following requirements:

- The data must be protected and recoverable.
- The server must be available for use.

The disaster recovery plan might require maintaining a replica of the database in a different region as a backup. Depending on the requirements for server availability and data recovery, the solution might range from an active-active or active-passive replica site to periodic offline backups of the data. Relational databases, such as SQL Server and Oracle, provide various options for replication. For SQL Server, use [SQL Server Always On Availability Groups](#) for high availability.

NoSQL databases, like MongoDB, also support [replicas](#) for redundancy. The replicas for high availability are used.

### Scenario 2: A cluster of redundant VMs

Consider a workload handled by a cluster of VMs that provide redundancy and load balancing. One example is a Cassandra cluster deployed in a region. This type of architecture already provides a high level of redundancy within that region. However, to protect the workload from a regional-level failure, you should consider spreading the cluster across two regions or making periodic backups to another region.

### Scenario 3: IaaS application workload

Let's look at the IaaS application workload. For example, this application might be a typical production workload running on an Azure VM. It might be a web server or file server holding the content and other resources of a site. It might also be a custom-built business application running on a VM that stored its data, resources, and application state on the VM disks. In this case, it's important to make sure you take backups on a regular basis. Backup frequency should be based on the nature of the VM workload. For example, if the application runs every day and modifies data, then the backup should be taken every hour.

Another example is a reporting server that pulls data from other sources and generates aggregated reports. The loss of this VM or disks might lead to the loss of the reports. However, it might be possible to rerun the reporting process and regenerate the output. In that case, you don't really have a loss of data, even if the reporting server is hit with a disaster. As a result, you might have a higher level of tolerance for losing part of the data on the reporting server. In that case, less frequent backups are an option to reduce costs.

### Scenario 4: IaaS application data issues

IaaS application data issues are another possibility. Consider an application that computes, maintains, and serves critical commercial data, such as pricing information. A new version of your application had a software bug that incorrectly computed the pricing and corrupted the existing commerce data served by the platform. Here, the best course of action is to revert to the earlier version of the application and the data. To enable this, take periodic backups of your system.

## Disaster recovery solution: Azure Backup

[Azure Backup](#) is used for backups and DR, and it works with [managed disks](#) as well as unmanaged disks. You can create a backup job with time-based backups, easy VM restoration, and backup retention policies.

If you use [premium SSDs](#), [managed disks](#), or other disk types with the [locally redundant storage](#) option, it's especially important to make periodic DR backups. Azure Backup stores the data in your recovery services vault for long-term retention. Choose the [geo-redundant storage](#) option for the backup recovery services vault. That option ensures that backups are replicated to a different Azure region for safeguarding from regional disasters.

For unmanaged disks, you can use the locally redundant storage type for IaaS disks, but ensure that Azure Backup is enabled with the geo-redundant storage option for the recovery services vault.

**NOTE**

If you use the [geo-redundant storage](#) or [read-access geo-redundant storage](#) option for your unmanaged disks, you still need consistent snapshots for backup and DR. Use either [Azure Backup](#) or [consistent snapshots](#).

The following table is a summary of the solutions available for DR.

SCENARIO	AUTOMATIC REPLICATION	DR SOLUTION
Premium SSD disks	Local ( <a href="#">locally redundant storage</a> )	<a href="#">Azure Backup</a>
Managed disks	Local ( <a href="#">locally redundant storage</a> )	<a href="#">Azure Backup</a>
Unmanaged locally redundant storage disks	Local ( <a href="#">locally redundant storage</a> )	<a href="#">Azure Backup</a>
Unmanaged geo-redundant storage disks	Cross region ( <a href="#">geo-redundant storage</a> )	<a href="#">Azure Backup</a> <a href="#">Consistent snapshots</a>
Unmanaged read-access geo-redundant storage disks	Cross region ( <a href="#">read-access geo-redundant storage</a> )	<a href="#">Azure Backup</a> <a href="#">Consistent snapshots</a>

High availability is best met by using managed disks in an availability set along with Azure Backup. If you use unmanaged disks, you can still use Azure Backup for DR. If you are unable to use Azure Backup, then taking [consistent snapshots](#), as described in a later section, is an alternative solution for backup and DR.

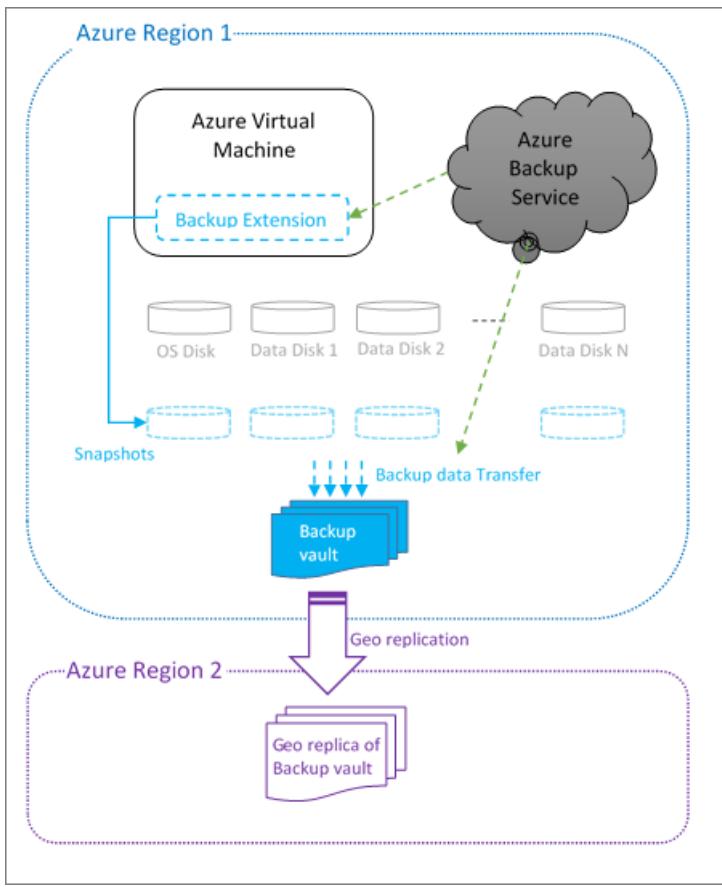

Your choices for high availability, backup, and DR at application or infrastructure levels can be represented as follows:

LEVEL	HIGH AVAILABILITY	BACKUP OR DR
Application	SQL Server Always On	<a href="#">Azure Backup</a>
Infrastructure	Availability set	Geo-redundant storage with consistent snapshots

## Using Azure Backup

[Azure Backup](#) can back up your VMs running Windows or Linux to the Azure recovery services vault. Backing up and restoring business-critical data is complicated by the fact that business-critical data must be backed up while the applications that produce the data are running.

To address this issue, Azure Backup provides application-consistent backups for Microsoft workloads. It uses the volume shadow service to ensure that data is written correctly to storage. For Linux VMs, the default backup consistency mode is file-consistent backups, because Linux does not have functionality equivalent to the volume shadow service as in the case of Windows. For Linux machines, see [Application-consistent backup of Azure Linux VMs](#).

When Azure Backup initiates a backup job at the scheduled time, it triggers the backup extension installed in the VM to take a point-in-time snapshot. A snapshot is taken in coordination with the volume shadow service to get a consistent snapshot of the disks in the virtual machine without having to shut it down. The backup extension in the VM flushes all writes before taking a consistent snapshot of all of the disks. After taking the snapshot, the data is transferred by Azure Backup to the backup vault. To make the backup process more efficient, the service identifies and transfers only the blocks of data that have changed after the last backup.

To restore, you can view the available backups through Azure Backup and then initiate a restore. You can create and restore Azure backups through the [Azure portal](#), by [using PowerShell](#), or by using the [Azure CLI](#).

### Steps to enable a backup

Use the following steps to enable backups of your VMs by using the [Azure portal](#). There is some variation depending on your exact scenario. Refer to the [Azure Backup](#) documentation for full details. Azure Backup also [supports VMs with managed disks](#).

1. Create a recovery services vault for a VM:
  - a. In the [Azure portal](#), browse All resources and find **Recovery Services vaults**.
  - b. On the **Recovery Services vaults** menu, click **Add** and follow the steps to create a new vault in the same region as the VM. For example, if your VM is in the West US region, pick West US for the vault.
2. Verify the storage replication for the newly created vault. Access the vault under **Recovery Services vaults** and go to **Properties > Backup Configuration > Update**. Ensure the **geo-redundant storage** option is selected by default. This option ensures that your vault is automatically replicated to a secondary datacenter. For example, your vault in West US is automatically replicated to East US.
3. Configure the backup policy and select the VM from the same UI.
4. Make sure the Backup Agent is installed on the VM. If your VM is created by using an Azure gallery image, then the Backup Agent is already installed. Otherwise (that is, if you use a custom image), use the instructions to [install the VM agent on a virtual machine](#).

5. After the previous steps are completed, the backup runs at regular intervals as specified in the backup policy. If necessary, you can trigger the first backup manually from the vault dashboard on the Azure portal.

For automating Azure Backup by using scripts, refer to [PowerShell cmdlets for VM backup](#).

### Steps for recovery

If you need to repair or rebuild a VM, you can restore the VM from any of the backup recovery points in the vault. There are a couple of different options for performing the recovery:

- You can create a new VM as a point-in-time representation of your backed-up VM.
- You can restore the disks, and then use the template for the VM to customize and rebuild the restored VM.

For more information, see the instructions to [use the Azure portal to restore virtual machines](#). This document also explains the specific steps for restoring backed-up VMs to a paired datacenter by using your geo-redundant backup vault if there is a disaster at the primary datacenter. In that case, Azure Backup uses the Compute service from the secondary region to create the restored virtual machine.

You can also use PowerShell for [creating a new VM from restored disks](#).

## Alternative solution: Consistent snapshots

If you are unable to use Azure Backup, you can implement your own backup mechanism by using snapshots. Creating consistent snapshots for all the disks used by a VM and then replicating those snapshots to another region is complicated. For this reason, Azure considers using the Backup service as a better option than building a custom solution.

If you use read-access geo-redundant storage/geo-redundant storage for disks, snapshots are automatically replicated to a secondary datacenter. If you use locally redundant storage for disks, you need to replicate the data yourself. For more information, see [Back up Azure-unmanaged VM disks with incremental snapshots](#).

A snapshot is a representation of an object at a specific point in time. A snapshot incurs billing for the incremental size of the data it holds. For more information, see [Create a blob snapshot](#).

### Create snapshots while the VM is running

Although you can take a snapshot at any time, if the VM is running, there is still data being streamed to the disks. The snapshots might contain partial operations that were in flight. Also, if there are several disks involved, the snapshots of different disks might have occurred at different times. These scenarios may cause the snapshots to be uncoordinated. This lack of coordination is especially problematic for striped volumes whose files might be corrupted if changes were being made during backup.

To avoid this situation, the backup process must implement the following steps:

1. Freeze all the disks.
2. Flush all the pending writes.
3. [Create a blob snapshot](#) for all the disks.

Some Windows applications, like SQL Server, provide a coordinated backup mechanism via a volume shadow service to create application-consistent backups. On Linux, you can use a tool like `fsfreeze` for coordinating the disks. This tool provides file-consistent backups, but not application-consistent snapshots. This process is complex, so you should consider using [Azure Backup](#) or a third-party backup solution that already implements this procedure.

The previous process results in a collection of coordinated snapshots for all of the VM disks, representing a

specific point-in-time view of the VM. This is a backup restore point for the VM. You can repeat the process at scheduled intervals to create periodic backups. See [Copy the backups to another region](#) for steps to copy the snapshots to another region for DR.

### Create snapshots while the VM is offline

Another option to create consistent backups is to shut down the VM and take blob snapshots of each disk. Taking blob snapshots is easier than coordinating snapshots of a running VM, but it requires a few minutes of downtime.

1. Shut down the VM.
2. Create a snapshot of each virtual hard drive blob, which only takes a few seconds.

To create a snapshot, you can use [PowerShell](#), the [Azure Storage REST API](#), [Azure CLI](#), or one of the Azure Storage client libraries, such as [the Storage client library for .NET](#).

3. Start the VM, which ends the downtime. Typically, the entire process finishes within a few minutes.

This process yields a collection of consistent snapshots for all the disks, providing a backup restore point for the VM.

### Copy the snapshots to another region

Creation of the snapshots alone might not be sufficient for DR. You must also replicate the snapshot backups to another region.

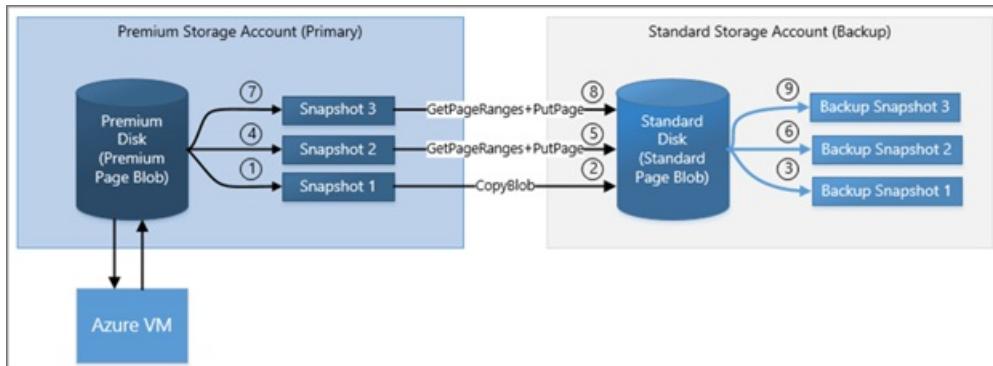

If you use geo-redundant storage or read-access geo-redundant storage for your disks, then the snapshots are replicated to the secondary region automatically. There can be a few minutes of lag before the replication. If the primary datacenter goes down before the snapshots finish replicating, you cannot access the snapshots from the secondary datacenter. The likelihood of this is small.

#### NOTE

Only having the disks in a geo-redundant storage or read-access geo-redundant storage account does not protect the VM from disasters. You must also create coordinated snapshots or use Azure Backup. This is required to recover a VM to a consistent state.

If you use locally redundant storage, you must copy the snapshots to a different storage account immediately after creating the snapshot. The copy target might be a locally redundant storage account in a different region, resulting in the copy being in a remote region. You can also copy the snapshot to a read-access geo-redundant storage account in the same region. In this case, the snapshot is lazily replicated to the remote secondary region. Your backup is protected from disasters at the primary site after the copying and replication is complete.

To copy your incremental snapshots for DR efficiently, review the instructions in [Back up Azure unmanaged VM disks with incremental snapshots](#).

### Recovery from snapshots

To retrieve a snapshot, copy it to make a new blob. If you are copying the snapshot from the primary account, you can copy the snapshot over to the base blob of the snapshot. This process reverts the disk to the snapshot. This process is known as promoting the snapshot. If you are copying the snapshot backup from a secondary account, in the case of a read-access geo-redundant storage account, you must copy it to a primary account. You can copy a snapshot by [using PowerShell](#) or by using the AzCopy utility. For more information, see [Transfer data with the AzCopy command-line utility](#).

For VMs with multiple disks, you must copy all the snapshots that are part of the same coordinated restore point. After you copy the snapshots to writable VHD blobs, you can use the blobs to recreate your VM by using the template for the VM.

## Other options

### SQL Server

SQL Server running in a VM has its own built-in capabilities to back up your SQL Server database to Azure Blob storage or a file share. If the storage account is geo-redundant storage or read-access geo-redundant storage, you can access those backups in the storage account's secondary datacenter in the event of a disaster, with the same restrictions as previously discussed. For more information, see [Back up and restore for SQL Server in Azure virtual machines](#). In addition to back up and restore, [SQL Server Always On availability groups](#) can maintain secondary replicas of databases. This ability greatly reduces the disaster recovery time.

## Other considerations

This article has discussed how to back up or take snapshots of your VMs and their disks to support disaster recovery and how to use those backups or snapshots to recover your data. With the Azure Resource Manager model, many people use templates to create their VMs and other infrastructures in Azure. You can use a template to create a VM that has the same configuration every time. If you use custom images for creating your VMs, you must also make sure that your images are protected by using a read-access geo-redundant storage account to store them.

Consequently, your backup process can be a combination of two things:

- Back up the data (disks).
- Back up the configuration (templates and custom images).

Depending on the backup option you choose, you might have to handle the backup of both the data and the configuration, or the backup service might handle all of that for you.

## Appendix: Understanding the impact of data redundancy

For storage accounts in Azure, there are three types of data redundancy that you should consider regarding disaster recovery: locally redundant, geo-redundant, or geo-redundant with read access.

Locally redundant storage retains three copies of the data in the same datacenter. When the VM writes the data, all three copies are updated before success is returned to the caller, so you know they are identical. Your disk is protected from local failures, because it's unlikely that all three copies are affected at the same time. In the case of locally redundant storage, there is no geo-redundancy, so the disk is not protected from catastrophic failures that can affect an entire datacenter or storage unit.

With geo-redundant storage and read-access geo-redundant storage, three copies of your data are retained in the primary region that is selected by you. Three more copies of your data are retained in a corresponding secondary region that is set by Azure. For example, if you store data in West US, the data is replicated to East US. Copy retention is done asynchronously, and there is a small delay between updates to the primary and secondary sites. Replicas of the disks on the secondary site are consistent on a per-disk basis (with the delay), but replicas of multiple active disks might not be in sync with each other. To have consistent replicas across

multiple disks, consistent snapshots are needed.

The main difference between geo-redundant storage and read-access geo-redundant storage is that with read-access geo-redundant storage, you can read the secondary copy at any time. If there is a problem that renders the data in the primary region inaccessible, the Azure team makes every effort to restore access. While the primary is down, if you have read-access geo-redundant storage enabled, you can access the data in the secondary datacenter. Therefore, if you plan to read from the replica while the primary is inaccessible, then read-access geo-redundant storage should be considered.

If it turns out to be a significant outage, the Azure team might trigger a geo-failover and change the primary DNS entries to point to secondary storage. At this point, if you have either geo-redundant storage or read-access geo-redundant storage enabled, you can access the data in the region that used to be the secondary. In other words, if your storage account is geo-redundant storage and there is a problem, you can access the secondary storage only if there is a geo-failover.

For more information, see [What to do if an Azure Storage outage occurs](#).

## Next steps

See [Back up Azure unmanaged Virtual Machine disks with incremental snapshots](#).

# Ephemeral OS disks for Azure VMs

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

Ephemeral OS disks are created on the local virtual machine (VM) storage and not saved to the remote Azure Storage. Ephemeral OS disks work well for stateless workloads, where applications are tolerant of individual VM failures but are more affected by VM deployment time or reimaging of individual VM instances. With Ephemeral OS disk, you get lower read/write latency to the OS disk and faster VM reimage.

The key features of ephemeral disks are:

- Ideal for stateless applications.
- Supported by Marketplace, custom images, and by [Azure Compute Gallery](#) (formerly known as Shared Image Gallery).
- Ability to fast reset or reimage VMs and scale set instances to the original boot state.
- Lower latency, similar to a temporary disk.
- Ephemeral OS disks are free, you incur no storage cost for OS disks.
- Available in all Azure regions.

Key differences between persistent and ephemeral OS disks:

	PERSISTENT OS DISK	EPHEMERAL OS DISK
Size limit for OS disk	2 TiB	Cache size or temp size for the VM size or 2040 GiB, whichever is smaller. For the <b>cache or temp size in GiB</b> , see <a href="#">DS</a> , <a href="#">ES</a> , <a href="#">M</a> , <a href="#">FS</a> , and <a href="#">GS</a>
VM sizes supported	All	VM sizes that support Premium storage such as DSv1, DSv2, DSv3, Esv3, Fs, FsV2, GS, M, Mdsv2, Bs, Dav4, Eav4
Disk type support	Managed and unmanaged OS disk	Managed OS disk only
Region support	All regions	All regions
Data persistence	OS disk data written to OS disk are stored in Azure Storage	Data written to OS disk is stored on local VM storage and isn't persisted to Azure Storage.
Stop-deallocated state	VMs and scale set instances can be stop-deallocated and restarted from the stop-deallocated state	Not Supported
Specialized OS disk support	Yes	No
OS disk resize	Supported during VM creation and after VM is stop-deallocated	Supported during VM creation only

	PERSISTENT OS DISK	EPHEMERAL OS DISK
Resizing to a new VM size	OS disk data is preserved	Data on the OS disk is deleted, OS is reprovisioned
Redeploy	OS disk data is preserved	Data on the OS disk is deleted, OS is reprovisioned
Stop/ Start of VM	OS disk data is preserved	Not Supported
Page file placement	For Windows, page file is stored on the resource disk	For Windows, page file is stored on the OS disk (for both OS cache placement and Temp disk placement).
Maintenance of VM/VMSS using <b>healing</b>	OS disk data is preserved	OS disk data is not preserved
Maintenance of VM/VMSS using <b>Live Migration</b>	OS disk data is preserved	OS disk data is preserved

## Placement options for Ephemeral OS disks

Ephemeral OS disk can be stored either on VM's OS cache disk or VM's temp/resource disk. [DiffDiskPlacement](#) is the new property that can be used to specify where you want to place the Ephemeral OS disk. With this feature, when a Windows VM is provisioned, we configure the pagefile to be located on the OS Disk.

## Size requirements

You can choose to deploy Ephemeral OS Disk on VM cache or VM temp disk. The image OS disk's size should be less than or equal to the temp/cache size of the VM size chosen.

For example, if you want to opt for **OS cache placement**: Standard Windows Server images from the marketplace are about 127 GiB, which means that you need a VM size that has a cache equal to or larger than 127 GiB. The Standard\_DS3\_v2 has a cache size of 127 GiB, which is large enough. In this case, the Standard\_DS3\_v2 is the smallest size in the DSv2 series that you can use with this image.

If you want to opt for **Temp disk placement**: Standard Ubuntu server image from marketplace is about 30 GiB. To enable Ephemeral OS disk on temp, the temp disk size must be equal to or larger than 30 GiB. Standard\_B4ms has a temp size of 32 GiB, which can fit the 30 GiB OS disk. Upon creation of the VM, the temp disk space would be 2 GiB.

### IMPORTANT

If opting for temp disk placement the Final Temp disk size = (Initial temp disk size - OS image size).

In the case of **Temp disk placement**, as Ephemeral OS disk is placed on temp disk it will share the IOPS with temp disk as per the VM size chosen by you.

Basic Linux and Windows Server images in the Marketplace that are denoted by `[smallsize]` tend to be around 30 GiB and can use most of the available VM sizes. Ephemeral disks also require that the VM size supports **Premium storage**. The sizes usually (but not always) have an `s` in the name, like DSv2 and EsV3. For more information, see [Azure VM sizes](#) for details around which sizes support Premium storage.

#### NOTE

Ephemeral disk will not be accessible through the portal. You will receive a "Resource not Found" or "404" error when accessing the ephemeral disk which is expected.

## Unsupported features

- Capturing VM images
- Disk snapshots
- Azure Disk Encryption
- Azure Backup
- Azure Site Recovery
- OS Disk Swap

## Trusted Launch for Ephemeral OS disks

Ephemeral OS disks can be created with Trusted launch. Not all VM sizes and regions are supported for trusted launch. Check [limitations of trusted launch](#) for supported sizes and regions. VM guest state (VMGS) is specific to trusted launch VMs. It is a blob that is managed by Azure and contains the unified extensible firmware interface (UEFI) secure boot signature databases and other security information. When using trusted launch by default 1 GiB from the **OS cache or temp storage** based on the chosen placement option is reserved for VMGS. The lifecycle of the VMGS blob is tied to that of the OS Disk.

For example, If you try to create a Trusted launch Ephemeral OS disk VM using OS image of size 56 GiB with VM size [Standard\\_DS4\\_v2](#) using temp disk placement you would get an error as "**OS disk of Ephemeral VM with size greater than 55 GB is not allowed for VM size Standard\_DS4\_v2 when the DiffDiskPlacement is ResourceDisk.**" This is because the temp storage for [Standard\\_DS4\\_v2](#) is 56 GiB, and 1 GiB is reserved for VMGS when using trusted launch. For the same example above, if you create a standard Ephemeral OS disk VM you would not get any errors and it would be a successful operation.

#### IMPORTANT

While using ephemeral disks for Trusted Launch VMs, keys and secrets generated or sealed by the vTPM after VM creation may not be persisted for operations like reimaging and platform events like service healing.

For more information on [how to deploy a trusted launch VM](#)

## Confidential VMs using Ephemeral OS disks (preview)

AMD-based Confidential VMs cater to high security and confidentiality requirements of customers. These VMs provide a strong, hardware-enforced boundary to help meet your security needs. There are limitations to use Confidential VMs. Check the [region](#), [size](#) and [OS supported](#) limitations for confidential VMs. Virtual machine guest state (VMGS) blob contains the security information of the confidential VM. Confidential VMs using Ephemeral OS disks by default 1 GiB from the **OS cache or temp storage** based on the chosen placement option is reserved for VMGS. The lifecycle of the VMGS blob is tied to that of the OS Disk.

#### IMPORTANT

When choosing a confidential VM with full OS disk encryption before VM deployment that uses a customer-managed key (CMK). [Updating a CMK key version](#) or [key rotation](#) is not supported with Ephemeral OS disk. Confidential VMs using Ephemeral OS disks need to be deleted before updating or rotating the keys and can be re-created subsequently.

For more information on [confidential VM](#)

## Customer Managed key (preview)

You can choose to use customer managed keys or platform managed keys when you enable end-to-end encryption for VMs using Ephemeral OS disk. Currently this option is available only via [PowerShell](#), [CLI](#) and SDK in all regions.

### IMPORTANT

Updating a CMK key version or key rotation of customer managed key is not supported with Ephemeral OS disk. VMs using Ephemeral OS disks need to be deleted before updating or rotating the keys and can be re-created subsequently.

For more information on [Encryption at host](#)

## Next steps

Create a VM with ephemeral OS disk using [Azure Portal/CLI/PowerShell/ARM template](#). Check out the [frequently asked questions on ephemeral os disk](#).

# How to deploy Ephemeral OS disks for Azure VMs

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

This article shows you how to create a virtual machine or virtual machine scale sets with Ephemeral OS disks through Portal, ARM template deployment, CLI and PowerShell.

## Portal

In the Azure portal, you can choose to use ephemeral disks when deploying a virtual machine or virtual machine scale sets by opening the **Advanced** section of the **Disks** tab. For choosing placement of Ephemeral OS disk, select **OS cache placement** or **Temp disk placement**.

Home >

## Create a virtual machine

[Review + create](#) [< Previous](#) [Next : Networking >](#)

If the option for using an ephemeral disk or OS cache placement or Temp disk placement is greyed out, you might have selected a VM size that doesn't have a cache/temp size larger than the OS image or that doesn't support Premium storage. Go back to the **Basics** page and try choosing another VM size.

## Scale set template deployment

The process to create a scale set that uses an ephemeral OS disk is to add the `diffDiskSettings` property to the `Microsoft.Compute/virtualMachineScaleSets/virtualMachineProfile` resource type in the template. Also, the caching policy must be set to `ReadOnly` for the ephemeral OS disk. placement can be changed to `CacheDisk` for OS cache disk placement.

          "caching": "ReadOnly",  
          "createOption": "FromImage"  
        },  
        "imageReference": {  
          "publisher": "Canonical",  
          "offer": "UbuntuServer",  
          "sku": "16.04-LTS",  
          "version": "latest"  
        }  
      },  
      "osProfile": {  
        "computerNamePrefix": "myvmss",  
        "adminUsername": "azureuser",  
        "adminPassword": "P@ssw0rd!"  
      }  
    }  
  }  
}
```

## VM template deployment

You can deploy a VM with an ephemeral OS disk using a template. The process to create a VM that uses ephemeral OS disks is to add the `diffDiskSettings` property to `Microsoft.Compute/virtualMachines` resource type in the template. Also, the caching policy must be set to `ReadOnly` for the ephemeral OS disk. placement option can be changed to `CacheDisk` for OS cache disk placement.

```
{
  "type": "Microsoft.Compute/virtualMachines",
  "name": "myVirtualMachine",
  "location": "East US 2",
  "apiVersion": "2019-12-01",
  "properties": {
    "storageProfile": {
      "osDisk": {
        "diffDiskSettings": {
          "option": "Local",
          "placement": "ResourceDisk"
        },
        "caching": "ReadOnly",
        "createOption": "FromImage"
      },
      "imageReference": {
        "publisher": "MicrosoftWindowsServer",
        "offer": "WindowsServer",
        "sku": "2016-Datacenter-smalldisk",
        "version": "latest"
      },
      "hardwareProfile": {
        "vmSize": "Standard_DS2_v2"
      }
    },
    "osProfile": {
      "computerNamePrefix": "myvirtualmachine",
      "adminUsername": "azureuser",
      "adminPassword": "P@ssw0rd!"
    }
  }
}
```

## CLI

To use an ephemeral disk for a CLI VM deployment, set the `--ephemeral-os-disk` parameter in `az vm create` to `true` and the `--ephemeral-os-disk-placement` parameter to `ResourceDisk` for temp disk placement or `CacheDisk` for cache disk placement and the `--os-disk-caching` parameter to `ReadOnly`.

```
az vm create \
--resource-group myResourceGroup \
--name myVM \
--image UbuntuLTS \
--ephemeral-os-disk true \
--ephemeral-os-disk-placement ResourceDisk \
--os-disk-caching ReadOnly \
--admin-username azureuser \
--generate-ssh-keys
```

For scale sets, you use the same `--ephemeral-os-disk true` parameter for `az-vmss-create` and set the `--os-disk-caching` parameter to `ReadOnly` and the `--ephemeral-os-disk-placement` parameter to `ResourceDisk` for temp disk placement or `CacheDisk` for cache disk placement.

## Reimage a VM using REST

You can reimagine a Virtual Machine instance with ephemeral OS disk using REST API as described below and via Azure portal by going to Overview pane of the VM. For scale sets, reimaging is already available through PowerShell, CLI, and the portal.

```
POST https://management.azure.com/subscriptions/{sub-  
id}/resourceGroups/{rgName}/providers/Microsoft.Compute/VirtualMachines/{vmName}/reimage?api-version=2019-  
12-01"
```

## PowerShell

To use an ephemeral disk for a PowerShell VM deployment, use [Set-AzVMOSDisk](#) in your VM configuration. Set the `-DiffDiskSetting` to `Local` and `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `ResourceDisk`.

```
Set-AzVMOSDisk -DiffDiskSetting Local -DiffDiskPlacement ResourceDisk -Caching ReadOnly
```

To use an ephemeral disk on cache disk for a PowerShell VM deployment, use [Set-AzVMOSDisk](#) in your VM configuration. Set the `-DiffDiskSetting` to `Local` , `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `CacheDisk` .

```
Set-AzVMOSDisk -DiffDiskSetting Local -DiffDiskPlacement CacheDisk -Caching ReadOnly
```

For scale set deployments, use the [Set-AzVmssStorageProfile](#) cmdlet in your configuration. Set the `-DiffDiskSetting` to `Local` , `-Caching` to `ReadOnly` and `-DiffDiskPlacement` to `ResourceDisk` or `CacheDisk` .

```
Set-AzVmssStorageProfile -DiffDiskSetting Local -DiffDiskPlacement ResourceDisk -OsDiskCaching ReadOnly
```

## Next steps

For more information on [Ephemeral OS disk](#).

# Frequently asked questions about Ephemeral OS disks

9/21/2022 • 2 minutes to read • [Edit Online](#)

**Q: What is the size of the local OS Disks?**

A: We support platform, Shared Image Gallery, and custom images, up to the VM cache size with OS cache placement and up to Temp disk size with Temp disk placement, where all read/writes to the OS disk will be local on the same node as the Virtual Machine.

**Q: Can the ephemeral OS disk be resized?**

A: No, once the ephemeral OS disk is provisioned, the OS disk cannot be resized.

**Q: Can the ephemeral OS disk placement be modified after creation of VM?**

A: No, once the ephemeral OS disk is provisioned, the OS disk placement cannot be changed. But the VM can be recreated via ARM template deployment/PowerShell/CLI by updating the OS disk placement of choosing. This would result in the recreation of the VM with Data on the OS disk deleted and OS is reprovisioned.

**Q: Is there any Temp disk created if image size equals to Temp disk size of VM size selected?**

A: No, in that case, there won't be any Temp disk drive created.

**Q: Are Ephemeral OS disks supported on low-priority VMs and Spot VMs?**

A: Yes. There is no option of Stop-Deallocate for Ephemeral VMs, rather users need to Delete instead of deallocating them.

**Q: Can I attach a Managed Disks to an Ephemeral VM?**

A: Yes, you can attach a managed data disk to a VM that uses an ephemeral OS disk.

**Q: Will all VM sizes be supported for ephemeral OS disks?**

A: No, most Premium Storage VM sizes are supported (DS, ES, FS, GS, M, etc.). To know whether a particular VM size supports ephemeral OS disks for an OS image size you can use the below script. It takes the OS image size and location as inputs and provides a list of VM SKUs and corresponding placement supported. If both OS Cache and temp disk placement are marked as not supported then Ephemeral OS disk cannot be used for the given OS image size.

```

[CmdletBinding()]
param([Parameter(Mandatory=$true)]
    [ValidateNotNullOrEmpty()])
    [string]$Location,
    [Parameter(Mandatory=$true)]
    [long]$OSImageSizeInGB
)

Function HasSupportEphemeralOSDisk([object[]] $capability)
{
    return $capability | where { $_.Name -eq "EphemeralOSDiskSupported" -and $_.Value -eq "True" }
}

Function Get-MaxTempDiskAndCacheSize([object[]] $capabilities)
{
    $MaxResourceVolumeGB = 0;
    $CachedDiskGB = 0;

    foreach($capability in $capabilities)
    {
        if ($capability.Name -eq "MaxResourceVolumeMB")
        { $MaxResourceVolumeGB = [int]($capability.Value / 1024) }

        if ($capability.Name -eq "CachedDiskBytes")
        { $CachedDiskGB = [int]($capability.Value / (1024 * 1024 * 1024)) }
    }

    return ($MaxResourceVolumeGB, $CachedDiskGB)
}

Function Get-EphemeralSupportedVMSku
{
    [CmdletBinding()]
    Param
    (
        [Parameter(Mandatory=$true)]
        [long]$OSImageSizeInGB,
        [Parameter(Mandatory=$true)]
        [string]$Location
    )

    $VmSkus = Get-AzComputeResourceSku $Location | Where-Object { $_.ResourceType -eq "virtualMachines" -and (HasSupportEphemeralOSDisk $_.Capabilities) -ne $null }

    $Response = @()
    foreach ($sku in $VmSkus)

        $Response += New-Object PSObject -Property @{
            ResourceSKU = $sku.Size
            TempDiskPlacement = @{ $true = "NOT SUPPORTED"; $false = "SUPPORTED"}[$MaxResourceVolumeGB -lt $OSImageSizeInGB]
            CacheDiskPlacement = @{ $true = "NOT SUPPORTED"; $false = "SUPPORTED"}[$CachedDiskGB -lt $OSImageSizeInGB]
        };
    }

    return $Response
}

Get-EphemeralSupportedVMSku -OSImageSizeInGB $OSImageSizeInGB -Location $Location | Format-Table

```

**Q: Can the ephemeral OS disk be applied to existing VMs and scale sets?**

A: No, ephemeral OS disk can only be used during VM and scale set creation.

**Q: Can you mix ephemeral and normal OS disks in a scale set?**

A: No, you can't have a mix of ephemeral and persistent OS disk instances within the same scale set.

**Q: Can the ephemeral OS disk be created using PowerShell or CLI?**

A: Yes, you can create VMs with Ephemeral OS Disk using REST, Templates, PowerShell, and CLI.

# Azure CLI - Restrict import/export access for managed disks with Private Links

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

You can use [private endpoints](#) to restrict the export and import of managed disks and securely access data over a [Private Link](#) from clients on your Azure virtual network. The private endpoint uses an IP address from the virtual network address space for your managed disks service. Network traffic between clients on their virtual network and managed disks only traverses over the virtual network and a private link on the Microsoft backbone network, eliminating exposure from the public internet.

To use Private Links to export/import managed disks, first you create a disk access resource and link it to a virtual network in the same subscription by creating a private endpoint. Then, associate a disk or a snapshot with an instance of disk access. Finally, set the `NetworkAccessPolicy` property of the disk or the snapshot to `AllowPrivate`. This will limit access to your virtual network.

You can set the `NetworkAccessPolicy` property to `DenyAll` to prevent anybody from exporting data of a disk or a snapshot. The default value for the `NetworkAccessPolicy` property is `AllowAll`.

## Limitations

- Your virtual network must be in the same subscription as your disk access object to link them.
- You cannot import or export more than 10 disks or snapshots at the same time with the same disk access object.
- You cannot request manual approval to link a virtual network to a disk access object.

## Log in into your subscription and set your variables

```
subscriptionId=yourSubscriptionId
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessForPrivateLinks
vnetName=yourVNETForPrivateLinks
subnetName=yourSubnetForPrivateLinks
privateEndPointName=yourPrivateLinkForSecureMDExportImport
privateEndPointConnectionName=yourPrivateLinkConnection

#The name of an existing disk which is the source of the snapshot
sourceDiskName=yourSourceDiskForSnapshot

#The name of the new snapshot which will be secured via Private Links
snapshotNameSecuredWithPL=yourSnapshotNameSecuredWithPL

az login

az account set --subscription $subscriptionId
```

## Create a disk access using Azure CLI

```
az disk-access create -n $diskAccessName -g $resourceGroupName -l $region  
diskAccessId=$(az disk-access show -n $diskAccessName -g $resourceGroupName --query [id] -o tsv)
```

## Create a Virtual Network

Network policies like network security groups (NSG) are not supported for private endpoints. In order to deploy a Private Endpoint on a given subnet, an explicit disable setting is required on that subnet.

```
az network vnet create --resource-group $resourceGroupName \  
--name $vnetName \  
--subnet-name $subnetName
```

## Disable subnet private endpoint policies

Azure deploys resources to a subnet within a virtual network, so you need to update the subnet to disable private endpoint network policies.

```
az network vnet subnet update --resource-group $resourceGroupName \  
--name $subnetName \  
--vnet-name $vnetName \  
--disable-private-endpoint-network-policies true
```

## Create a private endpoint for the disk access object

```
az network private-endpoint create --resource-group $resourceGroupName \  
--name $privateEndPointName \  
--vnet-name $vnetName \  
--subnet $subnetName \  
--private-connection-resource-id $diskAccessId \  
--group-ids disks \  
--connection-name $privateEndPointConnectionName
```

## Configure the Private DNS Zone

Create a Private DNS Zone for Storage blob domain, create an association link with the Virtual Network and create a DNS Zone Group to associate the private endpoint with the Private DNS Zone.

```
az network private-dns zone create --resource-group $resourceGroupName \  
--name "privatelink.blob.core.windows.net"  
  
az network private-dns link vnet create --resource-group $resourceGroupName \  
--zone-name "privatelink.blob.core.windows.net" \  
--name yourDNSLink \  
--virtual-network $vnetName \  
--registration-enabled false  
  
az network private-endpoint dns-zone-group create \  
--resource-group $resourceGroupName \  
--endpoint-name $privateEndPointName \  
--name yourZoneGroup \  
--private-dns-zone "privatelink.blob.core.windows.net" \  
--zone-name disks
```

## Create a disk protected with Private Links

```
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessName
diskName=yourDiskName
diskSkuName=Standard_LRS
diskSizeGB=128

diskAccessId=$(az resource show -n $diskAccessName -g $resourceGroupName --namespace Microsoft.Compute --
resource-type diskAccesses --query [id] -o tsv)

az disk create -n $diskName \
-g $resourceGroupName \
-l $region \
--size-gb $diskSizeGB \
--sku $diskSkuName \
--network-access-policy AllowPrivate \
--disk-access $diskAccessId
```

## Create a snapshot of a disk protected with Private Links

```
resourceGroupName=yourResourceGroupName
region=northcentralus
diskAccessName=yourDiskAccessName
sourceDiskName=yourSourceDiskForSnapshot
snapshotNameSecuredWithPL=yourSnapshotName

diskId=$(az disk show -n $sourceDiskName -g $resourceGroupName --query [id] -o tsv)

diskAccessId=$(az resource show -n $diskAccessName -g $resourceGroupName --namespace Microsoft.Compute --
resource-type diskAccesses --query [id] -o tsv)

az snapshot create -n $snapshotNameSecuredWithPL \
-g $resourceGroupName \
-l $region \
--source $diskId \
--network-access-policy AllowPrivate \
--disk-access $diskAccessId
```

## Next steps

- Upload a VHD to Azure or copy a managed disk to another region - [Azure CLI](#) or [Azure PowerShell module](#)
- Download a VHD - [Windows](#) or [Linux](#)
- [FAQ on Private Links](#)
- [Export/Copy managed snapshots as VHD to a storage account in different region with CLI](#)

# Restrict import/export access for managed disks using Azure Private Link

9/21/2022 • 2 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets ✓ Uniform scale sets

You can use [private endpoints](#) to restrict the export and import of managed disks and more securely access data over a [private link](#) from clients on your Azure virtual network. The private endpoint uses an IP address from the virtual network address space for your managed disks. Network traffic between clients on their virtual network and managed disks only traverses over the virtual network and a private link on the Microsoft backbone network, eliminating exposure from the public internet.

To use Private Link to export and import managed disks, first you create a disk access resource and link it to a virtual network in the same subscription by creating a private endpoint. Then, associate a disk or a snapshot with a disk access instance.

## Limitations

- Your virtual network must be in the same subscription as your disk access object to link them.
- You cannot import or export more than 10 disks or snapshots at the same time with the same disk access object.
- You cannot request manual approval to link a virtual network to a disk access object.

## Create a disk access resource

1. Sign in to the Azure portal and navigate to **Disk Accesses** with [this link](#).

### IMPORTANT

You must use the [provided link](#) to navigate to the Disk Accesses pane. It is not currently visible in the public portal without using the link.

2. Select **+ Create** to create a new disk access resource.
3. On the **Create a disk access** pane, select your subscription and a resource group. Under **Instance details**, enter a name and select a region.

## Create a disk access ...

Basics Tags Review + create

Private links provide protection from a SAS URI being available to anyone by locking down the access to a specific virtual network. This private "tunnel" gives users the security they need when sensitive data is contained on the disks or snapshots.

[Learn more](#)

<a href="#">+ Add</a>				

4. Select **Review + create**.

5. When your resource has been created, navigate directly to it.

[Go to resource](#)

## Create a private endpoint

Next, you'll need to create a private endpoint and configure it for disk access.

1. From your disk access resource, under **Settings**, select **Private endpoint connections**.

2. Select **+ Private endpoint**.

The screenshot shows the Azure portal interface for managing private endpoint connections for a disk access resource named 'example-disk-access-name'. The top navigation bar includes 'Disk Access' and 'Private endpoint connections'. The left sidebar lists 'Overview', 'Activity log', 'Access control (IAM)', 'Tags', 'Settings', 'Associated resources', 'Private endpoint connections' (which is highlighted with a red box), and 'Properties'. The main content area features a search bar, filter options for 'Filter by name...' and 'All connection states', and a table with columns for 'Connection name' and 'Connection state'. A message at the bottom states 'No results'.

3. In the **Create a private endpoint** pane, select a resource group.

- Provide a name and select the same region in which your disk access resource was created.

## Create a private endpoint

**1 Basics**   **2 Resource**   **3 Configuration**   **4 Tags**   **5 Review + create**

Use private endpoints to privately connect to a service or resource. Your private endpoint must be in the same region as your virtual network, but can be in a different region from the private link resource that you are connecting to. [Learn more](#)

# Upload a VHD to Azure or copy a managed disk to another region - Azure PowerShell

9/21/2022 • 8 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

This article explains how to either upload a VHD from your local machine to an Azure managed disk or copy a managed disk to another region, using the Azure PowerShell module. The process of uploading a managed disk, also known as direct upload, enables you to upload a VHD up to 32 TiB in size directly into a managed disk. Currently, direct upload is supported for standard HDD, standard SSD, and premium SSDs. It isn't supported for ultra disks, yet.

If you're providing a backup solution for IaaS VMs in Azure, you should use direct upload to restore customer backups to managed disks. When uploading a VHD from a source external to Azure, speeds depend on your local bandwidth. When uploading or copying from an Azure VM, your bandwidth would be the same as standard HDDs.

## Secure uploads with Azure AD (preview)

If you're using [Azure Active Directory \(Azure AD\)](#) to control resource access, you can now use it to restrict uploading of Azure managed disks. This feature is currently in preview. When a user attempts to upload a disk, Azure validates the identity of the requesting user in Azure AD, and confirms that user has the required permissions. At a higher level, a system administrator could set a policy at the Azure account or subscription level to ensure that an Azure AD identity has the necessary permissions for uploading before allowing a disk or a disk snapshot to be uploaded. If you have any questions on securing uploads with Azure AD, reach out to this email: [azuredisks@microsoft.com](mailto:azuredisks@microsoft.com)

### Prerequisites

- Install the latest [Azure PowerShell module](#).
- You must enable the preview on your subscription, use the following command to enable the preview:

```
Register-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

It may take some time for the feature registration to complete, you can confirm if it has with the following command:

```
Get-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

### Restrictions

- VHDs can't be uploaded to empty snapshots.

### Assign RBAC role

To access managed disks secured with Azure AD, the requesting user must have either the [Data Operator for Managed Disks](#) role, or a [custom role](#) with the following permissions:

- Microsoft.Compute/disks/download/action
- Microsoft.Compute/disks/upload/action

- Microsoft.Compute/snapshots/download/action
- Microsoft.Compute/snapshots/upload/action

For detailed steps on assigning a role, see [Assign Azure roles using Azure PowerShell](#). To create or update a custom role, see [Create or update Azure custom roles using Azure PowerShell](#).

## Get started

There are two ways you can upload a VHD with the Azure PowerShell module: You can either use the [Add-AzVHD](#) command, which will automate most of the process for you, or you can perform the upload manually with AzCopy.

Generally, you should use [Add-AzVHD](#). However, if you need to upload a VHD that is larger than 50 GiB, consider [uploading the VHD manually with AzCopy](#). VHDs 50 GiB and larger upload faster using AzCopy.

For guidance on how to copy a managed disk from one region to another, see [Copy a managed disk](#).

## Use Add-AzVHD

### Prerequisites

- [Install the Azure PowerShell module](#).
- A VHD [has been prepared for Azure](#), stored locally.
  - On Windows: You don't need to convert your VHD to VHDx, convert it a fixed size, or resize it to include the 512-byte offset. `Add-AzVhd` performs these functions for you.
  - [Hyper-V](#) must be enabled for Add-AzVHD to perform these functions.
- On Linux: You must perform these actions manually. See [Resizing VHDs](#) for details.

### Upload a VHD

#### (Optional) Grant access to the disk

If Azure AD is used to enforce upload restrictions on a subscription or at the account level, [Add-AzVHD](#) only succeeds if attempted by a user that has the [appropriate RBAC role or necessary permissions](#). You'll need to [assign RBAC permissions](#) to grant access to the disk and generate a writeable SAS.

```
New-AzRoleAssignment -SignInName <emailOrUserprincipalname> `  
-RoleDefinitionName "Data Operator for Managed Disks" `  
-Scope /subscriptions/<subscriptionId>
```

### Use Add-AzVHD

The following example uploads a VHD from your local machine to a new Azure managed disk using [Add-AzVHD](#). Replace `<your-filepath-here>`, `<your-resource-group-name>`, `<desired-region>`, and `<desired-managed-disk-name>` with your parameters:

#### NOTE

If you're using Azure AD to enforce upload restrictions, add `DataAccessAuthMode 'AzureActiveDirectory'` to the end of your `Add-AzVhd` command.

```

# Required parameters
$path = <your-filepath-here>.vhf
$resourceGroup = <your-resource-group-name>
$location = <desired-region>
$name = <desired-managed-disk-name>

# Optional parameters
# $Zone = <desired-zone>
# $sku=<desired-SKU>
# -DataAccessAuthMode 'AzureActiveDirectory'

# To use $Zone or #sku, add -Zone or -DiskSKU parameters to the command
Add-AzVhd -LocalFilePath $path -ResourceGroupName $resourceGroup -Location $location -DiskName $name

```

## Manual upload

### Prerequisites

- Download the latest [version of AzCopy v10](#).
- [Install the Azure PowerShell module](#).
- A fixed size VHD that [has been prepared for Azure](#), stored locally.

To upload your VHD to Azure, you'll need to create an empty managed disk that is configured for this upload process. Before you create one, there's some additional information you should know about these disks.

This kind of managed disk has two unique states:

- ReadyToUpload, which means the disk is ready to receive an upload but, no [secure access signature](#) (SAS) has been generated.
- ActiveUpload, which means that the disk is ready to receive an upload and the SAS has been generated.

#### NOTE

While in either of these states, the managed disk will be billed at [standard HDD pricing](#), regardless of the actual type of disk. For example, a P10 will be billed as an S10. This will be true until `revoke-access` is called on the managed disk, which is required in order to attach the disk to a VM.

### Create an empty managed disk

Before you can create an empty standard HDD for uploading, you'll need the file size of the VHD you want to upload, in bytes. The example code will get that for you but, to do it yourself you can use:

`$vhdSizeBytes = (Get-Item "<fullFilePathHere>").length`. This value is used when specifying the -

**UploadSizeInBytes** parameter.

Now, on your local shell, create an empty standard HDD for uploading by specifying the **Upload** setting in the -**CreateOption** parameter as well as the **-UploadSizeInBytes** parameter in the [New-AzDiskConfig](#) cmdlet. Then call [New-AzDisk](#) to create the disk.

Replace `<yourdiskname>`, `<yourresourcegroupname>`, and `<yourregion>` then run the following commands:

#### TIP

If you're creating an OS disk, add `-HyperVGeneration '<yourGeneration>'` to `New-AzDiskConfig`.

If you're using Azure AD to secure your uploads, add `-DataAccessAuthMode 'AzureActiveDirectory'` to `New-AzDiskConfig`.

```

$vhdSizeBytes = (Get-Item "<fullFilePathHere>").length

$diskconfig = New-AzDiskConfig -SkuName 'Standard_LRS' -OsType 'Windows' -UploadSizeInBytes $vhdSizeBytes -
Location '<yourregion>' -CreateOption 'Upload'

New-AzDisk -ResourceGroupName '<yourresourcegroupname>' -DiskName '<yourdiskname>' -Disk $diskconfig

```

If you would like to upload either a premium SSD or a standard SSD, replace **Standard\_LRS** with either **Premium\_LRS** or **StandardSSD\_LRS**. Ultra disks aren't currently supported.

### Generate writeable SAS

Now that you've created an empty managed disk that is configured for the upload process, you can upload a VHD to it. To upload a VHD to the disk, you'll need a writeable SAS, so that you can reference it as the destination for your upload.

To generate a writable SAS of your empty managed disk, replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following commands:

```

$diskSas = Grant-AzDiskAccess -ResourceGroupName '<yourresourcegroupname>' -DiskName '<yourdiskname>' -
DurationInSecond 86400 -Access 'Write'

$disk = Get-AzDisk -ResourceGroupName '<yourresourcegroupname>' -DiskName '<yourdiskname>'

```

### Upload a VHD

Now that you have a SAS for your empty managed disk, you can use it to set your managed disk as the destination for your upload command.

Use AzCopy v10 to upload your local VHD file to a managed disk by specifying the SAS URI you generated.

This upload has the same throughput as the equivalent [standard HDD](#). For example, if you have a size that equates to S4, you will have a throughput of up to 60 MiB/s. But, if you have a size that equates to S70, you will have a throughput of up to 500 MiB/s.

```
AzCopy.exe copy "c:\somewhere\mydisk.vhd" $diskSas.AccessSAS --blob-type PageBlob
```

After the upload is complete, and you no longer need to write any more data to the disk, revoke the SAS. Revoking the SAS will change the state of the managed disk and allow you to attach the disk to a VM.

Replace `<yourdiskname>` and `<yourresourcegroupname>`, then run the following command:

```
Revoke-AzDiskAccess -ResourceGroupName '<yourresourcegroupname>' -DiskName '<yourdiskname>'
```

### Copy a managed disk

Direct upload also simplifies the process of copying a managed disk. You can either copy within the same region or copy your managed disk to another region.

The following script will do this for you, the process is similar to the steps described earlier, with some differences, since you're working with an existing disk.

## IMPORTANT

You must add an offset of 512 when you're providing the disk size in bytes of a managed disk from Azure. This is because Azure omits the footer when returning the disk size. The copy will fail if you don't do this. The following script already does this for you.

Replace the `<sourceResourceGroupHere>`, `<sourceDiskNameHere>`, `<targetDiskNameHere>`, `<targetResourceGroupHere>`, `<yourOSTypeHere>` and `<yourTargetLocationHere>` (an example of a location value would be uswest2) with your values, then run the following script in order to copy a managed disk.

## TIP

If you are creating an OS disk, add `-HyperVGeneration '<yourGeneration>'` to `New-AzDiskConfig`.

```
$sourceRG = <sourceResourceGroupHere>
$sourceDiskName = <sourceDiskNameHere>
$targetDiskName = <targetDiskNameHere>
$targetRG = <targetResourceGroupHere>
$targetLocate = <yourTargetLocationHere>
#Expected value for OS is either "Windows" or "Linux"
$targetOS = <yourOSTypeHere>

$sourceDisk = Get-AzDisk -ResourceGroupName $sourceRG -DiskName $sourceDiskName

# Adding the sizeInBytes with the 512 offset, and the -Upload flag
$targetDiskconfig = New-AzDiskConfig -SkuName 'Standard_LRS' -osType $targetOS -UploadSizeInBytes
$(($sourceDisk.DiskSizeBytes+512)) -Location $targetLocate -CreateOption 'Upload'

$targetDisk = New-AzDisk -ResourceGroupName $targetRG -DiskName $targetDiskName -Disk $targetDiskconfig

$sourceDiskSas = Grant-AzDiskAccess -ResourceGroupName $sourceRG -DiskName $sourceDiskName -DurationInSecond
86400 -Access 'Read'

$targetDiskSas = Grant-AzDiskAccess -ResourceGroupName $targetRG -DiskName $targetDiskName -DurationInSecond
86400 -Access 'Write'

azcopy copy $sourceDiskSas.AccessSAS $targetDiskSas.AccessSAS --blob-type PageBlob

Revoke-AzDiskAccess -ResourceGroupName $sourceRG -DiskName $sourceDiskName

Revoke-AzDiskAccess -ResourceGroupName $targetRG -DiskName $targetDiskName
```

## Next steps

Now that you've successfully uploaded a VHD to a managed disk, you can attach your disk to a VM and begin using it.

To learn how to attach a data disk to a VM, see our article on the subject: [Attach a data disk to a Windows VM with PowerShell](#). To use the disk as the OS disk, see [Create a Windows VM from a specialized disk](#).

# Upload a VHD to Azure or copy a managed disk to another region - Azure CLI

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Windows VMs ✓ Flexible scale sets

This article explains how to either upload a VHD from your local machine to an Azure managed disk or copy a managed disk to another region, using AzCopy. This process, direct upload, enables you to upload a VHD up to 32 TiB in size directly into a managed disk. Currently, direct upload is supported for standard HDD, standard SSD, and premium SSD managed disks. It isn't supported for ultra disks, yet.

If you're providing a backup solution for IaaS VMs in Azure, you should use direct upload to restore customer backups to managed disks. When uploading a VHD from a source external to Azure, speeds depend on your local bandwidth. When uploading or copying from an Azure VM, your bandwidth would be the same as standard HDDs.

## Secure uploads with Azure AD (preview)

If you're using [Azure Active Directory \(Azure AD\)](#) to control resource access, you can now use it to restrict uploading of Azure managed disks. This feature is currently in preview. When a user attempts to upload a disk, Azure validates the identity of the requesting user in Azure AD, and confirms that user has the required permissions. At a higher level, a system administrator could set a policy at the Azure account or subscription level, to ensure that an Azure AD identity has the necessary permissions for uploading before allowing a disk or a disk snapshot to be uploaded. If you have any questions on securing uploads with Azure AD, reach out to this email: [azuredisks@microsoft.com](mailto:azuredisks@microsoft.com)

### Prerequisites

- [Install the Azure CLI](#).
- Use the following command to enable the preview on your subscription:

```
az feature register --name AllowAADAuthForDataAccess --namespace Microsoft.Compute
```

It may take some time for the feature registration to complete, you can confirm if it has with the following command:

```
az feature show --name AllowAADAuthForDataAccess --namespace Microsoft.Compute --output table
```

### Restrictions

- VHDs can't be uploaded to empty snapshots.

### Assign RBAC role

To access managed disks secured with Azure AD, the requesting user must have either the [Data Operator for Managed Disks](#) role, or a [custom role](#) with the following permissions:

- `Microsoft.Compute/disks/download/action`
- `Microsoft.Compute/disks/upload/action`
- `Microsoft.Compute/snapshots/download/action`
- `Microsoft.Compute/snapshots/upload/action`

For detailed steps on assigning a role, see [Assign Azure roles using Azure CLI](#). To create or update a custom role, see [Create or update Azure custom roles using Azure CLI](#).

## Get started

If you'd prefer to upload disks through a GUI, you can do so using Azure Storage Explorer. For details refer to: [Use Azure Storage Explorer to manage Azure managed disks](#)

### Prerequisites

- Download the latest [version of AzCopy v10](#).
- [Install the Azure CLI](#).
- If you intend to upload a VHD from on-premises: A fixed size VHD that [has been prepared for Azure](#), stored locally.
- Or, a managed disk in Azure, if you intend to perform a copy action.

To upload your VHD to Azure, you'll need to create an empty managed disk that is configured for this upload process. Before you create one, there's some additional information you should know about these disks.

This kind of managed disk has two unique states:

- ReadToUpload, which means the disk is ready to receive an upload but, no [secure access signature](#) (SAS) has been generated.
- ActiveUpload, which means that the disk is ready to receive an upload and the SAS has been generated.

#### NOTE

While in either of these states, the managed disk will be billed at [standard HDD pricing](#), regardless of the actual type of disk. For example, a P10 will be billed as an S10. This will be true until `revoke-access` is called on the managed disk, which is required in order to attach the disk to a VM.

## Create an empty managed disk

Before you can create an empty standard HDD for uploading, you'll need the file size of the VHD you want to upload, in bytes. To get that, you can use either `wc -c <yourFileName>.vhf` or `ls -al <yourFileName>.vhf`. This value is used when specifying the `--upload-size-bytes` parameter.

Create an empty standard HDD for uploading by specifying both the `--for-upload` parameter and the `--upload-size-bytes` parameter in a [disk create cmdlet](#):

Replace `<yourdiskname>`, `<yourresourcegroupname>`, `<yourregion>` with values of your choosing. The `--upload-size-bytes` parameter contains an example value of `34359738880`, replace it with a value appropriate for you.

#### TIP

If you're creating an OS disk, add `--hyper-v-generation <yourGeneration>` to `az disk create`.

If you're using Azure AD to secure disk uploads, add `-dataAccessAuthmode 'AzureActiveDirectory'`.

```
az disk create -n <yourdiskname> -g <yourresourcegroupname> -l <yourregion> --os-type Linux --for-upload --upload-size-bytes 34359738880 --sku standard_lrs
```

If you would like to upload either a premium SSD or a standard SSD, replace `standard_lrs` with either

`premium_LRS` or `standardssd_lrs`. Ultra disks are not supported for now.

### (Optional) Grant access to the disk

If you're using Azure AD to secure uploads, you'll need to [assign RBAC permissions](#) to grant access to the disk and generate a writeable SAS.

```
az role assignment create --assignee "{assignee}" \
--role "{Data Operator for Managed Disks}" \
--scope
"/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/{providerName}/{resourceType}/
{resourceSubType}/{diskName}"
```

### Generate writeable SAS

Now that you've created an empty managed disk that is configured for the upload process, you can upload a VHD to it. To upload a VHD to the disk, you'll need a writeable SAS, so that you can reference it as the destination for your upload.

To generate a writable SAS of your empty managed disk, replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following command:

```
az disk grant-access -n <yourdiskname> -g <yourresourcegroupname> --access-level Write --duration-in-seconds
86400
```

Sample returned value:

```
{
  "accessSas": "https://md-impexp-t0rdsfgsdfg4.blob.core.windows.net/w2c3mj0ksfg1/abcd?sv=2017-04-
17&sr=b&si=600a9281-d39e-4cc3-91d2-923c4a696537&sig=xTaT6mFgf139ycT87CADyFxb%2BnPXBElYirYRlbnJZbs%3D"
}
```

## Upload a VHD

Now that you have a SAS for your empty managed disk, you can use it to set your managed disk as the destination for your upload command.

Use AzCopy v10 to upload your local VHD file to a managed disk by specifying the SAS URI you generated.

This upload has the same throughput as the equivalent [standard HDD](#). For example, if you have a size that equates to S4, you will have a throughput of up to 60 MiB/s. But, if you have a size that equates to S70, you will have a throughput of up to 500 MiB/s.

```
AzCopy.exe copy "c:\somewhere\mydisk.vhd""sas-URI" --blob-type PageBlob
```

After the upload is complete, and you no longer need to write any more data to the disk, revoke the SAS. Revoking the SAS will change the state of the managed disk and allow you to attach the disk to a VM.

Replace `<yourdiskname>` and `<yourresourcegroupname>`, then use the following command to make the disk usable:

```
az disk revoke-access -n <yourdiskname> -g <yourresourcegroupname>
```

## Copy a managed disk

Direct upload also simplifies the process of copying a managed disk. You can either copy within the same region

or cross-region (to another region).

The following script will do this for you, the process is similar to the steps described earlier, with some differences since you're working with an existing disk.

#### IMPORTANT

You need to add an offset of 512 when you're providing the disk size in bytes of a managed disk from Azure. This is because Azure omits the footer when returning the disk size. The copy will fail if you don't do this. The following script already does this for you.

Replace the `<sourceResourceGroupHere>`, `<sourceDiskNameHere>`, `<targetDiskNameHere>`, `<targetResourceGroupHere>`, and `<yourTargetLocationHere>` (an example of a location value would be `uswest2`) with your values, then run the following script in order to copy a managed disk.

#### TIP

If you are creating an OS disk, add `--hyper-v-generation <yourGeneration>` to `az disk create`.

```
sourceDiskName=<sourceDiskNameHere>
sourceRG=<sourceResourceGroupHere>
targetDiskName=<targetDiskNameHere>
targetRG=<targetResourceGroupHere>
targetLocation=<yourTargetLocationHere>
#Expected value for OS is either "Windows" or "Linux"
targetOS=<yourOSTypeHere>

sourceDiskSizeBytes=$(az disk show -g $sourceRG -n $sourceDiskName --query '[diskSizeBytes]' -o tsv)

az disk create -g $targetRG -n $targetDiskName -l $targetLocation --os-type $targetOS --for-upload --upload-size-bytes $($sourceDiskSizeBytes+512) --sku standard_lrs

targetSASURI=$(az disk grant-access -n $targetDiskName -g $targetRG --access-level Write --duration-in-seconds 86400 -o tsv)

sourceSASURI=$(az disk grant-access -n $sourceDiskName -g $sourceRG --duration-in-seconds 86400 --query [accessSas] -o tsv)

azcopy copy $sourceSASURI $targetSASURI --blob-type PageBlob

az disk revoke-access -n $sourceDiskName -g $sourceRG

az disk revoke-access -n $targetDiskName -g $targetRG
```

## Next steps

Now that you've successfully uploaded a VHD to a managed disk, you can attach the disk as a [data disk to an existing VM](#) or [attach the disk to a VM as an OS disk](#), to create a new VM.

# Download a Linux VHD from Azure

9/21/2022 • 5 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

In this article, you learn how to download a Linux virtual hard disk (VHD) file from Azure using the Azure portal.

## Stop the VM

A VHD can't be downloaded from Azure if it's attached to a running VM. If you want to keep the VM running, you can [create a snapshot and then download the snapshot](#).

To stop the VM:

1. Sign in to the [Azure portal](#).
2. On the left menu, select **Virtual Machines**.
3. Select the VM from the list.
4. On the page for the VM, select **Stop**.

### Alternative: Snapshot the VM disk

Take a snapshot of the disk to download.

1. Select the VM in the [portal](#).
2. Select **Disk** in the left menu and then select the disk you want to snapshot. The details of the disk will be displayed.
3. Select **Create Snapshot** from the menu at the top of the page. The **Create snapshot** page will open.
4. In **Name**, type a name for the snapshot.
5. For **Snapshot type**, select **Full** or **Incremental**.
6. When you are done, select **Review + create**.

Your snapshot will be created shortly, and can then be used to download or create another VM.

#### NOTE

If you don't stop the VM first, the snapshot will not be clean. The snapshot will be in the same state as if the VM had been power cycled or crashed at the point in time when the snapshot was made. While usually safe, it could cause problems if the running applications running at the time were not crash resistant.

This method is only recommended for VMs with a single OS disk. VMs with one or more data disks should be stopped before download or before creating a snapshot for the OS disk and each data disk.

## Secure downloads and uploads with Azure AD (preview)

If you're using [Azure Active Directory \(Azure AD\)](#) to control resource access, you can now use it to restrict uploads and downloads of Azure managed disks. This feature is currently in preview. When a user attempts to upload or download a disk, Azure validates the identity of the requesting user in Azure AD, and confirms that user has the required permissions. At a higher level, a system administrator could set a policy at the Azure

account or subscription level, to ensure that all disks and snapshots must use Azure AD for uploads or downloads. If you have any questions on securing uploads or downloads with Azure AD, reach out to this email: [azuredisks@microsoft.com](mailto:azuredisks@microsoft.com)

## Restrictions

- VHDs can't be uploaded to empty snapshots.
- To download a VHD that is using Azure AD to restrict access, you must access the Azure portal from this link: <https://aka.ms/dataAccessAuthenticationMode>

## Prerequisites

- Install the latest [Azure PowerShell module](#).
- You must enable the preview on your subscription, use the following command to enable the preview:

```
Register-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

It may take some time for the feature registration to complete, you can confirm if it has with the following command:

```
Get-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

## Assign RBAC role

To access managed disks secured with Azure AD, the requesting user must have either the [Data Operator for Managed Disks](#) role, or a [custom role](#) with the following permissions:

- Microsoft.Compute/disks/download/action
- Microsoft.Compute/disks/upload/action
- Microsoft.Compute/snapshots/download/action
- Microsoft.Compute/snapshots/upload/action

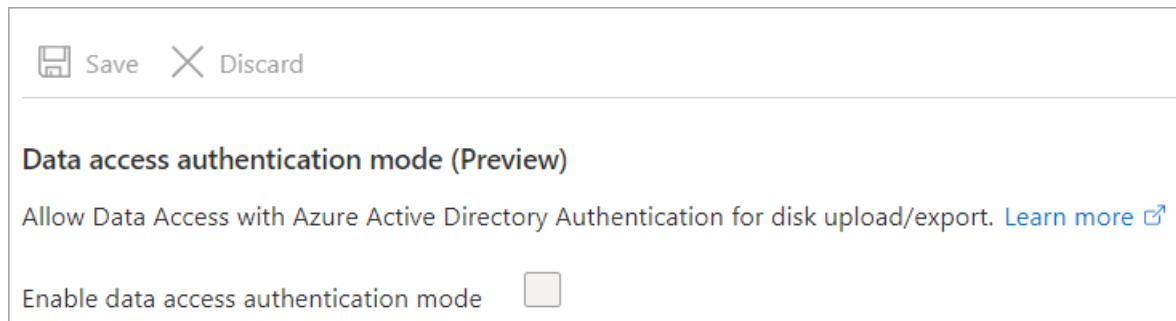

For detailed steps on assigning a role, see the following articles for [portal](#), [PowerShell](#), or [CLI](#). To create or update a custom role, see the following articles for [portal](#), [PowerShell](#), or [CLI](#).

## Enable data access authentication mode

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

Enable **data access authentication mode** to restrict access to the disk. You can either enable it when creating the disk, or you can enable it on the **Disk Export** page for existing disks. In order to enable **data access authentication mode** you must access the Azure portal from the following link:

<https://aka.ms/dataAccessAuthenticationMode>

## Generate SAS URL

To download the VHD file, you need to generate a [shared access signature \(SAS\)](#) URL. When the URL is generated, an expiration time is assigned to the URL.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. On the menu of the page for the VM, select **Disks**.
2. Select the operating system disk for the VM, and then select **Disk Export**.
3. If required, update the value of **URL expires in (seconds)** to give you enough time to complete the download. The default is 3600 seconds (one hour).
4. Select **Generate URL**.

## Download VHD

### NOTE

If you're using Azure AD to secure managed disk downloads, the user downloading the VHD must have the appropriate [RBAC permissions](#).

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Under the URL that was generated, select **Download the VHD file**.

The following URL can be used to download the VHD file for this disk. Copy it and keep it secure, it will not be shown again.

<https://md-sm1xb0fsrmql.blob.core.windows.net/1sv2pbtcgcqz/abcd?sv=2017-04-17&sr=b&si=1c73f2e3-09bc-45ac-a4c1-7d0bb2...> 

[Download the VHD file](#)

A SAS URL has been generated for this disk for export. While in this state, it can't be edited or attached to a running virtual machine. You can cancel the export by clicking the button below. This will revoke the SAS URL, and may cancel any in-progress transfers if the disk is currently being downloaded to another location.

[Cancel export](#)

2. You may need to select **Save** in the browser to start the download. The default name for the VHD file is *abcd*.

## Next steps

- Learn how to [upload and create a Linux VM from custom disk with the Azure CLI](#).
- [Manage Azure disks the Azure CLI](#).

# Download a Windows VHD from Azure

9/21/2022 • 6 minutes to read • [Edit Online](#)

Applies to: ✓ Windows VMs

In this article, you learn how to download a Windows virtual hard disk (VHD) file from Azure using the Azure portal.

## Optional: Generalize the VM

If you want to use the VHD as an [image](#) to create other VMs, you should use [Sysprep](#) to generalize the operating system. Otherwise, you will have to make a copy of the disk for each VM you want to create.

To use the VHD as an image to create other VMs, generalize the VM.

1. If you haven't already done so, sign in to the [Azure portal](#).
2. [Connect to the VM](#).
3. On the VM, open the Command Prompt window as an administrator.
4. Change the directory to `%windir%\system32\sysprep` and run `sysprep.exe`.
5. In the System Preparation Tool dialog box, select **Enter System Out-of-Box Experience (OOBE)**, and make sure that **Generalize** is selected.
6. In Shutdown Options, select **Shutdown**, and then click **OK**.

If you don't want to generalize your current VM, you can still create a generalized image by first [making a snapshot of the OS disk](#), creating a new VM from the snapshot, and then generalizing the copy.

## Stop the VM

A VHD can't be downloaded from Azure if it's attached to a running VM. If you want to keep the VM running, you can [create a snapshot and then download the snapshot](#).

1. On the Hub menu in the Azure portal, click **Virtual Machines**.
2. Select the VM from the list.
3. On the blade for the VM, click **Stop**.

## Alternative: Snapshot the VM disk

Take a snapshot of the disk to download.

1. Select the VM in the [portal](#).
2. Select **Disk** in the left menu and then select the disk you want to snapshot. The details of the disk will be displayed.
3. Select **Create Snapshot** from the menu at the top of the page. The **Create snapshot** page will open.
4. In **Name**, type a name for the snapshot.
5. For **Snapshot type**, select **Full** or **Incremental**.
6. When you are done, select **Review + create**.

Your snapshot will be created shortly, and can then be used to download or create another VM.

#### **NOTE**

If you don't stop the VM first, the snapshot will not be clean. The snapshot will be in the same state as if the VM had been power cycled or crashed at the point in time when the snapshot was made. While usually safe, it could cause problems if the running applications running at the time were not crash resistant.

This method is only recommended for VMs with a single OS disk. VMs with one or more data disks should be stopped before download or before creating a snapshot for the OS disk and each data disk.

## Secure downloads and uploads with Azure AD (preview)

If you're using [Azure Active Directory \(Azure AD\)](#) to control resource access, you can now use it to restrict uploads and downloads of Azure managed disks. This feature is currently in preview. When a user attempts to upload or download a disk, Azure validates the identity of the requesting user in Azure AD, and confirms that user has the required permissions. At a higher level, a system administrator could set a policy at the Azure account or subscription level, to ensure that all disks and snapshots must use Azure AD for uploads or downloads. If you have any questions on securing uploads or downloads with Azure AD, reach out to this email: [azuredisks@microsoft.com](mailto:azuredisks@microsoft.com)

#### **Restrictions**

- VHDS can't be uploaded to empty snapshots.
- To download a VHD that is using Azure AD to restrict access, you must access the Azure portal from this link: <https://aka.ms/dataAccessAuthenticationMode>

#### **Prerequisites**

- Install the latest [Azure PowerShell module](#).
- You must enable the preview on your subscription, use the following command to enable the preview:

```
Register-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

It may take some time for the feature registration to complete, you can confirm if it has with the following command:

```
Get-AzProviderFeature -FeatureName "AllowAADAuthForDataAccess" -ProviderNamespace "Microsoft.Compute"
```

#### **Assign RBAC role**

To access managed disks secured with Azure AD, the requesting user must have either the [Data Operator for Managed Disks](#) role, or a [custom role](#) with the following permissions:

- Microsoft.Compute/disks/download/action
- Microsoft.Compute/disks/upload/action
- Microsoft.Compute/snapshots/download/action
- Microsoft.Compute/snapshots/upload/action

For detailed steps on assigning a role, see the following articles for [portal](#), [PowerShell](#), or [CLI](#). To create or update a custom role, see the following articles for [portal](#), [PowerShell](#), or [CLI](#).

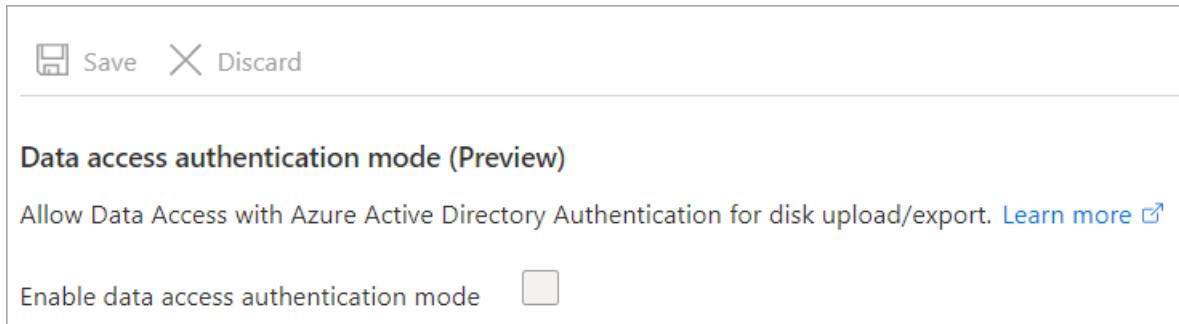

#### **Enable data access authentication mode**

- [Portal](#)
- [PowerShell](#)

- [Azure CLI](#)

Enable **data access authentication mode** to restrict access to the disk. You can either enable it when creating the disk, or you can enable it on the **Disk Export** page for existing disks. In order to enable **data access authentication mode** you must access the Azure portal from the following link:

<https://aka.ms/dataAccessAuthenticationMode>

## Generate download URL

To download the VHD file, you need to generate a [shared access signature \(SAS\)](#) URL. When the URL is generated, an expiration time is assigned to the URL.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. On the page for the VM, click **Disks** in the left menu.
2. Select the operating system disk for the VM.
3. On the page for the disk, select **Disk Export** from the left menu.
4. The default expiration time of the URL is 3600 seconds (one hour). You may need to increase this for Windows OS disks or large data disks. 36000 seconds (10 hours) is usually sufficient.
5. Click **Generate URL**.

### NOTE

The expiration time is increased from the default to provide enough time to download the large VHD file for a Windows Server operating system. Large VHDs can take up to several hours to download depending on your connection and the size of the VM.

## Download VHD

### NOTE

If you're using Azure AD to secure managed disk downloads, the user downloading the VHD must have the appropriate RBAC permissions.

- [Portal](#)
- [PowerShell](#)
- [Azure CLI](#)

1. Under the URL that was generated, click Download the VHD file.
2. You may need to click **Save** in your browser to start the download. The default name for the VHD file is *abcd.vhd*.

## Next steps

- Learn how to upload a VHD file to Azure.
- [Create managed disks from unmanaged disks in a storage account](#).
- [Manage Azure disks with PowerShell](#).

# Convert Azure managed disks storage from Standard to Premium or Premium to Standard

9/21/2022 • 3 minutes to read • [Edit Online](#)

Applies to: ✓ Linux VMs ✓ Flexible scale sets

There are four disk types of Azure managed disks: Azure ultra disks, premium SSD, standard SSD, and standard HDD. You can switch between premium SSD, standard SSD, and standard HDD based on your performance needs. You are not yet able to switch from or to an ultra disk, you must deploy a new one.

This functionality is not supported for unmanaged disks. But you can easily [convert an unmanaged disk to a managed disk](#) to be able to switch between disk types.

This article shows how to convert managed disks from one disk type to another by using the Azure CLI. To install or upgrade the tool, see [Install Azure CLI](#).

## Before you begin

- Disk conversion requires a restart of the virtual machine (VM), so schedule the migration of your disk storage during a pre-existing maintenance window.
- For unmanaged disks, first [convert to managed disks](#) so you can switch between storage options.

## Switch all managed disks of a VM between from one account to another

This example shows how to convert all of a VM's disks to premium storage. However, by changing the sku variable in this example, you can convert the VM's disks type to standard SSD or standard HDD. Please note that To use Premium managed disks, your VM must use a [VM size](#) that supports Premium storage. This example also switches to a size that supports Premium storage.

```

#resource group that contains the virtual machine
rgName='yourResourceGroup'

#Name of the virtual machine
vmName='yourVM'

#Premium capable size
#Required only if converting from Standard to Premium
size='Standard_DS2_v2'

#Choose between Standard_LRS, StandardSSD_LRS and Premium_LRS based on your scenario
sku='Premium_LRS'

#Deallocate the VM before changing the size of the VM
az vm deallocate --name $vmName --resource-group $rgName

#Change the VM size to a size that supports Premium storage
#Skip this step if converting storage from Premium to Standard
az vm resize --resource-group $rgName --name $vmName --size $size

#Update the SKU of all the data disks
az vm show -n $vmName -g $rgName --query storageProfile.dataDisks[*].managedDisk -o tsv \
| awk -v sku=$sku '{system("az disk update --sku \"sku\" --ids \"$1\"")}' 

#Update the SKU of the OS disk
az vm show -n $vmName -g $rgName --query storageProfile.osDisk.managedDisk -o tsv \
| awk -v sku=$sku '{system("az disk update --sku \"sku\" --ids \"$1\"")}' 

az vm start --name $vmName --resource-group $rgName

```

## Switch individual managed disks from one disk type to another

For your dev/test workload, you might want to have a mix of Standard and Premium disks to reduce your costs. You can choose to upgrade only those disks that need better performance. This example shows how to convert a single VM disk from Standard to Premium storage. However, by changing the sku variable in this example, you can convert the VM's disks type to standard SSD or standard HDD. To use Premium managed disks, your VM must use a [VM size](#) that supports Premium storage. This example also switches to a size that supports Premium storage.

```

#resource group that contains the managed disk
rgName='yourResourceGroup'

#Name of your managed disk
diskName='yourManagedDiskName'

#Premium capable size
#Required only if converting from Standard to Premium
size='Standard_DS2_v2'

#Choose between Standard_LRS, StandardSSD_LRS and Premium_LRS based on your scenario
sku='Premium_LRS'

#Get the parent VM Id
vmId=$(az disk show --name $diskName --resource-group $rgName --query managedBy --output tsv)

#Deallocate the VM before changing the size of the VM
az vm deallocate --ids $vmId

#Change the VM size to a size that supports Premium storage
#Skip this step if converting storage from Premium to Standard
az vm resize --ids $vmId --size $size

# Update the SKU
az disk update --sku $sku --name $diskName --resource-group $rgName

az vm start --ids $vmId

```

## Switch managed disks from one disk type to another

Follow these steps:

1. Sign in to the [Azure portal](#).
2. Select the VM from the list of **Virtual machines**.
3. If the VM isn't stopped, select **Stop** at the top of the **VM Overview** pane, and wait for the VM to stop.
4. In the pane for the VM, select **Disk**s from the menu.
5. Select the disk that you want to convert.
6. Select **Configuration** from the menu.
7. Change the **Account type** from the original disk type to the desired disk type.
8. Select **Save**, and close the disk pane.

The update of the disk type is instantaneous. You can restart your VM after the conversion.

## Next steps

Make a read-only copy of a VM by using [snapshots](#).

# Update the storage type of a managed disk
