Suppose you start a long-running app using the command `dotnet run --configuration Release`. In another window, you run the `dotnet-dump ps` command. The output you'll see is as follows. The command-line arguments, if any, are shown in `dotnet-dump` version 6.0.320703 and later.

```
> dotnet-dump ps

21932 dotnet      C:\Program Files\dotnet\dotnet.exe    run --configuration Release
36656 dotnet      C:\Program Files\dotnet\dotnet.exe
```

Using `dotnet-dump`

The first step is to collect a dump. This step can be skipped if a core dump has already been generated. The operating system or the .NET Core runtime's built-in [dump generation feature](#) can each create core dumps.

```
$ dotnet-dump collect --process-id 1902
Writing minidump to file ./core_20190226_135837
Written 98983936 bytes (24166 pages) to core file
Complete
```

Now analyze the core dump with the `analyze` command:

```
$ dotnet-dump analyze ./core_20190226_135850
Loading core dump: ./core_20190226_135850
Ready to process analysis commands. Type 'help' to list available commands or 'help [command]' to get
detailed help on a command.
Type 'quit' or 'exit' to exit the session.
>
```

This action brings up an interactive session that accepts commands like:

```
> clrstack
OS Thread Id: 0x573d (0)
    Child SP          IP Call Site

Special instructions for Docker

If you're running under Docker, dump collection requires `SYS_PTRACE` capabilities (`--cap-add=SYS_PTRACE` or `--privileged`).

On Microsoft .NET SDK Linux Docker images, some `dotnet-dump` commands can throw the following exception:

Unhandled exception: System.DllNotFoundException: Unable to load shared library 'libdl.so' or one of its dependencies' exception.

To work around this problem, install the "libc6-dev" package.

Heap analysis tool (dotnet-gcdump)

9/20/2022 • 4 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-gcdump` version 3.1.57502 and later versions

Install

There are two ways to download and install `dotnet-gcdump`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-gcdump` NuGet package, use the [dotnet tool install](#) command:

```
dotnet tool install --global dotnet-gcdump
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

NOTE

To use `dotnet-gcdump` on an x86 app, you need a corresponding x86 version of the tool.

Synopsis

```
dotnet-gcdump [-h|--help] [--version] <command>
```

Description

The `dotnet-gcdump` global tool collects GC (Garbage Collector) dumps of live .NET processes using [EventPipe](#). GC dumps are created by triggering a GC in the target process, turning on special events, and regenerating the graph of object roots from the event stream. This process allows for GC dumps to be collected while the process is running and with minimal overhead. These dumps are useful for several scenarios:

- Comparing the number of objects on the heap at several points in time.
- Analyzing roots of objects (answering questions like, "what still has a reference to this type?").
- Collecting general statistics about the counts of objects on the heap.

[View the GC dump captured from dotnet-gcdump](#)

On Windows, `.gcdump` files can be viewed in [PerfView](#) for analysis or in Visual Studio. Currently, there is no way of opening a `.gcdump` on non-Windows platforms.

You can collect multiple `.gcdump`s and open them simultaneously in Visual Studio to get a comparison experience.

Options

- `--version`

Displays the version of the `dotnet-gcdump` utility.

- `-h|--help`

Shows command-line help.

Commands

COMMAND

`dotnet-gcdump collect`

`dotnet-gcdump ps`

`dotnet-gcdump report`

`dotnet-gcdump collect`

Collects a GC dump from a currently running process.

WARNING

To walk the GC heap, this command triggers a generation 2 (full) garbage collection, which can suspend the runtime for a long time, especially when the GC heap is large. Don't use this command in performance-sensitive environments when the GC heap is large.

Synopsis

```
dotnet-gcdump collect [-h|--help] [-p|--process-id <pid>] [-o|--output <gcdump-file-path>] [-v|--verbose] [-t|--timeout <timeout>] [-n|--name <name>]
```

Options

- `-h|--help`

Shows command-line help.

- `-p|--process-id <pid>`

The process ID to collect the GC dump from.

- `-o|--output <gcdump-file-path>`

The path where collected GC dumps should be written. Defaults to
`.\YYYYMMDD_HHMMSS_<pid>.gcdump`.

- `-v|--verbose`

Output the log while collecting the GC dump.

- `-t|--timeout <timeout>`

Give up on collecting the GC dump if it takes longer than this many seconds. The default value is 30.

- `-n|--name <name>`

The name of the process to collect the GC dump from.

NOTE

On Linux and macOS, this command expects the target application and `dotnet-gcdump` to share the same `TMPDIR` environment variable. Otherwise, the command will time out.

NOTE

To collect a GC dump using `dotnet-gcdump`, it needs to be run as the same user as the user running target process or as root. Otherwise, the tool will fail to establish a connection with the target process.

`dotnet-gcdump ps`

Lists the dotnet processes that GC dumps can be collected for. `dotnet-gcdump` 6.0.320703 and later, also display the command-line arguments that each process was started with, if available.

Synopsis

```
dotnet-gcdump ps [-h|--help]
```

Example

Suppose you start a long-running app using the command `dotnet run --configuration Release`. In another window, you run the `dotnet-gcdump ps` command. The output you'll see is as follows. The command-line arguments, if any, are shown using `dotnet-gcdump` version 6.0.320703 and later.

```
> dotnet-gcdump ps

 21932 dotnet      C:\Program Files\dotnet\dotnet.exe      run --configuration Release
 36656 dotnet      C:\Program Files\dotnet\dotnet.exe
```

`dotnet-gcdump report <gcdump_filename>`

Generate a report from a previously generated GC dump or from a running process, and write to `stdout`.

Synopsis

```
dotnet-gcdump report [-h|--help] [-p|--process-id <pid>] [-t|--report-type <HeapStat>]
```

Options

- `-h|--help`

Shows command-line help.

- `-p|--process-id <pid>`

The process ID to collect the GC dump from.

- `-t|--report-type <HeapStat>`

The type of report to generate. Available options: heapstat (default).

Troubleshoot

- There is no type information in the gcdump.

Prior to .NET Core 3.1, there was an issue where a type cache was not cleared between gcdumps when they were invoked with EventPipe. This resulted in the events needed for determining type information not being sent for the second and subsequent gcdumps. This was fixed in .NET Core 3.1-preview2.

- COM and static types aren't in the GC dump.

Prior to .NET Core 3.1, there was an issue where static and COM types weren't sent when the GC dump was invoked via EventPipe. This has been fixed in .NET Core 3.1.

- `dotnet-gcdump` is unable to generate a `.gcdump` file due to missing information, for example, [Error] **Exception during gcdump: System.ApplicationException: ETL file shows the start of a heap dump but not its completion..** Or, the `.gcdump` file doesn't include the entire heap.

`dotnet-gcdump` works by collecting a trace of events emitted by the garbage collector during an induced generation 2 collection. If the heap is sufficiently large, or there isn't enough memory to scale the eventing buffers, then the events required to reconstruct the heap graph from the trace may be dropped. In this case, to diagnose issues with the heap, it's recommended to collect a dump of the process.

- `dotnet-gcdump` appears to cause an Out Of Memory issue in a memory constrained environment.

`dotnet-gcdump` works by collecting a trace of events emitted by the garbage collector during an induced generation 2 collection. The buffer for event collection is owned by the target application and can grow up to 256 MB. `dotnet-gcdump` itself also uses memory. If your environment is memory constrained, be sure to account for these factors when collecting a gcdump to prevent errors.

Diagnostic monitoring and collection utility (dotnet-monitor)

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-monitor` version 6.0.0 and later versions

Install

There are two ways to download `dotnet-monitor`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-monitor` NuGet package, use the [dotnet tool install](#) command:

```
dotnet tool install --global dotnet-monitor
```

- **Docker image:**

Download a Docker image for use in multi-container environments:

```
docker pull mcr.microsoft.com/dotnet/monitor
```

Synopsis

```
dotnet-monitor [-h|--help] [--version] <command>
```

Description

The `dotnet-monitor` global tool is a way to monitor .NET applications in production environments and to collect diagnostic artifacts (for example, dumps, traces, logs, and metrics) on-demand or using automated rules for collecting under specified conditions.

Options

- `--version`

Displays the version of the `dotnet-monitor` utility.

- `-h|--help`

Shows command-line help.

Commands

`COMMAND`

```
dotnet monitor collect
```

COMMAND

```
dotnet monitor config show
```

```
dotnet monitor generatekey
```

dotnet-monitor collect

Monitor .NET applications, allow collecting diagnostic artifacts, and send the results to a chosen destination.

Synopsis

```
dotnet-monitor collect [-h|--help] [-u|--urls] [-m|--metrics] [--metricUrls] [--diagnostic-port] [--no-auth]  
[--temp-apikey] [--no-http-egress]
```

Options

- `-h|--help`

Shows command-line help.

- `-u|--urls <urls>`

Bindings for the HTTP api. Default is `https://localhost:52323`.

- `-m|--metrics [true|false]`

Enable publishing of metrics to `/metrics` route. Default is `true`

- `--metricUrls <urls>`

Bindings for the metrics HTTP api. Default is `http://localhost:52325`.

- `--diagnostic-port <path>`

The fully qualified path and filename of the diagnostic port to which runtime instances can connect.

Specifying this option places `dotnet-monitor` into 'listen' mode. When not specified, `dotnet-monitor` is in 'connect' mode.

On Windows, this must be a valid named pipe name. On Linux and macOS, this must be a valid Unix Domain Socket path.

- `--no-auth`

Disables API key authentication. Default is `false`.

It is strongly recommended that this option is not used in production environments.

- `--temp-apikey`

Generates a temporary API key for the `dotnet-monitor` instance.

- `--no-http-egress`

Disables egress of diagnostic artifacts via the HTTP response. When specified, artifacts must be egressed using an egress provider.

dotnet-monitor config show

Shows configuration, as if `dotnet-monitor collect` was executed with these parameters.

Synopsis

```
dotnet-monitor config show [-h|--help] [-u|--urls] [-m|--metrics] [--metricUrls] [--diagnostic-port] [--no-auth] [--temp-apikey] [--no-http-egress] [--level] [--show-sources]
```

Options

- `-h|--help`

Shows command-line help.

- `-u|--urls <urls>`

Bindings for the HTTP api. Default is `https://localhost:52323`.

This value is mapped into configuration as the `urls` key.

- `-m|--metrics [true|false]`

Enable publishing of metrics to `/metrics` route. Default is `true`.

This value is mapped into configuration as the `Metrics:Enabled` key.

- `--metricUrls <urls>`

Bindings for the metrics HTTP api. Default is `http://localhost:52325`.

This value is mapped into configuration as the `Metrics:Endpoints` key.

- `--diagnostic-port <path>`

The fully qualified path and filename of the diagnostic port to which runtime instances can connect.

Specifying this option places `dotnet-monitor` into 'listen' mode. When not specified, `dotnet-monitor` is in 'connect' mode.

On Windows, this must be a valid named pipe name. On Linux and macOS, this must be a valid Unix Domain Socket path.

This value is mapped into configuration as the `DiagnosticPort:EndpointName` key.

- `--no-auth`

Disables API key authentication. Default is `false`.

It is strongly recommended that this option is not used in production environments.

This value is not mapped into configuration.

- `--temp-apikey`

Generates a temporary API key for the `dotnet-monitor` instance.

This value is mapped into configuration as the `Authentication:MonitorApiKey` key.

- `--no-http-egress`

Disables egress of diagnostic artifacts via the HTTP response. When specified, artifacts must be egressed using an egress provider.

This value is not mapped into configuration.

- `--level`

Configuration level. `Full` configuration can show sensitive information. There are two levels:

- `Full` - The full configuration without any redaction of any values.
- `Redacted` - The full configuration but sensitive information, such as known secrets, is redacted.

- `--show-sources`

Identifies from which configuration source each effective configuration value is provided.

dotnet-monitor generatekey

Generate an API key and hash for HTTP authentication.

Synopsis

```
dotnet-monitor generatekey [-h|--help] [-o|--output]
```

Options

- `-h|--help`

Shows command-line help.

- `-o|--output <Cmd|Json|MachineJson|PowerShell|Shell|Text>`

The output format in which the API key information is written to standard output.

The allowable values are:

- `Cmd` - Outputs in a format usable in Windows Command Prompt or batch files.
- `Json` - Outputs in a format of a JSON object.
- `MachineJson` - Outputs in a format of a JSON object without comments and explanation. Useful for automation scenarios.
- `PowerShell` - Outputs in a format usable in PowerShell prompts and scripts.
- `Shell` - Outputs in a format usable in Linux shells such as Bash.
- `Text` - Outputs in a format that is plain text.

dotnet-trace performance analysis utility

9/20/2022 • 12 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-trace` 3.0.47001 and later versions

Install

There are two ways to download and install `dotnet-trace`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-trace` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-trace
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

NOTE

To use `dotnet-trace` on an x86 app, you need a corresponding x86 version of the tool.

Synopsis

```
dotnet-trace [-h, --help] [--version] <command>
```

Description

The `dotnet-trace` tool:

- Is a cross-platform .NET Core tool.
- Enables the collection of .NET Core traces of a running process without a native profiler.
- Is built on `EventPipe` of the .NET Core runtime.
- Delivers the same experience on Windows, Linux, or macOS.

Options

- `-h|--help`

Shows command-line help.

- `--version`

Displays the version of the dotnet-trace utility.

Commands

COMMAND

[dotnet-trace collect](#)

[dotnet-trace convert](#)

[dotnet-trace ps](#)

[dotnet-trace list-profiles](#)

[dotnet-trace report](#)

dotnet-trace collect

Collects a diagnostic trace from a running process or launches a child process and traces it (.NET 5+ only). To have the tool run a child process and trace it from its startup, append `--` to the collect command.

Synopsis

```
dotnet-trace collect [--buffersize <size>] [--clreventlevel <clreventlevel>] [--clrevents <clrevents>]
    [--format <Chromium|NetTrace|Speedscope>] [-h|--help]
    [-n, --name <name>] [--diagnostic-port] [-o|--output <trace-file-path>] [-p|--process-id <pid>]
    [--profile <profile-name>] [--providers <list-of-comma-separated-providers>]
    [--show-child-io]
    [-- <command>] (for target applications running .NET 5 or later)
```

Options

- `--buffersize <size>`

Sets the size of the in-memory buffer, in megabytes. Default 256 MB.

NOTE

If the target process emits events faster than they can be written to disk, this buffer may overflow and some events will be dropped. You can mitigate this problem by increasing the buffer size or reducing the number of events being recorded.

- `--clreventlevel <clreventlevel>`

Verbosity of CLR events to be emitted.

- `--clrevents <clrevents>`

A list of CLR runtime provider keywords to enable separated by `+` signs. This is a simple mapping that lets you specify event keywords via string aliases rather than their hex values. For example,

```
dotnet-trace collect --providers Microsoft-Windows-DotNETRuntime:3:4
```

 requests the same set of events as

```
dotnet-trace collect --clrevents gc+gchandle --clreventlevel informational
```

. The table below shows the

list of available keywords:

KEYWORD STRING ALIAS	KEYWORD HEX VALUE
gc	0x1
gchandle	0x2
fusion	0x4
loader	0x8
jit	0x10

methoddiagnostic	0x4000000000
typediagnostic	0x8000000000

You can read about the CLR provider more in detail on the [.NET runtime provider reference documentation](#).

- `--format {Chromium|NetTrace|Speedscope}`

Sets the output format for the trace file conversion. The default is `NetTrace`.

- `-n, --name <name>`

The name of the process to collect the trace from.

- `--diagnostic-port <path-to-port>`

The name of the diagnostic port to create. See [Use diagnostic port to collect a trace from app startup](#) to learn how to use this option to collect a trace from app startup.

- `-o|--output <trace-file-path>`

The output path for the collected trace data. If not specified, it defaults to `trace.nettrace`.

- `-p|--process-id <PID>`

The process ID to collect the trace from.

- `--profile <profile-name>`

A named pre-defined set of provider configurations that allows common tracing scenarios to be specified succinctly. The following profiles are available:

PROFILE	DESCRIPTION
---------	-------------

PROFILE	DESCRIPTION
cpu-sampling	Useful for tracking CPU usage and general .NET runtime information. This is the default option if no profile or providers are specified.
gc-verbose	Tracks GC collections and samples object allocations.
gc-collect	Tracks GC collections only at very low overhead.

- `--providers <list-of-comma-separated-providers>`

A comma-separated list of `EventPipe` providers to be enabled. These providers supplement any providers implied by `--profile <profile-name>`. If there's any inconsistency for a particular provider, this configuration takes precedence over the implicit configuration from the profile.

This list of providers is in the form:

- `Provider[,Provider]`
- `Provider` is in the form: `KnownProviderName[:Flags[:Level][:KeyValueArgs]]`.
- `KeyValueArgs` is in the form: `[key1=value1][;key2=value2]`.

To learn more about some of the well-known providers in .NET, refer to [Well-known Event Providers](#).

- `-- <command>` (for target applications running .NET 5 only)

After the collection configuration parameters, the user can append `--` followed by a command to start a .NET application with at least a 5.0 runtime. This may be helpful when diagnosing issues that happen early in the process, such as startup performance issue or assembly loader and binder errors.

NOTE

Using this option monitors the first .NET 5 process that communicates back to the tool, which means if your command launches multiple .NET applications, it will only collect the first app. Therefore, it is recommended you use this option on self-contained applications, or using the `dotnet exec <app.dll>` option.

- `--show-child-io`

Shows the input and output streams of a launched child process in the current console.

NOTE

- Stopping the trace may take a long time (up to minutes) for large applications. The runtime needs to send over the type cache for all managed code that was captured in the trace.
- On Linux and macOS, this command expects the target application and `dotnet-trace` to share the same `TMPDIR` environment variable. Otherwise, the command will time out.
- To collect a trace using `dotnet-trace`, it needs to be run as the same user as the user running the target process or as root. Otherwise, the tool will fail to establish a connection with the target process.
- If you see an error message similar to:

[ERROR] System.ComponentModel.Win32Exception (299): A 32 bit processes cannot access modules of a 64 bit process.

, you are trying to use a version of `dotnet-trace` that has mismatched bitness against the target process.

Make sure to download the correct bitness of the tool in the [install](#) link.

- If you experience an unhandled exception while running `dotnet-trace collect`, this results in an incomplete trace. If finding the root cause of the exception is your priority, navigate to [Collect dumps on crash](#). As a result of the unhandled exception, the trace is truncated when the runtime shuts down to prevent other undesired behavior such as a hang or data corruption. Even though the trace is incomplete, you can still open it to see what happened leading up to the failure. However, it will be missing Rundown information (this happens at the end of a trace) so stacks might be unresolved (depending on what providers were turned on). Open the trace by executing PerfView with the `/ContinueOnError` flag at the command line. The logs will also contain the location the exception was fired.

dotnet-trace convert

Converts `nettrace` traces to alternate formats for use with alternate trace analysis tools.

Synopsis

```
dotnet-trace convert [<input-filename>] [--format <Chromium|NetTrace|Speedscope>] [-h|--help] [-o|--output <output-filename>]
```

Arguments

- `<input-filename>`

Input trace file to be converted. Defaults to `trace.nettrace`.

Options

- `--format <Chromium|NetTrace|Speedscope>`

Sets the output format for the trace file conversion.

- `-o|--output <output-filename>`

Output filename. Extension of target format will be added.

NOTE

Converting `nettrace` files to `chromium` or `speedscope` files is irreversible. `speedscope` and `chromium` files don't have all the information necessary to reconstruct `nettrace` files. However, the `convert` command preserves the original `nettrace` file, so don't delete this file if you plan to open it in the future.

dotnet-trace ps

Lists the dotnet processes that traces can be collected from. `dotnet-trace` 6.0.320703 and later, also display the command-line arguments that each process was started with, if available.

Synopsis

```
dotnet-trace ps [-h|--help]
```

Example

Suppose you start a long-running app using the command `dotnet run --configuration Release`. In another window, you run the `dotnet-trace ps` command. The output you'll see is as follows. The command-line arguments, if available, are shown in `dotnet-trace` version 6.0.320703 and later.

```
> dotnet-trace ps

21932 dotnet      C:\Program Files\dotnet\dotnet.exe    run --configuration Release
36656 dotnet      C:\Program Files\dotnet\dotnet.exe
```

dotnet-trace list-profiles

Lists pre-built tracing profiles with a description of what providers and filters are in each profile.

Synopsis

```
dotnet-trace list-profiles [-h|--help]
```

dotnet-trace report

Creates a report into stdout from a previously generated trace.

Synopsis

```
dotnet-trace report [-h|--help] <tracefile> [command]
```

Arguments

- `<tracefile>`

The file path for the trace being analyzed.

Commands

dotnet-trace report topN

Finds the top N methods that have been on the callstack the longest.

Synopsis

```
dotnet-trace report <tracefile> topN [-n|--number <n>] [--inclusive] [-v|--verbose] [-h|--help]
```

Options

- `-n|--number <n>`

Gives the top N methods on the callstack.

- `--inclusive`

Output the top N methods based on [inclusive](#) time. If not specified, exclusive time is used by default.

- `-v|--verbose`

Output the parameters of each method in full. If not specified, parameters will be truncated.

Collect a trace with dotnet-trace

To collect traces using `dotnet-trace`:

- Get the process identifier (PID) of the .NET Core application to collect traces from.

- On Windows, you can use Task Manager or the `tasklist` command, for example.
- On Linux, for example, the `ps` command.
- `dotnet-trace ps`
- Run the following command:

```
dotnet-trace collect --process-id <PID>
```

The preceding command generates output similar to the following:

```
Press <Enter> to exit...
Connecting to process: <Full-Path-To-Process-Being-Profiled>/dotnet.exe
Collecting to file: <Full-Path-To-Trace>/trace.nettrace
Session Id: <SessionId>
Recording trace 721.025 (KB)
```

- Stop collection by pressing the `<Enter>` key. `dotnet-trace` will finish logging events to the `trace.nettrace` file.

Launch a child application and collect a trace from its startup using dotnet-trace

IMPORTANT

This works for apps running .NET 5 or later only.

Sometimes it may be useful to collect a trace of a process from its startup. For apps running .NET 5 or later, it is possible to do this by using dotnet-trace.

This will launch `hello.exe` with `arg1` and `arg2` as its command-line arguments and collect a trace from its runtime startup:

```
dotnet-trace collect -- hello.exe arg1 arg2
```

The preceding command generates output similar to the following:

```
No profile or providers specified, defaulting to trace profile 'cpu-sampling'

Provider Name          Keywords          Level          Enabled By
Microsoft-DotNETCore-SampleProfiler 0x0000F00000000000 Informational(4)  --profile
Microsoft-Windows-DotNETRuntime     0x00000014C14FCCBD  Informational(4)  --profile

Process      : E:\temp\gcpersim\bin\Debug\net5.0\gcpersim.exe
Output File  : E:\temp\gcpersim\trace.nettrace

[00:00:00:05] Recording trace 122.244 (KB)
Press <Enter> or <Ctrl+C> to exit...
```

You can stop collecting the trace by pressing `<Enter>` or `<Ctrl + C>` key. Doing this will also exit `hello.exe`.

NOTE

Launching `hello.exe` via `dotnet-trace` will redirect its input/output and you won't be able to interact with it on the console by default. Use the `--show-child-io` switch to interact with its `stdin/stdout`. Exiting the tool via `CTRL+C` or `SIGTERM` will safely end both the tool and the child process. If the child process exits before the tool, the tool will exit as well and the trace should be safely viewable.

Use diagnostic port to collect a trace from app startup

IMPORTANT

This works for apps running .NET 5 or later only.

Diagnostic port is a runtime feature added in .NET 5 that allows you to start tracing from app startup. To do this using `dotnet-trace`, you can either use `dotnet-trace collect -- <command>` as described in the examples above, or use the `--diagnostic-port` option.

Using `dotnet-trace <collect|monitor> -- <command>` to launch the application as a child process is the simplest way to quickly trace the application from its startup.

However, when you want to gain a finer control over the lifetime of the app being traced (for example, monitor the app for the first 10 minutes only and continue executing) or if you need to interact with the app using the CLI, using `--diagnostic-port` option allows you to control both the target app being monitored and `dotnet-trace`.

1. The command below makes `dotnet-trace` create a diagnostics socket named `myport.sock` and wait for a connection.

```
dotnet-trace collect --diagnostic-port myport.sock
```

Output:

```
Waiting for connection on myport.sock
Start an application with the following environment variable:
DOTNET_DiagnosticPorts=/home/user/myport.sock
```

2. In a separate console, launch the target application with the environment variable `DOTNET_DiagnosticPorts` set to the value in the `dotnet-trace` output.

```
export DOTNET_DiagnosticPorts=/home/user/myport.sock
./my-dotnet-app arg1 arg2
```

This should then enable `dotnet-trace` to start tracing `my-dotnet-app`:

```
Waiting for connection on myport.sock
Start an application with the following environment variable: DOTNET_DiagnosticPorts=myport.sock
Starting a counter session. Press Q to quit.
```

IMPORTANT

Launching your app with `dotnet run` can be problematic because the dotnet CLI may spawn many child processes that are not your app and they can connect to `dotnet-trace` before your app, leaving your app to be suspended at run time. It is recommended you directly use a self-contained version of the app or use `dotnet exec` to launch the application.

View the trace captured from dotnet-trace

On Windows, you can view `.nettrace` files in [Visual Studio](#) or [PerfView](#) for analysis.

On Linux, you can view the trace by changing the output format of `dotnet-trace` to `speedscope`. Change the output file format by using the `-f|--format` option. You can choose between `nettrace` (the default option) and `speedscope`. The option `-f speedscope` will make `dotnet-trace` produce a `speedscope` file. `Speedscope` files can be opened at <https://www.speedscope.app>.

For traces collected on non-Windows platforms, you can also move the trace file to a Windows machine and view it in Visual Studio or PerfView.

NOTE

The .NET Core runtime generates traces in the `nettrace` format. The traces are converted to `speedscope` (if specified) after the trace is completed. Since some conversions may result in loss of data, the original `nettrace` file is preserved next to the converted file.

Use dotnet-trace to collect counter values over time

`dotnet-trace` can:

- Use `EventCounter` for basic health monitoring in performance-sensitive environments. For example, in production.
- Collect traces so they don't need to be viewed in real time.

For example, to collect runtime performance counter values, use the following command:

```
dotnet-trace collect --process-id <PID> --providers System.Runtime:0:1:EventCounterIntervalSec=1
```

The preceding command tells the runtime counters to report once every second for lightweight health monitoring. Replacing `EventCounterIntervalSec=1` with a higher value (for example, 60) allows collection of a smaller trace with less granularity in the counter data.

The following command reduces overhead and trace size more than the preceding one:

```
dotnet-trace collect --process-id <PID> --providers System.Runtime:0:1:EventCounterIntervalSec=1,Microsoft-Windows-DotNETRuntime:0:1,Microsoft-DotNETCore-SampleProfiler:0:1
```

The preceding command disables runtime events and the managed stack profiler.

Use .rsp file to avoid typing long commands

You can launch `dotnet-trace` with an `.rsp` file that contains the arguments to pass. This can be useful when enabling providers that expect lengthy arguments or when using a shell environment that strips characters.

For example, the following provider can be cumbersome to type out each time you want to trace:

```
dotnet-trace collect --providers Microsoft-Diagnostics-
DiagnosticSource:0x3:5:FilterAndPayloadSpecs="SqlClientDiagnosticListener/System.Data.SqlClient.WriteCommand
Before@Activity1Start:-
Command;Command.CommandText;ConnectionId;Operation;Command.Connection.ServerVersion;Command.CommandTimeout;C
ommand.CommandType;Command.Connection.ConnectionString;Command.Connection.Database;Command.Connection.DataSource;Command.Connection.PacketSize\r\nSqlClientDiagnosticListener/System.Data.SqlClient.WriteCommandAfter@Ac
tivity1Stop:\r\nMicrosoft.EntityFrameworkCore/Microsoft.EntityFrameworkCore.Database.Command.CommandExecutin
g@Activity2Start:-
Command;Command.CommandText;ConnectionId;IsAsync;Command.Connection.ClientConnectionId;Command.Connection.Se
rverVersion;Command.CommandTimeout;Command.CommandType;Command.Connection.ConnectionString;Command.Connectio
n.Database;Command.Connection.DataSource;Command.Connection.PacketSize\r\nMicrosoft.EntityFrameworkCore/Micr
osoft.EntityFrameworkCore.Database.Command.CommandExecuted@Activity2Stop:",OtherProvider,AnotherProvider
```

In addition, the previous example contains `"` as part of the argument. Because quotes are not handled equally by each shell, you may experience various issues when using different shells. For example, the command to enter in `zsh` is different to the command in `cmd`.

Instead of typing this each time, you can save the following text into a file called `myprofile.rsp`.

```
--providers
Microsoft-Diagnostics-
DiagnosticSource:0x3:5:FilterAndPayloadSpecs="SqlClientDiagnosticListener/System.Data.SqlClient.WriteCommand
Before@Activity1Start:-
Command;Command.CommandText;ConnectionId;Operation;Command.Connection.ServerVersion;Command.CommandTimeout;C
ommand.CommandType;Command.Connection.ConnectionString;Command.Connection.Database;Command.Connection.DataSource;Command.Connection.PacketSize\r\nSqlClientDiagnosticListener/System.Data.SqlClient.WriteCommandAfter@Ac
tivity1Stop:\r\nMicrosoft.EntityFrameworkCore/Microsoft.EntityFrameworkCore.Database.Command.CommandExecutin
g@Activity2Start:-
Command;Command.CommandText;ConnectionId;IsAsync;Command.Connection.ClientConnectionId;Command.Connection.Se
rverVersion;Command.CommandTimeout;Command.CommandType;Command.Connection.ConnectionString;Command.Connectio
n.Database;Command.Connection.DataSource;Command.Connection.PacketSize\r\nMicrosoft.EntityFrameworkCore/Micr
osoft.EntityFrameworkCore.Database.Command.CommandExecuted@Activity2Stop:",OtherProvider,AnotherProvider
```

Once you've saved `myprofile.rsp`, you can launch `dotnet-trace` with this configuration using the following command:

```
dotnet-trace @myprofile.rsp
```

Inspect managed stack traces (dotnet-stack)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ `dotnet-stack` version 5.0.221401 and later versions

Install

There are two ways to download and install `dotnet-stack`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-stack` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-stack
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

Synopsis

```
dotnet-stack [-h, --help] [--version] <command>
```

Description

The `dotnet-stack` tool:

- Is a cross-platform .NET Core tool.
- Captures and prints the managed stacks for all threads in the target .NET process.
- Utilizes `EventPipe` tracing provided by the .NET Core runtime.

Options

- `-h|--help`

Shows command-line help.

- `--version`

Displays the version of the dotnet-stack utility.

Commands

COMMAND	DESCRIPTION
<code>dotnet-stack report</code>	Prints the stack trace for each thread in the target process.
<code>dotnet-stack ps</code>	Lists the dotnet processes that stack traces can be collected from.

dotnet-stack report

Prints the stack trace for each thread in the target process.

Synopsis

```
dotnet-stack report -p|--process-id <pid>
                    -n|--name <process-name>
                    [-h|--help]
```

Options

- `-n, --name <name>`

The name of the process to collect the trace from.

- `-p|--process-id <PID>`

The process ID to collect the trace from.

dotnet-stack ps

Lists the dotnet processes that stack traces can be collected from. `dotnet-stack` version 6.0.320703 and later versions also display the command-line arguments that each process was started with, if available.

Synopsis

```
dotnet-stack ps [-h|--help]
```

Example

Suppose you start a long-running app using the command `dotnet run --configuration Release`. In another window, you run the `dotnet-stack ps` command. The output you'll see is as follows. The command-line arguments, if any, are shown in `dotnet-stack` version 6.0.320703 and later.

```
> dotnet-stack ps

21932 dotnet      C:\Program Files\dotnet\dotnet.exe    run --configuration Release
36656 dotnet      C:\Program Files\dotnet\dotnet.exe
```

Report managed stacks with dotnet-stack

To report managed stacks using `dotnet-stack`:

- Get the process identifier (PID) of the .NET Core application to report stacks from.
 - On Windows, you can use Task Manager or the `tasklist` command, for example.

- On Linux, for example, the `ps` command.
- `dotnet-stack ps`

- Run the following command:

```
dotnet-stack report --process-id <PID>
```

The preceding command generates output similar to the following:

```
Thread (0x48839B):
[Native Frames]
System.Console!System.IO.StdInReader.ReadKey(bool&)
System.Console!System.IO.SyncTextReader.ReadKey(bool&)
System.Console!System.ConsolePal.ReadKey(bool)
System.Console!System.Console.ReadKey()
StackTracee!Tracee.Program.Main(class System.String[])
```

The output of `dotnet-stack` follows the following form:

- Comments in the output are prefixed with `#`.
- Each thread has a header that includes the native thread ID: `Thread (<thread-id>):`.
- Stack frames follow the form `Module!Method`.
- Transitions to unmanaged code are represented as `[Native Frames]` in the output.

```
# comment
Thread (0x1234):
  module!Method
  module!Method

Thread (0x5678):
  [Native Frames]
  Module!Method
  Module!Method
```

NOTE

Stopping the process can take a long time (up to several minutes) for very large applications. The runtime needs to send over the type and method information for all managed code that was captured to resolve function names.

- [Use dotnet-dump to collect a dump of a .NET application](#)

Symbol downloader (dotnet-symbol)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

Install

To install the latest release version of the `dotnet-symbol` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-symbol
```

Synopsis

```
dotnet-symbol [-h|--help] [options] <FILES>
```

Description

The `dotnet-symbol` global tool downloads files (symbols, DAC, modules, etc.) needed for debugging core dumps and minidumps. This can be useful when debugging dumps captured on another machine. `dotnet-symbol` can download modules and symbols needed to analyze the dump.

Options

- `--microsoft-symbol-server`
Add 'http://msdl.microsoft.com/download/symbols' symbol server path (default).
- `--server-path <symbol server path>`
Add a symbol server to the server path.
- `authenticated-server-path <pat> <server path>`
Add an authenticated symbol server to the server path using a personal access token (PAT).
- `--cache-directory <file cache directory>`
Adds a cache directory.
- `--recurse-subdirectories`
Process input files in all subdirectories.
- `--host-only`
Download only the host program (that is, dotnet) that lldb needs for loading core dumps.
- `--symbols`
Download symbol files (.pdb, .dbg, .dwarf).
- `--modules`

Download the module files (.dll, .so, .dylib).

- `--debugging`

Download the special debugging modules (DAC, DBI, SOS).

- `--windows-pdbs`

Force the downloading of the Windows PDBs when Portable PDBs are also available.

- `-o, --output <output directory>`

Set the output directory. Otherwise, write next to the input file (default).

- `-d, --diagnostics`

Enable diagnostic output.

- `-h|--help`

Shows command-line help.

Download symbols

Running `dotnet-symbol` against a dump file will, by default, download all the modules, symbols, and DAC/DBI files needed to debug the dump including the managed assemblies. Because SOS can now download symbols when needed, most Linux core dumps can be analyzed using lldb with only the host (dotnet) and debugging modules. To get these files necessary for diagnosing a core dump with lldb run:

```
dotnet-symbol --host-only --debugging <dump file path>
```

Troubleshoot

- 404 Not Found while downloading symbols.

Symbol download is only supported for official .NET Core runtime versions acquired through official channels such as [the official web site](#) and the [default sources in the dotnet installation scripts](#). A 404 error while downloading debugging files may indicate that the dump was created with a .NET Core runtime from another source, such as one built from source locally or for a particular Linux distro, or from community sites like archlinux. In such cases, file necessary for debugging (dotnet, libcoreclr.so, and libmscordaccore.so) should be copied from those sources or from the environment the dump file was created in.

SOS installer (dotnet-sos)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

Install

There are two ways to download and install `dotnet-sos`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-sos` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-sos
```

- **Direct download:**

Download the tool executable that matches your platform:

OS	Platform
Windows	x86 x64 Arm Arm-x64
macOS	x64
Linux	x64 Arm Arm64 musl-x64 musl-Arm64

Synopsis

```
dotnet-sos [-h|--help] [options] [command]
```

Description

The `dotnet-sos` global tool installs the [SOS debugger extension](#). This extension lets you inspect managed .NET Core state from native debuggers like lldb and windbg.

NOTE

Installing SOS via the `dotnet-sos` tool is only needed on Linux or macOS. It may also be needed on Windows if you're using older debugging tools. Recent versions of the [Windows Debugger](#) (>= version 10.0.18317.1001 of WinDbg or cdb) load SOS automatically from the Microsoft extension gallery.

Options

- `--version`

Displays version information.

- `-h|--help`

Shows command-line help.

dotnet-sos install

Installs the [SOS extension](#) locally for debugging .NET Core processes. On macOS and Linux, the `.lldbinit` file will be updated so that the extension automatically loads at lldb startup. If you're installing SOS on Windows with older debugging tools (prior to version 10.0.18317.1001), you will need to manually load the extension in WinDbg or cdb by running `.load %USERPROFILE%\dotnet\sos\sos.dll` in the debugger.

Synopsis

```
dotnet-sos install [--architecture <arch>]
```

Options

- `--architecture <arch>`

Specifies the processor architecture of the SOS binaries to install. By default, `dotnet-sos` installs the architecture of the host machine. Use this option when you want to install SOS for an architecture that's different from the dotnet host architecture. For example, if you're running Arm32 binaries from an Arm64 host, you will need to install SOS with `dotnet-sos install --architecture Arm`.

The following architectures are available:

- `Arm`
- `Arm64`
- `X86`
- `X64`

dotnet-sos uninstall

Uninstalls the [SOS extension](#) and, on Linux and macOS, removes it from lldb configuration.

Synopsis

```
dotnet-sos uninstall
```

dotnet-dsrouter

9/20/2022 • 8 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET 6.0 SDK and later versions

Install

There are two ways to download and install `dotnet-dsrouter`:

- **dotnet global tool:**

To install the latest release version of the `dotnet-dsrouter` NuGet package, use the `dotnet tool install` command:

```
dotnet tool install --global dotnet-dsrouter
```

Synopsis

```
dotnet-dsrouter [-?, -h, --help] [--version] <command>
```

Description

The `dotnet-dsrouter` connects diagnostic tooling like `dotnet-trace` and `dotnet-counters` to .NET applications running on Android, iOS, and tvOS, regardless of whether they're running as an emulator, simulator, or on the device itself. Diagnostic tooling uses local inter-process communication (IPC) (Named Pipe, Unix Domain Socket) to connect and communicate with a .NET runtime. .NET applications running in sandboxed environments on emulators, simulators, and devices need alternative ways to communicate. The `dotnet-dsrouter` injects itself between existing diagnostic tooling and .NET mobile applications and creates a local representation of the application. The `dotnet-dsrouter` enables diagnostic tools to communicate with a remote .NET runtime as if it has been running on the local machine.

The communication between diagnostic tooling and `dotnet-dsrouter` uses the same IPC (Named Pipe, Unix Domain Socket) as used when connecting to a local .NET runtime. `dotnet-dsrouter` uses TCP/IP in its communication with remote .NET runtime and support several different connectivity scenarios to handle different needs and requirements used by different platforms. `dotnet-dsrouter` also implements additional support to simplify connectivity configuration when running in emulator, simulator, and on physical device attached over USB.

NOTE

`dotnet-dsrouter` is intended for development and testing and it's highly recommended to run `dotnet-dsrouter` over loopback interface (for example, `127.0.0.1`, `[::1]`). The connectivity features and port forwarding capabilities of `dotnet-dsrouter` handles all scenarios using local emulator, simulator or physical device connected over USB.

WARNING

Binding TCP server endpoint to anything except loopback interface (`localhost` , `127.0.0.1` or `[::1]`) is *not* recommended. Any connections towards TCP server endpoint will be unauthenticated and unencrypted.

`dotnet-dsrouter` is intended for development use and should only be run in development and testing environments.

Detailed usage of `dotnet-dsrouter` together with mobile applications is outline by respective .NET SDKs. This document will only include a couple of examples on how to run diagnostic tools against .NET application running on Android. For in-depth details on configuration and scenarios, see [Diagnostics Tracing](#).

Options

- `-?|-h|--help`

Shows command-line help.

- `--version`

Displays the version of the `dotnet-dsrouter` utility.

Commands

COMMAND

`dotnet-dsrouter client-server`

`dotnet-dsrouter server-server`

`dotnet-dsrouter server-client`

`dotnet-dsrouter client-client`

dotnet-dsrouter client-server

Start a .NET application diagnostics server routing local IPC server and remote TCP client. The router is configured using an IPC client (connecting diagnostic tool IPC server) and a TCP/IP server (accepting runtime TCP client).

Synopsis

```
dotnet-dsrouter client-server
  [-ipcc|--ipc-client <ipcClient>]
  [-tcps|--tcp-server <tcpServer>]
  [-rt|--runtime-timeout <timeout>]
  [-v|--verbose <level>]
  [-fp|--forward-port <platform>]
```

Options

- `-ipcc, --ipc-client <ipcClient>` The diagnostic tool diagnostics server IPC address (`--diagnostic-port` argument). Router connects diagnostic tool IPC server when establishing a new route between runtime and diagnostic tool.
- `-tcps, --tcp-server <tcpServer>` The router TCP/IP address using format `[host]:[port]` . Router can bind one (`127.0.0.1` , `[::1]` , `0.0.0.0` , `[::]` , IPv4 address, IPv6 address, hostname) or all (*) interfaces.

Launch runtime using `DOTNET_DiagnosticPorts` environment variable, connecting router TCP server during startup.

- `-rt, --runtime-timeout <runtimeTimeout>` Automatically shut down router if no runtime connects to it before specified timeout (seconds). If not specified, router won't trigger an automatic shutdown.
- `-v, --verbose <verbose>` Enable verbose logging (debug|trace)
- `-fp, --forward-port <forwardPort>` Enable port forwarding, values `Android` or `ios` for `TcpClient`, and only `Android` for `TcpServer`. Make sure to set `ANDROID_SDK_ROOT` before using this option on Android.

dotnet-dsrouter server-server

Start a .NET application diagnostics server routing local IPC client and remote TCP client. The router is configured using an IPC server (connecting to by diagnostic tools) and a TCP/IP server (accepting runtime TCP client).

Synopsis

```
dotnet-dsrouter server-server
  [-ipcs|--ipc-server <ipcServer>]
  [-tcps|--tcp-server <tcpServer>]
  [-rt|--runtime-timeout <timeout>]
  [-v|--verbose <level>]
  [-fp|--forward-port <platform>]
```

Options

- `-ipcs, --ipc-server <ipcServer>` The diagnostics server IPC address to route. Router accepts IPC connections from diagnostic tools establishing a new route between runtime and diagnostic tool. If not specified router will use default IPC diagnostics server path.
- `-tcps, --tcp-server <tcpServer>` The router TCP/IP address using format `[host]:[port]`. Router can bind one (`127.0.0.1`, `[:1]`, `0.0.0.0`, `[::]`, IPv4 address, IPv6 address, hostname) or all (*) interfaces.
Launch runtime using `DOTNET_DiagnosticPorts` environment variable, connecting router TCP server during startup.
- `-rt, --runtime-timeout <runtimeTimeout>` Automatically shut down router if no runtime connects to it before specified timeout (seconds). If not specified, router won't trigger an automatic shutdown.
- `-v, --verbose <verbose>` Enable verbose logging (debug|trace)
- `-fp, --forward-port <forwardPort>` Enable port forwarding, values `Android` or `ios` for `TcpClient`, and only `Android` for `TcpServer`. Make sure to set `ANDROID_SDK_ROOT` before using this option on Android.

dotnet-dsrouter server-client

Start a .NET application diagnostics server routing local IPC client and remote TCP server. The router is configured using an IPC server (connecting to by diagnostic tools) and a TCP/IP client (connecting runtime TCP server).

Synopsis

```
dotnet-dsrouter server-client
  [-ipcs|--ipc-server <ipcServer>]
  [-tcpc|--tcp-client <tcpClient>]
  [-rt|--runtime-timeout <timeout>]
  [-v|--verbose <level>]
  [-fp|--forward-port <platform>]
```

Options

- `-ipcs, --ipc-server <ipcServer>` The diagnostics server IPC address to route. Router accepts IPC connections from diagnostic tools establishing a new route between runtime and diagnostic tool. If not specified router will use default IPC diagnostics server path.
- `-tcpc, --tcp-client <tcpClient>` The runtime TCP/IP address using format `[host]:[port]`. Router can connect `127.0.0.1`, `[:1]`, IPv4 address, IPv6 address, hostname addresses. Launch runtime using `DOTNET_DiagnosticPorts` environment variable to set up listener.
- `-rt, --runtime-timeout <runtimeTimeout>` Automatically shut down router if no runtime connects to it before specified timeout (seconds). If not specified, router won't trigger an automatic shutdown.
- `-v, --verbose <verbose>` Enable verbose logging (debug|trace)
- `-fp, --forward-port <forwardPort>` Enable port forwarding, values `Android` or `ios` for `TcpClient`, and only `Android` for `TcpServer`. Make sure to set `ANDROID_SDK_ROOT` before using this option on Android.

dotnet-dsrouter client-client

Start a .NET application diagnostics server routing local IPC server and remote TCP server. The router is configured using an IPC client (connecting diagnostic tool IPC server) and a TCP/IP client (connecting runtime TCP server).

Synopsis

```
dotnet-dsrouter client-client
  [-ipcc|--ipc-client <ipcClient>]
  [-tcpc|--tcp-client <tcpClient>]
  [-rt|--runtime-timeout <timeout>]
  [-v|--verbose <level>]
  [-fp|--forward-port <platform>]
```

Options

- `-ipcc, --ipc-client <ipcClient>` The diagnostic tool diagnostics server IPC address (`--diagnostic-port argument`). Router connects diagnostic tool IPC server when establishing a new route between runtime and diagnostic tool.
- `-tcpc, --tcp-client <tcpClient>` The runtime TCP/IP address using format `[host]:[port]`. Router can connect `127.0.0.1`, `[:1]`, IPv4 address, IPv6 address, hostname addresses. Launch runtime using `DOTNET_DiagnosticPorts` environment variable to set up listener.
- `-rt, --runtime-timeout <runtimeTimeout>` Automatically shut down router if no runtime connects to it before specified timeout (seconds). If not specified, router won't trigger an automatic shutdown.
- `-v, --verbose <verbose>` Enable verbose logging (debug|trace)
- `-fp, --forward-port <forwardPort>` Enable port forwarding, values `Android` or `ios` for `TcpClient`, and only `Android` for `TcpServer`. Make sure to set `ANDROID_SDK_ROOT` before using this option on Android.

Collect a startup trace using dotnet-trace from a .NET application running on Android

Sometimes it may be useful to collect a trace of an application from its startup. The following steps illustrate the process of doing so targeting a .NET application running on Android. Since `dotnet-dsrouter` is run using port forwarding, the same scenario works against applications running on a local emulator and on a physical device attached over USB. Make sure to set `ANDROID_SDK_ROOT` before using this option, or `dotnet-dsrouter` won't be able to find `adb` needed to set up port forwarding.

- Launch `dotnet-dsrouter` in server-server mode:

```
dotnet-dsrouter server-server -ipcs ~/mylocalport -tcps 127.0.0.1:9000 --forward-port Android &
```

- Set `DOTNET_DiagnosticPorts` environment variable using `AndroidEnvironment`:

Create a file in the same directory as the `.csproj` using a name like `app.env`, add environment variables into file, `DOTNET_DiagnosticPorts=127.0.0.1:9000,suspend` and include following `ItemGroup` into `.csproj`:

```
<ItemGroup Condition="'$(AndroidEnableProfiler)'=='true'>
  <AndroidEnvironment Include="app.env" />
</ItemGroup>
```

It's also possible to set `DOTNET_DiagnosticPorts` using `adb shell setprop`:

```
adb shell setprop debug.mono.profile '127.0.0.1:9000,suspend'
```

- Build and launch the application using .NET Android SDK, and enable tracing by passing `/p:AndroidEnableProfiler=true` to MSBuild. Since the app has been configured to suspend on startup, it will connect back to the `dotnet-dsrouter` TCP/IP listener running on `127.0.0.1:9000` and wait for diagnostic tooling to connect before resuming application execution.
- Start `dotnet-trace` in collect mode, connecting to `dotnet-dsrouter` IPC server, `~/mylocalport`:

```
dotnet-trace collect --diagnostic-port ~/mylocalport,connect
```

`dotnet-trace` will start a trace session and resume application that will now continue to execute. A stream of events will start to flow from the mobile application, through `dotnet-dsrouter` into `dotnet-trace` nettrace file. When done tracing, press `Enter` to make sure trace session is properly closed making sure nettrace file includes all needed data before application gets closed.

It's possible to run several trace sessions against the same running application over time, leave `dotnet-dsrouter` running and rerun `dotnet-trace` when a new trace session is needed.

`dotnet-dsrouter` can be left running in background and reused if an application is configured to connect using its address and port.

`dotnet-dsrouter` is tied to one running application at any time. If there are needs to trace several different applications at the same time, each application needs to use its own `dotnet-dsrouter` instance, by setting up a unique IPC, TCP/IP address pair in `dotnet-dsrouter` and configure different application instances to connect back to its unique `dotnet-dsrouter` instance.

If `dotnet-dsrouter` is run with `--forward-port` targeting Android and `adb` server, emulator or device gets restarted, all `dotnet-dsrouter` instances need to be restarted as well to restore port forwarding rules.

When done using `dotnet-dsrouter`, press Q or Ctrl + C to quit application.

NOTE

When running `dotnet-dsrouter` on Windows it will use Named Pipes for its IPC channel. Replace `~/mylocalport` with `mylocalport` in above examples when running on Windows.

NOTE

TCP/IP port 9000 is just an example. Any free TCP/IP port can be used.

NOTE

Unix Domain Socket `~/mylocalport` is just an example. Any free Unix Domain Socket file path can be used.

Collect a trace using dotnet-trace from a .NET application running on Android

If there's no need to collect a trace during application startup, it's possible to launch application in `nosuspend` mode, meaning runtime won't block at startup waiting for diagnostic tooling to connect before resuming execution. Most of the above-described scenario applies to this mode as well, just replace `suspend` with `nosuspend` in `DOTNET_DiagnosticPorts` environment variable to launch application in `nosuspend` mode.

Trace .NET applications with PerfCollect

9/20/2022 • 10 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 2.1 SDK and later versions

When performance problems are encountered on Linux, collecting a trace with `perfcollect` can be used to gather detailed information about what was happening on the machine at the time of the performance problem.

`perfcollect` is a bash script that uses [Linux Trace Toolkit: next generation \(LTTng\)](#) to collect events written from the runtime or any [EventSource](#), as well as `perf` to collect CPU samples of the target process.

Prepare your machine

Follow these steps to prepare your machine to collect a performance trace with `perfcollect`.

NOTE

If you are in a container environment, your container needs to have `SYS_ADMIN` capability. For more information on tracing applications inside containers using PerfCollect, see [Collect diagnostics in containers](#).

1. Download `perfcollect`.

```
curl -OL https://aka.ms/perfcollect
```

2. Make the script executable.

```
chmod +x perfcollect
```

3. Install tracing prerequisites - these are the actual tracing libraries.

```
sudo ./perfcollect install
```

This will install the following prerequisites on your machine:

- a. `perf`: the Linux Performance Events subsystem and companion user-mode collection/viewer application. `perf` is part of the Linux kernel source, but is not usually installed by default.
- b. `LTTng`: Used to capture event data emitted at run time by CoreCLR. This data is then used to analyze the behavior of various runtime components such as the GC, JIT, and thread pool.

Recent versions of .NET Core and the Linux perf tool support automatic resolution of method names for framework code. If you are working with .NET Core version 3.1 or less, an extra step is necessary. See [Resolving Framework Symbols](#) for details.

For resolving method names of native runtime DLLs (such as libcoreclr.so), `perfcollect` will resolve symbols for them when it converts the data, but only if the symbols for these binaries are present. See [Getting Symbols for](#)

the Native Runtime section for details.

Collect a trace

1. Have two shells available - one for controlling tracing, referred to as [Trace], and one for running the application, referred to as [App].
2. [Trace] Start collection.

```
sudo ./perfcollect collect sampleTrace
```

Expected Output:

```
Collection started. Press CTRL+C to stop.
```

3. [App] Set up the application shell with the following environment variables - this enables tracing configuration of CoreCLR.

```
export DOTNET_PerfMapEnabled=1  
export DOTNET_EnableEventLog=1
```

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

4. [App] Run the app - let it run as long as you need to in order to capture the performance problem. The exact length can be as short as you need as long as it sufficiently captures the window of time where the performance problem you want to investigate occurs.

```
dotnet run
```

5. [Trace] Stop collection - hit CTRL+C.

```
^C
...STOPPED.

Starting post-processing. This may take some time.

Generating native image symbol files
...SKIPPED
Saving native symbols
...FINISHED
Exporting perf.data file
...FINISHED
Compressing trace files
...FINISHED
Cleaning up artifacts
...FINISHED

Trace saved to sampleTrace.trace.zip
```

The compressed trace file is now stored in the current working directory.

View a trace

There are a number of options for viewing the trace that was collected. Traces are best viewed using [PerfView](#) on Windows, but they can be viewed directly on Linux using `PerfCollect` itself or `TraceCompass`.

Use `PerfCollect` to view the trace file

You can use `perfcollect` itself to view the trace that you collected. To do this, use the following command:

```
./perfcollect view sampleTrace.trace.zip
```

By default, this will show the CPU trace of the application using `perf`.

To look at the events that were collected via `LTTng`, you can pass in the flag `-viewer lttng` to see the individual events:

```
./perfcollect view sampleTrace.trace.zip -viewer lttng
```

This will use `babeltrace` viewer to print the events payload:

```
# [01:02:18.189217659] (+0.020132603) ubuntu-xenial DotNETRuntime:ExceptionThrown_V1: { cpu_id = 0 }, {
ExceptionType = "System.Exception", ExceptionMessage = "An exception happened", ExceptionEIP =
139875671834775, ExceptionHRESULT = 2148734208, ExceptionFlags = 16, ClrInstanceID = 0 }
# [01:02:18.189250227] (+0.020165171) ubuntu-xenial DotNETRuntime:ExceptionCatchStart: { cpu_id = 0 }, {
EntryEIP = 139873639728404, MethodID = 139873626968120, MethodName = "void [helloworld]
helloworld.Program::Main(string[])", ClrInstanceID = 0 }
```

Use [PerfView](#) to open the trace file

To see an aggregate view of both the CPU sample and the events, you can use [PerfView](#) on a Windows machine.

1. Copy the trace.zip file from Linux to a Windows machine.
2. Download PerfView from <https://aka.ms/perfview>.
3. Run `PerfView.exe`

```
PerfView.exe <path to trace.zip file>
```

PerfView will display the list of views that are supported based on the data contained in the trace file.

- For CPU investigations, choose **CPU stacks**.
- For detailed GC information, choose **GCStats**.
- For per-process/module/method JIT information, choose **JITStats**.
- If there is not a view for the information you need, you can try looking for the events in the raw events view. Choose **Events**.

For more information on how to interpret views in PerfView, see help links in the view itself, or from the main window in PerfView, choose **Help->Users Guide**.

NOTE

Events written via [System.Diagnostics.Tracing.EventSource](#) API (including the events from Framework) won't show up under their provider name. Instead, they are written as `EventSourceEvent` events under `Microsoft-Windows-DotNETRuntime` provider and their payloads are JSON serialized.

Use TraceCompass to open the trace file

[Eclipse TraceCompass](#) is another option you can use to view the traces. `TraceCompass` works on Linux machines as well, so you don't need to move your trace over to a Windows machine. To use `TraceCompass` to open your trace file, you will need to unzip the file.

```
unzip myTrace.trace.zip
```

`perfcollect` will save the LTTng trace it collected into a CTF file format in a subdirectory in the `lttngTrace`. Specifically, the CTF file will be located in a directory that looks like `lttngTrace/auto-20201025-101230\ust\uid\1000\64-bit\`.

You can open the CTF trace file in `TraceCompass` by selecting `File -> Open Trace` and select the `metadata` file.

For more details, please refer to [TraceCompass documentation](#).

Resolve framework symbols

Framework symbols need to be manually generated at the time the trace is collected. They are different than app-level symbols because the framework is pre-compiled while app code is just-in-time-compiled. For framework code that was precompiled to native code, you need to call `crossgen` that knows how to generate the mapping from the native code to the name of the methods.

`perfcollect` can handle most of the details for you, but it needs to have `crossgen` available. By default it is not installed with .NET distribution. If `crossgen` is not there, `perfcollect` warns you and refers you to these instructions. To fix things you need to fetch exactly the right version of crossgen for the runtime you are using. If you place the crossgen tool in the same directory as the .NET Runtime DLLs (for example, libcoreclr.so), then `perfcollect` can find it and add the framework symbols to the trace file for you.

Normally when you create a .NET application, it just generates the DLL for the code you wrote, using a shared copy of the runtime for the rest. However you can also generate what is called a 'self-contained' version of an application and this contains all runtime DLLs. `crossgen` is part of the NuGet package that is used to create self-

contained apps, so one way of getting the right version of `crossgen` is to create a self-contained package of your application.

For example:

```
mkdir helloWorld
cd helloWorld
dotnet new console
dotnet publish --self-contained -r linux-x64
```

This creates a new Hello World application and builds it as a self-contained app.

As a side effect of creating the self-contained application the dotnet tool will download a NuGet package called `runtime.linux-x64.microsoft.netcore.app` and place it in the directory `~/.nuget/packages/runtime.linux-x64.microsoft.netcore.app/VERSION`, where `VERSION` is the version number of your .NET Core runtime (for example, `2.1.0`). Under that is a tools directory and inside there is the `crossgen` tool you need. Starting with .NET Core 3.0, the package location is `~/.nuget/packages/microsoft.netcore.app.runtime.linux-x64/VERSION`.

The `crossgen` tool needs to be put next to the runtime that is actually used by your application. Typically your app uses the shared version of .NET Core that is installed at `/usr/share/dotnet/shared/Microsoft.NETCore.App/VERSION` where `VERSION` is the version number of the .NET Runtime. This is a shared location, so you need to be super-user to modify it. If the `VERSION` is `2.1.0` the commands to update `crossgen` would be:

```
sudo bash
cp ~/.nuget/packages/runtime.linux-x64.microsoft.netcore.app/2.1.0/tools/crossgen
/usr/share/dotnet/shared/Microsoft.NETCore.App/2.1.0
```

Once you have done this, `perfcollect` will use `crossgen` to include framework symbols. The warning that `perfcollect` used to issue should go away. This only has to be one once per machine (until you update your runtime).

Alternative: Turn off use of precompiled code

If you don't have the ability to update the .NET Runtime (to add `crossgen`), or if the above procedure did not work for some reason, there is another approach to getting framework symbols. You can tell the runtime to simply not use the precompiled framework code. The code will be Just-In-Time compiled and `crossgen` is not needed.

NOTE

Choosing this approach may increase the startup time for your application.

To do this, you can add the following environment variable:

```
export DOTNET_ZapDisable=1
```

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

With this change, you should get the symbols for all .NET code.

Get symbols for the native runtime

Most of the time you are interested in your own code, which `perfcollect` resolves by default. Sometimes it is useful to see what is going on inside the .NET DLLs (which is what the last section was about), but sometimes what is going on in the native runtime DLLs (typically `libcoreclr.so`), is interesting. `perfcollect` will resolve the symbols for these when it converts its data, but only if the symbols for these native DLLs are present (and are beside the library they are for).

There is a global command called `dotnet-symbol` that does this. To use `dotnet-symbol` to get native runtime symbols:

1. Install `dotnet-symbol`:

```
dotnet tool install -g dotnet-symbol
```

2. Download the symbols. If your installed version of the .NET Core runtime is 2.1.0, the command to do this is:

```
mkdir mySymbols  
dotnet symbol --symbols --output mySymbols  
/usr/share/dotnet/shared/Microsoft.NETCore.App/2.1.0/lib*.so
```

3. Copy the symbols to the correct place.

```
sudo cp mySymbols/* /usr/share/dotnet/shared/Microsoft.NETCore.App/2.1.0
```

If this cannot be done because you do not have write access to the appropriate directory, you can use `perf buildid-cache` to add the symbols.

After this, you should get symbolic names for the native DLLs when you run `perfcollect`.

Collect in a Docker container

For more information on how to use `perfcollect` in container environments, see [Collect diagnostics in containers](#).

Learn more about collection options

You can specify the following optional flags with `perfcollect` to better suit your diagnostic needs.

Collect for a specific duration

When you want to collect a trace for a specific duration, you can use `-collectsec` option followed by a number specifying the total seconds to collect a trace for.

Collect threadtime traces

Specifying `-threadtime` with `perfcollect` lets you collect per-thread CPU usage data. This lets you analyze where every thread was spending its CPU time.

Collect traces for managed memory and garbage collector performance

The following options let you specifically collect the GC events from the runtime.

- `perfcollect collect -gccollectonly`

Collect only a minimal set of GC Collection events. This is the least verbose GC eventing collection profile with the lowest impact on the target app's performance. This command is analogous to `PerfView.exe /GCCollectOnly collect` command in PerfView.

- `perfcollect collect -gconly`

Collect more verbose GC collection events with JIT, Loader, and Exception events. This requests more verbose events (such as the allocation information and GC join information) and will have more impact to the target app's performance than `-gccollectonly` option. This command is analogous to `PerfView.exe /GCOonly collect` command in PerfView.

- `perfcollect collect -gcwithheap`

Collect the most verbose GC collection events, which tracks the heap survival and movements as well. This gives in-depth analysis of the GC behavior but will incur high performance cost as each GC can take more than two times longer. It is recommended you understand the performance implication of using this trace option when tracing in production environments.

Debug a memory leak in .NET Core

9/20/2022 • 5 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

A memory leak may happen when your app references objects that it no longer needs to perform the desired task. Referencing said objects makes the garbage collector to be unable to reclaim the memory used, often resulting in performance degradation and potentially end up throwing an [OutOfMemoryException](#).

This tutorial demonstrates the tools to analyze a memory leak in a .NET Core app using the .NET diagnostics CLI tools. If you are on Windows, you may be able to [use Visual Studio's Memory Diagnostic tools](#) to debug the memory leak.

This tutorial uses a sample app, which is designed to intentionally leak memory. The sample is provided as an exercise. You can analyze an app that is unintentionally leaking memory too.

In this tutorial, you will:

- Examine managed memory usage with [dotnet-counters](#).
- Generate a dump file.
- Analyze the memory usage using the dump file.

Prerequisites

The tutorial uses:

- [.NET Core 3.1 SDK](#) or a later version.
- [dotnet-counters](#) to check managed memory usage.
- [dotnet-dump](#) to collect and analyze a dump file.
- A [sample debug target](#) app to diagnose.

The tutorial assumes the sample and tools are installed and ready to use.

Examine managed memory usage

Before you start collecting diagnostics data to help us root cause this scenario, you need to make sure you're actually seeing a memory leak (memory growth). You can use the [dotnet-counters](#) tool to confirm that.

Open a console window and navigate to the directory where you downloaded and unzipped the [sample debug target](#). Run the target:

```
dotnet run
```

From a separate console, find the process ID:

```
dotnet-counters ps
```

The output should be similar to:

```
4807 DiagnosticScena  
/home/user/git/samples/core/diagnostics/DiagnosticScenarios/bin/Debug/netcoreapp3.0/DiagnosticScenarios
```

Now, check managed memory usage with the `dotnet-counters` tool. The `--refresh-interval` specifies the number of seconds between refreshes:

```
dotnet-counters monitor --refresh-interval 1 -p 4807
```

The live output should be similar to:

```
Press p to pause, r to resume, q to quit.  
Status: Running  
  
[System.Runtime]  
# of Assemblies Loaded 118  
% Time in GC (since last GC) 0  
Allocation Rate (Bytes / sec) 37,896  
CPU Usage (%) 0  
Exceptions / sec 0  
GC Heap Size (MB) 4  
Gen 0 GC / sec 0  
Gen 0 Size (B) 0  
Gen 1 GC / sec 0  
Gen 1 Size (B) 0  
Gen 2 GC / sec 0  
Gen 2 Size (B) 0  
LOH Size (B) 0  
Monitor Lock Contention Count / sec 0  
Number of Active Timers 1  
ThreadPool Completed Work Items / sec 10  
ThreadPool Queue Length 0  
ThreadPool Threads Count 1  
Working Set (MB) 83
```

Focusing on this line:

GC Heap Size (MB)	4
-------------------	---

You can see that the managed heap memory is 4 MB right after startup.

Now, hit the URL `https://localhost:5001/api/diagscenario/memleak/20000`.

Observe that the memory usage has grown to 30 MB.

GC Heap Size (MB)	30
-------------------	----

By watching the memory usage, you can safely say that memory is growing or leaking. The next step is to collect the right data for memory analysis.

Generate memory dump

When analyzing possible memory leaks, you need access to the app's memory heap. Then you can analyze the memory contents. Looking at relationships between objects, you create theories on why memory isn't being freed. A common diagnostics data source is a memory dump on Windows or the equivalent core dump on Linux. To generate a dump of a .NET Core application, you can use the `dotnet-dump` tool.

Using the `sample debug target` previously started, run the following command to generate a Linux core dump:

```
dotnet-dump collect -p 4807
```

The result is a core dump located in the same folder.

```
Writing minidump with heap to ./core_20190430_185145
Complete
```

Restart the failed process

Once the dump is collected, you should have sufficient information to diagnose the failed process. If the failed process is running on a production server, now it's the ideal time for short-term remediation by restarting the process.

In this tutorial, you're now done with the [Sample debug target](#) and you can close it. Navigate to the terminal that started the server, and press **Ctrl+C**.

Analyze the core dump

Now that you have a core dump generated, use the [dotnet-dump](#) tool to analyze the dump:

```
dotnet-dump analyze core_20190430_185145
```

Where `core_20190430_185145` is the name of the core dump you want to analyze.

NOTE

If you see an error complaining that `/libdl.so` cannot be found, you may have to install the `/libc6-dev` package. For more information, see [Prerequisites for .NET Core on Linux](#).

You'll be presented with a prompt where you can enter SOS commands. Commonly, the first thing you want to look at is the overall state of the managed heap:

```
> dumpheap -stat

Statistics:
    MT      Count    TotalSize Class Name
...
00007f6c1eefba8      576        59904 System.Reflection.RuntimeMethodInfo
00007f6c1dc021c8     1749       95696 System.SByte[]
00000000008c9db0     3847      116080     Free
00007f6c1e784a18     175        128640 System.Char[]
00007f6c1dbf5510     217        133504 System.Object[]
00007f6c1dc014c0     467        416464 System.Byte[]
00007f6c21625038      6        4063376 testwebapi.Controllers.Customer[]
00007f6c20a67498    200000      4800000 testwebapi.Controllers.Customer
00007f6c1dc00f90    206770      19494060 System.String
Total 428516 objects
```

Here you can see that most objects are either `String` or `Customer` objects.

You can use the `dumpheap` command again with the method table (MT) to get a list of all the `String` instances:

```
> dumpheap -mt 00007faddaa50f90

Address          MT      Size
...
00007f6ad09421f8 00007faddaa50f90      94
...
00007f6ad0965b20 00007f6c1dc00f90      80
00007f6ad0965c10 00007f6c1dc00f90      80
00007f6ad0965d00 00007f6c1dc00f90      80
00007f6ad0965df0 00007f6c1dc00f90      80
00007f6ad0965ee0 00007f6c1dc00f90      80

Statistics:
MT      Count      TotalSize Class Name
00007f6c1dc00f90    206770      19494060 System.String
Total 206770 objects
```

You can now use the `gcroot` command on a `System.String` instance to see how and why the object is rooted. Be patient because this command takes several minutes with a 30-MB heap:

```
> gcroot -all 00007f6ad09421f8

Thread 3f68:
00007F6795BB58A0 00007F6C1D7D0745 System.Diagnostics.Tracing.CounterGroup.PollForValues()
[/_/src/System.Private.CoreLib/shared/System/Diagnostics/Tracing/CounterGroup.cs @ 260]
rbx: (interior)
-> 00007F6BDFFFF038 System.Object[]
-> 00007F69D0033570 testwebapi.Controllers.Processor
-> 00007F69D0033588 testwebapi.Controllers.CustomerCache
-> 00007F69D00335A0 System.Collections.Generic.List`1[[testwebapi.Controllers.Customer,
DiagnosticScenarios]]
-> 00007F6C000148A0 testwebapi.Controllers.Customer[]
-> 00007F6AD0942258 testwebapi.Controllers.Customer
-> 00007F6AD09421F8 System.String

HandleTable:
00007F6C98BB15F8 (pinned handle)
-> 00007F6BDFFFF038 System.Object[]
-> 00007F69D0033570 testwebapi.Controllers.Processor
-> 00007F69D0033588 testwebapi.Controllers.CustomerCache
-> 00007F69D00335A0 System.Collections.Generic.List`1[[testwebapi.Controllers.Customer,
DiagnosticScenarios]]
-> 00007F6C000148A0 testwebapi.Controllers.Customer[]
-> 00007F6AD0942258 testwebapi.Controllers.Customer
-> 00007F6AD09421F8 System.String

Found 2 roots.
```

You can see that the `String` is directly held by the `Customer` object and indirectly held by a `CustomerCache` object.

You can continue dumping out objects to see that most `String` objects follow a similar pattern. At this point, the investigation provided sufficient information to identify the root cause in your code.

This general procedure allows you to identify the source of major memory leaks.

Clean up resources

In this tutorial, you started a sample web server. This server should have been shut down as explained in the [Restart the failed process](#) section.

You can also delete the dump file that was created.

[Debug high CPU in .NET Core](#)

Debug high CPU usage in .NET Core

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

In this tutorial, you'll learn how to debug an excessive CPU usage scenario. Using the provided example [ASP.NET Core web app](#) source code repository, you can cause a deadlock intentionally. The endpoint will stop responding and experience thread accumulation. You'll learn how you can use various tools to diagnose this scenario with several key pieces of diagnostics data.

In this tutorial, you will:

- Investigate high CPU usage
- Determine CPU usage with [dotnet-counters](#)
- Use [dotnet-trace](#) for trace generation
- Profile performance in PerfView
- Diagnose and solve excessive CPU usage

Prerequisites

The tutorial uses:

- [.NET Core 3.1 SDK](#) or a later version.
- [Sample debug target](#) to trigger the scenario.
- [dotnet-trace](#) to list processes and generate a profile.
- [dotnet-counters](#) to monitor cpu usage.

CPU counters

Before attempting to collect diagnostics data, you need to observe a high CPU condition. Run the [sample application](#) using the following command from the project root directory.

```
dotnet run
```

To find the process ID, use the following command:

```
dotnet-trace ps
```

Take note of the process ID from your command output. Our process ID was `22884`, but yours will be different.

To check the current CPU usage, use the [dotnet-counters](#) tool command:

```
dotnet-counters monitor --refresh-interval 1 -p 22884
```

The `refresh-interval` is the number of seconds between the counter polling CPU values. The output should be similar to the following:

```
Press p to pause, r to resume, q to quit.
```

```
Status: Running
```

```
[System.Runtime]
```

% Time in GC since last GC (%)	0
Allocation Rate / 1 sec (B)	0
CPU Usage (%)	0
Exception Count / 1 sec	0
GC Heap Size (MB)	4
Gen 0 GC Count / 60 sec	0
Gen 0 Size (B)	0
Gen 1 GC Count / 60 sec	0
Gen 1 Size (B)	0
Gen 2 GC Count / 60 sec	0
Gen 2 Size (B)	0
LOH Size (B)	0
Monitor Lock Contention Count / 1 sec	0
Number of Active Timers	1
Number of Assemblies Loaded	140
ThreadPool Completed Work Item Count / 1 sec	3
ThreadPool Queue Length	0
ThreadPool Thread Count	7
Working Set (MB)	63

With the web app running, immediately after startup, the CPU isn't being consumed at all and is reported at `0%`. Navigate to the `api/diagscenario/highcpu` route with `60000` as the route parameter:

```
https://localhost:5001/api/diagscenario/highcpu/60000
```

Now, rerun the `dotnet-counters` command. If interested in monitoring just the `cpu-usage` counter, add '`--counters System.Runtime[cpu-usage]`' to the previous command. We are unsure if the CPU is being consumed, so we will monitor the same list of counters as above to verify counter values are within expected range for our application.

```
dotnet-counters monitor -p 22884 --refresh-interval 1
```

You should see an increase in CPU usage as shown below (depending on the host machine, expect varying CPU usage):

```
Press p to pause, r to resume, q to quit.
```

```
Status: Running
```

[System.Runtime]	
% Time in GC since last GC (%)	0
Allocation Rate / 1 sec (B)	0
CPU Usage (%)	25
Exception Count / 1 sec	0
GC Heap Size (MB)	4
Gen 0 GC Count / 60 sec	0
Gen 0 Size (B)	0
Gen 1 GC Count / 60 sec	0
Gen 1 Size (B)	0
Gen 2 GC Count / 60 sec	0
Gen 2 Size (B)	0
LOH Size (B)	0
Monitor Lock Contention Count / 1 sec	0
Number of Active Timers	1
Number of Assemblies Loaded	140
ThreadPool Completed Work Item Count / 1 sec	3
ThreadPool Queue Length	0
ThreadPool Thread Count	7
Working Set (MB)	63

Throughout the duration of the request, the CPU usage will hover around the increased percentage.

TIP

To visualize an even higher CPU usage, you can exercise this endpoint in multiple browser tabs simultaneously.

At this point, you can safely say the CPU is running higher than you expect. Identifying the effects of a problem is key to finding the cause. We will use the effect of high CPU consumption in addition to diagnostic tools to find the cause of the problem.

Analyze High CPU with Profiler

When analyzing an app with high CPU usage, you need a diagnostics tool that can provide insights into what the code is doing. The usual choice is a profiler, and there are different profiler options to choose from.

`dotnet-trace` can be used on all operating systems, however, its limitations of safe-point bias and managed-only callstacks result in more general information compared to a kernel-aware profiler like 'perf' for Linux or ETW for Windows. If your performance investigation involves only managed code, generally `dotnet-trace` will be sufficient.

- [Linux](#)
- [Windows](#)

The `perf` tool can be used to generate .NET Core app profiles. We will demonstrate this tool, although `dotnet-trace` could be used as well. Exit the previous instance of the [sample debug target](#).

Set the `DOTNET_PerfMapEnabled` environment variable to cause the .NET app to create a `map` file in the `/tmp` directory. This `map` file is used by `perf` to map CPU addresses to JIT-generated functions by name. For more information, see [Export perf maps](#).

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Run the [sample debug target](#) in the same terminal session.

```
export DOTNET_PerfMapEnabled=1  
dotnet run
```

Exercise the high CPU API endpoint (<https://localhost:5001/api/diagscenario/highcpu/60000>) again. While it's running within the 1-minute request, run the `perf` command with your process ID:

```
sudo perf record -p 2266 -g
```

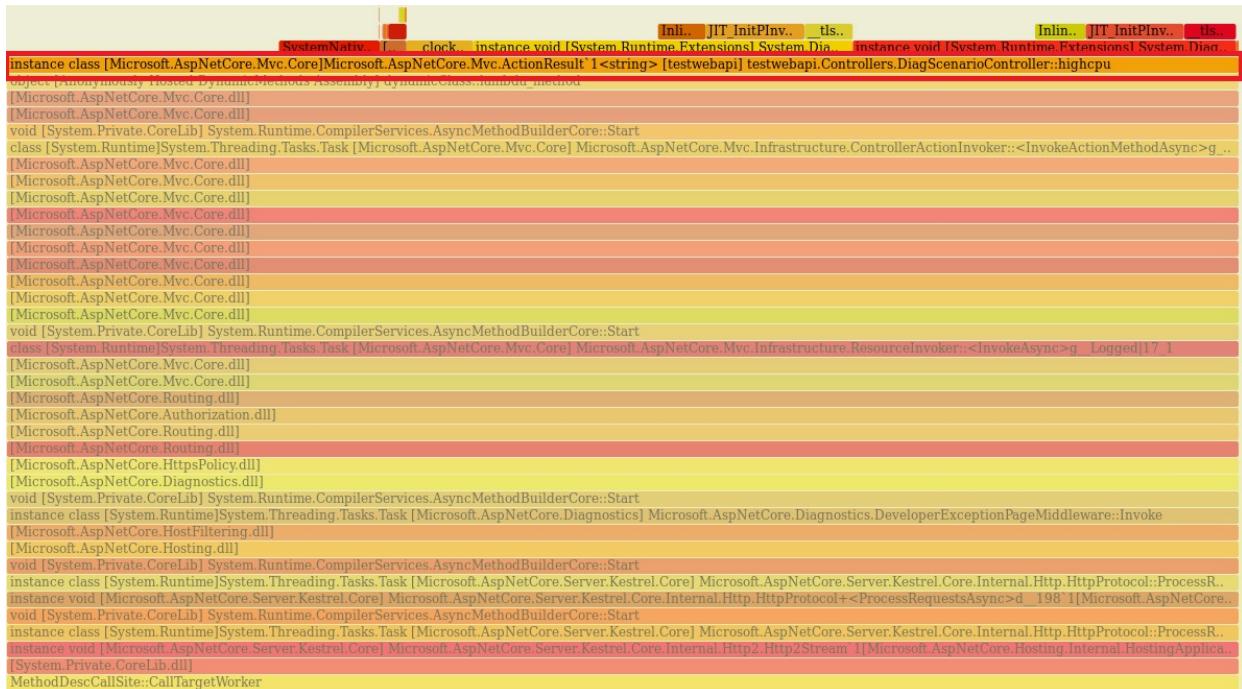

The `perf` command starts the performance collection process. Let it run for about 20-30 seconds, then press `Ctrl+C` to exit the collection process. You can use the same `perf` command to see the output of the trace.

```
sudo perf report -f
```

You can also generate a *flame-graph* by using the following commands:

```
git clone --depth=1 https://github.com/BrendanGregg/FlameGraph  
sudo perf script | FlameGraph/stackcollapse-perf.pl | FlameGraph/flamegraph.pl > flamegraph.svg
```

This command generates a `flamegraph.svg` that you can view in the browser to investigate the performance problem:

Analyzing High CPU Data with Visual Studio

All *.nettrace files can be analyzed in Visual Studio. To analyze a Linux *.nettrace file in Visual Studio, transfer the

*.nettrace file, in addition to the other necessary documents, to a Windows machine, and then open the *.nettrace file in Visual Studio. For more information, see [Analyze CPU Usage Data](#).

[Debug a deadlock in .NET Core](#)

Debug a deadlock in .NET Core

9/20/2022 • 6 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 SDK and later versions

In this tutorial, you'll learn how to debug a deadlock scenario. Using the provided example [ASP.NET Core web app](#) source code repository, you can cause a deadlock intentionally. The endpoint will stop responding and experience thread accumulation. You'll learn how you can use various tools to analyze the problem, such as core dumps, core dump analysis, and process tracing.

In this tutorial, you will:

- Investigate an app that has stopped responding
- Generate a core dump file
- Analyze process threads in the dump file
- Analyze callstacks and sync blocks
- Diagnose and solve a deadlock

Prerequisites

The tutorial uses:

- [.NET Core 3.1 SDK](#) or a later version
- [Sample debug target - web app](#) to trigger the scenario
- [dotnet-trace](#) to list processes
- [dotnet-dump](#) to collect, and analyze a dump file

Core dump generation

To investigate application unresponsiveness, a core dump or memory dump allows you to inspect the state of its threads and any possible locks that may have contention issues. Run the [sample debug](#) application using the following command from the sample root directory:

```
dotnet run
```

To find the process ID, use the following command:

```
dotnet-trace ps
```

Take note of the process ID from your command output. Our process ID was `4807`, but yours will be different. Navigate to the following URL, which is an API endpoint on the sample site:

```
https://localhost:5001/api/diagscenario/deadlock
```

The API request to the site will stop responding. Let the request run for about 10-15 seconds. Then create the core dump using the following command:

- [Linux](#)
- [Windows](#)

```
sudo dotnet-dump collect -p 4807
```

Analyze the core dump

To start the core dump analysis, open the core dump using the following `dotnet-dump analyze` command. The argument is the path to the core dump file that was collected earlier.

```
dotnet-dump analyze ~/.dotnet/tools/core_20190513_143916
```

Since you're looking at a potentially unresponsive application, you want an overall feel for the thread activity in the process. You can use the `threads` command as shown below:

```
> threads
*0 0x1DBFF (121855)
 1 0x1DC01 (121857)
 2 0x1DC02 (121858)
 3 0x1DC03 (121859)
 4 0x1DC04 (121860)
 5 0x1DC05 (121861)
 6 0x1DC06 (121862)
 7 0x1DC07 (121863)
 8 0x1DC08 (121864)
 9 0x1DC09 (121865)
10 0x1DC0A (121866)
11 0x1DC0D (121869)
12 0x1DC0E (121870)
13 0x1DC10 (121872)
14 0x1DC11 (121873)
15 0x1DC12 (121874)
16 0x1DC13 (121875)
17 0x1DC14 (121876)
18 0x1DC15 (121877)
19 0x1DC1C (121884)
20 0x1DC1D (121885)
21 0x1DC1E (121886)
22 0x1DC21 (121889)
23 0x1DC22 (121890)
24 0x1DC23 (121891)
25 0x1DC24 (121892)
26 0x1DC25 (121893)
...
...
317 0x1DD48 (122184)
318 0x1DD49 (122185)
319 0x1DD4A (122186)
320 0x1DD4B (122187)
321 0x1DD4C (122188)
```

The output shows all the threads currently running in the process with their associated debugger thread ID and operating system thread ID. Based on the output, there are over 300 threads.

The next step is to get a better understanding of what the threads are currently doing by getting each thread's callstack. The `clrstack` command can be used to output callstacks. It can either output a single callstack or all the callstacks. Use the following command to output all the callstacks for all the threads in the process:

```
clrstack -all
```

A representative portion of the output looks like:

...

...
...

```

Observing the callstacks for all 300+ threads shows a pattern where a majority of the threads share a common callstack:

```

OS Thread Id: 0x1dc88
    Child SP          IP Call Site
00007F2ADFFAE680 00007f305abc6360 [GCFrame: 00007f2adffae680]
00007F2ADFFAE770 00007f305abc6360 [GCFrame: 00007f2adffae770]
00007F2ADFFAE7D0 00007f305abc6360 [HelperMethodFrame_10B]: 00007f2adffae7d0]
System.Threading.Monitor.ReliableEnter(System.Object, Boolean ByRef)
00007F2ADFFAE920 00007F2FE392B31F testwebapi.Controllers.DiagScenarioController.<deadlock>b__3_1()
[/home/marioh/webapi/Controllers/diagscenario.cs @ 36]
00007F2ADFFAE950 00007F2FE392B46D
System.Threading.ExecutionContext.RunInternal(System.Threading.ExecutionContext,
System.Threading.ContextCallback, System.Object)
[/_w/3/s/src/System.Private.CoreLib/shared/System/Threading/ExecutionContext.cs @ 201]
00007F2ADFFAECA0 00007f30593044af [GCFrame: 00007f2adffaec0]
00007F2ADFFAED70 00007f30593044af [DebuggerU2MCatchHandlerFrame: 00007f2adffaed70]

```

The callstack seems to show that the request arrived in our deadlock method that in turn makes a call to `Monitor.ReliableEnter`. This method indicates that the threads are trying to enter a monitor lock. They're waiting on the availability of the lock. It's likely locked by a different thread.

The next step then is to find out which thread is actually holding the monitor lock. Since monitors typically store lock information in the sync block table, we can use the `syncblk` command to get more information:

```

> syncblk
Index      SyncBlock MonitorHeld Recursion Owning Thread Info      SyncBlock Owner
43 00000246E51268B8      603      1 0000024B713F4E30 5634 28  00000249654b14c0 System.Object
44 00000246E5126908      3      1 0000024B713F47E0 51d4 29  00000249654b14d8 System.Object
-----
Total      344
CCW       1
RCW       2
ComClassFactory 0
Free      0

```

The two interesting columns are **MonitorHeld** and **Owning Thread Info**. The **MonitorHeld** column shows whether a monitor lock is acquired by a thread and the number of waiting threads. The **Owning Thread Info** column shows which thread currently owns the monitor lock. The thread info has three different subcolumns. The second subcolumn shows operating system thread ID.

At this point, we know two different threads (0x5634 and 0x51d4) hold a monitor lock. The next step is to take a look at what those threads are doing. We need to check if they're stuck indefinitely holding the lock. Let's use the `setthread` and `clrstack` commands to switch to each of the threads and display the callstacks.

To look at the first thread, run the `setthread` command, and find the index of the 0x5634 thread (our index was 28). The deadlock function is waiting to acquire a lock, but it already owns the lock. It's in deadlock waiting for the lock it already holds.

```
> setthread 28
> clrstack
OS Thread Id: 0x5634 (28)
      Child SP          IP Call Site
0000004E46AFEEA8 00007fff43a5cbc4 [GCFrame: 0000004e46afeaa8]

0000004E46AFEF20 00007FFEBB234EAB System.Threading.ThreadHelper.ThreadStart()
[/_/src/System.Private.CoreLib/src/System/Threading/Thread.CoreCLR.cs @ 93]
0000004E46AFF138 00007ffebdcc6b63 [GCFrame: 0000004e46aff138]
0000004E46AFF3A0 00007ffebdcc6b63 [DebuggerU2MCatchHandlerFrame: 0000004e46aff3a0]
```

The second thread is similar. It's also trying to acquire a lock that it already owns. The remaining 300+ threads that are all waiting are most likely also waiting on one of the locks that caused the deadlock.

Debug ThreadPool Starvation

9/20/2022 • 9 minutes to read • [Edit Online](#)

This article applies to: ✓ .NET Core 3.1 and later versions

In this tutorial, you'll learn how to debug a ThreadPool starvation scenario. ThreadPool starvation occurs when the pool has no available threads to process new work items and it often causes applications to respond slowly. Using the provided example [ASP.NET Core web app](#), you can cause ThreadPool starvation intentionally and learn how to diagnose it.

In this tutorial, you will:

- Investigate an app that is responding to requests slowly
- Use the `dotnet-counters` tool to identify ThreadPool starvation is likely occurring
- Use the `dotnet-stack` tool to determine what work is keeping the ThreadPool threads busy

Prerequisites

The tutorial uses:

- [.NET Core 6.0 SDK](#) to build and run the sample app
- [Sample web app](#) to demonstrate ThreadPool starvation behavior
- [Bombardier](#) to generate load for the sample web app
- [dotnet-counters](#) to observe performance counters
- [dotnet-stack](#) to examine thread stacks

Running the sample app

1. Download the code for the [sample app](#) and build it using the .NET SDK:

```
E:\demo\DiagnosticScenarios>dotnet build
Microsoft (R) Build Engine version 17.1.1+a02f73656 for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
DiagnosticScenarios -> E:\demo\DiagnosticScenarios\bin\Debug\net6.0\DiagnosticScenarios.dll

Build succeeded.
  0 Warning(s)
  0 Error(s)

Time Elapsed 00:00:01.26
```

2. Run the app:

```
E:\demo\DiagnosticScenarios>bin\Debug\net6.0\DiagnosticScenarios.exe
info: Microsoft.Hosting.Lifetime[14]
      Now listening on: http://localhost:5000
info: Microsoft.Hosting.Lifetime[14]
      Now listening on: https://localhost:5001
info: Microsoft.Hosting.Lifetime[0]
      Application started. Press Ctrl+C to shut down.
info: Microsoft.Hosting.Lifetime[0]
      Hosting environment: Production
info: Microsoft.Hosting.Lifetime[0]
      Content root path: E:\demo\DiagnosticScenarios
```

If you use a web browser and send requests to `https://localhost:5001/api/diagscenario/taskwait`, you should see the response `success:taskwait` returned after about 500 ms. This shows that the web server is serving traffic as expected.

Observing slow performance

The demo web server has several endpoints which mock doing a database request and then returning a response to the user. Each of these endpoints has a delay of approximately 500 ms when serving requests one at a time but the performance is much worse when the web server is subjected to some load. Download the [Bombardier](#) load testing tool and observe the difference in latency when 125 concurrent requests are sent to each endpoint.

```
bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/taskwait
Bombarding https://localhost:5001/api/diagscenario/taskwait for 10s using 125 connection(s)
[=====] 10s
Done!
Statistics      Avg       Stdev       Max
  Req/sec      33.06     234.67    3313.54
  Latency       3.48s     1.39s     10.79s
HTTP codes:
  1xx - 0, 2xx - 454, 3xx - 0, 4xx - 0, 5xx - 0
  others - 0
Throughput:    75.37KB/s
```

This second endpoint uses a code pattern that performs even worse:

```
bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/tasksleepwait
Bombarding https://localhost:5001/api/diagscenario/tasksleepwait for 10s using 125 connection(s)
[=====] 10s
Done!
Statistics      Avg       Stdev       Max
  Req/sec      1.61      35.25    788.91
  Latency      15.42s    2.18s     18.30s
HTTP codes:
  1xx - 0, 2xx - 140, 3xx - 0, 4xx - 0, 5xx - 0
  others - 0
Throughput:    36.57KB/s
```

Both of these endpoints show dramatically more than the 500-ms average latency when load is high (3.48 s and 15.42 s respectively). If you run this example on an older version of .NET Core, you're likely to see both examples perform equally badly. .NET 6 has updated ThreadPool heuristics that reduce the performance impact of the bad coding pattern used in the first example.

Detecting ThreadPool starvation

If you observed the behavior above on a real world service, you would know it's responding slowly under load

but you wouldn't know the cause. [dotnet-counters](#) is a tool that can show live performance counters. These counters can provide clues about certain problems and are often easy to get. In production environments, you might have similar counters provided by remote monitoring tools and web dashboards. Install dotnet-counters and begin monitoring the web service:

```
dotnet-counters monitor -n DiagnosticScenarios
Press p to pause, r to resume, q to quit.
Status: Running

[System.Runtime]
% Time in GC since last GC (%) 0
Allocation Rate (B / 1 sec) 0
CPU Usage (%) 0
Exception Count (Count / 1 sec) 0
GC Committed Bytes (MB) 0
GC Fragmentation (%) 0
GC Heap Size (MB) 34
Gen 0 GC Count (Count / 1 sec) 0
Gen 0 Size (B) 0
Gen 1 GC Count (Count / 1 sec) 0
Gen 1 Size (B) 0
Gen 2 GC Count (Count / 1 sec) 0
Gen 2 Size (B) 0
IL Bytes Jitted (B) 279,021
LOH Size (B) 0
Monitor Lock Contention Count (Count / 1 sec) 0
Number of Active Timers 0
Number of Assemblies Loaded 121
Number of Methods Jitted 3,223
POH (Pinned Object Heap) Size (B) 0
ThreadPool Completed Work Item Count (Count / 1 sec) 0
ThreadPool Queue Length 0
ThreadPool Thread Count 1
Time spent in JIT (ms / 1 sec) 0.387
Working Set (MB) 87
```

The counters above are an example while the web server wasn't serving any requests. Run Bombardier again with the `api/diagscenario/tasksleepwait` endpoint and sustained load for 2 minutes so there's plenty of time to observe what happens to the performance counters.

```
bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/tasksleepwait -d 120s
```

ThreadPool starvation occurs when there are no free threads to handle the queued work items and the runtime responds by increasing the number of ThreadPool threads. You should observe the `ThreadPool Thread Count` rapidly increase to 2-3x the number of processor cores on your machine and then further threads are added 1-2 per second until eventually stabilizing somewhere above 125. The slow and steady increase of ThreadPool threads combined with CPU Usage much less than 100% are the key signals that ThreadPool starvation is currently a performance bottleneck. The thread count increase will continue until either the pool hits the maximum number of threads, enough threads have been created to satisfy all the incoming work items, or the CPU has been saturated. Often, but not always, ThreadPool starvation will also show large values for `ThreadPool Queue Length` and low values for `ThreadPool Completed Work Item Count`, meaning that there's a large amount of pending work and little work being completed. Here's an example of the counters while the thread count is still rising:

```
Press p to pause, r to resume, q to quit.
```

```
Status: Running
```

[System.Runtime]	
% Time in GC since last GC (%)	0
Allocation Rate (B / 1 sec)	24,480
CPU Usage (%)	0
Exception Count (Count / 1 sec)	0
GC Committed Bytes (MB)	56
GC Fragmentation (%)	40.603
GC Heap Size (MB)	89
Gen 0 GC Count (Count / 1 sec)	0
Gen 0 Size (B)	6,306,160
Gen 1 GC Count (Count / 1 sec)	0
Gen 1 Size (B)	8,061,400
Gen 2 GC Count (Count / 1 sec)	0
Gen 2 Size (B)	192
IL Bytes Jitted (B)	279,263
LOH Size (B)	98,576
Monitor Lock Contention Count (Count / 1 sec)	0
Number of Active Timers	124
Number of Assemblies Loaded	121
Number of Methods Jitted	3,227
POH (Pinned Object Heap) Size (B)	1,197,336
ThreadPool Completed Work Item Count (Count / 1 sec)	2
ThreadPool Queue Length	29
ThreadPool Thread Count	96
Time spent in JIT (ms / 1 sec)	0
Working Set (MB)	152

Once the count of ThreadPool threads stabilizes, the pool is no longer starving. But if it stabilizes at a high value (more than about three times the number of processor cores), that usually indicates the application code is blocking some ThreadPool threads and the ThreadPool is compensating by running with more threads. Running steady at high thread counts won't necessarily have large impacts on request latency, but if load varies dramatically over time or the app will be periodically restarted, then each time the ThreadPool is likely to enter a period of starvation where it's slowly increasing threads and delivering poor request latency. Each thread also consumes memory, so reducing the total number of threads needed provides another benefit.

Starting in .NET 6, ThreadPool heuristics were modified to scale up the number of ThreadPool threads much faster in response to certain blocking Task APIs. ThreadPool starvation can still occur with these APIs, but the duration is much briefer than it was with older .NET versions because the runtime responds more quickly. Run Bombardier again with the `api/diagscenario/taskwait` endpoint:

```
bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/taskwait -d 120s
```

On .NET 6 you should observe the pool increase the thread count more quickly than before and then stabilize at a high number of threads. ThreadPool starvation is occurring while the thread count is climbing.

Resolving ThreadPool starvation

To eliminate ThreadPool starvation, ThreadPool threads need to remain unblocked so that they're available to handle incoming work items. There are two ways to determine what each thread was doing, either using the `dotnet-stack` tool or capturing a dump with `dotnet-dump` that can be viewed in [Visual Studio](#). `dotnet-stack` can be faster because it shows the thread stacks immediately on the console, but Visual Studio dump debugging offers better visualizations that map frames to source, Just My Code can filter out runtime implementation frames, and the Parallel Stacks feature can help group large numbers of threads with similar stacks. This tutorial shows the `dotnet-stack` option. See the [diagnosing ThreadPool starvation tutorial video](#) for an example of investigating the thread stacks using Visual Studio.

Run Bombardier again to put the web server under load:

```
bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/taskwait -d 120s
```

Then run dotnet-stack to see the thread stack traces:

```
dotnet-stack report -n DiagnosticScenarios
```

You should see a long output containing a large number of stacks, many of which look like this:

```

am+<ReadAsyncInternal>d__27.MoveNext()
    System.Private.CoreLib.il!System.Threading.ExecutionContext.RunInternal(class
System.Threading.ExecutionContext, class System.Threading.ContextCallback, class System.Object)
    System.Private.CoreLib.il!System.Threading.ThreadPoolWorkQueue.Dispatch()
    System.Private.CoreLib.il!System.Threading.PortableThreadPool+WorkerThread.WorkerThreadStart()

```

The frames at the bottom of these stacks indicate that these threads are ThreadPool threads:

```

System.Private.CoreLib.il!System.Threading.ThreadPoolWorkQueue.Dispatch()
System.Private.CoreLib.il!System.Threading.PortableThreadPool+WorkerThread.WorkerThreadStart()

```

And the frames near the top reveal that the thread is blocked on a call to `GetResultCore(bool)` from the `DiagnosticScenarioController.TaskWait()` function:

```
Thread (0x25968):
[Native Frames]
System.Private.CoreLib.il!System.Threading.ManualResetEventSlim.Wait(int32,value class
System.Threading.CancellationToken)
System.Private.CoreLib.il!System.Threading.Tasks.Task.SpinThenBlockingWait(int32,value class
System.Threading.CancellationToken)
System.Private.CoreLib.il!System.Threading.Tasks.Task.InternalWaitCore(int32,value class
System.Threading.CancellationToken)
System.Private.CoreLib.il!System.Threading.Tasks.Task`1[System.__Canon].GetResultCore(bool)
DiagnosticScenarios!testwebapi.Controllers.DiagScenarioController.TaskWait()
```

Now you can navigate to the code for this controller in the sample app's *Controllers/DiagnosticScenarios.cs* file to see that it's calling an async API without using `await`. This is the [sync-over-async](#) code pattern, which is known to block threads and is the most common cause of ThreadPool starvation.

```
public ActionResult<string> TaskWait()
{
    // ...
    Customer c = PretendQueryCustomerFromDbAsync("Dana").Result;
    return "success:taskwait";
}
```

In this case the code can be readily changed to use the `async/await` instead as shown in the [TaskAsyncWait\(\)](#) endpoint. Using `await` allows the current thread to service other workitems while the database query is in progress. When the database lookup is complete a ThreadPool thread will resume execution. This way no thread is blocked in the code during each request:

```
public async Task<ActionResult<string>> TaskAsyncWait()
{
    // ...
    Customer c = await PretendQueryCustomerFromDbAsync("Dana");
    return "success:taskasyncwait";
}
```

Running Bombadier to send load to the [api/diagscenario/taskasyncwait](#) endpoint shows that the ThreadPool thread count stays much lower and average latency remains near 500ms when using the `async/await` approach:

```
>bombardier-windows-amd64.exe https://localhost:5001/api/diagscenario/taskasyncwait
Bombarding https://localhost:5001/api/diagscenario/taskasyncwait for 10s using 125 connection(s)
[=====] 10s
Done!
Statistics          Avg      Stdev      Max
  Req/sec       227.92     274.27   1263.48
  Latency       532.58ms    58.64ms    1.14s
HTTP codes:
  1xx - 0, 2xx - 2390, 3xx - 0, 4xx - 0, 5xx - 0
  others - 0
Throughput:    98.81KB/s
```

Debug StackOverflow errors

9/20/2022 • 2 minutes to read • [Edit Online](#)

A [StackOverflowException](#) is thrown when the execution stack overflows because it contains too many nested method calls.

For example, suppose you have an app as follows:

```
using System;

namespace temp
{
    class Program
    {
        static void Main(string[] args)
        {
            Main(args); // Oops, this recursion won't stop.
        }
    }
}
```

The `Main` method will continuously call itself until there is no more stack space. Once there is no more stack space, execution cannot continue and so it will throw a [StackOverflowException](#).

```
> dotnet run
Stack overflow.
```

NOTE

On .NET 5 and later, the callstack is output to the console.

NOTE

This article describes how to debug a stack overflow with lldb. If you are running on Windows, we suggest debugging the app with [Visual Studio](#) or [Visual Studio Code](#).

Example

1. Run the app with it configured to collect a dump on crash

```
> export DOTNET_DbEnableMiniDump=1
> dotnet run
Stack overflow.
Writing minidump with heap to file /tmp/coredump.6412
Written 58191872 bytes (14207 pages) to core file
```

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

2. Install the SOS extension using `dotnet-sos`

```
dotnet-sos install
```

3. Debug the dump in lldb to see the failing stack

```
lldb --core /temp/coredump.6412
(lldb) bt
...
frame #261930: 0x00007f59b40900cc

Overview of .NET source code analysis

9/20/2022 • 7 minutes to read • [Edit Online](#)

.NET compiler platform (Roslyn) analyzers inspect your C# or Visual Basic code for code quality and style issues. Starting in .NET 5, these analyzers are included with the .NET SDK and you don't need to install them separately. If your project targets .NET 5 or later, code analysis is enabled by default. If your project targets a different .NET implementation, for example, .NET Core, .NET Standard, or .NET Framework, you must manually enable code analysis by setting the `EnableNETAnalyzers` property to `true`.

If you don't want to move to the .NET 5+ SDK, have a non-SDK-style .NET Framework project, or prefer a NuGet package-based model, the analyzers are also available in the [Microsoft.CodeAnalysis.NetAnalyzers NuGet package](#). You might prefer a package-based model for on-demand version updates.

NOTE

.NET analyzers are target-framework agnostic. That is, your project does not need to target a specific .NET implementation. The analyzers work for projects that target .NET 5+ as well as earlier .NET versions, such as .NET Core 3.1 and .NET Framework 4.7.2. However, to enable code analysis using the `EnableNETAnalyzers` property, your project must reference a [project SDK](#).

If rule violations are found by an analyzer, they're reported as a suggestion, warning, or error, depending on how each rule is [configured](#). Code analysis violations appear with the prefix "CA" or "IDE" to differentiate them from compiler errors.

Code quality analysis

Code quality analysis ("CAxxxx") rules inspect your C# or Visual Basic code for security, performance, design and other issues. Analysis is enabled, by default, for projects that target .NET 5 or later. You can enable code analysis on projects that target earlier .NET versions by setting the `EnableNETAnalyzers` property to `true`. You can also disable code analysis for your project by setting `EnableNETAnalyzers` to `false`.

TIP

If you're using Visual Studio, many analyzer rules have associated *code fixes* that you can apply to correct the problem. Code fixes are shown in the light bulb icon menu.

Enabled rules

The following rules are enabled, by default, in .NET 6.

DIAGNOSTIC ID	CATEGORY	SEVERITY	DESCRIPTION
CA1416	Interoperability	Warning	Platform compatibility analyzer
CA1417	Interoperability	Warning	Do not use <code>OutAttribute</code> on string parameters for P/Invokes
CA1418	Interoperability	Warning	Use valid platform string
CA1831	Performance	Warning	Use <code>AsSpan</code> instead of range-based indexers for string when appropriate

DIAGNOSTIC ID	CATEGORY	SEVERITY	DESCRIPTION
CA2013	Reliability	Warning	Do not use <code>ReferenceEquals</code> with value types
CA2014	Reliability	Warning	Do not use <code>stackalloc</code> in loops
CA2015	Reliability	Warning	Do not define finalizers for types derived from <code>MemoryManager<T></code>
CA2017	Reliability	Warning	Parameter count mismatch
CA2018	Reliability	Warning	The <code>count</code> argument to <code>Buffer.BlockCopy</code> should specify the number of bytes to copy
CA2200	Usage	Warning	Rethrow to preserve stack details
CA2252	Usage	Error	Opt in to preview features
CA2247	Usage	Warning	Argument passed to <code>TaskCompletionSource</code> constructor should be <code>TaskCreationOptions</code> enum instead of <code>TaskContinuationOptions</code>
CA2255	Usage	Warning	The <code>ModuleInitializer</code> attribute should not be used in libraries
CA2256	Usage	Warning	All members declared in parent interfaces must have an implementation in a <code>DynamicInterfaceCastableImplementation</code> -attributed interface
CA2257	Usage	Warning	Members defined on an interface with the <code>DynamicInterfaceCastableImplementationAttribute</code> should be <code>static</code>
CA2258	Usage	Warning	Providing a <code>DynamicInterfaceCastableImplementation</code> interface in Visual Basic is unsupported

You can change the severity of these rules to disable them or elevate them to errors. You can also [enable more rules](#).

- For a list of rules that are included with each .NET SDK version, see [Analyzer releases](#).
- For a list of all the code quality rules, see [Code quality rules](#).

Enable additional rules

Analysis mode refers to a predefined code analysis configuration where none, some, or all rules are enabled. In the default analysis mode, only a small number of rules are [enabled as build warnings](#). You can change the analysis mode for your project by setting the `<AnalysisMode>` property in the project file. The allowable values are:

- None
- Default
- Minimum
- Recommended
- All

Starting in .NET 6, you can omit `<AnalysisMode>` in favor of a compound value for the `<AnalysisLevel>` property. For example, the following value enables the recommended set of rules for the latest release:

`<AnalysisLevel>latest-Recommended</AnalysisLevel>`. For more information, see [AnalysisLevel](#).

To find the default severity for each available rule and whether or not the rule is enabled in the default analysis mode, see the [full list of rules](#).

Treat warnings as errors

If you use the `-warnaserror` flag when you build your projects, all code analysis warnings are also treated as errors. If you do not want code quality warnings (CAxxxx) to be treated as errors in presence of `-warnaserror`, you can set the `CodeAnalysisTreatWarningsAsErrors` MSBuild property to `false` in your project file.

```
<PropertyGroup>
  <CodeAnalysisTreatWarningsAsErrors>false</CodeAnalysisTreatWarningsAsErrors>
</PropertyGroup>
```

You'll still see any code analysis warnings, but they won't break your build.

Latest updates

By default, you'll get the latest code analysis rules and default rule severities as you upgrade to newer versions of the .NET SDK. If you don't want this behavior, for example, if you want to ensure that no new rules are enabled or disabled, you can override it in one of the following ways:

- Set the `AnalysisLevel` MSBuild property to a specific value to lock the warnings to that set. When you upgrade to a newer SDK, you'll still get bug fixes for those warnings, but no new warnings will be enabled and no existing warnings will be disabled. For example, to lock the set of rules to those that ship with version 5.0 of the .NET SDK, add the following entry to your project file.

```
<PropertyGroup>
  <AnalysisLevel>5.0</AnalysisLevel>
</PropertyGroup>
```

TIP

The default value for the `AnalysisLevel` property is `latest`, which means you always get the latest code analysis rules as you move to newer versions of the .NET SDK.

For more information, and to see a list of possible values, see [AnalysisLevel](#).

- Install the [Microsoft.CodeAnalysis.NetAnalyzers NuGet package](#) to decouple rule updates from .NET SDK updates. For projects that target .NET 5+, installing the package turns off the built-in SDK analyzers. You'll get a build warning if the SDK contains a newer analyzer assembly version than that of the NuGet package. To disable the warning, set the `_SkipUpgradeNetAnalyzersNuGetWarning` property to `true`.

NOTE

If you install the Microsoft.CodeAnalysis.NetAnalyzers NuGet package, you should not add the `EnableNETAnalyzers` property to either your project file or a `Directory.Build.props` file. When the NuGet package is installed and the `EnableNETAnalyzers` property is set to `true`, a build warning is generated.

Code-style analysis

Code-style analysis ("IDExxxx") rules enable you to define and maintain consistent code style in your codebase. The default enablement settings are:

- Command-line build: Code-style analysis is disabled, by default, for all .NET projects on command-line builds.

Starting in .NET 5, you can [enable code-style analysis on build](#), both at the command line and inside Visual Studio. Code style violations appear as warnings or errors with an "IDE" prefix. This enables you to enforce consistent code styles at build time.
- Visual Studio: Code-style analysis is enabled, by default, for all .NET projects inside Visual Studio as [code refactoring quick actions](#).

For a full list of code-style analysis rules, see [Code style rules](#).

Enable on build

With the .NET 5 SDK and later versions, you can enable code-style analysis when building from the command-line and in Visual Studio. (However, for performance reasons, [a handful of code-style rules](#) will still apply only in the Visual Studio IDE.)

Follow these steps to enable code-style analysis on build:

1. Set the MSBuild property `EnforceCodeStyleInBuild` to `true`.
2. In an `.editorconfig` file, [configure](#) each "IDE" code style rule that you wish to run on build as a warning or an error. For example:

```
[*.{cs,vb}]
# IDE0040: Accessibility modifiers required (escalated to a build warning)
dotnet_diagnostic.IDE0040.severity = warning
```

Alternatively, you can configure an entire category to be a warning or error, by default, and then selectively turn off rules in that category that you don't want to run on build. For example:

```
[*.{cs,vb}]
# Default severity for analyzer diagnostics with category 'Style' (escalated to build warnings)
dotnet_analyzer_diagnostic.category-Style.severity = warning

# IDE0040: Accessibility modifiers required (disabled on build)
dotnet_diagnostic.IDE0040.severity = silent
```

NOTE

The code-style analysis feature is experimental and may change between the .NET 5 and .NET 6 releases.

Suppress a warning

One way to suppress a rule violation is to set the severity option for that rule ID to `none` in an EditorConfig file. For example:

```
dotnet_diagnostic.CA1822.severity = none
```

For more information and other ways to suppress warnings, see [How to suppress code analysis warnings](#).

Run code analysis as a GitHub Action

The [dotnet/code-analysis](#) GitHub Action lets you run .NET code analyzers as part of continuous integration (CI) in an offline mode. For more information, see [.NET code analysis GitHub Action](#).

Third-party analyzers

In addition to the official .NET analyzers, you can also install third party analyzers, such as [StyleCop](#), [Roslynator](#), [XUnit Analyzers](#), and [Sonar Analyzer](#).

Configuration options for code analysis

9/20/2022 • 5 minutes to read • [Edit Online](#)

Code analysis rules have various configuration options. Some of these options are specified as key-value pairs in an [analyzer configuration file](#) using the syntax `<option key> = <option value>`. Other options, which configure code analysis as a whole, are available as properties in your project file.

The most common option you'll configure is a [rule's severity](#). You can configure the severity level for any rule, including [code quality rules](#) and [code style rules](#). For example, to enable a rule as a warning, add the following key-value pair to an [analyzer configuration file](#):

```
dotnet_diagnostic.<rule ID>.severity = warning
```

You can also configure additional options to customize rule behavior:

- Code quality rules have [options](#) to configure behavior, such as which method names a rule should apply to.
- Code style rules have [options](#) to define style preferences, such as where new lines are desirable.
- Third-party analyzer rules can define their own configuration options, with custom key names and value formats.

General options

These options apply to code analysis as a whole. They cannot be applied only to a specific rule.

- [Analysis mode](#)
- [Enable code analysis](#)
- [Exclude generated code](#)

For additional options, see [Code analysis properties](#).

Enable code analysis

Code analysis is enabled by default for projects that target .NET 5 and later versions. If you have the .NET 5+ SDK but your project targets a different .NET implementation, you can manually enable code analysis by setting the [EnableNETAnalyzers](#) property in your project file to `true`.

```
<PropertyGroup>
  <EnableNETAnalyzers>true</EnableNETAnalyzers>
</PropertyGroup>
```

Analysis mode

While the .NET SDK includes all code analysis rules, only some of them are enabled by default. The *analysis mode* determines which, if any, set of rules is enabled. You can choose a more aggressive analysis mode where most or all rules are enabled, or a more conservative analysis mode where most or all rules are disabled and, you can then opt in to specific rules as needed. Set your analysis mode by adding the [AnalysisMode](#) property to your project file.

```
<PropertyGroup>
  <AnalysisMode>Recommended</AnalysisMode>
</PropertyGroup>
```

Exclude generated code

.NET code analyzer warnings aren't useful on generated code files, such as designer-generated files, which users can't edit to fix any violations. In most cases, code analyzers skip generated code files and don't report violations on these files.

By default, files with certain file extensions or auto-generated file headers are treated as generated code files. For example, a file name ending with `.designer.cs` or `.generated.cs` is considered generated code. This configuration option lets you specify additional naming patterns to be treated as generated code. You configure additional files and folders by adding a `generated_code = true | false` entry to your [configuration file](#). For example, to treat all files whose name ends with `.MyGenerated.cs` as generated code, add the following entry:

```
[*.MyGenerated.cs]  
generated_code = true
```

Rule-specific options

Rule-specific options can be applied to a single rule, a set of rules, or all rules. The rule-specific options include:

- [Rule severity level](#)
- [Options specific to *code-quality* rules](#)

Severity level

The following table shows the different rule severities that you can configure for all analyzer rules, including [code quality](#) and [code style](#) rules.

SEVERITY CONFIGURATION VALUE	BUILD-TIME BEHAVIOR
<code>error</code>	Violations appear as build <i>errors</i> and cause builds to fail.
<code>warning</code>	Violations appear as build <i>warnings</i> but do not cause builds to fail (unless you have an option set to treat warnings as errors).
<code>suggestion</code>	Violations appear as build <i>messages</i> and as suggestions in the Visual Studio IDE.
<code>silent</code>	Violations aren't visible to the user.
<code>none</code>	Rule is suppressed completely.
<code>default</code>	The default severity of the rule is used. The default severities for each .NET release are listed in the roslyn-analyzers repo . In that table, "Disabled" corresponds to <code>none</code> , "Hidden" corresponds to <code>silent</code> , and "Info" corresponds to <code>suggestion</code> .

TIP

For information about how rule severities surface in Visual Studio, see [Severity levels](#).

Scope

- [Single rule](#)

To set the rule severity for a single rule, use the following syntax.

```
dotnet_diagnostic.<rule ID>.severity = <severity value>
```

- **Category of rules**

To set the default rule severity for a category of rules, use the following syntax. However, this severity setting only affects rules in that category that are enabled by default.

```
dotnet_analyzer_diagnostic.category-<rule category>.severity = <severity value>
```

The different categories are listed and described at [Rule categories](#). In addition, you can find the category for a specific rule on its reference page, for example, [CA1000](#).

- **All rules**

To set the default rule severity for all analyzer rules, use the following syntax. However, this severity setting only affects rules that are enabled by default.

```
dotnet_analyzer_diagnostic.severity = <severity value>
```

IMPORTANT

When you configure the severity level for multiple rules with a single entry, either for a *category* of rules or for *all* rules, the severity only applies to rules that are [enabled by default](#). To enable rules that are disabled by default, you must either:

- Add an explicit `dotnet_diagnostic.<rule ID>.severity = <severity>` configuration entry for each rule.
- In .NET 6+, enable a category of rules by setting `<AnalysisMode<Category>>` to `A11`.
- Enable *all* rules by setting `<AnalysisMode>` to `A11` or by setting `<AnalysisLevel>` to `latest-A11`.

NOTE

The prefix for setting severity for a single rule, `dotnet_diagnostic`, is slightly different than the prefix for configuring severity via category or for all rules, `dotnet_analyzer_diagnostic`.

Precedence

If you have multiple severity configuration entries that can be applied to the same rule ID, precedence is chosen in the following order:

- An entry for an individual rule by ID takes precedence over an entry for a category.
- An entry for a category takes precedence over an entry for all analyzer rules.

Consider the following example, where [CA1822](#) has the category "Performance":

```
[*.cs]
dotnet_diagnostic.CA1822.severity = error
dotnet_analyzer_diagnostic.category-performance.severity = warning
dotnet_analyzer_diagnostic.severity = suggestion
```

In the preceding example, all three severity entries are applicable to CA1822. However, using the specified precedence rules, the first rule ID-based entry wins over the next entries. In this example, CA1822 will have an effective severity of `error`. All other rules within the "Performance" category will have a severity of `warning`.

For information about how inter-file precedence is decided, see the [Precedence section of the Configuration files](#)

article.

Configuration files for code analysis rules

9/20/2022 • 5 minutes to read • [Edit Online](#)

Code analysis rules have various [configuration options](#). You specify these options as key-value pairs in one of the following analyzer configuration files:

- [EditorConfig](#) file: File-based or folder-based configuration options.
- [Global AnalyzerConfig](#) file: Project-level configuration options. Useful when some project files reside outside the project folder.

TIP

You can also set code analysis configuration properties in your project file. These properties configure code analysis at the bulk level, from completely turning it on or off down to category-level configuration. For more information, see [EnableNETAnalyzers](#), [AnalysisLevel](#), [AnalysisLevel<Category>](#), and [AnalysisMode](#).

EditorConfig

[EditorConfig](#) files are used to provide **options that apply to specific source files or folders**. Options are placed under section headers to identify the applicable files and folders. Add an entry for each rule you want to configure, and place it under the corresponding file extension section, for example, `[*.cs]`.

```
[*.cs]
<option_name> = <option_value>
```

In the above example, `[*.cs]` is an editorconfig section header to select all C# files with `.cs` file extension within the current folder, including subfolders. The subsequent entry, `<option_name> = <option_value>`, is an analyzer option that will be applied to all the C# files.

You can apply EditorConfig file conventions to a folder, a project, or an entire repo by placing the file in the corresponding directory. These options are applied when executing the analysis at build time and while you edit code in Visual Studio.

NOTE

EditorConfig options apply only to *source* files in a project or directory. Files that are included in a project as [AdditionalFiles](#) are not considered *source* files, and EditorConfig options aren't applied to these files. To apply a rule option to non-source files, specify the option in a [global configuration file](#).

If you have an existing `.editorconfig` file for editor settings such as indent size or whether to trim trailing whitespace, you can place your code analysis configuration options in the same file.

TIP

Visual Studio provides an `.editorconfig` item template that makes it easy to add one of these files to your project. For more information, see [Add an EditorConfig file to a project](#).

Example

Following is an example EditorConfig file to configure options and rule severity:

```
# Remove the line below if you want to inherit .editorconfig settings from higher directories
root = true

# C# files
[*.cs]

##### Core EditorConfig Options #####
# Indentation and spacing
indent_size = 4
indent_style = space
tab_width = 4

##### .NET Coding Conventions #####
# this. and Me. preferences
dotnet_style_qualification_for_method = true

##### Diagnostic configuration #####
# CA1000: Do not declare static members on generic types
dotnet_diagnostic.CA1000.severity = warning
```

Global AnalyzerConfig

Starting with the .NET 5 SDK (which is supported in Visual Studio 2019 version 16.8 and later), you can also configure analyzer options with global *AnalyzerConfig* files. These files are used to provide **options that apply to all the source files in a project**, regardless of their file names or file paths.

Unlike [EditorConfig](#) files, global configuration files can't be used to configure editor style settings for IDEs, such as indent size or whether to trim trailing whitespace. Instead, they are designed purely for specifying project-level analyzer configuration options.

Format

Unlike EditorConfig files, which must have section headers, such as `[*.cs]`, to identify the applicable files and folders, global AnalyzerConfig files don't have section headers. Instead, they require a top level entry of the form `is_global = true` to differentiate them from regular EditorConfig files. This indicates that all the options in the file apply to the entire project. For example:

```
is_global = true
<option_name> = <option_value>
```

Naming

Unlike EditorConfig files, which must be named `.editorconfig`, global config files do not need to have a specific name or extension. However, if you name these files as `.globalconfig`, then they are implicitly applied to all the C# and Visual Basic projects within the current folder, including subfolders. Otherwise, you must explicitly add the `GlobalAnalyzerConfigFiles` item to your MSBuild project file:

```
<ItemGroup>
  <GlobalAnalyzerConfigFiles Include="<path_to_global_analyzer_config>＂ />
</ItemGroup>
```

Consider the following naming recommendations:

- End users should name their global configuration files `.globalconfig`.

- NuGet package creators should name their global config files `<%Package_Name%>.globalconfig`.
- MSBuild tooling-generated global config files should be named `<%Target_Name%>_Generated.globalconfig` or similar.

NOTE

The top-level entry `is_global = true` is not required when the file is named `.globalconfig`, but it is recommended for clarity.

Example

Following is an example global AnalyzerConfig file to configure options and rule severity at the project level:

```
# Top level entry required to mark this as a global AnalyzerConfig file
is_global = true

# NOTE: No section headers for configuration entries

#### .NET Coding Conventions ####

# this. and Me. preferences
dotnet_style_qualification_for_method = true:warning

#### Diagnostic configuration ####

# CA1000: Do not declare static members on generic types
dotnet_diagnostic.CA1000.severity = warning
```

Precedence

Both EditorConfig files and global AnalyzerConfig files specify a key-value pair for each option. Conflicts arise when there are multiple entries with the same key but different values. The following precedence rules are used to resolve conflicts.

CONFLICTING ENTRY LOCATIONS	PRECEDENCE RULE
In the same configuration file	The entry that appears later in the file wins. This is true for conflicting entries within a single EditorConfig file and also within a single global AnalyzerConfig file.
In two EditorConfig files	The entry in the EditorConfig file that's deeper in the file system, and hence has a longer file path, wins.
In two global AnalyzerConfig files	<p>.NET 5: A compiler warning is reported and both entries are ignored.</p> <p>.NET 6 and later versions: The entry from the file with a higher value for <code>global_level</code> takes precedence. If <code>global_level</code> isn't explicitly defined and the file is named <code>.globalconfig</code>, the <code>global_level</code> value defaults to <code>100</code>; for all other global AnalyzerConfig files, <code>global_level</code> defaults to <code>0</code>. If the <code>global_level</code> values for the configuration files with conflicting entries are equal, a compiler warning is reported and both entries are ignored.</p>
In an EditorConfig file and a Global AnalyzerConfig file	The entry in the EditorConfig file wins.

Severity options

For [severity configuration](#) options, the following *additional* precedence rules apply:

- Severity options specified at the command line as compiler options (`-nowarn` or `-warnaserror`) always override [severity configuration](#) options specified in EditorConfig and global AnalyzerConfig files.
- The precedence rules for conflicting severity entries from a [ruleset file](#) and an EditorConfig or global AnalyzerConfig file is *undefined*.

Ruleset files are deprecated in favor of EditorConfig and global AnalyzerConfig files. We recommend that you [convert ruleset files to an equivalent EditorConfig file](#).

- For information about precedence rules for related severity options with different keys, for example, when different severities are specified for a single rule and for the category that rule falls under, see [Configuration options for code analysis](#).

See also

- [EditorConfig vs global AnalyzerConfig design issue](#)

How to suppress code analysis warnings

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article covers the various ways you can suppress warnings from code analysis when you build your .NET app. You can suppress code quality rules, code style rules, and third-party analyzer rules using the information provided here.

TIP

If you're using Visual Studio as your development environment, the *light bulb* menu provides options that generate the code to suppress warnings for you. For more information, see [Suppress violations](#).

Disable the rule

By disabling the code analysis rule that's causing the warning, you disable the rule for your entire file or project (depending on the scope of the [configuration file](#) that you use). To disable the rule, set its severity to `none` in the configuration file.

```
[*.{cs,vb}]\ndotnet_diagnostic.<rule-ID>.severity = none
```

For more information about rule severities, see [Configure rule severity](#).

Use a preprocessor directive

Use a [#pragma warning \(C#\)](#) or [Disable \(Visual Basic\)](#) directive to suppress the warning for only a specific line of code.

```
try { ... }\ncatch (Exception e)\n{\n#pragma warning disable CA2200 // Rethrow to preserve stack details\n    throw e;\n#pragma warning restore CA2200 // Rethrow to preserve stack details\n}
```

```
Try\n...\nCatch e As Exception\n#Disable Warning CA2200 ' Rethrow to preserve stack details\n    Throw e\n#Enable Warning CA2200 ' Rethrow to preserve stack details\nEnd Try
```

Use the SuppressMessageAttribute

You can use a [SuppressMessageAttribute](#) to suppress a warning either in the source file or in a global suppressions file for the project (*GlobalSuppressions.cs* or *GlobalSuppressions.vb*). This attribute provides a way to suppress a warning in only certain parts of your project or file.

The two required, positional parameters for the `SuppressMessageAttribute` attribute are the *category* of the rule and the *rule ID*. The following code snippet passes "Usage" and "CA2200:Rethrow to preserve stack details" for these parameters.

```
[System.Diagnostics.CodeAnalysis.SuppressMessage("Usage", "CA2200:Rethrow to preserve stack details",
Justification = "Not production code.")]
private static void IgnorableCharacters()
{
    try
    {
        ...
    }
    catch (Exception e)
    {
        throw e;
    }
}
```

If you add the attribute to the global suppressions file, you *scope* the suppression to the desired level, for example "member". You specify the API where the warning should be suppressed using the `Target` property.

```
[assembly: SuppressMessage("Usage", "CA2200:Rethrow to preserve stack details", Justification = "Not
production code.", Scope = "member", Target = "~M:MyApp.Program.IgnorableCharacters")]
```

Use the *documentation ID* for the API you want to reference in the `Target` attribute. For information about documentation IDs, see [Documentation ID format](#).

To suppress warnings for compiler-generated code that doesn't map to explicitly provided user source, you must put the suppression attribute in a global suppressions file. For example, the following code suppresses a violation against a compiler-emitted constructor:

```
[module: SuppressMessage("Design", "CA1055:AbstractTypesDoNotHavePublicConstructors", Scope="member",
Target="MyTools.Type..ctor")]
```

See also

- [Suppress violations \(Visual Studio\)](#)

Code quality rule configuration options

9/20/2022 • 5 minutes to read • [Edit Online](#)

The *code quality* rules have additional configuration options, besides just [configuring their severity](#). For example, each code quality analyzer can be configured to only apply to specific parts of your codebase. You specify these options by adding key-value pairs to the same [EditorConfig](#) file where you specify rule severities and general editor preferences.

NOTE

This article does not detail how to configure a rule's severity. The `.editorconfig` option to set a rule's severity has a different prefix (`dotnet_diagnostic`) to the options described here (`dotnet_code_quality`). In addition, the options described here pertain to code quality rules only, whereas the severity option applies to code style rules as well. As a quick reference, you can configure a rule's severity using the following option syntax:

```
dotnet_diagnostic.<rule ID>.severity = <severity value>
```

However, for detailed information about configuring rule severity, see [Severity level](#).

Option scopes

Each refining option can be configured for all rules, for a category of rules (for example, Security or Design), or for a specific rule.

All rules

The syntax for configuring an option for *all*/rules is as follows:

SYNTAX	EXAMPLE
<code>dotnet_code_quality.<OptionName> = <OptionValue></code>	<code>dotnet_code_quality.api_surface = public</code>

The values for `<OptionName>` are listed under [Options](#).

Category of rules

The syntax for configuring an option for a *category of rules* is as follows:

SYNTAX	EXAMPLE
<code>dotnet_code_quality.<RuleCategory>.<OptionName> = OptionValue</code>	<code>dotnet_code_quality.Naming.api_surface = public</code>

The following table lists the available values for `<RuleCategory>`.

Design

Documentation

Globalization

Interoperability

Maintainability

Naming

Performance

SingleFile

Reliability

Security

Usage

Specific rule

The syntax for configuring an option for a *specific* rule is as follows:

SYNTAX	EXAMPLE
<code>dotnet_code_quality.<RuleId>.<OptionName> = <OptionValue></code>	<code>dotnet_code_quality.CA1040.api_surface = public</code>

Options

This section lists some of the available options. To see the full list of available options, see [Analyzer configuration](#).

- [api_surface](#)
- [exclude_async_void_methods](#)
- [exclude_single_letter_type_parameters](#)

api_surface

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Which part of the API surface to analyze	<input type="checkbox"/> public <input type="checkbox"/> internal or <input type="checkbox"/> friend <input type="checkbox"/> private <input type="checkbox"/> all	<input type="checkbox"/> public	CA1000 CA1002 CA1003 CA1005 CA1008 CA1010 CA1012 CA1021 CA1024 CA1027 CA1028 CA1030 CA1036 CA1040 CA1041 CA1043 CA1044 CA1045 CA1046 CA1047 CA1051 CA1052 CA1054 CA1055 CA1056 CA1058 CA1062 CA1063 CA1068 CA1070 CA1700 CA1707 CA1708 CA1710 CA1711 CA1714 CA1715 CA1716 CA1717 CA1720 CA1721 CA1725 CA1801 CA1802 CA1815 CA1819 CA1822 CA2208 CA2217 CA2225 CA2226 CA2231 CA2234

exclude_async_void_methods

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Whether to ignore asynchronous methods that don't return a value	<input type="checkbox"/> true <input type="checkbox"/> false	<input type="checkbox"/> false	CA2007

NOTE

This option was named `skip_async_void_methods` in an earlier version.

exclude_single_letter_type_parameters

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Whether to exclude single-character type parameters from the rule, for example, <code>s</code> in <code>Collection<s></code>	<input type="checkbox"/> true <input type="checkbox"/> false	<input type="checkbox"/> false	CA1715

NOTE

This option was named `allow_single_letter_type_parameters` in an earlier version.

output_kind

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Specifies that code in a project that generates this type of assembly should be analyzed	One or more fields of the OutputKind enumeration Separate multiple values with a comma (,)	All output kinds	CA2007

required_modifiers

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Specifies the required modifiers for APIs that should be analyzed	One or more values from the below allowed modifiers table Separate multiple values with a comma (,)	Depends on each rule	CA1802

ALLOWED MODIFIER	SUMMARY
<code>none</code>	No modifier requirement
<code>static</code> or <code>Shared</code>	Must be declared as <code>static</code> (<code>Shared</code> in Visual Basic)
<code>const</code>	Must be declared as <code>const</code>
<code>readonly</code>	Must be declared as <code>readonly</code>
<code>abstract</code>	Must be declared as <code>abstract</code>
<code>virtual</code>	Must be declared as <code>virtual</code>
<code>override</code>	Must be declared as <code>override</code>
<code>sealed</code>	Must be declared as <code>sealed</code>
<code>extern</code>	Must be declared as <code>extern</code>
<code>async</code>	Must be declared as <code>async</code>

exclude_extension_method_this_parameter

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Whether to skip analysis for the <code>this</code> parameter of extension methods	<code>true</code> <code>false</code>	<code>false</code>	CA1062

null_check_validation_methods

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Names of null-check validation methods that validate that arguments passed to the method are non-null	Allowed method name formats (separated by): - Method name only (includes all methods with the name, regardless of the containing type or namespace) - Fully qualified names in the symbol's documentation ID format , with an optional <code>M:</code> prefix	None	CA1062

additional_string_formatting_methods

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Names of additional string formatting methods	Allowed method name formats (separated by): - Method name only (includes all methods with the name, regardless of the containing type or namespace) - Fully qualified names in the symbol's documentation ID format , with an optional <code>M:</code> prefix	None	CA2241

excluded_type_names_with_derived_types

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Names of types, such that the type and all its derived types are excluded for analysis	Allowed symbol name formats (separated by): - Type name only (includes all types with the name, regardless of the containing type or namespace) - Fully qualified names in the symbol's documentation ID format , with an optional <code>T:</code> prefix	None	CA1001 CA1054 CA1055] (quality-rules/ca1056.md) CA1062 CA1068 CA1303 CA1304 CA1508 CA2000 CA2100 CA2301 CA2302 CA2311 CA2312 CA2321 CA2322 CA2327 CA2328 CA2329 CA2330 CA3001 CA3002 CA3003 CA3004 CA3005 CA3006 CA3007 CA3008 CA3009 CA3010 CA3011 CA3012 CA5361 CA5376 CA5377 CA5378 CA5380 CA5381 CA5382 CA5383 CA5384 CA5387 CA5388 CA5389 CA5390

excluded_symbol_names

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Names of symbols that are excluded for analysis	<p>Allowed symbol name formats (separated by):</p> <ul style="list-style-type: none"> - Symbol name only (includes all symbols with the name, regardless of the containing type or namespace) - Fully qualified names in the symbol's documentation ID format. <p>Each symbol name requires a symbol kind prefix, such as <code>M:</code> prefix for methods, <code>T:</code> prefix for types, and <code>N:</code> prefix for namespaces.</p> <ul style="list-style-type: none"> - <code>.ctor</code> for constructors and <code>.cctor</code> for static constructors 	None	CA1001 CA1054 CA1055] (quality-rules/ca1056.md) CA1062 CA1068 CA1303 CA1304 CA1508 CA2000 CA2100 CA2301 CA2302 CA2311 CA2312 CA2321 CA2322 CA2327 CA2328 CA2329 CA2330 CA3001 CA3002 CA3003 CA3004 CA3005 CA3006 CA3007 CA3008 CA3009 CA3010 CA3011 CA3012 CA5361 CA5376 CA5377 CA5378 CA5380 CA5381 CA5382 CA5383 CA5384 CA5387 CA5388 CA5389 CA5390

disallowed_symbol_names

DESCRIPTION	ALLOWABLE VALUES	DEFAULT VALUE	CONFIGURABLE RULES
Names of symbols that are disallowed in the context of the analysis	<p>Allowed symbol name formats (separated by):</p> <ul style="list-style-type: none"> - Symbol name only (includes all symbols with the name, regardless of the containing type or namespace) - Fully qualified names in the symbol's documentation ID format. <p>Each symbol name requires a symbol kind prefix, such as <code>M:</code> prefix for methods, <code>T:</code> prefix for types, and <code>N:</code> prefix for namespaces.</p> <ul style="list-style-type: none"> - <code>.ctor</code> for constructors and <code>.cctor</code> for static constructors 	None	CA1031

Predefined configuration files

9/20/2022 • 2 minutes to read • [Edit Online](#)

Predefined EditorConfig and rule set files are available that make it quick and easy to enable a category of code quality rules, such as security or design rules. By enabling a specific category of rules, you can identify targeted issues and specific conditions. To access these predefined files, install the [Microsoft.CodeAnalysis.NetAnalyzers](#) NuGet analyzer package.

[Microsoft.CodeAnalysis.NetAnalyzers](#) includes predefined EditorConfig files and rule sets for the following rule categories:

- All rules
- Dataflow
- Design
- Documentation
- Globalization
- Interoperability
- Maintainability
- Naming
- Performance
- Ported from FxCop
- Reliability
- Security
- Usage

Each of those categories of rules has an EditorConfig or rule set file to:

- Enable all the rules in the category (and disable all other rules)
- Use each rule's default severity and enabled by default setting (and disable all other rules)

TIP

The "all rules" category has an additional EditorConfig or rule set file to disable all rules. Use this file to quickly get rid of any analyzer warnings or errors in a project.

Predefined EditorConfig files

The predefined EditorConfig files for the [Microsoft.CodeAnalysis.NetAnalyzers](#) analyzer package are located in the *editorconfig* subdirectory of where the NuGet package was installed. For example, the EditorConfig file to enable all security rules is located at *editorconfig/SecurityRulesEnabled/.editorconfig*.

Copy the chosen *.editorconfig* file to your project's root directory.

Predefined rule sets

The predefined rule set files for the [Microsoft.CodeAnalysis.NetAnalyzers](#) analyzer package are located in the *rulesets* subdirectory of where the NuGet package was installed. For example, the rule set file to enable all security rules is located at *rulesets/SecurityRulesEnabled.ruleset*. Copy one or more of the rule sets and paste them in the directory that contains your project.

Code-style rule options

9/20/2022 • 4 minutes to read • [Edit Online](#)

You can define and maintain consistent *code style* in your codebase by defining .NET code-style rules and their associated options in a [configuration file](#). These rules are surfaced by various development IDEs, such as Visual Studio, as you edit your code. For .NET projects, these rules can also be [enforced at build time](#). You can enable or disable individual rules and configure the degree to which you want each rule enforced, via a severity level.

TIP

- When you define code style options in an EditorConfig file, you're configuring how you want the [code style analyzers](#) to analyze your code. The EditorConfig file is the configuration file for these analyzers.
- Code style options can also be set in Visual Studio in the [Text editor options](#) dialog. These are per-user options that are only respected while editing in Visual Studio. These options are not respected at build time or by other IDEs. Additionally, if the project or solution opened inside Visual Studio has an EditorConfig file, then options from the EditorConfig file take precedence. In Visual Studio on Windows, you can also generate an EditorConfig file from your text-editor options. Select **Tools > Options > Text Editor > [C# or Basic] > Code Style > General**, and then click **Generate .editorconfig file from settings**. For more information, see [Code style preferences](#).

Code style rules are divided into following subcategories:

- [Language rules](#)
- [Unnecessary code rules](#)
- [Formatting rules](#)
- [Naming rules](#)

Each of these subcategories defines its own syntax for specifying options. For more information about these rules and the corresponding options, see [Code-style rule reference](#).

Example EditorConfig file

To help you get started, here's an example `.editorconfig` file with the default options.

NOTE

The concise syntax seen in this file, where the severity is specified after the option value for language rules, for example, `dotnet_style_READONLY_FIELD = true:suggestion`, is only fully understood by Visual Studio. Compilers don't understand the `:<severity-level>` suffix and it is ignored if you compile your code from the command line. To set severity in a way that's understood by both Visual Studio and the C# and Visual Basic compilers, set the severity on the rule that contains the option by using the following syntax:

```
dotnet_diagnostic.<rule-ID>.severity = <severity-level>
```

For more information, see [Option format](#).

TIP

In Visual Studio, you can add the following default .NET .editorconfig file to your project from the **Add New Item** dialog box.

```

Rule categories

9/20/2022 • 2 minutes to read • [Edit Online](#)

Each code analysis rule belongs to a category of rules. For example, design rules support adherence to the .NET design guidelines, and security rules help prevent security flaws. You can [configure the severity level](#) for an entire category of rules. You can also [configure additional options](#) on a per-category basis.

The following table shows the different code analysis rule categories and provides a link to the rules in each category. It also lists the configuration value to use in an EditorConfig file to [bulk-configure rule severity](#) on a per-category basis. For example, to set the severity of security rule violations to be errors, the EditorConfig entry is `dotnet_analyzer_diagnostic.category-Security.severity = error`.

TIP

Setting the severity for a category of rules using the `dotnet_analyzer_diagnostic.category-<category>.severity` syntax doesn't apply to rules that are disabled by default. However, starting in .NET 6, you can use the [AnalysisMode<Category>](#) project property to enable all the rules in a category.

CATEGORY	DESCRIPTION	EDITORCONFIG VALUE
Design rules	Design rules support adherence to the .NET Framework Design Guidelines .	<code>dotnet_analyzer_diagnostic.category-Design.severity</code>
Documentation rules	Documentation rules support writing well-documented libraries through the correct use of XML documentation comments for externally visible APIs.	<code>dotnet_analyzer_diagnostic.category-Documentation.severity</code>
Globalization rules	Globalization rules support world-ready libraries and applications.	<code>dotnet_analyzer_diagnostic.category-Globalization.severity</code>
Portability and interoperability rules	Portability rules support portability across different platforms. Interoperability rules support interaction with COM clients.	<code>dotnet_analyzer_diagnostic.category-Interoperability.severity</code>
Maintainability rules	Maintainability rules support library and application maintenance.	<code>dotnet_analyzer_diagnostic.category-Maintainability.severity</code>
Naming rules	Naming rules support adherence to the naming conventions of the .NET design guidelines.	<code>dotnet_analyzer_diagnostic.category-Naming.severity</code>
Performance rules	Performance rules support high-performance libraries and applications.	<code>dotnet_analyzer_diagnostic.category-Performance.severity</code>
SingleFile rules	Single-file rules support single-file applications.	<code>dotnet_analyzer_diagnostic.category-SingleFile.severity</code>

CATEGORY	DESCRIPTION	EDITORCONFIG VALUE
Reliability rules	Reliability rules support library and application reliability, such as correct memory and thread usage.	<code>dotnet_analyzer_diagnostic.category-Reliability.severity</code>
Security rules	Security rules support safer libraries and applications. These rules help prevent security flaws in your program.	<code>dotnet_analyzer_diagnostic.category-Security.severity</code>
Style rules	Style rules support consistent code style in your codebase. These rules start with the "IDE" prefix.	<code>dotnet_analyzer_diagnostic.category-Style.severity</code>
Usage rules	Usage rules support proper usage of .NET.	<code>dotnet_analyzer_diagnostic.category-Usage.severity</code>
N/A	You can use this EditorConfig value to enable the following rules: IDE0051 , IDE0064 , IDE0076 . While these rules start with "IDE", they are not technically part of the <code>Style</code> category.	<code>dotnet_analyzer_diagnostic.category-CodeQuality.severity</code>

Code quality rules

9/20/2022 • 53 minutes to read • [Edit Online](#)

.NET code analysis provides rules that aim to improve code quality. The rules are organized into areas such as design, globalization, performance, and security. Certain rules are specific to .NET API usage, while others are about generic code quality.

Index of rules

The following table lists code quality analysis rules.

RULE ID AND WARNING	DESCRIPTION
CA1000: Do not declare static members on generic types	When a static member of a generic type is called, the type argument must be specified for the type. When a generic instance member that does not support inference is called, the type argument must be specified for the member. In these two cases, the syntax for specifying the type argument is different and easily confused.
CA1001: Types that own disposable fields should be disposable	A class declares and implements an instance field that is a System.IDisposable type, and the class does not implement IDisposable. A class that declares an IDisposable field indirectly owns an unmanaged resource and should implement the IDisposable interface.
CA1002: Do not expose generic lists	System.Collections.Generic.List<(Of <(T>)>) is a generic collection that is designed for performance, not inheritance. Therefore, List does not contain any virtual members. The generic collections that are designed for inheritance should be exposed instead.
CA1003: Use generic event handler instances	A type contains a delegate that returns void, whose signature contains two parameters (the first an object and the second a type that is assignable to EventArgs), and the containing assembly targets Microsoft .NET Framework 2.0.
CA1005: Avoid excessive parameters on generic types	The more type parameters a generic type contains, the more difficult it is to know and remember what each type parameter represents. It is usually obvious with one type parameter, as in List<T>, and in certain cases that have two type parameters, as in Dictionary< TKey, TValue >. However, if more than two type parameters exist, the difficulty becomes too great for most users.
CA1008: Enums should have zero value	The default value of an uninitialized enumeration, just as other value types, is zero. A nonflags-attributed enumeration should define a member by using the value of zero so that the default value is a valid value of the enumeration. If an enumeration that has the FlagsAttribute attribute applied defines a zero-valued member, its name should be "None" to indicate that no values have been set in the enumeration.
CA1010: Collections should implement generic interface	To broaden the usability of a collection, implement one of the generic collection interfaces. Then the collection can be used to populate generic collection types.

Rule ID and Warning	Description
CA1012: Abstract types should not have constructors	Constructors on abstract types can be called only by derived types. Because public constructors create instances of a type, and you cannot create instances of an abstract type, an abstract type that has a public constructor is incorrectly designed.
CA1014: Mark assemblies with CLSCompliantAttribute	The Common Language Specification (CLS) defines naming restrictions, data types, and rules to which assemblies must conform if they will be used across programming languages. Good design dictates that all assemblies explicitly indicate CLS compliance by using CLSCompliantAttribute . If this attribute is not present on an assembly, the assembly is not compliant.
CA1016: Mark assemblies with AssemblyVersionAttribute	.NET uses the version number to uniquely identify an assembly and to bind to types in strongly named assemblies. The version number is used together with version and publisher policy. By default, applications run only with the assembly version with which they were built.
CA1017: Mark assemblies with ComVisibleAttribute	ComVisibleAttribute determines how COM clients access managed code. Good design dictates that assemblies explicitly indicate COM visibility. COM visibility can be set for the whole assembly and then overridden for individual types and type members. If this attribute is not present, the contents of the assembly are visible to COM clients.
CA1018: Mark attributes with AttributeUsageAttribute	When you define a custom attribute, mark it by using AttributeUsageAttribute to indicate where in the source code the custom attribute can be applied. The meaning and intended usage of an attribute will determine its valid locations in code.
CA1019: Define accessors for attribute arguments	Attributes can define mandatory arguments that must be specified when you apply the attribute to a target. These are also known as positional arguments because they are supplied to attribute constructors as positional parameters. For every mandatory argument, the attribute should also provide a corresponding read-only property so that the value of the argument can be retrieved at execution time. Attributes can also define optional arguments, which are also known as named arguments. These arguments are supplied to attribute constructors by name and should have a corresponding read/write property.
CA1021: Avoid out parameters	Passing types by reference (using out or ref) requires experience with pointers, understanding how value types and reference types differ, and handling methods with multiple return values. Also, the difference between out and ref parameters is not widely understood.
CA1024: Use properties where appropriate	A public or protected method has a name that starts with "Get", takes no parameters, and returns a value that is not an array. The method might be a good candidate to become a property.
CA1027: Mark enums with FlagsAttribute	An enumeration is a value type that defines a set of related named constants. Apply FlagsAttribute to an enumeration when its named constants can be meaningfully combined.
CA1028: Enum storage should be Int32	An enumeration is a value type that defines a set of related named constants. By default, the System.Int32 data type is used to store the constant value. Although you can change this underlying type, it is not required or recommended for most scenarios.

Rule ID and Warning	Description
CA1030: Use events where appropriate	This rule detects methods that have names that ordinarily would be used for events. If a method is called in response to a clearly defined state change, the method should be invoked by an event handler. Objects that call the method should raise events instead of calling the method directly.
CA1031: Do not catch general exception types	General exceptions should not be caught. Catch a more specific exception, or rethrow the general exception as the last statement in the catch block.
CA1032: Implement standard exception constructors	Failure to provide the full set of constructors can make it difficult to correctly handle exceptions.
CA1033: Interface methods should be callable by child types	An unsealed externally visible type provides an explicit method implementation of a public interface and does not provide an alternative externally visible method that has the same name.
CA1034: Nested types should not be visible	A nested type is a type that is declared in the scope of another type. Nested types are useful to encapsulate private implementation details of the containing type. Used for this purpose, nested types should not be externally visible.
CA1036: Override methods on comparable types	A public or protected type implements the System.IComparable interface. It does not override Object.Equals nor does it overload the language-specific operator for equality, inequality, less than, or greater than.
CA1040: Avoid empty interfaces	Interfaces define members that provide a behavior or usage contract. The functionality that is described by the interface can be adopted by any type, regardless of where the type appears in the inheritance hierarchy. A type implements an interface by providing implementations for the members of the interface. An empty interface does not define any members; therefore, it does not define a contract that can be implemented.
CA1041: Provide ObsoleteAttribute message	A type or member is marked by using a System.ObsoleteAttribute attribute that does not have its ObsoleteAttribute.Message property specified. When a type or member that is marked by using ObsoleteAttribute is compiled, the Message property of the attribute is displayed. This gives the user information about the obsolete type or member.
CA1043: Use integral or string argument for indexers	Indexers (that is, indexed properties) should use integral or string types for the index. These types are typically used for indexing data structures and they increase the usability of the library. Use of the Object type should be restricted to those cases where the specific integral or string type cannot be specified at design time.
CA1044: Properties should not be write only	Although it is acceptable and often necessary to have a read-only property, the design guidelines prohibit the use of write-only properties. This is because letting a user set a value, and then preventing the user from viewing that value, does not provide any security. Also, without read access, the state of shared objects cannot be viewed, which limits their usefulness.

Rule ID and Warning	Description
CA1045: Do not pass types by reference	Passing types by reference (using <code>out</code> or <code>ref</code>) requires experience with pointers, understanding how value types and reference types differ, and handling methods that have multiple return values. Library architects who design for a general audience should not expect users to become proficient in working with <code>out</code> or <code>ref</code> parameters.
CA1046: Do not overload operator equals on reference types	For reference types, the default implementation of the equality operator is almost always correct. By default, two references are equal only if they point to the same object.
CA1047: Do not declare protected members in sealed types	Types declare protected members so that inheriting types can access or override the member. By definition, sealed types cannot be inherited, which means that protected methods on sealed types cannot be called.
CA1050: Declare types in namespaces	Types are declared in namespaces to prevent name collisions and as a way to organize related types in an object hierarchy.
CA1051: Do not declare visible instance fields	The primary use of a field should be as an implementation detail. Fields should be private or internal and should be exposed by using properties.
CA1052: Static holder types should be sealed	A public or protected type contains only static members and is not declared by using the <code>sealed</code> (C# Reference) (<code>NotInheritable</code>) modifier. A type that is not meant to be inherited should be marked by using the <code>sealed</code> modifier to prevent its use as a base type.
CA1053: Static holder types should not have constructors	A public or nested public type declares only static members and has a public or protected default constructor. The constructor is unnecessary because calling static members does not require an instance of the type. The string overload should call the uniform resource identifier (URI) overload by using the string argument for safety and security.
CA1054: URI parameters should not be strings	If a method takes a string representation of a URI, a corresponding overload should be provided that takes an instance of the <code>Uri</code> class, which provides these services in a safe and secure manner.
CA1055: URI return values should not be strings	This rule assumes that the method returns a URI. A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The <code>System.Uri</code> class provides these services in a safe and secure manner.
CA1056: URI properties should not be strings	This rule assumes that the property represents a Uniform Resource Identifier (URI). A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The <code>System.Uri</code> class provides these services in a safe and secure manner.
CA1058: Types should not extend certain base types	An externally visible type extends certain base types. Use one of the alternatives.
CA1060: Move P/Invokes to NativeMethods class	Platform Invocation methods, such as those that are marked by using the <code>System.Runtime.InteropServices.DllImportAttribute</code> attribute, or methods that are defined by using the <code>Declare</code> keyword in Visual Basic, access unmanaged code. These methods should be of the <code>NativeMethods</code> , <code>SafeNativeMethods</code> , or <code>UnsafeNativeMethods</code> class.

Rule ID and Warning	Description
CA1061: Do not hide base class methods	A method in a base type is hidden by an identically named method in a derived type, when the parameter signature of the derived method differs only by types that are more weakly derived than the corresponding types in the parameter signature of the base method.
CA1062: Validate arguments of public methods	All reference arguments that are passed to externally visible methods should be checked against null.
CA1063: Implement IDisposable correctly	All IDisposable types should implement the Dispose pattern correctly.
CA1064: Exceptions should be public	An internal exception is visible only inside its own internal scope. After the exception falls outside the internal scope, only the base exception can be used to catch the exception. If the internal exception is inherited from Exception , SystemException , or ApplicationException , the external code will not have sufficient information to know what to do with the exception.
CA1065: Do not raise exceptions in unexpected locations	A method that is not expected to throw exceptions throws an exception.
CA1066: Implement IEquatable when overriding Equals	A value type overrides Equals method, but does not implement IEquatable<T> .
CA1067: Override Equals when implementing IEquatable	A type implements IEquatable<T> , but does not override Equals method.
CA1068: CancellationToken parameters must come last	A method has a CancellationToken parameter that is not the last parameter.
CA1069: Enums should not have duplicate values	An enumeration has multiple members which are explicitly assigned the same constant value.
CA1070: Do not declare event fields as virtual	A field-like event was declared as virtual.
CA1200: Avoid using cref tags with a prefix	The <code>cref</code> attribute in an XML documentation tag means "code reference". It specifies that the inner text of the tag is a code element, such as a type, method, or property. Avoid using <code>cref</code> tags with prefixes, because it prevents the compiler from verifying references. It also prevents the Visual Studio integrated development environment (IDE) from finding and updating these symbol references during refactorings.
CA1303: Do not pass literals as localized parameters	An externally visible method passes a string literal as a parameter to a .NET constructor or method, and that string should be localizable.
CA1304: Specify CultureInfo	A method or constructor calls a member that has an overload that accepts a <code>System.Globalization.CultureInfo</code> parameter, and the method or constructor does not call the overload that takes the <code>CultureInfo</code> parameter. When a <code>CultureInfo</code> or <code>System.IFormatProvider</code> object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales.

Rule ID and Warning	Description
CA1305: Specify IFormatProvider	A method or constructor calls one or more members that have overloads that accept a System.IFormatProvider parameter, and the method or constructor does not call the overload that takes the IFormatProvider parameter. When a System.Globalization.CultureInfo or IFormatProvider object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales.
CA1307: Specify StringComparison for clarity	A string comparison operation uses a method overload that does not set a StringComparison parameter.
CA1308: Normalize strings to uppercase	Strings should be normalized to uppercase. A small group of characters cannot make a round trip when they are converted to lowercase.
CA1309: Use ordinal StringComparison	A string comparison operation that is nonlinguistic does not set the StringComparison parameter to either Ordinal or OrdinalIgnoreCase. By explicitly setting the parameter to either StringComparison.Ordinal or StringComparison.OrdinalIgnoreCase, your code often gains speed, becomes more correct, and becomes more reliable.
CA1310: Specify StringComparison for correctness	A string comparison operation uses a method overload that does not set a StringComparison parameter and uses culture-specific string comparison by default.
CA1401: P/Invokes should not be visible	A public or protected method in a public type has the System.Runtime.InteropServices.DllImportAttribute attribute (also implemented by the Declare keyword in Visual Basic). Such methods should not be exposed.
CA1416: Validate platform compatibility	Using platform-dependent APIs on a component makes the code no longer work across all platforms.
CA1417: Do not use <code>outAttribute</code> on string parameters for P/Invokes	String parameters passed by value with the <code>outAttribute</code> can destabilize the runtime if the string is an interned string.
CA1418: Use valid platform string	Platform compatibility analyzer requires a valid platform name and version.
CA1419: Provide a parameterless constructor that is as visible as the containing type for concrete types derived from 'System.Runtime.InteropServices.SafeHandle'	Providing a parameterless constructor that is as visible as the containing type for a type derived from <code>System.Runtime.InteropServices.SafeHandle</code> enables better performance and usage with source-generated interop solutions.
CA1501: Avoid excessive inheritance	A type is more than four levels deep in its inheritance hierarchy. Deeply nested type hierarchies can be difficult to follow, understand, and maintain.
CA1502: Avoid excessive complexity	This rule measures the number of linearly independent paths through the method, which is determined by the number and complexity of conditional branches.
CA1505: Avoid unmaintainable code	A type or method has a low maintainability index value. A low maintainability index indicates that a type or method is probably difficult to maintain and would be a good candidate for redesign.
CA1506: Avoid excessive class coupling	This rule measures class coupling by counting the number of unique type references that a type or method contains.

RULE ID AND WARNING	DESCRIPTION
CA1507: Use nameof in place of string	A string literal is used as an argument where a <code>nameof</code> expression could be used.
CA1508: Avoid dead conditional code	A method has conditional code that always evaluates to <code>true</code> or <code>false</code> at run time. This leads to dead code in the <code>false</code> branch of the condition.
CA1509: Invalid entry in code metrics configuration file	Code metrics rules, such as CA1501 , CA1502 , CA1505 and CA1506 , supplied a configuration file named <code>CodeMetricsConfig.txt</code> that has an invalid entry.
CA1700: Do not name enum values 'Reserved'	This rule assumes that an enumeration member that has a name that contains "reserved" is not currently used but is a placeholder to be renamed or removed in a future version. Renaming or removing a member is a breaking change.
CA1707: Identifiers should not contain underscores	By convention, identifier names do not contain the underscore (<code>_</code>) character. This rule checks namespaces, types, members, and parameters.
CA1708: Identifiers should differ by more than case	Identifiers for namespaces, types, members, and parameters cannot differ only by case because languages that target the common language runtime are not required to be case-sensitive.
CA1710: Identifiers should have correct suffix	By convention, the names of types that extend certain base types or that implement certain interfaces, or types that are derived from these types, have a suffix that is associated with the base type or interface.
CA1711: Identifiers should not have incorrect suffix	By convention, only the names of types that extend certain base types or that implement certain interfaces, or types that are derived from these types, should end with specific reserved suffixes. Other type names should not use these reserved suffixes.
CA1712: Do not prefix enum values with type name	Names of enumeration members are not prefixed by using the type name because development tools are expected to provide type information.
CA1713: Events should not have before or after prefix	The name of an event starts with "Before" or "After". To name related events that are raised in a specific sequence, use the present or past tense to indicate the relative position in the sequence of actions.
CA1714: Flags enums should have plural names	A public enumeration has the <code>System.FlagsAttribute</code> attribute, and its name does not end in "s". Types that are marked by using <code>FlagsAttribute</code> have names that are plural because the attribute indicates that more than one value can be specified.
CA1715: Identifiers should have correct prefix	The name of an externally visible interface does not start with an uppercase "I". The name of a generic type parameter on an externally visible type or method does not start with an uppercase "T".
CA1716: Identifiers should not match keywords	A namespace name or a type name matches a reserved keyword in a programming language. Identifiers for namespaces and types should not match keywords that are defined by languages that target the common language runtime.

Rule ID and Warning	Description
CA1717: Only FlagsAttribute enums should have plural names	Naming conventions dictate that a plural name for an enumeration indicates that more than one value of the enumeration can be specified at the same time.
CA1720: Identifiers should not contain type names	The name of a parameter in an externally visible member contains a data type name, or the name of an externally visible member contains a language-specific data type name.
CA1721: Property names should not match get methods	The name of a public or protected member starts with "Get" and otherwise matches the name of a public or protected property. "Get" methods and properties should have names that clearly distinguish their function.
CA1724: Type Names Should Not Match Namespaces	Type names should not match the names of .NET namespaces. Violating this rule can reduce the usability of the library.
CA1725: Parameter names should match base declaration	Consistent naming of parameters in an override hierarchy increases the usability of the method overrides. A parameter name in a derived method that differs from the name in the base declaration can cause confusion about whether the method is an override of the base method or a new overload of the method.
CA1727: Use PascalCase for named placeholders	Use PascalCase for named placeholders in the logging message template.
CA1801: Review unused parameters	A method signature includes a parameter that is not used in the method body.
CA1802: Use Literals Where Appropriate	A field is declared static and read-only (Shared and ReadOnly in Visual Basic), and is initialized by using a value that is computable at compile time. Because the value that is assigned to the targeted field is computable at compile time, change the declaration to a const (Const in Visual Basic) field so that the value is computed at compile time instead of at run time.
CA1805: Do not initialize unnecessarily	The .NET runtime initializes all fields of reference types to their default values before running the constructor. In most cases, explicitly initializing a field to its default value is redundant, which adds to maintenance costs and may degrade performance (such as with increased assembly size).
CA1806: Do not ignore method results	A new object is created but never used; or a method that creates and returns a new string is called and the new string is never used; or a COM or P/Invoke method returns an HRESULT or error code that is never used.
CA1810: Initialize reference type static fields inline	When a type declares an explicit static constructor, the just-in-time (JIT) compiler adds a check to each static method and instance constructor of the type to make sure that the static constructor was previously called. Static constructor checks can decrease performance.
CA1812: Avoid uninstantiated internal classes	An instance of an assembly-level type is not created by code in the assembly.
CA1813: Avoid unsealed attributes	.NET provides methods for retrieving custom attributes. By default, these methods search the attribute inheritance hierarchy. Sealing the attribute eliminates the search through the inheritance hierarchy and can improve performance.

Rule ID and Warning	Description
CA1814: Prefer jagged arrays over multidimensional	A jagged array is an array whose elements are arrays. The arrays that make up the elements can be of different sizes, leading to less wasted space for some sets of data.
CA1815: Override equals and operator equals on value types	For value types, the inherited implementation of Equals uses the Reflection library and compares the contents of all fields. Reflection is computationally expensive, and comparing every field for equality might be unnecessary. If you expect users to compare or sort instances, or to use instances as hash table keys, your value type should implement Equals.
CA1816: Call GC.SuppressFinalize correctly	A method that is an implementation of Dispose does not call GC.SuppressFinalize; or a method that is not an implementation of Dispose calls GC.SuppressFinalize; or a method calls GC.SuppressFinalize and passes something other than this (Me in Visual Basic).
CA1819: Properties should not return arrays	Arrays that are returned by properties are not write-protected, even when the property is read-only. To keep the array tamper-proof, the property must return a copy of the array. Typically, users will not understand the adverse performance implications of calling such a property.
CA1820: Test for empty strings using string length	Comparing strings by using the String.Length property or the String.IsNullOrEmpty method is significantly faster than using Equals.
CA1821: Remove empty finalizers	Whenever you can, avoid finalizers because of the additional performance overhead that is involved in tracking object lifetime. An empty finalizer incurs added overhead and delivers no benefit.
CA1822: Mark members as static	Members that do not access instance data or call instance methods can be marked as static (Shared in Visual Basic). After you mark the methods as static, the compiler will emit nonvirtual call sites to these members. This can give you a measurable performance gain for performance-sensitive code.
CA1823: Avoid unused private fields	Private fields were detected that do not appear to be accessed in the assembly.
CA1824: Mark assemblies with NeutralResourcesLanguageAttribute	The NeutralResourcesLanguage attribute informs the resource manager of the language that was used to display the resources of a neutral culture for an assembly. This improves lookup performance for the first resource that you load and can reduce your working set.
CA1825: Avoid zero-length array allocations	Initializing a zero-length array leads to unnecessary memory allocation. Instead, use the statically allocated empty array instance by calling Array.Empty . The memory allocation is shared across all invocations of this method.
CA1826: Use property instead of Linq Enumerable method	Enumerable LINQ method was used on a type that supports an equivalent, more efficient property.
CA1827: Do not use Count/LongCount when Any can be used	Count or LongCount method was used where Any method would be more efficient.
CA1828: Do not use CountAsync/LongCountAsync when AnyAsync can be used	CountAsync or LongCountAsync method was used where AnyAsync method would be more efficient.

RULE ID AND WARNING	DESCRIPTION
CA1829: Use Length/Count property instead of Enumerable.Count method	Count LINQ method was used on a type that supports an equivalent, more efficient <code>Length</code> or <code>Count</code> property.
CA1830: Prefer strongly-typed Append and Insert method overloads on StringBuilder	Append and Insert provide overloads for multiple types beyond <code>String</code> . When possible, prefer the strongly-typed overloads over using <code>ToString()</code> and the string-based overload.
CA1831: Use AsSpan instead of Range-based indexers for string when appropriate	When using a range-indexer on a string and implicitly assigning the value to <code>ReadOnlySpan<char></code> type, the method Substring will be used instead of Slice, which produces a copy of requested portion of the string.
CA1832: Use AsSpan or AsMemory instead of Range-based indexers for getting ReadOnlySpan or ReadOnlyMemory portion of an array	When using a range-indexer on an array and implicitly assigning the value to a <code>ReadOnlySpan<T></code> or <code>ReadOnlyMemory<T></code> type, the method <code>GetSubArray</code> will be used instead of <code>Slice</code> , which produces a copy of requested portion of the array.
CA1833: Use AsSpan or AsMemory instead of Range-based indexers for getting Span or Memory portion of an array	When using a range-indexer on an array and implicitly assigning the value to a <code>Span<T></code> or <code>Memory<T></code> type, the method <code>GetSubArray</code> will be used instead of <code>Slice</code> , which produces a copy of requested portion of the array.
CA1834: Use <code>StringBuilder.Append(char)</code> for single character strings	<code>StringBuilder</code> has an <code>Append</code> overload that takes a <code>char</code> as its argument. Prefer calling the <code>char</code> overload for performance reasons.
CA1835: Prefer the 'Memory'-based overloads for 'ReadAsync' and 'WriteAsync'	'Stream' has a 'ReadAsync' overload that takes a 'Memory<Byte>' as the first argument, and a 'WriteAsync' overload that takes a 'ReadOnlyMemory<Byte>' as the first argument. Prefer calling the memory based overloads, which are more efficient.
CA1836: Prefer <code>IsEmpty</code> over <code>Count</code> when available	Prefer <code>IsEmpty</code> property that is more efficient than <code>Count</code> , <code>Length</code> , <code>Count<TSource>(IEnumerable<TSource>)</code> or <code>LongCount<TSource>(IEnumerable<TSource>)</code> to determine whether the object contains or not any items.
CA1837: Use <code>Environment.ProcessId</code> instead of <code>Process.GetCurrentProcess().Id</code>	<code>Environment.ProcessId</code> is simpler and faster than <code>Process.GetCurrentProcess().Id</code> .
CA1838: Avoid <code>StringBuilder</code> parameters for P/Invokes	Marshalling of 'StringBuilder' always creates a native buffer copy, resulting in multiple allocations for one marshalling operation.
CA1839: Use <code>Environment.ProcessPath</code> instead of <code>Process.GetCurrentProcess().MainModule.FileName</code>	<code>Environment.ProcessPath</code> is simpler and faster than <code>Process.GetCurrentProcess().MainModule.FileName</code> .
CA1840: Use <code>Environment.CurrentManagedThreadId</code> instead of <code>Thread.CurrentThread.ManagedThreadId</code>	<code>Environment.CurrentManagedThreadId</code> is more compact and efficient than <code>Thread.CurrentThread.ManagedThreadId</code> .
CA1841: Prefer Dictionary Contains methods	Calling <code>Contains</code> on the <code>Keys</code> or <code>Values</code> collection may often be more expensive than calling <code>ContainsKey</code> or <code>ContainsValue</code> on the dictionary itself.
CA1842: Do not use 'WhenAll' with a single task	Using <code>WhenAll</code> with a single task may result in performance loss. Await or return the task instead.

RULE ID AND WARNING	DESCRIPTION
CA1843: Do not use 'WaitAll' with a single task	Using <code>WaitAll</code> with a single task may result in performance loss. Await or return the task instead.
CA1844: Provide memory-based overrides of async methods when subclassing 'Stream'	To improve performance, override the memory-based async methods when subclassing 'Stream'. Then implement the array-based methods in terms of the memory-based methods.
CA1845: Use span-based 'string.Concat'	It is more efficient to use <code>AsSpan</code> and <code>string.Concat</code> , instead of <code>Substring</code> and a concatenation operator.
CA1846: Prefer <code>AsSpan</code> over <code>Substring</code>	<code>AsSpan</code> is more efficient than <code>Substring</code> . <code>Substring</code> performs an O(n) string copy, while <code>AsSpan</code> does not and has a constant cost. <code>AsSpan</code> also does not perform any heap allocations.
CA1847: Use char literal for a single character lookup	Use <code>string.Contains(char)</code> instead of <code>string.Contains(string)</code> when searching for a single character.
CA1848: Use the <code>LoggerMessage</code> delegates	For improved performance, use the <code>LoggerMessage</code> delegates.
CA1849: Call async methods when in an async method	In a method which is already asynchronous, calls to other methods should be to their async versions, where they exist.
CA1850: Prefer static <code>HashData</code> method over <code>ComputeHash</code>	It's more efficient to use the static <code>HashData</code> method over creating and managing a <code>HashAlgorithm</code> instance to call <code>ComputeHash</code> .
CA1851: Possible multiple enumerations of <code>IEnumerable</code> collection	Possible multiple enumerations of <code>IEnumerable</code> collection. Consider using an implementation that avoids multiple enumerations.
CA1854: Prefer the 'IDictionary.TryGetValue(TKey, out TValue)' method	Prefer 'TryGetValue' over a Dictionary indexer access guarded by a 'ContainsKey' check. 'ContainsKey' and the indexer both look up the key, so using 'TryGetValue' avoids the extra lookup.
CA2000: Dispose objects before losing scope	Because an exceptional event might occur that will prevent the finalizer of an object from running, the object should be explicitly disposed before all references to it are out of scope.
CA2002: Do not lock on objects with weak identity	An object is said to have a weak identity when it can be directly accessed across application domain boundaries. A thread that tries to acquire a lock on an object that has a weak identity can be blocked by a second thread in a different application domain that has a lock on the same object.
CA2007: Do not directly await a Task	An asynchronous method <code>awaits</code> a <code>Task</code> directly. When an asynchronous method awaits a <code>Task</code> directly, continuation occurs in the same thread that created the task. This behavior can be costly in terms of performance and can result in a deadlock on the UI thread. Consider calling <code>Task.ConfigureAwait(Boolean)</code> to signal your intention for continuation.
CA2008: Do not create tasks without passing a <code>TaskScheduler</code>	A task creation or continuation operation uses a method overload that does not specify a <code>TaskScheduler</code> parameter.

RULE ID AND WARNING	DESCRIPTION
CA2009: Do not call <code>ToImmutableCollection</code> on an <code>ImmutableCollection</code> value	<code>ToImmutable</code> method was unnecessarily called on an immutable collection from <code>System.Collections.Immutable</code> namespace.
CA2011: Do not assign property within its setter	A property was accidentally assigned a value within its own <code>set accessor</code> .
CA2012: Use <code>ValueTasks</code> correctly	ValueTasks returned from member invocations are intended to be directly awaited. Attempts to consume a <code>ValueTask</code> multiple times or to directly access one's result before it's known to be completed may result in an exception or corruption. Ignoring such a <code>ValueTask</code> is likely an indication of a functional bug and may degrade performance.
CA2013: Do not use <code>ReferenceEquals</code> with value types	When comparing values using <code>System.Object.ReferenceEquals</code> , if <code>objA</code> and <code>objB</code> are value types, they are boxed before they are passed to the <code>ReferenceEquals</code> method. This means that even if both <code>objA</code> and <code>objB</code> represent the same instance of a value type, the <code>ReferenceEquals</code> method nevertheless returns false.
CA2014: Do not use <code>stackalloc</code> in loops.	Stack space allocated by a <code>stackalloc</code> is only released at the end of the current method's invocation. Using it in a loop can result in unbounded stack growth and eventual stack overflow conditions.
CA2015: Do not define finalizers for types derived from <code>MemoryManager<T></code>	Adding a finalizer to a type derived from <code>MemoryManager<T></code> may permit memory to be freed while it is still in use by a <code>Span<T></code> .
CA2016: Forward the <code>CancellationToken</code> parameter to methods that take one	Forward the <code>CancellationToken</code> parameter to methods that take one to ensure the operation cancellation notifications gets properly propagated, or pass in <code>CancellationToken.None</code> explicitly to indicate intentionally not propagating the token.
CA2017: Parameter count mismatch	Number of parameters supplied in the logging message template do not match the number of named placeholders.
CA2018: The <code>count</code> argument to <code>Buffer.BlockCopy</code> should specify the number of bytes to copy	When using <code>Buffer.BlockCopy</code> , the <code>count</code> argument specifies the number of bytes to copy. You should only use <code>Array.Length</code> for the <code>count</code> argument on arrays whose elements are exactly one byte in size. <code>byte</code> , <code>sbyte</code> , and <code>bool</code> arrays have elements that are one byte in size.
CA2100: Review SQL queries for security vulnerabilities	A method sets the <code>System.Data.IDbCommand.CommandText</code> property by using a string that is built from a string argument to the method. This rule assumes that the string argument contains user input. A SQL command string that is built from user input is vulnerable to SQL injection attacks.
CA2101: Specify marshalling for P/Invoke string arguments	A platform invoke member allows partially trusted callers, has a string parameter, and does not explicitly marshal the string. This can cause a potential security vulnerability.
CA2109: Review visible event handlers	A public or protected event-handling method was detected. Event-handling methods should not be exposed unless absolutely necessary.
CA2119: Seal methods that satisfy private interfaces	An inheritable public type provides an overridable method implementation of an internal (Friend in Visual Basic) interface. To fix a violation of this rule, prevent the method from being overridden outside the assembly.

RULE ID AND WARNING	DESCRIPTION
CA2153: Avoid handling Corrupted State Exceptions	Corrupted State Exceptions (CSEs) indicate that memory corruption exists in your process. Catching these rather than allowing the process to crash can lead to security vulnerabilities if an attacker can place an exploit into the corrupted memory region.
CA2200: Rethrow to preserve stack details	An exception is rethrown and the exception is explicitly specified in the throw statement. If an exception is rethrown by specifying the exception in the throw statement, the list of method calls between the original method that threw the exception and the current method is lost.
CA2201: Do not raise reserved exception types	This makes the original error difficult to detect and debug.
CA2207: Initialize value type static fields inline	A value type declares an explicit static constructor. To fix a violation of this rule, initialize all static data when it is declared and remove the static constructor.
CA2208: Instantiate argument exceptions correctly	A call is made to the default (parameterless) constructor of an exception type that is or derives from ArgumentException, or an incorrect string argument is passed to a parameterized constructor of an exception type that is or derives from ArgumentException.
CA2211: Non-constant fields should not be visible	Static fields that are neither constants nor read-only are not thread-safe. Access to such a field must be carefully controlled and requires advanced programming techniques to synchronize access to the class object.
CA2213: Disposable fields should be disposed	A type that implements System.IDisposable declares fields that are of types that also implement IDisposable. The Dispose method of the field is not called by the Dispose method of the declaring type.
CA2214: Do not call overridable methods in constructors	When a constructor calls a virtual method, the constructor for the instance that invokes the method may not have executed.
CA2215: Dispose methods should call base class dispose	If a type inherits from a disposable type, it must call the Dispose method of the base type from its own Dispose method.
CA2216: Disposable types should declare finalizer	A type that implements System.IDisposable and has fields that suggest the use of unmanaged resources does not implement a finalizer, as described by Object.Finalize.
CA2217: Do not mark enums with FlagsAttribute	An externally visible enumeration is marked by using FlagsAttribute, and it has one or more values that are not powers of two or a combination of the other defined values on the enumeration.
CA2218: Override GetHashCode on overriding Equals	A public type overrides System.Object.Equals but does not override System.Object.GetHashCode .
CA2219: Do not raise exceptions in exception clauses	When an exception is raised in a finally or fault clause, the new exception hides the active exception. When an exception is raised in a filter clause, the run time silently catches the exception. This makes the original error difficult to detect and debug.
CA2224: Override equals on overloading operator equals	A public type implements the equality operator but doesn't override System.Object.Equals .

Rule ID and Warning	Description
CA2225: Operator overloads have named alternates	An operator overload was detected, and the expected named alternative method was not found. The named alternative member provides access to the same functionality as the operator and is provided for developers who program in languages that do not support overloaded operators.
CA2226: Operators should have symmetrical overloads	A type implements the equality or inequality operator and does not implement the opposite operator.
CA2227: Collection properties should be read only	A writable collection property allows a user to replace the collection with a different collection. A read-only property stops the collection from being replaced but still allows the individual members to be set.
CA2229: Implement serialization constructors	To fix a violation of this rule, implement the serialization constructor. For a sealed class, make the constructor private; otherwise, make it protected.
CA2231: Overload operator equals on overriding ValueType.Equals	A value type overrides Object.Equals but does not implement the equality operator.
CA2234: Pass System.Uri objects instead of strings	A call is made to a method that has a string parameter whose name contains "uri", "URI", "urn", "URN", "url", or "URL". The declaring type of the method contains a corresponding method overload that has a System.Uri parameter.
CA2235: Mark all non-serializable fields	An instance field of a type that is not serializable is declared in a type that is serializable.
CA2237: Mark ISerializable types with SerializableAttribute	To be recognized by the common language runtime as serializable, types must be marked by using the SerializableAttribute attribute even when the type uses a custom serialization routine through implementation of the ISerializable interface.
CA2241: Provide correct arguments to formatting methods	The format argument that is passed to System.String.Format does not contain a format item that corresponds to each object argument, or vice versa.
CA2242: Test for NaN correctly	This expression tests a value against Single.NaN or Double.NaN. Use Single.IsNaN(Single) or Double.IsNaN(Double) to test the value.
CA2243: Attribute string literals should parse correctly	The string literal parameter of an attribute does not parse correctly for a URL, a GUID, or a version.
CA2244: Do not duplicate indexed element initializations	An object initializer has more than one indexed element initializer with the same constant index. All but the last initializer are redundant.
CA2245: Do not assign a property to itself	A property was accidentally assigned to itself.
CA2246: Do not assign a symbol and its member in the same statement	Assigning a symbol and its member, that is, a field or a property, in the same statement is not recommended. It is not clear if the member access was intended to use the symbol's old value prior to the assignment or the new value from the assignment in this statement.

RULE ID AND WARNING	DESCRIPTION
CA2247: Argument passed to TaskCompletionSource constructor should be TaskCreationOptions enum instead of TaskContinuationOptions enum.	TaskCompletionSource has constructors that take TaskCreationOptions that control the underlying Task, and constructors that take object state that's stored in the task. Accidentally passing a TaskContinuationOptions instead of a TaskCreationOptions will result in the call treating the options as state.
CA2248: Provide correct enum argument to Enum.HasFlag	The enum type passed as an argument to the <code>HasFlag</code> method call is different from the calling enum type.
CA2249: Consider using String.Contains instead of String.IndexOf	Calls to <code>string.IndexOf</code> where the result is used to check for the presence/absence of a substring can be replaced by <code>string.Contains</code> .
CA2250: Use <code>ThrowIfCancellationRequested</code>	<code>ThrowIfCancellationRequested</code> automatically checks whether the token has been canceled, and throws an <code>OperationCanceledException</code> if it has.
CA2251: Use <code>String.Equals</code> over <code>String.Compare</code>	It is both clearer and likely faster to use <code>String.Equals</code> instead of comparing the result of <code>String.Compare</code> to zero.
CA2252: Opt in to preview features	Opt in to preview features before using preview APIs.
CA2253: Named placeholders should not be numeric values	Named placeholders in the logging message template should not be comprised of only numeric characters.
CA2254: Template should be a static expression	The logging message template should not vary between calls.
CA2255: The <code>ModuleInitializer</code> attribute should not be used in libraries	Module initializers are intended to be used by application code to ensure an application's components are initialized before the application code begins executing.
CA2256: All members declared in parent interfaces must have an implementation in a DynamicInterfaceCastableImplementation-attributed interface	Types attributed with <code>DynamicInterfaceCastableImplementationAttribute</code> act as an interface implementation for a type that implements the <code>IDynamicInterfaceCastable</code> type. As a result, it must provide an implementation of all of the members defined in the inherited interfaces, because the type that implements <code>IDynamicInterfaceCastable</code> will not provide them otherwise.
CA2257: Members defined on an interface with 'DynamicInterfaceCastableImplementationAttribute' should be 'static'	Since a type that implements <code>IDynamicInterfaceCastable</code> may not implement a dynamic interface in metadata, calls to an instance interface member that is not an explicit implementation defined on this type are likely to fail at run time. Mark new interface members <code>static</code> to avoid run-time errors.
CA2258: Providing a 'DynamicInterfaceCastableImplementation' interface in Visual Basic is unsupported	Providing a functional <code>DynamicInterfaceCastableImplementationAttribute</code> -attributed interface requires the Default Interface Members feature, which is unsupported in Visual Basic.
CA2300: Do not use insecure deserializer BinaryFormatter	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.

Rule ID and Warning	Description
CA2301: Do not call <code>BinaryFormatter.Deserialize</code> without first setting <code>BinaryFormatterBinder</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2302: Ensure <code>BinaryFormatterBinder</code> is set before calling <code>BinaryFormatter.Deserialize</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2305: Do not use insecure deserializer <code>LoSFormatter</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2310: Do not use insecure deserializer <code>NetDataContractSerializer</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2311: Do not deserialize without first setting <code>NetDataContractSerializer.Binder</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2312: Ensure <code>NetDataContractSerializer.Binder</code> is set before deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2315: Do not use insecure deserializer <code>ObjectStateFormatter</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2321: Do not deserialize with <code>JavaScriptSerializer</code> using a <code>SimpleTypeResolver</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2322: Ensure <code>JavaScriptSerializer</code> is not initialized with <code>SimpleTypeResolver</code> before deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2326: Do not use <code>TypeNameHandling</code> values other than <code>None</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2327: Do not use insecure <code>JsonSerializerSettings</code>	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2328: Ensure that <code>JsonSerializerSettings</code> are secure	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.

Rule ID and Warning	Description
CA2329: Do not deserialize with JsonSerializer using an insecure configuration	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2330: Ensure that JsonSerializer has a secure configuration when deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2350: Ensure DataTable.ReadXml()'s input is trusted	When deserializing a DataTable with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2351: Ensure DataSet.ReadXml()'s input is trusted	When deserializing a DataSet with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2352: Unsafe DataSet or DataTable in serializable type can be vulnerable to remote code execution attacks	A class or struct marked with SerializableAttribute contains a DataSet or DataTable field or property, and doesn't have a GeneratedCodeAttribute .
CA2353: Unsafe DataSet or DataTable in serializable type	A class or struct marked with an XML serialization attribute or a data contract attribute contains a DataSet or DataTable field or property.
CA2354: Unsafe DataSet or DataTable in deserialized object graph can be vulnerable to remote code execution attack	Deserializing with an System.Runtime.Serialization.IFormatter serialized, and the casted type's object graph can include a DataSet or DataTable .
CA2355: Unsafe DataSet or DataTable in serialized object graph	Deserializing when the casted or specified type's object graph can include a DataSet or DataTable .
CA2356: Unsafe DataSet or DataTable in web deserialized object graph	A method with a System.Web.Services.WebMethodAttribute or System.ServiceModel.OperationContractAttribute has a parameter that may reference a DataSet or DataTable .
CA2361: Ensure autogenerated class containing DataSet.ReadXml() is not used with untrusted data	When deserializing a DataSet with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2362: Unsafe DataSet or DataTable in autogenerated serializable type can be vulnerable to remote code execution attacks	When deserializing untrusted input with BinaryFormatter and the deserialized object graph contains a DataSet or DataTable , an attacker can craft a malicious payload to perform a remote code execution attack.
CA3001: Review code for SQL injection vulnerabilities	When working with untrusted input and SQL commands, be mindful of SQL injection attacks. An SQL injection attack can execute malicious SQL commands, compromising the security and integrity of your application.
CA3002: Review code for XSS vulnerabilities	When working with untrusted input from web requests, be mindful of cross-site scripting (XSS) attacks. An XSS attack injects untrusted input into raw HTML output, allowing the attacker to execute malicious scripts or maliciously modify content in your web page.
CA3003: Review code for file path injection vulnerabilities	When working with untrusted input from web requests, be mindful of using user-controlled input when specifying paths to files.

Rule ID and Warning	Description
CA3004: Review code for information disclosure vulnerabilities	Disclosing exception information gives attackers insight into the internals of your application, which can help attackers find other vulnerabilities to exploit.
CA3006: Review code for process command injection vulnerabilities	When working with untrusted input, be mindful of command injection attacks. A command injection attack can execute malicious commands on the underlying operating system, compromising the security and integrity of your server.
CA3007: Review code for open redirect vulnerabilities	When working with untrusted input, be mindful of open redirect vulnerabilities. An attacker can exploit an open redirect vulnerability to use your website to give the appearance of a legitimate URL, but redirect an unsuspecting visitor to a phishing or other malicious webpage.
CA3008: Review code for XPath injection vulnerabilities	When working with untrusted input, be mindful of XPath injection attacks. Constructing XPath queries using untrusted input may allow an attacker to maliciously manipulate the query to return an unintended result, and possibly disclose the contents of the queried XML.
CA3009: Review code for XML injection vulnerabilities	When working with untrusted input, be mindful of XML injection attacks.
CA3010: Review code for XAML injection vulnerabilities	When working with untrusted input, be mindful of XAML injection attacks. XAML is a markup language that directly represents object instantiation and execution. That means elements created in XAML can interact with system resources (for example, network access and file system IO).
CA3011: Review code for DLL injection vulnerabilities	When working with untrusted input, be mindful of loading untrusted code. If your web application loads untrusted code, an attacker may be able to inject malicious DLLs into your process and execute malicious code.
CA3012: Review code for regex injection vulnerabilities	When working with untrusted input, be mindful of regex injection attacks. An attacker can use regex injection to maliciously modify a regular expression, to make the regex match unintended results, or to make the regex consume excessive CPU resulting in a Denial of Service attack.
CA3061: Do not add schema by URL	Do not use the unsafe overload of the Add method because it may cause dangerous external references.
CA3075: Insecure DTD Processing	If you use insecure DTDProcessing instances or reference external entity sources, the parser may accept untrusted input and disclose sensitive information to attackers.
CA3076: Insecure XSLT Script Execution	If you execute Extensible Stylesheet Language Transformations (XSLT) in .NET applications insecurely, the processor may resolve untrusted URI references that could disclose sensitive information to attackers, leading to Denial of Service and Cross-Site attacks.
CA3077: Insecure Processing in API Design, XML Document and XML Text Reader	When designing an API derived from XmlDocument and XmlTextReader, be mindful of DtdProcessing. Using insecure DTDProcessing instances when referencing or resolving external entity sources or setting insecure values in the XML may lead to information disclosure.

Rule ID and Warning	Description
CA3147: Mark verb handlers with ValidateAntiForgeryToken	When designing an ASP.NET MVC controller, be mindful of cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET MVC controller.
CA5350: Do Not Use Weak Cryptographic Algorithms	Weak encryption algorithms and hashing functions are used today for a number of reasons, but they should not be used to guarantee the confidentiality or integrity of the data they protect. This rule triggers when it finds TripleDES, SHA1, or RIPEMD160 algorithms in the code.
CA5351 Do Not Use Broken Cryptographic Algorithms	Broken cryptographic algorithms are not considered secure and their use should be strongly discouraged. This rule triggers when it finds the MD5 hash algorithm or either the DES or RC2 encryption algorithms in code.
CA5358: Do Not Use Unsafe Cipher Modes	Do Not Use Unsafe Cipher Modes
CA5359 Do not disable certificate validation	A certificate can help authenticate the identity of the server. Clients should validate the server certificate to ensure requests are sent to the intended server. If the <code>ServerCertificateValidationCallback</code> always returns <code>true</code> , any certificate will pass validation.
CA5360 Do not call dangerous methods in deserialization	Insecure deserialization is a vulnerability which occurs when untrusted data is used to abuse the logic of an application, inflict a Denial-of-Service (DoS) attack, or even execute arbitrary code upon it being deserialized. It's frequently possible for malicious users to abuse these deserialization features when the application is deserializing untrusted data which is under their control. Specifically, invoke dangerous methods in the process of deserialization. Successful insecure deserialization attacks could allow an attacker to carry out attacks such as DoS attacks, authentication bypasses, and remote code execution.
CA5361: Do not disable Schannel use of strong crypto	Setting <code>Switch.System.Net.DontEnableSchUseStrongCrypto</code> to <code>true</code> weakens the cryptography used in outgoing Transport Layer Security (TLS) connections. Weaker cryptography can compromise the confidentiality of communication between your application and the server, making it easier for attackers to eavesdrop sensitive data.
CA5362 Potential reference cycle in deserialized object graph	If deserializing untrusted data, then any code processing the deserialized object graph needs to handle reference cycles without going into infinite loops. This includes both code that's part of a deserialization callback and code that processes the object graph after deserialization completed. Otherwise, an attacker could perform a Denial-of-Service attack with malicious data containing a reference cycle.
CA5363: Do not disable request validation	Request validation is a feature in ASP.NET that examines HTTP requests and determines whether they contain potentially dangerous content that can lead to injection attacks, including cross-site-scripting.
CA5364: Do not use deprecated security protocols	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk.

Rule ID and Warning	Description
CA5365 Do Not Disable HTTP Header Checking	HTTP header checking enables encoding of the carriage return and newline characters, \r and \n, that are found in response headers. This encoding can help to avoid injection attacks that exploit an application that echoes untrusted data contained by the header.
CA5366 Use XmlReader For DataSet Read XML	Using a DataSet to read XML with untrusted data may load dangerous external references, which should be restricted by using an XmlReader with a secure resolver or with DTD processing disabled.
CA5367 Do Not Serialize Types With Pointer Fields	This rule checks whether there's a serializable class with a pointer field or property. Members that can't be serialized can be a pointer, such as static members or fields marked with NonSerializedAttribute .
CA5368 Set ViewStateUserKey For Classes Derived From Page	Setting the ViewStateUserKey property can help you prevent attacks on your application by allowing you to assign an identifier to the view-state variable for individual users so that attackers cannot use the variable to generate an attack. Otherwise, there will be vulnerabilities to cross-site request forgery.
CA5369: Use XmlReader for Deserialize	Processing untrusted DTD and XML schemas may enable loading dangerous external references, which should be restricted by using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled.
CA5370: Use XmlReader for validating reader	Processing untrusted DTD and XML schemas may enable loading dangerous external references. This dangerous loading can be restricted by using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled.
CA5371: Use XmlReader for schema read	Processing untrusted DTD and XML schemas may enable loading dangerous external references. Using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled restricts this.
CA5372: Use XmlReader for XPathDocument	Processing XML from untrusted data may load dangerous external references, which can be restricted by using an XmlReader with a secure resolver or with DTD processing disabled.
CA5373: Do not use obsolete key derivation function	This rule detects the invocation of weak key derivation methods System.Security.Cryptography.PasswordDeriveBytes and Rfc2898DeriveBytes.CryptDeriveKey . System.Security.Cryptography.PasswordDeriveBytes used a weak algorithm PBKDF1.
CA5374 Do Not Use XslTransform	This rule checks if System.Xml.Xsl.XslTransform is instantiated in the code. System.Xml.Xsl.XslTransform is now obsolete and shouldn't be used.
CA5375 Do not use account shared access signature	An account SAS can delegate access to read, write, and delete operations on blob containers, tables, queues, and file shares that are not permitted with a service SAS. However, it doesn't support container-level policies and has less flexibility and control over the permissions that are granted. Once malicious users get it, your storage account will be compromised easily.
CA5376 Use SharedAccessProtocolHttpsOnly	SAS is sensitive data that can't be transported in plain text on HTTP.

Rule ID and Warning	Description
CA5377 Use container level access policy	A container-level access policy can be modified or revoked at any time. It provides greater flexibility and control over the permissions that are granted.
CA5378: Do not disable ServicePointManagerSecurityProtocols	<p>Setting</p> <pre>Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocol to true limits Windows Communication Framework's (WCF) Transport Layer Security (TLS) connections to using TLS 1.0. That version of TLS will be deprecated.</pre>
CA5379 Do not use weak key derivation function algorithm	The Rfc2898DeriveBytes class defaults to using the SHA1 algorithm. You should specify the hash algorithm to use in some overloads of the constructor with SHA256 or higher. Note, HashAlgorithm property only has a <code>get</code> accessor and doesn't have a <code>overridden</code> modifier.
CA5380: Do not add certificates to root store	This rule detects code that adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public CAs that has met the requirements of the Microsoft Root Certificate Program.
CA5381: Ensure certificates are not added to root store	This rule detects code that potentially adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public certification authorities (CAs) that has met the requirements of the Microsoft Root Certificate Program.
CA5382 Use secure cookies in ASP.NET Core	Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Secure Sockets Layer (SSL).
CA5383 Ensure use secure cookies in ASP.NET Core	Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Secure Sockets Layer (SSL).
CA5384 Do not use digital signature algorithm (DSA)	DSA is a weak asymmetric encryption algorithm.
CA5385 Use Rivest–Shamir–Adleman (RSA) algorithm with sufficient key size	An RSA key smaller than 2048 bits is more vulnerable to brute force attacks.
CA5386: Avoid hardcoding SecurityProtocolType value	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version and target at least .NET Framework v4.7.1.
CA5387 Do not use weak key derivation function with insufficient iteration count	This rule checks if a cryptographic key was generated by Rfc2898DeriveBytes with an iteration count of less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.
CA5388 Ensure sufficient iteration count when using weak key derivation function	This rule checks if a cryptographic key was generated by Rfc2898DeriveBytes with an iteration count that may be less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.

Rule ID and Warning	Description
CA5389: Do not add archive item's path to the target file system path	File path can be relative and can lead to file system access outside of the expected file system target path, leading to malicious config changes and remote code execution via lay-and-wait technique.
CA5390 Do not hard-code encryption key	For a symmetric algorithm to be successful, the secret key must be known only to the sender and the receiver. When a key is hard-coded, it is easily discovered. Even with compiled binaries, it is easy for malicious users to extract it. Once the private key is compromised, the cipher text can be decrypted directly and is not protected anymore.
CA5391 Use antiforgery tokens in ASP.NET Core MVC controllers	Handling a <code>POST</code> , <code>PUT</code> , <code>PATCH</code> , or <code>DELETE</code> request without validating an antiforgery token may be vulnerable to cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET Core MVC controller.
CA5392 Use DefaultDllImportSearchPaths attribute for P/Invokes	By default, P/Invoke functions using <code>DllImportAttribute</code> probe a number of directories, including the current working directory for the library to load. This can be a security issue for certain applications, leading to DLL hijacking.
CA5393 Do not use unsafe DllImportSearchPath value	There could be a malicious DLL in the default DLL search directories and assembly directories. Or, depending on where your application is run from, there could be a malicious DLL in the application's directory.
CA5394 Do not use insecure randomness	Using a cryptographically weak pseudo-random number generator may allow an attacker to predict what security-sensitive value will be generated.
CA5395 Miss <code>HttpVerb</code> attribute for action methods	All the action methods that create, edit, delete, or otherwise modify data needs to be protected with the antiforgery attribute from cross-site request forgery attacks. Performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.
CA5396 Set <code>HttpOnly</code> to true for <code>HttpCookie</code>	As a defense in depth measure, ensure security sensitive HTTP cookies are marked as <code>HttpOnly</code> . This indicates web browsers should disallow scripts from accessing the cookies. Injected malicious scripts are a common way of stealing cookies.
CA5397: Do not use deprecated <code>SslProtocols</code> values	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk.
CA5398: Avoid hardcoded <code>SslProtocols</code> values	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version.
CA5399 Definitely disable <code>HttpClient</code> certificate revocation list check	A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.

RULE ID AND WARNING	DESCRIPTION
CA5400 Ensure HttpClient certificate revocation list check is not disabled	A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.
CA5401 Do not use CreateEncryptor with non-default IV	Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.
CA5402 Use CreateEncryptor with the default IV	Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.
CA5403: Do not hard-code certificate	The <code>data</code> or <code>rawData</code> parameter of a <code>X509Certificate</code> or <code>X509Certificate2</code> constructor is hard-coded.
CA5404: Do not disable token validation checks	<code>TokenValidationParameters</code> properties that control token validation should not be set to <code>false</code> .
CA5405: Do not always skip token validation in delegates	The callback assigned to <code>AudienceValidator</code> or <code>LifetimeValidator</code> always returns <code>true</code> .
IL3000 Avoid accessing Assembly file path when publishing as a single file	Avoid accessing Assembly file path when publishing as a single file.
IL3001 Avoid accessing Assembly file path when publishing as a single-file	Avoid accessing Assembly file path when publishing as a single file.
IL3002 Avoid calling members annotated with 'RequiresAssemblyFilesAttribute' when publishing as a single file	Avoid calling members annotated with 'RequiresAssemblyFilesAttribute' when publishing as a single file
IL3003 'RequiresAssemblyFilesAttribute' annotations must match across all interface implementations or overrides.	'RequiresAssemblyFilesAttribute' annotations must match across all interface implementations or overrides.

Legend

The following table shows the type of information that is provided for each rule in the reference documentation.

ITEM	DESCRIPTION
Type	The TypeName for the rule.
Rule ID	The unique identifier for the rule. RuleId and Category are used for in-source suppression of a warning.
Category	The category of the rule, for example, security.
Fix is breaking or non-breaking	Whether the fix for a violation of the rule is a breaking change. Breaking change means that an assembly that has a dependency on the target that caused the violation will not recompile with the new fixed version or might fail at run time because of the change. When multiple fixes are available and at least one fix is a breaking change and one fix is not, both 'Breaking' and 'Non-breaking' are specified.
Cause	The specific managed code that causes the rule to generate a warning.
Description	Discusses the issues that are behind the warning.
How to fix violations	Explains how to change the source code to satisfy the rule and prevent it from generating a warning.

ITEM	DESCRIPTION
When to suppress warnings	Describes when it is safe to suppress a warning from the rule.
Example code	Examples that violate the rule and corrected examples that satisfy the rule.
Related rules	Related rules.

Design rules

9/20/2022 • 10 minutes to read • [Edit Online](#)

Design rules support adherence to the [.NET Framework design guidelines](#).

In this section

RULE	DESCRIPTION
CA1000: Do not declare static members on generic types	When a static member of a generic type is called, the type argument must be specified for the type. When a generic instance member that does not support inference is called, the type argument must be specified for the member. In these two cases, the syntax for specifying the type argument is different and easily confused.
CA1001: Types that own disposable fields should be disposable	A class declares and implements an instance field that is a System.IDisposable type and the class does not implement IDisposable. A class that declares an IDisposable field indirectly owns an unmanaged resource and should implement the IDisposable interface.
CA1002: Do not expose generic lists	System.Collections.Generic.List<(Of <(T>)>) is a generic collection that is designed for performance, not inheritance. Therefore, List does not contain any virtual members. The generic collections that are designed for inheritance should be exposed instead.
CA1003: Use generic event handler instances	A type contains a delegate that returns void, whose signature contains two parameters (the first an object and the second a type that is assignable to EventArgs), and the containing assembly targets .NET Framework 2.0.
CA1005: Avoid excessive parameters on generic types	The more type parameters a generic type contains, the more difficult it is to know and remember what each type parameter represents. It is usually obvious with one type parameter, as in List<T>, and in certain cases with two type parameters, as in Dictionary< TKey, TValue >. However, if more than two type parameters exist, the difficulty becomes too great for most users.
CA1008: Enums should have zero value	The default value of an uninitialized enumeration, just as other value types, is zero. A nonflags attributed enumeration should define a member by using the value of zero so that the default value is a valid value of the enumeration. If an enumeration that has the FlagsAttribute attribute applied defines a zero-valued member, its name should be "None" to indicate that no values have been set in the enumeration.
CA1010: Collections should implement generic interface	To broaden the usability of a collection, implement one of the generic collection interfaces. Then the collection can be used to populate generic collection types.

Rule	Description
CA1012: Abstract types should not have constructors	Constructors on abstract types can be called only by derived types. Because public constructors create instances of a type, and you cannot create instances of an abstract type, an abstract type that has a public constructor is incorrectly designed.
CA1014: Mark assemblies with CLSCompliantAttribute	The Common Language Specification (CLS) defines naming restrictions, data types, and rules to which assemblies must conform if they will be used across programming languages. Good design dictates that all assemblies explicitly indicate CLS compliance by using CLSCompliantAttribute. If this attribute is not present on an assembly, the assembly is not compliant.
CA1016: Mark assemblies with AssemblyVersionAttribute	.NET uses the version number to uniquely identify an assembly, and to bind to types in strongly named assemblies. The version number is used together with version and publisher policy. By default, applications run only with the assembly version with which they were built.
CA1017: Mark assemblies with ComVisibleAttribute	ComVisibleAttribute determines how COM clients access managed code. Good design dictates that assemblies explicitly indicate COM visibility. COM visibility can be set for the whole assembly and then overridden for individual types and type members. If this attribute is not present, the contents of the assembly are visible to COM clients.
CA1018: Mark attributes with AttributeUsageAttribute	When you define a custom attribute, mark it by using AttributeUsageAttribute to indicate where in the source code the custom attribute can be applied. The meaning and intended usage of an attribute will determine its valid locations in code.
CA1019: Define accessors for attribute arguments	Attributes can define mandatory arguments that must be specified when you apply the attribute to a target. These are also known as positional arguments because they are supplied to attribute constructors as positional parameters. For every mandatory argument, the attribute should also provide a corresponding read-only property so that the value of the argument can be retrieved at execution time. Attributes can also define optional arguments, which are also known as named arguments. These arguments are supplied to attribute constructors by name and should have a corresponding read/write property.
CA1021: Avoid out parameters	Passing types by reference (using out or ref) requires experience with pointers, understanding how value types and reference types differ, and handling methods with multiple return values. Also, the difference between out and ref parameters is not widely understood.
CA1024: Use properties where appropriate	A public or protected method has a name that starts with "Get", takes no parameters, and returns a value that is not an array. The method might be a good candidate to become a property.

Rule	Description
CA1027: Mark enums with FlagsAttribute	An enumeration is a value type that defines a set of related named constants. Apply FlagsAttribute to an enumeration when its named constants can be meaningfully combined.
CA1028: Enum storage should be Int32	An enumeration is a value type that defines a set of related named constants. By default, the System.Int32 data type is used to store the constant value. Even though you can change this underlying type, it is not required or recommended for most scenarios.
CA1030: Use events where appropriate	This rule detects methods that have names that ordinarily would be used for events. If a method is called in response to a clearly defined state change, the method should be invoked by an event handler. Objects that call the method should raise events instead of calling the method directly.
CA1031: Do not catch general exception types	General exceptions should not be caught. Catch a more-specific exception, or rethrow the general exception as the last statement in the catch block.
CA1032: Implement standard exception constructors	Failure to provide the full set of constructors can make it difficult to correctly handle exceptions.
CA1033: Interface methods should be callable by child types	An unsealed externally visible type provides an explicit method implementation of a public interface and does not provide an alternative externally visible method that has the same name.
CA1034: Nested types should not be visible	A nested type is a type that is declared in the scope of another type. Nested types are useful to encapsulate private implementation details of the containing type. Used for this purpose, nested types should not be externally visible.
CA1036: Override methods on comparable types	A public or protected type implements the System.IComparable interface. It does not override Object.Equals nor does it overload the language-specific operator for equality, inequality, less than, or greater than.
CA1040: Avoid empty interfaces	Interfaces define members that provide a behavior or usage contract. The functionality that is described by the interface can be adopted by any type, regardless of where the type appears in the inheritance hierarchy. A type implements an interface by providing implementations for the members of the interface. An empty interface does not define any members; therefore, it does not define a contract that can be implemented.
CA1041: Provide ObsoleteAttribute message	A type or member is marked by using a System.ObsoleteAttribute attribute that does not have its ObsoleteAttribute.Message property specified. When a type or member that is marked by using ObsoleteAttribute is compiled, the Message property of the attribute is displayed, which gives the user information about the obsolete type or member.

Rule	Description
CA1043: Use integral or string argument for indexers	Indexers (that is, indexed properties) should use integral or string types for the index. These types are typically used for indexing data structures and they increase the usability of the library. Use of the Object type should be restricted to those cases where the specific integral or string type cannot be specified at design time.
CA1044: Properties should not be write only	Although it is acceptable and often necessary to have a read-only property, the design guidelines prohibit the use of write-only properties. This is because letting a user set a value, and then preventing the user from viewing that value, does not provide any security. Also, without read access, the state of shared objects cannot be viewed, which limits their usefulness.
CA1045: Do not pass types by reference	Passing types by reference (using out or ref) requires experience with pointers, understanding how value types and reference types differ, and handling methods with multiple return values. Library architects who design for a general audience should not expect users to become proficient in working with out or ref parameters.
CA1046: Do not overload operator equals on reference types	For reference types, the default implementation of the equality operator is almost always correct. By default, two references are equal only if they point to the same object.
CA1047: Do not declare protected members in sealed types	Types declare protected members so that inheriting types can access or override the member. By definition, sealed types cannot be inherited, which means that protected methods on sealed types cannot be called.
CA1050: Declare types in namespaces	Types are declared in namespaces to prevent name collisions and as a way to organize related types in an object hierarchy.
CA1051: Do not declare visible instance fields	The primary use of a field should be as an implementation detail. Fields should be private or internal and should be exposed by using properties.
CA1052: Static holder types should be sealed	A public or protected type contains only static members and is not declared by using the sealed (C#) or NotInheritable (Visual Basic) modifier. A type that is not meant to be inherited should be marked by using the sealed modifier to prevent its use as a base type.
CA1053: Static holder types should not have constructors	A public or nested public type declares only static members and has a public or protected default constructor. The constructor is unnecessary because calling static members does not require an instance of the type. The string overload should call the uniform resource identifier (URI) overload by using the string argument for safety and security.
CA1054: URI parameters should not be strings	If a method takes a string representation of a URI, a corresponding overload should be provided that takes an instance of the Uri class, which provides these services in a safe and secure manner.

Rule	Description
CA1055: URI return values should not be strings	This rule assumes that the method returns a URI. A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The System.Uri class provides these services in a safe and secure manner.
CA1056: URI properties should not be strings	This rule assumes that the property represents a URI. A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The System.Uri class provides these services in a safe and secure manner.
CA1058: Types should not extend certain base types	An externally visible type extends certain base types. Use one of the alternatives.
CA1060: Move P/Invokes to NativeMethods class	Platform Invocation methods, such as those marked with the System.Runtime.InteropServices.DllImportAttribute or methods defined by using the Declare keyword in Visual Basic, access unmanaged code. These methods should be of the NativeMethods, SafeNativeMethods, or UnsafeNativeMethods class.
CA1061: Do not hide base class methods	A method in a base type is hidden by an identically named method in a derived type, when the parameter signature of the derived method differs only by types that are more weakly derived than the corresponding types in the parameter signature of the base method.
CA1062: Validate arguments of public methods	All reference arguments that are passed to externally visible methods should be checked against null.
CA1063: Implement IDisposable correctly	All IDisposable types should implement the Dispose pattern correctly.
CA1064: Exceptions should be public	An internal exception is visible only inside its own internal scope. After the exception falls outside the internal scope, only the base exception can be used to catch the exception. If the internal exception is inherited from System.Exception , System.SystemException , or System.ApplicationException , the external code will not have sufficient information to know what to do with the exception.
CA1065: Do not raise exceptions in unexpected locations	A method that is not expected to throw exceptions throws an exception.
CA1066: Implement IEquatable when overriding Equals	A value type overrides Equals method, but does not implement IEquatable<T> .
CA1067: Override Equals when implementing IEquatable	A type implements IEquatable<T> , but does not override Equals method.
CA1068: CancellationToken parameters must come last	A method has a CancellationToken parameter that is not the last parameter.
CA1069: Enums should not have duplicate values	An enumeration has multiple members which are explicitly assigned the same constant value.

RULE	DESCRIPTION
CA1070: Do not declare event fields as virtual	A field-like event was declared as virtual.

CA1000: Do not declare static members on generic types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1000
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A generic type contains a `static` (`Shared` in Visual Basic) member.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

When a `static` member of a generic type is called, the type argument must be specified for the type. When a generic instance member that does not support inference is called, the type argument must be specified for the member. The syntax for specifying the type argument in these two cases is different and easily confused, as the following calls demonstrate:

```
' Shared method in a generic type.  
GenericType(Of Integer).SharedMethod()  
  
' Generic instance method that does not support inference.  
someObject.GenericMethod(Of Integer)()
```

```
// Static method in a generic type.  
GenericType<int>.StaticMethod();  
  
// Generic instance method that does not support inference.  
someObject.GenericMethod<int>();
```

Generally, both of the prior declarations should be avoided so that the type argument does not have to be specified when the member is called. This results in a syntax for calling members in generics that is no different from the syntax for non-generics.

How to fix violations

To fix a violation of this rule, remove the static member or change it to an instance member.

When to suppress warnings

Do not suppress a warning from this rule. Providing generics in a syntax that is easy to understand and use reduces the time that is required to learn and increases the adoption rate of new libraries.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1000
// The code that's violating the rule is on this line.
#pragma warning restore CA1000
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1000.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Related rules

CA1001: Types that own disposable fields should be disposable

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1001
Category	Design
Fix is breaking or non-breaking	Non-breaking - If the type is not visible outside the assembly. Breaking - If the type is visible outside the assembly.

Cause

A class declares and implements an instance field that is an [System.IDisposable](#) type, and the class does not implement [IDisposable](#).

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

A class that declares an [IDisposable](#) field indirectly owns an unmanaged resource. The class should implement the [IDisposable](#) interface to dispose of the unmanaged resource that it owns once the resource is no longer in use. If the class does not *directly* own any unmanaged resources, it should not implement a finalizer.

This rule respects types implementing [System.IAsyncDisposable](#) as disposable types.

How to fix violations

To fix a violation of this rule, implement the [IDisposable](#) interface. In the [IDisposable.Dispose](#) method, call the [Dispose](#) method of the field's type.

When to suppress warnings

In general, do not suppress a warning from this rule. It's okay to suppress the warning when the dispose ownership of the field is not held by the containing type.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1001
// The code that's violating the rule is on this line.
#pragma warning restore CA1001
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1001.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

These options can be configured for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should

not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following example shows a class that violates the rule and a class that satisfies the rule by implementing [IDisposable](#). The class does not implement a finalizer because the class does not directly own any unmanaged resources.

```
Imports System
Imports System.IO

Namespace ca1001

    ' This class violates the rule.
    Public Class NoDisposeMethod

        Dim newFile As FileStream

        Sub New()
            newFile = New FileStream("c:\temp.txt", FileMode.Open)
        End Sub

    End Class

    ' This class satisfies the rule.
    Public Class HasDisposeMethod
        Implements IDisposable

        Dim newFile As FileStream

        Sub New()
            newFile = New FileStream("c:\temp.txt", FileMode.Open)
        End Sub

        Protected Overridable Overloads Sub Dispose(disposing As Boolean)

            If disposing Then
                ' dispose managed resources
                newFile.Close()
            End If

            ' free native resources

        End Sub 'Dispose

        Public Overloads Sub Dispose() Implements IDisposable.Dispose

            Dispose(True)
            GC.SuppressFinalize(Me)

        End Sub 'Dispose

    End Class

End Namespace
```

```
// This class violates the rule.
public class NoDisposeMethod
{
    FileStream _newFile;

    public NoDisposeMethod()
    {
        _newFile = new FileStream(@"c:\temp.txt", FileMode.Open);
    }
}

// This class satisfies the rule.
public class HasDisposeMethod : IDisposable
{
    FileStream _newFile;

    public HasDisposeMethod()
    {
        _newFile = new FileStream(@"c:\temp.txt", FileMode.Open);
    }

    protected virtual void Dispose(bool disposing)
    {
        if (disposing)
        {
            // Dispose managed resources.
            _newFile.Close();
        }
        // Free native resources.
    }

    public void Dispose()
    {
        Dispose(true);
        GC.SuppressFinalize(this);
    }
}
```

See also

- [Implement a Dispose method](#)

CA1002: Do not expose generic lists

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1002
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type contains an externally visible member that is a `System.Collections.Generic.List<T>` type, returns a `List<T>` type, or whose signature includes a `List<T>` parameter.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

`System.Collections.Generic.List<T>` is a generic collection that's designed for performance and not inheritance. `List<T>` does not contain virtual members that make it easier to change the behavior of an inherited class. The following generic collections are designed for inheritance and should be exposed instead of `List<T>`.

- `System.Collections.ObjectModel.Collection<T>`
- `System.Collections.ObjectModel.ReadOnlyCollection<T>`
- `System.Collections.ObjectModel.KeyedCollection<TKey,TItem>`
- `System.Collections.Generic.IList<T>`
- `System.Collections.Generic.ICollection<T>`

How to fix violations

To fix a violation of this rule, change the `System.Collections.Generic.List<T>` type to one of the generic collections that's designed for inheritance.

When to suppress warnings

Do not suppress a warning from this rule unless the assembly that raises this warning is not meant to be a reusable library. For example, it would be safe to suppress this warning in a performance-tuned application where a performance benefit was gained from the use of generic lists.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1002
// The code that's violating the rule is on this line.
#pragma warning restore CA1002
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1002.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Related rules

See also

[Generics](#)

CA1003: Use generic event handler instances

9/20/2022 • 3 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1003
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type contains a delegate that returns void and whose signature contains two parameters (the first an object and the second a type that is assignable to EventArgs), and the containing assembly targets .NET.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Before .NET Framework 2.0, in order to pass custom information to the event handler, a new delegate had to be declared that specified a class that was derived from the [System.EventArgs](#) class. In .NET Framework 2.0 and later versions, the generic [System.EventHandler<TEventArgs>](#) delegate allows any class that's derived from [EventArgs](#) to be used together with the event handler.

How to fix violations

To fix a violation of this rule, remove the delegate and replace its use by using the [System.EventHandler<TEventArgs>](#) delegate.

If the delegate is autogenerated by the Visual Basic compiler, change the syntax of the event declaration to use the [System.EventHandler<TEventArgs>](#) delegate.

When to suppress warnings

Do not suppress a warning from this rule.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows a delegate that violates the rule. In the Visual Basic example, comments describe how to modify the example to satisfy the rule. For the C# example, an example follows that shows the modified code.

```

Imports System

Namespace ca1003

    Public Class CustomEventArgs
        Inherits EventArgs

        Public info As String = "data"

    End Class

    Public Class ClassThatRaisesEvent

        ' This statement creates a new delegate, which violates the rule.
        Event SomeEvent(sender As Object, e As CustomEventArgs)

        ' To satisfy the rule, comment out the previous line
        ' and uncomment the following line.
        'Event SomeEvent As EventHandler(Of CustomEventArgs)

        Protected Overridable Sub OnSomeEvent(e As CustomEventArgs)
            RaiseEvent SomeEvent(Me, e)
        End Sub

        Sub SimulateEvent()
            OnSomeEvent(New CustomEventArgs())
        End Sub

    End Class

    Public Class ClassThatHandlesEvent

        Sub New(eventRaiser As ClassThatRaisesEvent)
            AddHandler eventRaiser.SomeEvent, AddressOf HandleEvent
        End Sub

        Private Sub HandleEvent(sender As Object, e As CustomEventArgs)
            Console.WriteLine("Event handled: {0}", e.info)
        End Sub

    End Class

    Class Test

        Shared Sub Main()

            Dim eventRaiser As New ClassThatRaisesEvent()
            Dim eventHandler As New ClassThatHandlesEvent(eventRaiser)

            eventRaiser.SimulateEvent()

        End Sub

    End Class

End Namespace

```

```

// This delegate violates the rule.
public delegate void CustomEventHandler(object sender, CustomEventArgs e);

public class CustomEventArgs : EventArgs
{
    public string info = "data";
}

public class ClassThatRaisesEvent
{
    public event CustomEventHandler SomeEvent;

    protected virtual void OnSomeEvent(CustomEventArgs e)
    {
        SomeEvent?.Invoke(this, e);
    }

    public void SimulateEvent()
    {
        OnSomeEvent(new CustomEventArgs());
    }
}

public class ClassThatHandlesEvent
{
    public ClassThatHandlesEvent(ClassThatRaisesEvent eventRaiser)
    {
        eventRaiser.SomeEvent += new CustomEventHandler(HandleEvent);
    }

    private void HandleEvent(object sender, CustomEventArgs e)
    {
        Console.WriteLine("Event handled: {0}", e.info);
    }
}

class Test
{
    static void MainEvent()
    {
        var eventRaiser = new ClassThatRaisesEvent();
        var eventHandler = new ClassThatHandlesEvent(eventRaiser);

        eventRaiser.SimulateEvent();
    }
}

```

The following code snippet removes the delegate declaration from the previous example, which satisfies the rule. It replaces its use in the `ClassThatRaisesEvent` and `ClassThatHandlesEvent` methods by using the `System.EventHandler<TEventArgs>` delegate.

```

public class CustomEventArgs : EventArgs
{
    public string info = "data";
}

public class ClassThatRaisesEvent
{
    public event EventHandler<CustomEventArgs> SomeEvent;

    protected virtual void OnSomeEvent(CustomEventArgs e)
    {
        SomeEvent?.Invoke(this, e);
    }

    public void SimulateEvent()
    {
        OnSomeEvent(new CustomEventArgs());
    }
}

public class ClassThatHandlesEvent
{
    public ClassThatHandlesEvent(ClassThatRaisesEvent eventRaiser)
    {
        eventRaiser.SomeEvent += new EventHandler<CustomEventArgs>(HandleEvent);
    }

    private void HandleEvent(object sender, CustomEventArgs e)
    {
        Console.WriteLine("Event handled: {0}", e.info);
    }
}

class Test
{
    static void MainEvent()
    {
        var eventRaiser = new ClassThatRaisesEvent();
        var eventHandler = new ClassThatHandlesEvent(eventRaiser);

        eventRaiser.SimulateEvent();
    }
}

```

CA1005: Avoid excessive parameters on generic types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1005
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

An externally visible generic type has more than two type parameters.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

The more type parameters a generic type contains, the more difficult it is to know and remember what each type parameter represents. It is usually obvious with one type parameter, as in `List<T>`, and in certain cases with two type parameters, as in `Dictionary< TKey, TValue >`. If more than two type parameters exist, the difficulty becomes too great for most users (for example, `TooManyTypeParameters<T, K, v>` in C# or `TooManyTypeParameters(Of T, K, V)` in Visual Basic).

How to fix violations

To fix a violation of this rule, change the design to use no more than two type parameters.

When to suppress warnings

Do not suppress a warning from this rule unless the design absolutely requires more than two type parameters. Providing generics in a syntax that is easy to understand and use reduces the time that is required to learn and increases the adoption rate of new libraries.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1005
// The code that's violating the rule is on this line.
#pragma warning restore CA1005
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1005.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Rule ID	CA1008
Category	Design
Fix is breaking or non-breaking	Non-breaking - When you're prompted to add a <code>None</code> value to a non-flag enumeration. Breaking - When you're prompted to rename or remove any enumeration values.

Cause

An enumeration without an applied `System.FlagsAttribute` does not define a member that has a value of zero. Or, an enumeration that has an applied `FlagsAttribute` defines a member that has a value of zero but its name is not 'None'. Or, the enumeration defines multiple, zero-valued members.

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

The default value of an uninitialized enumeration, just like other value types, is zero. A non-flags-attributed enumeration should define a member that has the value of zero so that the default value is a valid value of the enumeration. If appropriate, name the member 'None' (or one of the [additional permitted names](#)). Otherwise, assign zero to the most frequently used member. By default, if the value of the first enumeration member is not set in the declaration, its value is zero.

If an enumeration that has the `FlagsAttribute` applied defines a zero-valued member, its name should be 'None' (or one of the [additional permitted names](#)) to indicate that no values have been set in the enumeration. Using a zero-valued member for any other purpose is contrary to the use of the `FlagsAttribute` in that the `AND` and `OR` bitwise operators are useless with the member. This implies that only one member should be assigned the value zero. If multiple members that have the value zero occur in a flags-attributed enumeration, `Enum.ToString()` returns incorrect results for members that are not zero.

How to fix violations

To fix a violation of this rule for non-flags-attributed enumerations, define a member that has the value of zero; this is a non-breaking change. For flags-attributed enumerations that define a zero-valued member, name this member 'None' and delete any other members that have a value of zero; this is a breaking change.

When to suppress warnings

Do not suppress a warning from this rule except for flags-attributed enumerations that have previously shipped.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1008
// The code that's violating the rule is on this line.
#pragma warning restore CA1008
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1008.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Additional zero-value field names](#)

You can configure this option for just this rule, for all rules, or for all rules in this category (Design). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Additional zero-value field names

In .NET 7 and later versions, you can configure other allowable names for a zero-value enumeration field, besides `None`. Separate multiple names by the `|` character. The following table shows some examples.

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1008.additional_enum_none_names = Never</code>	Allows both <code>None</code> and <code>Never</code>
<code>dotnet_code_quality.CA1008.additional_enum_none_names = Never Nothing</code>	Allows <code>None</code> , <code>Never</code> , and <code>Nothing</code>

Example

The following example shows two enumerations that satisfy the rule and an enumeration, `BadTraceOptions`, that violates the rule.

```
using System;

namespace ca1008
{
    public enum TraceLevel
    {
        Off = 0,
        Error = 1,
        Warning = 2,
        Info = 3,
        Verbose = 4
    }

    [Flags]
    public enum TraceOptions
    {
        None = 0,
        CallStack = 0x01,
        LogicalStack = 0x02,
        DateTime = 0x04,
        Timestamp = 0x08,
    }

    [Flags]
    public enum BadTraceOptions
    {
        CallStack = 0,
        LogicalStack = 0x01,
        DateTime = 0x02,
        Timestamp = 0x04,
    }

    class UseBadTraceOptions
    {
        static void MainTrace()
        {
            // Set the flags.
            BadTraceOptions badOptions =
                BadTraceOptions.LogicalStack | BadTraceOptions.Timestamp;

            // Check whether CallStack is set.
            if ((badOptions & BadTraceOptions.CallStack) ==
                BadTraceOptions.CallStack)
            {
                // This 'if' statement is always true.
            }
        }
    }
}
```

```

Imports System

Namespace ca1008

    Public Enum TraceLevel
        Off = 0
        AnError = 1
        Warning = 2
        Info = 3
        Verbose = 4
    End Enum

    <Flags>
    Public Enum TraceOptions
        None = 0
        CallStack = &H1
        LogicalStack = &H2
        DateTime = &H4
        Timestamp = &H8
    End Enum

    <Flags>
    Public Enum BadTraceOptions
        CallStack = 0
        LogicalStack = &H1
        DateTime = &H2
        Timestamp = &H4
    End Enum

    Class UseBadTraceOptions

        Shared Sub Main1008()

            ' Set the flags.
            Dim badOptions As BadTraceOptions =
                BadTraceOptions.LogicalStack Or BadTraceOptions.Timestamp

            ' Check whether CallStack is set.
            If ((badOptions And BadTraceOptions.CallStack) =
                BadTraceOptions.CallStack) Then
                ' This 'If' statement is always true.
            End If

        End Sub

    End Class

End Namespace

```

CA1010: Collections should implement generic interface

9/20/2022 • 4 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1010
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type implements the [System.Collections.IEnumerable](#) interface but does not implement the [System.Collections.Generic.IEnumerable<T>](#) interface, and the containing assembly targets .NET. This rule ignores types that implement [System.Collections.IDictionary](#).

By default, this rule only looks at externally visible types, but this is [configurable](#). You can also configure additional interfaces to require that a generic interface be implemented.

Rule description

To broaden the usability of a collection, implement one of the generic collection interfaces. Then the collection can be used to populate generic collection types such as the following:

- [System.Collections.Generic.List<T>](#)
- [System.Collections.Generic.Queue<T>](#)
- [System.Collections.Generic.Stack<T>](#)

How to fix violations

To fix a violation of this rule, implement one of the following generic collection interfaces:

- [System.Collections.Generic.IEnumerable<T>](#)
- [System.Collections.Generic.ICollection<T>](#)
- [System.Collections.Generic.IList<T>](#)

When to suppress warnings

It is safe to suppress a warning from this rule; however, the use of the collection will be more limited.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1010
// The code that's violating the rule is on this line.
#pragma warning restore CA1010
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1010.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Additional required generic interfaces](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Additional required generic interfaces

You can configure the list of interface names (separated by `|`) with their required generic fully qualified interface (separated by `->`).

Allowed interface formats:

- Interface name only (includes all interfaces with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#) with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1010.additional_required_generic_interfaces = ISomething->System.Collections.Generic.IEnumerable`1</code>	All types that implement <code>ISomething</code> regardless of its namespace are expected to also implement <code>System.Collections.Generic.IEnumerable<T></code> .
<code>dotnet_code_quality.CA1010.additional_required_generic_interfaces = T:System.Collections.IDictionary->T:System.Collections.Generic.IDictionary`2</code>	All types that implement <code>System.Collections.IDictionary</code> are expected to also implement <code>System.Collections.Generic.IDictionary<TKey, TValue></code> .

Example

The following example shows a class that derives from the non-generic `CollectionBase` class and violates this rule.

```
public class Book
{
    public Book()
    {
    }
}

public class BookCollection : CollectionBase
{
    public BookCollection()
    {
    }

    public void Add(Book value)
    {
        InnerList.Add(value);
    }

    public void Remove(Book value)
    {
        InnerList.Remove(value);
    }

    public void Insert(int index, Book value)
    {
        InnerList.Insert(index, value);
    }

    public Book this[int index]
    {
        get { return (Book)InnerList[index]; }
        set { InnerList[index] = value; }
    }

    public bool Contains(Book value)
    {
        return InnerList.Contains(value);
    }

    public int IndexOf(Book value)
    {
        return InnerList.IndexOf(value);
    }

    public void CopyTo(Book[] array, int arrayIndex)
    {
        InnerList.CopyTo(array, arrayIndex);
    }
}
```

To fix a violation of this rule, do one of the following:

- [Implement the generic interface](#).
- [Change the base class](#) to a type that already implements both the generic and non-generic interfaces, such as the `Collection<T>` class.

Fix by interface implementation

The following example fixes the violation by implementing these generic interfaces: `IEnumerable<T>`, `ICollection<T>`, and `IList<T>`.

```
public class Book
{
    public Book()
    {
    }
}

public class BookCollection : CollectionBase, IList<Book>
{
    public BookCollection()
    {
    }

    int IList<Book>.IndexOf(Book item)
    {
        return this.List.IndexOf(item);
    }

    void IList<Book>.Insert(int location, Book item)
    {
    }

    Book IList<Book>.this[int index]
    {
        get { return (Book)this.List[index]; }
        set { }
    }

    void ICollection<Book>.Add(Book item)
    {
    }

    bool ICollection<Book>.Contains(Book item)
    {
        return true;
    }

    void ICollection<Book>.CopyTo(Book[] array, int arrayIndex)
    {
    }

    bool ICollection<Book>.IsReadOnly
    {
        get { return false; }
    }

    bool ICollection<Book>.Remove(Book item)
    {
        if (InnerList.Contains(item))
        {
            InnerList.Remove(item);
            return true;
        }
        return false;
    }

    IEnumerator<Book> IEnumerable<Book>.GetEnumerator()
    {
        return new BookCollectionEnumerator(InnerList.GetEnumerator());
    }

    private class BookCollectionEnumerator : IEnumerator<Book>
    {
        private IEnumerator _Enumerator;

        public BookCollectionEnumerator(IEnumerable enumerator)
        {
            _Enumerator = enumerator;
        }
    }
}
```

```

    }

    public Book Current
    {
        get { return (Book)_Enumerator.Current; }
    }

    object IEnumerator.Current
    {
        get { return _Enumerator.Current; }
    }

    public bool MoveNext()
    {
        return _Enumerator.MoveNext();
    }

    public void Reset()
    {
        _Enumerator.Reset();
    }

    public void Dispose()
    {
    }
}
}

```

Fix by base class change

The following example fixes the violation by changing the base class of the collection from the non-generic `CollectionBase` class to the generic `Collection<T>` (`Collection(Of T)` in Visual Basic) class.

```

public class Book
{
    public Book()
    {
    }
}

public class BookCollection : Collection<Book>
{
    public BookCollection()
    {
    }
}

```

Changing the base class of an already released class is considered a breaking change to existing consumers.

CA1012: Abstract types should not have public constructors

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1012
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type is abstract and has a public constructor.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Constructors on abstract types can be called only by derived types. Because public constructors create instances of a type and you cannot create instances of an abstract type, an abstract type that has a public constructor is incorrectly designed.

How to fix violations

To fix a violation of this rule, either make the constructor protected or don't declare the type as abstract.

When to suppress warnings

Do not suppress a warning from this rule. The abstract type has a public constructor.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1012
// The code that's violating the rule is on this line.
#pragma warning restore CA1012
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1012.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example

The following code snippet contains an abstract type that violates this rule.

```
' Violates this rule
Public MustInherit Class Book

    Public Sub New()
    End Sub

End Class
```

```
// Violates this rule
public abstract class Book
{
    public Book()
    {
    }
}
```

The following code snippet fixes the previous violation by changing the accessibility of the constructor from `public` to `protected`.

```
// Does not violate this rule
public abstract class Book
{
    protected Book()
    {
    }
}
```

```
' Violates this rule
Public MustInherit Class Book

Protected Sub New()
End Sub

End Class
```

CA1014: Mark assemblies with CLSCompliantAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1014
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

An assembly does not have the [System.CLSCompliantAttribute](#) attribute applied to it.

Rule description

The Common Language Specification (CLS) defines naming restrictions, data types, and rules to which assemblies must conform if they will be used across programming languages. Good design dictates that all assemblies explicitly indicate CLS compliance with [CLSCompliantAttribute](#). If the attribute is not present on an assembly, the assembly is not compliant.

It is possible for a CLS-compliant assembly to contain types or type members that are not compliant.

How to fix violations

To fix a violation of this rule, add the attribute to the assembly. Instead of marking the whole assembly as noncompliant, you should determine which type or type members are not compliant and mark these elements as such. If possible, you should provide a CLS-compliant alternative for noncompliant members so that the widest possible audience can access all the functionality of your assembly.

When to suppress warnings

Do not suppress a warning from this rule. If you do not want the assembly to be compliant, apply the attribute and set its value to `false`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1014
// The code that's violating the rule is on this line.
#pragma warning restore CA1014
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1014.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows an assembly that has the [System.CLSCompliantAttribute](#) attribute applied that declares it CLS-compliant.

```
[assembly:CLSCompliant(true)]
namespace DesignLibrary {}
```

```
<assembly:CLSCompliant(true)>
Namespace DesignLibrary
End Namespace
```

CA1016: Mark assemblies with AssemblyVersionAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1016
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

The assembly does not have a version number.

Rule description

The identity of an assembly is composed of the following information:

- Assembly name
- Version number
- Culture
- Public key (for strongly named assemblies).

.NET uses the version number to uniquely identify an assembly and to bind to types in strongly named assemblies. The version number is used together with version and publisher policy. By default, applications run only with the assembly version with which they were built.

How to fix violations

To fix a violation of this rule, add a version number to the assembly by using the [System.Reflection.AssemblyVersionAttribute](#) attribute.

When to suppress warnings

Do not suppress a warning from this rule for assemblies that are used by third parties or in a production environment.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1016
// The code that's violating the rule is on this line.
#pragma warning restore CA1016
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1016.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows an assembly that has the [AssemblyVersionAttribute](#) attribute applied.

```
using System;
using System.Reflection;

[assembly: AssemblyVersionAttribute("4.3.2.1")]
namespace DesignLibrary {}
```

```
<Assembly: AssemblyVersionAttribute("4.3.2.1")>
Namespace DesignLibrary
End Namespace
```

See also

- [Assembly versioning](#)
- [How to: Create a publisher policy](#)

CA1017: Mark assemblies with ComVisibleAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1017
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

An assembly does not have the [System.Runtime.InteropServices.ComVisibleAttribute](#) attribute applied to it.

Rule description

The [ComVisibleAttribute](#) attribute determines how COM clients access managed code. Good design dictates that assemblies explicitly indicate COM visibility. COM visibility can be set for a whole assembly and then overridden for individual types and type members. If the attribute is not present, the contents of the assembly are visible to COM clients.

How to fix violations

To fix a violation of this rule, add the attribute to the assembly. If you do not want the assembly to be visible to COM clients, apply the attribute and set its value to `false`.

When to suppress warnings

Do not suppress a warning from this rule. If you want the assembly to be visible, apply the attribute and set its value to `true`.

Example

The following example shows an assembly that has the [ComVisibleAttribute](#) attribute applied to prevent it from being visible to COM clients.

```
<Assembly: System.Runtime.InteropServices.ComVisible(False)>
Namespace DesignLibrary
End Namespace
```

```
[assembly: System.Runtime.InteropServices.ComVisible(false)]
namespace DesignLibrary {}
```

CA1018: Mark attributes with AttributeUsageAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1018
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

The [System.AttributeUsageAttribute](#) attribute is not present on the custom attribute.

Rule description

When you define a custom attribute, mark it by using [AttributeUsageAttribute](#) to indicate where in the source code the custom attribute can be applied. The meaning and intended usage of an attribute will determine its valid locations in code. For example, you might define an attribute that identifies the person who is responsible for maintaining and enhancing each type in a library, and that responsibility is always assigned at the type level. In this case, compilers should enable the attribute on classes, enumerations, and interfaces, but should not enable it on methods, events, or properties. Organizational policies and procedures would dictate whether the attribute should be enabled on assemblies.

The [System.AttributeTargets](#) enumeration defines the targets that you can specify for a custom attribute. If you omit [AttributeUsageAttribute](#), your custom attribute will be valid for all targets, as defined by the `All` value of [AttributeTargets](#) enumeration.

How to fix violations

To fix a violation of this rule, specify targets for the attribute by using [AttributeUsageAttribute](#). See the following example.

When to suppress warnings

You should fix a violation of this rule instead of excluding the message. Even if the attribute inherits [AttributeUsageAttribute](#), the attribute should be present to simplify code maintenance.

Example

The following example defines two attributes. `BadCodeMaintainerAttribute` incorrectly omits the [AttributeUsageAttribute](#) statement, and `GoodCodeMaintainerAttribute` correctly implements the attribute that is described earlier in this section. (The property `DeveloperName` is required by the design rule [CA1019: Define accessors for attribute arguments](#) and is included for completeness.)

```

using System;

namespace ca1018
{
    // Violates rule: MarkAttributesWithAttributeUsage.
    public sealed class BadCodeMaintainerAttribute : Attribute
    {
        public BadCodeMaintainerAttribute(string developerName)
        {
            DeveloperName = developerName;
        }
        public string DeveloperName { get; }
    }

    // Satisfies rule: Attributes specify AttributeUsage.
    // This attribute is valid for type-level targets.
    [AttributeUsage(AttributeTargets.Class | AttributeTargets.Enum | AttributeTargets.Interface | AttributeTargets.Delegate)]
    public sealed class GoodCodeMaintainerAttribute : Attribute
    {
        public GoodCodeMaintainerAttribute(string developerName)
        {
            DeveloperName = developerName;
        }
        public string DeveloperName { get; }
    }
}

```

```

Imports System

Namespace ca1018

    ' Violates rule: MarkAttributesWithAttributeUsage.
    Public NotInheritable Class BadCodeMaintainerAttribute
        Inherits Attribute

        Public Sub New(developerName As String)
            Me.DeveloperName = developerName
        End Sub 'New

        Public ReadOnly Property DeveloperName() As String
    End Class

    ' Satisfies rule: Attributes specify AttributeUsage.
    ' The attribute is valid for type-level targets.
    <AttributeUsage(AttributeTargets.Class Or AttributeTargets.Enum Or AttributeTargets.Interface Or AttributeTargets.Delegate)>
    Public NotInheritable Class GoodCodeMaintainerAttribute
        Inherits Attribute

        Public Sub New(developerName As String)
            Me.DeveloperName = developerName
        End Sub 'New

        Public ReadOnly Property DeveloperName() As String
    End Class

End Namespace

CA1019: Define accessors for attribute arguments

9/20/2022 • 3 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1019
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

In its constructor, an attribute defines arguments that do not have corresponding properties.

Rule description

Attributes can define mandatory arguments that must be specified when you apply the attribute to a target. These are also known as positional arguments because they are supplied to attribute constructors as positional parameters. For every mandatory argument, the attribute should also provide a corresponding read-only property so that the value of the argument can be retrieved at execution time. This rule checks that for each constructor parameter, you have defined the corresponding property.

Attributes can also define optional arguments, which are also known as named arguments. These arguments are supplied to attribute constructors by name and should have a corresponding read/write property.

For mandatory and optional arguments, the corresponding properties and constructor parameters should use the same name but different casing. Properties use Pascal casing, and parameters use camel casing.

How to fix violations

To fix a violation of this rule, add a read-only property for each constructor parameter that does not have one.

When to suppress warnings

Suppress a warning from this rule if you do not want the value of the mandatory argument to be retrievable.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1019
// The code that's violating the rule is on this line.
#pragma warning restore CA1019
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1019.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Examples

Custom attributes

The following example shows two attributes that define a mandatory (positional) parameter. The first implementation of the attribute is incorrectly defined. The second implementation is correct.

```
// Violates rule: DefineAccessorsForAttributeArguments.
[AttributeUsage(AttributeTargets.All)]
public sealed class BadCustomAttribute : Attribute
{
    string _data;

    // Missing the property that corresponds to
    // the someStringData constructor parameter.

    public BadCustomAttribute(string someStringData)
    {
        _data = someStringData;
    }
}

// Satisfies rule: Attributes should have accessors for all arguments.
[AttributeUsage(AttributeTargets.All)]
public sealed class GoodCustomAttribute : Attribute
{
    public GoodCustomAttribute(string someStringData)
    {
        SomeStringData = someStringData;
    }

    //The constructor parameter and property
    //name are the same except for case.

    public string SomeStringData { get; }
}
```

```

Imports System

Namespace ca1019

    ' Violates rule: DefineAccessorsForAttributeArguments.
    <AttributeUsage(AttributeTargets.All)>
    Public NotInheritable Class BadCustomAttribute
        Inherits Attribute
        Private data As String

        ' Missing the property that corresponds to
        ' the someStringData parameter.
        Public Sub New(someStringData As String)
            data = someStringData
        End Sub 'New
    End Class 'BadCustomAttribute

    ' Satisfies rule: Attributes should have accessors for all arguments.
    <AttributeUsage(AttributeTargets.All)>
    Public NotInheritable Class GoodCustomAttribute
        Inherits Attribute

        Public Sub New(someStringData As String)
            Me.SomeStringData = someStringData
        End Sub 'New

        'The constructor parameter and property
        'name are the same except for case.

        Public ReadOnly Property SomeStringData() As String
    End Class

End Namespace

```

Positional and named arguments

Positional and named arguments make it clear to consumers of your library which arguments are mandatory for the attribute and which arguments are optional.

The following example shows an implementation of an attribute that has both positional and named arguments:

```

[AttributeUsage(AttributeTargets.All)]
public sealed class GoodCustomAttribute : Attribute
{
    public GoodCustomAttribute(string mandatoryData)
    {
        MandatoryData = mandatoryData;
    }

    public string MandatoryData { get; }

    public string OptionalData { get; set; }
}

```

The following example shows how to apply the custom attribute to two properties:

```

[GoodCustomAttribute("ThisIsSomeMandatoryData", OptionalData = "ThisIsSomeOptionalData")]
public string MyProperty { get; set; }

[GoodCustomAttribute("ThisIsSomeMoreMandatoryData")]
public string MyOtherProperty { get; set; }

```

CA1021: Avoid out parameters

9/20/2022 • 7 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1021
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A public or protected method in a public type has an `out` parameter.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Passing types by reference (using `out` or `ref`) requires experience with pointers, understanding how value types and reference types differ, and handling methods with multiple return values. Also, the difference between `out` and `ref` parameters is not widely understood.

When a reference type is passed "by reference," the method intends to use the parameter to return a different instance of the object. Passing a reference type by reference is also known as using a double pointer, pointer to a pointer, or double indirection. By using the default calling convention, which is pass "by value," a parameter that takes a reference type already receives a pointer to the object. The pointer, not the object to which it points, is passed by value. Pass by value means that the method cannot change the pointer to have it point to a new instance of the reference type. However, it can change the contents of the object to which it points. For most applications this is sufficient and yields the desired behavior.

If a method must return a different instance, use the return value of the method to accomplish this. See the [System.String](#) class for a variety of methods that operate on strings and return a new instance of a string. When this model is used, the caller must decide whether the original object is preserved.

Although return values are commonplace and heavily used, the correct application of `out` and `ref` parameters requires intermediate design and coding skills. Library architects who design for a general audience should not expect users to become proficient in working with `out` or `ref` parameters.

How to fix violations

To fix a violation of this rule that is caused by a value type, have the method return the object as its return value. If the method must return multiple values, redesign it to return a single instance of an object that holds the values.

To fix a violation of this rule that is caused by a reference type, make sure that the desired behavior is to return a new instance of the reference. If it is, the method should use its return value to do this.

When to suppress warnings

It is safe to suppress a warning from this rule. However, this design could cause usability issues.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1021
// The code that's violating the rule is on this line.
#pragma warning restore CA1021
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1021.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

EXAMPLE 1

The following library shows two implementations of a class that generates responses to user feedback. The first implementation (`BadRefAndOut`) forces the library user to manage three return values. The second implementation (`RedesignedRefAndOut`) simplifies the user experience by returning an instance of a container class (`ReplyData`) that manages the data as a single unit.

```
public enum Actions
{
    Unknown,
    Discard,
    ForwardToManagement,
    ForwardToDeveloper
}

public enum TypeOfFeedback
{
```

```

    Complaint,
    Praise,
    Suggestion,
    Incomprehensible
}

public class BadRefAndOut
{
    // Violates rule: DoNotPassTypesByReference.

    public static bool ReplyInformation(TypeOfFeedback input,
        out string reply, ref Actions action)
    {
        bool returnReply = false;
        string replyText = "Your feedback has been forwarded " +
            "to the product manager.";

        reply = String.Empty;
        switch (input)
        {
            case TypeOfFeedback.Complaint:
            case TypeOfFeedback.Praise:
                action = Actions.ForwardToManagement;
                reply = "Thank you. " + replyText;
                returnReply = true;
                break;
            case TypeOfFeedback.Suggestion:
                action = Actions.ForwardToDeveloper;
                reply = replyText;
                returnReply = true;
                break;
            case TypeOfFeedback.Incomprehensible:
            default:
                action = Actions.Discard;
                returnReply = false;
                break;
        }
        return returnReply;
    }
}

// Redesigned version does not use out or ref parameters.
// Instead, it returns this container type.

public class ReplyData
{
    bool _returnReply;

    // Constructors.
    public ReplyData()
    {
        this.Reply = String.Empty;
        this.Action = Actions.Discard;
        this._returnReply = false;
    }

    public ReplyData(Actions action, string reply, bool returnReply)
    {
        this.Reply = reply;
        this.Action = action;
        this._returnReply = returnReply;
    }

    // Properties.
    public string Reply { get; }
    public Actions Action { get; }

    public override string ToString()

```

```

    {
        return String.Format("Reply: {0} Action: {1} return? {2}",
            Reply, Action.ToString(), _returnReply.ToString());
    }
}

public class RedesignedRefAndOut
{
    public static ReplyData ReplyInformation(TypeOfFeedback input)
    {
        ReplyData answer;
        string replyText = "Your feedback has been forwarded " +
            "to the product manager.";

        switch (input)
        {
            case TypeOfFeedback.Complaint:
            case TypeOfFeedback.Praise:
                answer = new ReplyData(
                    Actions.ForwardToManagement,
                    "Thank you. " + replyText,
                    true);
                break;
            case TypeOfFeedback.Suggestion:
                answer = new ReplyData(
                    Actions.ForwardToDeveloper,
                    replyText,
                    true);
                break;
            case TypeOfFeedback.Incomprehensible:
            default:
                answer = new ReplyData();
                break;
        }
        return answer;
    }
}

```

Example 2

The following application illustrates the experience of the user. The call to the redesigned library (`UseTheSimplifiedClass` method) is more straightforward, and the information returned by the method is easily managed. The output from the two methods is identical.

```

public class UseComplexMethod
{
    static void UseTheComplicatedClass()
    {
        // Using the version with the ref and out parameters.
        // You do not have to initialize an out parameter.

        string[] reply = new string[5];

        // You must initialize a ref parameter.
        Actions[] action = {Actions.Unknown,Actions.Unknown,
                            Actions.Unknown,Actions.Unknown,
                            Actions.Unknown,Actions.Unknown};

        bool[] disposition = new bool[5];
        int i = 0;

        foreach (TypeOfFeedback t in Enum.GetValues(typeof(TypeOfFeedback)))
        {
            // The call to the library.
            disposition[i] = BadRefAndOut.ReplyInformation(
                t, out reply[i], ref action[i]);
            Console.WriteLine("Reply: {0} Action: {1} return? {2} ",
                reply[i], action[i], disposition[i]);
            i++;
        }
    }

    static void UseTheSimplifiedClass()
    {
        ReplyData[] answer = new ReplyData[5];
        int i = 0;
        foreach (TypeOfFeedback t in Enum.GetValues(typeof(TypeOfFeedback)))
        {
            // The call to the library.
            answer[i] = RedesignedRefAndOut.ReplyInformation(t);
            Console.WriteLine(answer[i++]);
        }
    }

    public static void UseClasses()
    {
        UseTheComplicatedClass();

        // Print a blank line in output.
        Console.WriteLine("");

        UseTheSimplifiedClass();
    }
}

```

Example 3

The following example library illustrates how `ref` parameters for reference types are used and shows a better way to implement this functionality.

```

public class ReferenceTypesAndParameters
{
    // The following syntax will not work. You cannot make a
    // reference type that is passed by value point to a new
    // instance. This needs the ref keyword.

    public static void BadPassTheObject(string argument)
    {
        argument += " ABCDE";
    }

    // The following syntax works, but is considered bad design.
    // It reassigned the argument to point to a new instance of string.
    // Violates rule DoNotPassTypesByReference.

    public static void PassTheReference(ref string argument)
    {
        argument += " ABCDE";
    }

    // The following syntax works and is a better design.
    // It returns the altered argument as a new instance of string.

    public static string BetterThanPassTheReference(string argument)
    {
        return argument + " ABCDE";
    }
}

```

Example 4

The following application calls each method in the library to demonstrate the behavior.

```

public class Test
{
    public static void MainTest()
    {
        string s1 = "12345";
        string s2 = "12345";
        string s3 = "12345";

        Console.WriteLine("Changing pointer - passed by value:");
        Console.WriteLine(s1);
        ReferenceTypesAndParameters.BadPassTheObject(s1);
        Console.WriteLine(s1);

        Console.WriteLine("Changing pointer - passed by reference:");
        Console.WriteLine(s2);
        ReferenceTypesAndParameters.PassTheReference(ref s2);
        Console.WriteLine(s2);

        Console.WriteLine("Passing by return value:");
        s3 = ReferenceTypesAndParameters.BetterThanPassTheReference(s3);
        Console.WriteLine(s3);
    }
}

```

This example produces the following output:

```
Changing pointer - passed by value:  
12345  
12345  
Changing pointer - passed by reference:  
12345  
12345 ABCDE  
Passing by return value:  
12345 ABCDE
```

Try pattern methods

Methods that implement the `Try<Something>` pattern, such as [System.Int32.TryParse](#), do not raise this violation. The following example shows a structure (value type) that implements the [System.Int32.TryParse](#) method.

```

public struct Point
{
    public Point(int axisX, int axisY)
    {
        X = axisX;
        Y = axisY;
    }

    public int X { get; }

    public int Y { get; }

    public override int GetHashCode()
    {
        return X ^ Y;
    }

    public override bool Equals(object obj)
    {
        if (!(obj is Point))
            return false;

        return Equals((Point)obj);
    }

    public bool Equals(Point other)
    {
        if (X != other.X)
            return false;

        return Y == other.Y;
    }

    public static bool operator ==(Point point1, Point point2)
    {
        return point1.Equals(point2);
    }

    public static bool operator !=(Point point1, Point point2)
    {
        return !point1.Equals(point2);
    }

    // Does not violate this rule
    public static bool TryParse(string value, out Point result)
    {
        // TryParse Implementation
        result = new Point(0, 0);
        return false;
    }
}

```

Related rules

[CA1045: Do not pass types by reference](#)

CA1024: Use properties where appropriate

9/20/2022 • 6 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1024
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A method has a name that starts with `Get`, takes no parameters, and returns a value that's not an array.

By default, this rule only looks at externally visible methods, but this is [configurable](#).

Rule description

In most cases, properties represent data and methods perform actions. Properties are accessed like fields, which makes them easier to use. A method is a good candidate to become a property if one of these conditions is present:

- The method takes no arguments and returns the state information of an object.
- The method accepts a single argument to set some part of the state of an object.

How to fix violations

To fix a violation of this rule, change the method to a property.

When to suppress warnings

Suppress a warning from this rule if the method meets one of the following criteria. In these situations, a method is preferable to a property.

- The method can't behave as a field.
- The method performs a time-consuming operation. The method is perceptibly slower than the time that is required to set or get the value of a field.
- The method performs a conversion. Accessing a field does not return a converted version of the data that it stores.
- The `Get` method has an observable side effect. Retrieving the value of a field does not produce any side effects.
- The order of execution is important. Setting the value of a field does not rely on the occurrence of other operations.
- Calling the method two times in succession creates different results.
- The method is `static` but returns an object that can be changed by the caller. Retrieving the value of a field does not allow the caller to change the data that's stored by the field.
- The method returns an array.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1024
// The code that's violating the rule is on this line.
#pragma warning restore CA1024
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1024.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

EXAMPLE

The following example contains several methods that should be converted to properties and several that should not because they don't behave like fields.

```
public class Appointment
{
    static long nextAppointmentID;
    static double[] discountScale = { 5.0, 10.0, 33.0 };
    string customerName;
    long customerID;
    DateTime when;

    // Static constructor.
    static Appointment()
    {
        // Initializes the static variable for Next appointment ID.
    }
}
```

```
// This method violates the rule, but should not be a property.  
// This method has an observable side effect.  
// Calling the method twice in succession creates different results.  
public static long GetNextAvailableID()  
{  
    nextAppointmentID++;  
    return nextAppointmentID - 1;  
}  
  
// This method violates the rule, but should not be a property.  
// This method performs a time-consuming operation.  
// This method returns an array.  
public Appointment[] GetCustomerHistory()  
{  
    // Connect to a database to get the customer's appointment history.  
    return LoadHistoryFromDB(customerID);  
}  
  
// This method violates the rule, but should not be a property.  
// This method is static but returns a mutable object.  
public static double[] GetDiscountScaleForUpdate()  
{  
    return discountScale;  
}  
  
// This method violates the rule, but should not be a property.  
// This method performs a conversion.  
public string GetWeekDayString()  
{  
    return DateTimeFormatInfo.CurrentInfo.GetDayName(when.DayOfWeek);  
}  
  
// These methods violate the rule and should be properties.  
// They each set or return a piece of the current object's state.  
  
public DayOfWeek GetWeekDay()  
{  
    return when.DayOfWeek;  
}  
  
public void SetCustomerName(string customerName)  
{  
    this.customerName = customerName;  
}  
  
public string GetCustomerName()  
{  
    return customerName;  
}  
  
public void SetCustomerID(long customerID)  
{  
    this.customerID = customerID;  
}  
  
public long GetCustomerID()  
{  
    return customerID;  
}  
  
public void SetScheduleTime(DateTime when)  
{  
    this.when = when;  
}  
  
public DateTime GetScheduleTime()  
{  
    return when;  
}
```

```

}

// Time-consuming method that is called by GetCustomerHistory.
Appointment[] LoadHistoryFromDB(long customerID)
{
    ArrayList records = new ArrayList();
    // Load from database.
    return (Appointment[])records.ToArray();
}
}

```

```

Public Class Appointment
    Shared nextAppointmentID As Long
    Shared discountScale As Double() = {5.0, 10.0, 33.0}
    Private customerName As String
    Private customerID As Long
    Private [when] As Date

    ' Static constructor.
    Shared Sub New()
        ' Initializes the static variable for Next appointment ID.
    End Sub

    ' This method violates the rule, but should not be a property.
    ' This method has an observable side effect.
    ' Calling the method twice in succession creates different results.
    Public Shared Function GetNextAvailableID() As Long
        nextAppointmentID += 1
        Return nextAppointmentID - 1
    End Function

    ' This method violates the rule, but should not be a property.
    ' This method performs a time-consuming operation.
    ' This method returns an array.
    Public Function GetCustomerHistory() As Appointment()
        ' Connect to a database to get the customer's appointment history.
        Return LoadHistoryFromDB(customerID)
    End Function

    ' This method violates the rule, but should not be a property.
    ' This method is static but returns a mutable object.
    Public Shared Function GetDiscountScaleForUpdate() As Double()
        Return discountScale
    End Function

    ' This method violates the rule, but should not be a property.
    ' This method performs a conversion.
    Public Function GetWeekDayString() As String
        Return DateTimeFormatInfo.CurrentInfo.GetDayName([when].DayOfWeek)
    End Function

    ' These methods violate the rule and should be properties.
    ' They each set or return a piece of the current object's state.

    Public Function GetWeekDay() As DayOfWeek
        Return [when].DayOfWeek
    End Function

    Public Sub SetCustomerName(customerName As String)
        Me.customerName = customerName
    End Sub

    Public Function GetCustomerName() As String
        Return customerName
    End Function

    Public Sub SetCustomerID(customerID As Long)
        Me.customerID = customerID
    End Sub

```

```

Me.CustomerID = customerID
End Sub

Public Function GetCustomerID() As Long
    Return customerID
End Function

Public Sub SetScheduleTime([when] As Date)
    Me.[when] = [when]
End Sub

Public Function GetScheduleTime() As Date
    Return [when]
End Function

' Time-consuming method that is called by GetCustomerHistory.
Private Function LoadHistoryFromDB(customerID As Long) As Appointment()
    Dim records As ArrayList = New ArrayList()
    Return CType(records.ToArray(), Appointment())
End Function
End Class

```

Control property expansion in the debugger

One reason programmers avoid using a property is because they do not want the debugger to autoexpand it. For example, the property might involve allocating a large object or calling a P/Invoke, but it might not actually have any observable side effects.

You can prevent the debugger from auto-expanding properties by applying [System.Diagnostics.DebuggerBrowsableAttribute](#). The following example shows this attribute being applied to an instance property.

```

Imports System.Diagnostics

Namespace Microsoft.Samples
    Public Class TestClass
        ' [...]

        <DebuggerBrowsable(DebuggerBrowsableState.Never)> _
        Public ReadOnly Property LargeObject() As LargeObject
            Get
                ' Allocate large object
                ' [...]
            End Get
        End Property
    End Class
End Namespace

```

```
using System.Diagnostics;

namespace Microsoft.Samples
{
    class TestClass
    {
        // [...]

        [DebuggerBrowsable(DebuggerBrowsableState.Never)]
        public LargeObject LargeObject
        {
            get
            {
                // Allocate large object
                // [...]
            }
        }
    }
}
```

CA1027: Mark enums with FlagsAttribute

9/20/2022 • 3 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1027
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

The values of an enumeration are powers of two or are combinations of other values that are defined in the enumeration, and the [System.FlagsAttribute](#) attribute is not present. To reduce false positives, this rule does not report a violation for enumerations that have contiguous values.

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

An enumeration is a value type that defines a set of related named constants. Apply [FlagsAttribute](#) to an enumeration when its named constants can be meaningfully combined. For example, consider an enumeration of the days of the week in an application that keeps track of which day's resources are available. If the availability of each resource is encoded by using the enumeration that has [FlagsAttribute](#) present, any combination of days can be represented. Without the attribute, only one day of the week can be represented.

For fields that store combinable enumerations, the individual enumeration values are treated as groups of bits in the field. Therefore, such fields are sometimes referred to as *bit fields*. To combine enumeration values for storage in a bit field, use the Boolean conditional operators. To test a bit field to determine whether a specific enumeration value is present, use the Boolean logical operators. For a bit field to store and retrieve combined enumeration values correctly, each value that is defined in the enumeration must be a power of two. Unless this is so, the Boolean logical operators will not be able to extract the individual enumeration values that are stored in the field.

How to fix violations

To fix a violation of this rule, add [FlagsAttribute](#) to the enumeration.

When to suppress warnings

Suppress a warning from this rule if you do not want the enumeration values to be combinable.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1027
// The code that's violating the rule is on this line.
#pragma warning restore CA1027
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1027.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example

In the following example, `DaysEnumNeedsFlags` is an enumeration that meets the requirements for using [FlagsAttribute](#) but doesn't have it. The `ColorEnumShouldNotHaveFlag` enumeration does not have values that are powers of two but incorrectly specifies [FlagsAttribute](#). This violates rule [CA2217: Do not mark enums with FlagsAttribute](#).

```
// Violates rule: MarkEnumsWithFlags.
public enum DaysEnumNeedsFlags
{
    None = 0,
    Monday = 1,
    Tuesday = 2,
    Wednesday = 4,
    Thursday = 8,
    Friday = 16,
    All = Monday | Tuesday | Wednesday | Thursday | Friday
}

// Violates rule: DoNotMarkEnumsWithFlags.
[FlagsAttribute]
public enum ColorEnumShouldNotHaveFlag
{
    None = 0,
    Red = 1,
    Orange = 3,
    Yellow = 4
}
```

- [System.FlagsAttribute](#)

CA1028: Enum storage should be Int32

9/20/2022 • 3 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1028
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

The underlying type of an enumeration is not [System.Int32](#).

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

An enumeration is a value type that defines a set of related named constants. By default, the [System.Int32](#) data type is used to store the constant value. Even though you can change this underlying type, it is not necessary or recommended for most scenarios. No significant performance gain is achieved by using a data type that is smaller than [Int32](#). If you cannot use the default data type, you should use one of the Common Language System (CLS)-compliant integral types, [Byte](#), [Int16](#), [Int32](#), or [Int64](#) to make sure that all values of the enumeration can be represented in CLS-compliant programming languages.

How to fix violations

To fix a violation of this rule, unless size or compatibility issues exist, use [Int32](#). For situations where [Int32](#) is not large enough to hold the values, use [Int64](#). If backward compatibility requires a smaller data type, use [Byte](#) or [Int16](#).

When to suppress warnings

Suppress a warning from this rule only if backward compatibility issues require it. In applications, failure to comply with this rule usually does not cause problems. In libraries, where language interoperability is required, failure to comply with this rule might adversely affect your users.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1028
// The code that's violating the rule is on this line.
#pragma warning restore CA1028
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1028.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows two enumerations that don't use the recommended underlying data type.

```
[Flags]
public enum Days : uint
{
    None = 0,
    Monday = 1,
    Tuesday = 2,
    Wednesday = 4,
    Thursday = 8,
    Friday = 16,
    All = Monday | Tuesday | Wednesday | Thursday | Friday
}

public enum Color : sbyte
{
    None = 0,
    Red = 1,
    Orange = 3,
    Yellow = 4
}
```

```

<Flags()
Public Enum Days As UInteger
    None = 0
    Monday = 1
    Tuesday = 2
    Wednesday = 4
    Thursday = 8
    Friday = 16
    All = Monday Or Tuesday Or Wednesday Or Thursday Or Friday
End Enum

Public Enum Color As SByte
    None = 0
    Red = 1
    Orange = 3
    Yellow = 4
End Enum

```

The following example fixes the previous violation by changing the underlying data type to [Int32](#).

```

[Flags]
public enum Days : int
{
    None = 0,
    Monday = 1,
    Tuesday = 2,
    Wednesday = 4,
    Thursday = 8,
    Friday = 16,
    All = Monday | Tuesday | Wednesday | Thursday | Friday
}

public enum Color : int
{
    None = 0,
    Red = 1,
    Orange = 3,
    Yellow = 4
}

```

```

<Flags()
Public Enum Days As Integer
    None = 0
    Monday = 1
    Tuesday = 2
    Wednesday = 4
    Thursday = 8
    Friday = 16
    All = Monday Or Tuesday Or Wednesday Or Thursday Or Friday
End Enum

Public Enum Color As Integer
    None = 0
    Red = 1
    Orange = 3
    Yellow = 4
End Enum

```

CA1030: Use events where appropriate

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1030
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A method name begins with one of the following:

- AddOn
- RemoveOn
- Fire
- Raise

By default, this rule only looks at externally visible methods, but this is [configurable](#).

Rule description

This rule detects methods that have names that ordinarily would be used for events. Events follow the Observer or Publish-Subscribe design pattern; they are used when a state change in one object must be communicated to other objects. If a method gets called in response to a clearly defined state change, the method should be invoked by an event handler. Objects that call the method should raise events instead of calling the method directly.

Some common examples of events are found in user interface applications where a user action such as clicking a button causes a segment of code to execute. The .NET event model is not limited to user interfaces. It should be used anywhere you must communicate state changes to one or more objects.

How to fix violations

If the method is called when the state of an object changes, consider changing the design to use the .NET event model.

When to suppress warnings

Suppress a warning from this rule if the method does not work with the .NET event model.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1030
// The code that's violating the rule is on this line.
#pragma warning restore CA1030
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1030.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

CA1031: Do not catch general exception types

9/20/2022 • 3 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1031
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A general exception such as `System.Exception` or `System.SystemException` is caught in a `catch` statement, or a general catch clause such as `catch()` is used.

By default, this rule only flags general exception types being caught, but this is [configurable](#).

Rule description

General exceptions should not be caught.

How to fix violations

To fix a violation of this rule, catch a more specific exception, or rethrow the general exception as the last statement in the `catch` block.

When to suppress warnings

Do not suppress a warning from this rule. Catching general exception types can hide run-time problems from the library user and can make debugging more difficult.

NOTE

Starting with .NET Framework 4, the common language runtime (CLR) no longer delivers corrupted state exceptions that occur in the operating system and managed code, such as access violations in Windows, to be handled by managed code. If you want to compile an application in .NET Framework 4 or later versions and maintain handling of corrupted state exceptions, you can apply the `HandleProcessCorruptedStateExceptionsAttribute` attribute to the method that handles the corrupted state exception.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Disallowed exception type names](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Disallowed exception type names

You can configure which exception types are disallowed from being caught. For example, to specify that the rule should flag `catch` handlers with `NullReferenceException`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1031.disallowed_symbol_names = NullReferenceException
```

Allowed type name formats in the option value (separated by `|`):

- Type name only (includes all symbols with the name, regardless of the containing type or namespace)
- Fully qualified names in the symbol's [documentation ID format](#) with a `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1031.disallowed_symbol_names = ExceptionType</code>	Matches all symbols named 'ExceptionType' in the compilation
<code>dotnet_code_quality.CA1031.disallowed_symbol_names = ExceptionType1 ExceptionType2</code>	Matches all symbols named either 'ExceptionType1' or 'ExceptionType2' in the compilation
<code>dotnet_code_quality.CA1031.disallowed_symbol_names = T:NS.ExceptionType</code>	Matches specific types named 'ExceptionType' with given fully qualified name.
<code>dotnet_code_quality.CA1031.disallowed_symbol_names = T:NS1.ExceptionType1 T:NS1.ExceptionType2</code>	Matches types named 'ExceptionType1' and 'ExceptionType2' with respective fully qualified names

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Example

The following example shows a type that violates this rule and a type that correctly implements the `catch` block.

```

Imports System
Imports System.IO

Namespace ca1031

    ' Creates two violations of the rule.
    Public Class GenericExceptionsCaught

        Dim inStream As FileStream
        Dim outStream As FileStream

        Sub New(inFile As String, outFile As String)

            Try
                inStream = File.Open(inFile, FileMode.Open)
            Catch ex As SystemException
                Console.WriteLine("Unable to open {0}.", inFile)
            End Try

            Try
                outStream = File.Open(outFile, FileMode.Open)
            Catch
                Console.WriteLine("Unable to open {0}.", outFile)
            End Try

        End Sub

    End Class

    Public Class GenericExceptionsCaughtFixed

        Dim inStream As FileStream
        Dim outStream As FileStream

        Sub New(inFile As String, outFile As String)

            Try
                inStream = File.Open(inFile, FileMode.Open)

                ' Fix the first violation by catching a specific exception.
            Catch ex As FileNotFoundException
                Console.WriteLine("Unable to open {0}.", inFile)
                ' For functionally equivalent code, also catch the
                ' remaining exceptions that may be thrown by File.Open
            End Try

            Try
                outStream = File.Open(outFile, FileMode.Open)

                ' Fix the second violation by re-throwing the generic
                ' exception at the end of the catch block.
            Catch
                Console.WriteLine("Unable to open {0}.", outFile)
                Throw
            End Try

        End Sub

    End Class

End Namespace

```

```

// Creates two violations of the rule.
public class GenericExceptionsCaught
{
    FileStream inStream;
    FileStream outStream;

    public GenericExceptionsCaught(string inFile, string outFile)
    {
        try
        {
            inStream = File.Open(inFile, FileMode.Open);
        }
        catch (SystemException)
        {
            Console.WriteLine("Unable to open {0}.". , inFile);
        }

        try
        {
            outStream = File.Open(outFile, FileMode.Open);
        }
        catch
        {
            Console.WriteLine("Unable to open {0}.". , outFile);
        }
    }
}

public class GenericExceptionsCaughtFixed
{
    FileStream inStream;
    FileStream outStream;

    public GenericExceptionsCaughtFixed(string inFile, string outFile)
    {
        try
        {
            inStream = File.Open(inFile, FileMode.Open);
        }

        // Fix the first violation by catching a specific exception.
        catch (FileNotFoundException)
        {
            Console.WriteLine("Unable to open {0}.". , inFile);
        };

        // For functionally equivalent code, also catch
        // remaining exceptions that may be thrown by File.Open

        try
        {
            outStream = File.Open(outFile, FileMode.Open);
        }

        // Fix the second violation by rethrowing the generic
        // exception at the end of the catch block.
        catch
        {
            Console.WriteLine("Unable to open {0}.". , outFile);
            throw;
        }
    }
}

```

Related rules

CA2200: Rethrow to preserve stack details

CA1032: Implement standard exception constructors

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1032
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type extends `System.Exception` but doesn't declare all the required constructors.

Rule description

Exception types must implement the following three public constructors:

- `public NewException()`
- `public NewException(string)`
- `public NewException(string, Exception)`

Failure to provide the full set of constructors can make it difficult to correctly handle exceptions. For example, the constructor that has the signature `NewException(string, Exception)` is used to create exceptions that are caused by other exceptions. Without this constructor, you can't create and throw an instance of your custom exception that contains an inner (nested) exception, which is what managed code should do in such a situation.

For more information, see [CA2229: Implement serialization constructors](#).

How to fix violations

To fix a violation of this rule, add the missing constructors to the exception, and make sure that they have the correct accessibility.

When to suppress warnings

It's safe to suppress a warning from this rule when the violation is caused by using a different access level for the public constructors.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1032
// The code that's violating the rule is on this line.
#pragma warning restore CA1032
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1032.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example contains an exception type that violates this rule and an exception type that is correctly implemented.

```
// Violates rule ImplementStandardExceptionConstructors.
public class BadException : Exception
{
    public BadException()
    {
        // Add any type-specific logic, and supply the default message.
    }
}

[Serializable()]
public class GoodException : Exception
{
    public GoodException()
    {
        // Add any type-specific logic, and supply the default message.
    }

    public GoodException(string message) : base(message)
    {
        // Add any type-specific logic.
    }

    public GoodException(string message, Exception innerException) :
        base(message, innerException)
    {
        // Add any type-specific logic for inner exceptions.
    }
}
```

See also

[CA2229: Implement serialization constructors](#)

CA1033: Interface methods should be callable by child types

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1033
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

An unsealed externally visible type provides an explicit method implementation of a public interface and does not provide an alternative externally visible method that has the same name.

Rule description

Consider a base type that explicitly implements a public interface method. A type that derives from the base type can access the inherited interface method only through a reference to the current instance (`this` in C#) that is cast to the interface. If the derived type reimplements (explicitly) the inherited interface method, the base implementation can no longer be accessed. The call through the current instance reference will invoke the derived implementation; this causes recursion and an eventual stack overflow.

This rule does not report a violation for an explicit implementation of `System.IDisposable.Dispose` when an externally visible `Close()` or `System.IDisposable.Dispose(Boolean)` method is provided.

How to fix violations

To fix a violation of this rule, implement a new method that exposes the same functionality and is visible to derived types or change to a nonexplicit implementation. If a breaking change is acceptable, an alternative is to make the type sealed.

When to suppress warnings

It is safe to suppress a warning from this rule if an externally visible method is provided that has the same functionality but a different name than the explicitly implemented method.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1033
// The code that's violating the rule is on this line.
#pragma warning restore CA1033
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1033.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type, `ViolatingBase`, that violates the rule and a type, `FixedBase`, that shows a fix for the violation.

```
public interface ITest
{
    void SomeMethod();
}

public class ViolatingBase : ITest
{
    void ITest.SomeMethod()
    {
        // ...
    }
}

public class FixedBase : ITest
{
    void ITest.SomeMethod()
    {
        SomeMethod();
    }

    protected void SomeMethod()
    {
        // ...
    }
}

sealed public class Derived : FixedBase, ITest
{
    public void SomeMethod()
    {
        // The following would cause recursion and a stack overflow.
        // ((ITest)this).SomeMethod();

        // The following is unavailable if derived from ViolatingBase.
        base.SomeMethod();
    }
}
```

CA1034: Nested types should not be visible

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1034
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

An externally visible type contains an externally visible type declaration. Nested enumerations, protected types, and builder patterns are exempt from this rule.

Rule description

A nested type is a type declared within the scope of another type. Nested types are useful for encapsulating private implementation details of the containing type. Used for this purpose, nested types should not be externally visible.

Do not use externally visible nested types for logical grouping or to avoid name collisions; instead, use namespaces.

Nested types include the notion of member accessibility, which some programmers do not understand clearly.

Protected types can be used in subclasses and nested types in advance customization scenarios.

How to fix violations

If you do not intend the nested type to be externally visible, change the type's accessibility. Otherwise, remove the nested type from its parent. If the purpose of the nesting is to categorize the nested type, use a namespace to create the hierarchy instead.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows a type that violates the rule.

```
public class ParentType
{
    public class NestedType
    {
        public NestedType()
        {
        }
    }

    public ParentType()
    {
        NestedType nt = new NestedType();
    }
}
```

```
Imports System

Namespace ca1034

Class ParentType

    Public Class NestedType
        Sub New()
        End Sub
    End Class

    Sub New()
    End Sub

End Class

End Namespace
```

CA1036: Override methods on comparable types

9/20/2022 • 4 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1036
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type implements the [System.IComparable](#) interface and does not override [System.Object.Equals](#) or does not overload the language-specific operator for equality, inequality, less-than, or greater-than. The rule does not report a violation if the type inherits only an implementation of the interface.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Types that define a custom sort order implement the [IComparable](#) interface. The [CompareTo](#) method returns an integer value that indicates the correct sort order for two instances of the type. This rule identifies types that set a sort order. Setting a sort order implies that the ordinary meaning of equality, inequality, less-than, and greater-than don't apply. When you provide an implementation of [IComparable](#), you must usually also override [Equals](#) so that it returns values that are consistent with [CompareTo](#). If you override [Equals](#) and are coding in a language that supports operator overloads, you should also provide operators that are consistent with [Equals](#).

How to fix violations

To fix a violation of this rule, override [Equals](#). If your programming language supports operator overloading, supply the following operators:

- `op_Equality`
- `op_Inequality`
- `op_LessThan`
- `op_GreaterThan`

In C#, the tokens that are used to represent these operators are as follows:

```
==  
!=  
<  
>
```

When to suppress warnings

It is safe to suppress a warning from rule CA1036 when the violation is caused by missing operators and your programming language does not support operator overloading, as is the case with Visual Basic. If you

determine that implementing the operators does not make sense in your app context, it's also safe to suppress a warning from this rule when it fires on equality operators other than `op_Equality`. However, you should always override `op_Equality` and the `==` operator if you override [Object.Equals](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1036
// The code that's violating the rule is on this line.
#pragma warning restore CA1036
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1036.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Examples

The following code contains a type that correctly implements [IComparable](#). Code comments identify the methods that satisfy various rules that are related to [Equals](#) and the [IComparable](#) interface.

```
// Valid ratings are between A and C.
// A is the highest rating; it is greater than any other valid rating.
// C is the lowest rating; it is less than any other valid rating.

public class RatingInformation : IComparable, IComparable<RatingInformation>
{
    public string Rating
    {
        ...
    }
}
```

```

        get;
        private set;
    }

    public RatingInformation(string rating)
    {
        if (rating == null)
        {
            throw new ArgumentNullException("rating");
        }

        string v = rating.ToUpper(CultureInfo.InvariantCulture);
        if (v.Length != 1 || string.Compare(v, "C", StringComparison.OrdinalIgnoreCase) > 0 || string.Compare(v, "A", StringComparison.OrdinalIgnoreCase) < 0)
        {
            throw new ArgumentException("Invalid rating value was specified.", "rating");
        }

        Rating = v;
    }

    public int CompareTo(object obj)
    {
        if (obj == null)
        {
            return 1;
        }

        RatingInformation other = obj as RatingInformation; // avoid double casting
        if (other == null)
        {
            throw new ArgumentException("A RatingInformation object is required for comparison.", "obj");
        }

        return CompareTo(other);
    }

    public int CompareTo(RatingInformation other)
    {
        if (other is null)
        {
            return 1;
        }

        // Ratings compare opposite to normal string order,
        // so reverse the value returned by String.CompareTo.
        return -string.Compare(this.Rating, other.Rating, StringComparison.OrdinalIgnoreCase);
    }

    public static int Compare(RatingInformation left, RatingInformation right)
    {
        if (object.ReferenceEquals(left, right))
        {
            return 0;
        }
        if (left is null)
        {
            return -1;
        }
        return left.CompareTo(right);
    }

    // Omitting Equals violates rule: OverrideMethodsOnComparableTypes.
    public override bool Equals(object obj)
    {
        RatingInformation other = obj as RatingInformation; //avoid double casting
        if (other is null)
        {
            return false;
        }
    }
}

```

```

        }
        return this.CompareTo(other) == 0;
    }

// Omitting GetHashCode violates rule: OverrideGetHashCodeOnOverridingEquals.
public override int GetHashCode()
{
    char[] c = this.Rating.ToCharArray();
    return (int)c[0];
}

// Omitting any of the following operator overloads
// violates rule: OverrideMethodsOnComparableTypes.
public static bool operator ==(RatingInformation left, RatingInformation right)
{
    if (left is null)
    {
        return right is null;
    }
    return left.Equals(right);
}
public static bool operator !=(RatingInformation left, RatingInformation right)
{
    return !(left == right);
}
public static bool operator <(RatingInformation left, RatingInformation right)
{
    return (Compare(left, right) < 0);
}
public static bool operator >(RatingInformation left, RatingInformation right)
{
    return (Compare(left, right) > 0);
}
}

```

The following application code tests the behavior of the [IComparable](#) implementation that was shown earlier.

```

public class Test
{
    public static void Main1036(string[] args)
    {
        if (args.Length < 2)
        {
            Console.WriteLine("usage - TestRatings string1 string2");
            return;
        }
        RatingInformation r1 = new RatingInformation(args[0]);
        RatingInformation r2 = new RatingInformation(args[1]);
        string answer;

        if (r1.CompareTo(r2) > 0)
            answer = "greater than";
        else if (r1.CompareTo(r2) < 0)
            answer = "less than";
        else
            answer = "equal to";

        Console.WriteLine("{0} is {1} {2}", r1.Rating, answer, r2.Rating);
    }
}

```

CA1040: Avoid empty interfaces

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1040
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

The interface does not declare any members or implement two or more other interfaces.

By default, this rule only looks at externally visible interfaces, but this is [configurable](#).

Rule description

Interfaces define members that provide a behavior or usage contract. The functionality that is described by the interface can be adopted by any type, regardless of where the type appears in the inheritance hierarchy. A type implements an interface by providing implementations for the members of the interface. An empty interface does not define any members. Therefore, it does not define a contract that can be implemented.

If your design includes empty interfaces that types are expected to implement, you are probably using an interface as a marker or a way to identify a group of types. If this identification will occur at run time, the correct way to accomplish this is to use a custom attribute. Use the presence or absence of the attribute, or the properties of the attribute, to identify the target types. If the identification must occur at compile time, then it is acceptable to use an empty interface.

How to fix violations

Remove the interface or add members to it. If the empty interface is being used to label a set of types, replace the interface with a custom attribute.

When to suppress warnings

It is safe to suppress a warning from this rule when the interface is used to identify a set of types at compile time.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1040
// The code that's violating the rule is on this line.
#pragma warning restore CA1040
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1040.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows an empty interface.

```
// Violates rule
public interface IBadInterface
{}
```

```
' Violates rule
Public Interface IBadInterface
End Interface
```

CA1041: Provide ObsoleteAttribute message

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA1041
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type or member is marked by using a [System.ObsoleteAttribute](#) attribute that does not have its [System.ObsoleteAttribute.Message](#) property specified.

By default, this rule only looks at externally visible types and members, but this is [configurable](#).

Rule description

[ObsoleteAttribute](#) is used to mark deprecated library types and members. Library consumers should avoid the use of any type or member that is marked obsolete. This is because it might not be supported and will eventually be removed from later versions of the library. When a type or member marked by using [ObsoleteAttribute](#) is compiled, the [Message](#) property of the attribute is displayed. This gives the user information about the obsolete type or member. This information generally includes how long the obsolete type or member will be supported by the library designers and the preferred replacement to use.

How to fix violations

To fix a violation of this rule, add the `message` parameter to the [ObsoleteAttribute](#) constructor.

When to suppress warnings

Do not suppress a warning from this rule because the [Message](#) property provides critical information about the obsolete type or member.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows an obsolete member that has a correctly declared [ObsoleteAttribute](#).

```
[ObsoleteAttribute("This property is obsolete and will be removed in a " +  
    "future version. Use the FullName property instead.", false)]  
public string Name  
{  
    get => "Name";  
}
```

```
Imports System  
  
Namespace ca1041  
  
    Public Class ObsoleteAttributeOnMember  
  
        <ObsoleteAttribute("This property is obsolete and will " &  
            "be removed in a future version. Use the FirstName " &  
            "and LastName properties instead.", False)>  
        ReadOnly Property Name As String  
            Get  
                Return "Name"  
            End Get  
        End Property  
  
        ReadOnly Property FirstName As String  
            Get  
                Return "FirstName"  
            End Get  
        End Property  
  
        ReadOnly Property LastName As String  
            Get  
                Return "LastName"  
            End Get  
        End Property  
  
    End Class  
  
End Namespace
```

CA1043: Use integral or string argument for indexers

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1043
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type contains an indexer that uses an index type other than [System.Int32](#), [System.Int64](#), [System.Object](#), or [System.String](#).

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Indexers, that is, indexed properties, should use integer or string types for the index. These types are typically used for indexing data structures and increase the usability of the library. Use of the [Object](#) type should be restricted to those cases where the specific integer or string type cannot be specified at design time. If the design requires other types for the index, reconsider whether the type represents a logical data store. If it does not represent a logical data store, use a method.

How to fix violations

To fix a violation of this rule, change the index to an integer or string type or use a method instead of the indexer.

When to suppress warnings

Suppress a warning from this rule only after carefully considering the need for the nonstandard indexer.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1043
// The code that's violating the rule is on this line.
#pragma warning restore CA1043
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1043.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows an indexer that uses an [Int32](#) index.

```
string[] Month = new string[] { "Jan", "Feb", "..." };

public string this[int index]
{
    get => Month[index];
}
```

```
Private month() As String = {"Jan", "Feb", "..."}

Default ReadOnly Property Item(index As Integer) As String
    Get
        Return month(index)
    End Get
End Property
```

Related rules

- [CA1024: Use properties where appropriate](#)

CA1044: Properties should not be write only

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1044
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A property has a set accessor but not a get accessor.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Get accessors provide read access to a property and set accessors provide write access. Although it is acceptable and often necessary to have a read-only property, the design guidelines prohibit the use of write-only properties. This is because letting a user set a value and then preventing the user from viewing the value does not provide any security. Also, without read access, the state of shared objects cannot be viewed, which limits their usefulness.

How to fix violations

To fix a violation of this rule, add a get accessor to the property. Alternatively, if the behavior of a write-only property is necessary, consider converting this property to a method.

When to suppress warnings

It's recommended that you don't suppress warnings from this rule.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example

In the following example, `BadClassWithWriteOnlyProperty` is a type with a write-only property.

`GoodClassWithReadWriteProperty` contains the corrected code.

```
Imports System

Namespace ca1044

    Public Class BadClassWithWriteOnlyProperty

        Dim someName As String

        ' Violates rule PropertiesShouldNotBeWriteOnly.
        WriteOnly Property Name As String
            Set
                someName = Value
            End Set
        End Property

    End Class

    Public Class GoodClassWithReadWriteProperty

        Property Name As String

    End Class

End Namespace
```

```
public class BadClassWithWriteOnlyProperty
{
    string _someName;

    // Violates rule PropertiesShouldNotBeWriteOnly.
    public string Name
    {
        set
        {
            _someName = value;
        }
    }
}

public class GoodClassWithReadWriteProperty
{
    public string Name { get; set; }
}
```

CA1045: Do not pass types by reference

9/20/2022 • 7 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1045
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A public or protected method in a public type has a `ref` parameter that takes a primitive type, a reference type, or a value type that is not one of the built-in types.

Rule description

Passing types by reference (using `out` or `ref`) requires experience with pointers, understanding how value types and reference types differ, and handling methods that have multiple return values. Also, the difference between `out` and `ref` parameters is not widely understood.

When a reference type is passed "by reference," the method intends to use the parameter to return a different instance of the object. (Passing a reference type by reference is also known as using a double pointer, pointer to a pointer, or double indirection.) Using the default calling convention, which is pass "by value," a parameter that takes a reference type already receives a pointer to the object. The pointer, not the object to which it points, is passed by value. Passing by value means that the method cannot change the pointer to have it point to a new instance of the reference type, but can change the contents of the object to which it points. For most applications this is sufficient and yields the behavior that you want.

If a method must return a different instance, use the return value of the method to accomplish this. See the [System.String](#) class for a variety of methods that operate on strings and return a new instance of a string. By using this model, it is left to the caller to decide whether the original object is preserved.

Although return values are commonplace and heavily used, the correct application of `out` and `ref` parameters requires intermediate design and coding skills. Library architects who design for a general audience should not expect users to become proficient in working with `out` or `ref` parameters.

NOTE

When you work with parameters that are large structures, the additional resources that are required to copy these structures could cause a performance effect when you pass by value. In these cases, you might consider using `ref` or `out` parameters.

How to fix violations

To fix a violation of this rule that is caused by a value type, have the method return the object as its return value. If the method must return multiple values, redesign it to return a single instance of an object that holds the values.

To fix a violation of this rule that is caused by a reference type, make sure that the behavior that you want is to return a new instance of the reference. If it is, the method should use its return value to do this.

When to suppress warnings

It is safe to suppress a warning from this rule; however, this design could cause usability issues.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1045
// The code that's violating the rule is on this line.
#pragma warning restore CA1045
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1045.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example 1

The following library shows two implementations of a class that generates responses to the feedback of the user. The first implementation (`BadRefAndOut`) forces the library user to manage three return values. The second implementation (`RedesignedRefAndOut`) simplifies the user experience by returning an instance of a container class (`ReplyData`) that manages the data as a single unit.

```
public enum Actions
{
```

```

        Unknown,
        Discard,
        ForwardToManagement,
        ForwardToDeveloper
    }

    public enum TypeOfFeedback
    {
        Complaint,
        Praise,
        Suggestion,
        Incomprehensible
    }

    public class BadRefAndOut
    {
        // Violates rule: DoNotPassTypesByReference.

        public static bool ReplyInformation(TypeOfFeedback input,
            out string reply, ref Actions action)
        {
            bool returnReply = false;
            string replyText = "Your feedback has been forwarded " +
                "to the product manager.";

            reply = String.Empty;
            switch (input)
            {
                case TypeOfFeedback.Complaint:
                case TypeOfFeedback.Praise:
                    action = Actions.ForwardToManagement;
                    reply = "Thank you. " + replyText;
                    returnReply = true;
                    break;
                case TypeOfFeedback.Suggestion:

        {
            this.reply = String.Empty;
            this.action = Actions.Discard;
            this.returnReply = false;
        }

        public ReplyData(Actions action, string reply, bool returnReply)
        {
            this.reply = reply;

```

```

        this.action = action;
        this.returnReply = returnReply;
    }

    // Properties.
    public string Reply { get { return reply; } }
    public Actions Action { get { return action; } }

    public override string ToString()
    {
        return String.Format("Reply: {0} Action: {1} return? {2}",
            reply, action.ToString(), returnReply.ToString());
    }
}

public class RedesignedRefAndOut
{
    public static ReplyData ReplyInformation(TypeOfFeedback input)
    {
        ReplyData answer;
        string replyText = "Your feedback has been forwarded " +
            "to the product manager.";

        switch (input)
        {
            case TypeOfFeedback.Complaint:
            case TypeOfFeedback.Praise:
                answer = new ReplyData(
                    Actions.ForwardToManagement,
                    "Thank you. " + replyText,
                    true);
                break;
            case TypeOfFeedback.Suggestion:
                answer = new ReplyData(
                    Actions.ForwardToDeveloper,
                    replyText,
                    true);
                break;
            case TypeOfFeedback.Incomprehensible:
            default:
                answer = new ReplyData();
                break;
        }
        return answer;
    }
}

```

Example 2

The following application illustrates the experience of the user. The call to the redesigned library (`UseTheSimplifiedClass` method) is more straightforward, and the information that is returned by the method is easily managed. The output from the two methods is identical.

```

public class UseComplexMethod
{
    static void UseTheComplicatedClass()
    {
        // Using the version with the ref and out parameters.
        // You do not have to initialize an out parameter.

        string[] reply = new string[5];

        // You must initialize a ref parameter.
        Actions[] action = {Actions.Unknown,Actions.Unknown,
                            Actions.Unknown,Actions.Unknown,
                            Actions.Unknown,Actions.Unknown};
        bool[] disposition = new bool[5];
        int i = 0;

        foreach (TypeOfFeedback t in Enum.GetValues(typeof(TypeOfFeedback)))
        {
            // The call to the library.
            disposition[i] = BadRefAndOut.ReplyInformation(
                t, out reply[i], ref action[i]);
            Console.WriteLine("Reply: {0} Action: {1}  return? {2} ",
                reply[i], action[i], disposition[i]);
            i++;
        }
    }

    static void UseTheSimplifiedClass()
    {
        ReplyData[] answer = new ReplyData[5];
        int i = 0;
        foreach (TypeOfFeedback t in Enum.GetValues(typeof(TypeOfFeedback)))
        {
            // The call to the library.
            answer[i] = RedesignedRefAndOut.ReplyInformation(t);
            Console.WriteLine(answer[i++]);
        }
    }

    public static void Main1045()
    {
        UseTheComplicatedClass();

        // Print a blank line in output.
        Console.WriteLine("");

        UseTheSimplifiedClass();
    }
}

```

Example 3

The following example library illustrates how `ref` parameters for reference types are used, and shows a better way to implement this functionality.

```

public class ReferenceTypesAndParameters
{
    // The following syntax will not work. You cannot make a
    // reference type that is passed by value point to a new
    // instance. This needs the ref keyword.

    public static void BadPassTheObject(string argument)
    {
        argument = argument + " ABCDE";
    }

    // The following syntax will work, but is considered bad design.
    // It reassigned the argument to point to a new instance of string.
    // Violates rule DoNotPassTypesByReference.

    public static void PassTheReference(ref string argument)
    {
        argument = argument + " ABCDE";
    }

    // The following syntax will work and is a better design.
    // It returns the altered argument as a new instance of string.

    public static string BetterThanPassTheReference(string argument)
    {
        return argument + " ABCDE";
    }
}

```

Example 4

The following application calls each method in the library to demonstrate the behavior.

```

public class Test
{
    public static void Main1045()
    {
        string s1 = "12345";
        string s2 = "12345";
        string s3 = "12345";

        Console.WriteLine("Changing pointer - passed by value:");
        Console.WriteLine(s1);
        ReferenceTypesAndParameters.BadPassTheObject(s1);
        Console.WriteLine(s1);

        Console.WriteLine("Changing pointer - passed by reference:");
        Console.WriteLine(s2);
        ReferenceTypesAndParameters.PassTheReference(ref s2);
        Console.WriteLine(s2);

        Console.WriteLine("Passing by return value:");
        s3 = ReferenceTypesAndParameters.BetterThanPassTheReference(s3);
        Console.WriteLine(s3);
    }
}

```

This example produces the following output:

```
Changing pointer - passed by value:  
12345  
12345  
Changing pointer - passed by reference:  
12345  
12345 ABCDE  
Passing by return value:  
12345 ABCDE
```

Related rules

[CA1021: Avoid out parameters](#)

CA1046: Do not overload operator equals on reference types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1046
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A public or nested public reference type overloads the equality operator.

Rule description

For reference types, the default implementation of the equality operator is almost always correct. By default, two references are equal only if they point to the same object.

How to fix violations

To fix a violation of this rule, remove the implementation of the equality operator.

When to suppress warnings

It is safe to suppress a warning from this rule when the reference type behaves like a built-in value type. If it is meaningful to do addition or subtraction on instances of the type, it is probably correct to implement the equality operator and suppress the violation.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1046
// The code that's violating the rule is on this line.
#pragma warning restore CA1046
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1046.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category (Design). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example 1

The following example demonstrates the default behavior when comparing two references.

```
public class MyReferenceType
{
    private int a, b;
    public MyReferenceType(int a, int b)
    {
        this.a = a;
        this.b = b;
    }

    public override string ToString()
    {
        return String.Format("({0},{1})", a, b);
    }
}
```

Example 2

The following application compares some references.

```
public class ReferenceTypeEquality
{
    public static void Main1046()
    {
        MyReferenceType a = new MyReferenceType(2, 2);
        MyReferenceType b = new MyReferenceType(2, 2);
        MyReferenceType c = a;

        Console.WriteLine("a = new {0} and b = new {1} are equal? {2}", a, b, a.Equals(b) ? "Yes" : "No");
        Console.WriteLine("c and a are equal? {0}", c.Equals(a) ? "Yes" : "No");
        Console.WriteLine("b and a are == ? {0}", b == a ? "Yes" : "No");
        Console.WriteLine("c and a are == ? {0}", c == a ? "Yes" : "No");
    }
}
```

This example produces the following output:

```
a = new (2,2) and b = new (2,2) are equal? No
c and a are equal? Yes
b and a are == ? No
c and a are == ? Yes
```

CA1047: Do not declare protected members in sealed types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1047
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A public type is `sealed` (`NotInheritable` in Visual basic) and declares a protected member or a protected nested type. This rule does not report violations for `Finalize` methods, which must follow this pattern.

Rule description

Types declare protected members so that inheriting types can access or override the member. By definition, you cannot inherit from a sealed type, which means that protected methods on sealed types cannot be called.

The C# compiler issues a warning for this error.

How to fix violations

To fix a violation of this rule, change the access level of the member to private, or make the type inheritable.

When to suppress warnings

Do not suppress a warning from this rule. Leaving the type in its current state can cause maintenance issues and does not provide any benefits.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example

The following example shows a type that violates this rule.

```
public sealed class SealedClass
{
    protected void ProtectedMethod(){}
}
```

```
Public NotInheritable Class BadSealedType
    Protected Sub MyMethod
    End Sub
End Class
```

CA1050: Declare types in namespaces

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1050
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A public or protected type is defined outside the scope of a named namespace.

Rule description

Types are declared in namespaces to prevent name collisions, and as a way to organize related types in an object hierarchy. Types that are outside any named namespace are in a global namespace that cannot be referenced in code.

How to fix violations

To fix a violation of this rule, place the type in a namespace.

When to suppress warnings

Although you never have to suppress a warning from this rule, it is safe to do this when the assembly will never be used together with other assemblies.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1050
// The code that's violating the rule is on this line.
#pragma warning restore CA1050
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1050.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example 1

The following example shows a library that has a type incorrectly declared outside a namespace, and a type that has the same name declared in a namespace.

```
// Violates rule: DeclareTypesInNamespaces.
using System;

public class Test
{
    public override string ToString()
    {
        return "Test does not live in a namespace!";
    }
}

namespace ca1050
{
    public class Test
    {
        public override string ToString()
        {
            return "Test lives in a namespace!";
        }
    }
}
```

```
' Violates rule: DeclareTypesInNamespaces.
Public Class Test

    Public Overrides Function ToString() As String
        Return "Test does not live in a namespace!"
    End Function

End Class

Namespace ca1050

    Public Class Test

        Public Overrides Function ToString() As String
            Return "Test lives in a namespace!"
        End Function

    End Class

End Namespace
```

Example 2

The following application uses the library that was defined previously. The type that's declared outside a namespace is created when the name `Test` is not qualified by a namespace. To access the `Test` type that's declared inside a namespace, the namespace name is required.

```
public class MainHolder
{
    public static void Main1050()
    {
        Test t1 = new Test();
        Console.WriteLine(t1.ToString());

        ca1050.Test t2 = new ca1050.Test();
        Console.WriteLine(t2.ToString());
    }
}
```

```
Public Class MainHolder

    Public Shared Sub Main1050()
        Dim t1 As New Test()
        Console.WriteLine(t1.ToString())

        Dim t2 As New ca1050.Test()
        Console.WriteLine(t2.ToString())
    End Sub

End Class
```

CA1051: Do not declare visible instance fields

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1051
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type has a non-private instance field.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

The primary use of a field should be as an implementation detail. Fields should be `private` or `internal` and should be exposed by using properties. It's as easy to access a property as it is to access a field, and the code in the accessors of a property can change as the features of the type expand without introducing breaking changes.

Properties that just return the value of a private or internal field are optimized to perform on par with accessing a field; the performance gain from using externally visible fields instead of properties is minimal. *Externally visible* refers to `public`, `protected`, and `protected internal` (`Public`, `Protected`, and `Protected Friend` in Visual Basic) accessibility levels.

Additionally, public fields cannot be protected by [Link demands](#). (Link demands don't apply to .NET Core apps.)

How to fix violations

To fix a violation of this rule, make the field `private` or `internal` and expose it by using an externally visible property.

When to suppress warnings

Only suppress this warning if you're certain that consumers need direct access to the field. For most applications, exposed fields do not provide performance or maintainability benefits over properties.

Consumers may need field access in the following situations:

- In ASP.NET Web Forms content controls.
- When the target platform makes use of `ref` to modify fields, such as model-view-viewmodel (MVVM) frameworks for WPF and UWP.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1051
// The code that's violating the rule is on this line.
#pragma warning restore CA1051
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1051.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Include or exclude APIs

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude structs](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Exclude structs

You can exclude `struct` (`Structure` in Visual Basic) fields from being analyzed.

```
dotnet_code_quality.ca1051.exclude_structs = true
```

Example

The following example shows a type (`BadPublicInstanceFields`) that violates this rule. `GoodPublicInstanceFields` shows the corrected code.

```
public class BadPublicInstanceFields
{
    // Violates rule DoNotDeclareVisibleInstanceFields.
    public int instanceData = 32;
}

public class GoodPublicInstanceFields
{
    private int instanceData = 32;

    public int InstanceData
    {
        get { return instanceData; }
        set { instanceData = value; }
    }
}
```

CA1052: Static holder types should be Static or NotInheritable

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1052
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A non-abstract type contains only static members (other than a possible default constructor) and is not declared with the [static](#) or [Shared](#) modifier.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Rule CA1052 assumes that a type that contains only static members is not designed to be inherited, because the type does not provide any functionality that can be overridden in a derived type. A type that is not meant to be inherited should be marked with the `static` modifier in C# to prohibit its use as a base type. Additionally, its default constructor should be removed. In Visual Basic, the class should be converted to a [module](#).

This rule does not fire for abstract classes or classes that have a base class. However, the rule does fire for classes that support an empty interface.

NOTE

In the latest analyzer implementation of this rule, it also encompasses the functionality of [rule CA1053](#).

How to fix violations

To fix a violation of this rule, mark the type as `static` and remove the default constructor (C#), or convert it to a module (Visual Basic).

When to suppress warnings

You can suppress violations in the following cases:

- The type is designed to be inherited. The absence of the `static` modifier suggests that the type is useful as a base type.
- The type is used as a type argument. Static types can't be used as type arguments.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then

re-enable the rule.

```
#pragma warning disable CA1052
// The code that's violating the rule is on this line.
#pragma warning restore CA1052
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1052.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example of a violation

The following example shows a type that violates the rule:

```
public class StaticMembers
{
    public static int SomeProperty { get; set; }
    public static void SomeMethod() { }
}
```

```
Imports System

Namespace ca1052

    Public Class StaticMembers

        Shared Property SomeProperty As Integer

        Private Sub New()
        End Sub

        Shared Sub SomeMethod()
        End Sub

    End Class

End Namespace
```

Fix with the static modifier

The following example shows how to fix a violation of this rule by marking the type with the `static` modifier in C#:

```
public static class StaticMembers
{
    public static int SomeProperty { get; set; }
    public static void SomeMethod() { }
}
```

CA1053: Static holder types should not have default constructors

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1053
Category	Design
Fix is breaking or non-breaking	Breaking

NOTE

Rule CA1053 only applies to legacy Visual Studio code analysis. In the .NET code-quality analyzers, it's combined into rule [CA1052: Static holder types should be Static or NotInheritable](#).

Cause

A public or nested public type declares only static members and has a default constructor.

Rule description

The default constructor is unnecessary because calling static members does not require an instance of the type. Also, because the type does not have non-static members, creating an instance does not provide access to any of the type's members.

How to fix violations

To fix a violation of this rule, remove the default constructor.

When to suppress warnings

Do not suppress a warning from this rule. The presence of the default constructor suggests that the type is not a static type.

CA1054: URI parameters should not be strings

9/20/2022 • 5 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1054
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type declares a method with a string parameter whose name contains "uri", "Uri", "urn", "Urn", "url", or "Url", and the type does not declare a corresponding overload that takes a [System.Uri](#) parameter.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

This rule splits the parameter name into tokens based on the camel casing convention and checks whether each token equals "uri", "Uri", "urn", "Urn", "url", or "Url". If there's a match, the rule assumes that the parameter represents a uniform resource identifier (URI). A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. If a method takes a string representation of a URI, a corresponding overload should be provided that takes an instance of the [Uri](#) class, which provides these services in a safe and secure manner.

How to fix violations

To fix a violation of this rule, change the parameter to a [Uri](#) type; this is a breaking change. Alternately, provide an overload of the method that takes a [Uri](#) parameter; this is a non-breaking change.

When to suppress warnings

It's safe to suppress a warning from this rule if the parameter doesn't represent a URI.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1054
// The code that's violating the rule is on this line.
#pragma warning restore CA1054
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1054.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following example shows a type, `ErrorProne`, that violates this rule, and a type, `SaferWay`, that satisfies the rule.

```
public class ErrorProne
{
    // Violates rule UriPropertiesShouldNotBeStrings.
    public string SomeUri { get; set; }

    // Violates rule UriParametersShouldNotBeStrings.
    public void AddToHistory(string uriString) { }

    // Violates rule UriReturnValuesShouldNotBeStrings.
    public string GetRefererUri(string httpHeader)
    {
        return "http://www.adventure-works.com";
    }
}

public class SaferWay
{
    // To retrieve a string, call SomeUri.ToString().
    // To set using a string, call SomeUri = new Uri(string).
    public Uri SomeUri { get; set; }

    public void AddToHistory(string uriString)
    {
        // Check for UriFormatException.
        AddToHistory(new Uri(uriString));
    }

    public void AddToHistory(Uri uriType) { }

    public Uri GetRefererUri(string httpHeader)
    {
        return new Uri("http://www.adventure-works.com");
    }
}
```

```

Imports System

Namespace ca1054

    Public Class ErrorProne

        ' Violates rule UriPropertiesShouldNotBeStrings.
        Property SomeUri As String

        ' Violates rule UriParametersShouldNotBeStrings.
        Sub AddToHistory(uriString As String)
            End Sub

        ' Violates rule UriReturnValuesShouldNotBeStrings.
        Function GetRefererUri(httpHeader As String) As String
            Return "http://www.adventure-works.com"
        End Function

    End Class

    Public Class SaferWay

        ' To retrieve a string, call SomeUri.ToString().
        ' To set using a string, call SomeUri = New Uri(string).
        Property SomeUri As Uri

        Sub AddToHistory(uriString As String)
            ' Check for UriFormatException.
            AddToHistory(New Uri(uriString))
        End Sub

        Sub AddToHistory(uriString As Uri)
        End Sub

        Function GetRefererUri(httpHeader As String) As Uri
            Return New Uri("http://www.adventure-works.com")
        End Function

    End Class

End Namespace

```

- [CA2234: Pass System.Uri objects instead of strings](#)

CA1055: URI return values should not be strings

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1055
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

The name of a method contains "uri", "Uri", "urn", "Urn", "url", or "Url", and the method returns a string.

By default, this rule only looks at externally visible methods, but this is [configurable](#).

Rule description

This rule splits the method name into tokens based on the Pascal casing convention and checks whether each token equals "uri", "Uri", "urn", "Urn", "url", or "Url". If there's a match, the rule assumes that the method returns a uniform resource identifier (URI). A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The [System.Uri](#) class provides these services in a safe and secure manner.

How to fix violations

To fix a violation of this rule, change the return type to a [Uri](#).

When to suppress warnings

It's safe to suppress a warning from this rule if the return value does not represent a URI.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1055
// The code that's violating the rule is on this line.
#pragma warning restore CA1055
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1055.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following example shows a type, `ErrorProne`, that violates this rule, and a type, `SaferWay`, that satisfies the rule.

```
public class ErrorProne
{
    // Violates rule UriPropertiesShouldNotBeStrings.
    public string SomeUri { get; set; }

    // Violates rule UriParametersShouldNotBeStrings.
    public void AddToHistory(string uriString) { }

    // Violates rule UriReturnValuesShouldNotBeStrings.
    public string GetReferrerUri(string httpHeader)
    {
        return "http://www.adventure-works.com";
    }
}

public class SaferWay
{
    // To retrieve a string, call SomeUri.ToString().
    // To set using a string, call SomeUri = new Uri(string).
    public Uri SomeUri { get; set; }

    public void AddToHistory(string uriString)
    {
        // Check for UriFormatException.
        AddToHistory(new Uri(uriString));
    }

    public void AddToHistory(Uri uriType) { }

    public Uri GetReferrerUri(string httpHeader)
    {
        return new Uri("http://www.adventure-works.com");
    }
}
```

```

Imports System

Namespace ca1055

    Public Class ErrorProne

        ' Violates rule UriPropertiesShouldNotBeStrings.
        Property SomeUri As String

        ' Violates rule UriParametersShouldNotBeStrings.
        Sub AddToHistory(uriString As String)
            End Sub

        ' Violates rule UriReturnValuesShouldNotBeStrings.
        Function GetRefererUri(httpHeader As String) As String
            Return "http://www.adventure-works.com"
        End Function

    End Class

    Public Class SaferWay

        ' To retrieve a string, call SomeUri.ToString().
        ' To set using a string, call SomeUri = New Uri(string).
        Property SomeUri As Uri

        Sub AddToHistory(uriString As String)
            ' Check for UriFormatException.
            AddToHistory(New Uri(uriString))
        End Sub

        Sub AddToHistory(uriString As Uri)
        End Sub

        Function GetRefererUri(httpHeader As String) As Uri
            Return New Uri("http://www.adventure-works.com")
        End Function

    End Class

End Namespace

```

CA1056: URI properties should not be strings

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1056
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type declares a string property whose name contains "uri", "Uri", "urn", "Urn", "url", or "Url".

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

This rule splits the property name into tokens based on the Pascal casing convention and checks whether each token equals "uri", "Uri", "urn", "Urn", "url", or "Url". If there's a match, the rule assumes that the property represents a uniform resource identifier (URI). A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The [System.Uri](#) class provides these services in a safe and secure manner.

How to fix violations

To fix a violation of this rule, change the property to a [Uri](#) type.

When to suppress warnings

It's safe to suppress a warning from this rule if the property doesn't represent a URI.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1056
// The code that's violating the rule is on this line.
#pragma warning restore CA1056
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1056.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following example shows a type, `ErrorProne`, that violates this rule, and a type, `SaferWay`, that satisfies the rule.

```
public class ErrorProne
{
    // Violates rule UriPropertiesShouldNotBeStrings.
    public string SomeUri { get; set; }

    // Violates rule UriParametersShouldNotBeStrings.
    public void AddToHistory(string uriString) { }

    // Violates rule UriReturnValuesShouldNotBeStrings.
    public string GetRefererUri(string httpHeader)
    {
        return "http://www.adventure-works.com";
    }
}

public class SaferWay
{
    // To retrieve a string, call SomeUri.ToString().
    // To set using a string, call SomeUri = new Uri(string).
    public Uri SomeUri { get; set; }

    public void AddToHistory(string uriString)
    {
        // Check for UriFormatException.
        AddToHistory(new Uri(uriString));
    }

    public void AddToHistory(Uri uriType) { }

    public Uri GetRefererUri(string httpHeader)
    {
        return new Uri("http://www.adventure-works.com");
    }
}
```

```

Imports System

Namespace ca1056

    Public Class ErrorProne

        ' Violates rule UriPropertiesShouldNotBeStrings.
        Property SomeUri As String

        ' Violates rule UriParametersShouldNotBeStrings.
        Sub AddToHistory(uriString As String)
            End Sub

        ' Violates rule UriReturnValuesShouldNotBeStrings.
        Function GetRefererUri(httpHeader As String) As String
            Return "http://www.adventure-works.com"
        End Function

    End Class

    Public Class SaferWay

        ' To retrieve a string, call SomeUri.ToString().
        ' To set using a string, call SomeUri = New Uri(string).
        Property SomeUri As Uri

        Sub AddToHistory(uriString As String)
            ' Check for UriFormatException.
            AddToHistory(New Uri(uriString))
        End Sub

        Sub AddToHistory(uriString As Uri)
        End Sub

        Function GetRefererUri(httpHeader As String) As Uri
            Return New Uri("http://www.adventure-works.com")
        End Function

    End Class

End Namespace

```

- [CA2234: Pass System.Uri objects instead of strings](#)

CA1058: Types should not extend certain base types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1058
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A type extends one of the following base types:

- [System.ApplicationException](#)
- [System.Xml.XmlDocument](#)
- [System.Collections.CollectionBase](#)
- [System.Collections.DictionaryBase](#)
- [System.Collections.Queue](#)
- [System.Collections.ReadOnlyCollectionBase](#)
- [System.Collections.SortedList](#)
- [System.Collections.Stack](#)

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Exceptions should derive from [System.Exception](#) or one of its subclasses in the [System](#) namespace.

Do not create a subclass of [XmlDocument](#) if you want to create an XML view of an underlying object model or data source.

Non-generic collections

Use and/or extend generic collections whenever possible. Do not extend non-generic collections in your code, unless you shipped it previously.

Examples of Incorrect Usage

```
public class MyCollection : CollectionBase
{
}

public class MyReadOnlyCollection : ReadOnlyCollectionBase
{
}
```

Examples of Correct Usage

```
public class MyCollection : Collection<T>
{
}

public class MyReadOnlyCollection : ReadOnlyCollection<T>
{
}
```

How to fix violations

To fix a violation of this rule, derive the type from a different base type or a generic collection.

When to suppress warnings

Do not suppress a warning from this rule for violations about [ApplicationException](#). It is safe to suppress a warning from this rule for violations about [XmlDocument](#). It is safe to suppress a warning about a non-generic collection if the code was released previously.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1058
// The code that's violating the rule is on this line.
#pragma warning restore CA1058
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1058.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

CA1060: Move P/Invokes to NativeMethods class

9/20/2022 • 5 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1060
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A method uses Platform Invocation Services to access unmanaged code and is not a member of one of the **NativeMethods** classes.

Rule description

Platform Invocation methods, such as those that are marked by using the [System.Runtime.InteropServices.DllImportAttribute](#) attribute, or methods that are defined by using the [Declare](#) keyword in Visual Basic, access unmanaged code. These methods should be in one of the following classes:

- **NativeMethods** - This class does not suppress stack walks for unmanaged code permission. ([System.Security.SuppressUnmanagedCodeSecurityAttribute](#) must not be applied to this class.) This class is for methods that can be used anywhere because a stack walk will be performed.
- **SafeNativeMethods** - This class suppresses stack walks for unmanaged code permission. ([System.Security.SuppressUnmanagedCodeSecurityAttribute](#) is applied to this class.) This class is for methods that are safe for anyone to call. Callers of these methods are not required to perform a full security review to make sure that the usage is secure because the methods are harmless for any caller.
- **UnsafeNativeMethods** - This class suppresses stack walks for unmanaged code permission. ([System.Security.SuppressUnmanagedCodeSecurityAttribute](#) is applied to this class.) This class is for methods that are potentially dangerous. Any caller of these methods must perform a full security review to make sure that the usage is secure because no stack walk will be performed.

These classes are declared as `internal` (`Friend` in Visual Basic) and declare a private constructor to prevent new instances from being created. The methods in these classes should be `static` and `internal` (`Shared` and `Friend` in Visual Basic).

How to fix violations

To fix a violation of this rule, move the method to the appropriate **NativeMethods** class. For most applications, moving P/Invokes to a new class that is named **NativeMethods** is enough.

However, if you are developing libraries for use in other applications, you should consider defining two other classes that are called **SafeNativeMethods** and **UnsafeNativeMethods**. These classes resemble the **NativeMethods** class; however, they are marked by using a special attribute called [SuppressUnmanagedCodeSecurityAttribute](#). When this attribute is applied, the runtime does not perform a full stack walk to make sure that all callers have the **UnmanagedCode** permission. The runtime ordinarily

checks for this permission at startup. Because the check is not performed, it can greatly improve performance for calls to these unmanaged methods. It also enables code that has limited permissions to call these methods.

However, you should use this attribute with great care. It can have serious security implications if it is implemented incorrectly.

For information about how to implement the methods, see the **NativeMethods** example, **SafeNativeMethods** example, and **UnsafeNativeMethods** example.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example declares a method that violates this rule. To correct the violation, the **RemoveDirectory** P/Invoke should be moved to an appropriate class that is designed to hold only P/Invokes.

```
' Violates rule: MovePIvokesToNativeMethodsClass.  
Friend Class UnmanagedApi  
    Friend Declare Function RemoveDirectory Lib "kernel32" (  
        ByVal Name As String) As Boolean  
End Class
```

```
// Violates rule: MovePIvokesToNativeMethodsClass.  
internal class UnmanagedApi  
{  
    [DllImport("kernel32.dll", CharSet = CharSet.Unicode)]  
    internal static extern bool RemoveDirectory(string name);  
}
```

NativeMethods example

Because the **NativeMethods** class should not be marked by using **SuppressUnmanagedCodeSecurityAttribute**, P/Invokes that are put in it will require **UnmanagedCode** permission. Because most applications run from the local computer and run together with full trust, this is usually not a problem. However, if you are developing reusable libraries, you should consider defining a **SafeNativeMethods** or **UnsafeNativeMethods** class.

The following example shows an **Interaction.Beep** method that wraps the **MessageBeep** function from user32.dll. The **MessageBeep** P/Invoke is put in the **NativeMethods** class.

```

Public NotInheritable Class Interaction

    Private Sub New()
        End Sub

        ' Callers require Unmanaged permission
        Public Shared Sub Beep()
            ' No need to demand a permission as callers of Interaction.Beep
            ' will require UnmanagedCode permission
            If Not NativeMethods.MessageBeep(-1) Then
                Throw New Win32Exception()
            End If

        End Sub

    End Class

    Friend NotInheritable Class NativeMethods

        Private Sub New()
            End Sub

            <DllImport("user32.dll", CharSet:=CharSet.Auto)>
            Friend Shared Function MessageBeep(ByVal uType As Integer) As <MarshalAs(UnmanagedType.Bool)> Boolean
            End Function

    End Class

```

```

public static class Interaction
{
    // Callers require Unmanaged permission
    public static void Beep()
    {
        // No need to demand a permission as callers of Interaction.Beep
        // will require UnmanagedCode permission
        if (!NativeMethods.MessageBeep(-1))
            throw new Win32Exception();
    }
}

internal static class NativeMethods
{
    [DllImport("user32.dll", CharSet = CharSet.Auto)]
    [return: MarshalAs(UnmanagedType.Bool)]
    internal static extern bool MessageBeep(int uType);
}

```

SafeNativeMethods example

P/Invoke methods that can be safely exposed to any application and that do not have any side effects should be put in a class that is named **SafeNativeMethods**. You do not have to pay much attention to where they are called from.

The following example shows an **Environment.TickCount** property that wraps the **GetTickCount** function from kernel32.dll.

```

Public NotInheritable Class Environment

    Private Sub New()
        End Sub

        ' Callers do not require Unmanaged permission
        Public Shared ReadOnly Property TickCount() As Integer
            Get
                ' No need to demand a permission in place of
                ' UnmanagedType as GetTickCount is considered
                ' a safe method
                Return SafeNativeMethods.GetTickCount()
            End Get
        End Property

    End Class

<SuppressUnmanagedCodeSecurityAttribute()>
Friend NotInheritable Class SafeNativeMethods

    Private Sub New()
        End Sub

    <DllImport("kernel32.dll", CharSet:=CharSet.Auto, ExactSpelling:=True)>
    Friend Shared Function GetTickCount() As Integer
        End Function

    End Class

```

```

public static class Environment
{
    // Callers do not require UnmanagedType permission
    public static int TickCount
    {
        get
        {
            // No need to demand a permission in place of
            // UnmanagedType as GetTickCount is considered
            // a safe method
            return SafeNativeMethods.GetTickCount();
        }
    }
}

[SuppressUnmanagedCodeSecurityAttribute]
internal static class SafeNativeMethods
{
    [DllImport("kernel32.dll", CharSet = CharSet.Auto, ExactSpelling = true)]
    internal static extern int GetTickCount();
}

```

UnsafeNativeMethods example

P/Invoke methods that cannot be safely called and that could cause side effects should be put in a class that is named **UnsafeNativeMethods**. These methods should be rigorously checked to make sure that they are not exposed to the user unintentionally.

The following example shows a **Cursor.Hide** method that wraps the **ShowCursor** function from user32.dll.

```

Public NotInheritable Class Cursor

    Private Sub New()
        End Sub

        ' Callers do not require Unmanaged permission, however,
        ' they do require UIPermission.AllWindows
        Public Shared Sub Hide()
            ' Need to demand an appropriate permission
            ' in place of UnmanagedCode permission as
            ' ShowCursor is not considered a safe method
            Dim permission As New UIPermission(UIPermissionWindow.AllWindows)
            permission.Demand()
            UnsafeNativeMethods.ShowCursor(False)

        End Sub

    End Class

<SuppressUnmanagedCodeSecurityAttribute()>
Friend NotInheritable Class UnsafeNativeMethods

    Private Sub New()
        End Sub

        <DllImport("user32.dll", CharSet:=CharSet.Auto, ExactSpelling:=True)>
        Friend Shared Function ShowCursor(<MarshalAs(UnmanagedType.Bool)> ByVal bShow As Boolean) As Integer
            End Function

    End Class

```

```

public static class Cursor
{
    public static void Hide()
    {
        UnsafeNativeMethods.ShowCursor(false);
    }
}

[SuppressUnmanagedCodeSecurityAttribute]
internal static class UnsafeNativeMethods
{
    [DllImport("user32.dll", CharSet = CharSet.Auto, ExactSpelling = true)]
    internal static extern int ShowCursor([MarshalAs(UnmanagedType.Bool)] bool bShow);
}

```

CA1061: Do not hide base class methods

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1061
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A derived type declares a method with the same name and with the same number of parameters as one of its base methods; one or more of the parameters is a base type of the corresponding parameter in the base method; and any remaining parameters have types that are identical to the corresponding parameters in the base method.

Rule description

A method in a base type is hidden by an identically named method in a derived type when the parameter signature of the derived method differs only by types that are more weakly derived than the corresponding types in the parameter signature of the base method.

How to fix violations

To fix a violation of this rule, remove or rename the method, or change the parameter signature so that the method does not hide the base method.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows a method that violates the rule.

```
class BaseType
{
    internal void MethodOne(string inputOne, object inputTwo)
    {
        Console.WriteLine("Base: {0}, {1}", inputOne, inputTwo);
    }

    internal void MethodTwo(string inputOne, string inputTwo)
    {
        Console.WriteLine("Base: {0}, {1}", inputOne, inputTwo);
    }
}

class DerivedType : BaseType
{
    internal void MethodOne(string inputOne, string inputTwo)
    {
        Console.WriteLine("Derived: {0}, {1}", inputOne, inputTwo);
    }

    // This method violates the rule.
    internal void MethodTwo(string inputOne, object inputTwo)
    {
        Console.WriteLine("Derived: {0}, {1}", inputOne, inputTwo);
    }
}

class Test
{
    static void Main1061()
    {
        DerivedType derived = new DerivedType();

        // Calls DerivedType.MethodOne.
        derived.MethodOne("string1", "string2");

        // Calls BaseType.MethodOne.
        derived.MethodOne("string1", (object)"string2");

        // Both of these call DerivedType.MethodTwo.
        derived.MethodTwo("string1", "string2");
        derived.MethodTwo("string1", (object)"string2");
    }
}
```

CA1062: Validate arguments of public methods

9/20/2022 • 6 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1062
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

An externally visible method dereferences one of its reference arguments without verifying whether that argument is `null` (`Nothing` in Visual Basic).

You can [configure](#) this rule to exclude certain types and parameters from analysis. You can also [indicate null-check validation methods](#).

Rule description

All reference arguments that are passed to externally visible methods should be checked against `null`. If appropriate, throw an [ArgumentNullException](#) when the argument is `null`.

If a method can be called from an unknown assembly because it is declared public or protected, you should validate all parameters of the method. If the method is designed to be called only by known assemblies, mark the method `internal` and apply the [InternalsVisibleToAttribute](#) attribute to the assembly that contains the method.

How to fix violations

To fix a violation of this rule, validate each reference argument against `null`.

When to suppress warnings

You can suppress a warning from this rule if you are sure that the dereferenced parameter has been validated by another method call in the function.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1062
// The code that's violating the rule is on this line.
#pragma warning restore CA1062
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1062.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)
- [Exclude extension method 'this' parameter](#)
- [Null check validation methods](#)

These options can be configured for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

NOTE

This option is supported for CA1062 in .NET 7 and later versions only.

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Exclude extension method 'this' parameter

By default, this rule analyzes and flags the `this` parameter for extension methods. You can exclude analysis of the `this` parameter for extension methods by adding the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1062.exclude_extension_method_this_parameter = true
```

Null check validation methods

This rule can lead to false positives if your code calls special null-check validation methods in referenced libraries or projects. You can avoid these false positives by specifying the name or signature of null-check

validation methods. The analysis assumes that arguments passed to these methods are non-null after the call. For example, to mark all methods named `Validate` as null-check validation methods, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1062.null_check_validation_methods = Validate
```

Allowed method name formats in the option value (separated by `|`):

- Method name only (includes all methods with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `M:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1062.null_check_validation_methods = Validate</code>	Matches all methods named <code>Validate</code> in the compilation
<code>dotnet_code_quality.CA1062.null_check_validation_methods = Validate1 Validate2</code>	Matches all methods named either <code>Validate1</code> or <code>Validate2</code> in the compilation
<code>dotnet_code_quality.CA1062.null_check_validation_methods = NS.MyType.Validate(ParamType)</code>	Matches specific method <code>Validate</code> with given fully qualified signature
<code>dotnet_code_quality.CA1062.null_check_validation_methods = NS1.MyType1.Validate1(ParamType) NS2.MyType2.Validate2(ParamType)</code>	Matches specific methods <code>Validate1</code> and <code>Validate2</code> with respective fully qualified signature

Example 1

The following example shows a method that violates the rule and a method that satisfies the rule.

```

using System;

namespace DesignLibrary
{
    public class Test
    {
        // This method violates the rule.
        public void DoNotValidate(string input)
        {
            if (input.Length != 0)
            {
                Console.WriteLine(input);
            }
        }

        // This method satisfies the rule.
        public void Validate(string input)
        {
            if (input == null)
            {
                throw new ArgumentNullException(nameof(input));
            }
            if (input.Length != 0)
            {
                Console.WriteLine(input);
            }
        }
    }
}

```

```

Imports System

Namespace DesignLibrary

    Public Class Test

        ' This method violates the rule.
        Sub DoNotValidate(ByVal input As String)

            If input.Length <> 0 Then
                Console.WriteLine(input)
            End If

        End Sub

        ' This method satisfies the rule.
        Sub Validate(ByVal input As String)

            If input Is Nothing Then
                Throw New ArgumentNullException(NameOf(input))
            End If

            If input.Length <> 0 Then
                Console.WriteLine(input)
            End If

        End Sub

    End Class

End Namespace

```

Example 2

Copy constructors that populate fields or properties that are reference objects can also violate rule CA1062. The violation occurs because the copied object that's passed to the copy constructor might be `null` (`Nothing` in Visual Basic). To resolve the violation, use a `static` (`Shared` in Visual Basic) method to check that the copied object is not null.

In the following `Person` class example, the `other` object that is passed to the `Person` copy constructor might be `null`.

```
public class Person
{
    public string Name { get; private set; }
    public int Age { get; private set; }

    public Person(string name, int age)
    {
        Name = name;
        Age = age;
    }

    // Copy constructor CA1062 fires because other is dereferenced
    // without being checked for null
    public Person(Person other)
        : this(other.Name, other.Age)
    {
    }
}
```

Example 3

In the following revised `Person` example, the `other` object that's passed to the copy constructor is first checked for null in the `PassThroughNonNull` method.

```
public class Person
{
    public string Name { get; private set; }
    public int Age { get; private set; }

    public Person(string name, int age)
    {
        Name = name;
        Age = age;
    }

    // Copy constructor
    public Person(Person other)
        : this(PassThroughNonNull(other).Name, other.Age)
    {
    }

    // Null check method
    private static Person PassThroughNonNull(Person person)
    {
        if (person == null)
            throw new ArgumentNullException(nameof(person));
        return person;
    }
}
```

CA1063: Implement IDisposable correctly

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1063
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

The `System.IDisposable` interface is not implemented correctly. Possible reasons for this include:

- `IDisposable` is reimplemented in the class.
- `Finalize` is overridden again.
- `Dispose()` is overridden.
- The `Dispose()` method is not public, `sealed`, or named `Dispose`.
- `Dispose(bool)` is not protected, virtual, or unsealed.
- In unsealed types, `Dispose()` must call `Dispose(true)`.
- For unsealed types, the `Finalize` implementation does not call either or both `Dispose(bool)` or the base class finalizer.

Violation of any one of these patterns triggers warning CA1063.

Every unsealed type that declares and implements the `IDisposable` interface must provide its own `protected virtual void Dispose(bool)` method. `Dispose()` should call `Dispose(true)`, and the finalizer should call `Dispose(false)`. If you create an unsealed type that declares and implements the `IDisposable` interface, you must define `Dispose(bool)` and call it. For more information, see [Clean up unmanaged resources \(.NET guide\)](#) and [Dispose pattern](#).

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

All `IDisposable` types should implement the [Dispose pattern](#) correctly.

How to fix violations

Examine your code and determine which of the following resolutions will fix this violation:

- Remove `IDisposable` from the list of interfaces that are implemented by your type, and override the base class `Dispose` implementation instead.
- Remove the finalizer from your type, override `Dispose(bool disposing)`, and put the finalization logic in the code path where 'disposing' is false.

- Override `Dispose(bool disposing)`, and put the dispose logic in the code path where 'disposing' is true.
- Make sure that `Dispose()` is declared as public and [sealed](#).
- Rename your dispose method to **Dispose** and make sure that it's declared as public and [sealed](#).
- Make sure that `Dispose(bool)` is declared as protected, virtual, and unsealed.
- Modify `Dispose()` so that it calls `Dispose(true)`, then calls [SuppressFinalize](#) on the current object instance (`this`, or `Me` in Visual Basic), and then returns.
- Modify your finalizer so that it calls `Dispose(false)` and then returns.
- If you create an unsealed type that declares and implements the [IDisposable](#) interface, make sure that the implementation of [IDisposable](#) follows the pattern that is described earlier in this section.

When to suppress warnings

Do not suppress a warning from this rule.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Pseudo-code example

The following pseudo-code provides a general example of how `Dispose(bool)` should be implemented in a class that uses managed and native resources.

```
public class Resource : IDisposable
{
    private bool isDisposed;
    private IntPtr nativeResource = Marshal.AllocHGlobal(100);
    private AnotherResource managedResource = new AnotherResource();

    // Dispose() calls Dispose(true)
    public void Dispose()
    {
        Dispose(true);
        GC.SuppressFinalize(this);
    }

    // The bulk of the clean-up code is implemented in Dispose(bool)
    protected virtual void Dispose(bool disposing)
    {
        if (isDisposed) return;

        if (disposing)
        {
            // free managed resources
            managedResource.Dispose();
        }

        // free native resources if there are any.
        if (nativeResource != IntPtr.Zero)
        {
            Marshal.FreeHGlobal(nativeResource);
            nativeResource = IntPtr.Zero;
        }

        isDisposed = true;
    }

    // NOTE: Leave out the finalizer altogether if this class doesn't
    // own unmanaged resources, but leave the other methods
    // exactly as they are.
    ~Resource()
    {
        // Finalizer calls Dispose(false)
        Dispose(false);
    }
}
```

CA1064: Exceptions should be public

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1064
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A non-public exception derives directly from [Exception](#), [SystemException](#), or [ApplicationException](#).

Rule description

An internal exception is only visible inside its own internal scope. After the exception falls outside the internal scope, only the base exception can be used to catch the exception. If the internal exception is inherited from [Exception](#), [SystemException](#), or [ApplicationException](#), the external code will not have sufficient information to know what to do with the exception.

But, if the code has a public exception that later is used as the base for an internal exception, it is reasonable to assume the code further out will be able to do something intelligent with the base exception. The public exception will have more information than what is provided by [Exception](#), [SystemException](#), or [ApplicationException](#).

How to fix violations

Make the exception public, or derive the internal exception from a public exception that is not [Exception](#), [SystemException](#), or [ApplicationException](#).

When to suppress warnings

Suppress a message from this rule if you are sure in all cases that the private exception will be caught within its own internal scope.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1064
// The code that's violating the rule is on this line.
#pragma warning restore CA1064
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1064.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

This rule fires on the first example method, `FirstCustomException` because the exception class derives directly from `Exception` and is internal. The rule does not fire on the `SecondCustomException` class because although the class also derives directly from `Exception`, the class is declared public. The third class also does not fire the rule because it does not derive directly from [System.Exception](#), [System.SystemException](#), or [System.ApplicationException](#).

```
// Violates this rule
[Serializable]
internal class FirstCustomException : Exception
{
    internal FirstCustomException()
    {
    }

    internal FirstCustomException(string message)
        : base(message)
    {
    }

    internal FirstCustomException(string message, Exception innerException)
        : base(message, innerException)
    {
    }

    protected FirstCustomException(SerializationInfo info, StreamingContext context)
        : base(info, context)
    {
    }
}

// Does not violate this rule because
// SecondCustomException is public
[Serializable]
public class SecondCustomException : Exception
{
    public SecondCustomException()
    {
    }

    public SecondCustomException(string message)
        : base(message)
    {
    }

    public SecondCustomException(string message, Exception innerException)
        : base(message, innerException)
    {
    }
}
```

```
protected SecondCustomException(SerializationInfo info, StreamingContext context)
    : base(info, context)
{
}

// Does not violate this rule because
// ThirdCustomException it does not derive directly from
// Exception, SystemException, or ApplicationException
[Serializable]
internal class ThirdCustomException : SecondCustomException
{
    internal ThirdCustomException()
    {

    }

    internal ThirdCustomException(string message)
        : base(message)
    {

    }

    internal ThirdCustomException(string message, Exception innerException)
        : base(message, innerException)
    {

    }
}

protected ThirdCustomException(SerializationInfo info, StreamingContext context)
    : base(info, context)
{
}
}
```

CA1065: Do not raise exceptions in unexpected locations

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1065
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A method that is not expected to throw exceptions throws an exception.

Rule description

Methods that are not expected to throw exceptions can be categorized as follows:

- Property Get Methods
- Event Accessor Methods
- Equals Methods
- GetHashCode Methods
- ToString Methods
- Static Constructors
- Finalizers
- Dispose Methods
- Equality Operators
- Implicit Cast Operators

The following sections discuss these method types.

Property Get Methods

Properties are basically smart fields. Therefore, they should behave like a field as much as possible. Fields don't throw exceptions and neither should properties. If you have a property that throws an exception, consider making it a method.

The following exceptions can be thrown from a property get method:

- [System.InvalidOperationException](#) and all derivatives (including [System.ObjectDisposedException](#))
- [System.NotSupportedException](#) and all derivatives
- [System.ArgumentException](#) (only from indexed get)

- `KeyNotFoundException` (only from indexed get)

Event Accessor Methods

Event accessors should be simple operations that don't throw exceptions. An event should not throw an exception when you try to add or remove an event handler.

The following exceptions can be thrown from an event accessor:

- `System.InvalidOperationException` and all derivatives (including `System.ObjectDisposedException`)
- `System.NotSupportedException` and all derivatives
- `ArgumentException` and derivatives

Equals Methods

The following `Equals` methods should not throw exceptions:

- `System.Object.Equals`
- `Equals`

An `Equals` method should return `true` or `false` instead of throwing an exception. For example, if `Equals` is passed two mismatched types it should just return `false` instead of throwing an `ArgumentException`.

GetHashCode Methods

The following `GetHashCode` methods should usually not throw exceptions:

- `GetHashCode`
- `GetHashCode`

`GetHashCode` should always return a value. Otherwise, you can lose items in the hash table.

The versions of `GetHashCode` that take an argument can throw an `ArgumentException`. However, `Object.GetHashCode` should never throw an exception.

ToString Methods

The debugger uses `System.Object.ToString` to help display information about objects in string format. Therefore, `ToString` should not change the state of an object, and it shouldn't throw exceptions.

Static Constructors

Throwing exceptions from a static constructor causes the type to be unusable in the current application domain. You should have a good reason (such as a security issue) for throwing an exception from a static constructor.

Finalizers

Throwing an exception from a finalizer causes the CLR to fail fast, which tears down the process. Therefore, throwing exceptions in a finalizer should always be avoided.

Dispose Methods

A `System.IDisposable.Dispose` method should not throw an exception. `Dispose` is often called as part of the cleanup logic in a `finally` clause. Therefore, explicitly throwing an exception from `Dispose` forces the user to add exception handling inside the `finally` clause.

The `Dispose(false)` code path should never throw exceptions, because `Dispose` is almost always called from a finalizer.

Equality Operators (`==`, `!=`)

Like `Equals` methods, equality operators should return either `true` or `false`, and should not throw exceptions.

Implicit Cast Operators

Because the user is often unaware that an implicit cast operator has been called, an exception thrown by the implicit cast operator is unexpected. Therefore, no exceptions should be thrown from implicit cast operators.

How to fix violations

For property getters, either change the logic so that it no longer has to throw an exception, or change the property into a method.

For all other method types listed previously, change the logic so that it no longer must throw an exception.

When to suppress warnings

If the violation was caused by an exception declaration instead of a thrown exception, it is safe to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1065
// The code that's violating the rule is on this line.
#pragma warning restore CA1065
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1065.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1066: Implement IEquatable when overriding Equals

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1066
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A value type (struct) overrides [Equals](#) method, but does not implement [IEquatable<T>](#).

Rule description

A value type overriding [Equals](#) method indicates that it supports comparing two instances of the type for value equality. Consider implementing the [IEquatable<T>](#) interface to support strongly typed tests for equality. This ensures that callers performing equality checks invoke the strongly typed [System.IEquatable<T>.Equals](#) method and avoid boxing the argument, improving performance. For more information, see [here](#).

Your [System.IEquatable<T>.Equals](#) implementation should return results that are consistent with [Equals](#).

How to fix violations

To fix a violation, implement [IEquatable<T>](#) and update [Equals](#) override to invoke this implemented method. For example, the following two code snippets show a violation of the rule and how to fix it:

```
public struct S
{
    private readonly int _value;
    public S(int f)
    {
        _value = f;
    }

    public override int GetHashCode()
        => _value.GetHashCode();

    public override bool Equals(object other)
        => other is S otherS && _value == otherS._value;
}
```

```
using System;

public struct S : IEquatable<S>
{
    private readonly int _value;
    public S(int f)
    {
        _value = f;
    }

    public override int GetHashCode()
        => _value.GetHashCode();

    public override bool Equals(object other)
        => other is S otherS && Equals(otherS);

    public bool Equals(S other)
        => _value == other._value;
}
```

When to suppress warnings

It is safe to suppress violations from this rule if the design and performance benefits from implementing the interface are not critical.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1066
// The code that's violating the rule is on this line.
#pragma warning restore CA1066
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1066.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [Design rules](#)

CA1067: Override Equals when implementing IEquatable

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1067
Category	Design
Fix is breaking or non-breaking	Non-breaking

Cause

A type implements [IEquatable<T>](#), but does not override [Equals](#) method.

Rule description

A type implementing [IEquatable<T>](#) interface indicates that it supports comparing two instances of the type for equality. You should also override the base class implementations of [Equals](#) and [GetHashCode\(\)](#) methods so that their behavior is consistent with that of the [System.IEquatable<T>.Equals](#) implementation. See [here](#) for more details.

Your [Equals](#) implementation should return results that are consistent with [System.IEquatable<T>.Equals](#) implementation.

How to fix violations

To fix a violation, override [Equals](#) and implement it by invoking the [System.IEquatable<T>.Equals](#) implementation. For example, the following two code snippets show a violation of the rule and how to fix it:

```
using System;

public struct S : IEquatable<S>
{
    private readonly int _value;
    public S(int f)
    {
        _value = f;
    }

    public bool Equals(S other)
        => _value == other._value;
}
```

```
using System;

public struct S : IEquatable<S>
{
    private readonly int _value;
    public S(int f)
    {
        _value = f;
    }

    public bool Equals(S other)
    => _value == other._value;

    public override bool Equals(object obj)
    => obj is S objs && Equals(objs);

    public override int GetHashCode()
    => _value.GetHashCode();
}
```

When to suppress warnings

Do not suppress violations of this rule.

CA1068: CancellationToken parameters must come last

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1068
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A method has a [CancellationToken](#) parameter that is not the last parameter.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Methods that perform long running operations or asynchronous operations and are cancelable normally take a cancellation token parameter. Each cancellation token has a [CancellationTokenSource](#) that creates the token and uses it for cancelable computations. It is common practice to have a long chain of method calls that pass around the cancellation token from the callers to the callees. Hence, a large number of methods that take part in a cancelable computation end up having a cancellation token parameter. However, the cancellation token itself is not usually relevant to the core functionality of a majority of these methods. It's considered a good API design practice to have such parameters be the last parameter in the list.

Special cases

Rule CA1068 does not fire in the following special cases:

- Method has one or more [optional](#) parameters ([Optional](#) in Visual Basic) following a non-optional cancellation token parameter. The compiler requires that all optional parameters are defined after all the non-optional parameters.
- Method has one or more [ref](#) or [out](#) parameters ([ByRef](#) in Visual Basic) following a cancellation token parameter. It is common practice to have [ref](#) or [out](#) parameters be at the end of the list, because they usually indicate output values for the method.

How to fix violations

Change the method signature to move the cancellation token parameter to the end of the list. For example, the following two code snippets show a violation of the rule and how to fix it:

```
// Violates CA1068
public void LongRunningOperation(CancellationToken token, string usefulParameter)
{
    ...
}
```

```
// Does not violate CA1068
public void LongRunningOperation(string usefulParameter, CancellationToken token)
{
    ...
}
```

When to suppress warnings

If the method is an externally visible public API that is already part of a shipped library, then it is safe to suppress a warning from this rule to avoid a breaking change for the library consumers.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1068
// The code that's violating the rule is on this line.
#pragma warning restore CA1068
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1068.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA1069: Enums should not have duplicate values

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1069
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

An [enumeration](#) has multiple members which are explicitly assigned the same constant value.

Rule description

Every enum member should either have a unique constant value or be explicitly assigned with a prior member in the enum to indicate explicit intent of sharing value. For example:

```
enum E
{
    Field1 = 1,
    AnotherNameForField1 = Field1,    // This is fine
    Field2 = 2,
    Field3 = 2,    // CA1069: This is not fine. Either assign a different constant value or 'Field2' to
    indicate explicit intent of sharing value.
}
```

This rule helps in catching functional bugs introduced from the following scenarios:

- Accidental typing mistakes, where the user accidentally typed the same constant value for multiple members.
- Copy paste mistakes, where the user copied an existing member definition, then renamed the member but forgot to change the value.
- Merge resolution from multiple branches, where a new member was added with a different name but the same value in different branches.

How to fix violations

To fix a violation, either assign a new unique constant value or assign with a prior member in the enum to indicate explicit intent of sharing the same value. For example, the following code snippet shows a violation of the rule and couple of ways to fix the violation:

```
enum E
{
    Field1 = 1,
    AnotherNameForField1 = Field1,    // This is fine
    Field2 = 2,
    Field3 = 2,    // CA1069: This is not fine. Either assign a different constant value or 'Field2' to
    indicate explicit intent of sharing value.
}
```

```
enum E
{
    Field1 = 1,
    AnotherNameForField1 = Field1,    // This is fine
    Field2 = 2,
    Field3 = 3,    // This is now fine
}
```

```
enum E
{
    Field1 = 1,
    AnotherNameForField1 = Field1,    // This is fine
    Field2 = 2,
    Field3 = Field2,    // This is also fine
}
```

When to suppress warnings

Do not suppress violations of this rule.

See also

- [Design rules](#)

CA1070: Do not declare event fields as virtual

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1070
Category	Design
Fix is breaking or non-breaking	Breaking

Cause

A [field-like event](#) was declared as virtual.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Follow these [.NET design guidelines](#) to raise base class events in derived classes. Do not declare virtual events in a base class. Overridden events in a derived class have undefined behavior. The C# compiler does not handle this correctly and it is unpredictable whether a subscriber to the derived event will actually be subscribing to the base class event.

```
using System;
public class C
{
    // CA1070: Event 'ThresholdReached' should not be declared virtual.
    public virtual event EventHandler ThresholdReached;
}
```

How to fix violations

Follow these [.NET design guidelines](#) and avoid virtual field-like events.

When to suppress warnings

If the event is an externally visible public API that is already part of a shipped library, then it is safe to suppress a warning from this rule to avoid a breaking change for the library consumers.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1070
// The code that's violating the rule is on this line.
#pragma warning restore CA1070
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1070.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Design.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Design](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

- [Design rules](#)

Documentation rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Documentation rules support writing well-documented libraries through the correct use of [XML documentation comments](#) for externally visible APIs.

In this section

RULE	DESCRIPTION
CA1200: Avoid using cref tags with a prefix	The <code>cref</code> attribute in an XML documentation tag means "code reference". It specifies that the inner text of the tag is a code element, such as a type, method, or property. Avoid using <code>cref</code> tags with prefixes, because it prevents the compiler from verifying references. It also prevents the Visual Studio integrated development environment (IDE) from finding and updating these symbol references during refactorings.

CA1200: Avoid using cref tags with a prefix

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1200
Category	Documentation
Fix is breaking or non-breaking	Non-breaking

Cause

The `cref` tag in an XML documentation comment uses a [prefix](#).

Rule description

The `cref` attribute in an XML documentation tag means "code reference". It specifies that the inner text of the tag is a code element, such as a type, method, or property. Avoid using `cref` tags with prefixes, because it prevents the compiler from verifying references. It also prevents the Visual Studio integrated development environment (IDE) from finding and updating these symbol references during refactorings. It is recommended that you use the full syntax without prefixes to reference symbol names in cref tags.

How to fix violations

To fix a violation of this rule, remove the prefix from the `cref` tag. For example, the following two code snippets show a violation of the rule and how to fix it:

```
// Violates CA1200
/// <summary>
/// Type <see cref="T:C" /> contains method <see cref="F:C.F" />
/// </summary>
class C
{
    public void F() { }
}
```

```
// Does not violate CA1200
/// <summary>
/// Type <see cref="C" /> contains method <see cref="F" />
/// </summary>
class C
{
    public void F() { }
}
```

When to suppress warnings

It's safe to suppress this warning if the code reference must use a prefix because the referenced type is not findable by the compiler. For example, if a code reference references a special attribute in the full framework, but

the file compiles against the portable framework, you can suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1200
// The code that's violating the rule is on this line.
#pragma warning restore CA1200
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1200.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Documentation.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Documenting your code with XML comments](#)

Globalization rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Globalization rules support world-ready libraries and applications.

In this section

RULE	DESCRIPTION
CA1303: Do not pass literals as localized parameters	An externally visible method passes a string literal as a parameter to a .NET constructor or method, and that string should be localizable.
CA1304: Specify CultureInfo	A method or constructor calls a member that has an overload that accepts a System.Globalization.CultureInfo parameter, and the method or constructor does not call the overload that takes the CultureInfo parameter. When a CultureInfo or System.IFormatProvider object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales.
CA1305: Specify IFormatProvider	A method or constructor calls one or more members that have overloads that accept a System.IFormatProvider parameter, and the method or constructor does not call the overload that takes the IFormatProvider parameter. When a System.Globalization.CultureInfo or IFormatProvider object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales.
CA1307: Specify StringComparison for clarity	A string comparison operation uses a method overload that does not set a StringComparison parameter.
CA1308: Normalize strings to uppercase	Strings should be normalized to uppercase. A small group of characters cannot make a round trip when they are converted to lowercase.
CA1309: Use ordinal StringComparison	A string comparison operation that is nonlinguistic does not set the StringComparison parameter to either Ordinal or OrdinalIgnoreCase. By explicitly setting the parameter to either StringComparison.Ordinal or StringComparison.OrdinalIgnoreCase, your code often gains speed, becomes more correct, and becomes more reliable.
CA1310: Specify StringComparison for correctness	A string comparison operation uses a method overload that does not set a StringComparison parameter and uses culture-specific string comparison by default.
CA2101: Specify marshalling for P/Invoke string arguments	A platform invoke member allows for partially trusted callers, has a string parameter, and does not explicitly marshal the string. This can cause a potential security vulnerability.

CA1303: Do not pass literals as localized parameters

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1303
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A method passes a string literal as a parameter to a .NET constructor or method and that string should be localizable.

This warning is raised when a literal string is passed as a value to a parameter or property and one or more of the following situations is true:

- The [LocalizableAttribute](#) attribute of the parameter or property is set to `true`.
- The literal string is passed to the `string value` or `string format` parameter of a [Console.WriteLine](#) or [Console.WriteLine](#) method overload.
- Rule CA1303 is [configured to use the naming heuristic](#), and a parameter or property name contains the phrase `Text`, `Message`, or `Caption`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

String literals that are embedded in source code are difficult to localize.

How to fix violations

To fix a violation of this rule, replace the string literal with a string retrieved through an instance of the [ResourceManager](#) class.

For methods that don't require localized strings, you can eliminate unnecessary CA1303 warnings in the following ways:

- If the [naming heuristic option](#) is enabled, rename the parameter or property.
- Remove the [LocalizableAttribute](#) attribute on the parameter or property, or set it to `false` (`[Localizable(false)]`).

When to suppress warnings

It's safe to suppress a warning from this rule if either of the following statements applies:

- The code library will not be localized.
- The string is not exposed to the end user or a developer using the code library.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1303
// The code that's violating the rule is on this line.
#pragma warning restore CA1303
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1303.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)
- [Use naming heuristic](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Globalization](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Use naming heuristic

You can configure whether parameters or property names containing `Text`, `Message`, or `Caption` will trigger this rule.

```
dotnet_code_quality.CA1303.use_naming_heuristic = true
```

Example

The following example shows a method that writes to the console when either of its two arguments are out of range. For the `hour` argument check, a literal string is passed to `Console.WriteLine`, which violates this rule. For the `minute` argument check, a string that's retrieved through a [ResourceManager](#) is passed to `Console.WriteLine`, which satisfies the rule.

```

<Assembly: System.Resources.NeutralResourcesLanguageAttribute("en-US")>
Namespace GlobalizationLibrary

Public Class DoNotPassLiterals

    Dim stringManager As System.Resources.ResourceManager

    Sub New()
        stringManager = New System.Resources.ResourceManager(
            "en-US", System.Reflection.Assembly.GetExecutingAssembly())
    End Sub

    Sub TimeMethod(hour As Integer, minute As Integer)

        If (hour < 0 Or hour > 23) Then
            'CA1303 fires because a literal string
            'is passed as the 'value' parameter.
            Console.WriteLine("The valid range is 0 - 23.")
        End If

        If (minute < 0 Or minute > 59) Then
            Console.WriteLine(
                stringManager.GetString("minuteOutOfRangeMessage",
                    System.Globalization.CultureInfo.CurrentCulture))
        End If

    End Sub

End Class

End Namespace

```

```

public class DoNotPassLiterals
{
    ResourceManager stringManager;
    public DoNotPassLiterals()
    {
        stringManager = new ResourceManager("en-US", Assembly.GetExecutingAssembly());
    }

    public void TimeMethod(int hour, int minute)
    {
        if (hour < 0 || hour > 23)
        {
            // CA1303 fires because a literal string
            // is passed as the 'value' parameter.
            Console.WriteLine("The valid range is 0 - 23.");
        }

        if (minute < 0 || minute > 59)
        {
            Console.WriteLine(stringManager.GetString(
                "minuteOutOfRangeMessage", CultureInfo.CurrentCulture));
        }
    }
}

```

CA1304: Specify CultureInfo

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1304
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A method or constructor calls a member that has an overload that accepts a `System.Globalization.CultureInfo` parameter, and the method or constructor does not call the overload that takes the `CultureInfo` parameter. This rule ignores calls to the following methods:

- `Activator.CreateInstance`
- `ResourceManager.GetObject`
- `ResourceManager.GetString`

You can also [configure](#) more symbols to be excluded by this rule.

Rule description

When a `CultureInfo` or `System.IFormatProvider` object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales. Also, .NET members choose default culture and formatting based on assumptions that might not be correct for your code. To ensure the code works as expected for your scenarios, you should supply culture-specific information according to the following guidelines:

- If the value will be displayed to the user, use the current culture. See `CultureInfo.CurrentCulture`.
- If the value will be stored and accessed by software, that is, persisted to a file or database, use the invariant culture. See `CultureInfo.InvariantCulture`.
- If you do not know the destination of the value, have the data consumer or provider specify the culture.

Even if the default behavior of the overloaded member is appropriate for your needs, it is better to explicitly call the culture-specific overload so that your code is self-documenting and more easily maintained.

NOTE

`CultureInfo.CurrentCulture` is used only to retrieve localized resources by using an instance of the `System.Resources.ResourceManager` class.

How to fix violations

To fix a violation of this rule, use the overload that takes a `CultureInfo` argument.

When to suppress warnings

It is safe to suppress a warning from this rule when it is certain that the default culture is the correct choice, and where code maintainability is not an important development priority.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1304
// The code that's violating the rule is on this line.
#pragma warning restore CA1304
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1304.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Globalization](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example showing how to fix violations

In the following example, `BadMethod` causes two violations of this rule. `GoodMethod` corrects the first violation by passing the invariant culture to [String.Compare](#), and corrects the second violation by passing the current culture to [String.ToLower](#) because `string3` is displayed to the user.

```

public class CultureInfoTest
{
    public void BadMethod(String string1, String string2, String string3)
    {
        if (string.Compare(string1, string2, false) == 0)
        {
            Console.WriteLine(string3.ToLower());
        }
    }

    public void GoodMethod(String string1, String string2, String string3)
    {
        if (string.Compare(string1, string2, false,
                           CultureInfo.InvariantCulture) == 0)
        {
            Console.WriteLine(string3.ToLower(CultureInfo.CurrentCulture));
        }
    }
}

```

Example showing formatted output

The following example shows the effect of current culture on the default [IFormatProvider](#) that is selected by the [DateTime](#) type.

```

public class IFormatProviderTest
{
    public static void Main1304()
    {
        string dt = "6/4/1900 12:15:12";

        // The default behavior of DateTime.Parse is to use
        // the current culture.

        // Violates rule: SpecifyIFormatProvider.
        DateTime myDateTime = DateTime.Parse(dt);
        Console.WriteLine(myDateTime);

        // Change the current culture to the French culture,
        // and parsing the same string yields a different value.

        Thread.CurrentThread.CurrentCulture = new CultureInfo("Fr-fr", true);
        myDateTime = DateTime.Parse(dt);

        Console.WriteLine(myDateTime);
    }
}

```

This example produces the following output:

```

6/4/1900 12:15:12 PM
06/04/1900 12:15:12

```

CA1305: Specify IFormatProvider

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1305
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A call is made to a method that has an overload that accepts a [System.IFormatProvider](#) parameter, and that overload isn't called.

This rule ignores calls to .NET methods that are documented as ignoring the [IFormatProvider](#) parameter. The rule also ignores the following methods:

- [Activator.CreateInstance](#)
- [ResourceManager.GetObject](#)
- [ResourceManager.GetString](#)
- [Boolean.ToString](#)
- [Char.ToString](#)
- [Guid.ToString](#)

Rule description

When a [System.Globalization.CultureInfo](#) or [IFormatProvider](#) object is not supplied, the default value that is supplied by the overloaded member might not have the effect that you want in all locales. Also, .NET members choose default culture and formatting based on assumptions that might not be correct for your code. To make sure that the code works as expected for your scenarios, you should supply culture-specific information according to the following guidelines:

- If the value will be displayed to the user, use the current culture. See [CultureInfo.CurrentCulture](#).
- If the value will be stored and accessed by software (persisted to a file or database), use the invariant culture. See [CultureInfo.InvariantCulture](#).
- If you do not know the destination of the value, have the data consumer or provider specify the culture.

Even if the default behavior of the overloaded member is appropriate for your needs, it is better to explicitly call the culture-specific overload so that your code is self-documenting and more easily maintained.

How to fix violations

To fix a violation of this rule, use the overload that takes an [IFormatProvider](#) argument. Or, use a [C# interpolated string](#) and pass it to the [FormattableString.Invariant](#) method.

When to suppress warnings

It is safe to suppress a warning from this rule when it is certain that the default format is the correct choice, and where code maintainability is not an important development priority.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1305
// The code that's violating the rule is on this line.
#pragma warning restore CA1305
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1305.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

In the following code, the `example1` string violates rule CA1305. The `example2` string satisfies rule CA1305 by passing `CultureInfo.CurrentCulture`, which implements `IFormatProvider`, to `String.Format(IFormatProvider, String, Object)`. The `example3` string satisfies rule CA1305 by passing an interpolated string to `Invariant`.

```
string name = "Georgette";

// Violates CA1305
string example1 = String.Format("Hello {0}", name);

// Satisfies CA1305
string example2 = String.Format(CultureInfo.CurrentCulture, "Hello {0}", name);

// Satisfies CA1305
string example3 = FormattableString.Invariant($"Hello {name}");
```

Related rules

CA1307: Specify StringComparison for clarity

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1307
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A string comparison operation uses a method overload that does not set a `StringComparison` parameter.

Rule description

Many string compare operations provide an overload that accepts a `StringComparison` enumeration value as a parameter.

Whenever an overload exists that takes a `StringComparison` parameter, it should be used instead of an overload that does not take this parameter. By explicitly setting this parameter, your code is often made clearer and easier to maintain. For more information, see [Specifying string comparisons explicitly](#).

NOTE

This rule does not consider the default `StringComparison` value used by the comparison method. Hence, it can be potentially noisy for methods that use the `Ordinal` string comparison by default and the user intended to use this default compare mode. If you only want to see violations only for known string methods that use culture-specific string comparison by default, please use [CA1310: Specify StringComparison for correctness](#) instead.

How to fix violations

To fix a violation of this rule, change string comparison methods to overloads that accept the `StringComparison` enumeration as a parameter. For example, change `str1.IndexOf(ch1)` to
`str1.IndexOf(ch1, StringComparison.Ordinal)`.

When to suppress warnings

It is safe to suppress a warning from this rule when clarity of intent is not required. For example, test code or non-localizable code may not require it.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1307
// The code that's violating the rule is on this line.
#pragma warning restore CA1307
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1307.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1308: Normalize strings to uppercase

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1308
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

An operation normalizes a string to lowercase.

Rule description

Strings should be normalized to uppercase. A small group of characters, when they are converted to lowercase, cannot make a round trip. To make a round trip means to convert the characters from one locale to another locale that represents character data differently, and then to accurately retrieve the original characters from the converted characters.

How to fix violations

Change operations that convert strings to lowercase so that the strings are converted to uppercase instead. For example, change `String.ToLower(CultureInfo.InvariantCulture)` to `String.ToUpper(CultureInfo.InvariantCulture)`.

When to suppress warnings

It's safe to suppress a warning when you're not making security decisions based on the result of the normalization (for example, when you're displaying the result in the UI).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1308
// The code that's violating the rule is on this line.
#pragma warning restore CA1308
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1308.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Best practices for comparing strings](#)
- [Globalization rules](#)

CA1309: Use ordinal StringComparison

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1309
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A string comparison operation that is nonlinguistic does not set the `StringComparison` parameter to either `Ordinal` or `OrdinalIgnoreCase`.

Rule description

Many string operations, most importantly the `System.String.Compare` and `System.String.Equals` methods, now provide an overload that accepts a `System.StringComparison` enumeration value as a parameter.

When you specify either `StringComparison.Ordinal` or `StringComparison.OrdinalIgnoreCase`, the string comparison is non-linguistic. That is, the features that are specific to the natural language are ignored when comparison decisions are made. Ignoring natural language features means the decisions are based on simple byte comparisons and not on casing or equivalence tables that are parameterized by culture. As a result, by explicitly setting the parameter to either the `StringComparison.Ordinal` or `StringComparison.OrdinalIgnoreCase`, your code often gains speed, increases correctness, and becomes more reliable.

How to fix violations

To fix a violation of this rule, change the string comparison method to an overload that accepts the `System.StringComparison` enumeration as a parameter, and specify either `Ordinal` or `OrdinalIgnoreCase`. For example, change `String.Compare(str1, str2)` to `String.Compare(str1, str2, StringComparison.Ordinal)`.

When to suppress warnings

It is safe to suppress a warning from this rule when the library or application is intended for a limited local audience, or when the semantics of the current culture should be used.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1309
// The code that's violating the rule is on this line.
#pragma warning restore CA1309
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1309.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

CA1310: Specify StringComparison for correctness

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1310
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A string comparison operation uses a method overload that does not set a [StringComparison](#) parameter and uses culture-specific string comparison by default. Hence, its behavior will vary based on the current user's locale settings.

Rule description

A string comparison method that uses culture-specific string comparison by default can have potentially unintentional runtime behavior that does not match user intent. It is recommended that you use the overload with the [StringComparison](#) parameter for correctness and clarity of intent.

This rule flags string comparison methods that use the culture-specific [StringComparison](#) value by default. For more information, see [String comparisons that use the current culture](#).

NOTE

If you want to see violations for all string comparison methods, regardless of the default string comparison used by the method, please use [CA1307: Specify StringComparison for clarity](#) instead.

How to fix violations

To fix a violation of this rule, change string comparison methods to overloads that accept the [StringComparison](#) enumeration as a parameter. For example, change `String.Compare(str1, str2)` to
`String.Compare(str1, str2, StringComparison.Ordinal)`.

When to suppress warnings

It is safe to suppress a warning from this rule when the library or application is not intended to be localized.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1310
// The code that's violating the rule is on this line.
#pragma warning restore CA1310
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1310.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Globalization.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2101: Specify marshalling for P/Invoke string arguments

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2101
Category	Globalization
Fix is breaking or non-breaking	Non-breaking

Cause

A platform invoke member allows for partially trusted callers, has a string parameter, and does not explicitly marshal the string.

Rule description

When you convert from Unicode to ANSI, it is possible that not all Unicode characters can be represented in a specific ANSI code page. *Best-fit mapping* tries to solve this problem by substituting a character for the character that cannot be represented. The use of this feature can cause a potential security vulnerability because you cannot control the character that is chosen. For example, malicious code could intentionally create a Unicode string that contains characters that are not found in a particular code page, which are converted to file system special characters such as '..' or '/'. Note also that security checks for special characters frequently occur before the string is converted to ANSI.

Best-fit mapping is the default for the unmanaged conversion, WChar to MByte. Unless you explicitly disable best-fit mapping, your code might contain an exploitable security vulnerability because of this issue.

Caution

[Code Access Security](#) (CAS) should not be considered a security boundary.

How to fix violations

To fix a violation of this rule, explicitly marshal string data types.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows a method that violates this rule, and then shows how to fix the violation.

```
class NativeMethods
{
    // Violates rule: SpecifyMarshalingForPInvokeStringArguments.
    [DllImport("advapi32.dll", CharSet = CharSet.Auto)]
    internal static extern int RegCreateKey(IntPtr key, String subKey, out IntPtr result);

    // Satisfies rule: SpecifyMarshalingForPInvokeStringArguments.
    [DllImport("advapi32.dll", CharSet = CharSet.Unicode)]
    internal static extern int RegCreateKey2(IntPtr key, String subKey, out IntPtr result);
}
```

Portability and interoperability rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Portability rules support portability across different platforms. Interoperability rules support interaction with COM clients.

In this section

RULE	DESCRIPTION
CA1401: P/Invokes should not be visible	A public or protected method in a public type has the <code>System.Runtime.InteropServices.DllImportAttribute</code> attribute (also implemented by the <code>Declare</code> keyword in Visual Basic). Such methods should not be exposed.
CA1416: Validate platform compatibility	Using platform-dependent APIs on a component makes the code no longer work across all platforms.
CA1417: Do not use <code>outAttribute</code> on string parameters for P/Invokes	String parameters passed by value with the <code>outAttribute</code> can destabilize the runtime if the string is an interned string.
CA1418: Use valid platform string	Platform compatibility analyzer requires a valid platform name and version.
CA1419: Provide a parameterless constructor that is as visible as the containing type for concrete types derived from 'System.Runtime.InteropServices.SafeHandle'	Providing a parameterless constructor that is as visible as the containing type for a type derived from <code>System.Runtime.InteropServices.SafeHandle</code> enables better performance and usage with source-generated interop solutions.

CA1401: P/Invokes should not be visible

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1401
Category	Interoperability
Fix is breaking or non-breaking	Breaking

Cause

A public or protected method in a public type has the [System.Runtime.InteropServices.DllImportAttribute](#) attribute (also implemented by the `Declare` keyword in Visual Basic).

Rule description

Methods that are marked with the [DllImportAttribute](#) attribute (or methods that are defined by using the `Declare` keyword in Visual Basic) use Platform Invocation Services to access unmanaged code. Such methods should not be exposed. By keeping these methods private or internal, you make sure that your library cannot be used to breach security by allowing callers access to unmanaged APIs that they could not call otherwise.

How to fix violations

To fix a violation of this rule, change the access level of the method.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example declares a method that violates this rule.

```
// Violates rule: PInvokesShouldNotBeVisible.
public class NativeMethods
{
    [DllImport("kernel32.dll", CharSet = CharSet.Unicode)]
    public static extern bool RemoveDirectory(string name);
}
```

```
Imports System

Namespace ca1401

    ' Violates rule: PInvokesShouldNotBeVisible.
    Public Class NativeMethods
        Public Declare Function RemoveDirectory Lib "kernel32" (
            ByVal Name As String) As Boolean
    End Class

End Namespace
```

CA1416: Validate platform compatibility

9/20/2022 • 8 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1416
Category	Interoperability
Fix is breaking or non-breaking	Non-breaking

Cause

Violations are reported if a platform-specific API is used in the context of a different platform or if the platform isn't verified (platform-neutral). Violations are also reported if an API that's not supported for the target platform of the project is used.

This rule is enabled by default only for projects that target .NET 5 or later. However, you can [enable](#) it for projects that target other frameworks.

Rule description

.NET 5.0 added new attributes, [SupportedOSPlatformAttribute](#) and [UnsupportedOSPlatformAttribute](#), to annotate platform-specific APIs. Both attributes can be instantiated with or without version numbers as part of the platform name. They can also be applied multiple times with different platforms.

- An unannotated API is considered to work on all operating system (OS) platforms.
- An API marked with `[SupportedOSPlatform("platformName")]` is considered to be portable to the specified OS platforms only. If the platform is a [subset of another platform](#), the attribute implies that that platform is also supported.
- An API marked with `[UnsupportedOSPlatform("platformName")]` is considered to be unsupported on the specified OS platforms. If the platform is a [subset of another platform](#), the attribute implies that that platform is also unsupported.

You can combine `[SupportedOSPlatform]` and `[UnsupportedOSPlatform]` attributes on a single API. In this case, the following rules apply:

- **Allow list.** If the lowest version for each OS platform is a `[SupportedOSPlatform]` attribute, the API is considered to only be supported by the listed platforms and unsupported by all other platforms. The list can have an `[UnsupportedOSPlatform]` attribute with the same platform, but only with a higher version, which denotes that the API is removed from that version.
- **Deny list.** If the lowest version for each OS platform is an `[UnsupportedOSPlatform]` attribute, then the API is considered to only be unsupported by the listed platforms and supported by all other platforms. The list can have a `[SupportedOSPlatform]` attribute with the same platform, but only with a higher version, which denotes that the API is supported since that version.
- **Inconsistent list.** If the lowest version for some platforms is `[SupportedOSPlatform]` but `[UnsupportedOSPlatform]` for other platforms, this combination is considered inconsistent. Some annotations on the API are ignored. In the future, we may introduce an analyzer that produces a warning in case of inconsistency.

If you access an API annotated with these attributes from the context of a different platform, you can see CA1416 violations.

TFM target platforms

The analyzer does not check target framework moniker (TFM) target platforms from MSBuild properties, such as `<TargetFramework>` or `<TargetFrameworks>`. If the TFM has a target platform, the .NET SDK injects a `SupportedOSPlatform` attribute with the targeted platform name in the `AssemblyInfo.cs` file, which is consumed by the analyzer. For example, if the TFM is `net5.0-windows10.0.0.19041`, the SDK injects the `[assembly: System.Runtime.Versioning.SupportedOSPlatform("windows10.0.0.19041")]` attribute into the `AssemblyInfo.cs` file, and the entire assembly is considered to be Windows only. Therefore, calling Windows-only APIs versioned with 7.0 or below would not cause any warnings in the project.

NOTE

If the `AssemblyInfo.cs` file generation is disabled for the project (that is, the `<GenerateAssemblyInfo>` property is set to `false`), the required assembly level `SupportedOSPlatform` attribute can't be added by the SDK. In this case, you could see warnings for a platform-specific APIs usage even if you're targeting that platform. To resolve the warnings, enable the `AssemblyInfo.cs` file generation or add the attribute manually in your project.

Violations

- If you access an API that's supported only on a specified platform (`[SupportedOSPlatform("platformName")]`) from code reachable on other platforms, you'll see the following violation: '**API**' is supported on '**platformName**'.

```
// An API supported only on Linux.  
[SupportedOSPlatform("linux")]  
public void LinuxOnlyApi() { }  
  
// API is supported on Windows, iOS from version 14.0, and MacCatalyst from version 14.0.  
[SupportedOSPlatform("windows")]  
[SupportedOSPlatform("ios14.0")] // MacCatalyst is a superset of iOS, therefore it's also supported.  
public void SupportedOnWindowsIos14AndMacCatalyst14() { }  
  
public void Caller()  
{  
    LinuxOnlyApi(); // This call site is reachable on all platforms. 'LinuxOnlyApi()' is only  
    supported on: 'linux'  
  
    SupportedOnWindowsIos14AndMacCatalyst14(); // This call site is reachable on all platforms.  
    'SupportedOnWindowsIos14AndMacCatalyst14()' // is only supported on: 'windows', 'ios' 14.0 and  
    later, 'MacCatalyst' 14.0 and later.  
}
```

NOTE

A violation only occurs if the project does not target the supported platform (`net5.0-differentPlatform`). This also applies to multi-targeted projects. No violation occurs if the project targets the specified platform (`net5.0-platformName`) and the `AssemblyInfo.cs` file generation is enabled for the project.

- Accessing an API that's attributed with `[UnsupportedOSPlatform("platformName")]` from a context that targets the unsupported platform could produce a violation: '**API**' is unsupported on '**platformName**'.

```

// An API not supported on Android but supported on all other platforms.
[UnsupportedOSPlatform("android")]
public void DoesNotWorkOnAndroid() { }

// An API was unsupported on Windows until version 10.0.18362.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows10.0.18362")]
public void StartedWindowsSupportFromCertainVersion() { }

public void Caller()
{
    DoesNotWorkOnAndroid(); // This call site is reachable on all platforms. 'DoesNotWorkOnAndroid()' is unsupported on: 'android'

    StartedWindowsSupportFromCertainVersion(); // This call site is reachable on all platforms. 'StartedWindowsSupportFromCertainVersion()' is unsupported on: 'windows' 10.0.18362 and before
}

```

NOTE

If you're building an app that doesn't target the unsupported platform, you won't get any violations. A violation only occurs in the following cases:

- The project targets the platform attributed as unsupported.
- The `platformName` is included in the default MSBuild `<SupportedPlatform>` items group.
- `platformName` is manually included in the MSBuild `<SupportedPlatform>` items group.

```

<ItemGroup>
    <SupportedPlatform Include="platformName" />
</ItemGroup>

```

How to fix violations

The recommended way to deal with violations is to make sure you only call platform-specific APIs when running on an appropriate platform. You can achieve this by excluding the code at build time using `#if` and multi-targeting, or by conditionally calling the code at run time. The analyzer recognizes the platform guards in the [OperatingSystem](#) class and [System.Runtime.InteropServices.RuntimeInformation.IsOSPlatform](#).

- Suppress violations by surrounding the call site with the standard platform guard methods or custom guard APIs annotated with `SupportedOSPlatformGuardAttribute` OR `UnsupportedOSPlatformGuardAttribute`.

```

// An API supported only on Linux.
[SupportedOSPlatform("linux")]
public void LinuxOnlyApi() { }

// API is supported on Windows, iOS from version 14.0, and MacCatalyst from version 14.0.
[SupportedOSPlatform("windows")]
[SupportedOSPlatform("ios14.0")] // MacCatalyst is a superset of iOS, therefore it's also supported.
public void SupportedOnWindowsIos14AndMacCatalyst14() { }

public void Caller()
{
    LinuxOnlyApi(); // This call site is reachable on all platforms. 'LinuxOnlyApi()' is only supported on: 'linux'.

    SupportedOnWindowsIos14AndMacCatalyst14(); // This call site is reachable on all platforms.
    'SupportedOnWindowsIos14AndMacCatalyst14()' // is only supported on: 'windows', 'ios' 14.0 and later, 'MacCatalyst' 14.0 and later.
}

```

```
}

[SupportedOSPlatformGuard("windows")] // The platform guard attributes used
[SupportedOSPlatformGuard("ios14.0")]
private readonly bool _isWindowOrIOS14 = OperatingSystem.IsWindows() ||
OperatingSystem.IsIOSVersionAtLeast(14);

// The warnings are avoided using platform guard methods.
public void Caller()
{
    if (OperatingSystem.IsLinux()) // standard guard examples
    {
        LinuxOnlyApi(); // no diagnostic
    }

    if (OperatingSystem.IsIOSVersionAtLeast(14))
    {
        SupportedOnWindowsAndIos14(); // no diagnostic
    }

    if (RuntimeInformation.IsOSPlatform(OSPlatform.Windows))
    {
        SupportedOnWindowsAndIos14(); // no diagnostic
    }

    if (_isWindowOrMacOS14) // custom guard example
    {
        SupportedOnWindowsAndIos14(); // no diagnostic
    }
}

// An API not supported on Android but supported on all other platforms.
[UnsupportedOSPlatform("android")]
public void DoesNotWorkOnAndroid() { }

// An API was unsupported on Windows until version 10.0.18362.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows10.0.18362")]
public void StartedWindowsSupportFromCertainVersion();

public void Caller()
{
    DoesNotWorkOnAndroid(); // This call site is reachable on all platforms.'DoesNotWorkOnAndroid()'
    is unsupported on: 'android'

    StartedWindowsSupportFromCertainVersion(); // This call site is reachable on all platforms.
    'StartedWindowsSupportFromCertainVersion()' is unsupported on: 'windows' 10.0.18362 and before.
}

[UnsupportedOSPlatformGuard("android")] // The platform guard attribute
bool IsNotAndroid => !OperatingSystem.IsAndroid();

public void Caller()
{
    if (!OperatingSystem.IsAndroid()) // using standard guard methods
    {
        DoesNotWorkOnAndroid(); // no diagnostic
    }

    // Use the && and || logical operators to guard combined attributes.
    if (!OperatingSystem.IsWindows() || OperatingSystem.IsWindowsVersionAtLeast(10, 0, 18362))
    {
        StartedWindowsSupportFromCertainVersion(); // no diagnostic
    }

    if (IsNotAndroid) // custom guard example
    {
        DoesNotWorkOnAndroid(); // no diagnostic
    }
}
```

```
        DOESNOTCONTAINDEBUG(), // No diagnostic
    }
}
```

- The analyzer also respects [System.Diagnostics.Debug.Assert](#) as a means for preventing the code from being reached on unsupported platforms. Using `Debug.Assert` allows the check to be trimmed out of release builds, if desired.

```
// An API supported only on Linux.
[SupportedOSPlatform("linux")]
public void LinuxOnlyApi() { }

public void Caller()
{
    Debug.Assert(OperatingSystem.IsLinux());

    LinuxOnlyApi(); // No diagnostic
}
```

- You can choose to mark your own APIs as being platform-specific, effectively forwarding the requirements to your callers. You can apply platform attributes to any of the following APIs:

- Types
- Members (methods, fields, properties, and events)
- Assemblies

```
[SupportedOSPlatform("windows")]
[SupportedOSPlatform("ios14.0")]
public void SupportedOnWindowsAndIos14() { }

[SupportedOSPlatform("ios15.0")] // call site version should be equal to or higher than the API
// version
public void Caller()
{
    SupportedOnWindowsAndIos14(); // No diagnostics
}

[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows10.0.18362")]
public void StartedWindowsSupportFromCertainVersion();

[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows10.0.18362")]
public void Caller()
{
    StartedWindowsSupportFromCertainVersion(); // No diagnostics
}
```

- When an assembly or type-level attribute is applied, all members within the assembly or type are considered to be platform specific.

```
[assembly:SupportedOSPlatform("windows")]
public namespace ns
{
    public class Sample
    {
        public void SupportedOnWindows() { }

        public void Caller()
        {
            SupportedOnWindows(); // No diagnostic as call site and calling method both windows only
        }
    }
}
```

When to suppress warnings

Referencing platform-specific APIs without a proper platform context or guard is not recommended. However, you can suppress these diagnostics using `#pragma` or the **NoWarn** compiler flag, or by [setting the rule's severity](#) to `none` in an `.editorconfig` file.

```
[SupportedOSPlatform("linux")]
public void LinuxOnlyApi() { }

public void Caller()
{
    #pragma warning disable CA1416
    LinuxOnlyApi();
    #pragma warning restore CA1416
}
```

Configure code to analyze

The analyzer is enabled by default only for projects that target .NET 5 or later and have an [AnalysisLevel](#) of 5 or higher. You can enable it for target frameworks lower than `net5.0` by adding the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.enable_platform_analyzer_on_pre_net5_target=true
```

CA1417: Do not use `[OutAttribute]` on string parameters for P/Invokes

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1417
Category	Interoperability
Fix is breaking or non-breaking	Non-breaking

Cause

A [P/Invoke](#) string parameter is passed by value and marked with [OutAttribute](#).

Rule description

The .NET runtime automatically performs [string interning](#). If an interned string marked with [OutAttribute](#) is passed by value to a P/Invoke, the runtime can be destabilized.

How to fix violations

If marshalling of modified string data back to the caller is required, pass the string by reference instead. Otherwise, the [OutAttribute](#) can be removed without any other changes.

```
// Violation
[DllImport("MyLibrary")]
private static extern void Foo([Out] string s);

// Fixed: passed by reference
[DllImport("MyLibrary")]
private static extern void Foo(out string s);

// Fixed: marshalling data back to caller is not required
[DllImport("MyLibrary")]
private static extern void Foo(string s);
```

When to suppress warnings

It is not safe to suppress a warning from this rule.

See also

- [Interoperability rules](#)
- [Native interoperability best practices](#)

CA1418: Validate platform compatibility

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1418
Category	Interoperability
Fix is breaking or non-breaking	Non-breaking

Cause

The platform compatibility analyzer requires a valid platform name and version. Violations are reported if the platform string provided to the [OSPlatformAttribute](#) constructor consists of an unknown platform name or if the optional version part is invalid.

Rule description

The platform compatibility attributes derived from [OSPlatformAttribute](#) use string literals for operating system (OS) platform names with an optional version part. The string should consist of a known platform name and either no version part or a valid version part.

The known platform names list is populated from two places:

- The `PlatformName` part of [OperatingSystem](#) guard methods named `OperatingSystem.Is<PlatformName>[VersionAtLeast]()`. For example, guard method `OperatingSystem.IsWindows()` adds `Windows` to the known platform names list.
- The project's MSBuild item group of `SupportedPlatform` items, including the default [MSBuild SupportedPlatforms list](#). This is the project specific knowledge of known platforms. It allows class library authors to add more platforms into the known platforms list. For example:

```
<ItemGroup>
  <SupportedPlatform Include="PlatformName" />
</ItemGroup>
```

If the platform string contains a *version* part, it should be a valid [Version](#) with the following format:

```
major.minor[.build[.revision]]
```

Violations

- `Solaris` is an **unknown** platform name because it's not included in the default [MSBuild SupportedPlatforms list](#) and there's no guard method named `OperatingSystem.IsSolaris()` in the [OperatingSystem](#) class.

```
[SupportedOSPlatform("Solaris")] // Warns: The platform 'Solaris' is not a known platform name.
public void SolarisApi() { }
```

- `Android` is a **known** platform because there is a `OperatingSystem.IsAndroid()` guard method in the

[OperatingSystem](#) type. However, the version part is not a valid version. It should have at least two integers separated by a dot.

```
[UnsupportedOSPlatform("Android10")] // Warns: Version '10' is not valid for platform 'Android'. Use  
a version with 2-4 parts for this platform.  
public void DoesNotWorkOnAndroid() { }
```

- `Linux` is a **known** platform because it is included in the default [MSBuild SupportedPlatforms list](#), and there's also a guard method named [OperatingSystem.IsLinux\(\)](#). However, there are no versioned guard methods like `System.OperatingSystem.IsLinuxVersionAtLeast(int,int)` for the `Linux` platform, therefore no version part is supported on Linux.

```
[SupportedOSPlatform("Linux4.8")] // Warns: Version '4.8' is not valid for platform 'Linux'. Do not  
use versions for this platform.  
public void LinuxApi() { }
```

How to fix violations

- Change the platform to a known platform name.
- If the platform name is correct and you want to make it a known platform, then add it to the MSBuild SupportedPlatforms list in your project file:

```
<ItemGroup>  
  <SupportedPlatform Include="Solaris" />  
</ItemGroup>
```

```
[SupportedOSPlatform("Solaris")] // No warning  
public void SolarisApi() { }
```

- Fix the invalid version. For example, for `Android`, `10` is not a valid version, but `10.0` is valid.

```
// Before  
[UnsupportedOSPlatform("Android10")] // Warns: Version '10' is not valid for platform 'Android'. Use  
a version with 2-4 parts for this platform.  
public void DoesNotWorkOnAndroid() { }  
  
// After  
[UnsupportedOSPlatform("Android10.0")] // No warning.  
public void DoesNotWorkOnAndroid() { }
```

- If the platform doesn't support a version, remove the version part.

```
// Before  
[SupportedOSPlatform("Linux4.8")] // Warns: Version '4.8' is not valid for platform 'Linux'. Do not  
use versions for this platform.  
public void LinuxApi() { }  
  
// After  
[SupportedOSPlatform("Linux")] // No warning.  
public void LinuxApi() { }
```

When to suppress warnings

Using an unknown platform name or an invalid version is not recommended.

Suppress a warning

One way to suppress a warning is to disable the rule for a file, folder, or project by setting its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1418.severity = none
```

```
#pragma warning disable CA1418
[SupportedOSPlatform("platform")]
#pragma warning restore CA1418
public void PlatformSpecificApi() { }
```

For more information, see [How to suppress code analysis warnings](#).

CA1419: Provide a parameterless constructor that is as visible as the containing type for concrete types derived from

'System.Runtime.InteropServices.SafeHandle'

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1419
Category	Interoperability
Fix is breaking or non-breaking	Non-breaking

Cause

A concrete [SafeHandle](#) type requires a parameterless constructor that is at least as visible as the containing type.

Rule description

Providing a public parameterless constructor for a type derived from [SafeHandle](#) enables better performance and usage with source-generated interop solutions.

How to fix violations

Add a parameterless constructor to your type.

When to suppress warnings

Do not suppress a warning from this rule.

See also

- [Interoperability rules](#)
- [Native interoperability best practices](#)

Maintainability rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Maintainability rules support library and application maintenance.

In this section

RULE	DESCRIPTION
CA1501: Avoid excessive inheritance	A type is more than four levels deep in its inheritance hierarchy. Deeply nested type hierarchies can be difficult to follow, understand, and maintain.
CA1502: Avoid excessive complexity	This rule measures the number of linearly independent paths through the method, which is determined by the number and complexity of conditional branches.
CA1505: Avoid unmaintainable code	A type or method has a low maintainability index value. A low maintainability index indicates that a type or method is probably difficult to maintain and would be a good candidate for redesign.
CA1506: Avoid excessive class coupling	This rule measures class coupling by counting the number of unique type references that a type or method contains.
CA1507: Use nameof in place of string	A string literal is used as an argument where a <code>nameof</code> expression could be used.
CA1508: Avoid dead conditional code	A method has conditional code that always evaluates to <code>true</code> or <code>false</code> at run time. This leads to dead code in the <code>false</code> branch of the condition.
CA1509: Invalid entry in code metrics configuration file	Code metrics rules, such as CA1501 , CA1502 , CA1505 and CA1506 , supplied a configuration file named <code>CodeMetricsConfig.txt</code> that has an invalid entry.

See also

- [Measure Complexity and Maintainability of Managed Code](#)

CA1501: Avoid excessive inheritance

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1501
Category	Maintainability
Fix is breaking or non-breaking	Breaking

Cause

A type is more than four levels deep in its inheritance hierarchy.

By default, the rule only excludes types from the `System` namespace, but this is [configurable](#).

Rule description

Deeply nested type hierarchies can be difficult to follow, understand, and maintain. This rule limits analysis to hierarchies in the same module.

How to fix violations

To fix a violation of this rule, derive the type from a base type that is less deep in the inheritance hierarchy or eliminate some of the intermediate base types.

When to suppress warnings

It is safe to suppress a warning from this rule. However, the code might be more difficult to maintain. Depending on the visibility of base types, resolving violations of this rule might create breaking changes. For example, removing public base types is a breaking change.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1501
// The code that's violating the rule is on this line.
#pragma warning restore CA1501
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1501.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Inheritance excluded type or namespace names](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Maintainability](#)). For more information, see [Code quality rule configuration options](#).

Inheritance excluded type or namespace names

You can configure the rule to exclude certain types or namespaces from the inheritance hierarchy tree. By default, all types from the `System.*` namespace are excluded. No matter what value you set, this default value is added.

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = MyType</code>	Matches all types named <code>MyType</code> or whose containing namespace contains <code>MyType</code> (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> or whose containing namespace contains either <code>MyType1</code> or <code>MyType2</code> (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = T:NS.MyType</code>	Matches specific type <code>MyType</code> in the namespace <code>NS</code> (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = T:NS1.MyType1 T:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with respective fully qualified names (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = N:NS</code>	Matches all types from the <code>NS</code> namespace (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = My*</code>	Matches all types whose name starts with <code>My</code> or whose containing namespace parts starts with <code>My</code> (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = T:NS.My*</code>	Matches all types whose name starts with <code>My</code> in the namespace <code>NS</code> (and all types from the <code>System</code> namespace)
<code>dotnet_code_quality.CA1501.additional_inheritance_excluded = N:My*</code>	Matches all types whose containing namespace starts with <code>My</code> (and all types from the <code>System</code> namespace)

Example

The following example shows a type that violates the rule:

```
class BaseClass {}
class FirstDerivedClass : BaseClass {}
class SecondDerivedClass : FirstDerivedClass {}
class ThirdDerivedClass : SecondDerivedClass {}
class FourthDerivedClass : ThirdDerivedClass {}

// This class violates the rule.
class FifthDerivedClass : FourthDerivedClass {}
```

```
Imports System

Namespace ca1501

    Class BaseClass
        End Class

    Class FirstDerivedClass
        Inherits BaseClass
        End Class

    Class SecondDerivedClass
        Inherits FirstDerivedClass
        End Class

    Class ThirdDerivedClass
        Inherits SecondDerivedClass
        End Class

    Class FourthDerivedClass
        Inherits ThirdDerivedClass
        End Class

    ' This class violates the rule.
    Class FifthDerivedClass
        Inherits FourthDerivedClass
        End Class

End Namespace
```

CA1502: Avoid excessive complexity

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1502
Category	Maintainability
Fix is breaking or non-breaking	Non-breaking

Cause

A method has an excessive cyclomatic complexity.

Rule description

Cyclomatic complexity measures the number of linearly independent paths through the method, which is determined by the number and complexity of conditional branches. A low cyclomatic complexity generally indicates a method that is easy to understand, test, and maintain. The cyclomatic complexity is calculated from a control flow graph of the method and is given as follows:

cyclomatic complexity = the number of edges - the number of nodes + 1

A *node* represents a logic branch point and an *edge* represents a line between nodes.

The rule reports a violation when the cyclomatic complexity is more than 25.

You can learn more about code metrics at [Measure complexity of managed code](#).

How to fix violations

To fix a violation of this rule, refactor the method to reduce its cyclomatic complexity.

When to suppress warnings

It is safe to suppress a warning from this rule if the complexity cannot easily be reduced and the method is easy to understand, test, and maintain. In particular, a method that contains a large `switch` (`Select` in Visual Basic) statement is a candidate for exclusion. The risk of destabilizing the code base late in the development cycle or introducing an unexpected change in run-time behavior in previously shipped code might outweigh the maintainability benefits of refactoring the code.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1502
// The code that's violating the rule is on this line.
#pragma warning restore CA1502
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1502.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

How cyclomatic complexity is calculated

The cyclomatic complexity is calculated by adding 1 to the following:

- Number of branches (such as `if`, `while`, and `do`)
- Number of `case` statements in a `switch`

Examples

The following examples show methods that have varying cyclomatic complexities.

Cyclomatic complexity of 1

```
public void Method()
{
    Console.WriteLine("Hello World!");
}
```

```
Public Sub Method()
    Console.WriteLine("Hello World!")
End Sub
```

Cyclomatic complexity of 2

```
void Method(bool condition)
{
    if (condition)
    {
        Console.WriteLine("Hello World!");
    }
}
```

```
Public Sub Method(ByVal condition As Boolean)
    If (condition) Then
        Console.WriteLine("Hello World!")
    End If
End Sub
```

Cyclomatic complexity of 3

```

public void Method(bool condition1, bool condition2)
{
    if (condition1 || condition2)
    {
        Console.WriteLine("Hello World!");
    }
}

```

```

Public Sub Method(ByVal condition1 As Boolean, ByVal condition2 As Boolean)
    If (condition1 OrElse condition2) Then
        Console.WriteLine("Hello World!")
    End If
End Sub

```

Cyclomatic complexity of 8

```

public void Method(DayOfWeek day)
{
    switch (day)
    {
        case DayOfWeek.Monday:
            Console.WriteLine("Today is Monday!");
            break;
        case DayOfWeek.Tuesday:
            Console.WriteLine("Today is Tuesday!");
            break;
        case DayOfWeek.Wednesday:
            Console.WriteLine("Today is Wednesday!");
            break;
        case DayOfWeek.Thursday:
            Console.WriteLine("Today is Thursday!");
            break;
        case DayOfWeek.Friday:
            Console.WriteLine("Today is Friday!");
            break;
        case DayOfWeek.Saturday:
            Console.WriteLine("Today is Saturday!");
            break;
        case DayOfWeek.Sunday:
            Console.WriteLine("Today is Sunday!");
            break;
    }
}

```

```
Public Sub Method(ByVal day As DayOfWeek)
    Select Case day
        Case DayOfWeek.Monday
            Console.WriteLine("Today is Monday!")
        Case DayOfWeek.Tuesday
            Console.WriteLine("Today is Tuesday!")
        Case DayOfWeek.Wednesday
            Console.WriteLine("Today is Wednesday!")
        Case DayOfWeek.Thursday
            Console.WriteLine("Today is Thursday!")
        Case DayOfWeek.Friday
            Console.WriteLine("Today is Friday!")
        Case DayOfWeek.Saturday
            Console.WriteLine("Today is Saturday!")
        Case DayOfWeek.Sunday
            Console.WriteLine("Today is Sunday!")
    End Select
End Sub
```

CA1505: Avoid unmaintainable code

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1505
Category	Maintainability
Fix is breaking or non-breaking	Non-breaking

Cause

A type or method has a low maintainability index value.

Rule description

The maintainability index is calculated by using the following metrics: lines of code, program volume, and cyclomatic complexity. Program volume is a measure of the difficulty of understanding of a type or method that's based on the number of operators and operands in the code. Cyclomatic complexity is a measure of the structural complexity of the type or method. You can learn more about code metrics at [Measure complexity and maintainability of managed code](#).

A low maintainability index indicates that a type or method is probably difficult to maintain and would be a good candidate to redesign.

How to fix violations

To fix this violation, redesign the type or method and try to split it into smaller and more focused types or methods.

When to suppress warnings

You can suppress this warning when the type or method cannot be split or is considered maintainable despite its large size.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1505
// The code that's violating the rule is on this line.
#pragma warning restore CA1505
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1505.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1506: Avoid excessive class coupling

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1506
Category	Maintainability
Fix is breaking or non-breaking	Breaking

Cause

A type or method is coupled with many other types. Compiler-generated types are excluded from this metric.

Rule description

This rule measures class coupling by counting the number of unique type references that a type or method contains. The default coupling threshold is 95 for types and 40 for methods.

Types and methods that have a high degree of class coupling can be difficult to maintain. It's a good practice to have types and methods that exhibit low coupling and high cohesion.

How to fix violations

To fix this violation, try to redesign the type or method to reduce the number of types to which it's coupled.

When to suppress warnings

You can suppress this warning when the type or method is considered maintainable despite its large number of dependencies on other types.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1506
// The code that's violating the rule is on this line.
#pragma warning restore CA1506
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1506.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1507: Use `nameof` in place of string

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1507
Category	Maintainability
Fix is breaking or non-breaking	Non-breaking

Cause

A `string` literal or constant that matches the name of a parameter of the containing method or the name of a property of the containing type is used as an argument to a method.

Rule description

Rule CA1507 flags the use of a `string` literal as an argument to a method or constructor where a `nameof` (`NameOf` in Visual Basic) expression would add maintainability. The rule fires if all of the following conditions are met:

- The argument is a `string` literal or constant.
- The argument corresponds to a `string`-typed parameter of the method or the constructor that's being invoked (that is, there is no conversion involved at the call site).
- Either:
 - The declared name of the parameter is `paramName` and the constant value of the `string` literal matches the name of a parameter of the method, lambda, or local function within which the method or constructor is being invoked.
 - The declared name of the parameter is `propertyName` and the constant value of the `string` literal matches the name of a property of the type within which the method or constructor is being invoked.

Rule CA1507 improves code maintainability in cases where the parameter may be renamed in the future, but the `string` literal is mistakenly not renamed. By using `nameof`, the symbol will be renamed when the parameter is renamed through a refactoring operation. In addition, any spelling mistakes in the name of the parameter are caught by the compiler.

How to fix violations

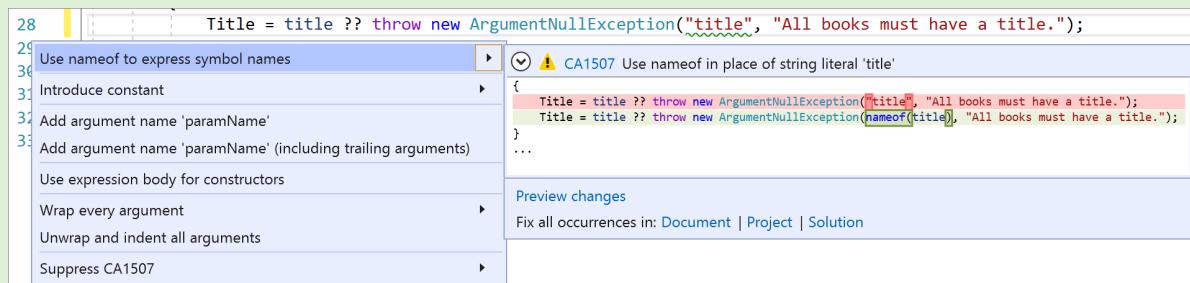

To fix a violation, replace the `string` literal with a `nameof` (`NameOf` in Visual Basic) expression. For example, the following two code snippets show a violation of the rule and how to fix it:

```
public Book(string title)
{
    // Violates rule CA1507
    Title = title ?? throw new ArgumentNullException("title", "All books must have a title.");
}
```

```
public Book(string title)
{
    // Resolves rule CA1507 violation
    Title = title ?? throw new ArgumentNullException(nameof(title), "All books must have a title.");
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the `string` literal and press **Ctrl+.** (period). Choose **Use nameof to express symbol names** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the maintainability of your code.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1507
// The code that's violating the rule is on this line.
#pragma warning restore CA1507
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1507.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CA2208: Instantiate argument exceptions correctly](#)

See also

- [Maintainability rules](#)

CA1508: Avoid dead conditional code

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1508
Category	Maintainability
Fix is breaking or non-breaking	Non-Breaking

Cause

A method has conditional code that always evaluates to `true` or `false` at run time. This leads to dead code in the `false` branch of the condition.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Methods can have conditional code, such as if statements, binary expressions (`==`, `!=`, `<`, `>`), null checks, etc. For example, consider the following code:

```
public void M(int i, int j)
{
    if (i != 0)
    {
        return;
    }

    if (j != 0)
    {
        return;
    }

    // Below condition will always evaluate to 'false' as 'i' and 'j' are both '0' here.
    if (i != j)
    {
        // Code in this 'if' branch is dead code.
        // It can either be removed or refactored.
        ...
    }
}
```

C# and VB compilers perform analysis of conditional checks involving compile-time *constant values* that always evaluate to `true` or `false`. This analyzer performs data flow analysis of non-constant variables to determine redundant conditional checks involving *non-constant values*. In the preceding code, the analyzer determines that `i` and `j` are both `0` for all code paths that reach `i != j` check. Hence, this check will always evaluate to `false` at run time. The code inside the if statement is dead code and can be removed or refactored. Similarly, the analyzer tracks nullness of variables and reports redundant null checks.

NOTE

This analyzer performs an expensive dataflow analysis of non-constant values. This can increase the overall compile time on certain code bases.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the maintainability of your code. It is also fine to suppress violations that are identified to be false positives. These are possible in the presence of concurrent code that can execute from multiple threads.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1508
// The code that's violating the rule is on this line.
#pragma warning restore CA1508
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1508.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Maintainability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Maintainability](#)).

For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).

- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA1509: Invalid entry in code metrics configuration file

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1509
Category	Maintainability
Fix is breaking or non-breaking	Non-Breaking

Cause

Code metrics rules, such as [CA1501](#), [CA1502](#), [CA1505](#) and [CA1506](#), supplied a configuration file named `CodeMetricsConfig.txt` that has an invalid entry.

Rule description

.NET code-quality analyzers implementation of [code metrics](#) analysis rules allow end users to supply an [additional file](#) named `CodeMetricsConfig.txt`. This file contains entries to configure code metric thresholds for analysis. Following rules are configurable in this file:

- [CA1501: Avoid excessive inheritance](#)
- [CA1502: Avoid excessive complexity](#)
- [CA1505: Avoid unmaintainable code](#)
- [CA1506: Avoid excessive class coupling](#)

This configuration file expects each entry to be in following format:

```
'RuleId'(Optional 'SymbolKind'): 'Threshold'
```

- Valid values for 'RuleId' are [CA1501](#), [CA1502](#), [CA1505](#), and [CA1506](#).
- Valid values for optional 'SymbolKind' are [Assembly](#), [Namespace](#), [Type](#), [Method](#), [Field](#), [Event](#), and [Property](#).
- Valid values for 'Threshold' are non-negative integers.
- Lines starting with '#' are treated as comment lines

For example, the following is a valid configuration file:

```
# Comment text

CA1501: 1

CA1502(Type): 4
CA1502(Method): 2
```

An invalid entry in this configuration file is flagged with the [CA1509](#) diagnostic.

How to fix violations

To fix a violation of this rule, make sure the invalid entry in `CodeMetricsConfig.txt` gets the required format.

When to suppress warnings

Do not suppress violations of this rule.

Naming rules

9/20/2022 • 3 minutes to read • [Edit Online](#)

Naming rules support adherence to the [naming conventions of the .NET design guidelines](#).

In this section

RULE	DESCRIPTION
CA1700: Do not name enum values 'Reserved'	This rule assumes that an enumeration member that has a name that contains "reserved" is not currently used but is a placeholder to be renamed or removed in a future version. Renaming or removing a member is a breaking change.
CA1707: Identifiers should not contain underscores	By convention, identifier names do not contain the underscore (_) character. This rule checks namespaces, types, members, and parameters.
CA1708: Identifiers should differ by more than case	Identifiers for namespaces, types, members, and parameters cannot differ only by case because languages that target the common language runtime are not required to be case-sensitive.
CA1710: Identifiers should have correct suffix	By convention, the names of types that extend certain base types or that implement certain interfaces, or types derived from these types, have a suffix that is associated with the base type or interface.
CA1711: Identifiers should not have incorrect suffix	By convention, only the names of types that extend certain base types or that implement certain interfaces, or types that are derived from these types, should end with specific reserved suffixes. Other type names should not use these reserved suffixes.
CA1712: Do not prefix enum values with type name	Names of enumeration members are not prefixed with the type name because type information is expected to be provided by development tools.
CA1713: Events should not have before or after prefix	The name of an event starts with "Before" or "After". To name related events that are raised in a specific sequence, use the present or past tense to indicate the relative position in the sequence of actions.
CA1714: Flags enums should have plural names	A public enumeration has the System.FlagsAttribute attribute and its name does not end in "s". Types that are marked with FlagsAttribute have names that are plural because the attribute indicates that more than one value can be specified.
CA1715: Identifiers should have correct prefix	The name of an externally visible interface does not start with a capital "I". The name of a generic type parameter on an externally visible type or method does not start with a capital "T".

RULE	DESCRIPTION
CA1716: Identifiers should not match keywords	A namespace name or a type name matches a reserved keyword in a programming language. Identifiers for namespaces and types should not match keywords that are defined by languages that target the common language runtime.
CA1717: Only FlagsAttribute enums should have plural names	Naming conventions dictate that a plural name for an enumeration indicates that more than one value of the enumeration can be specified at the same time.
CA1720: Identifiers should not contain type names	The name of a parameter in an externally visible member contains a data type name, or the name of an externally visible member contains a language-specific data type name.
CA1721: Property names should not match get methods	The name of a public or protected member starts with "Get" and otherwise matches the name of a public or protected property. "Get" methods and properties should have names that clearly distinguish their function.
CA1724: Type Names Should Not Match Namespaces	Type names should not match the names of .NET namespaces. Violation of this rule can reduce the usability of the library.
CA1725: Parameter names should match base declaration	Consistent naming of parameters in an override hierarchy increases the usability of the method overrides. A parameter name in a derived method that differs from the name in the base declaration can cause confusion about whether the method is an override of the base method or a new overload of the method.
CA1727: Use PascalCase for named placeholders	Use PascalCase for named placeholders in the logging message template.

CA1700: Do not name enum values 'Reserved'

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1700
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of an enumeration member contains the word "reserved".

Rule description

This rule assumes that an enumeration member that has a name that contains "reserved" is not currently used but is a placeholder to be renamed or removed in a future version. Renaming or removing a member is a breaking change. You should not expect users to ignore a member just because its name contains "reserved", nor can you rely on users to read or abide by documentation. Furthermore, because reserved members appear in object browsers and smart integrated development environments, they can cause confusion about which members are actually being used.

Instead of using a reserved member, add a new member to the enumeration in the future version. In most cases the addition of the new member is not a breaking change, as long as the addition does not cause the values of the original members to change.

In a limited number of cases the addition of a member is a breaking change even when the original members retain their original values. Primarily, the new member cannot be returned from existing code paths without breaking callers that use a `switch` (`Select` in Visual Basic) statement on the return value that encompasses the whole member list and that throw an exception in the default case. A secondary concern is that client code might not handle the change in behavior from reflection methods such as `System.Enum.IsDefined`. Accordingly, if the new member has to be returned from existing methods or a known application incompatibility occurs because of poor reflection usage, the only nonbreaking solution is to:

1. Add a new enumeration that contains the original and new members.
2. Mark the original enumeration with the `System.ObsoleteAttribute` attribute.

Follow the same procedure for any externally visible types or members that expose the original enumeration.

How to fix violations

To fix a violation of this rule, remove or rename the member.

When to suppress warnings

It is safe to suppress a warning from this rule for a member that is currently used or for libraries that have previously shipped.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1700
// The code that's violating the rule is on this line.
#pragma warning restore CA1700
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1700.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

RELATED RULES

[CA2217: Do not mark enums with FlagsAttribute](#)

[CA1712: Do not prefix enum values with type name](#)

[CA1028: Enum storage should be Int32](#)

[CA1008: Enums should have zero value](#)

[CA1027: Mark enums with FlagsAttribute](#)

CA1707: Identifiers should not contain underscores

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1707
Category	Naming
Fix is breaking or non-breaking	Breaking - when raised on assemblies Non-breaking - when raised on type parameters

Cause

The name of an identifier contains the underscore (_) character.

Rule description

By convention, identifier names do not contain the underscore (_) character. The rule checks namespaces, types, members, and parameters.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

Remove all underscore characters from the name.

When to suppress warnings

Do not suppress warnings for production code. However, it's safe to suppress this warning for test code.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1707
// The code that's violating the rule is on this line.
#pragma warning restore CA1707
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1707.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

For well-known methods in Microsoft code that currently use an underscore and cannot be modified, the rule should be suppressed.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an *.editorconfig* file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Related rules

- [CA1708: Identifiers should differ by more than case](#)

CA1708: Identifiers should differ by more than case

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1708
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The names of two types, members, parameters, or fully qualified namespaces are identical when they're converted to lowercase.

By default, this rule only looks at externally visible types, members, and namespaces, but this is [configurable](#).

Rule description

Identifiers for namespaces, types, members, and parameters cannot differ only by case because languages that target the common language runtime are not required to be case-sensitive. For example, Visual Basic is a widely used case-insensitive language.

This rule fires on publicly visible members only.

How to fix violations

Select a name that is unique when it is compared to other identifiers in a case-insensitive manner.

When to suppress warnings

Do not suppress a warning from this rule. The library might not be usable in all available languages in .NET.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example of a violation

The following example demonstrates a violation of this rule.

```
public class Class1
{
    protected string someProperty;

    public string SomeProperty
    {
        get { return someProperty; }
    }
}
```

CA1710: Identifiers should have correct suffix

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1710
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

An identifier does not have the correct suffix.

By default, this rule only looks at externally visible identifiers, but this is [configurable](#).

Rule description

By convention, the names of types that extend certain base types or that implement certain interfaces, or types derived from these types, have a suffix that is associated with the base type or interface.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

The following table lists the base types and interfaces that have associated suffixes.

BASE TYPE/INTERFACE	SUFFIX
System.Attribute	Attribute
System.EventArgs	EventArgs
System.Exception	Exception
System.Collections.ICollection	Collection
System.Collections.IDictionary	Dictionary
System.Collections.IEnumerable	Collection
System.Collections.Generic.IReadOnlyDictionary< TKey, TValue >	Dictionary
System.Collections.Queue	Collection or Queue
System.Collections.Stack	Collection or Stack
System.Collections.Generic.ICollection< T >	Collection

BASE TYPE/INTERFACE	SUFFIX
<code>System.Collections.Generic.IDictionary< TKey, TValue ></code>	Dictionary
<code>System.Data.DataSet</code>	DataSet
<code>System.Data.DataTable</code>	Collection or DataTable
<code>System.IO.Stream</code>	Stream
<code>System.Security.IPermission</code>	Permission
<code>System.Security.Policy.IMembershipCondition</code>	Condition
An event-handler delegate.	EventHandler

Types that implement [ICollection](#) and are a generalized type of data structure, such as a dictionary, stack, or queue, are allowed names that provide meaningful information about the intended usage of the type.

Types that implement [ICollection](#) and are a collection of specific items have names that end with the word 'Collection'. For example, a collection of [Queue](#) objects would have the name 'QueueCollection'. The 'Collection' suffix signifies that the members of the collection can be enumerated by using the `foreach` ([For Each](#) in Visual Basic) statement.

Types that implement [IDictionary](#) or [IReadOnlyDictionary< TKey, TValue >](#) have names that end with the word 'Dictionary' even if the type also implements [IEnumerable](#) or [ICollection](#). The 'Collection' and 'Dictionary' suffix naming conventions enable users to distinguish between the following two enumeration patterns.

Types with the 'Collection' suffix follow this enumeration pattern.

```
foreach(SomeType x in SomeCollection) { }
```

Types with the 'Dictionary' suffix follow this enumeration pattern.

```
foreach(SomeType x in SomeDictionary.Values) { }
```

A [DataSet](#) object consists of a collection of [DataTable](#) objects, which consist of collections of [System.Data DataColumn](#) and [System.Data DataRow](#) objects, among others. These collections implement [ICollection](#) through the base [System.Data.InternalDataCollectionBase](#) class.

How to fix violations

Rename the type so that it is suffixed with the correct term.

When to suppress warnings

It is safe to suppress a warning to use the 'Collection' suffix if the type is a generalized data structure that might be extended or that will hold an arbitrary set of diverse items. In this case, a name that provides meaningful information about the implementation, performance, or other characteristics of the data structure might make sense (for example, [BinaryTree](#)). In cases where the type represents a collection of a specific type (for example, [StringCollection](#)), do not suppress a warning from this rule because the suffix indicates that the type can be enumerated by using a `foreach` statement.

For other suffixes, do not suppress a warning from this rule. The suffix allows the intended usage to be evident from the type name.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1710
// The code that's violating the rule is on this line.
#pragma warning restore CA1710
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1710.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Exclude indirect base types](#)
- [Additional required suffixes](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

INCLUDE SPECIFIC API SURFACES

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

EXCLUDE INDIRECT BASE TYPES

You can configure whether to exclude indirect base types from the rule. By default, this option is set to true, which restricts analysis to the current base type.

```
dotnet_code_quality.CA1710.exclude_indirect_base_types = false
```

ADDITIONAL REQUIRED SUFFIXES

You can provide additional required suffixes or override the behavior of some hardcoded suffixes by adding the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1710.additional_required_suffixes = [type]->[suffix]
```

Separate multiple values with a `|` character. Types can be specified in either of the following formats:

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#) with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1710.additional_required_suffixes = MyClass->Class</code>	All types that inherit from 'MyClass' are required to have the 'Class' suffix.
<code>dotnet_code_quality.CA1710.additional_required_suffixes = MyClass->Class MyNamespace.IPath->Path</code>	All types that inherit from 'MyClass' are required to have the 'Class' suffix AND all types that implement 'MyNamespace.IPath' are required to have the 'Path' suffix.
<code>dotnet_code_quality.CA1710.additional_required_suffixes = T:System.Data.IDataReader->{}</code>	Overrides built-in suffixes. In this case, all types that implement 'IDataReader' are no longer required to end in 'Collection'.

Related rules

[CA1711: Identifiers should not have incorrect suffix](#)

See also

- [Attributes](#)
- [Handling and raising events](#)

CA1711: Identifiers should not have incorrect suffix

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1711
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

An identifier has an incorrect suffix.

By default, this rule only looks at externally visible identifiers, but this is [configurable](#).

Rule description

By convention, only the names of types that extend certain base types or that implement certain interfaces, or types derived from these types, should end with specific reserved suffixes. Other type names should not use these reserved suffixes.

The following table lists the reserved suffixes and the base types and interfaces with which they are associated.

SUFFIX	BASE TYPE/INTERFACE
Attribute	System.Attribute
Collection	System.Collections.ICollection System.Collections.IEnumerable System.Collections.Queue System.Collections.Stack System.Collections.Generic.ICollection<T> System.Data.DataSet System.Data.DataTable
Dictionary	System.Collections.IDictionary System.Collections.Generic.IDictionary< TKey, TValue >
EventArgs	System.EventArgs
EventHandler	An event-handler delegate
Exception	System.Exception

SUFFIX	BASE TYPE/INTERFACE
Permission	System.Security.IPermission
Queue	System.Collections.Queue
Stack	System.Collections.Stack
Stream	System.IO.Stream

In addition, the following suffixes should **not** be used:

- `Delegate`
- `Enum`
- `Impl` (use `Core` instead)
- `Ex` or similar suffix to distinguish it from an earlier version of the same type
- `Flag` or `Flags` for enum types

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code. For more information, see [Naming guidelines: Classes, Structs, and Interfaces](#).

How to fix violations

Remove the suffix from the type name.

When to suppress warnings

Do not suppress a warning from this rule unless the suffix has an unambiguous meaning in the application domain.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1711
// The code that's violating the rule is on this line.
#pragma warning restore CA1711
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1711.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Allow suffixes](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Allow suffixes

You can configure a list of allowed suffixes, with each suffix separated by the pipe character ("|"). For example, to specify that the rule should not run against Flag and Flags suffixes, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.ca1711.allowed_suffixes = Flag|Flags
```

Related rules

- [CA1710: Identifiers should have correct suffix](#)

CA1712: Do not prefix enum values with type name

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1712
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

An enumeration contains a member whose name starts with the type name of the enumeration.

Rule description

Names of enumeration members are not prefixed with the type name because type information is expected to be provided by development tools.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the time that is required for to learn a new software library, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

To fix a violation of this rule, remove the type name prefix from the enumeration member.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows an incorrectly named enumeration followed by the corrected version.

```
public enum DigitalImageMode
{
    DigitalImageModeBitmap = 0,
    DigitalImageModeGrayscale = 1,
    DigitalImageModeIndexed = 2,
    DigitalImageModeRGB = 3
}

public enum DigitalImageMode2
{
    Bitmap = 0,
    Grayscale = 1,
    Indexed = 2,
    RGB = 3
}
```

```

Imports System

Namespace ca1712

    Enum DigitalImageMode

        DigitalImageModeBitmap = 0
        DigitalImageModeGrayscale = 1
        DigitalImageModeIndexed = 2
        DigitalImageModeRGB = 3

    End Enum

    Enum DigitalImageMode2

        Bitmap = 0
        Grayscale = 1
        Indexed = 2
        RGB = 3

    End Enum

End Namespace

```

Related rules

- [CA1711: Identifiers should not have incorrect suffix](#)
- [CA1027: Mark enums with FlagsAttribute](#)
- [CA2217: Do not mark enums with FlagsAttribute](#)

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Enum values prefix trigger](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Enum values prefix trigger

You can configure the number of enumeration values required to trigger the rule. For example, to specify that the rule is triggered if one or more the enum values starts with the enum type name, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1712.enum_values_prefix_trigger = AnyEnumValue
```

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA1712.enum_values_prefix_trigger = AnyEnumValue</code>	The rule is triggered if <i>any</i> of the enum values starts with the enum type name.
<code>dotnet_code_quality.CA1712.enum_values_prefix_trigger = AllEnumValues</code>	The rule is triggered if <i>all</i> of the enum values start with the enum type name.

OPTION VALUE	SUMMARY
<pre>dotnet_code_quality.CA1712.enum_values_prefix_trigger = Heuristic</pre>	The rule is triggered using the default heuristic, that is, when at least 75% of the enum values start with the enum type name.

See also

- [System.Enum](#)

CA1713: Events should not have before or after prefix

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1713
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of an event starts with 'Before' or 'After'.

Rule description

Event names should describe the action that raises the event. To name related events that are raised in a specific sequence, use the present or past tense to indicate the relative position in the sequence of actions. For example, when naming a pair of events that is raised when closing a resource, you might name it 'Closing' and 'Closed', instead of 'BeforeClose' and 'AfterClose'.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

Remove the prefix from the event name, and consider changing the name to use the present or past tense of a verb.

When to suppress warnings

Do not suppress a warning from this rule.

CA1714: Flags enums should have plural names

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1714
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

An enumeration has the [System.FlagsAttribute](#) and its name does not end in 's'.

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

Types that are marked with [FlagsAttribute](#) have names that are plural because the attribute indicates that more than one value can be specified. For example, an enumeration that defines the days of the week might be intended for use in an application where you can specify multiple days. This enumeration should have the [FlagsAttribute](#) and could be called 'Days'. A similar enumeration that allows only a single day to be specified would not have the attribute, and could be called 'Day'.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

Make the name of the enumeration a plural word, or remove the [FlagsAttribute](#) attribute if multiple enumeration values should not be specified simultaneously.

When to suppress warnings

It is safe to suppress a violation if the name is a plural word but does not end in 's'. For example, if the multiple-day enumeration that was described previously were named 'DaysOfTheWeek', this would violate the logic of the rule but not its intent. Such violations should be suppressed.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1714
// The code that's violating the rule is on this line.
#pragma warning restore CA1714
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1714.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Related rules

- [CA2217: Do not mark enums with FlagsAttribute](#)

See also

- [System.FlagsAttribute](#)
- [Enum design](#)

CA1715: Identifiers should have correct prefix

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1715
Category	Naming
Fix is breaking or non-breaking	Breaking - when fired on interfaces. Non-breaking - when raised on generic type parameters.

Cause

The name of an interface does not start with an uppercase 'I'.

-or-

The name of a [generic type parameter](#) on a type or method does not start with an uppercase 'T'.

By default, this rule only looks at externally visible interfaces, types, and methods, but this is [configurable](#).

Rule description

By convention, the names of certain programming elements start with a specific prefix.

Interface names should start with an uppercase 'I' followed by another uppercase letter. This rule reports violations for interface names such as 'MyInterface' and 'IsolatedInterface'.

Generic type parameter names should start with an uppercase 'T' and optionally may be followed by another uppercase letter. This rule reports violations for generic type parameter names such as 'V' and 'Type'.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the learning curve that is required for new software libraries, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Single-character type parameters](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Single-character type parameters

You can configure whether or not to exclude single-character type parameters from this rule. For example, to specify that this rule *should not* analyze single-character type parameters, add one of the following key-value pairs to an .editorconfig file in your project:

```
# Package version 2.9.0 and later  
dotnet_code_quality.CA1715.exclude_single_letter_type_parameters = true  
  
# Package version 2.6.3 and earlier  
dotnet_code_quality.CA2007.allow_single_letter_type_parameters = true
```

NOTE

This rule never fires for a type parameter named `T`, for example, `Collection<T>`.

How to fix violations

Rename the identifier so that it is correctly prefixed.

When to suppress warnings

Do not suppress a warning from this rule.

Interface naming example

The following code snippet shows an incorrectly named interface:

```
' Violates this rule  
Public Interface Book  
  
    ReadOnly Property Title() As String  
  
    Sub Read()  
  
End Interface
```

```
// Violation.  
public interface Book  
{  
    string Title  
    {  
        get;  
    }  
  
    void Read();  
}
```

The following code snippet fixes the previous violation by prefixing the interface with 'I':

```
// Fixes the violation by prefixing the interface with 'I'.
public interface IBook
{
    string Title
    {
        get;
    }

    void Read();
}
```

```
' Fixes the violation by prefixing the interface with 'I'
Public Interface IBook

    ReadOnly Property Title() As String

    Sub Read()

End Interface
```

Type parameter naming example

The following code snippet shows an incorrectly named generic type parameter:

```
' Violates this rule
Public Class Collection(Of Item)

End Class
```

```
// Violation.
public class Collection<Item>
{
```

The following code snippet fixes the previous violation by prefixing the generic type parameter with 'T':

```
// Fixes the violation by prefixing the generic type parameter with 'T'.
public class Collection<TItem>
{
```

```
' Fixes the violation by prefixing the generic type parameter with 'T'
Public Class Collection(Of TItem)

End Class
```

CA1716: Identifiers should not match keywords

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1716
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of a namespace, type, or virtual or interface member matches a reserved keyword in a programming language.

By default, this rule only looks at externally visible namespaces, types, and members, but you can [configure visibility](#) and [symbol kinds](#).

Rule description

Identifiers for namespaces, types, and virtual and interface members should not match keywords that are defined by languages that target the common language runtime. Depending on the language that is used and the keyword, compiler errors and ambiguities can make the library difficult to use.

This rule checks against keywords in the following languages:

- Visual Basic
- C#
- C++/CLI

Case-insensitive comparison is used for Visual Basic keywords, and case-sensitive comparison is used for the other languages.

How to fix violations

Select a name that does not appear in the list of keywords.

When to suppress warnings

You can suppress a warning from this rule if you're sure that the identifier won't confuse users of the API, and that the library is usable in all available languages in .NET.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1716
// The code that's violating the rule is on this line.
#pragma warning restore CA1716
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1716.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Analyzed symbol kinds](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Analyzed symbol kinds

You can configure the kinds of symbols that will be analyzed by this rule. The allowable values are:

- `Namespace`
- `NamedType`
- `Method`
- `Property`
- `Event`
- `Parameter`

Separate multiple values with a comma (`,`). The default value includes all of the symbol kinds in the previous list.

```
dotnet_code_quality.CA1716.analyzed_symbol_kinds = Namespace, NamedType, Method, Property, Event
```

CA1717: Only FlagsAttribute enums should have plural names

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1717
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of an enumeration ends in a plural word and the enumeration is not marked with the [System.FlagsAttribute](#) attribute.

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

Naming conventions dictate that a plural name for an enumeration indicates that more than one value of the enumeration can be specified simultaneously. The [FlagsAttribute](#) tells compilers that the enumeration should be treated as a bit field that enables bitwise operations on the enumeration.

If only one value of an enumeration can be specified at a time, the name of the enumeration should be a singular word. For example, an enumeration that defines the days of the week might be intended for use in an application where you can specify multiple days. This enumeration should have the [FlagsAttribute](#) and could be called 'Days'. A similar enumeration that allows only a single day to be specified would not have the attribute, and could be called 'Day'.

Naming conventions provide a common look for libraries that target the common language runtime. This reduces the time that is required to learn a new software library, and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

Make the name of the enumeration a singular word or add the [FlagsAttribute](#).

When to suppress warnings

It is safe to suppress a warning from the rule if the name ends in a singular word.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1717
// The code that's violating the rule is on this line.
#pragma warning restore CA1717
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1717.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Related rules

CA1720: Identifiers should not contain type names

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1720
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of a parameter in a member contains a data type name.

-or-

The name of a member contains a language-specific data type name.

By default, this rule only looks at externally visible members, but this is [configurable](#).

Rule description

Names of parameters and members are better used to communicate their meaning than to describe their type, which is expected to be provided by development tools. For names of members, if a data type name must be used, use a language-independent name instead of a language-specific one. For example, instead of the C# type name `int`, use the language-independent data type name, `Int32`.

Each discrete token in the name of the parameter or member is checked against the following language-specific data type names in a case-insensitive manner:

- Bool
- WChar
- Int8
- UInt8
- Short
- UShort
- Int
- UInt
- Integer
- UInteger
- Long
- ULong
- Unsigned
- Signed
- Float
- Float32
- Float64

In addition, the names of a parameter are also checked against the following language-independent data type names in a case-insensitive manner:

- Object
- Boolean
- Char
- String
- SByte
- Byte
- UByte
- Int16
- UInt16
- Int32
- UInt32
- Int64
- UInt64
- IntPtr
- Ptr
- Pointer
- UIntptr
- UPtr
- UPointer
- Single
- Double
- Decimal
- Guid

How to fix violations

If fired against a parameter:

Replace the data type identifier in the name of the parameter with either a term that better describes its meaning or a more generic term, such as 'value'.

If fired against a member:

Replace the language-specific data type identifier in the name of the member with a term that better describes its meaning, a language-independent equivalent, or a more generic term, such as 'value'.

When to suppress warnings

Occasional use of type-based parameter and member names might be appropriate. However, for new development, no known scenarios occur where you should suppress a warning from this rule. For libraries that have previously shipped, you might have to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1720
// The code that's violating the rule is on this line.
#pragma warning restore CA1720
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1720.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Related rules

- [CA1707: Identifiers should not contain underscores](#)

CA1721: Property names should not match get methods

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1721
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of a member starts with 'Get' and otherwise matches the name of a property. For example, a type that contains a method that's named 'GetColor' and a property that's named 'Color' cause a rule violation. This rule will not fire if either the property or the method is marked with the [ObsoleteAttribute](#).

By default, this rule only looks at externally visible members and properties, but this is [configurable](#).

Rule description

"Get" methods and properties should have names that clearly distinguish their function.

Naming conventions provide a common look for libraries that target the common language runtime. This consistency reduces the time that's required to learn a new software library and increases customer confidence that the library was developed by someone who has expertise in developing managed code.

How to fix violations

Change the name so that it does not match the name of a method that is prefixed with 'Get'.

When to suppress warnings

Do not suppress a warning from this rule. One exception to that rule is if the "Get" method is caused by implementing the [IExtenderProvider](#) interface.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1721
// The code that's violating the rule is on this line.
#pragma warning restore CA1721
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1721.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example contains a method and property that violate this rule.

```
public class Test
{
    public DateTime Date
    {
        get { return DateTime.Today; }
    }

    // Violates rule: PropertyNamesShouldNotMatchGetMethods.
    public string GetDate()
    {
        return this.Date.ToString();
    }
}
```

```
Imports System

Namespace ca1721

    Public Class Test

        Public ReadOnly Property [Date]() As DateTime
            Get
                Return DateTime.Today
            End Get
        End Property

        ' Violates rule: PropertyNamesShouldNotMatchGetMethods.
        Public Function GetDate() As String
            Return Me.Date.ToString()
        End Function

    End Class

End Namespace
```

Related rules

CA1724: Type names should not match namespaces

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1724
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

A type name matches a referenced namespace name that has one or more externally visible types. The name comparison is case-insensitive.

Rule description

User-created type names should not match the names of referenced namespaces that have externally visible types. Violating this rule can reduce the usability of your library.

How to fix violations

Rename the type such that it doesn't match the name of a referenced namespace that has externally visible types.

When to suppress warnings

For new development, no known scenarios occur where you must suppress a warning from this rule. Before you suppress the warning, carefully consider how the users of your library might be confused by the matching name. For shipping libraries, you might have to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1724
// The code that's violating the rule is on this line.
#pragma warning restore CA1724
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1724.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

```
namespace MyNamespace\n{\n    // This class violates the rule\n    public class System\n    {\n    }\n}
```

CA1725: Parameter names should match base declaration

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1725
Category	Naming
Fix is breaking or non-breaking	Breaking

Cause

The name of a parameter in a method override does not match the name of the parameter in the base declaration of the method or the name of the parameter in the interface declaration of the method.

By default, this rule only looks at externally visible methods, but this is [configurable](#).

Rule description

Consistent naming of parameters in an override hierarchy increases the usability of the method overrides. A parameter name in a derived method that differs from the name in the base declaration can cause confusion about whether the method is an override of the base method or a new overload of the method.

How to fix violations

To fix a violation of this rule, rename the parameter to match the base declaration. The fix is a breaking change for COM visible methods.

When to suppress warnings

Do not suppress a warning from this rule except for COM visible methods in libraries that have previously shipped.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1725
// The code that's violating the rule is on this line.
#pragma warning restore CA1725
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1725.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Naming](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

CA1727: Use PascalCase for named placeholders

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1727
Category	Naming
Fix is breaking or non-breaking	Non-breaking

Cause

A named placeholder used with [ILogger](#) is not PascalCase.

Rule description

A named placeholder used with [ILogger](#) should be PascalCase, a naming convention where the first letter of each compound word in a name is capitalized. This naming convention is recommended for structured logging, where each named placeholder is used as a property name in the structured data.

How to fix violations

Use PascalCase for named placeholders. For example, change `{firstName}` to `{FirstName}`.

When to suppress warnings

It is safe to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1727
// The code that's violating the rule is on this line.
#pragma warning restore CA1727
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1727.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Naming.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Performance rules

9/20/2022 • 7 minutes to read • [Edit Online](#)

Performance rules support high-performance libraries and applications.

In this section

RULE	DESCRIPTION
CA1802: Use Literals Where Appropriate	A field is declared static and read-only (Shared and ReadOnly in Visual Basic), and is initialized with a value that is computable at compile time. Because the value that is assigned to the targeted field is computable at compile time, change the declaration to a const (Const in Visual Basic) field so that the value is computed at compile time instead of at run time.
CA1805: Do not initialize unnecessarily	The .NET runtime initializes all fields of reference types to their default values before running the constructor. In most cases, explicitly initializing a field to its default value is redundant, which adds to maintenance costs and may degrade performance (such as with increased assembly size).
CA1806: Do not ignore method results	A new object is created but never used, or a method that creates and returns a new string is called and the new string is never used, or a Component Object Model (COM) or P/Invoke method returns an HRESULT or error code that is never used.
CA1810: Initialize reference type static fields inline	When a type declares an explicit static constructor, the just-in-time (JIT) compiler adds a check to each static method and instance constructor of the type to make sure that the static constructor was previously called. Static constructor checks can decrease performance.
CA1812: Avoid uninstantiated internal classes	An instance of an assembly-level type is not created by code in the assembly.
CA1813: Avoid unsealed attributes	.NET provides methods for retrieving custom attributes. By default, these methods search the attribute inheritance hierarchy. Sealing the attribute eliminates the search through the inheritance hierarchy and can improve performance.
CA1814: Prefer jagged arrays over multidimensional	A jagged array is an array whose elements are arrays. The arrays that make up the elements can be of different sizes, which can result in less wasted space for some sets of data.
CA1815: Override equals and operator equals on value types	For value types, the inherited implementation of Equals uses the Reflection library and compares the contents of all fields. Reflection is computationally expensive, and comparing every field for equality might be unnecessary. If you expect users to compare or sort instances, or to use instances as hash table keys, your value type should implement Equals.

Rule	Description
CA1819: Properties should not return arrays	Arrays that are returned by properties are not write-protected, even if the property is read-only. To keep the array tamper-proof, the property must return a copy of the array. Typically, users will not understand the adverse performance implications of calling such a property.
CA1820: Test for empty strings using string length	Comparing strings by using the <code>String.Length</code> property or the <code>String.IsNullOrEmpty</code> method is significantly faster than using <code>Equals</code> .
CA1821: Remove empty finalizers	Whenever you can, avoid finalizers because of the additional performance overhead that is involved in tracking object lifetime. An empty finalizer incurs added overhead without any benefit.
CA1822: Mark members as static	Members that do not access instance data or call instance methods can be marked as static (Shared in Visual Basic). After you mark the methods as static, the compiler will emit nonvirtual call sites to these members. This can give you a measurable performance gain for performance-sensitive code.
CA1823: Avoid unused private fields	Private fields were detected that do not appear to be accessed in the assembly.
CA1824: Mark assemblies with <code>NeutralResourcesLanguageAttribute</code>	The <code>NeutralResourcesLanguage</code> attribute informs the Resource Manager of the language that was used to display the resources of a neutral culture for an assembly. This improves lookup performance for the first resource that you load and can reduce your working set.
CA1825: Avoid zero-length array allocations	Initializing a zero-length array leads to unnecessary memory allocation. Instead, use the statically allocated empty array instance by calling <code>Array.Empty</code> . The memory allocation is shared across all invocations of this method.
CA1826: Use property instead of Linq Enumerable method	<code>Enumerable</code> LINQ method was used on a type that supports an equivalent, more efficient property.
CA1827: Do not use Count/LongCount when Any can be used	<code>Count</code> or <code>LongCount</code> method was used where <code>Any</code> method would be more efficient.
CA1828: Do not use CountAsync/LongCountAsync when AnyAsync can be used	<code>CountAsync</code> or <code>LongCountAsync</code> method was used where <code>AnyAsync</code> method would be more efficient.
CA1829: Use Length/Count property instead of <code>Enumerable.Count</code> method	<code>Count</code> LINQ method was used on a type that supports an equivalent, more efficient <code>Length</code> or <code>Count</code> property.
CA1830: Prefer strongly-typed Append and Insert method overloads on <code>StringBuilder</code>	<code>Append</code> and <code>Insert</code> provide overloads for multiple types beyond <code>System.String</code> . When possible, prefer the strongly-typed overloads over using <code>ToString()</code> and the string-based overload.

RULE	DESCRIPTION
CA1831: Use AsSpan instead of Range-based indexers for string when appropriate	When using a range-indexer on a string and implicitly assigning the value to a <code>ReadOnlySpan<char></code> type, the method <code>Substring</code> will be used instead of <code>Slice</code> , which produces a copy of requested portion of the string.
CA1832: Use AsSpan or AsMemory instead of Range-based indexers for getting <code>ReadOnlySpan</code> or <code>ReadOnlyMemory</code> portion of an array	When using a range-indexer on an array and implicitly assigning the value to a <code>ReadOnlySpan<T></code> or <code>ReadOnlyMemory<T></code> type, the method <code>GetSubArray</code> will be used instead of <code>Slice</code> , which produces a copy of requested portion of the array.
CA1833: Use AsSpan or AsMemory instead of Range-based indexers for getting <code>Span</code> or <code>Memory</code> portion of an array	When using a range-indexer on an array and implicitly assigning the value to a <code>Span<T></code> or <code>Memory<T></code> type, the method <code>GetSubArray</code> will be used instead of <code>Slice</code> , which produces a copy of requested portion of the array.
CA1834: Use <code>StringBuilder.Append(char)</code> for single character strings	<code>StringBuilder</code> has an <code>Append</code> overload that takes a <code>char</code> as its argument. Prefer calling the <code>char</code> overload to improve performance.
CA1835: Prefer the 'Memory'-based overloads for 'ReadAsync' and 'WriteAsync'	'Stream' has a 'ReadAsync' overload that takes a 'Memory<Byte>' as the first argument, and a 'WriteAsync' overload that takes a 'ReadOnlyMemory<Byte>' as the first argument. Prefer calling the memory based overloads, which are more efficient.
CA1836: Prefer <code>IsEmpty</code> over <code>Count</code> when available	Prefer <code>IsEmpty</code> property that is more efficient than <code>Count</code> , <code>Length</code> , <code>Count<TSource>(IEnumerable<TSource>)</code> or <code>LongCount<TSource>(IEnumerable<TSource>)</code> to determine whether the object contains or not any items.
CA1837: Use <code>Environment.ProcessId</code> instead of <code>Process.GetCurrentProcess().Id</code>	<code>Environment.ProcessId</code> is simpler and faster than <code>Process.GetCurrentProcess().Id</code> .
CA1838: Avoid <code>StringBuilder</code> parameters for P/Invokes	Marshalling of <code>StringBuilder</code> always creates a native buffer copy, resulting in multiple allocations for one marshalling operation.
CA1839: Use <code>Environment.ProcessPath</code> instead of <code>Process.GetCurrentProcess().MainModule.FileName</code>	<code>Environment.ProcessPath</code> is simpler and faster than <code>Process.GetCurrentProcess().MainModule.FileName</code> .
CA1840: Use <code>Environment.CurrentManagedThreadId</code> instead of <code>Thread.CurrentThread.ManagedThreadId</code>	<code>Environment.CurrentManagedThreadId</code> is more compact and efficient than <code>Thread.CurrentThread.ManagedThreadId</code> .
CA1841: Prefer Dictionary Contains methods	Calling <code>Contains</code> on the <code>Keys</code> or <code>Values</code> collection may often be more expensive than calling <code>ContainsKey</code> or <code>ContainsValue</code> on the dictionary itself.
CA1842: Do not use 'WhenAll' with a single task	Using <code>WhenAll</code> with a single task may result in performance loss. Await or return the task instead.
CA1843: Do not use 'WaitAll' with a single task	Using <code>WaitAll</code> with a single task may result in performance loss. Await or return the task instead.

RULE	DESCRIPTION
CA1844: Provide memory-based overrides of async methods when subclassing 'Stream'	To improve performance, override the memory-based async methods when subclassing 'Stream'. Then implement the array-based methods in terms of the memory-based methods.
CA1845: Use span-based <code>string.Concat</code>	It is more efficient to use <code>AsSpan</code> and <code>string.Concat</code> , instead of <code>Substring</code> and a concatenation operator.
CA1846: Prefer <code>AsSpan</code> over <code>Substring</code>	<code>AsSpan</code> is more efficient than <code>Substring</code> . <code>Substring</code> performs an O(n) string copy, while <code>AsSpan</code> does not and has a constant cost. <code>AsSpan</code> also does not perform any heap allocations.
CA1847: Use char literal for a single character lookup	Use <code>string.Contains(char)</code> instead of <code>string.Contains(string)</code> when searching for a single character.
CA1848: Use the <code>LoggerMessage</code> delegates	For improved performance, use the <code>LoggerMessage</code> delegates.
CA1849: Call async methods when in an async method	In a method which is already asynchronous, calls to other methods should be to their async versions, where they exist.
CA1850: Prefer static <code>HashData</code> method over <code>ComputeHash</code>	It's more efficient to use the static <code>HashData</code> method over creating and managing a <code>HashAlgorithm</code> instance to call <code>ComputeHash</code> .
CA1851: Possible multiple enumerations of <code>IEnumerable</code> collection	Possible multiple enumerations of <code>IEnumerable</code> collection. Consider using an implementation that avoids multiple enumerations.
CA1854: Prefer the ' <code>IDictionary.TryGetValue(TKey, out TValue)</code> ' method	Prefer 'TryGetValue' over a Dictionary indexer access guarded by a 'ContainsKey' check. 'ContainsKey' and the indexer both look up the key, so using 'TryGetValue' avoids the extra lookup.

CA1802: Use Literals Where Appropriate

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1802
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A field is declared `static` and `readonly` (`Shared` and `ReadOnly` in Visual Basic), and is initialized with a value that is computable at compile time.

By default, this rule only looks at externally visible, static, readonly fields, but this is [configurable](#).

Rule description

The value of a `static readonly` field is computed at run time when the static constructor for the declaring type is called. If the `static readonly` field is initialized when it is declared and a static constructor is not declared explicitly, the compiler emits a static constructor to initialize the field.

The value of a `const` field is computed at compile time and stored in the metadata, which increases run-time performance when it is compared to a `static readonly` field.

Because the value assigned to the targeted field is computable at compile time, change the declaration to a `const` field so that the value is computed at compile time instead of at run time.

How to fix violations

To fix a violation of this rule, replace the `static` and `readonly` modifiers with the `const` modifier.

NOTE

The use of the `const` modifier is not recommended for all scenarios.

When to suppress warnings

It is safe to suppress a warning from this rule, or disable the rule, if performance is not of concern.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1802
// The code that's violating the rule is on this line.
#pragma warning restore CA1802
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1802.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)
- [Required modifiers](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Performance](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Required modifiers

You can configure this rule to override the required field modifiers. By default, `static` and `readonly` are both required modifiers for fields that are analyzed. You can override this to a comma separated list of one or more modifier values from the below table:

OPTION VALUE	SUMMARY
<code>none</code>	No modifier requirement.
<code>static</code> or <code>Shared</code>	Must be declared as 'static' ('Shared' in Visual Basic).
<code>const</code>	Must be declared as 'const'.
<code>readonly</code>	Must be declared as 'readonly'.

For example, to specify that the rule should run against both static and instance fields, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA1802.required_modifiers = none
```

Example

The following example shows a type, `UseReadOnly`, that violates the rule and a type, `UseConstant`, that satisfies the rule.

```
Imports System

Namespace ca1802

    ' This class violates the rule.
    Public Class UseReadOnly

        Shared ReadOnly x As Integer = 3
        Shared ReadOnly y As Double = x + 2.1
        Shared ReadOnly s As String = "readonly"

    End Class

    ' This class satisfies the rule.
    Public Class UseConstant

        Const x As Integer = 3
        Const y As Double = x + 2.1
        Const s As String = "const"

    End Class

End Namespace
```

```
// This class violates the rule.
public class UseReadOnly
{
    static readonly int x = 3;
    static readonly double y = x + 2.1;
    static readonly string s = "readonly";

    public void Print()
    {
        Console.WriteLine(s);
    }
}

// This class satisfies the rule.
public class UseConstant
{
    const int x = 3;
    const double y = x + 2.1;
    const string s = "const";
}
```

CA1805: Do not initialize unnecessarily.

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1805
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A field of a class is explicitly initialized to the default value of that field's type.

Rule description

The .NET runtime initializes all fields of reference types to their default values before running the constructor. In most cases, explicitly initializing a field to its default value in a constructor is redundant, adding maintenance costs and potentially degrading performance (such as with increased assembly size), and the explicit initialization can be removed.

How to fix violations

In most cases, the proper fix is to delete the unnecessary initialization.

```
class C
{
    // Violation
    int _value1 = 0;

    // Fixed
    int _value1;
}
```

In some cases, deleting the initialization may result in subsequent [CS0649](#) warnings being issued due to the field retaining its default value forever. In such cases, a better fix may be to delete the field entirely or replace it with a property:

```
class C
{
    // Violation
    private static readonly int s_value = 0;

    // Fixed
    private static int Value => 0;
}
```

When to suppress warnings

It is always safe to suppress the warning, as the warning simply highlights potentially unnecessary code and

work that may be avoided.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1805
// The code that's violating the rule is on this line.
#pragma warning restore CA1805
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1805.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Performance rules](#)

CA1806: Do not ignore method results

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1806
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

There are several possible reasons for this warning:

- A new object is created but never used.
- A method that creates and returns a new string is called and the new string is never used.
- A COM or P/Invoke method that returns a `HRESULT` or error code that's never used.
- A language-integrated query (LINQ) method that returns a result that's never used.

Rule description

Unnecessary object creation and the associated garbage collection of the unused object degrade performance.

Strings are immutable and methods such as `String.ToUpper` return a new instance of a string instead of modifying the instance of the string in the calling method.

Ignoring `HRESULT` or an error code can lead to low-resource conditions or unexpected behavior in error conditions.

LINQ methods are known to not have side effects, and the result should not be ignored.

How to fix violations

If a method creates a new instance of an object that's never used, pass the instance as an argument to another method or assign the instance to a variable. If the object creation is unnecessary, remove it.

-or-

If method A calls method B but does not use the new string instance that method B returns, pass the instance as an argument to another method or assign the instance to a variable. Or remove the call if it's unnecessary.

-or-

If method A calls method B but does not use the `HRESULT` or error code that the method returns, use the result in a conditional statement, assign the result to a variable, or pass it as an argument to another method.

-or-

If a LINQ method A calls method B but does not use the result, use the result in a conditional statement, assign the result to a variable, or pass it as an argument to another method.

When to suppress warnings

Do not suppress a warning from this rule unless the act of creating the object serves some purpose.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1806
// The code that's violating the rule is on this line.
#pragma warning restore CA1806
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1806.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following option to configure which parts of your codebase to run this rule on.

Additional methods to enforce

You can configure this rule to check that results from additional custom APIs are used. Specify one or more methods as the *value* of the `additional_use_results_methods` option. To specify multiple method names, separate them with `|`. The allowable formats for the method name are:

- Method name only (which will include all methods with that name, regardless of their containing type or namespace).
- Fully qualified name in the [documentation ID format](#), with an optional `M:` prefix.

For example, to specify that rule CA1806 should also check that the result from a method named `MyMethod1` is used, add the following key-value pair to an `.editorconfig` file in your project.

```
dotnet_code_quality.CA1806.additional_use_results_methods = MyMethod1
```

Or, use the fully qualified name to disambiguate or ensure that only a specific method with that name is included.

```
dotnet_code_quality.CA1806.additional_use_results_methods = M:MyNamespace.MyType.MyMethod1(ParamType)
```

EXAMPLE 1

The following example shows a class that ignores the result of calling `String.Trim`.

```

public class Book
{
    private readonly string _Title;

    public Book(string title)
    {
        if (title != null)
        {
            // Violates this rule
            title.Trim();
        }

        _Title = title;
    }

    public string Title
    {
        get { return _Title; }
    }
}

```

```

Public Class Book
    Public Sub New(ByVal title As String)

        If title IsNot Nothing Then
            ' Violates this rule
            title.Trim()
        End If

        Me.Title = title

    End Sub

    Public ReadOnly Property Title() As String

End Class

```

Example 2

The following example fixes the [Example 1](#) violation by assigning the result of `String.Trim` back to the variable it was called on.

```

public class Book
{
    private readonly string _Title;

    public Book(string title)
    {
        if (title != null)
        {
            title = title.Trim();
        }

        _Title = title;
    }

    public string Title
    {
        get { return _Title; }
    }
}

```

```

Public Class Book
    Public Sub New(ByVal title As String)

        If title IsNot Nothing Then
            title = title.Trim()
        End If

        Me.Title = title

    End Sub

    Public ReadOnly Property Title() As String

End Class

```

Example 3

The following example shows a method that does not use an object that it creates.

NOTE

This violation cannot be reproduced in Visual Basic.

```

public class Book
{
    public Book()
    {

    }

    public static Book CreateBook()
    {
        // Violates this rule
        new Book();
        return new Book();
    }
}

```

Example 4

The following example fixes the [Example 3](#) violation by removing the unnecessary creation of an object.

```

public class Book
{
    public Book()
    {

    }

    public static Book CreateBook()
    {
        return new Book();
    }
}

```

CA1810: Initialize reference type static fields inline

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1810
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A reference type declares an explicit static constructor.

Rule description

When a type declares an explicit static constructor, the just-in-time (JIT) compiler adds a check to each static method and instance constructor of the type to make sure that the static constructor was previously called. Static initialization is triggered when any static member is accessed or when an instance of the type is created. However, static initialization is not triggered if you declare a variable of the type but do not use it, which can be important if the initialization changes global state.

When all static data is initialized inline and an explicit static constructor is not declared, Microsoft intermediate language (MSIL) compilers add the `beforefieldinit` flag and an implicit static constructor, which initializes the static data, to the MSIL type definition. When the JIT compiler encounters the `beforefieldinit` flag, most of the time the static constructor checks are not added. Static initialization is guaranteed to occur at some time before any static fields are accessed but not before a static method or instance constructor is invoked. Note that static initialization can occur at any time after a variable of the type is declared.

Static constructor checks can decrease performance. Often a static constructor is used only to initialize static fields, in which case you must only make sure that static initialization occurs before the first access of a static field. The `beforefieldinit` behavior is appropriate for these and most other types. It is only inappropriate when static initialization affects global state and one of the following is true:

- The effect on global state is expensive and is not required if the type is not used.
- The global state effects can be accessed without accessing any static fields of the type.

How to fix violations

To fix a violation of this rule, initialize all static data when it is declared and remove the static constructor.

When to suppress warnings

It is safe to suppress a warning from this rule if one of the following applies:

- Performance is not a concern.
- Global state changes that are caused by static initialization are expensive or must be guaranteed to occur before a static method of the type is called or an instance of the type is created.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1810
// The code that's violating the rule is on this line.
#pragma warning restore CA1810
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1810.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type, `StaticConstructor`, that violates the rule and a type, `NoStaticConstructor`, that replaces the static constructor with inline initialization to satisfy the rule.

```
public class StaticConstructor
{
    static int someInteger;
    static string resourceString;

    static StaticConstructor()
    {
        someInteger = 3;
        ResourceManager stringManager =
            new ResourceManager("strings", Assembly.GetExecutingAssembly());
        resourceString = stringManager.GetString("string");
    }

    public void Print()
    {
        Console.WriteLine(someInteger);
    }
}

public class NoStaticConstructor
{
    static int someInteger = 3;
    static string resourceString = InitializeResourceString();

    static string InitializeResourceString()
    {
        ResourceManager stringManager =
            new ResourceManager("strings", Assembly.GetExecutingAssembly());
        return stringManager.GetString("string");
    }

    public void Print()
    {
        Console.WriteLine(someInteger);
    }
}
```

```

Imports System
Imports System.Resources

Namespace ca1810

    Public Class StaticConstructor

        Shared someInteger As Integer
        Shared resourceString As String

        Shared Sub New()

            someInteger = 3
            Dim stringManager As New ResourceManager("strings",
                System.Reflection.Assembly.GetExecutingAssembly())
            resourceString = stringManager.GetString("string")

        End Sub

    End Class

    Public Class NoStaticConstructor

        Shared someInteger As Integer = 3
        Shared resourceString As String = InitializeResourceString()

        Private Shared Function InitializeResourceString()

            Dim stringManager As New ResourceManager("strings",
                System.Reflection.Assembly.GetExecutingAssembly())
            Return stringManager.GetString("string")

        End Function

    End Class

End Namespace

```

Note the addition of the `beforefieldinit` flag on the MSIL definition for the `NoStaticConstructor` class.

```

.class public auto ansi StaticConstructor
extends [mscorlib]System.Object
{
} // end of class StaticConstructor

.class public auto ansi beforefieldinit NoStaticConstructor
extends [mscorlib]System.Object
{
} // end of class NoStaticConstructor

```

Related rules

- [CA2207: Initialize value type static fields inline](#)

CA1812: Avoid uninstantiated internal classes

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1812
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An internal (assembly-level) type is never instantiated.

Rule description

This rule tries to locate a call to one of the constructors of the type and reports a violation if no call is found.

The following types are not examined by this rule:

- Value types
- Abstract types
- Enumerations
- Delegates
- Compiler-emitted array types
- Types that cannot be instantiated and that only define `static` (`Shared` in Visual Basic) methods.

If you apply the `System.Runtime.CompilerServices.InternalsVisibleToAttribute` to the assembly that's being analyzed, this rule will not flag types that are marked as `internal` (`Friend` in Visual Basic) because a field may be used by a friend assembly.

How to fix violations

To fix a violation of this rule, remove the type or add code that uses it. If the type contains only `static` methods, add one of the following to the type to prevent the compiler from emitting a default public instance constructor:

- The `static` modifier for C# types that target .NET Framework 2.0 or later.
- A private constructor for types that target .NET Framework versions 1.0 and 1.1.

When to suppress warnings

It is safe to suppress a warning from this rule. We recommend that you suppress this warning in the following situations:

- The class is created through late-bound reflection methods such as `System.Activator.CreateInstance`.
- The class is registered in an inversion of control (IoC) container as part of the `dependency injection`

pattern.

- The class is created automatically by the runtime or ASP.NET. Some examples of automatically created classes are those that implement [System.Configuration.IConfigurationSectionHandler](#) or [System.Web.IHttpHandler](#).
- The class is used as a type parameter in a class definition and has a [new](#) constraint. The following example will be flagged by rule CA1812:

```
internal class MyClass
{
    public void DoSomething()
    {
    }
}
public class MyGeneric<T> where T : new()
{
    public T Create()
    {
        return new T();
    }
}

MyGeneric<MyClass> mc = new MyGeneric<MyClass>();
mc.Create();
```

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1812
// The code that's violating the rule is on this line.
#pragma warning restore CA1812
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1812.severity = none
```

To disable this entire category of rules, set the severity for the category to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CA1801: Review unused parameters](#)

CA1813: Avoid unsealed attributes

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1813
Category	Performance
Fix is breaking or non-breaking	Breaking

Cause

A public type inherits from [System.Attribute](#), is not abstract, and is not sealed (`NotInheritable` in Visual Basic).

Rule description

.NET provides methods for retrieving custom attributes. By default, these methods search the attribute inheritance hierarchy. For example, [System.Attribute.GetCustomAttribute](#) searches for the specified attribute type or any attribute type that extends the specified attribute type. Sealing the attribute eliminates the search through the inheritance hierarchy, and can improve performance.

How to fix violations

To fix a violation of this rule, seal the attribute type or make it abstract.

When to suppress warnings

It is safe to suppress a warning from this rule. Suppress only if you are defining an attribute hierarchy and cannot seal the attribute or make it abstract.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1813
// The code that's violating the rule is on this line.
#pragma warning restore CA1813
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1813.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a custom attribute that satisfies this rule.

```
// Satisfies rule: AvoidUnsealedAttributes.
[AttributeUsage(AttributeTargets.Class | AttributeTargets.Struct)]
public sealed class DeveloperAttribute : Attribute
{
    private string nameValue;
    public DeveloperAttribute(string name)
    {
        nameValue = name;
    }

    public string Name
    {
        get
        {
            return nameValue;
        }
    }
}
```

```
Imports System

Namespace ca1813

    ' Satisfies rule: AvoidUnsealedAttributes.
    <AttributeUsage(AttributeTargets.Class Or AttributeTargets.Struct)>
    Public NotInheritable Class DeveloperAttribute
        Inherits Attribute

        Public Sub New(name As String)
            Me.Name = name
        End Sub

        Public ReadOnly Property Name() As String
    End Class

End Namespace
```

CA1814: Prefer jagged arrays over multidimensional

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1814
Category	Performance
Fix is breaking or non-breaking	Breaking

Cause

A member is declared as a multidimensional array, which can result in wasted space for some data sets.

Rule description

In a [multidimensional array](#), each element in each dimension has the same, fixed size as the other elements in that dimension. In a [jagged array](#), which is an array of arrays, each inner array can be of a different size. By only using the space that's needed for a given array, no space is wasted. This rule, CA1814, recommends switching to a jagged array to conserve memory.

How to fix violations

To fix a violation of this rule, change the multidimensional array to a jagged array.

When to suppress warnings

It's okay to suppress a warning from this rule if the multidimensional array does not waste space.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1814
// The code that's violating the rule is on this line.
#pragma warning restore CA1814
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1814.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows declarations for jagged and multidimensional arrays.

```
Imports System

Public Class ArrayHolder
    Private jaggedArray As Integer()() = {New Integer() {1, 2, 3, 4}, _
                                           New Integer() {5, 6, 7}, _
                                           New Integer() {8}, _
                                           New Integer() {9}}

    Private multiDimArray As Integer(,) = {{1, 2, 3, 4}, _
                                            {5, 6, 7, 0}, _
                                            {8, 0, 0, 0}, _
                                            {9, 0, 0, 0}}
End Class
```

```
public class ArrayHolder
{
    int[][] jaggedArray = { new int[] {1,2,3,4},
                           new int[] {5,6,7},
                           new int[] {8},
                           new int[] {9}
                         };

    int[,] multiDimArray = {{1,2,3,4},
                           {5,6,7,0},
                           {8,0,0,0},
                           {9,0,0,0}
                         };
}
```

CA1815: Override equals and operator equals on value types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1815
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A value type does not override [System.Object.Equals](#) or does not implement the equality operator (==). This rule does not check enumerations.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

For [non-blittable](#) value types, the inherited implementation of [Equals](#) uses the [System.Reflection](#) library to compare the contents of all fields. Reflection is computationally expensive, and comparing every field for equality might be unnecessary. If you expect users to compare or sort instances, or use them as hash table keys, your value type should implement [Equals](#). If your programming language supports operator overloading, you should also provide an implementation of the equality and inequality operators.

How to fix violations

To fix a violation of this rule, provide an implementation of [Equals](#). If you can, implement the equality operator.

When to suppress warnings

It's safe to suppress a warning from this rule if instances of the value type will not be compared to each other.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1815
// The code that's violating the rule is on this line.
#pragma warning restore CA1815
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1815.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Performance](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following code shows a structure (value type) that violates this rule:

```
// Violates this rule
public struct Point
{
    public Point(int x, int y)
    {
        X = x;
        Y = y;
    }

    public int X { get; }

    public int Y { get; }
}
```

The following code fixes the previous violation by overriding `System.ValueType.Equals` and implementing the equality operators (`==` and `!=`):

```

public struct Point : IEquatable<Point>
{
    public Point(int x, int y)
    {
        X = x;
        Y = y;
    }

    public int X { get; }

    public int Y { get; }

    public override int GetHashCode()
    {
        return X ^ Y;
    }

    public override bool Equals(object obj)
    {
        if (!(obj is Point))
            return false;

        return Equals((Point)obj);
    }

    public bool Equals(Point other)
    {
        if (X != other.X)
            return false;

        return Y == other.Y;
    }

    public static bool operator ==(Point point1, Point point2)
    {
        return point1.Equals(point2);
    }

    public static bool operator !=(Point point1, Point point2)
    {
        return !point1.Equals(point2);
    }
}

```

- [System.Object.Equals](#)

CA1819: Properties should not return arrays

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1819
Category	Performance
Fix is breaking or non-breaking	Breaking

Cause

A property returns an array.

By default, this rule only looks at externally visible properties and types, but this is [configurable](#).

Rule description

Arrays returned by properties are not write-protected, even if the property is read-only. To keep the array tamper-proof, the property must return a copy of the array. Typically, users won't understand the adverse performance implications of calling such a property. Specifically, they might use the property as an indexed property.

How to fix violations

To fix a violation of this rule, either make the property a method or change the property to return a collection.

When to suppress warnings

You can suppress a warning that's raised for a property of an attribute that's derived from the [Attribute](#) class. Attributes can contain properties that return arrays, but can't contain properties that return collections.

You can suppress the warning if the property is part of a [Data Transfer Object \(DTO\)](#) class.

Otherwise, do not suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1819
// The code that's violating the rule is on this line.
#pragma warning restore CA1819
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1819.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Performance](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example violation

The following example shows a property that violates this rule:

```
public class Book
{
    private string[] _Pages;

    public Book(string[] pages)
    {
        _Pages = pages;
    }

    public string[] Pages
    {
        get { return _Pages; }
    }
}
```

```
Public Class Book
    Public Sub New(ByVal pages As String())
        Me.Pages = pages
    End Sub

    Public ReadOnly Property Pages() As String()
End Class
```

To fix a violation of this rule, either make the property a method or change the property to return a collection instead of an array.

Change the property to a method

The following example fixes the violation by changing the property to a method:

```
Public Class Book

    Private _Pages As String()

    Public Sub New(ByVal pages As String())
        _Pages = pages
    End Sub

    Public Function GetPages() As String()
        ' Need to return a clone of the array so that consumers
        ' of this library cannot change its contents
        Return DirectCast(_Pages.Clone(), String())
    End Function

End Class
```

```
public class Book
{
    private string[] _Pages;

    public Book(string[] pages)
    {
        _Pages = pages;
    }

    public string[] GetPages()
    {
        // Need to return a clone of the array so that consumers
        // of this library cannot change its contents
        return (string[])_Pages.Clone();
    }
}
```

Change the property to return a collection

The following example fixes the violation by changing the property to return a [System.Collections.ObjectModel.ReadOnlyCollection<T>](#):

```
public class Book
{
    private ReadOnlyCollection<string> _Pages;
    public Book(string[] pages)
    {
        _Pages = new ReadOnlyCollection<string>(pages);
    }

    public ReadOnlyCollection<string> Pages
    {
        get { return _Pages; }
    }
}
```

```

Public Class Book
    Public Sub New(ByVal pages As String())
        Me.Pages = New ReadOnlyCollection(Of String)(pages)
    End Sub

    Public ReadOnly Property Pages() As ReadOnlyCollection(Of String)

End Class

```

Allow users to modify a property

You might want to allow the consumer of the class to modify a property. The following example shows a read/write property that violates this rule:

```

public class Book
{
    private string[] _Pages;

    public Book(string[] pages)
    {
        _Pages = pages;
    }

    public string[] Pages
    {
        get { return _Pages; }
        set { _Pages = value; }
    }
}

```

```

Public Class Book
    Public Sub New(ByVal pages As String())
        Me.Pages = pages
    End Sub

    Public Property Pages() As String()

End Class

```

The following example fixes the violation by changing the property to return a [System.Collections.ObjectModel.Collection<T>](#):

```

Public Class Book
    Public Sub New(ByVal pages As String())
        Me.Pages = New Collection(Of String)(pages)
    End Sub

    Public ReadOnly Property Pages() As Collection(Of String)
End Class

```

```
public class Book
{
    private Collection<string> _Pages;

    public Book(string[] pages)
    {
        _Pages = new Collection<string>(pages);
    }

    public Collection<string> Pages
    {
        get { return _Pages; }
    }
}
```

Related rules

- [CA1024: Use properties where appropriate](#)

CA1820: Test for empty strings using string length

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1820
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A string is compared to the empty string by using `Object.Equals`.

Rule description

Comparing strings using the `String.Length` property or the `String.IsNullOrEmpty` method is faster than using `Equals`. This is because `Equals` executes significantly more MSIL instructions than either `IsNullOrEmpty` or the number of instructions executed to retrieve the `Length` property value and compare it to zero.

For null strings, `Equals` and `<string>.Length == 0` behave differently. If you try to get the value of the `Length` property on a null string, the common language runtime throws a `System.NullReferenceException`. If you perform a comparison between a null string and the empty string, the common language runtime does not throw an exception and returns `false`. Testing for null does not significantly affect the relative performance of these two approaches. When targeting .NET Framework 2.0 or later, use the `IsNullOrEmpty` method. Otherwise, use the `Length == 0` comparison whenever possible.

How to fix violations

To fix a violation of this rule, change the comparison to use the `IsNullOrEmpty` method.

When to suppress warnings

It's safe to suppress a warning from this rule if performance is not an issue.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1820
// The code that's violating the rule is on this line.
#pragma warning restore CA1820
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1820.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example illustrates the different techniques that are used to look for an empty string.

```
public class StringTester
{
    string s1 = "test";

    public void EqualsTest()
    {
        // Violates rule: TestForEmptyStringsUsingStringLength.
        if (s1 == "")
        {
            Console.WriteLine("s1 equals empty string.");
        }
    }

    // Use for .NET Framework 1.0 and 1.1.
    public void LengthTest()
    {
        // Satisfies rule: TestForEmptyStringsUsingStringLength.
        if (s1 != null && s1.Length == 0)
        {
            Console.WriteLine("s1.Length == 0.");
        }
    }

    // Use for .NET Framework 2.0.
    public void NullOrEmptyTest()
    {
        // Satisfies rule: TestForEmptyStringsUsingStringLength.
        if (!String.IsNullOrEmpty(s1))
        {
            Console.WriteLine("s1 != null and s1.Length != 0.");
        }
    }
}
```

CA1821: Remove empty finalizers

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1821
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A type implements a finalizer that is empty, calls only the base type finalizer, or calls only conditionally emitted methods.

Rule description

Whenever you can, avoid finalizers because of the additional performance overhead that's involved in tracking object lifetime. The garbage collector runs the finalizer before it collects the object. This means that at least two collections are required to collect the object. An empty finalizer incurs this added overhead without any benefit.

How to fix violations

Remove the empty finalizer. If a finalizer is required for debugging, enclose the whole finalizer in

`#if DEBUG / #endif` directives.

When to suppress warnings

Do not suppress a message from this rule.

Example

The following example shows an empty finalizer that should be removed, a finalizer that should be enclosed in

`#if DEBUG / #endif` directives, and a finalizer that uses the `#if DEBUG / #endif` directives correctly.

```
public class Class1
{
    // Violation occurs because the finalizer is empty.
    ~Class1()
    {
    }
}

public class Class2
{
    // Violation occurs because Debug.Fail is a conditional method.
    // The finalizer will contain code only if the DEBUG directive
    // symbol is present at compile time. When the DEBUG
    // directive is not present, the finalizer will still exist, but
    // it will be empty.
    ~Class2()
    {
        Debug.Fail("Finalizer called!");
    }
}

public class Class3
{
#if DEBUG
    // Violation will not occur because the finalizer will exist and
    // contain code when the DEBUG directive is present. When the
    // DEBUG directive is not present, the finalizer will not exist,
    // and therefore not be empty.
    ~Class3()
    {
        Debug.Fail("Finalizer called!");
    }
#endif
}
```

CA1822: Mark members as static

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1822
Category	Performance
Fix is breaking or non-breaking	<p>Non-breaking - If the member is not visible outside the assembly, regardless of the change you make.</p> <p>Non-breaking - If you just change the member to an instance member with the <code>this</code> keyword.</p> <p>Breaking - If you change the member from an instance member to a static member and it is visible outside the assembly.</p>

Cause

A member that does not access instance data is not marked as static (Shared in Visual Basic).

Rule description

Members that do not access instance data or call instance methods can be marked as static (Shared in Visual Basic). After you mark the methods as static, the compiler will emit nonvirtual call sites to these members. Emitting nonvirtual call sites will prevent a check at run time for each call that makes sure that the current object pointer is non-null. This can achieve a measurable performance gain for performance-sensitive code. In some cases, the failure to access the current object instance represents a correctness issue.

How to fix violations

Mark the member as static (or Shared in Visual Basic) or use 'this'/'Me' in the method body, if appropriate.

When to suppress warnings

It is safe to suppress a warning from this rule for previously shipped code for which the fix would be a breaking change.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1822
// The code that's violating the rule is on this line.
#pragma warning restore CA1822
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1822.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Performance](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Related rules

- [CA1812: Avoid uninstantiated internal classes](#)

CA1823: Avoid unused private fields

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1823
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule is reported when a private field exists in your code but is not used by any code path.

Rule description

Private fields were detected that do not appear to be accessed in the assembly.

How to fix violations

To fix a violation of this rule, remove the field or add code that uses it.

When to suppress warnings

It is safe to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1823
// The code that's violating the rule is on this line.
#pragma warning restore CA1823
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1823.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CA1812: Avoid uninstantiated internal classes](#)
- [CA1801: Review unused parameters](#)

CA1824: Mark assemblies with NeutralResourcesLanguageAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1824
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An assembly contains a ResX-based resource but does not have the [System.Resources.NeutralResourcesLanguageAttribute](#) applied to it.

Rule description

The [NeutralResourcesLanguageAttribute](#) attribute informs the resource manager of an app's default culture. If the default culture's resources are embedded in the app's main assembly, and [ResourceManager](#) has to retrieve resources that belong to the same culture as the default culture, the [ResourceManager](#) automatically uses the resources located in the main assembly instead of searching for a satellite assembly. This bypasses the usual assembly probe, improves lookup performance for the first resource you load, and can reduce your working set.

TIP

See [Package and deploy resources](#) for the process that [ResourceManager](#) uses to probe for resource files.

Fix violations

To fix a violation of this rule, add the attribute to the assembly, and specify the language of the resources of the neutral culture.

To specify the neutral language for resources

1. In [Solution Explorer](#), right-click your project, and then select [Properties](#).
2. Select the [Package](#) tab.

NOTE

If your project is a .NET Framework project, select the [Application](#) tab, and then select [Assembly Information](#).

3. Select the language from the [Neutral language](#) or [Assembly neutral language](#) drop-down list.
4. Select [OK](#).

When to suppress warnings

It's permissible to suppress a warning from this rule. However, startup performance might degrade. To suppress this warning, add `dotnet_diagnostic.CA1824.severity = none` to your `.globalconfig` or `.editorconfig` file.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1824
// The code that's violating the rule is on this line.
#pragma warning restore CA1824
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1824.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

SEE ALSO

- [NeutralResourcesLanguageAttribute](#)
- [Resources in .NET apps](#)

CA1825: Avoid zero-length array allocations

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1825
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An empty [Array](#) with no elements is allocated.

Rule description

Initializing a zero-length array leads to an unnecessary memory allocation. Instead, use the statically allocated empty array instance by calling the [Array.Empty](#) method. The memory allocation is shared across all invocations of this method.

How to fix violations

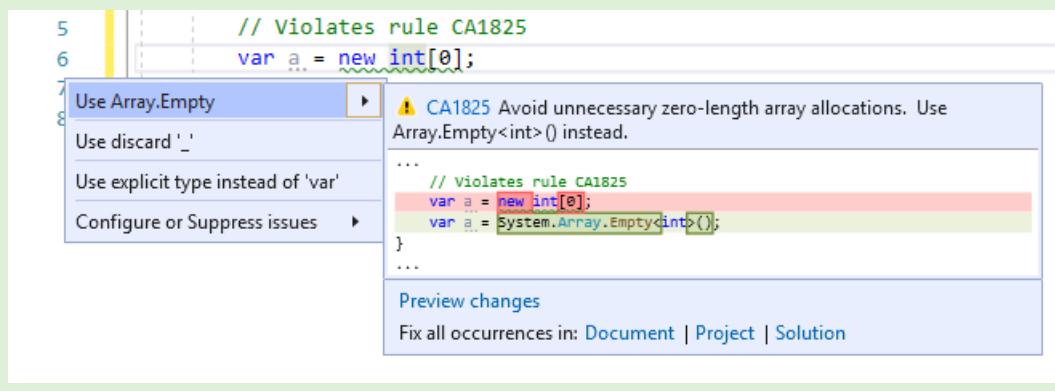

To fix a violation, replace the zero-length array allocation with a call to [Array.Empty](#). For example, the following two code snippets show a violation of the rule and how to fix it:

```
class C
{
    public void M1()
    {
        // Violates rule CA1825.
        var a = new int[0];
    }
}
```

```
class C
{
    public void M1()
    {
        // Resolves rule CA1825 violation.
        var a = System.Array.Empty<int>();
    }
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the array allocation and press **Ctrl+.** (period). Choose **Use Array.Empty** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the additional memory allocation.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1825
// The code that's violating the rule is on this line.
#pragma warning restore CA1825
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1825.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CA1814: Prefer jagged arrays over multidimensional](#)

See also

- [Performance rules](#)

CA1826: Use property instead of Linq Enumerable method

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1826
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

The [Enumerable](#) LINQ method was used on a type that supports an equivalent, more efficient property.

Rule description

This rule flags the [Enumerable](#) LINQ method calls on collections of types that have equivalent, but more efficient properties to fetch the same data.

This rule analyzes the following collection types:

- A type that implements [IReadOnlyList<T>](#), but not [IList<T>](#)

This rule flags calls to following methods on these collection types:

- [System.Linq.Enumerable.Count](#) method
- [System.Linq.Enumerable.First](#) method
- [System.Linq.Enumerable.FirstOrDefault](#) method
- [System.Linq.Enumerable.Last](#) method
- [System.Linq.Enumerable.LastOrDefault](#) method

The analyzed collection types and/or methods may be extended in future to cover more cases.

How to fix violations

To fix a violation, replace the [Enumerable](#) method calls with property access. For example, the following two code snippets show a violation of the rule and how to fix it:

```
using System;
using System.Collections.Generic;
using System.Linq;

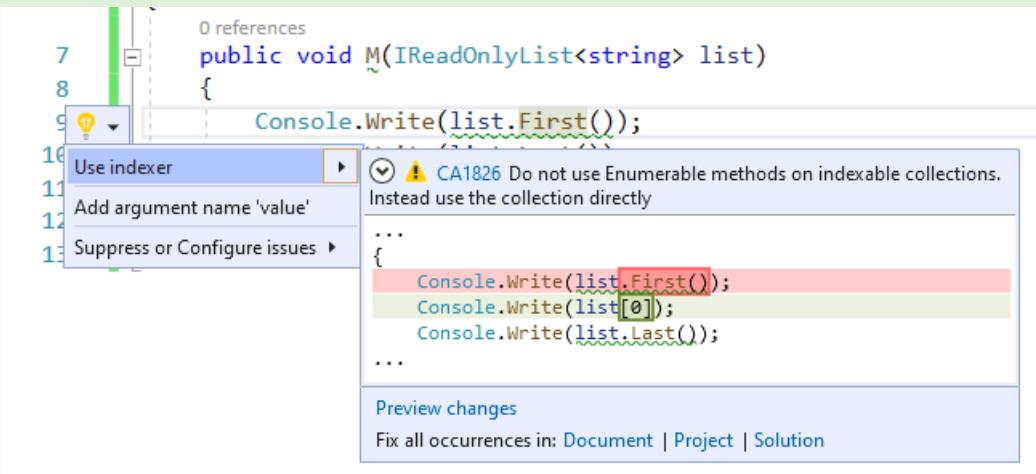

class C
{
    public void M(IReadOnlyList<string> list)
    {
        Console.WriteLine(list.First());
        Console.WriteLine(list.Last());
        Console.WriteLine(list.Count());
    }
}
```

```
using System;
using System.Collections.Generic;

class C
{
    public void M(IReadOnlyList<string> list)
    {
        Console.WriteLine(list[0]);
        Console.WriteLine(list[list.Count - 1]);
        Console.WriteLine(list.Count);
    }
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use indexer** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from specific [Enumerable](#) method calls.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1826
// The code that's violating the rule is on this line.
#pragma warning restore CA1826
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1826.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CA1827: Do not use Count/LongCount when Any can be used](#)
- [CA1828: Do not use CountAsync/LongCountAsync when AnyAsync can be used](#)
- [CA1829: Use Length/Count property instead of Enumerable.Count method](#)

See also

- [Performance rules](#)

CA1827: Do not use Count/LongCount when Any can be used

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1827
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

The [Count](#) or [LongCount](#) method was used where [Any](#) method would be more efficient.

Rule description

This rule flags the [Count](#) and [LongCount](#) LINQ method calls used to check if the collection has at least one element. These method calls require enumerating the entire collection to compute the count. The same check is faster with the [Any](#) method as it avoids enumerating the collection.

How to fix violations

To fix a violation, replace the [Count](#) or [LongCount](#) method call with the [Any](#) method. For example, the following two code snippets show a violation of the rule and how to fix it:

```
using System.Collections.Generic;
using System.Linq;

class C
{
    public string M1(IEnumerable<string> list)
        => list.Count() != 0 ? "Not empty" : "Empty";

    public string M2(IEnumerable<string> list)
        => list.LongCount() > 0 ? "Not empty" : "Empty";
}
```

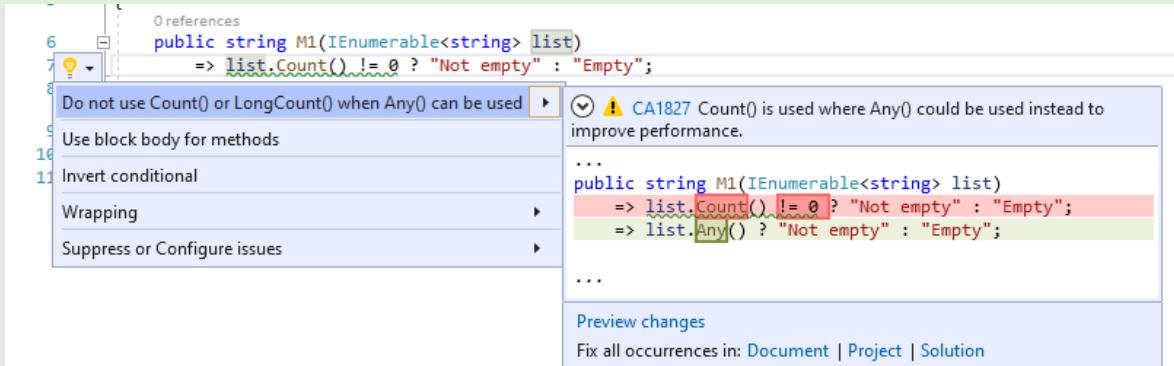

```
using System.Collections.Generic;
using System.Linq;

class C
{
    public string M1(IEnumerable<string> list)
        => list.Any() ? "Not empty" : "Empty";

    public string M2(IEnumerable<string> list)
        => list.Any() ? "Not empty" : "Empty";
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Do not use Count() or LongCount() when Any() can be used** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary collection enumeration to compute the count.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1827
// The code that's violating the rule is on this line.
#pragma warning restore CA1827
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1827.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1828: Do not use CountAsync/LongCountAsync when AnyAsync can be used

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1828
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

[CountAsync](#) or The [LongCountAsync](#) method was used where the [AnyAsync](#) method would be more efficient.

Rule description

This rule flags the [CountAsync](#) and [LongCountAsync](#) LINQ method calls used to check if the collection has at least one element. These method calls require enumerating the entire collection to compute the count. The same check is faster with the [AnyAsync](#) method as it avoids enumerating the collection.

How to fix violations

To fix a violation, replace the [CountAsync](#) or [LongCountAsync](#) method call with the [AnyAsync](#) method. For example, the following two code snippets show a violation of the rule and how to fix it:

```
using System.Linq;
using System.Threading.Tasks;
using static Microsoft.EntityFrameworkCore.EntityFrameworkQueryExtensions;

class C
{
    public async Task<string> M1Async(IQueryable<string> list)
        => await list.CountAsync() != 0 ? "Not empty" : "Empty";

    public async Task<string> M2Async(IQueryable<string> list)
        => await list.LongCountAsync() > 0 ? "Not empty" : "Empty";
}
```

```

using System.Linq;
using System.Threading.Tasks;
using static Microsoft.EntityFrameworkCore.EntityFrameworkQueryExtensions;

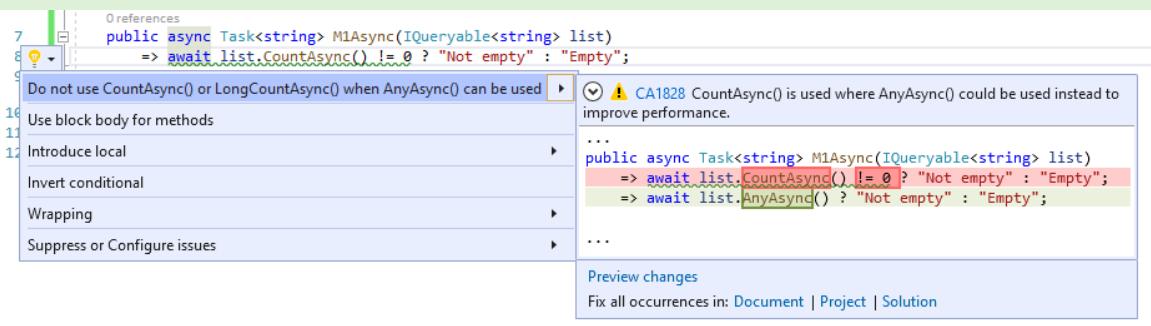

class C
{
    public async Task<string> M1Async(IQueryable<string> list)
        => await list.AnyAsync() ? "Not empty" : "Empty";

    public async Task<string> M2Async(IQueryable<string> list)
        => await list.AnyAsync() ? "Not empty" : "Empty";
}

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Do not use CountAsync() or LongCountAsync() when AnyAsync() can be used** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary collection enumeration to compute the count.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```

#pragma warning disable CA1828
// The code that's violating the rule is on this line.
#pragma warning restore CA1828

```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```

[*.{cs,vb}]
dotnet_diagnostic.CA1828.severity = none

```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```

[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none

```

For more information, see [How to suppress code analysis warnings](#).

Related rules

CA1829: Use Length/Count property instead of Enumerable.Count method

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1829
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

The `Count` LINQ method was used on a type that supports an equivalent, more efficient `Length` or `Count` property.

Rule description

This rule flags the `Count` LINQ method calls on collections of types that have equivalent, but more efficient `Length` or `Count` property to fetch the same data. `Length` or `Count` property does not enumerate the collection, hence is more efficient.

This rule flags `Count` calls on the following collection types with `Length` property:

- `System.Array`
- `System.Collections.Immutable.ImmutableArray<T>`

This rule flags `Count` calls on the following collection types with the `Count` property:

- `System.Collections.ICollection`
- `System.Collections.Generic.ICollection<T>`
- `System.Collections.Generic.IReadOnlyCollection<T>`

The analyzed collection types may be extended in future to cover more cases.

How to fix violations

To fix a violation, replace the `Count` method call with use of the `Length` or `Count` property access. For example, the following two code snippets show a violation of the rule and how to fix it:

```

using System.Collections.Generic;
using System.Linq;

class C
{
    public int GetCount(int[] array)
        => array.Count();

    public int GetCount(ICollection<int> collection)
        => collection.Count();
}

```

```

using System.Collections.Generic;

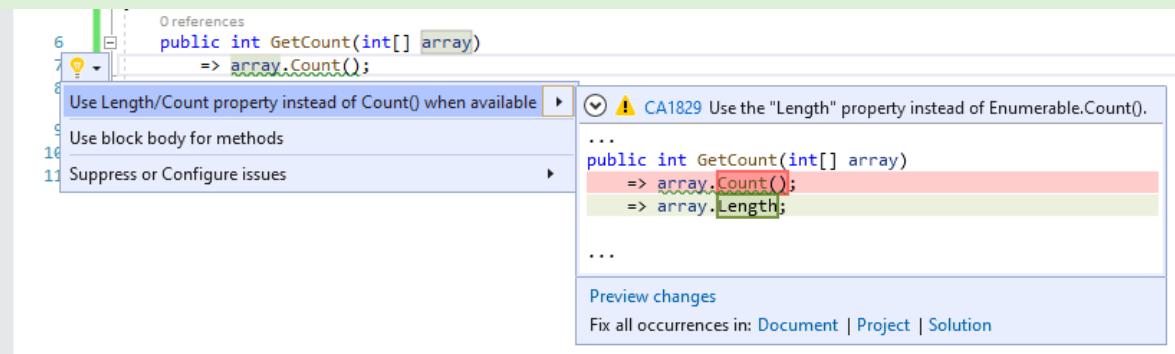

class C
{
    public int GetCount(int[] array)
        => array.Length;

    public int GetCount(ICollection<int> collection)
        => collection.Count();
}

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use Length/Count property instead of Count() when available** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary collection enumeration to compute the count.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```

#pragma warning disable CA1829
// The code that's violating the rule is on this line.
#pragma warning restore CA1829

```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1829.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1830: Prefer strongly-typed Append and Insert method overloads on StringBuilder.

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1830
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An `StringBuilder` `Append` or `Insert` method was called with an argument that was the result of calling `ToString` on a type for which the `Append` or `Insert` method has a dedicated overload.

Rule description

`Append` and `Insert` provide overloads for multiple types beyond `String`. When possible, prefer the strongly-typed overloads over using `ToString()` and the string-based overload.

How to fix violations

Delete the unnecessary `ToString()` from the invocation.

```
using System.Text;

class C
{
    int _value;

    // Violation
    public void Log(StringBuilder destination)
    {
        destination.Append("Value: ").Append(_value.ToString()).AppendLine();
    }

    // Fixed
    public void Log(StringBuilder destination)
    {
        destination.Append("Value: ").Append(_value).AppendLine();
    }
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary string allocations.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1830
// The code that's violating the rule is on this line.
#pragma warning restore CA1830
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1830.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1831: Use AsSpan instead of Range-based indexers for string when appropriate

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1831
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A range-indexer is used on a string and the value is implicitly assigned to `ReadOnlySpan<char>`.

Rule description

This rule fires when you use a range-indexer on a string and assign it to a span type. The range indexer on a `Span<T>` is a non-copying `Slice` operation, but for the range indexer on a string, the method `Substring` will be used instead of `Slice`. This produces a copy of the requested portion of the string. This copy is usually unnecessary when it's implicitly used as a `ReadOnlySpan<T>` or `ReadOnlyMemory<T>` value. If a copy isn't intended, use the `AsSpan` method to avoid the unnecessary copy. If the copy is intended, either assign it to a local variable first or add an explicit cast. The analyzer only reports when an implicit cast is used on the result of the range indexer operation.

Detects

Implicit conversion:

```
ReadOnlySpan<char> slice = str[a..b];
```

Does not detect

Explicit conversion:

```
ReadOnlySpan<char> slice = (ReadOnlySpan<char>)str[a..b];
```

How to fix violations

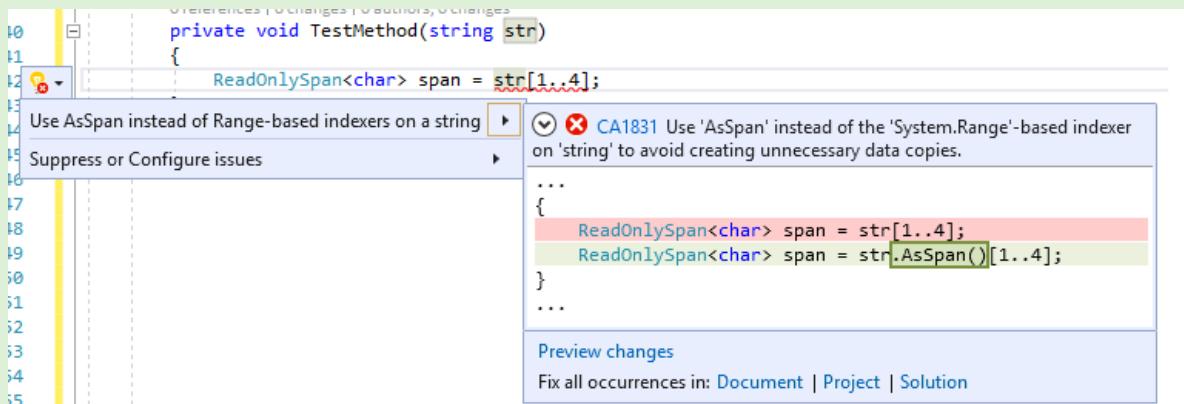

To fix a violation of this rule, use `AsSpan` instead of the `Range`-based indexer on the string to avoid creating unnecessary data copies.

```
public void TestMethod(string str)
{
    // The violation occurs
    ReadOnlySpan<char> slice = str[1..3];
    ...
}
```

```
public void TestMethod(string str)
{
    // The violation fixed with AsSpan extension method
    ReadOnlySpan<char> slice = str.AsSpan()[1..3];
    ...
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use AsSpan instead of the Range-based indexer on a string** from the list of options that's presented.

You can also add an explicit cast to avoid this warning.

```
public void TestMethod(string str)
{
    // The violation occurs.
    ReadOnlySpan<char> slice = str[1..3];
    ...
}
```

```
public void TestMethod(string str)
{
    // The violation avoided with explicit casting.
    ReadOnlySpan<char> slice = (ReadOnlySpan<char>)str[1..3];
    ...
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if creating a copy is intended.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1831
// The code that's violating the rule is on this line.
#pragma warning restore CA1831
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1831.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1832: Use AsSpan or AsMemory instead of Range-based indexers for getting ReadOnlySpan or ReadOnlyMemory portion of an array

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1832
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

When using a range-indexer on an array and implicitly assigning the value to `ReadOnlySpan<T>` or `ReadOnlyMemory<T>`.

Rule description

Using a range-indexer on an array and assigning to a memory or span type: The range indexer on a `Span<T>` is a non-copying `Slice` operation, but for the range indexer on array the method `GetSubArray` will be used instead of `Slice`, which produces a copy of requested portion of the array. This copy is usually unnecessary when it is implicitly used as a `ReadOnlySpan<T>` or `ReadOnlyMemory<T>` value. If a copy isn't intended, use the `AsSpan` or `AsMemory` method to avoid the unnecessary copy. If the copy is intended, either assign it to a local variable first or add an explicit cast. The analyzer only reports when an implicit cast is used on the result of the range indexer operation.

Detects

Implicit conversions:

- `ReadOnlySpan<SomeT> slice = arr[a..b];`
- `ReadOnlyMemory<SomeT> slice = arr[a..b];`

Does not detect

Explicit conversions:

- `ReadOnlySpan<SomeT> slice = (ReadOnlySpan<SomeT>)arr[a..b];`
- `ReadOnlyMemory<SomeT> slice = (ReadOnlyMemory<SomeT>)arr[a..b];`

How to fix violations

To fix the violation of this rule: use the `AsSpan` or `AsMemory` extension method to avoid creating unnecessary data copies.

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violation occurs for both statements below
        ReadOnlySpan<byte> tmp1 = arr[0..2];
        ReadOnlyMemory<byte> tmp3 = arr[5..8];
        ...
    }
}

```

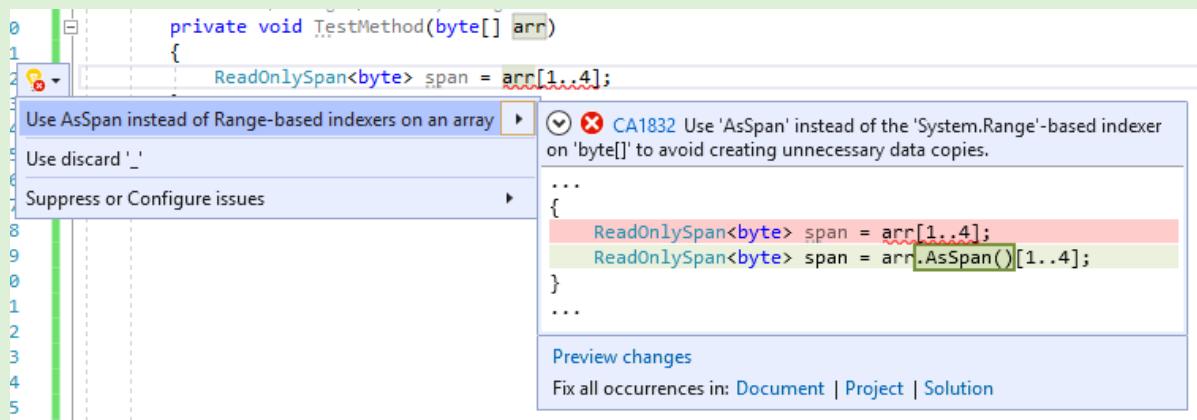

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violations fixed with AsSpan or AsMemory accordingly
        ReadOnlySpan<byte> tmp1 = arr.AsSpan()[0..2];
        ReadOnlyMemory<byte> tmp3 = arr.AsMemory()[5..8];
        ...
    }
}

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use AsSpan instead of the Range-based indexer on an array** from the list of options that is presented.

You can also avoid this warning by adding an explicit cast.

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violation occurs
        ReadOnlySpan<byte> tmp1 = arr[0..2];
        ReadOnlyMemory<byte> tmp3 = arr[5..8];
        ...
    }
}

```

```
class C
{
    public void TestMethod(byte arr[])
    {
        // The violation fixed with explicit casting
        ReadOnlySpan<byte> tmp1 = (ReadOnlySpan<byte>)arr[0..2];
        ReadOnlyMemory<byte> tmp3 = (ReadOnlyMemory<byte>)arr[5..8];
        ...
    }
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if creating a copy is intended.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1832
// The code that's violating the rule is on this line.
#pragma warning restore CA1832
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1832.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

- `Span<SomeT> slice = (Span<SomeT>)arr[a..b];`
- `Memory<SomeT> slice = (Memory<SomeT>)arr[a..b];`

How to fix violations

To fix the violation of this rule: use the `AsSpan` or `AsMemory` extension method to avoid creating unnecessary data copies.

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violation occurs for both statements below
        Span<byte> tmp2 = arr[0..5];
        Memory<byte> tmp4 = arr[5..10];
        ...
    }
}

```

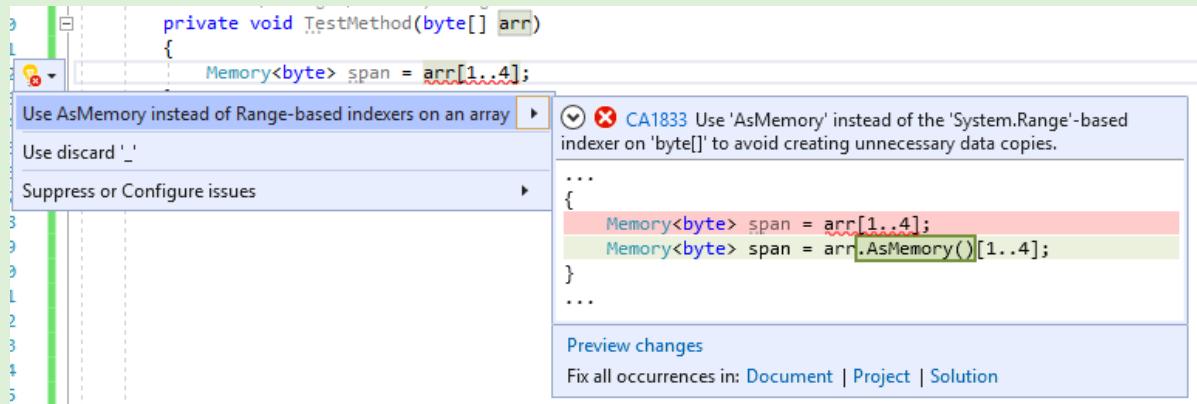

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violations fixed with AsSpan or AsMemory accordingly
        Span<byte> tmp2 = arr.AsSpan()[0..5];
        Memory<byte> tmp4 = arr.AsMemory()[5..10];
        ...
    }
}

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use AsMemory instead of the Range-based indexer on an array** from the list of options that's presented.

You can also avoid this warning by adding an explicit cast.

```

class C
{
    public void TestMethod(byte[] arr)
    {
        // The violation occurs
        Span<byte> tmp1 = arr[0..5];
        Memory<byte> tmp2 = arr[5..10];
        ...
    }
}

```

```
class C
{
    public void TestMethod(byte arr[])
    {
        // The violation fixed with explicit casting
        Span<byte> tmp1 = (Span<byte>)arr[0..5];
        Memory<byte> tmp2 = (Memory<byte>)arr[5..10];
        ...
    }
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if creating a copy is intended.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1833
// The code that's violating the rule is on this line.

CA1834: Use `StringBuilder.Append(char)` for single character strings

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1834
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when a unit length string is passed to the `Append` method.

Rule description

When calling `StringBuilder.Append` with a unit length string, consider using a `const char` rather than a unit length `const string` to improve performance.

How to fix violations

The violation can either be fixed manually, or, in some cases, using Quick Actions to fix code in Visual Studio.

Examples:

Example 1

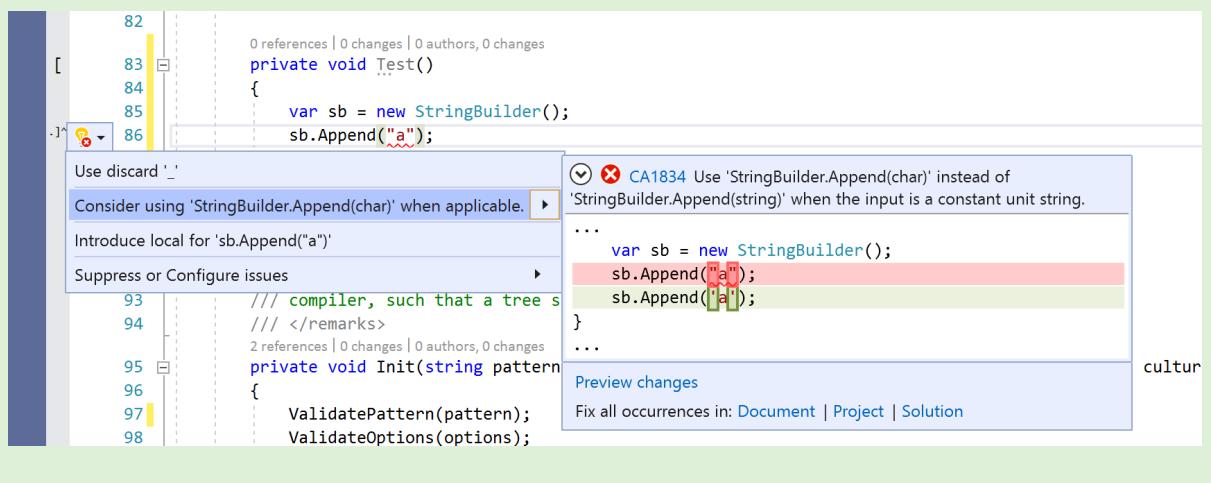

Invocations of `StringBuilder.Append` with a string literal of unit length:

```
using System;
using System.Text;

namespace TestNamespace
{
    class TestClass
    {
        private void TestMethod()
        {
            StringBuilder sb = new StringBuilder();
            sb.Append("a");
        }
    }
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.**. Choose **Consider using 'StringBuilder.Append(char)' when applicable.** from the list of options that is presented.

Fix applied by Visual Studio:

```
using System;
using System.Text;

namespace TestNamespace
{
    class TestClass
    {
        private void TestMethod()
        {
            StringBuilder sb = new StringBuilder();
            sb.Append('a');
        }
    }
}
```

In some cases, for example when using a unit length `const string` class field, a code-fix is not suggested by Visual Studio (but the analyzer still fires). These instances require a manual fix.

Example 2

Invocations of `StringBuilder.Append` with a `const string` class field of unit length:

```
using System;
using System.Text;

namespace TestNamespace
{
    public class Program
    {
        public const string unitString = "a";

        static void Main(string[] args)
        {
            StringBuilder sb = new StringBuilder();
            sb.Append(unitString);
        }
    }
}
```

After careful analysis, `unitString` here can be changed to a `char` without causing any build errors.

```
using System;
using System.Text;

namespace TestNamespace
{
    public class Program
    {
        public const char unitString = 'a';

        static void Main(string[] args)
        {
            StringBuilder sb = new StringBuilder();
            sb.Append(unitString);
        }
    }
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about improving performance when using `StringBuilder`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1834
// The code that's violating the rule is on this line.
#pragma warning restore CA1834
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1834.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Performance rules](#)

CA1835: Prefer the memory-based overloads of ReadAsync/WriteAsync methods in stream-based classes

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Type name	PreferStreamAsyncMemoryOverloads
Rule ID	CA1835
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates awaited invocations of the byte-array-based method overloads for `ReadAsync` and `WriteAsync`, and suggests using the memory-based method overloads instead, because they are more efficient.

Rule description

The memory-based method overloads have a more efficient memory usage than the byte array-based ones.

The rule works on `ReadAsync` and `WriteAsync` invocations of any class that inherits from `Stream`.

The rule only works when the method is preceded by the `await` keyword.

DETECTED METHOD	SUGGESTED METHOD
<code>ReadAsync(Byte[], Int32, Int32, CancellationToken)</code>	<code>ReadAsync(Memory<Byte>, CancellationToken)</code>
<code>ReadAsync(Byte[], Int32, Int32)</code>	<code>ReadAsync(Memory<Byte>, CancellationToken)</code> with <code>CancellationToken</code> set to <code>default</code> in C#, or <code>Nothing</code> in Visual Basic.
<code>WriteAsync(Byte[], Int32, Int32, CancellationToken)</code>	<code>WriteAsync(ReadOnlyMemory<Byte>, CancellationToken)</code>
<code>WriteAsync(Byte[], Int32, Int32)</code>	<code>WriteAsync(ReadOnlyMemory<Byte>, CancellationToken)</code> with <code>CancellationToken</code> set to <code>default</code> in C#, or <code>Nothing</code> in Visual Basic.

IMPORTANT

Make sure to pass the `offset` and `count` integer arguments to the created `Memory` or `ReadOnlyMemory` instances.

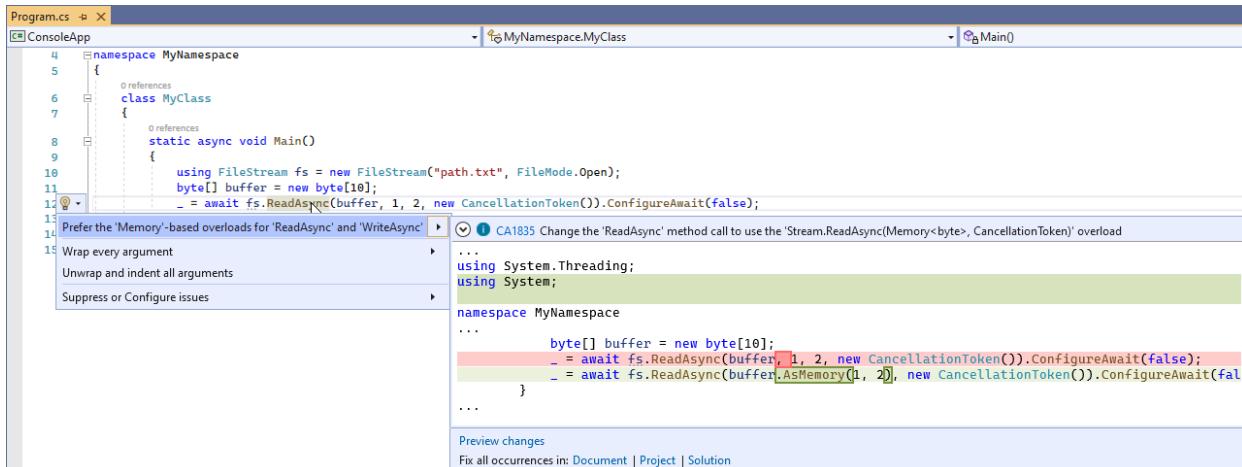

NOTE

Rule CA1835 is available in all .NET versions where the memory-based overloads are available:

- .NET Standard 2.1 and above.
- .NET Core 2.1 and above.

How to fix violations

You can either fix them manually, or you can opt to let Visual Studio do it for you, by hovering over the light bulb that shows up next to the method invocation, and selecting the suggested change. Example:

The rule can detect a variety of violations for the `ReadAsync` and `WriteAsync` methods. Here are examples of the cases that the rule can detect:

Example 1

Invocations of `ReadAsync`, without and with a `CancellationToken` argument:

```
using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod(CancellationToken ct)
    {
        using (FileStream s = new FileStream("path.txt", FileMode.Create))
        {
            byte[] buffer = new byte[s.Length];
            await s.ReadAsync(buffer, 0, buffer.Length);
            await s.ReadAsync(buffer, 0, buffer.Length, ct);
        }
    }
}
```

Fix:

```

using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod(CancellationToken ct)
    {
        using (FileStream s = new FileStream("path.txt", FileMode.Create))
        {
            byte[] buffer = new byte[s.Length];
            await s.ReadAsync(buffer.AsMemory(0, buffer.Length));
            await s.ReadAsync(buffer.AsMemory(0, buffer.Length), ct);
        }
    }
}

```

Example 2

Invocations of `WriteAsync`, without and with a `CancellationToken` argument:

```

using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod(CancellationToken ct)
    {
        using (FileStream s = File.Open("path.txt", FileMode.Open))
        {
            byte[] buffer = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
            await s.WriteAsync(buffer, 0, buffer.Length);
            await s.WriteAsync(buffer, 0, buffer.Length, ct);
        }
    }
}

```

Fix:

```

using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod()
    {
        using (FileStream s = File.Open("path.txt", FileMode.Open))
        {
            byte[] buffer = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
            await s.WriteAsync(buffer.AsMemory(0, buffer.Length));
            await s.WriteAsync(buffer.AsMemory(0, buffer.Length), ct);
        }
    }
}

```

Example 3

Invocations with `ConfigureAwait`:

```

using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod()
    {
        using (FileStream s = File.Open("path.txt", FileMode.Open))
        {
            byte[] buffer1 = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
            await s.WriteAsync(buffer1, 0, buffer1.Length).ConfigureAwait(false);

            byte[] buffer2 = new byte[s.Length];
            await s.ReadAsync(buffer2, 0, buffer2.Length).ConfigureAwait(true);
        }
    }
}

```

Fix:

```

using System;
using System.IO;
using System.Threading;

class MyClass
{
    public async void MyMethod()
    {
        using (FileStream s = File.Open("path.txt", FileMode.Open))
        {
            byte[] buffer1 = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
            await s.WriteAsync(buffer1.AsMemory(0, buffer1.Length)).ConfigureAwait(false);

            byte[] buffer2 = new byte[s.Length];
            await s.ReadAsync(buffer2.AsMemory(0, buffer2.Length)).ConfigureAwait(true);
        }
    }
}

```

Non-violations

Following are some examples of invocations where the rule will **not** be fired.

The return value is saved in a `Task` variable instead of being awaited:

```

using System;
using System.IO;
using System.Threading;
using System.Threading.Tasks;

class MyClass
{
    public void MyMethod()
    {
        byte[] buffer = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
        using (FileStream s = new FileStream("path.txt", FileMode.Create))
        {
            Task t = s.WriteAsync(buffer, 0, buffer.Length);
        }
    }
}

```

The return value is returned by the wrapping method instead of being awaited:

```
using System;
using System.IO;
using System.Threading;
using System.Threading.Tasks;

class MyClass
{
    public Task MyMethod(FileStream s, byte[] buffer)
    {
        return s.WriteAsync(buffer, 0, buffer.Length);
    }
}
```

The return value is used to call `ContinueWith`, which is the method being awaited:

```
using System;
using System.IO;
using System.Threading;
using System.Threading.Tasks;

class MyClass
{
    public void MyMethod()
    {
        byte[] buffer = { 0xBA, 0x5E, 0xBA, 0x11, 0xF0, 0x07, 0xBA, 0x11 };
        using (FileStream s = new FileStream("path.txt", FileMode.Create))
        {
            await s.WriteAsync(buffer, 0, buffer.Length).ContinueWith(c => { /* ... */ });
        }
    }
}
```

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about improving performance when reading or writing buffers in stream-based classes.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1835
// The code that's violating the rule is on this line.
#pragma warning restore CA1835
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1835.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1836: Prefer IsEmpty over Count when available

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1836
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

The `Count` or `Length` property or the `Count<TSource>(IEnumerable<TSource>)` extension method was used to determine whether or not the object contains any items by comparing the value to `0` or `1`, and the object has a more efficient `IsEmpty` property that could be used instead.

Rule description

This rule flags the calls to the `Count` and `Length` properties or `Count<TSource>(IEnumerable<TSource>)` and `LongCount<TSource>(IEnumerable<TSource>)` LINQ methods when they are used to determine if the object contains any items and the object has a more efficient `IsEmpty` property.

The analysis of this rule originally overlapped with similar rules CA1827, CA1828, and CA1829; the analyzers of such rules were merged along with the one for CA1836 to report the best diagnosis in case of overlap.

How to fix violations

To fix a violation, replace the `Count<TSource>(IEnumerable<TSource>)` or `LongCount<TSource>(IEnumerable<TSource>)` method call or the `Length` or `Count` property access when it's used in an operation that determines if the object is empty with use of the `IsEmpty` property access. For example, the following two code snippets show a violation of the rule and how to fix it:

```
using System.Collections.Concurrent;

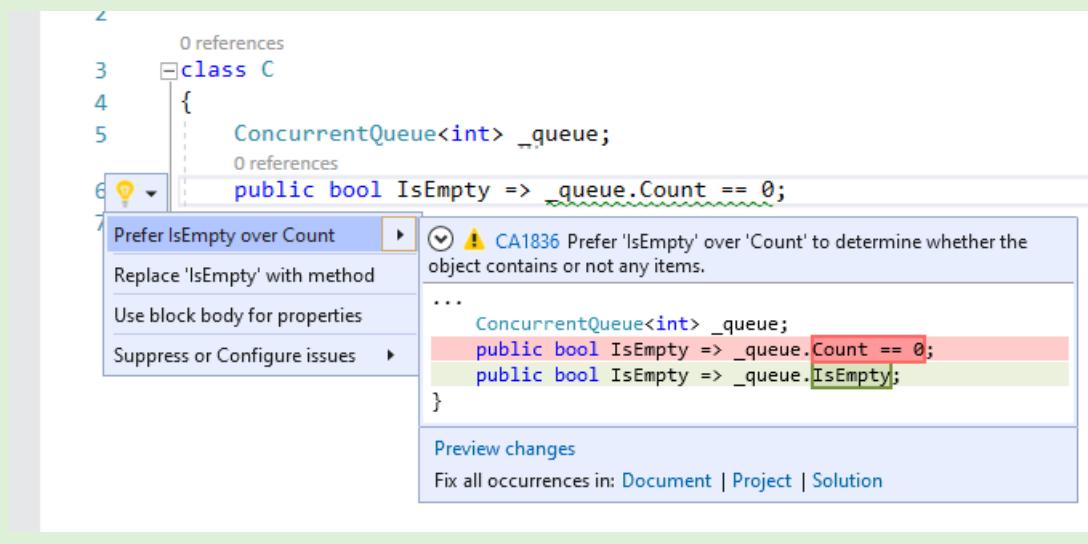

class C
{
    ConcurrentQueue<int> _queue;
    public bool IsEmpty => _queue.Count == 0;
}
```

```
using System.Collections.Concurrent;

class C
{
    ConcurrentQueue<int> _queue;
    public bool IsEmpty => _queue.IsEmpty;
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **'Prefer 'IsEmpty' over 'Count'** to determine whether the object contains or not any items from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary item enumeration to compute the count.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1836
// The code that's violating the rule is on this line.
#pragma warning restore CA1836
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1836.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1837: Use Environment.ProcessId instead of Process.GetCurrentProcess().Id

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1837
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates calls to `System.Diagnostics.Process.GetCurrentProcess().Id` and suggests using `System.Environment.ProcessId` instead, because it is more efficient.

Rule description

`System.Diagnostics.Process.GetCurrentProcess().Id` is expensive:

- It allocates a `Process` instance, usually just to get the `Id`.
- The `Process` instance needs to be disposed, which has a performance impact.
- It's easy to forget to call `Dispose()` on the `Process` instance.
- If nothing else besides `Id` uses the `Process` instance, then the linked size grows unnecessarily by increasing the graph of types referenced.
- It is somewhat difficult to discover or find this API.

`System.Environment.ProcessId` avoids all the above.

Note

Rule CA1837 is available starting on .NET 5.0.

How to fix violations

The violation can either be fixed manually, or, in some cases, using Quick Actions to fix code in Visual Studio.

The following two code snippets show a violation of the rule and how to fix it:

```
using System.Diagnostics;

class MyClass
{
    void MyMethod()
    {
        int pid = Process.GetCurrentProcess().Id;
    }
}
```

```

Imports System.Diagnostics

Class MyClass
    Private Sub MyMethod()
        Dim pid As Integer = Process.GetCurrentProcess().Id
    End Function
End Class

```

```

using System.Diagnostics;

class MyClass
{
    void MyMethod()
    {
        int pid = System.Environment.ProcessId;
    }
}

```

```

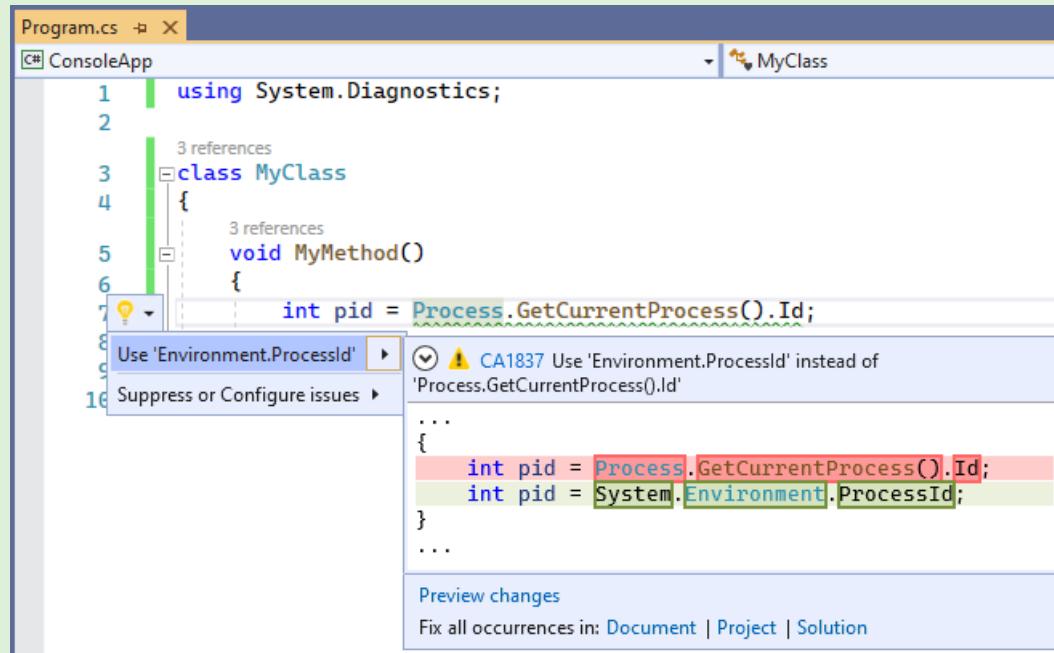

Imports System.Diagnostics

Class MyClass
    Private Sub MyMethod()
        Dim pid As Integer = System.Environment.ProcessId
    End Function
End Class

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use 'Environment.ProcessId' instead of 'Process.GetCurrentProcess().Id'** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary allocation and eventual disposal of a `Process` instance.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1837
// The code that's violating the rule is on this line.
#pragma warning restore CA1837
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1837.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1838: Avoid `StringBuilder` parameters for P/Invokes

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1838
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A [P/Invoke](#) has a `StringBuilder` parameter.

Rule description

Marshalling of `StringBuilder` always creates a native buffer copy, resulting in multiple allocations for one P/Invoke call. To marshal a `StringBuilder` as a P/Invoke parameter, the runtime will:

- Allocate a native buffer.
- If it is an `In` parameter, copy the contents of the `StringBuilder` to the native buffer.
- If it is an `Out` parameter, copy the native buffer into a newly allocated managed array.

By default, `StringBuilder` is `In` and `Out`.

For more information about marshalling strings, see [Default marshalling for strings](#).

This rule is disabled by default, because it can require case-by-case analysis of whether the violation is of interest and potentially non-trivial refactoring to address the violation. Users can explicitly enable this rule by [configuring its severity](#).

How to fix violations

In general, addressing a violation involves reworking the P/Invoke and its callers to use a buffer instead of `StringBuilder`. The specifics would depend on the use cases for the P/Invoke.

Here is an example for the common scenario of using `StringBuilder` as an output buffer to be filled by the native function:

```

// Violation
[DllImport("MyLibrary", CharSet = CharSet.Unicode)]
private static extern void Foo(StringBuilder sb, ref int length);

public void Bar()
{
    int BufferSize = ...
    StringBuilder sb = new StringBuilder(BufferSize);
    int len = sb.Capacity;
    Foo(sb, ref len);
    string result = sb.ToString();
}

```

For use cases where the buffer is small and `unsafe` code is acceptable, `stackalloc` can be used to allocate the buffer on the stack:

```

[DllImport("MyLibrary", CharSet = CharSet.Unicode)]
private static extern unsafe void Foo(char* buffer, ref int length);

public void Bar()
{
    int BufferSize = ...
    unsafe
    {
        char* buffer = stackalloc char[BufferSize];
        int len = BufferSize;
        Foo(buffer, ref len);
        string result = new string(buffer);
    }
}

```

For larger buffers, a new array can be allocated as the buffer:

```

[DllImport("MyLibrary", CharSet = CharSet.Unicode)]
private static extern void Foo([Out] char[] buffer, ref int length);

public void Bar()
{
    int BufferSize = ...
    char[] buffer = new char[BufferSize];
    int len = buffer.Length;
    Foo(buffer, ref len);
    string result = new string(buffer);
}

```

When the P/Invoke is frequently called for larger buffers, `ArrayPool<T>` can be used to avoid the repeated allocations and memory pressure that comes with them:

```
[DllImport("MyLibrary", CharSet = CharSet.Unicode)]
private static extern unsafe void Foo([Out] char[] buffer, ref int length);

public void Bar()
{
    int BufferSize = ...
    char[] buffer = ArrayPool<char>.Shared.Rent(BufferSize);
    try
    {
        int len = buffer.Length;
        Foo(buffer, ref len);
        string result = new string(buffer);
    }
    finally
    {
        ArrayPool<char>.Shared.Return(buffer);
    }
}
```

If the buffer size is not known until runtime, the buffer may need to be created differently based on the size to avoid allocating large buffers with `stackalloc`.

The preceding examples use 2-byte wide characters (`CharSet.Unicode`). If the native function uses 1-byte characters (`CharSet.Ansi`), a `byte` buffer can be used instead of a `char` buffer. For example:

```
[DllImport("MyLibrary", CharSet = CharSet.Ansi)]
private static extern unsafe void Foo(byte* buffer, ref int length);

public void Bar()
{
    int BufferSize = ...
    unsafe
    {
        byte* buffer = stackalloc byte[BufferSize];
        int len = BufferSize;
        Foo(buffer, ref len);
        string result = Marshal.PtrToStringAnsi((IntPtr)buffer);
    }
}
```

If the parameter is also used as input, the buffers need to be populated with the string data with any null terminator explicitly added.

When to suppress warnings

Suppress a violation of this rule if you're not concerned about the performance impact of marshalling a `StringBuilder`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1838
// The code that's violating the rule is on this line.
#pragma warning restore CA1838
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_diagnostic.CA1838.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1839: Use Environment.ProcessPath instead of Process.GetCurrentProcess().MainModule.FileName

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1839
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

Using `Process.GetCurrentProcess().MainModule.FileName` for getting the path to the file that launched the process instead of `Environment.ProcessPath`.

Rule description

`System.Diagnostics.Process.GetCurrentProcess().MainModule.FileName` is expensive:

- It allocates a `Process` and `ProcessModule` instance, usually just to get the `FileName`.
- The `Process` instance needs to be disposed, which has a performance impact.
- It's easy to forget to call `Dispose()` on the `Process` instance.
- If nothing else besides `FileName` uses the `Process` instance, then the linked size grows unnecessarily by increasing the graph of types referenced.
- It is somewhat difficult to discover or find this API.

`System.Environment.ProcessPath` avoids all of these downsides and produces the same information.

NOTE

`System.Environment.ProcessPath` is available starting in .NET 6.

How to fix violations

The violation can either be fixed manually, or, in some cases, using Quick Actions to fix code in Visual Studio.

The following two code snippets show a violation of the rule and how to fix it:

```
using System.Diagnostics;

class MyClass
{
    void MyMethod()
    {
        string path = Process.GetCurrentProcess().MainModule.FileName; // Violation occurs
    }
}
```

```

Imports System.Diagnostics

Class MyClass
    Private Sub MyMethod()
        Dim path As String = Process.GetCurrentProcess().MainModule.FileName ' Violation occurs.
    End Function
End Class

```

```

using System.Diagnostics;

class MyClass
{
    void MyMethod()
    {
        string path = System.Environment.ProcessPath; // Violation fixed
    }
}

```

```

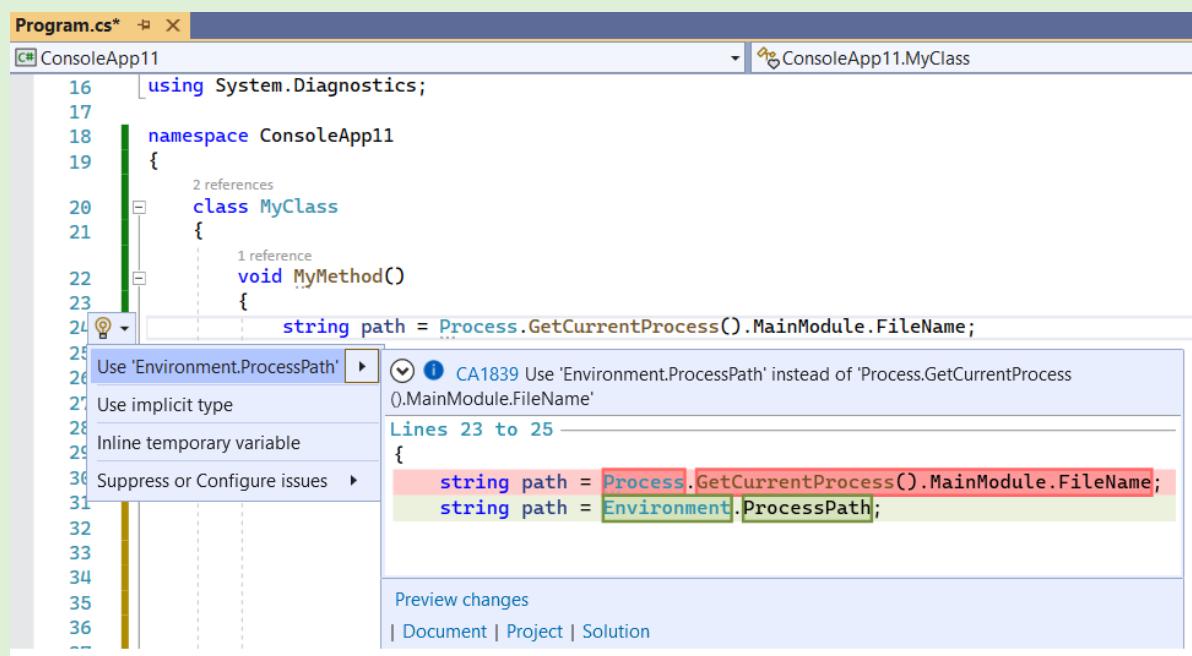

Imports System.Diagnostics

Class MyClass
    Private Sub MyMethod()
        Dim path As String = System.Environment.ProcessPath ' Violation fixed.
    End Function
End Class

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use 'Environment.ProcessPath'** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from unnecessary allocation and eventual disposal of the [Process](#) and [ProcessModule](#) instances.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1839
// The code that's violating the rule is on this line.
#pragma warning restore CA1839
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA1839.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1840: Use Environment.CurrentManagedThreadId instead of Thread.CurrentThread.ManagedThreadId

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1840
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

Using `Thread.CurrentThread.ManagedThreadId` for getting the current managed thread ID instead of `System.Environment.CurrentManagedThreadId`.

Rule description

`System.Environment.CurrentManagedThreadId` is a compact and efficient replacement of the `Thread.CurrentThread.ManagedThreadId` pattern.

How to fix violations

The violation can either be fixed manually, or, in some cases, using Quick Actions to fix code in Visual Studio.

The following two code snippets show a violation of the rule and how to fix it:

```
using System.Threading;

class MyClass
{
    void MyMethod()
    {
        int id = Thread.CurrentThread.ManagedThreadId; // Violation occurs
    }
}
```

```
Imports System.Threading

Class MyClass
    Private Sub MyMethod()
        Dim id As Integer = Thread.CurrentThread.ManagedThreadId ' Violation occurs.
    End Function
End Class
```

```

using System.Threading;

class MyClass
{
    void MyMethod()
    {
        int id = System.Environment.CurrentManagedThreadId; // Violation fixed
    }
}

```

```

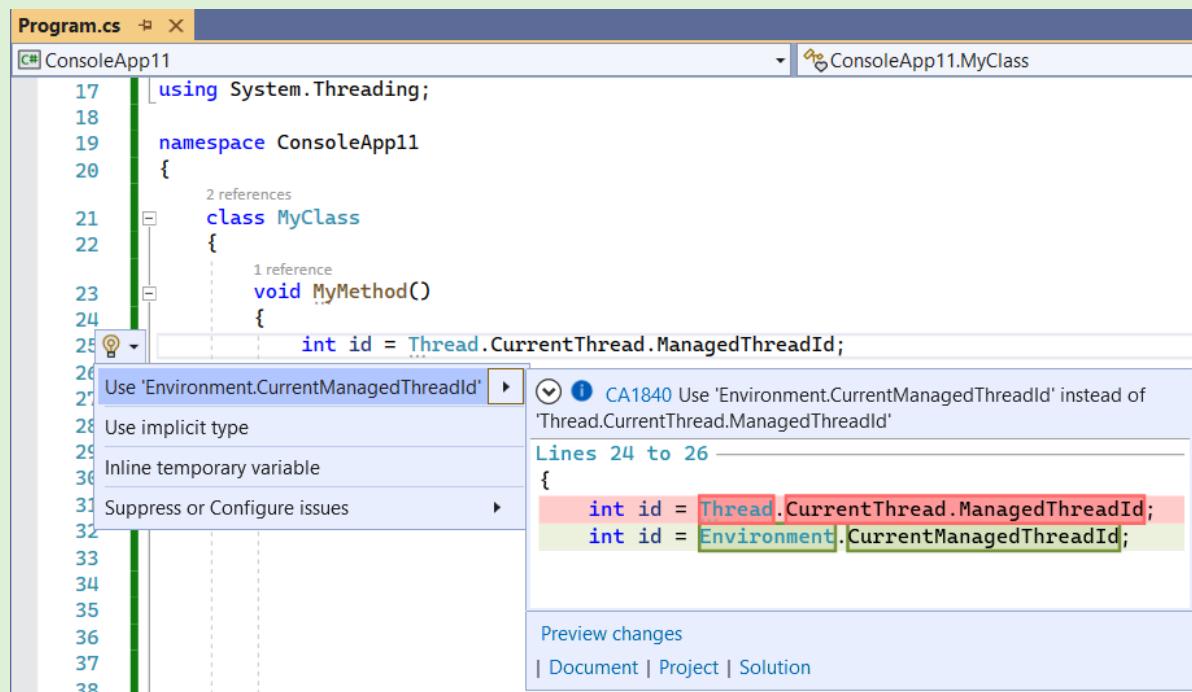

Imports System.Threading

Class MyClass
    Private Sub MyMethod()
        Dim id As Integer = System.Environment.CurrentManagedThreadId ' Violation fixed.
    End Function
End Class

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Use 'Environment.CurrentManagedThreadId'** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if you're not concerned about the performance impact from using `Thread.CurrentThread.ManagedThreadId`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1840
// The code that's violating the rule is on this line.
#pragma warning restore CA1840
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1840.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Use 'Environment.ProcessPath' instead of 'Process.GetCurrentProcess\(\).MainModule.FileName'](#)

CA1841: Prefer Dictionary Contains methods

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1841
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates calls to a `Contains` method on the `Keys` or `Values` collection of an `IDictionary< TKey, TValue >` that could be replaced with a call to a `ContainsKey` or `ContainsValue` method on the dictionary itself.

Rule description

Calling `Contains` on the `Keys` or `Values` collection can often be more expensive than calling `ContainsKey` or `ContainsValue` on the dictionary itself:

- Many dictionary implementations lazily instantiate the key and value collections, which means that accessing the `Keys` or `Values` collection may result in extra allocations.
- You may end up calling an extension method on `IEnumerable<T>` if the keys or values collection uses explicit interface implementation to hide methods on `ICollection<T>`. This can lead to reduced performance, especially when accessing the key collection. Most dictionary implementations are able to provide a fast O(1) containment check for keys, while the `Contains` extension method on `IEnumerable<T>` usually does a slow O(n) containment check.

How to fix violations

To fix violations, replace calls to `dictionary.Keys.Contains` or `dictionary.Values.Contains` with calls to `dictionary.ContainsKey` or `dictionary.ContainsValue`, respectively.

The following code snippet shows examples of violations, and how to fix them.

```

using System.Collections.Generic;
// Importing this namespace brings extension methods for IEnumarable<T> into scope.
using System.Linq;

class Example
{
    void Method()
    {
        var dictionary = new Dictionary<string, int>();

        // Violation
        dictionary.Keys.Contains("hello world");

        // Fixed
        dictionary.ContainsKey("hello world");

        // Violation
        dictionary.Values.Contains(17);

        // Fixed
        dictionary.ContainsValue(17);
    }
}

```

```

Imports System.Collection.Generic
' Importing this namespace brings extension methods for IEnumarable(Of T) into scope.
' Note that in Visual Basic, this namespace is often imported automatically throughout the project.
Imports System.Linq

Class Example
    Private Sub Method()
        Dim dictionary = New Dictionary(Of String, Of Integer)

        ' Violation
        dictionary.Keys.Contains("hello world")

        ' Fixed
        dictionary.ContainsKey("hello world")

        ' Violation
        dictionary.Values.Contains(17)

        ' Fixed
        dictionary.ContainsValue(17)
    End Sub
End Class

```

When to suppress warnings

It is safe to suppress warnings from this rule if the code in question is not performance-critical.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```

#pragma warning disable CA1841
// The code that's violating the rule is on this line.
#pragma warning restore CA1841

```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1841.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA1842: Do not use 'WhenAll' with a single task

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1842
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

[WhenAll](#) is called with a single task.

Rule description

Using `WhenAll` with a single task may result in performance loss.

How to fix violations

You should await or return the task instead.

When to suppress warnings

Do not suppress a warning from this rule.

See also

- [CA1843: Do not use 'WaitAll' with a single task](#)
- [Performance rules](#)

CA1843: Do not use 'WaitAll' with a single task

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1843
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

`WaitAll` is called with a single task.

Rule description

Using `WaitAll` with a single task may result in performance loss.

How to fix violations

You should await or return the task instead.

When to suppress warnings

Do not suppress a warning from this rule.

CA1844: Provide memory-based overrides of async methods when subclassing 'Stream'

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1844
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

A type derived from `Stream` overrides `ReadAsync(Byte[], Int32, Int32, CancellationToken)` but does not override `ReadAsync(Memory<Byte>, CancellationToken)`. Or, a type derived from `Stream` overrides `WriteAsync(Byte[], Int32, Int32, CancellationToken)` but does not override `WriteAsync(ReadOnlyMemory<Byte>, CancellationToken)`.

Rule description

The memory-based `ReadAsync` and `WriteAsync` methods were added to improve performance, which they accomplish in multiple ways:

- They return `ValueTask` and `ValueTask<int>` instead of `Task` and `Task<int>`, respectively.
- They allow any type of buffer to be passed in without having to perform an extra copy to an array.

In order to realize these performance benefits, types that derive from `Stream` must provide their own memory-based implementation. Otherwise, the default implementation will be forced to copy the memory into an array in order to call the array-based implementation, resulting in reduced performance. When the caller passes in a `Memory<T>` or `ReadOnlyMemory<T>` instance that's not backed by an array, performance is affected more.

How to fix violations

The easiest way to fix violations is to rewrite your array-based implementation as a memory-based implementation, and then implement the array-based methods in terms of the memory-based methods.

When to suppress warnings

It's safe to suppress a warning from this rule if any of the following situations apply:

- The performance hit is not a concern.
- You know that your `Stream` subclass will only ever use the array-based methods.
- Your `Stream` subclass has dependencies that don't support memory-based buffers.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1844
// The code that's violating the rule is on this line.
#pragma warning restore CA1844
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1844.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Performance rules](#)

CA1845: Use span-based 'string.Concat'

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1845
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates string-concatenation expressions that contain `Substring` calls and suggests replacing `Substring` with `AsSpan` and using the span-based overload of `String.Concat`.

Rule description

Calling `Substring` produces a copy of the extracted substring. By using `AsSpan` instead of `Substring` and calling the overload of `string.Concat` that accepts spans, you can eliminate the unnecessary string allocation.

How to fix violations

To fix violations:

1. Replace the string concatenation with a call to `string.Concat`, and
2. Replace calls to `Substring` with calls to `AsSpan`.

The following code snippet shows examples of violations, and how to fix them.

```
using System;

class Example
{
    public void Method()
    {
        string text = "fwobz the fwutzle";

        // Violation: allocations by Substring are wasteful.
        string s1 = text.Substring(10) + "___" + text.Substring(0, 5);

        // Fixed: using AsSpan avoids allocations of temporary strings.
        string s2 = string.Concat(text.Aspans(10), "___", text.Aspans(0, 5));
    }
}
```

When to suppress warnings

Do not suppress warnings from this rule. There is no reason to use `Substring` over `AsSpan` when the extracted substring is only being passed to a method with a span-based equivalent.

See also

- [Performance rules](#)

CA1846: Prefer `AsSpan` over `Substring`

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1846
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

The result of a call to one of the `String.Substring` overloads is passed to a method with an available overload that accepts `ReadOnlySpan<Char>`.

Rule description

`Substring` allocates a new `string` object on the heap and performs a full copy of the extracted text. String manipulation is a performance bottleneck for many programs. Allocating many small, short-lived strings on a hot path can create enough collection pressure to impact performance. The O(n) copies created by `Substring` become relevant when the substrings get large. The `Span<T>` and `ReadOnlySpan<T>` types were created to solve these performance problems.

Many APIs that accept strings also have overloads that accept a `ReadOnlySpan<System.Char>` argument. When such overloads are available, you can improve performance by calling `AsSpan` instead of `Substring`.

How to fix violations

To fix a violation of this rule, replace the call to `string.Substring` with a call to one of the `MemoryExtensions.AsSpan` extension methods.

```
using System;

public void MyMethod(string iniFileLine)
{
    // Violation
    int.TryParse(iniFileLine.Substring(7), out int x);
    int.TryParse(iniFileLine.Substring(2, 5), out int y);

    // Fix
    int.TryParse(iniFileLine.AsSpan(7), out int x);
    int.TryParse(iniFileLine.AsSpan(2, 5), out int y);
}
```

```
Imports System

Public Sub MyMethod(iniFileLine As String)
    Dim x As Integer
    Dim y As Integer

    ' Violation
    Integer.TryParse(iniFileLine.Substring(7), x)
    Integer.TryParse(iniFileLine.Substring(2, 5), y)

    ' Fix
    Integer.TryParse(iniFileLine.AsSpan(7), x)
    Integer.TryParse(iniFileLine.AsSpan(2, 5), y)
End Sub
```

When to suppress warnings

It is safe to suppress warnings from this rule if performance is not a concern.

See also

- [Performance warnings](#)

CA1847: Use string.Contains(char) instead of string.Contains(string) with single characters

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1847
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

`string.Contains(string)` is used when `string.Contains(char)` was available.

Rule description

When searching for a single character, using `string.Contains(char)` offers better performance than `string.Contains(string)`.

How to fix violations

In general, the rule is fixed simply by using a char literal instead of a string literal.

```
public bool ContainsLetterI()
{
    var testString = "I am a test string.";
    return testString.Contains("I");
}
```

```
Public Function ContainsLetterI() As Boolean
    Dim testString As String = "I am a test string."
    Return testString.Contains("I")
End Function
```

This code can be changed to use a char literal instead.

```
public bool ContainsLetterI()
{
    var testString = "I am a test string.";
    return testString.Contains('I');
}
```

```
Public Function ContainsLetterI() As Boolean
    Dim testString As String = "I am a test string."
    Return testString.Contains("I"c)
End Function
```

When to suppress warnings

Suppress a violation of this rule if you're not concerned about the performance impact of the search invocation in question.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1847
// The code that's violating the rule is on this line.
#pragma warning restore CA1847
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1847.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Performance rules](#)

CA1848: Use the LoggerMessage delegates

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1848
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

Use of [logger extension methods](#), such as [LogInformation](#) and [LogDebug](#).

Rule description

For high-performance logging scenarios, use the [LoggerMessage](#) pattern.

How to fix violations

Use [LoggerMessage](#) to fix violations of this rule.

[LoggerMessage](#) provides the following performance advantages over Logger extension methods:

- Logger extension methods require "boxing" (converting) value types, such as `int`, into `object`. The [LoggerMessage](#) pattern avoids boxing by using static `Action` fields and extension methods with strongly typed parameters.
- Logger extension methods must parse the message template (named format string) every time a log message is written. [LoggerMessage](#) only requires parsing a template once when the message is defined.

When to suppress warnings

Do not suppress a warning from this rule.

See also

- [High-performance logging with LoggerMessage in ASP.NET Core](#)
- [Performance rules](#)

CA1849: Call async methods when in an async method

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1849
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

All methods where an Async-suffixed equivalent exists will produce this warning when called from a Task-returning method. In addition, calling `Task.Wait()`, `Task<T>.Result`, or `Task.GetAwaiter().GetResult()` will produce this warning.

Rule description

In a method which is already asynchronous, calls to other methods should be to their async versions, where they exist.

How to fix violations

Violation:

```
Task DoAsync()
{
    file.Read(buffer, 0, 10);
}
```

Fix:

Await the async version of the method:

```
async Task DoAsync()
{
    await file.ReadAsync(buffer, 0, 10);
}
```

When to suppress warnings

It's safe to suppress a warning from this rule in the case where there are two separate code paths for sync and async code, using an if condition. Also if there is a check for whether the Task has resolved, it is safe to use sync methods and properties.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1849
// The code that's violating the rule is on this line.
#pragma warning restore CA1849
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1849.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Performance rules](#)

CA1850: Prefer static `HashData` method over

`ComputeHash`

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1850
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An instance of a type that derives from `HashAlgorithm` is created to call its `computeHash` method, and that type has a static `HashData` method.

Rule description

Static `HashData` methods were introduced in .NET 5 on the following types:

- [MD5](#)
- [SHA1](#)
- [SHA256](#)
- [SHA384](#)
- [SHA512](#)

These methods help simplify code in cases where you just want to hash some data.

It's more efficient to use these static `HashData` methods than to create and manage a `HashAlgorithm` instance to call `ComputeHash`.

How to fix violations

In general, you can fix the rule by changing your code to call `HashData` and remove use of the `HashAlgorithm` instance.

```
public bool CheckHash(byte[] buffer)
{
    using (var sha256 = SHA256.Create())
    {
        byte[] digest = sha256.ComputeHash(buffer);
        return DoesHashExist(digest);
    }
}
```

```
Public Function CheckHash(buffer As Byte()) As Boolean
    Using sha256 As SHA256 = SHA256.Create()
        Dim digest As Byte() = sha256.ComputeHash(buffer)
        Return DoesHashExist(digest)
    End Using
End Function
```

The previous code can be changed to call the static [HashData\(Byte\[\]\)](#) method directly.

```
public bool CheckHash(byte[] buffer)
{
    byte[] digest = SHA256.HashData(buffer);
    return DoesHashExist(digest);
}
```

```
Public Function CheckHash(buffer As Byte()) As Boolean
    Dim digest As Byte() = SHA256.HashData(buffer)
    Return DoesHashExist(digest)
End Function
```

When to suppress warnings

It is safe to suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1850
// The code that's violating the rule is on this line.
#pragma warning restore CA1850
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1850.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Performance rules](#)

CA1851: Possible multiple enumerations of `IEnumerable` collection

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1851
Category	Performance
Fix is breaking or non-breaking	Non-breaking
Introduced version	.NET 7

Cause

Detected multiple enumerations of an `IEnumerable` collection.

Rule description

A collection of type `IEnumerable` or `IEnumerable<T>` has the ability to defer enumeration when it's generated. Many LINQ methods, such as `Select`, use `deferred execution`. Enumeration starts when the collection is passed into a LINQ enumeration method, like `ElementAt`, or used in a `for each statement`. The enumeration result is not calculated once and cached, like `Lazy`.

If the enumeration operation itself is expensive, for example, a query into a database, multiple enumerations would hurt the performance of the program.

If the enumeration operation has side effects, multiple enumerations might result in bugs.

How to fix violations

If the underlying type of your `IEnumerable` collection is some other type, such as `List` or `Array`, it's safe to convert the collection to its underlying type to fix the diagnostic.

Violation:

```
public void MyMethod(IEnumerable<int> input)
{
    var count = input.Count();
    foreach (var i in input) { }
}
```

```
Public Sub MyMethod(input As IEnumerable(Of Integer))
    Dim count = input.Count()
    For Each i In input
        Next
    End Sub
```

Fix:

```
public void MyMethod(IEnumerable<int> input)
{
    // If the underlying type of 'input' is List<int>
    var inputList = (List<int>)input;
    var count = inputList.Count();
    foreach (var i in inputList) { }
}
```

```
Public Sub MyMethod(input As IEnumerable(Of Integer))
    ' If the underlying type of 'input' is array
    Dim inputArray = CType(input, Integer())
    Dim count = inputArray.Count()
    For Each i In inputArray
        Next
End Sub
```

If the underlying type of the `IEnumerable` collection uses an iterator-based implementation (for example, if it's generated by LINQ methods like `Select` or by using the `yield` keyword), you can fix the violation by materializing the collection. However, this allocates extra memory.

For example:

Violation:

```
public void MyMethod()
{
    var someStrings = GetStrings().Select(i => string.Concat("Hello"));

    // It takes 2 * O(n) to complete 'Count()' and 'Last()' calls, where 'n' is the length of 'someStrings'.
    var count = someStrings.Count();
    var lastElement = someStrings.Last();
}
```

```
Public Sub MyMethod()
    Dim someStrings = GetStrings().Select(Function(i) String.Concat(i, "Hello"))

    ' It takes 2 * O(n) to complete 'Count()' and 'Last()' calls, where 'n' is the length of 'someStrings'.
    Dim count = someStrings.Count()
    Dim lastElement = someStrings.Last()
End Sub
```

Fix:

```
public void MyMethod()
{
    var someStrings = GetStrings().Select(i => string.Concat("Hello"));
    // Materialize it into an array.
    // Note: This operation would allocate O(n) memory,
    // and it takes O(n) time to finish, where 'n' is the length of 'someStrings'.
    var someStringsArray = someStrings.ToArray()

    // It takes 2 * O(1) to complete 'Count()' and 'Last()' calls.
    var count = someStringsArray.Count();
    var lastElement = someStringsArray.Last();
}
```

```

Public Sub MyMethod()
    Dim someStrings = GetStrings().Select(Function(i) String.Concat(i, "Hello"))
    ' Materialize it into an array.
    ' Note: This operation would allocate O(n) memory,
    ' and it takes O(n) time to finish, where 'n' is the length of 'someStrings'.
    Dim someStringsArray = someStrings.ToArray()

    ' It takes 2 * O(1) to complete 'Count()' and 'Last()' calls.
    Dim count = someStrings.Count()
    Dim lastElement = someStrings.Last()
End Sub

```

Configure customized enumeration methods and LINQ chain methods

By default, all the methods in the `System.Linq` namespace are included in the analysis scope. You can add custom methods that enumerate an `IEnumerable` argument into the scope by setting the `enumeration_methods` option in an `.editorconfig` file.

You can also add customized LINQ chain methods (that is, methods take an `IEnumerable` argument and return a new `IEnumerable` instance) to the analysis scope by setting the `linq_chain_methods` option in an `.editorconfig` file.

Configure the default assumption of methods take `IEnumerable` parameters

By default, all customized methods that accept an `IEnumerable` argument are assumed not to enumerate the argument. You can change this by setting the `assume_method_enumerates_parameters` option in an `.editorconfig` file.

When to suppress warnings

It's safe to suppress this warning if the underlying type of the `IEnumerable` collection is some other type like `List` or `Array`, or if you're sure that methods that take an `IEnumerable` collection don't enumerate it.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```

#pragma warning disable CA1851
// The code that's violating the rule is on this line.
#pragma warning restore CA1851

```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```

[*.{cs,vb}]
dotnet_diagnostic.CA1851.severity = none

```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Deferred execution example \(LINQ to XML\)](#)

CA1854: Prefer the

`IDictionary.TryGetValue(TKey, out TValue)`

method

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1854
Category	Performance
Fix is breaking or non-breaking	Non-breaking

Cause

An `IDictionary` element access that's guarded by an `IDictionary.ContainsKey` check.

Rule description

When an element of an `IDictionary` is accessed, the indexer implementation checks for a null value by calling the `IDictionary.ContainsKey` method. If you also call `IDictionary.ContainsKey` in an `if` clause to guard a value lookup, two lookups are performed when only one is needed.

How to fix violations

Replace the `IDictionary.ContainsKey` invocation and element access with a call to the `IDictionary.TryGetValue` method.

Violation:

```
public string? GetValue(string key)
{
    if (_dictionary.ContainsKey(key))
    {
        return _dictionary[key];
    }

    return null;
}
```

```
Public Function GetValue(key As String) As String
    If _dictionary.ContainsKey(key) Then
        Return _dictionary(key)
    End If

    Return Nothing
End Function
```

Fix:

```
public string? GetValue(string key)
{
    if (_dictionary.TryGetValue(key, out string? value))
    {
        return value;
    }

    return null;
}
```

```
Public Function GetValue(key As String) As String
    Dim value as String

    If _dictionary.TryGetValue(key, value) Then
        Return value
    End If

    Return Nothing
End Function
```

When to suppress warnings

It's safe to suppress this warning if you're using a custom implementation of `IDictionary` that avoids a value lookup when performing the `IDictionary.ContainsKey` check.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1854
// The code that's violating the rule is on this line.
#pragma warning restore CA1854
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1854.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Performance.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

SingleFile rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

SingleFile rules for .NET.

NOTE

Prior to .NET 6, this category was named `Publish`.

In this section

RULE	DESCRIPTION
IL3000 Avoid accessing Assembly file path when publishing as a single file	Avoid accessing Assembly file path when publishing as a single file
IL3001 Avoid accessing Assembly file path when publishing as a single file	Avoid accessing Assembly file path when publishing as a single file
IL3002 Avoid calling members annotated with 'RequiresAssemblyFilesAttribute' when publishing as a single file	Avoid calling members annotated with 'RequiresAssemblyFilesAttribute' when publishing as a single file
IL3003 'RequiresAssemblyFilesAttribute' annotations must match across all interface implementations or overrides.	'RequiresAssemblyFilesAttribute' annotations must match across all interface implementations or overrides.

IL3000: Avoid accessing Assembly file path when publishing as a single file

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	IL3000
Category	SingleFile
Fix is breaking or non-breaking	Non-breaking

Cause

When publishing as a single-file (for example, by setting the PublishSingleFile property in a project to true), calling the `Assembly.Location` property for assemblies embedded inside the single-file bundle always returns an empty string.

How to fix violations

If the app only needs the containing directory for the single-file bundle, consider using the `AppContext.BaseDirectory` property instead. Otherwise, consider removing the call entirely.

When to suppress warnings

It's appropriate to silence this warning if the assembly being accessed is definitely not in the single-file bundle. This may be the case if the assembly is being loaded dynamically from a file path.

IL3001: Avoid accessing Assembly file path when publishing as a single file

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	IL3001
Category	SingleFile
Fix is breaking or non-breaking	Non-breaking

Cause

When publishing as a single file (for example, by setting the PublishSingleFile property in a project to true), calling the `Assembly.GetFile(s)` methods for assemblies embedded inside the single-file bundle always throws an exception, as these methods are not single-file compatible.

How to fix violations

To embed files in assemblies in single-file bundles, consider using embedded resources and the `Assembly.GetManifestResourceStream` method.

When to suppress warnings

It's appropriate to silence this warning if the assembly being accessed is definitely not in the single-file bundle. This may be the case if the assembly is being loaded dynamically from a file path.

IL3002: Avoid calling members annotated with 'RequiresAssemblyFilesAttribute' when publishing as a single file.

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	IL3002
Category	SingleFile
Fix is breaking or non-breaking	Non-breaking

Cause

When publishing an app as a single file (for example, by setting the `PublishSingleFile` property in a project to `true`), calling members annotated with the `RequiresAssemblyFilesAttribute` attribute is not single-file compatible. These calls are not compatible because members annotated with this attribute require assembly files to be on disk, and the assemblies embedded in a single-file app are memory loaded.

Example:

```
[RequiresAssemblyFiles(Message="Use 'MethodFriendlyToSingleFile' instead", Url="http://help/assemblyfiles")]
void MethodWithAssemblyFilesUsage()
{
}
void TestMethod()
{
    // IL3002: Using member 'MethodWithAssemblyFilesUsage' which has 'RequiresAssemblyFilesAttribute'
    // can break functionality when embedded in a single-file app. Use 'MethodFriendlyToSingleFile' instead.
    http://help/assemblyfiles
    MethodWithAssemblyFilesUsage();
}
```

How to fix violations

Members annotated with the 'RequiresAssemblyFilesAttribute' attribute have a message intended to give useful information to users who are publishing as a single file. Consider adapting existing code to the attribute's message or removing the violating call.

When to suppress warnings

It's appropriate to suppress the warning when the existing code has been adapted to the recommendation outlined in the 'RequiresAssemblyFilesAttribute' attribute's message.

IL3003: 'RequiresAssemblyFilesAttribute' annotations must match across all interface implementations or overrides.

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	IL3003
Category	SingleFile
Fix is breaking or non-breaking	Non-breaking

Cause

When publishing as a single file (for example, by setting the `PublishSingleFile` property in a project to `true`), interface implementations or derived classes with members that don't have matching annotations of `[RequiresAssemblyFiles]` can lead to calling a member with the attribute, which is not single-file compatible.

There are four possible scenarios where the warning can be generated:

A member of a base class has the attribute but the overriding member of the derived class does not have the attribute:

```
public class Base
{
    [RequiresAssemblyFiles]
    public virtual void TestMethod() {}

    public class Derived : Base
    {
        // IL3003: Base member 'Base.TestMethod' with 'RequiresAssemblyFilesAttribute' has a derived member
        // 'Derived.TestMethod()' without 'RequiresAssemblyFilesAttribute'. For all interfaces and overrides the
        // implementation attribute must match the definition attribute.
        public override void TestMethod() {}
    }
}
```

A member of a base class does not have the attribute but the overriding member of the derived class does have the attribute:

```
public class Base
{
    public virtual void TestMethod() {}

    public class Derived : Base
    {
        // IL3003: Member 'Derived.TestMethod()' with 'RequiresAssemblyFilesAttribute' overrides base member
        // 'Base.TestMethod()' without 'RequiresAssemblyFilesAttribute'. For all interfaces and overrides the
        // implementation attribute must match the definition attribute.
        [RequiresAssemblyFiles]
        public override void TestMethod() {}
    }
}
```

An interface member has the attribute but its implementation does not have the attribute:

```
interface IRAF
{
    [RequiresAssemblyFiles]
    void TestMethod();
}

class Implementation : IRAF
{
    // IL3003: Interface member 'IRAF.TestMethod()' with 'RequiresAssemblyFilesAttribute' has an
    // implementation member 'Implementation.TestMethod()' without 'RequiresAssemblyFilesAttribute'. For all
    // interfaces and overrides the implementation attribute must match the definition attribute.
    public void TestMethod () { }
}
```

An interface member does not have the attribute but its implementation does have the attribute:

```
interface INoRAF
{
    void TestMethod();
}

class Implementation : INoRAF
{
    [RequiresAssemblyFiles]
    // IL3003: Member 'Implementation.TestMethod()' with 'RequiresAssemblyFilesAttribute' implements
    // interface member 'INoRAF.TestMethod()' without 'RequiresAssemblyFilesAttribute'. For all interfaces and
    // overrides the implementation attribute must match the definition attribute.
    public void TestMethod () { }
}
```

How to fix violations

For all interfaces and overrides, the implementation must match the definition in terms of the presence or absence of the 'RequiresAssemblyFilesAttribute' attribute. Either both the members contain the attribute or neither of them. Remove or add the attribute on the interface/base class member or implementing/deriving class member so that the attribute is on both or neither.

When to suppress warnings

This warning should not be suppressed.

Reliability rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Reliability rules support library and application reliability, such as correct memory and thread usage. The reliability rules include:

RULE	DESCRIPTION
CA2000: Dispose objects before losing scope	Because an exceptional event might occur that will prevent the finalizer of an object from running, the object should be explicitly disposed before all references to it are out of scope.
CA2002: Do not lock on objects with weak identity	An object is said to have a weak identity when it can be directly accessed across application domain boundaries. A thread that tries to acquire a lock on an object that has a weak identity can be blocked by a second thread in a different application domain that has a lock on the same object.
CA2007: Do not directly await a Task	An asynchronous method <code>awaits</code> a <code>Task</code> directly.
CA2008: Do not create tasks without passing a TaskScheduler	A task creation or continuation operation uses a method overload that does not specify a <code>TaskScheduler</code> parameter.
CA2009: Do not call ToImmutableCollection on an ImmutableCollection value	<code>ToImmutable</code> method was unnecessarily called on an immutable collection from <code>System.Collections.Immutable</code> namespace.
CA2011: Do not assign property within its setter	A property was accidentally assigned a value within its own <code>set accessor</code> .
CA2012: Use ValueTasks correctly	ValueTasks returned from member invocations are intended to be directly awaited. Attempts to consume a ValueTask multiple times or to directly access one's result before it's known to be completed may result in an exception or corruption. Ignoring such a ValueTask is likely an indication of a functional bug and may degrade performance.
CA2013: Do not use ReferenceEquals with value types	When comparing values using <code>System.Object.ReferenceEquals</code> , if objA and objB are value types, they are boxed before they are passed to the <code>ReferenceEquals</code> method. This means that even if both objA and objB represent the same instance of a value type, the <code>ReferenceEquals</code> method nevertheless returns false.
CA2014: Do not use stackalloc in loops.	Stack space allocated by a <code>stackalloc</code> is only released at the end of the current method's invocation. Using it in a loop can result in unbounded stack growth and eventual stack overflow conditions.
CA2015: Do not define finalizers for types derived from MemoryManager<T>	Adding a finalizer to a type derived from <code>MemoryManager<T></code> may permit memory to be freed while it is still in use by a <code>Span<T></code> .

RULE	DESCRIPTION
CA2016: Forward the <code>CancellationToken</code> parameter to methods that take one	Forward the <code>CancellationToken</code> parameter to methods that take one to ensure the operation cancellation notifications gets properly propagated, or pass in <code>CancellationToken.None</code> explicitly to indicate intentionally not propagating the token.
CA2017: Parameter count mismatch	Number of parameters supplied in the logging message template do not match the number of named placeholders.
CA2018: The <code>count</code> argument to <code>Buffer.BlockCopy</code> should specify the number of bytes to copy	When using <code>Buffer.BlockCopy</code> , the <code>count</code> argument specifies the number of bytes to copy. You should only use <code>Array.Length</code> for the <code>count</code> argument on arrays whose elements are exactly one byte in size. <code>byte</code> , <code>sbyte</code> , and <code>bool</code> arrays have elements that are one byte in size.

CA2000: Dispose objects before losing scope

9/20/2022 • 7 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2000
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

A local object of an [IDisposable](#) type is created, but the object is not disposed before all references to the object are out of scope.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

If a disposable object is not explicitly disposed before all references to it are out of scope, the object will be disposed at some indeterminate time when the garbage collector runs the finalizer of the object. Because an exceptional event might occur that will prevent the finalizer of the object from running, the object should be explicitly disposed instead.

Special cases

Rule CA2000 does not fire for local objects of the following types even if the object is not disposed:

- [System.IO.Stream](#)
- [System.IO.StringReader](#)
- [System.IO.TextReader](#)
- [System.IO.TextWriter](#)
- [System.Resources.IResourceReader](#)

Passing an object of one of these types to a constructor and then assigning it to a field indicates a *dispose ownership transfer* to the newly constructed type. That is, the newly constructed type is now responsible for disposing of the object. If your code passes an object of one of these types to a constructor, no violation of rule CA2000 occurs even if the object is not disposed before all references to it are out of scope.

How to fix violations

To fix a violation of this rule, call [Dispose](#) on the object before all references to it are out of scope.

You can use the [using statement](#) ([Using](#) in Visual Basic) to wrap objects that implement [IDisposable](#). Objects that are wrapped in this manner are automatically disposed at the end of the [using](#) block. However, the following situations should not or cannot be handled with a [using](#) statement:

- To return a disposable object, the object must be constructed in a [try/finally](#) block outside of a [using](#) block.

- Do not initialize members of a disposable object in the constructor of a `using` statement.
- When constructors that are protected by only one exception handler are nested in the [acquisition part of a `using` statement](#), a failure in the outer constructor can result in the object created by the nested constructor never being closed. In the following example, a failure in the `StreamReader` constructor can result in the `FileStream` object never being closed. CA2000 flags a violation of the rule in this case.

```
using (StreamReader sr = new StreamReader(new FileStream("C:/myfile.txt", FileMode.Create)))
{ ... }
```

- Dynamic objects should use a shadow object to implement the dispose pattern of [IDisposable](#) objects.

When to suppress warnings

Do not suppress a warning from this rule unless:

- You've called a method on your object that calls `Dispose`, such as `Close`.
- The method that raised the warning returns an [IDisposable](#) object that wraps your object.
- The allocating method does not have dispose ownership; that is, the responsibility to dispose the object is transferred to another object or wrapper that's created in the method and returned to the caller.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2000
// The code that's violating the rule is on this line.
#pragma warning restore CA2000
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2000.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Reliability](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Related rules

- [CA2213: Disposable fields should be disposed](#)

Example 1

If you're implementing a method that returns a disposable object, use a try/finally block without a catch block to make sure that the object is disposed. By using a try/finally block, you allow exceptions to be raised at the fault point and make sure that object is disposed.

In the OpenPort1 method, the call to open the ISerializable object SerialPort or the call to SomeMethod can fail. A CA2000 warning is raised on this implementation.

In the OpenPort2 method, two SerialPort objects are declared and set to null:

- `tempPort`, which is used to test that the method operations succeed.
- `port`, which is used for the return value of the method.

The `tempPort` is constructed and opened in a `try` block, and any other required work is performed in the same `try` block. At the end of the `try` block, the opened port is assigned to the `port` object that will be returned and the `tempPort` object is set to `null`.

The `finally` block checks the value of `tempPort`. If it is not null, an operation in the method has failed, and `tempPort` is closed to make sure that any resources are released. The returned port object will contain the opened SerialPort object if the operations of the method succeeded, or it will be null if an operation failed.

```

public SerialPort OpenPort1(string portName)
{
    SerialPort port = new SerialPort(portName);
    port.Open(); //CA2000 fires because this might throw
    SomeMethod(); //Other method operations can fail
    return port;
}

public SerialPort OpenPort2(string portName)
{
    SerialPort tempPort = null;
    SerialPort port = null;
    try
    {
        tempPort = new SerialPort(portName);
        tempPort.Open();
        SomeMethod();
        //Add any other methods above this line
        port = tempPort;
        tempPort = null;
    }
    finally
    {
        if (tempPort != null)
        {
            tempPort.Close();
        }
    }
    return port;
}

```

```

Public Function OpenPort1(ByVal PortName As String) As SerialPort

    Dim port As New SerialPort(PortName)
    port.Open()      'CA2000 fires because this might throw
    SomeMethod()    'Other method operations can fail
    Return port

End Function

Public Function OpenPort2(ByVal PortName As String) As SerialPort

    Dim tempPort As SerialPort = Nothing
    Dim port As SerialPort = Nothing

    Try
        tempPort = New SerialPort(PortName)
        tempPort.Open()
        SomeMethod()
        'Add any other methods above this line
        port = tempPort
        tempPort = Nothing

    Finally
        If Not tempPort Is Nothing Then
            tempPort.Close()
        End If

    End Try

    Return port

End Function

```

Example 2

By default, the Visual Basic compiler has all arithmetic operators check for overflow. Therefore, any Visual Basic arithmetic operation might throw an [OverflowException](#). This could lead to unexpected violations in rules such as CA2000. For example, the following CreateReader1 function will produce a CA2000 violation because the Visual Basic compiler is emitting an overflow checking instruction for the addition that could throw an exception that would cause the StreamReader not to be disposed.

To fix this, you can disable the emitting of overflow checks by the Visual Basic compiler in your project or you can modify your code as in the following CreateReader2 function.

To disable the emitting of overflow checks, right-click the project name in Solution Explorer and then click **Properties**. Click **Compile**, click **Advanced Compile Options**, and then check **Remove integer overflow checks**.

```
Imports System.IO

Class CA2000
    Public Function CreateReader1(ByVal x As Integer) As StreamReader
        Dim local As New StreamReader("C:\Temp.txt")
        x += 1
        Return local
    End Function

    Public Function CreateReader2(ByVal x As Integer) As StreamReader
        Dim local As StreamReader = Nothing
        Dim localTemp As StreamReader = Nothing
        Try
            localTemp = New StreamReader("C:\Temp.txt")
            x += 1
            local = localTemp
            localTemp = Nothing
        Finally
            If (Not (localTemp Is Nothing)) Then
                localTemp.Dispose()
            End If
        End Try
        Return local
    End Function
End Class
```

CA2002: Do not lock on objects with weak identity

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2002
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

A thread attempts to acquire a lock on an object that has a weak identity.

Rule description

An object is said to have a weak identity when it can be directly accessed across application domain boundaries. A thread that tries to acquire a lock on an object that has a weak identity can be blocked by a second thread in a different application domain that has a lock on the same object.

The following types have a weak identity and are flagged by the rule:

- [String](#)
- Arrays of value types, including [integral types](#), [floating-point types](#), and [Boolean](#).
- [MarshalByRefObject](#)
- [ExecutionEngineException](#)
- [OutOfMemoryException](#)
- [StackOverflowException](#)
- [MemberInfo](#)
- [ParameterInfo](#)
- [Thread](#)
- [this](#) or [Me](#) object

How to fix violations

To fix a violation of this rule, use an object from a type that is not in the list in the Description section.

When to suppress warnings

It is safe to suppress the warning if the locked object is `this` or `Me` and the visibility of the self object type is private or internal, and the instance is not accessible using any public reference.

Otherwise, do not suppress a warning from this rule.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2002
// The code that's violating the rule is on this line.
#pragma warning restore CA2002
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2002.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2007: Do not directly await a Task

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2007
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

An asynchronous method `awaits` a `Task` directly.

Rule description

When an asynchronous method awaits a `Task` directly, continuation usually occurs in the same thread that created the task, depending on the async context. This behavior can be costly in terms of performance and can result in a deadlock on the UI thread. Consider calling `Task.ConfigureAwait(Boolean)` to signal your intention for continuation.

How to fix violations

To fix violations, call `ConfigureAwait` on the awaited `Task`. You can pass either `true` or `false` for the `continueOnCapturedContext` parameter.

- Calling `ConfigureAwait(true)` on the task has the same behavior as not explicitly calling `ConfigureAwait`. By explicitly calling this method, you're letting readers know you intentionally want to perform the continuation on the original synchronization context.
- Call `ConfigureAwait(false)` on the task to schedule continuations to the thread pool, thereby avoiding a deadlock on the UI thread. Passing `false` is a good option for app-independent libraries.

Example

The following code snippet generates the warning:

```
public async Task Execute()
{
    Task task = null;
    await task;
}
```

To fix the violation, call `ConfigureAwait` on the awaited `Task`:

```
public async Task Execute()
{
    Task task = null;
    await task.ConfigureAwait(false);
}
```

When to suppress warnings

This warning is intended for libraries, where the code may be executed in arbitrary environments and where code shouldn't make assumptions about the environment or how the caller of the method may be invoking or waiting on it. It is generally appropriate to suppress the warning entirely for projects that represent application code rather than library code; in fact, running this analyzer on application code (for example, button click event handlers in a WinForms or WPF project) is likely to lead to the wrong actions being taken.

You can suppress this warning in any situation where either the continuation should be scheduled back to the original context or where there is no such context in place. For example, when writing code in a button click event handler in a WinForms or WPF application, in general the continuation from an await should run on the UI thread, and thus the default behavior of scheduling the continuation back to the originating context is desirable. As another example, when writing code in an ASP.NET Core application, by default there is no [SynchronizationContext](#) or [TaskScheduler](#), for which reason a `ConfigureAwait` wouldn't actually change any behavior.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2007
// The code that's violating the rule is on this line.
#pragma warning restore CA2007
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2007.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude async void methods](#)
- [Output kind](#)

You can configure all of these options for just this rule, for all rules, or for all rules in this category ([Reliability](#)). For more information, see [Code quality rule configuration options](#).

Exclude async void methods

You can configure whether you want to exclude asynchronous methods that don't return a value from this rule.

To exclude these kinds of methods, add the following key-value pair to an `.editorconfig` file in your project:

```
# Package version 2.9.0 and later  
dotnet_code_quality.CA2007.exclude_async_void_methods = true  
  
# Package version 2.6.3 and earlier  
dotnet_code_quality.CA2007.skip_async_void_methods = true
```

Output kind

You can also configure which output assembly kinds to apply this rule to. For example, to only apply this rule to code that produces a console application or a dynamically linked library (that is, not a UI app), add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA2007.output_kind = ConsoleApplication, DynamicallyLinkedLibrary
```

CA2008: Do not create tasks without passing a TaskScheduler

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2008
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

A task creation or continuation operation uses a method overload that does not specify a [TaskScheduler](#) parameter.

Rule description

The following .NET task creation and continuation methods have overloads that allow specifying or omitting a [TaskScheduler](#) instance:

- [System.Threading.Tasks.TaskFactory.StartNew](#) methods
- [System.Threading.Tasks.Task.ContinueWith](#) methods

Always specify an explicit [TaskScheduler](#) argument to avoid the default [Current](#) value, whose behavior is defined by the caller and may vary at run time. [Current](#) returns the scheduler associated with whatever [Task](#) is currently running on that thread. If there is no such task, it returns [Default](#), which represents the thread pool. Using [Current](#) could lead to deadlocks or UI responsiveness issues in some situations, when it was intended to create the task on the thread pool, but instead it waits to get back onto the UI thread.

For further information and detailed examples, see [New TaskCreationOptions and TaskContinuationOptions in .NET Framework 4.5](#).

NOTE

[VSTHRD105 - Avoid method overloads that assume TaskScheduler.Current](#) is a similar rule implemented in [Microsoft.VisualStudio.Threading.Analyzers](#) package.

How to fix violations

To fix violations, call the method overload that takes a [TaskScheduler](#) and explicitly pass in [Default](#) or [Current](#) to make the intent clear.

When to suppress warnings

This warning is intended primarily for libraries, where the code may be executed in arbitrary environments and where code shouldn't make assumptions about the environment or how the caller of the method may be

invoking or waiting on it. It may be appropriate to suppress the warning for projects that represent application code rather than library code.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2008
// The code that's violating the rule is on this line.
#pragma warning restore CA2008
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2008.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2009: Do not call `ToImmutableCollection` on an `ImmutableCollection` value

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2009
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

`ToImmutable` method was unnecessarily called on an immutable collection from `System.Collections.Immutable` namespace.

Rule description

`System.Collections.Immutable` namespace contains types that define immutable collections. This rule analyzes the following immutable collection types:

- `System.Collections.Immutable.ImmutableArray<T>`
- `System.Collections.Immutable.ImmutableList<T>`
- `System.Collections.Immutable.ImmutableHashSet<T>`
- `System.Collections.Immutable.ImmutableSortedSet<T>`
- `System.Collections.Immutable.ImmutableDictionary<TKey,TValue>`
- `System.Collections.Immutable.ImmutableSortedDictionary<TKey,TValue>`

These types define extension methods that create a new immutable collection from an existing `IEnumerable<T>` collection.

- `ImmutableArray<T>` defines `ToImmutableArray`.
- `ImmutableList<T>` defines `ToImmutableList`.
- `ImmutableHashSet<T>` defines `ToImmutableHashSet`.
- `ImmutableSortedSet<T>` defines `ToImmutableSortedSet`.
- `ImmutableDictionary<TKey,TValue>` defines `ToImmutableDictionary`.
- `ImmutableSortedDictionary<TKey,TValue>` defines `ToImmutableSortedDictionary`.

These extension methods are designed to convert a mutable collection to an immutable collection. However, the caller might accidentally pass in an immutable collection as input to these methods. This can represent a performance and/or a functional issue.

- Performance issue: Unnecessary boxing, unboxing, and/or runtime type checks on an immutable collection.
- Potential functional issue: Caller assumed to be operating on a mutable collection, when it actually had an immutable collection.

How to fix violations

To fix violations, remove the redundant `ToImmutable` call on an immutable collection. For example, the following two code snippets show a violation of the rule and how to fix them:

```
using System;
using System.Collections.Generic;
using System.Collections.Immutable;

public class C
{
    public void M(IEnumerable<int> collection, ImmutableList<int> immutableArray)
    {
        // This is fine.
        M2(collection.ToImmutableArray());

        // This leads to CA2009.
        M2(immutableArray.ToImmutableArray());
    }

    private void M2(ImmutableList<int> immutableArray)
    {
        Console.WriteLine(immutableArray.Length);
    }
}
```

```
using System;
using System.Collections.Generic;
using System.Collections.Immutable;

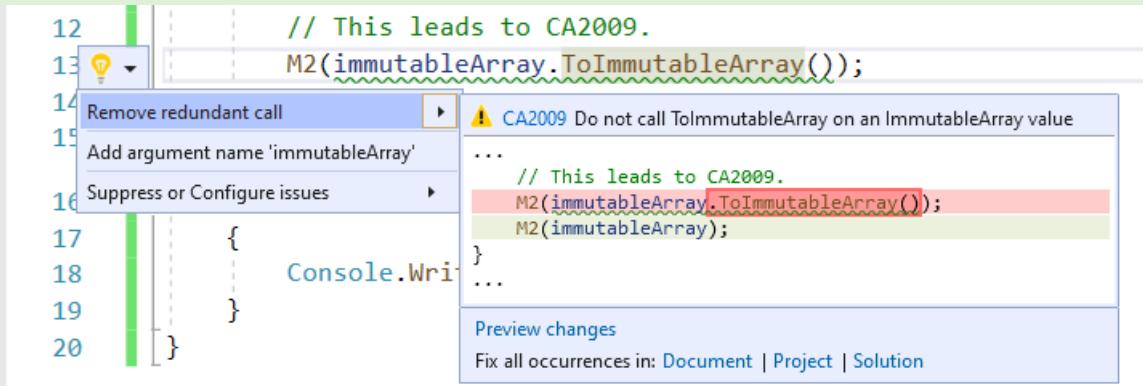

public class C
{
    public void M(IEnumerable<int> collection, ImmutableList<int> immutableArray)
    {
        // This is fine.
        M2(collection.ToImmutableArray());

        // This is now fine.
        M2(immutableArray);
    }

    private void M2(ImmutableList<int> immutableArray)
    {
        Console.WriteLine(immutableArray.Length);
    }
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Remove redundant call** from the list of options that's presented.

When to suppress warnings

Do not suppress violations from this rule, unless you're not concerned about the performance impact from unnecessary allocations of immutable collections.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2009
// The code that's violating the rule is on this line.
#pragma warning restore CA2009
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2009.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2011: Do not assign property within its setter

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2011
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

A property was accidentally assigned a value within its own [set accessor](#).

Rule description

Assigning a property to itself in its [set accessor](#) leads to an infinite chain of recursive calls to the set accessor. This results in a [StackOverflowException](#) at run time. Such a mistake is common when the property and the backing field to store the property value have similar names. Instead of assigning the value to the backing field, it was accidentally assigned to the property itself.

How to fix violations

To fix violations, replace the violating assignment to the property with either an assignment to the backing field or switch to using an [auto-property](#). For example, the following code snippet shows a violation of the rule and a couple of ways to fix it:

```
public class C
{
    // Backing field for property 'P'
    private int p;

    public int P
    {
        get
        {
            return p;
        }
        set
        {
            // CA2011: Accidentally assigned to property, instead of the backing field.
            P = value;
        }
    }
}
```

```
public class C
{
    // Backing field for property 'P'
    private int _p;

    public int P
    {
        get
        {
            return _p;
        }
        set
        {
            // Option 1: Assign to backing field and rename the backing field for clarity.
            _p = value;
        }
    }
}
```

```
public class C
{
    // Option 2: Use auto-property.
    public int P { get; set; }
}
```

When to suppress warnings

It is fine to suppress violations from this rule if you are sure that the recursive calls to the set accessor are conditionally guarded to prevent infinite recursion.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2011
// The code that's violating the rule is on this line.
#pragma warning restore CA2011
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2011.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2012: Use ValueTasks correctly

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2012
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

A [ValueTask](#) instance returned from a member invocation is used in a way that could lead to exceptions, corruption, or poor performance.

Rule description

[ValueTask](#) instances returned from member invocations are intended to be directly awaited. Attempts to consume a ValueTask multiple times or to directly access one's result before it's known to be completed may result in an exception or corruption. Ignoring such a ValueTask is likely an indication of a functional bug and may degrade performance.

How to fix violations

In general, ValueTasks should be directly awaited rather than discarded or stored into other locations like local variables or fields.

When to suppress warnings

For `valueTask` objects returned from arbitrary member calls, the caller needs to assume that the `ValueTask` must be consumed (for example, awaited) once and only once. However, if the developer also controls the member being invoked and has complete knowledge of its implementation, the developer may know it's safe to suppress the warning, for example, if the return `ValueTask` always wraps a [Task](#) object.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2012
// The code that's violating the rule is on this line.
#pragma warning restore CA2012
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2012.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2013: Do not use ReferenceEquals with value types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2013
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

Using `System.Object.ReferenceEquals` method to test one or more value types for equality.

Rule description

When comparing values using `ReferenceEquals`, if `objA` and `objB` are value types, they are boxed before they are passed to the `ReferenceEquals` method. This means that even if both `objA` and `objB` represent the same instance of a value type, the `ReferenceEquals` method nevertheless returns false, as the following example shows.

How to fix violations

To fix the violation, replace it with a more appropriate equality check such as `==`.

```
int int1 = 1, int2 = 1;

// Violation occurs, returns false.
Console.WriteLine(Object.ReferenceEquals(int1, int2)); // false

// Use appropriate equality operator or method instead
Console.WriteLine(int1 == int2); // true
Console.WriteLine(object.Equals(int1, int2)); // true
```

When to suppress warnings

It is not safe to suppress a warning from this rule. We recommend using the more appropriate equality operator, such as `==`.

CA2014: Do not use stackalloc in loops

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2014
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

Using the C# `stackalloc` expression inside of a loop.

Rule description

The C# `stackalloc` expression allocates memory from the current stack frame, and that memory may not be released until the current method call returns. If `stackalloc` is used in a loop, it can lead to stack overflows due to exhausting the stack memory.

How to fix violations

Move the `stackalloc` expression outside of all loops in the method.

When to suppress warnings

It may be safe to suppress the warning when the containing loop or loops are invoked only a finite number of times, such that the overall amount of memory allocated across all `stackalloc` operations is known to be relatively small.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2014
// The code that's violating the rule is on this line.
#pragma warning restore CA2014
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2014.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Reliability rules](#)

CA2015: Do not define finalizers for types derived from MemoryManager<T>

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2015
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

Defining finalizers for types derived from [MemoryManager<T>](#)

Rule description

Adding a finalizer to a type derived from [MemoryManager<T>](#) is likely an indication of a bug, as it suggests a native resource that could have been handed out in a [Span<T>](#) is getting cleaned up and potentially while it is still in use by the [Span<T>](#).

NOTE

The [MemoryManager<T>](#) class is intended for advanced scenarios. Most developers do not need to use it.

How to fix violations

To fix the violation, remove the finalizer definition.

```
class DerivedClass <T> : MemoryManager<T>
{
    public override bool Dispose(bool disposing)
    {
        if (disposing)
        {
            _handle.Dispose();
        }
    }

    ...

    // Violation occurs, remove the finalizer to fix the warning.
    ~DerivedClass() => Dispose(false);
}
```

When to suppress warnings

It is safe to suppress a violation of this rule if the intent is to create a finalizer for debugging or validation purposes.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2015
// The code that's violating the rule is on this line.
#pragma warning restore CA2015
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2015.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Reliability rules](#)

CA2016: Forward the CancellationToken parameter to methods that take one

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Type name	ForwardCancellationTokenToInvocations
Rule ID	CA2016
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates method invocations that could accept a [CancellationToken](#) parameter, but are not passing any, and suggests to forward the parent method's `CancellationToken` to them.

Rule description

This rule analyzes method definitions that take a `CancellationToken` as their last parameter, then analyzes all methods invoked in its body. If any of the method invocations can either accept a `CancellationToken` as the last parameter, or have an overload that takes a `CancellationToken` as the last parameter, then the rule suggests using that option instead to ensure that the cancellation notification gets propagated to all operations that can listen to it.

NOTE

Rule CA2016 is available in all .NET versions where the `CancellationToken` type is available. For the applicable versions, see the [CancellationToken "Applies to"](#) section.

How to fix violations

You can either fix violations manually, or use the code fix available in Visual Studio. Hover the light bulb that appears next to the method invocation and select the suggested change.

The following example shows two suggested changes:

The screenshot shows the Visual Studio IDE. The top part displays the code for `Program.cs`. The code defines a class `MyTestClass` with three static methods: `MyMethodWithDefault`, `MyMethodWithOverload`, and `MyMethod`. The `MyMethodWithDefault` method takes a `CancellationToken` parameter. The `MyMethodWithOverload` method also takes a `CancellationToken` parameter. The `MyMethod` method takes a `CancellationToken` parameter and calls the other two methods. The bottom part shows the `Error List - Current Document (Program.cs)` window, which contains two warning entries for rule CA2016:

Line	Code	Description
22	CA2016	Forward the 'c' parameter to the 'MyMethodWithDefault' method or pass in 'CancellationToken.None' explicitly to indicate intentionally not propagating the token.
23	CA2016	Forward the 'c' parameter to the 'MyMethodWithOverload' method or pass in 'CancellationToken.None' explicitly to indicate intentionally not propagating the token.

It's safe to suppress a violation of this rule if you're not concerned about forwarding the canceled operation notification to lower method invocations. You can also explicitly pass `default` in C# (`Nothing` in Visual Basic) or `None` to suppress the rule violation.

The rule can detect a variety of violations. The following examples show cases that the rule can detect:

Example 1

The rule will suggest forwarding the `c` parameter from `MyMethod` to the `MyMethodWithDefault` invocation, because the method defines an optional token parameter:

```

using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithDefault(CancellationToken ct = default)
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithDefault();
        }
    }
}

```

Fix:

Forward the `c` parameter:

```

public static void MyMethod(CancellationToken c)
{
    MyMethodWithDefault(c);
}

```

If you are not concerned about forwarding cancellation notifications to lower invocations, you can either:

Explicitly pass `default`:

```

public static void MyMethod(CancellationToken c)
{
    MyMethodWithDefault(default);
}

```

Or explicitly pass `CancellationToken.None`:

```

public static void MyMethod(CancellationToken c)
{
    MyMethodWithDefault(CancellationToken.None);
}

```

Example 2

The rule will suggest forwarding the `c` parameter from `MyMethod` to the `MyMethodWithOverload` invocation, because the method has an overload that takes a `CancellationToken` parameter:

```
using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithOverload()
        {
        }

        public static void MyMethodWithOverload(CancellationToken ct = default)
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithOverload();
        }
    }
}
```

Fix:

Forward the `c` parameter:

```
public static void MyMethod(CancellationToken c)
{
    MyMethodWithOverload(c);
}
```

If you are not concerned about forwarding cancellation notifications to lower invocations, you can either:

Explicitly pass `default`:

```
public static void MyMethod(CancellationToken c)
{
    MyMethodWithOverload(default);
}
```

Or explicitly pass `CancellationToken.None`:

```
public static void MyMethod(CancellationToken c)
{
    MyMethodWithOverload(CancellationToken.None);
}
```

Non-violation examples

The `cancellationToken` parameter in the parent method is not in the last position:

```

using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithDefault(CancellationToken ct = default)
        {
        }

        public static void MyMethod(CancellationToken c, int lastParameter)
        {
            MyMethodWithDefault();
        }
    }
}

```

The `cancellationToken` parameter in the default method is not in the last position:

```

using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithDefault(CancellationToken ct = default, int lastParameter = 0)
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithDefault();
        }
    }
}

```

The `cancellationToken` parameter in the overload method is not in the last position:

```

using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithOverload(int lastParameter)
        {
        }

        public static void MyMethodWithOverload(CancellationToken ct, int lastParameter)
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithOverload();
        }
    }
}

```

The parent method defines more than one `CancellationToken` parameter:

```
using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithDefault(CancellationToken ct = default)
        {
        }

        public static void MyMethod(CancellationToken c1, CancellationToken c2)
        {
            MyMethodWithDefault();
        }
    }
}
```

The method with defaults defines more than one `CancellationToken` parameter:

```
using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithDefault(CancellationToken c1 = default, CancellationToken c2 = default)
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithDefault();
        }
    }
}
```

The method overload defines more than one `CancellationToken` parameter:

```
using System.Threading;

namespace ConsoleApp
{
    public static class MyTestClass
    {
        public static void MyMethodWithOverload(CancellationToken c1, CancellationToken c2)
        {
        }

        public static void MyMethodWithOverload()
        {
        }

        public static void MyMethod(CancellationToken c)
        {
            MyMethodWithOverload();
        }
    }
}
```

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2016
// The code that's violating the rule is on this line.
#pragma warning restore CA2016
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2016.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Reliability.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2017: Parameter count mismatch

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2017
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

The number of parameters supplied in the logging message template does not match the number of named placeholders.

Rule description

This rule flags logger calls that have an incorrect number of message arguments.

How to fix violations

Match the number of placeholders in the template format with the number of passed arguments.

When to suppress warnings

Do not suppress a warning from this rule.

- [Reliability rules](#)

CA2018: The `count` argument to `Buffer.BlockCopy` should specify the number of bytes to copy

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2018
Category	Reliability
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when `Array.Length` is used for the `count` argument of `Buffer.BlockCopy` on arrays whose elements are larger than one byte in size.

Rule description

When using `Buffer.BlockCopy`, the `count` argument specifies the number of bytes to copy. You should only use `Array.Length` for the `count` argument on arrays whose elements are exactly one byte in size. `byte`, `sbyte`, and `bool` arrays have elements that are one byte in size.

How to fix violations

Specify the number of bytes that you intend to copy for the `count` argument.

Example

Violation:

```
using System;
class Program
{
    static void Main()
    {
        int[] src = new int[] {1, 2, 3, 4};
        int[] dst = new int[] {0, 0, 0, 0};

        Buffer.BlockCopy(src, 0, dst, 0, src.Length);
    }
}
```

Fix:

If your array's elements are larger than one byte in size, you can multiply the length of the array by the element size to get the number of bytes.

```
using System;
class Program
{
    static void Main()
    {
        int[] src = new int[] {1, 2, 3, 4};
        int[] dst = new int[] {0, 0, 0, 0};

        Buffer.BlockCopy(src, 0, dst, 0, src.Length * sizeof(int));
    }
}
```

When to suppress warnings

It is generally NOT safe to suppress a warning from this rule.

Security rules

9/20/2022 • 18 minutes to read • [Edit Online](#)

Security rules support safer libraries and applications. These rules help prevent security flaws in your program. If you disable any of these rules, you should clearly mark the reason in code and also inform the designated security officer for your development project.

In this section

RULE	DESCRIPTION
CA2100: Review SQL queries for security vulnerabilities	A method sets the System.Data.IDbCommand.CommandText property by using a string that is built from a string argument to the method. This rule assumes that the string argument contains user input. A SQL command string built from user input is vulnerable to SQL injection attacks.
CA2109: Review visible event handlers	A public or protected event-handling method was detected. Event-handling methods should not be exposed unless absolutely necessary.
CA2119: Seal methods that satisfy private interfaces	An inheritable public type provides an overridable method implementation of an internal (Friend in Visual Basic) interface. To fix a violation of this rule, prevent the method from being overridden outside the assembly.
CA2153: Avoid Handling Corrupted State Exceptions	Corrupted State Exceptions (CSE) indicate that memory corruption exists in your process. Catching these rather than allowing the process to crash can lead to security vulnerabilities if an attacker can place an exploit into the corrupted memory region.
CA2300: Do not use insecure deserializer BinaryFormatter	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2301: Do not call BinaryFormatter.Deserialize without first setting BinaryFormatter.Binder	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2302: Ensure BinaryFormatter.Binder is set before calling BinaryFormatter.Deserialize	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2305: Do not use insecure deserializer LosFormatter	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.

Rule	Description
CA2310: Do not use insecure deserializer NetDataContractSerializer	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2311: Do not deserialize without first setting NetDataContractSerializer.Binder	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2312: Ensure NetDataContractSerializer.Binder is set before deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2315: Do not use insecure deserializer ObjectStateFormatter	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2321: Do not deserialize with JavaScriptSerializer using a SimpleTypeResolver	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2322: Ensure JavaScriptSerializer is not initialized with SimpleTypeResolver before deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2326: Do not use TypeNameHandling values other than None	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2327: Do not use insecure JsonSerializerSettings	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2328: Ensure that JsonSerializerSettings are secure	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2329: Do not deserialize with JsonSerializer using an insecure configuration	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.
CA2330: Ensure that JsonSerializer has a secure configuration when deserializing	Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects.

Rule	Description
CA2350: Ensure <code>DataTable.ReadXml()</code> 's input is trusted	When deserializing a <code>DataTable</code> with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2351: Ensure <code>DataSet.ReadXml()</code> 's input is trusted	When deserializing a <code>DataSet</code> with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2352: Unsafe <code>DataSet</code> or <code>DataTable</code> in serializable type can be vulnerable to remote code execution attacks	A class or struct marked with <code>SerializableAttribute</code> contains a <code>DataSet</code> or <code>DataTable</code> field or property, and doesn't have a <code>GeneratedCodeAttribute</code> .
CA2353: Unsafe <code>DataSet</code> or <code>DataTable</code> in serializable type	A class or struct marked with an XML serialization attribute or a data contract attribute contains a <code>DataSet</code> or <code>DataTable</code> field or property.
CA2354: Unsafe <code>DataSet</code> or <code>DataTable</code> in deserialized object graph can be vulnerable to remote code execution attack	Deserializing with an <code>System.Runtime.Serialization.IFormatter</code> serialized, and the casted type's object graph can include a <code>DataSet</code> or <code>DataTable</code> .
CA2355: Unsafe <code>DataSet</code> or <code>DataTable</code> in deserialized object graph	Deserializing when the casted or specified type's object graph can include a <code>DataSet</code> or <code>DataTable</code> .
CA2356: Unsafe <code>DataSet</code> or <code>DataTable</code> in web deserialized object graph	A method with a <code>System.Web.Services.WebMethodAttribute</code> or <code>System.ServiceModel.OperationContractAttribute</code> has a parameter that may reference a <code>DataSet</code> or <code>DataTable</code> .
CA2361: Ensure autogenerated class containing <code>DataSet.ReadXml()</code> is not used with untrusted data	When deserializing a <code>DataSet</code> with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.
CA2362: Unsafe <code>DataSet</code> or <code>DataTable</code> in autogenerated serializable type can be vulnerable to remote code execution attacks	When deserializing untrusted input with <code>BinaryFormatter</code> and the deserialized object graph contains a <code>DataSet</code> or <code>DataTable</code> , an attacker can craft a malicious payload to perform a remote code execution attack.
CA3001: Review code for SQL injection vulnerabilities	When working with untrusted input and SQL commands, be mindful of SQL injection attacks. An SQL injection attack can execute malicious SQL commands, compromising the security and integrity of your application.
CA3002: Review code for XSS vulnerabilities	When working with untrusted input from web requests, be mindful of cross-site scripting (XSS) attacks. An XSS attack injects untrusted input into raw HTML output, allowing the attacker to execute malicious scripts or maliciously modify content in your web page.
CA3003: Review code for file path injection vulnerabilities	When working with untrusted input from web requests, be mindful of using user-controlled input when specifying paths to files.

Rule	Description
CA3004: Review code for information disclosure vulnerabilities	Disclosing exception information gives attackers insight into the internals of your application, which can help attackers find other vulnerabilities to exploit.
CA3006: Review code for process command injection vulnerabilities	When working with untrusted input, be mindful of command injection attacks. A command injection attack can execute malicious commands on the underlying operating system, compromising the security and integrity of your server.
CA3007: Review code for open redirect vulnerabilities	When working with untrusted input, be mindful of open redirect vulnerabilities. An attacker can exploit an open redirect vulnerability to use your website to give the appearance of a legitimate URL, but redirect an unsuspecting visitor to a phishing or other malicious webpage.
CA3008: Review code for XPath injection vulnerabilities	When working with untrusted input, be mindful of XPath injection attacks. Constructing XPath queries using untrusted input may allow an attacker to maliciously manipulate the query to return an unintended result, and possibly disclose the contents of the queried XML.
CA3009: Review code for XML injection vulnerabilities	When working with untrusted input, be mindful of XML injection attacks.
CA3010: Review code for XAML injection vulnerabilities	When working with untrusted input, be mindful of XAML injection attacks. XAML is a markup language that directly represents object instantiation and execution. That means elements created in XAML can interact with system resources (for example, network access and file system IO).
CA3011: Review code for DLL injection vulnerabilities	When working with untrusted input, be mindful of loading untrusted code. If your web application loads untrusted code, an attacker may be able to inject malicious DLLs into your process and execute malicious code.
CA3012: Review code for regex injection vulnerabilities	When working with untrusted input, be mindful of regex injection attacks. An attacker can use regex injection to maliciously modify a regular expression, to make the regex match unintended results, or to make the regex consume excessive CPU resulting in a Denial of Service attack.
CA3061: Do not add schema by URL	Do not use the unsafe overload of the Add method because it may cause dangerous external references.
CA3075: Insecure DTD Processing	If you use insecure DTDProcessing instances or reference external entity sources, the parser may accept untrusted input and disclose sensitive information to attackers.
CA3076: Insecure XSLT Script Execution	If you execute Extensible StyleSheet Language Transformations (XSLT) in .NET applications insecurely, the processor may resolve untrusted URI references that could disclose sensitive information to attackers, leading to Denial of Service and Cross-Site attacks.

RULE	DESCRIPTION
CA3077: Insecure Processing in API Design, XML Document and XML Text Reader	When designing an API derived from <code>XMLDocument</code> and <code>XMLTextReader</code> , be mindful of <code>DtdProcessing</code> . Using insecure <code>DTDProcessing</code> instances when referencing or resolving external entity sources or setting insecure values in the XML may lead to information disclosure.
CA3147: Mark verb handlers with ValidateAntiForgeryToken	When designing an ASP.NET MVC controller, be mindful of cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET MVC controller.
CA5350: Do Not Use Weak Cryptographic Algorithms	Weak encryption algorithms and hashing functions are used today for a number of reasons, but they should not be used to guarantee the confidentiality or integrity of the data they protect. This rule triggers when it finds <code>TripleDES</code> , <code>SHA1</code> , or <code>RIPEMD160</code> algorithms in the code.
CA5351: Do Not Use Broken Cryptographic Algorithms	Broken cryptographic algorithms are not considered secure and their use should be strongly discouraged. This rule triggers when it finds the <code>MD5</code> hash algorithm or either the <code>DES</code> or <code>RC2</code> encryption algorithms in code.
CA5358: Do Not Use Unsafe Cipher Modes	Do Not Use Unsafe Cipher Modes
CA5359: Do not disable certificate validation	A certificate can help authenticate the identity of the server. Clients should validate the server certificate to ensure requests are sent to the intended server. If the <code>ServerCertificateValidationCallback</code> always returns <code>true</code> , any certificate will pass validation.
CA5360: Do not call dangerous methods in deserialization	Insecure deserialization is a vulnerability that occurs when untrusted data is used to abuse the logic of an application, inflict a Denial-of-Service (DoS) attack, or even execute arbitrary code upon it being deserialized. It's frequently possible for malicious users to abuse these deserialization features when the application is deserializing untrusted data that is under their control. Specifically, invoke dangerous methods in the process of deserialization. Successful insecure deserialization attacks could allow an attacker to carry out attacks such as DoS attacks, authentication bypasses, and remote code execution.
CA5361: Do not disable SChannel use of strong crypto	<p>Setting <code>Switch.System.Net.DontEnableSchUseStrongCrypto</code> to <code>true</code> weakens the cryptography used in outgoing Transport Layer Security (TLS) connections. Weaker cryptography can compromise the confidentiality of communication between your application and the server, making it easier for attackers to eavesdrop sensitive data.</p>
CA5362: Potential reference cycle in deserialized object graph	If deserializing untrusted data, then any code processing the deserialized object graph needs to handle reference cycles without going into infinite loops. This includes both code that's part of a deserialization callback and code that processes the object graph after deserialization completed. Otherwise, an attacker could perform a Denial-of-Service attack with malicious data containing a reference cycle.

Rule	Description
CA5363: Do not disable request validation	Request validation is a feature in ASP.NET that examines HTTP requests and determines whether they contain potentially dangerous content that can lead to injection attacks, including cross-site-scripting.
CA5364: Do not use deprecated security protocols	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk.
CA5365: Do Not Disable HTTP Header Checking	HTTP header checking enables encoding of the carriage return and newline characters, \r and \n, that are found in response headers. This encoding can help to avoid injection attacks that exploit an application that echoes untrusted data contained by the header.
CA5366: Use XmlReader For DataSet Read XML	Using a DataSet to read XML with untrusted data may load dangerous external references, which should be restricted by using an XmlReader with a secure resolver or with DTD processing disabled.
CA5367: Do Not Serialize Types With Pointer Fields	This rule checks whether there's a serializable class with a pointer field or property. Members that can't be serialized can be a pointer, such as static members or fields marked with NonSerializedAttribute .
CA5368: Set ViewStateUserKey For Classes Derived From Page	Setting the ViewStateUserKey property can help you prevent attacks on your application by allowing you to assign an identifier to the view-state variable for individual users so that attackers cannot use the variable to generate an attack. Otherwise, there will be vulnerabilities to cross-site request forgery.
CA5369: Use XmlReader for Deserialize	Processing untrusted DTD and XML schemas may enable loading dangerous external references, which should be restricted by using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled.
CA5370: Use XmlReader for validating reader	Processing untrusted DTD and XML schemas may enable loading dangerous external references. This dangerous loading can be restricted by using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled.
CA5371: Use XmlReader for schema read	Processing untrusted DTD and XML schemas may enable loading dangerous external references. Using an XmlReader with a secure resolver or with DTD and XML inline schema processing disabled restricts this.
CA5372: Use XmlReader for XPathDocument	Processing XML from untrusted data may load dangerous external references, which can be restricted by using an XmlReader with a secure resolver or with DTD processing disabled.

RULE	DESCRIPTION
CA5373: Do not use obsolete key derivation function	<p>This rule detects the invocation of weak key derivation methods <code>System.Security.Cryptography.PasswordDeriveBytes</code> and <code>Rfc2898DeriveBytes.CryptDeriveKey</code>. <code>System.Security.Cryptography.PasswordDeriveBytes</code> used a weak algorithm PBKDF1.</p>
CA5374: Do Not Use XslTransform	<p>This rule checks if <code>System.Xml.Xsl.XslTransform</code> is instantiated in the code. <code>System.Xml.Xsl.XslTransform</code> is now obsolete and shouldn't be used.</p>
CA5375: Do not use account shared access signature	<p>An account SAS can delegate access to read, write, and delete operations on blob containers, tables, queues, and file shares that are not permitted with a service SAS. However, it doesn't support container-level policies and has less flexibility and control over the permissions that are granted. Once malicious users get it, your storage account will be compromised easily.</p>
CA5376: Use SharedAccessProtocol HttpsOnly	<p>SAS is sensitive data that can't be transported in plain text on HTTP.</p>
CA5377: Use container level access policy	<p>A container-level access policy can be modified or revoked at any time. It provides greater flexibility and control over the permissions that are granted.</p>
CA5378: Do not disable ServicePointManagerSecurityProtocols	<p>Setting <code>DisableUsingServicePointManagerSecurityProtocols</code> to <code>true</code> limits Windows Communication Framework's (WCF) Transport Layer Security (TLS) connections to using TLS 1.0. That version of TLS will be deprecated.</p>
CA5379: Ensure key derivation function algorithm is sufficiently strong	<p>The <code>Rfc2898DeriveBytes</code> class defaults to using the <code>SHA1</code> algorithm. You should specify the hash algorithm to use in some overloads of the constructor with <code>SHA256</code> or higher. Note, <code>HashAlgorithm</code> property only has a <code>get</code> accessor and doesn't have a <code>overridden</code> modifier.</p>
CA5380: Do not add certificates to root store	<p>This rule detects code that adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public CAs that has met the requirements of the Microsoft Root Certificate Program.</p>
CA5381: Ensure certificates are not added to root store	<p>This rule detects code that potentially adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public certification authorities (CAs) that has met the requirements of the Microsoft Root Certificate Program.</p>
CA5382: Use secure cookies in ASP.NET Core	<p>Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Transport Layer Security (TLS).</p>

Rule	Description
CA5383: Ensure use secure cookies in ASP.NET Core	Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Transport Layer Security (TLS).
CA5384: Do not use digital signature algorithm (DSA)	DSA is a weak asymmetric encryption algorithm.
CA5385: Use Rivest–Shamir–Adleman (RSA) algorithm with sufficient key size	An RSA key smaller than 2048 bits is more vulnerable to brute force attacks.
CA5386: Avoid hardcoding SecurityProtocolType value	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version and target at least .NET Framework v4.7.1.
CA5387: Do not use weak key derivation function with insufficient iteration count	This rule checks if a cryptographic key was generated by Rfc2898DeriveBytes with an iteration count of less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.
CA5388: Ensure sufficient iteration count when using weak key derivation function	This rule checks if a cryptographic key was generated by Rfc2898DeriveBytes with an iteration count that may be less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.
CA5389: Do not add archive item's path to the target file system path	File path can be relative and can lead to file system access outside of the expected file system target path, leading to malicious config changes and remote code execution via lay-and-wait technique.
CA5390: Do not hard-code encryption key	For a symmetric algorithm to be successful, the secret key must be known only to the sender and the receiver. When a key is hard-coded, it is easily discovered. Even with compiled binaries, it is easy for malicious users to extract it. Once the private key is compromised, the cipher text can be decrypted directly and is not protected anymore.
CA5391: Use antiforgery tokens in ASP.NET Core MVC controllers	Handling a <code>POST</code> , <code>PUT</code> , <code>PATCH</code> , or <code>DELETE</code> request without validating an antiforgery token may be vulnerable to cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET Core MVC controller.
CA5392: Use DefaultDllImportSearchPaths attribute for P/Invokes	By default, P/Invoke functions using DllImportAttribute probe a number of directories, including the current working directory for the library to load. This can be a security issue for certain applications, leading to DLL hijacking.
CA5393: Do not use unsafe DllImportSearchPath value	There could be a malicious DLL in the default DLL search directories and assembly directories. Or, depending on where your application is run from, there could be a malicious DLL in the application's directory.

Rule	Description
CA5394: Do not use insecure randomness	Using a cryptographically weak pseudo-random number generator may allow an attacker to predict what security-sensitive value will be generated.
CA5395: Miss <code>HttpVerb</code> attribute for action methods	All the action methods that create, edit, delete, or otherwise modify data needs to be protected with the <code>antiforgery</code> attribute from cross-site request forgery attacks. Performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.
CA5396: Set <code>HttpOnly</code> to true for <code>HttpCookie</code>	As a defense in depth measure, ensure security sensitive HTTP cookies are marked as <code>HttpOnly</code> . This indicates web browsers should disallow scripts from accessing the cookies. Injected malicious scripts are a common way of stealing cookies.
CA5397: Do not use deprecated <code>SslProtocols</code> values	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk.
CA5398: Avoid hardcoded <code>SslProtocols</code> values	Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version.
CA5399: Definitely disable <code>HttpClient</code> certificate revocation list check	A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.
CA5400: Ensure <code>HttpClient</code> certificate revocation list check is not disabled	A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.
CA5401: Do not use <code>CreateEncryptor</code> with non-default IV	Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.
CA5402: Use <code>CreateEncryptor</code> with the default IV	Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.
CA5403: Do not hard-code certificate	The <code>data</code> or <code>rawData</code> parameter of a <code>X509Certificate</code> or <code>X509Certificate2</code> constructor is hard-coded.
CA5404: Do not disable token validation checks	<code>TokenValidationParameters</code> properties that control token validation should not be set to <code>false</code> .
CA5405: Do not always skip token validation in delegates	The callback assigned to <code>AudienceValidator</code> or <code>LifetimeValidator</code> always returns <code>true</code> .

CA2100: Review SQL queries for security vulnerabilities

9/20/2022 • 6 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2100
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A method sets the [System.Data.IDbCommand.CommandText](#) property by using a string that is built from a string argument to the method.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

This rule assumes that any string, whose value can't be determined at compile time, may contain user input. A SQL command string that is built from user input is vulnerable to SQL injection attacks. In a SQL injection attack, a malicious user supplies input that alters the design of a query in an attempt to damage or gain unauthorized access to the underlying database. Typical techniques include injection of a single quotation mark or apostrophe, which is the SQL literal string delimiter; two dashes, which signifies a SQL comment; and a semicolon, which indicates that a new command follows. If user input must be part of the query, use one of the following, listed in order of effectiveness, to reduce the risk of attack.

- Use a stored procedure.
- Use a parameterized command string.
- Validate the user input for both type and content before you build the command string.

The following .NET types implement the [CommandText](#) property or provide constructors that set the property by using a string argument.

- [System.Data.Odbc.OdbcCommand](#) and [System.Data.Odbc.OdbcDataAdapter](#)
- [System.Data.OleDb.OleDbCommand](#) and [System.Data.OleDb.OleDbDataAdapter](#)
- [System.Data.OracleClient.OracleCommand](#) and [System.Data.OracleClient.OracleDataAdapter](#)
- [System.Data.SqlClient.SqlCommand](#) and [System.Data.SqlClient.SqlDataAdapter](#)

In some cases, this rule might not determine a string's value at compile time, even though you can. In those cases, this rule produces false positives when using those strings as SQL commands. The following is an example of such a string.

```
int x = 10;
string query = "SELECT TOP " + x.ToString() + " FROM Table";
```

The same applies when using `ToString()` implicitly.

```
int x = 10;
string query = String.Format("SELECT TOP {0} FROM Table", x);
```

How to fix violations

To fix a violation of this rule, use a parameterized query.

When to suppress warnings

It is safe to suppress a warning from this rule if the command text does not contain any user input.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2100
// The code that's violating the rule is on this line.
#pragma warning restore CA2100
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2100.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following example shows a method, `UnsafeQuery`, that violates the rule and a method, `SaferQuery`, that satisfies the rule by using a parameterized command string.

```

Imports System
Imports System.Data
Imports System.Data.SqlClient

Namespace ca2100

    Public Class SqlQueries

        Function UnsafeQuery(connection As String,
                             name As String, password As String) As Object

            Dim someConnection As New SqlConnection(connection)
            Dim someCommand As New SqlCommand()
            someCommand.Connection = someConnection

            someCommand.CommandText = "SELECT AccountNumber FROM Users " &
            "WHERE Username=''' & name & "' AND Password=''' & password & ''"

            someConnection.Open()
            Dim accountNumber As Object = someCommand.ExecuteScalar()
            someConnection.Close()
            Return accountNumber

        End Function

        Function SaferQuery(connection As String,
                             name As String, password As String) As Object

            Dim someConnection As New SqlConnection(connection)
            Dim someCommand As New SqlCommand()
            someCommand.Connection = someConnection

            someCommand.Parameters.Add(
                "@username", SqlDbType.NChar).Value = name
            someCommand.Parameters.Add(
                "@password", SqlDbType.NChar).Value = password
            someCommand.CommandText = "SELECT AccountNumber FROM Users " &
            "WHERE Username=@username AND Password=@password"

            someConnection.Open()
            Dim accountNumber As Object = someCommand.ExecuteScalar()
            someConnection.Close()
            Return accountNumber

        End Function

    End Class

    Class MaliciousCode

        Shared Sub Main2100(args As String())

            Dim queries As New SqlQueries()
            queries.UnsafeQuery(args(0), "' OR 1=1 --", "[PLACEHOLDER]")
            ' Resultant query (which is always true):
            ' SELECT AccountNumber FROM Users WHERE Username='' OR 1=1

            queries.SaferQuery(args(0), "' OR 1=1 --", "[PLACEHOLDER]")
            ' Resultant query (notice the additional single quote character):
            ' SELECT AccountNumber FROM Users WHERE Username=''' OR 1=1 --
            '                                         AND Password='[PLACEHOLDER]'

        End Sub

    End Class

End Namespace

```

```

public class SqlQueries
{
    public object UnsafeQuery(
        string connection, string name, string password)
    {
        SqlConnection someConnection = new SqlConnection(connection);
        SqlCommand someCommand = new SqlCommand();
        someCommand.Connection = someConnection;

        someCommand.CommandText = "SELECT AccountNumber FROM Users " +
            "WHERE Username=' " + name +
            "' AND Password=' " + password + "'";

        someConnection.Open();
        object accountNumber = someCommand.ExecuteScalar();
        someConnection.Close();
        return accountNumber;
    }

    public object SaferQuery(
        string connection, string name, string password)
    {
        SqlConnection someConnection = new SqlConnection(connection);
        SqlCommand someCommand = new SqlCommand();
        someCommand.Connection = someConnection;

        someCommand.Parameters.Add(
            "@username", SqlDbType.NChar).Value = name;
        someCommand.Parameters.Add(
            "@password", SqlDbType.NChar).Value = password;
        someCommand.CommandText = "SELECT AccountNumber FROM Users " +
            "WHERE Username=@username AND Password=@password";

        someConnection.Open();
        object accountNumber = someCommand.ExecuteScalar();
        someConnection.Close();
        return accountNumber;
    }
}

class MaliciousCode
{
    static void Main2100(string[] args)
    {
        SqlQueries queries = new SqlQueries();
        queries.UnsafeQuery(args[0], "' OR 1=1 --", "[PLACEHOLDER]");
        // Resultant query (which is always true):
        // SELECT AccountNumber FROM Users WHERE Username='' OR 1=1

        queries.SaferQuery(args[0], "' OR 1=1 --", "[PLACEHOLDER]");
        // Resultant query (notice the additional single quote character):
        // SELECT AccountNumber FROM Users WHERE Username=''' OR 1=1 --
        //                                         AND Password='[PLACEHOLDER]'
    }
}

CA2109: Review visible event handlers

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2109
Category	Security
Fix is breaking or non-breaking	Breaking

Cause

A public or protected event-handling method was detected.

Rule description

An externally visible event-handling method presents a security issue that requires review.

Do not expose event-handling methods unless absolutely necessary. An event handler, a delegate type, that invokes the exposed method can be added to any event as long as the handler and event signatures match. Events can potentially be raised by any code, and are frequently raised by highly trusted system code in response to user actions such as clicking a button. Adding a security check to an event-handling method does not prevent code from registering an event handler that invokes the method.

A demand cannot reliably protect a method invoked by an event handler. Security demands help protect code from untrusted callers by examining the callers on the call stack. Code that adds an event handler to an event is not necessarily present on the call stack when the event handler's methods run. Therefore, the call stack might have only highly trusted callers when the event handler method is invoked. This causes demands made by the event handler method to succeed. Also, the demanded permission might be asserted when the method is invoked. For these reasons, the risk of not fixing a violation of this rule can only be assessed after reviewing the event-handling method. When you review your code, consider the following issues:

- Does your event handler perform any operations that are dangerous or exploitable, such as asserting permissions or suppressing unmanaged code permission?
- What are the security threats to and from your code because it can run at any time with only highly trusted callers on the stack?

How to fix violations

To fix a violation of this rule, review the method and evaluate the following:

- Can you make the event-handling method non-public?
- Can you move all dangerous functionality out of the event handler?
- If a security demand is imposed, can this be accomplished in some other manner?

When to suppress warnings

SUPPRESS A WARNING FROM THIS RULE ONLY AFTER A CAREFUL SECURITY REVIEW TO MAKE SURE THAT YOUR CODE DOES NOT POSE

a security threat.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2109
// The code that's violating the rule is on this line.
#pragma warning restore CA2109
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2109.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following code shows an event-handling method that can be misused by malicious code.

```
public class HandleEvents
{
    // Due to the access level and signature, a malicious caller could
    // add this method to system-triggered events where all code in the call
    // stack has the demanded permission.

    // Also, the demand might be canceled by an asserted permission.

    [SecurityPermissionAttribute(SecurityAction.Demand, UnmanagedCode = true)]

    // Violates rule: ReviewVisibleEventHandlers.
    public static void SomeActionHappened(Object sender, EventArgs e)
    {
        Console.WriteLine("Do something dangerous from unmanaged code.");
    }
}
```

CA2119: Seal methods that satisfy private interfaces

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2119
Category	Security
Fix is breaking or non-breaking	Breaking

Cause

An inheritable public type provides an overridable method implementation of an `internal` (`Friend` in Visual Basic) interface.

Rule description

Interface methods have public accessibility, which cannot be changed by the implementing type. An internal interface creates a contract that is not intended to be implemented outside the assembly that defines the interface. A public type that implements a method of an internal interface using the `virtual` (`Overridable` in Visual Basic) modifier allows the method to be overridden by a derived type that is outside the assembly. If a second type in the defining assembly calls the method and expects an internal-only contract, behavior might be compromised when, instead, the overridden method in the outside assembly is executed. This creates a security vulnerability.

How to fix violations

To fix a violation of this rule, prevent the method from being overridden outside the assembly by using one of the following:

- Make the declaring type `sealed` (`NotInheritable` in Visual Basic).
- Change the accessibility of the declaring type to `internal` (`Friend` in Visual Basic).
- Remove all public constructors from the declaring type.
- Implement the method without using the `virtual` modifier.
- Implement the method explicitly.

When to suppress warnings

It is safe to suppress a warning from this rule if, after careful review, no security issues exist that might be exploitable if the method is overridden outside the assembly.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2119
// The code that's violating the rule is on this line.
#pragma warning restore CA2119
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2119.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example 1

The following example shows a type, `BaseImplementation`, that violates this rule.

```
// Internal by default.
interface IValidate
{
    bool UserIsValidated();
}

public class BaseImplementation : IValidate
{
    public virtual bool UserIsValidated()
    {
        return false;
    }
}

public class UseBaseImplementation
{
    public void SecurityDecision(BaseImplementation someImplementation)
    {
        if (someImplementation.UserIsValidated() == true)
        {
            Console.WriteLine("Account number & balance.");
        }
        else
        {
            Console.WriteLine("Please login.");
        }
    }
}
```

```

Interface IValidate
    Function UserIsValidated() As Boolean
End Interface

Public Class BaseImplementation
    Implements IValidate

        Overridable Function UserIsValidated() As Boolean _
            Implements IValidate.UserIsValidated
            Return False
        End Function

    End Class

    Public Class UseBaseImplementation

        Sub SecurityDecision(someImplementation As BaseImplementation)

            If (someImplementation.UserIsValidated() = True) Then
                Console.WriteLine("Account number & balance.")
            Else
                Console.WriteLine("Please login.")
            End If

        End Sub

    End Class

```

Example 2

The following example exploits the virtual method implementation of the previous example.

```

public class BaseImplementation
{
    public virtual bool UserIsValidated()
    {
        return false;
    }
}

public class UseBaseImplementation
{
    public void SecurityDecision(BaseImplementation someImplementation)
    {
        if (someImplementation.UserIsValidated() == true)
        {
            Console.WriteLine("Account number & balance.");
        }
        else
        {
            Console.WriteLine("Please login.");
        }
    }
}

```

```
Public Class BaseImplementation

    Overridable Function UserIsValidated() As Boolean
        Return False
    End Function

End Class

Public Class UseBaseImplementation

    Sub SecurityDecision(someImplementation As BaseImplementation)

        If (someImplementation.UserIsValidated() = True) Then
            Console.WriteLine("Account number & balance.")
        Else
            Console.WriteLine("Please login.")
        End If

    End Sub

End Class
```

CA2153: Avoid handling Corrupted State Exceptions

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2153
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Corrupted State Exceptions (CSEs) indicate that memory corruption exists in your process. Catching these rather than allowing the process to crash can lead to security vulnerabilities if an attacker can place an exploit into the corrupted memory region.

Rule description

CSE indicates that the state of a process has been corrupted and not caught by the system. In the corrupted state scenario, a general handler only catches the exception if you mark your method with the [System.Runtime.ExceptionServices.HandleProcessCorruptedStateExceptionsAttribute](#) attribute. By default, the [Common Language Runtime \(CLR\)](#) does not invoke catch handlers for CSEs.

The safest option is to allow the process to crash without catching these kinds of exceptions. Even logging code can allow attackers to exploit memory corruption bugs.

This warning triggers when catching CSEs with a general handler that catches all exceptions, for example,

`catch (System.Exception e)` or `catch` with no exception parameter.

How to fix violations

To resolve this warning, do one of the following:

- Remove the [HandleProcessCorruptedStateExceptionsAttribute](#) attribute. This reverts to the default runtime behavior where CSEs are not passed to catch handlers.
- Remove the general catch handler in preference of handlers that catch specific exception types. This may include CSEs, assuming the handler code can safely handle them (rare).
- Rethrow the CSE in the catch handler, which passes the exception to the caller and should result in ending the running process.

When to suppress warnings

Do not suppress a warning from this rule.

Pseudo-code example

Violation

The following pseudo-code illustrates the pattern detected by this rule.

```
[HandleProcessCorruptedStateExceptions]
// Method that handles CSE exceptions.
void TestMethod1()
{
    try
    {
        FileStream fileStream = new FileStream("name", FileMode.Create);
    }
    catch (Exception e)
    {
        // Handle exception.
    }
}
```

Solution 1 - remove the attribute

Removing the [HandleProcessCorruptedStateExceptionsAttribute](#) attribute ensures that Corrupted State Exceptions are not handled by your method.

```
void TestMethod1()
{
    try
    {
        FileStream fileStream = new FileStream("name", FileMode.Create);
    }
    catch (Exception e)
    {
        // Handle exception.
    }
}
```

Solution 2 - catch specific exceptions

Remove the general catch handler and catch only specific exception types.

```
void TestMethod1()
{
    try
    {
        FileStream fileStream = new FileStream("name", FileMode.Create);
    }
    catch (IOException e)
    {
        // Handle IOException.
    }
    catch (UnauthorizedAccessException e)
    {
        // Handle UnauthorizedAccessException.
    }
}
```

Solution 3 - rethrow

Rethrow the exception.

```
[HandleProcessCorruptedStateExceptions]
void TestMethod1()
{
    try
    {
        FileStream fileStream = new FileStream("name", FileMode.Create);
    }
    catch (Exception e)
    {
        // Rethrow the exception.
        throw;
    }
}
```

CA2300: Do not use insecure deserializer BinaryFormatter

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2300
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method was called or referenced.

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method calls or references. If you want to deserialize only when the `Binder` property is set to restrict types, disable this rule and enable rules [CA2301](#) and [CA2302](#) instead. Limiting which types can be deserialized can help mitigate against known remote code execution attacks, but your deserialization will still be vulnerable to denial of service attacks.

`BinaryFormatter` is insecure and can't be made secure. For more information, see the [BinaryFormatter security guide](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- This option makes code vulnerable to denial of service attacks and possible remote code execution attacks in the future. For more information, see the [BinaryFormatter security guide](#). Restrict serialized types. Implement a custom `System.Runtime.Serialization.SerializationBinder`. Before deserializing, set the `Binder` property to an instance of your custom `SerializationBinder` in all code paths. In the overridden `BindToType` method, if the type is unexpected, throw an exception to stop deserialization.

When to suppress warnings

`BinaryFormatter` is insecure and can't be made secure.

Pseudo-code examples

Violation

```
using System.IO;
using System.Runtime.Serialization.Formatters.Binary;

public class ExampleClass
{
    public object MyDeserialize(byte[] bytes)
    {
        BinaryFormatter formatter = new BinaryFormatter();
        return formatter.Deserialize(new MemoryStream(bytes));
    }
}
```

```
Imports System.IO
Imports System.Runtime.Serialization.Formatters.Binary

Public Class ExampleClass
    Public Function MyDeserialize(bytes As Byte()) As Object
        Dim formatter As BinaryFormatter = New BinaryFormatter()
        Return formatter.Deserialize(New MemoryStream(bytes))
    End Function
End Class
```

Related rules

[CA2301: Do not call BinaryFormatter.Deserialize without first setting BinaryFormatter.Binder](#)

[CA2302: Ensure BinaryFormatter.Binder is set before calling BinaryFormatter.Deserialize](#)

CA2301: Do not call BinaryFormatter.Deserialize without first setting BinaryFormatter.Binder

9/20/2022 • 5 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2301
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method was called or referenced without the `Binder` property set.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

WARNING

Restricting types with a `SerializationBinder` can't prevent all attacks. For more information, see the [BinaryFormatter security guide](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method calls or references, when `BinaryFormatter` doesn't have its `Binder` set. If you want to disallow any deserialization with `BinaryFormatter` regardless of the `Binder` property, disable this rule and [CA2302](#), and enable rule [CA2300](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- This option makes code vulnerable to denial of service attacks and possible remote code execution attacks in the future. For more information, see the [BinaryFormatter security guide](#). Restrict serialized types. Implement a custom `System.Runtime.Serialization.SerializationBinder`. Before deserializing, set the `Binder` property to an instance of your custom `SerializationBinder` in all code paths. In the overridden `BindToType` method, if the type is unexpected, throw an exception to stop deserialization.

When to suppress warnings

`BinaryFormatter` is insecure and can't be made secure.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).

- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

[CA2300: Do not use insecure deserializer BinaryFormatter](#)

[CA2302: Ensure BinaryFormatter.Binder is set before calling BinaryFormatter.Deserialize](#)

CA2302: Ensure BinaryFormatter.Binder is set before calling BinaryFormatter.Deserialize

9/20/2022 • 8 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2302
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method was called or referenced and the `Binder` property may be null.

This rule is similar to [CA2301](#), but analysis can't determine if the `Binder` is definitely null.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

WARNING

Restricting types with a `SerializationBinder` can't prevent all attacks. For more information, see the [BinaryFormatter security guide](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Runtime.Serialization.Formatters.Binary.BinaryFormatter` deserialization method calls or references when the `Binder` might be null. If you want to disallow any deserialization with `BinaryFormatter` regardless of the `Binder` property, disable this rule and [CA2301](#), and enable rule [CA2300](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- This option makes code vulnerable to denial of service attacks and possible remote code execution attacks in the future. For more information, see the [BinaryFormatter security guide](#). Restrict serialized types. Implement a custom `System.Runtime.Serialization.SerializationBinder`. Before deserializing, set the `Binder` property to an instance of your custom `SerializationBinder` in all code paths. In the overridden `BindToType`

method, if the type is unexpected, throw an exception to stop deserialization.

When to suppress warnings

`BinaryFormatter` is insecure and can't be made secure.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- Exclude specific symbols
- Exclude specific types and their derived types

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

- [CA2300: Do not use insecure deserializer BinaryFormatter](#)
- [CA2301: Do not call BinaryFormatter.Deserialize without first setting BinaryFormatter.Binder](#)

CA2305: Do not use insecure deserializer LosFormatter

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2305
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A [System.Web.UI.LosFormatter](#) deserialization method was called or referenced.

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds [System.Web.UI.LosFormatter](#) deserialization method calls or references.

[LosFormatter](#) is insecure and can't be made secure. For more information, see the [BinaryFormatter security guide](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

[LosFormatter](#) is insecure and can't be made secure.

Violation

```
using System.IO;
using System.Web.UI;

public class ExampleClass
{
    public object MyDeserialize(byte[] bytes)
    {
        LosFormatter formatter = new LosFormatter();
        return formatter.Deserialize(new MemoryStream(bytes));
    }
}
```

```
Imports System.IO
Imports System.Web.UI

Public Class ExampleClass
    Public Function MyDeserialize(bytes As Byte()) As Object
        Dim formatter As LosFormatter = New LosFormatter()
        Return formatter.Deserialize(New MemoryStream(bytes))
    End Function
End Class
```

CA2310: Do not use insecure deserializer NetDataContractSerializer

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2310
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Runtime.Serialization.NetDataContractSerializer` deserialization method was called or referenced.

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Runtime.Serialization.NetDataContractSerializer` deserialization method calls or references. If you want to deserialize only when the `Binder` property is set to restrict types, disable this rule and enable rules [CA2311](#) and [CA2312](#) instead. Limiting which types can be deserialized can help mitigate against known remote code execution attacks, but your deserialization will still be vulnerable to denial of service attacks.

`NetDataContractSerializer` is insecure and can't be made secure. For more information, see the [BinaryFormatter security guide](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- This option makes code vulnerable to denial of service attacks and possible remote code execution attacks in the future. For more information, see the [BinaryFormatter security guide](#). Restrict serialized types. Implement a custom `System.Runtime.Serialization.SerializationBinder`. Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).

- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

[CA2310: Do not use insecure deserializer NetDataContractSerializer](#)

[CA2312: Ensure NetDataContractSerializer.Binder is set before deserializing](#)

CA2312: Ensure `NetDataContractSerializer.Binder` is set before deserializing

9/20/2022 • 9 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2312
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Runtime.Serialization.NetDataContractSerializer` deserialization method was called or referenced and the `Binder` property may be null.

This rule is similar to [CA2311](#), but analysis can't determine if the `Binder` is definitely null.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

WARNING

Restricting types with a `SerializationBinder` can't prevent all attacks. For more information, see the [BinaryFormatter security guide](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Runtime.Serialization.NetDataContractSerializer` deserialization method calls or references when the `Binder` might be null. If you want to disallow any deserialization with `NetDataContractSerializer` regardless of the `Binder` property, disable this rule and [CA2311](#), and enable rule [CA2310](#).

`NetDataContractSerializer` is insecure and can't be made secure. For more information, see the [BinaryFormatter security guide](#).

How to fix violations

- Use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. For more information see the [Preferred alternatives](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- This option makes code vulnerable to denial of service attacks and possible remote code execution attacks in

the future. For more information, see the [BinaryFormatter security guide](#). Restrict deserialized types. Implement a custom [System.Runtime.Serialization.SerializationBinder](#). Before deserializing, set the [BINDER](#) property to an instance of your custom [SerializationBinder](#) in all code paths. In the overridden [BindToType](#) method, if the type is unexpected, throw an exception to stop deserialization.

When to suppress warnings

`NetDataContractSerializer` is insecure and can't be made secure.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Related rules

- [CA2310: Do not use insecure deserializer NetDataContractSerializer](#)
- [CA2311: Do not deserialize without first setting NetDataContractSerializer.Binder](#)

CA2315: Do not use insecure deserializer ObjectStateFormatter

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2315
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A [System.Web.UI.ObjectStateFormatter](#) deserialization method was called or referenced.

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds [System.Web.UI.ObjectStateFormatter](#) deserialization method calls or references.

How to fix violations

- If possible, use a secure serializer instead, and **don't allow an attacker to specify an arbitrary type to deserialize**. Some safer serializers include:
 - [System.Runtime.Serialization.DataContractSerializer](#)
 - [System.Runtime.Serialization.JsonDataContractJsonSerializer](#)
 - [System.Web.Script.Serialization.JavaScriptSerializer](#) - Never use [System.Web.Script.Serialization.SimpleTypeResolver](#). If you must use a type resolver, restrict serialized types to an expected list.
 - [System.Xml.Serialization.XmlSerializer](#)
 - Newtonsoft.Json.NET - Use `TypeNameHandling.None`. If you must use another value for `TypeNameHandling`, restrict serialized types to an expected list with a custom `ISerializationBinder`.
 - Protocol Buffers
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change

over time.

- You've taken one of the precautions in [How to fix violations](#).

Pseudo-code examples

Violation

```
using System.IO;
using System.Web.UI;

public class ExampleClass
{
    public object MyDeserialize(byte[] bytes)
    {
        ObjectStateFormatter formatter = new ObjectStateFormatter();
        return formatter.Deserialize(new MemoryStream(bytes));
    }
}
```

```
Imports System.IO
Imports System.Web.UI

Public Class ExampleClass
    Public Function MyDeserialize(bytes As Byte()) As Object
        Dim formatter As ObjectStateFormatter = New ObjectStateFormatter()
        Return formatter.Deserialize(New MemoryStream(bytes))
    End Function
End Class
```

CA2321: Do not deserialize with JavaScriptSerializer using a SimpleTypeResolver

9/20/2022 • 6 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2321
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Web.Script.Serialization.JavaScriptSerializer` deserialization method was called or referenced after initializing with a `System.Web.Script.Serialization.SimpleTypeResolver`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Web.Script.Serialization.JavaScriptSerializer` deserialization method calls or references, after initializing the `JavaScriptSerializer` with a `System.Web.Script.Serialization.SimpleTypeResolver`.

How to fix violations

- Don't initialize `JavaScriptTypeResolver` with a `System.Web.Script.Serialization.SimpleTypeResolver`.
- If your code needs to read data serialized using a `SimpleTypeResolver`, restrict deserialized types to an expected list by implementing a custom `JavaScriptTypeResolver`.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then

re-enable the rule.

```
#pragma warning disable CA2321
// The code that's violating the rule is on this line.
#pragma warning restore CA2321
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2321.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType	Matches all types named <code>MyType</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA2322: Ensure JavaScriptSerializer is not initialized with SimpleTypeResolver before deserializing

9/20/2022 • 6 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2322
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `System.Web.Script.Serialization.JavaScriptSerializer` deserialization method was called or referenced and the `JavaScriptSerializer` may have been initialized with a `System.Web.Script.Serialization.SimpleTypeResolver`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `System.Web.Script.Serialization.JavaScriptSerializer` deserialization method calls or references, when the `JavaScriptSerializer` may have been initialized with a `System.Web.Script.Serialization.SimpleTypeResolver`.

How to fix violations

- Ensure `JavaScriptTypeResolver` objects aren't initialized with a `System.Web.Script.Serialization.SimpleTypeResolver`.
- If your code needs to read data serialized using a `SimpleTypeResolver`, restrict deserialized types to an expected list by implementing a custom `JavaScriptTypeResolver`.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2322
// The code that's violating the rule is on this line.
#pragma warning restore CA2322
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2322.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Related rules

[CA2321: Do not deserialize with JavaScriptSerializer using a SimpleTypeResolver](#)

CA2326: Do not use TypeNameHandling values other than None

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2326
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when either of the following conditions are met:

- A `Newtonsoft.Json.TypeNameHandling` enumeration value, other than `None`, is referenced.
- An integer value representing a non-zero value is assigned to a `TypeNameHandling` variable.

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `Newtonsoft.Json.TypeNameHandling` values other than `None`. If you want to deserialize only when a `Newtonsoft.Json.Serialization.ISerializationBinder` is specified to restrict serialized types, disable this rule and enable rules [CA2327](#), [CA2328](#), [CA2329](#), and [CA2330](#) instead.

How to fix violations

- Use `TypeNameHandling`'s `None` value, if possible.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- Restrict serialized types. Implement a custom `Newtonsoft.Json.Serialization.ISerializationBinder`. Before deserializing with Json.NET, ensure your custom `ISerializationBinder` is specified in the `Newtonsoft.Json.JsonSerializerSettings.SerializationBinder` property. In the overridden `Newtonsoft.Json.Serialization.ISerializationBinder.BindToType` method, if the type is unexpected, return `null` or throw an exception to stop deserialization.
 - If you restrict serialized types, you may want to disable this rule and enable rules [CA2327](#), [CA2328](#), [CA2329](#), and [CA2330](#). Rules [CA2327](#), [CA2328](#), [CA2329](#), and [CA2330](#) help to ensure that you use an `ISerializationBinder` when using `TypeNameHandling` values other than `None`.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2326
// The code that's violating the rule is on this line.
#pragma warning restore CA2326
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2326.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```

9/20/2022 • 7 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2327
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when both of the following conditions are true for a `Newtonsoft.Json.JsonSerializerSettings` instance:

- The `TypeNameHandling` property is a value other than `None`.
- The `SerializationBinder` property is null.

The `JsonSerializerSettings` instance must be used in one of the following ways:

- Initialized as a class field or property.
- Returned by a method.
- Passed to `JsonSerializer.Create` or `JsonSerializer.CreateDefault`.
- Passed to a `JsonConvert` method that has a `JsonSerializerSettings` parameter.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `Newtonsoft.Json.JsonSerializerSettings` instances that are configured to deserialize types specified from input, but not configured to restrict deserialized types with a `Newtonsoft.Json.Serialization.ISerializationBinder`. If you want to disallow deserialization of types specified from input completely, disable rules CA2327, [CA2328](#), [CA2329](#), and [CA2330](#), and enable rule [CA2326](#) instead.

How to fix violations

- Use `TypeNameHandling`'s `None` value, if possible.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- Restrict deserialized types. Implement a custom `Newtonsoft.Json.Serialization.ISerializationBinder`. Before deserializing with Json.NET, ensure your custom `ISerializationBinder` is specified in the `Newtonsoft.Json.JsonSerializerSettings.SerializationBinder` property. In the overridden

`Newtonsoft.Json.Serialization.ISerializationBinder.BindToType` method, if the type is unexpected, return `null` or throw an exception to stop deserialization.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2327
// The code that's violating the rule is on this line.
#pragma warning restore CA2327
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2327.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind

prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.

- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

	VALUE
Rule ID	CA2328
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when both of the following conditions *might be* true for a `Newtonsoft.Json.JsonSerializerSettings` instance:

- The `TypeNameHandling` property is a value other than `None`.
- The `SerializationBinder` property is null.

The `JsonSerializerSettings` instance must be used in one of the following ways:

- Initialized as a class field or property.
- Returned by a method.
- Passed to `JsonSerializer.Create` or `JsonSerializer.CreateDefault`.
- Passed to a `JsonConvert` method that has a `JsonSerializerSettings` parameter.

This rule is similar to [CA2327](#), but in this case, analysis can't definitively determine if the settings are insecure.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `Newtonsoft.Json.JsonSerializerSettings` instances that might be configured to deserialize types specified from input, but may not be configured to restrict deserialized types with a `Newtonsoft.Json.Serialization.ISerializationBinder`. If you want to disallow deserialization of types specified from input completely, disable rules [CA2327](#), CA2328, [CA2329](#), and [CA2330](#), and enable rule [CA2326](#) instead.

How to fix violations

- Use `TypeNameHandling`'s `None` value, if possible.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

- Restrict deserialized types. Implement a custom `Newtonsoft.Json.Serialization.ISerializationBinder`. Before deserializing with Json.NET, ensure your custom `ISerializationBinder` is specified in the `Newtonsoft.Json.JsonSerializerSettings.SerializationBinder` property. In the overridden `Newtonsoft.Json.Serialization.ISerializationBinder.BindToType` method, if the type is unexpected, return `null` or throw an exception to stop deserialization.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).
- You know that the `Newtonsoft.Json.JsonSerializerSettings.SerializationBinder` property is always set when `TypeNameHandling` property is a value other than `None`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2328
// The code that's violating the rule is on this line.
#pragma warning restore CA2328
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2328.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA2329: Do not deserialize with JsonSerializer using an insecure configuration

9/20/2022 • 6 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2329
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when both of the following conditions are true for a `Newtonsoft.Json.JsonSerializer` instance that's passed to a deserialization method or initialized as a field or property:

- The `TypeNameHandling` property is a value other than `None`.
- The `SerializationBinder` property is null.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `Newtonsoft.Json.JsonSerializer` instances that are configured to deserialize types specified from input, but not configured to restrict serialized types with a `Newtonsoft.Json.Serialization.ISerializationBinder`. If you want to disallow deserialization of types specified from input completely, disable rules [CA2327](#), [CA2328](#), [CA2329](#), and [CA2330](#), and enable rule [CA2326](#) instead.

How to fix violations

- Use `TypeNameHandling`'s `None` value, if possible.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- Restrict serialized types. Implement a custom `Newtonsoft.Json.Serialization.ISerializationBinder`. Before deserializing with Json.NET, ensure your custom `ISerializationBinder` is specified in the `Newtonsoft.Json.JsonSerializer.SerializationBinder` property. In the overridden `Newtonsoft.Json.Serialization.ISerializationBinder.BindToType` method, if the type is unexpected, return `null` or throw an exception to stop deserialization.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2329
// The code that's violating the rule is on this line.
#pragma warning restore CA2329
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2329.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA2330: Ensure that JsonSerializer has a secure configuration when deserializing

9/20/2022 • 8 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2330
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when both of the following conditions *might be* true for a `Newtonsoft.Json.JsonSerializer` instance that's passed to a deserialization method or initialized as a field or property:

- The `TypeNameHandling` property is a value other than `None`.
- The `SerializationBinder` property is null.

This rule is similar to [CA2329](#), but in this case, analysis can't definitively determine if the serializer is configured insecurely.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Insecure deserializers are vulnerable when deserializing untrusted data. An attacker could modify the serialized data to include unexpected types to inject objects with malicious side effects. An attack against an insecure deserializer could, for example, execute commands on the underlying operating system, communicate over the network, or delete files.

This rule finds `Newtonsoft.Json.JsonSerializer` instances that might be configured to deserialize types specified from input, but may not be configured to restrict deserialized types with a `Newtonsoft.Json.Serialization.ISerializationBinder`. If you want to disallow deserialization of types specified from input completely, disable rules [CA2327](#), [CA2328](#), [CA2329](#), and [CA2330](#), and enable rule [CA2326](#) instead.

How to fix violations

- Use `TypeNameHandling`'s `None` value, if possible.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- Restrict deserialized types. Implement a custom `Newtonsoft.Json.Serialization.ISerializationBinder`. Before deserializing with Json.NET, ensure your custom `ISerializationBinder` is specified in the `Newtonsoft.Json.JsonSerializer.SerializationBinder` property. In the overridden `Newtonsoft.Json.Serialization.ISerializationBinder.BindToType` method, if the type is unexpected, return `null` or throw an exception to stop deserialization.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).
- You know that the `Newtonsoft.Json.JsonSerializer.SerializationBinder` property is always set when `TypeNameHandling` property is a value other than `None`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2330
// The code that's violating the rule is on this line.
#pragma warning restore CA2330
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2330.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.

- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA2350: Ensure DataTable.ReadXml()'s input is trusted

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2350
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `DataTable.ReadXml` method was called or referenced.

Rule description

When deserializing a `DataTable` with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.

For more information, see [DataSet and DataTable security guidance](#).

How to fix violations

- If possible, use [Entity Framework](#) rather than the `DataTable`.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2350
// The code that's violating the rule is on this line.
#pragma warning restore CA2350
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2350.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System.Data;

public class ExampleClass
{
    public DataTable MyDeserialize(string untrustedXml)
    {
        DataTable dt = new DataTable();
        dt.ReadXml(untrustedXml);
    }
}
```

	VALUE
Rule ID	CA2351
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `DataSet.ReadXml` method was called or referenced, and not within autogenerated code.

This rule classifies autogenerated code b:

- Being inside a method named `ReadXmlSerializable`.
- The `ReadXmlSerializable` method has a `System.Diagnostics.DebuggerNonUserCodeAttribute`.
- The `ReadXmlSerializable` method is within a type that has a `System.ComponentModel.DesignerCategoryAttribute`.

CA2361 is a similar rule, for when `DataSet.ReadXml` appears within autogenerated code.

Rule description

When deserializing a `DataSet` with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.

For more information, see [DataSet and DataTable security guidance](#).

How to fix violations

- If possible, use [Entity Framework](#) rather than the `DataSet`.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

CA2361: Ensure autogenerated class containing DataSet.ReadXml() is not used with untrusted data

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2361
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `DataSet.ReadXml` method was called or referenced, and is within autogenerated code.

This rule classifies autogenerated code b:

- Being inside a method named `ReadXmlSerializable`.
- The `ReadXmlSerializable` method has a `System.Diagnostics.DebuggerNonUserCodeAttribute`.
- The `ReadXmlSerializable` method is within a type that has a `System.ComponentModel.DesignerCategoryAttribute`.

[CA2351](#) is a similar rule, for when `DataSet.ReadXml` appears within non-autogenerated code.

Rule description

When deserializing a `DataSet` with untrusted input, an attacker can craft malicious input to perform a denial of service attack. There may be unknown remote code execution vulnerabilities.

This rule is like [CA2351](#), but for autogenerated code for an in-memory representation of data within a GUI application. Usually, these autogenerated classes aren't serialized from untrusted input. Your application's usage may vary.

For more information, see [DataSet and DataTable security guidance](#).

How to fix violations

- If possible, use [Entity Framework](#) rather than the `DataSet`.
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2361
// The code that's violating the rule is on this line.
#pragma warning restore CA2361
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2361.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

CA2362: Unsafe DataSet or DataTable in autogenerated serializable type can be vulnerable to remote code execution attacks

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2362
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A class or struct marked with [SerializableAttribute](#) contains a [DataSet](#) or [DataTable](#) field or property, and does have a [DesignerCategoryAttribute](#).

[CA2352](#) is a similar rule, for when there isn't a [DesignerCategoryAttribute](#).

Rule description

When deserializing untrusted input with [BinaryFormatter](#) and the deserialized object graph contains a [DataSet](#) or [DataTable](#), an attacker can craft a malicious payload to perform a remote code execution attack.

This rule is like [CA2352](#), but for autogenerated code for an in-memory representation of data within a GUI application. Usually, these autogenerated classes aren't deserialized from untrusted input. Your application's usage may vary.

This rule finds types which are insecure when serialized. If your code doesn't deserialize the types found, then you don't have a serialization vulnerability.

For more information, see [DataSet and DataTable security guidance](#).

How to fix violations

- If possible, use [Entity Framework](#) rather than [DataSet](#) and [DataTable](#).
- Make the serialized data tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The type found by this rule is never serialized, either directly or indirectly.
- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- You've taken one of the precautions in [How to fix violations](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2362
// The code that's violating the rule is on this line.
#pragma warning restore CA2362
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2362.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA3001: Review code for SQL injection vulnerabilities

9/20/2022 • 5 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3001
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches an SQL command's text.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input and SQL commands, be mindful of SQL injection attacks. An SQL injection attack can execute malicious SQL commands, compromising the security and integrity of your application.

Typical techniques include using a single quotation mark or apostrophe for delimiting literal strings, two dashes for a comment, and a semicolon for the end of a statement. For more information, see [SQL Injection](#).

This rule attempts to find input from HTTP requests reaching an SQL command's text.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that executes the SQL command, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Use parameterized SQL commands, or stored procedures, with parameters containing the untrusted input.

When to suppress warnings

It's safe to suppress a warning from this rule if you know that the input is always validated against a known safe set of characters.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3001
// The code that's violating the rule is on this line.
#pragma warning restore CA3001
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3001.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA3002: Review code for XSS vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3002
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches raw HTML output.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input from web requests, be mindful of cross-site scripting (XSS) attacks. An XSS attack injects untrusted input into raw HTML output, allowing the attacker to execute malicious scripts or maliciously modify content in your web page. A typical technique is putting `<script>` elements with malicious code in input. For more information, see [OWASP's XSS](#).

This rule attempts to find input from HTTP requests reaching raw HTML output.

Note

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that outputs raw HTML, this rule won't produce a warning.

Note

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

- Instead of outputting raw HTML, use a method or property that first HTML-encodes its input.
- HTML-encode untrusted data before outputting raw HTML.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know that the input is validated against a known safe set of characters not containing HTML.
- You know the data is HTML-encoded in a way not detected by this rule.

NOTE

This rule may report false positives for some methods or properties that HTML-encode their input.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3002
// The code that's violating the rule is on this line.
#pragma warning restore CA3002
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3002.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CONFIGURE CODE TO ANALYZE

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

        Me.Response.Write("<HTML>" + Me.Server.HtmlEncode(input) + "</HTML>")
    End Sub
End Class

```

CA3003: Review code for file path injection vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3003
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches the path of a file operation.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input from web requests, be mindful of using user-controlled input when specifying paths to files. An attacker may be able to read an unintended file, resulting in information disclosure of sensitive data. Or, an attacker may be able to write to an unintended file, resulting in unauthorized modification of sensitive data or compromising the server's security. A common attacker technique is [Path Traversal](#) to access files outside of the intended directory.

This rule attempts to find input from HTTP requests reaching a path in a file operation.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that writes to a file, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

- If possible, limit file paths based on user input to an explicitly known safe list. For example, if your application only needs to access "red.txt", "green.txt", or "blue.txt", only allow those values.
- Check for untrusted filenames and validate that the name is well formed.
- Use full path names when specifying paths.
- Avoid potentially dangerous constructs such as path environment variables.
- Only accept long filenames and validate long name if user submits short names.
- Restrict end user input to valid characters.

- Reject names where MAX_PATH length is exceeded.
- Handle filenames literally, without interpretation.
- Determine if the filename represents a file or a device.

When to suppress warnings

If you've validated input as described in the previous section, it's okay to suppress this warning.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;
using System.IO;

public partial class WebForm : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
        string userInput = Request.Params["UserInput"];
        // Assume the following directory structure:
        // wwwroot\currentWebDirectory\user1.txt
        // wwwroot\currentWebDirectory\user2.txt
        // wwwroot\secret\allsecrets.txt
        // There is nothing wrong if the user inputs:
        // user1.txt
        // However, if the user input is:
        // ..\secret\allsecrets.txt
        // Then an attacker can now see all the secrets.

        // Avoid this:
        using (File.Open(userInput, FileMode.Open))
        {
            // Read a file with the name supplied by user
            // Input through request's query string and display
            // The content to the webpage.
        }
    }
}
```

```
Imports System
Imports System.IO

Partial Public Class WebForm
    Inherits System.Web.UI.Page

    Protected Sub Page_Load(sender As Object, e As EventArgs)
        Dim userInput As String = Me.Request.Params("UserInput")
        ' Assume the following directory structure:
        '   wwwroot\currentWebDirectory\user1.txt
        '   wwwroot\currentWebDirectory\user2.txt
        '   wwwroot\secret\allsecrets.txt
        ' There is nothing wrong if the user inputs:
        '   user1.txt
        ' However, if the user input is:
        '   ..\secret\allsecrets.txt
        ' Then an attacker can now see all the secrets.

        ' Avoid this:
        Using File.Open(userInput, FileMode.Open)
            ' Read a file with the name supplied by user
            ' Input through request's query string and display
            ' The content to the webpage.
        End Using
    End Sub
End Class
```

CA3004: Review code for information disclosure vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3004
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

An exception's message, stack trace, or string representation reaches web output.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Disclosing exception information gives attackers insight into the internals of your application, which can help attackers find other vulnerabilities to exploit.

This rule attempts to find an exception message, stack trace, or string representation being output to an HTTP response.

NOTE

This rule can't track data across assemblies. For example, if one assembly catches an exception and then passes it to another assembly that outputs the exception, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. For information about how to configure the limit in an EditorConfig file, see [Analyzer Configuration](#).

How to fix violations

Don't output exception information to HTTP responses. Instead, provide a generic error message. For more information, see [OWASP's Improper Error Handling page](#).

When to suppress warnings

If you know your web output is within your application's trust boundary and never exposed outside, it's okay to suppress this warning. This is rare. Take into consideration that your application's trust boundary and data flows may change over time.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3004
// The code that's violating the rule is on this line.
#pragma warning restore CA3004
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3004.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

            o.ToString()
        Catch e As Exception
            Me.Response.Write("An error occurred. Please try again later.")
        End Try
    End Sub
End Class
```

CA3005: Review code for LDAP injection vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3005
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches an LDAP statement.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of Lightweight Directory Access Protocol (LDAP) injection attacks. An attacker can potentially run malicious LDAP statements against information directories. Applications that use user input to construct dynamic LDAP statements to access directory services are particularly vulnerable.

This rule attempts to find input from HTTP requests reaching an LDAP statement.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that executes an LDAP statement, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

For the user-controlled portion of LDAP statements, consider one of:

- Allow only a safe list of non-special characters.
- Disallow special character
- Escape special characters.

See [OWASP's LDAP Injection Prevention Cheat Sheet](#) for more guidance.

When to suppress warnings

If you know the input has been validated or escaped to be safe, it's okay to suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3005
// The code that's violating the rule is on this line.
#pragma warning restore CA3005
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3005.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

        Dim userName As String = Me.Request.Params("user")
        Dim filter As String = """(uid="" + userName + """)""      ' searching for the user entry

        ' In this example, if we send the * character in the user parameter which will
        ' result in the filter variable in the code to be initialized with (uid=*).
        ' The resulting LDAP statement will make the server return any object that
        ' contains a uid attribute.
        Dim searcher As DirectorySearcher = new DirectorySearcher(filter)
        Dim results As SearchResultCollection = searcher.FindAll()

        ' Iterate through each SearchResult in the SearchResultCollection.
        For Each searchResult As SearchResult in results
            ' ...
            Next searchResult
        End Sub
    End Class

```

CA3006: Review code for process command injection vulnerabilities

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3006
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches a process command.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of command injection attacks. A command injection attack can execute malicious commands on the underlying operating system, compromising the security and integrity of your server.

This rule attempts to find input from HTTP requests reaching a process command.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that starts a process, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

- If possible, avoid starting processes based on user input.
- Validate input against a known safe set of characters and length.

When to suppress warnings

If you know the input has been validated or escaped to be safe, it's safe to suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then

re-enable the rule.

```
#pragma warning disable CA3006
// The code that's violating the rule is on this line.
#pragma warning restore CA3006
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3006.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType	Matches all types named <code>MyType</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;
using System.Diagnostics;

public partial class WebForm : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
        string input = Request.Form["in"];
        Process p = Process.Start(input);
    }
}
```

```
Imports System
Imports System.Diagnostics

Partial Public Class WebForm
    Inherits System.Web.UI.Page

    Protected Sub Page_Load(sender As Object, eventArgs as EventArgs)
        Dim input As String = Me.Request.Form("in")
        Dim p As Process = Process.Start(input)
    End Sub
End Class
```

CA3007: Review code for open redirect vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3007
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches an HTTP response redirect.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of open redirect vulnerabilities. An attacker can exploit an open redirect vulnerability to use your website to give the appearance of a legitimate URL, but redirect an unsuspecting visitor to a phishing or other malicious webpage.

This rule attempts to find input from HTTP requests reaching an HTTP redirect URL.

Note

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that responds with an HTTP redirect, this rule won't produce a warning.

Note

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Some approaches to fixing open redirect vulnerabilities include:

- Don't allow users to initiate redirects.
- Don't allow users to specify any part of the URL in a redirect scenario.
- Restrict redirects to a predefined "allow list" of URLs.
- Validate redirect URLs.
- If applicable, consider using a disclaimer page when users are being redirected away from your site.

When to suppress warnings

If you know you've validated the input to be restricted to intended URLs, it's okay to suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3007
// The code that's violating the rule is on this line.
#pragma warning restore CA3007
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3007.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;

public partial class WebForm : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
        string input = Request.Form["url"];
        this.Response.Redirect(input);
    }
}
```

```
Imports System

Partial Public Class WebForm
    Inherits System.Web.UI.Page

    Protected Sub Page_Load(sender As Object, eventArgs As EventArgs)
        Dim input As String = Me.Request.Form("url")
        Me.Response.Redirect(input)
    End Sub
End Class
```

Solution

```
using System;

public partial class WebForm : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
        string input = Request.Form["in"];
        if (String.IsNullOrEmpty(input))
        {
            this.Response.Redirect("https://example.org/login.html");
        }
    }
}
```

```
Imports System

Partial Public Class WebForm
    Inherits System.Web.UI.Page

    Protected Sub Page_Load(sender As Object, eventArgs As EventArgs)
        Dim input As String = Me.Request.Form("in")
        If String.IsNullOrEmpty(input) Then
            Me.Response.Redirect("https://example.org/login.html")
        End If
    End Sub
End Class
```

CA3008: Review code for XPath injection vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3008
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches an XPath query.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of XPath injection attacks. Constructing XPath queries using untrusted input may allow an attacker to maliciously manipulate the query to return an unintended result, and possibly disclose the contents of the queried XML.

This rule attempts to find input from HTTP requests reaching an XPath expression.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that performs an XPath query, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Some approaches to fixing XPath injection vulnerabilities include:

- Don't construct XPath queries from user input.
- Validate that the input only contains a safe set of characters.
- Escape quotation marks.

When to suppress warnings

If you know you've validated the input to be safe, it's okay to suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3008
// The code that's violating the rule is on this line.
#pragma warning restore CA3008
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA3008.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```

```

CA3009: Review code for XML injection vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3009
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches raw XML output.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of XML injection attacks. An attacker can use XML injection to insert special characters into an XML document, making the document invalid XML. Or, an attacker could maliciously insert XML nodes of their choosing.

This rule attempts to find input from HTTP requests reaching a raw XML write.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that writes raw XML, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Don't write raw XML. Instead, use methods or properties that XML-encode their input.

Or, XML-encode input before writing raw XML.

Or, validate user input by using sanitizers for primitive type conversion and XML encoding.

When to suppress warnings

Don't suppress warnings from this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType	Matches all types named <code>MyType</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

CA3010: Review code for XAML injection vulnerabilities

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3010
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches a [System.Windows.Markup.XamlReader Load](#) method.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of XAML injection attacks. XAML is a markup language that directly represents object instantiation and execution. That means elements created in XAML can interact with system resources (for example, network access and file system IO). If an attacker can control the input to a [System.Windows.Markup.XamlReader Load](#) method call, then the attacker can execute code.

This rule attempts to find input from HTTP requests that reaches a [System.Windows.Markup.XamlReader Load](#) method.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that loads XAML, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Don't load untrusted XAML.

When to suppress warnings

Don't suppress warnings from this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType	Matches all types named <code>MyType</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

        Dim input As String = Request.Form("in")
        Dim bytes As Byte() = Convert.FromBase64String(input)
        Dim ms As MemoryStream = New MemoryStream(bytes)
        System.Windows.Markup.XamlReader.Load(ms)
    End Sub
End Class
```

CA3011: Review code for DLL injection vulnerabilities

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3011
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches a method that loads an assembly.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of loading untrusted code. If your web application loads untrusted code, an attacker may be able to inject malicious DLLs into your process and execute malicious code.

This rule attempts to find input from an HTTP request that reaches a method that loads an assembly.

NOTE

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that loads an assembly, this rule won't produce a warning.

NOTE

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Don't load untrusted DLLs from user input.

When to suppress warnings

Don't suppress warnings from this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)

- Exclude specific types and their derived types

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;
using System.Reflection;

public partial class WebForm : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
        string input = Request.Form["in"];
        byte[] rawAssembly = Convert.FromBase64String(input);
        Assembly.Load(rawAssembly);
    }
}
```

```
Imports System
Imports System.Reflection

Public Partial Class WebForm
    Inherits System.Web.UI.Page

    Protected Sub Page_Load(sender As Object, e As EventArgs)
        Dim input As String = Request.Form("in")
        Dim rawAssembly As Byte() = Convert.FromBase64String(input)
        Assembly.Load(rawAssembly)
    End Sub
End Class
```

CA3012: Review code for regex injection vulnerabilities

9/20/2022 • 4 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3012
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Potentially untrusted HTTP request input reaches a regular expression.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

When working with untrusted input, be mindful of regex injection attacks. An attacker can use regex injection to maliciously modify a regular expression, to make the regex match unintended results, or to make the regex consume excessive CPU resulting in a Denial of Service attack.

This rule attempts to find input from HTTP requests reaching a regular expression.

Note

This rule can't track data across assemblies. For example, if one assembly reads the HTTP request input and then passes it to another assembly that creates a regular expression, this rule won't produce a warning.

Note

There is a configurable limit to how deep this rule will analyze data flow across method calls. See [Analyzer Configuration](#) for how to configure the limit in an EditorConfig file.

How to fix violations

Some mitigations against regex injections include:

- Always use a [match timeout](#) when using regular expressions.
- Avoid using regular expressions based on user input.
- Escape special characters from user input by calling [System.Text.RegularExpressions.Regex.Escape](#) or another method.
- Allow only non-special characters from user input.

When to suppress warnings

If you know you're using a [match timeout](#) and the user input is free of special characters, it's okay to suppress this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3012
// The code that's violating the rule is on this line.
#pragma warning restore CA3012
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3012.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;
using System.Text.RegularExpressions;

public partial class WebForm : System.Web.UI.Page
{
    public string SearchableText { get; set; }

    protected void Page_Load(object sender, EventArgs e)
    {
        string findTerm = Request.Form["findTerm"];
        Match m = Regex.Match(SearchableText, "^term=" + findTerm);
    }
}
```

```
Imports System
Imports System.Text.RegularExpressions

Public Partial Class WebForm
    Inherits System.Web.UI.Page

    Public Property SearchableText As String

    Protected Sub Page_Load(sender As Object, e As EventArgs)
        Dim findTerm As String = Request.Form("findTerm")
        Dim m As Match = Regex.Match(SearchableText, "^term=" + findTerm)
    End Sub
End Class
```

CA3061: Do not add schema by URL

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3061
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Overload of `XmlSchemaCollection.Add(String, String)` is using `XmlUrlResolver` to specify external XML schema in the form of an URI. If the URI String is tainted, it may lead to parsing of a malicious XML schema, which allows for the inclusion of XML bombs and malicious external entities. This could allow a malicious attacker to perform a denial of service, information disclosure, or server-side request forgery attack.

Rule description

Do not use the unsafe overload of the `Add` method because it may cause dangerous external references.

How to fix violations

- Do not use `XmlSchemaCollection.Add(String, String)`.

When to suppress warnings

Suppress this rule if you are sure your XML does not resolve dangerous external references.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3061
// The code that's violating the rule is on this line.
#pragma warning restore CA3061
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3061.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. The second parameter's type is `string`.

```
using System;
using System.Xml.Schema;
...
XmlSchemaCollection xsc = new XmlSchemaCollection();
xsc.Add("urn: bookstore - schema", "books.xsd");
```

Solution

```
using System;
using System.IO;
using System.Xml;
using System.Xml.Schema;
...
XmlSchemaCollection xsc = new XmlSchemaCollection();
xsc.Add("urn: bookstore - schema", new XmlTextReader(new FileStream("xmlFilename", FileMode.Open)));
```

CA3075: Insecure DTD Processing

9/20/2022 • 5 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA3075
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

If you use insecure [DtdProcessing](#) instances or reference external entity sources, the parser may accept untrusted input and disclose sensitive information to attackers.

Rule description

A *Document Type Definition (DTD)* is one of two ways an XML parser can determine the validity of a document, as defined by the [World Wide Web Consortium \(W3C\) Extensible Markup Language \(XML\) 1.0](#). This rule seeks properties and instances where untrusted data is accepted to warn developers about potential [Information Disclosure](#) threats or [Denial of Service \(DoS\)](#) attacks. This rule triggers when:

- DtdProcessing is enabled on the [XmlReader](#) instance, which resolves external XML entities using [XmlUrlResolver](#).
- The [InnerText](#) property in the XML is set.
- [DtdProcessing](#) property is set to Parse.
- Untrusted input is processed using [XmlResolver](#) instead of [XmlSecureResolver](#).
- The [XmlReader.Create](#) method is invoked with an insecure [XmlReaderSettings](#) instance or no instance at all.
- [XmlReader](#) is created with insecure default settings or values.

In each of these cases, the outcome is the same: the contents from either the file system or network shares from the machine where the XML is processed will be exposed to the attacker, or DTD processing can be used as a DoS vector.

How to fix violations

- Catch and process all [XmlTextReader](#) exceptions properly to avoid path information disclosure.
- Use the [XmlSecureResolver](#) to restrict the resources that the [XmlTextReader](#) can access.
- Do not allow the [XmlReader](#) to open any external resources by setting the [XmlResolver](#) property to **null**.
- Ensure that the [DataViewManager.DataViewSettingCollectionString](#) property is assigned from a trusted source.

.NET Framework 3.5 and earlier

- Disable DTD processing if you are dealing with untrusted sources by setting the [ProhibitDtd](#) property to `true`.
- `XmlTextReader` class has a full trust inheritance demand.

.NET Framework 4 and later

- Avoid enabling `DtdProcessing` if you're dealing with untrusted sources by setting the [XmlReaderSettings.DtdProcessing](#) property to `Prohibit` or `Ignore`.
- Ensure that the `Load()` method takes an `XmlReader` instance in all `InnerXml` cases.

NOTE

This rule might report false positives on some valid `XmlSecureResolver` instances.

When to suppress warnings

Unless you're sure that the input is known to be from a trusted source, do not suppress a rule from this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3075
// The code that's violating the rule is on this line.
#pragma warning restore CA3075
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3075.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation 1

```

using System.IO;
using System.Xml.Schema;

class TestClass
{
    public XmlSchema Test
    {
        get
        {
            var src = "";
            TextReader tr = new StreamReader(src);
            XmlSchema schema = XmlSchema.Read(tr, null); // warn
            return schema;
        }
    }
}

```

Solution 1

```

using System.IO;
using System.Xml;
using System.Xml.Schema;

class TestClass
{
    public XmlSchema Test
    {
        get
        {
            var src = "";
            TextReader tr = new StreamReader(src);
            XmlReader reader = XmlReader.Create(tr, new XmlReaderSettings() { XmlResolver = null });
            XmlSchema schema = XmlSchema.Read(reader, null);
            return schema;
        }
    }
}

```

Violation 2

```

using System.Xml;

namespace TestNamespace
{
    public class TestClass
    {
        public XmlReaderSettings settings = new XmlReaderSettings();
        public void TestMethod(string path)
        {
            var reader = XmlReader.Create(path, settings); // warn
        }
    }
}

```

Solution 2

```

using System.Xml;

namespace TestNamespace
{
    public class TestClass
    {
        public XmlReaderSettings settings = new XmlReaderSettings()
        {
            DtdProcessing = DtdProcessing.Prohibit
        };

        public void TestMethod(string path)
        {
            var reader = XmlReader.Create(path, settings);
        }
    }
}

```

Violation 3

```

using System.Xml;

namespace TestNamespace
{
    public class DoNotUseSetInnerXml
    {
        public void TestMethod(string xml)
        {
            XmlDocument doc = new XmlDocument() { XmlResolver = null };
            doc.InnerXml = xml; // warn
        }
    }
}

```

```

using System.Xml;

namespace TestNamespace
{
    public class DoNotUseLoadXml
    {
        public void TestMethod(string xml)
        {
            XmlDocument doc = new XmlDocument(){ XmlResolver = null };
            doc.LoadXml(xml); // warn
        }
    }
}

```

Solution 3

```

using System.Xml;

public static void TestMethod(string xml)
{
    XmlDocument doc = new XmlDocument() { XmlResolver = null };
    System.IO.StringReader sreader = new System.IO.StringReader(xml);
    XmlReader reader = XmlReader.Create(sreader, new XmlReaderSettings() { XmlResolver = null });
    doc.Load(reader);
}

```

Violation 4

```

using System.IO;
using System.Xml;
using System.Xml.Serialization;

namespace TestNamespace
{
    public class UseXmlReaderForDeserialize
    {
        public void TestMethod(Stream stream)
        {
            XmlSerializer serializer = new XmlSerializer(typeof(UseXmlReaderForDeserialize));
            serializer.Deserialize(stream); // warn
        }
    }
}

```

Solution 4

```

using System.IO;
using System.Xml;
using System.Xml.Serialization;

namespace TestNamespace
{
    public class UseXmlReaderForDeserialize
    {
        public void TestMethod(Stream stream)
        {
            XmlSerializer serializer = new XmlSerializer(typeof(UseXmlReaderForDeserialize));
            XmlReader reader = XmlReader.Create(stream, new XmlReaderSettings() { XmlResolver = null });
            serializer.Deserialize(reader );
        }
    }
}

```

Violation 5

```

using System.Xml;
using System.Xml.XPath;

namespace TestNamespace
{
    public class UseXmlReaderForXPathDocument
    {
        public void TestMethod(string path)
        {
            XPathDocument doc = new XPathDocument(path); // warn
        }
    }
}

```

Solution 5

```

using System.Xml;
using System.Xml.XPath;

namespace TestNamespace
{
    public class UseXmlReaderForXPathDocument
    {
        public void TestMethod(string path)
        {
            XmlReader reader = XmlReader.Create(path, new XmlReaderSettings() { XmlResolver = null });
            XPathDocument doc = new XPathDocument(reader);
        }
    }
}

```

Violation 6

```

using System.Xml;

namespace TestNamespace
{
    class TestClass
    {
        public XmlDocument doc = new XmlDocument() { XmlResolver = new XmlUrlResolver() };
    }
}

```

Solution 6

```

using System.Xml;

namespace TestNamespace
{
    class TestClass
    {
        public XmlDocument doc = new XmlDocument() { XmlResolver = null }; // or set to a XmlSecureResolver
instance
    }
}

```

Violation 7

```

using System.Xml;

namespace TestNamespace
{
    class TestClass
    {
        private static void TestMethod()
        {
            var reader = XmlTextReader.Create("doc.xml"); //warn
        }
    }
}

```

```
using System.Xml;

namespace TestNamespace
{
    public class TestClass
    {
        public void TestMethod(string path)
        {
            try {
                XmlTextReader reader = new XmlTextReader(path); // warn
            }
            catch { throw ; }
            finally {}
        }
    }
}
```

Solution 7

```
using System.Xml;

namespace TestNamespace
{
    public class TestClass
    {
        public void TestMethod(string path)
        {
            XmlReaderSettings settings = new XmlReaderSettings() { XmlResolver = null };
            XmlReader reader = XmlReader.Create(path, settings);
        }
    }
}
```

NOTE

Although `XmlReader.Create` is the recommended way to create an `XmlReader` instance, there are behavior differences from `XmlTextReader`. An `XmlReader` from `Create` normalizes `\r\n` to `\n` in XML values, while `XmlTextReader` preserves the `\r\n` sequence.

CA3076: Insecure XSLT Script Execution

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3076
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

If you execute Extensible Stylesheets Language Transformations (XSLT) in .NET applications insecurely, the processor may resolve untrusted URL references that could disclose sensitive information to attackers, leading to Denial of Service and Cross-Site attacks. For more information, see [XSLT Security Considerations\(.NET Guide\)](#).

Rule description

XSLT is a World Wide Web Consortium (W3C) standard for transforming XML data. XSLT is typically used to write style sheets to transform XML data to other formats such as HTML, fixed-length text, comma-separated text, or a different XML format. Although prohibited by default, you may choose to enable it for your project.

To ensure you're not exposing an attack surface, this rule triggers whenever the `XslCompiledTransform.Load` receives insecure combination instances of `XsltSettings` and `XmlResolver`, which allows malicious script processing.

How to fix violations

- Replace the insecure `XsltSettings` argument with `XsltSettings.Default` or with an instance that has disabled document function and script execution.
- Replace the `XmlResolver` argument with null or an `XmlSecureResolver` instance.

When to suppress warnings

Unless you're sure that the input is known to be from a trusted source, do not suppress a rule from this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3076
// The code that's violating the rule is on this line.
#pragma warning restore CA3076
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3076.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation that uses `XsltSettings.TrustedXslt`

```
using System.Xml;
using System.Xml.Xsl;

namespace TestNamespace
{
    class TestClass
    {
        void TestMethod()
        {
            XslCompiledTransform xslCompiledTransform = new XslCompiledTransform();
            var settings = XsltSettings.TrustedXslt;
            var resolver = new XmlUrlResolver();
            xslCompiledTransform.Load("testStylesheet", settings, resolver); // warn
        }
    }
}
```

Solution that uses `XsltSettings.Default`

```
using System.Xml;
using System.Xml.Xsl;

namespace TestNamespace
{
    class TestClass
    {
        void TestMethod()
        {
            XslCompiledTransform xslCompiledTransform = new XslCompiledTransform();
            var settings = XsltSettings.Default;
            var resolver = new XmlUrlResolver();
            xslCompiledTransform.Load("testStylesheet", settings, resolver);
        }
    }
}
```

Violation—document function and script execution not disabled

```

using System.Xml;
using System.Xml.Xsl;

namespace TestNamespace
{
    class TestClass
    {
        private static void TestMethod(XsltSettings settings)
        {
            try
            {
                XslCompiledTransform xslCompiledTransform = new XslCompiledTransform();
                var resolver = new XmlUrlResolver();
                xslCompiledTransform.Load("testStylesheet", settings, resolver); // warn
            }
            catch { throw; }
            finally { }
        }
    }
}

```

Solution—disable document function and script execution

```

using System.Xml;
using System.Xml.Xsl;

namespace TestNamespace
{
    class TestClass
    {
        private static void TestMethod(XsltSettings settings)
        {
            try
            {
                XslCompiledTransform xslCompiledTransform = new XslCompiledTransform();
                settings.EnableDocumentFunction = false;
                settings.EnableScript = false;
                var resolver = new XmlUrlResolver();
                xslCompiledTransform.Load("testStylesheet", settings, resolver);
            }
            catch { throw; }
            finally { }
        }
    }
}

```

CA3077: Insecure Processing in API Design, XML Document and XML Text Reader

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3077
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

When designing an API derived from `XMLDocument` and `XMLTextReader`, be mindful of [DtdProcessing](#). Using insecure `DTDProcessing` instances when referencing or resolving external entity sources or setting insecure values in the XML may lead to information disclosure.

Rule description

A *Document Type Definition (DTD)* is one of two ways an XML parser can determine the validity of a document, as defined by the [World Wide Web Consortium \(W3C\) Extensible Markup Language \(XML\) 1.0](#). This rule seeks properties and instances where untrusted data is accepted to warn developers about potential [Information Disclosure](#) threats, which may lead to [Denial of Service \(DoS\)](#) attacks. This rule triggers when:

- `XmlDocument` or `XmlTextReader` classes use default resolver values for DTD processing .
- No constructor is defined for the `XmlDocument` or `XmlTextReader` derived classes or no secure value is used for `XmlResolver`.

How to fix violations

- Catch and process all `XmlTextReader` exceptions properly to avoid path information disclosure .
- Use `XmlSecureResolver` instead of `XmlResolver` to restrict the resources the `XmlTextReader` can access.

When to suppress warnings

Unless you're sure that the input is known to be from a trusted source, do not suppress a rule from this warning.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3077
// The code that's violating the rule is on this line.
#pragma warning restore CA3077
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3077.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System;
using System.Xml;

namespace TestNamespace
{
    class TestClass : XmlDocument
    {
        public TestClass () {} // warn
    }

    class TestClass2 : XmlTextReader
    {
        public TestClass2() // warn
        {
        }
    }
}
```

Solution

```
using System;
using System.Xml;

namespace TestNamespace
{
    class TestClass : XmlDocument
    {
        public TestClass ()
        {
            XmlResolver = null;
        }
    }

    class TestClass2 : XmlTextReader
    {
        public TestClass2()
        {
            XmlResolver = null;
        }
    }
}
```

CA3147: Mark verb handlers with ValidateAntiForgeryTokenToken

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA3147
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

An ASP.NET MVC controller action method isn't marked with [ValidateAntiForgeryTokenAttribute](#), or an attribute specifying the HTTP verb, such as [HttpGetAttribute](#) or [AcceptVerbsAttribute](#).

Rule description

When designing an ASP.NET MVC controller, be mindful of cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET MVC controller. For more information, see [XSRF/CSRF prevention in ASP.NET MVC and web pages](#).

This rule checks that ASP.NET MVC controller action methods either:

- Have the [ValidateAntiForgeryTokenAttribute](#) and specify allowed HTTP verbs, not including HTTP GET.
- Specify HTTP GET as an allowed verb.

How to fix violations

- For ASP.NET MVC controller actions that handle HTTP GET requests and don't have potentially harmful side effects, add an [HttpGetAttribute](#) to the method.

If you have an ASP.NET MVC controller action that handles HTTP GET requests and has potentially harmful side effects such as modifying sensitive data, then your application is vulnerable to cross-site request forgery attacks. You'll need to redesign your application so that only HTTP POST, PUT, or DELETE requests perform sensitive operations.

- For ASP.NET MVC controller actions that handle HTTP POST, PUT, or DELETE requests, add [ValidateAntiForgeryTokenAttribute](#) and attributes specifying the allowed HTTP verbs ([AcceptVerbsAttribute](#), [HttpPostAttribute](#), [HttpPutAttribute](#), or [HttpDeleteAttribute](#)). Additionally, you need to call the [HtmlHelper.AntiForgeryToken\(\)](#) method from your MVC view or Razor web page. For an example, see [Examining the edit methods and edit view](#).

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The ASP.NET MVC controller action has no harmful side effects.

- The application validates the antiforgery token in a different way.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA3147
// The code that's violating the rule is on this line.
#pragma warning restore CA3147
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA3147.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

ValidateAntiForgeryToken attribute example

Violation:

```
namespace TestNamespace
{
    using System.Web.Mvc;

    public class TestController : Controller
    {
        public ActionResult TransferMoney(string toAccount, string amount)
        {
            // You don't want an attacker to specify to who and how much money to transfer.

            return null;
        }
    }
}
```

Solution:

```
using System;
using System.Xml;

namespace TestNamespace
{
    using System.Web.Mvc;

    public class TestController : Controller
    {
        [HttpPost]
        [ValidateAntiForgeryToken]
        public ActionResult TransferMoney(string toAccount, string amount)
        {
            return null;
        }
    }
}
```

HttpGet attribute example

Violation:

```
namespace TestNamespace
{
    using System.Web.Mvc;

    public class TestController : Controller
    {
        public ActionResult Help(int topicId)
        {
            // This Help method is an example of a read-only operation with no harmful side effects.
            return null;
        }
    }
}
```

Solution:

```
namespace TestNamespace
{
    using System.Web.Mvc;

    public class TestController : Controller
    {
        [HttpGet]
        public ActionResult Help(int topicId)
        {
            return null;
        }
    }
}
```

CA5350: Do Not Use Weak Cryptographic Algorithms

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5350
Category	Security
Fix is breaking or non-breaking	Non-breaking

Note

This warning was last updated on November 2015.

Cause

Encryption algorithms such as [TripleDES](#) and hashing algorithms such as [SHA1](#) and [RIPEMD160](#) are considered to be weak.

These cryptographic algorithms do not provide as much security assurance as more modern counterparts. Cryptographic hashing algorithms [SHA1](#) and [RIPEMD160](#) provide less collision resistance than more modern hashing algorithms. The encryption algorithm [TripleDES](#) provides fewer bits of security than more modern encryption algorithms.

Rule description

Weak encryption algorithms and hashing functions are used today for a number of reasons, but they should not be used to guarantee the confidentiality of the data they protect.

The rule triggers when it finds 3DES, SHA1 or RIPEMD160 algorithms in the code and throws a warning to the user.

How to fix violations

Use cryptographically stronger options:

- For TripleDES encryption, use [Aes](#) encryption.
- For SHA1 or RIPEMD160 hashing functions, use ones in the [SHA-2](#) family (e.g. [SHA512](#), [SHA384](#), [SHA256](#)).

When to suppress warnings

SUPPRESS a warning from this rule when the level of protection needed for the data does not require a security guarantee.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5350
// The code that's violating the rule is on this line.
#pragma warning restore CA5350
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5350.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

As of the time of this writing, the following pseudo-code sample illustrates the pattern detected by this rule.

SHA-1 Hashing Violation

```
using System.Security.Cryptography;
...
var hashAlg = SHA1.Create();
```

Solution:

```
using System.Security.Cryptography;
...
var hashAlg = SHA256.Create();
```

RIPEMD160 Hashing Violation

```
using System.Security.Cryptography;
...
var hashAlg = RIPEMD160Managed.Create();
```

Solution:

```
using System.Security.Cryptography;
...
var hashAlg = SHA256.Create();
```

TripleDES Encryption Violation

```
using System.Security.Cryptography;
...
using (TripleDES encAlg = TripleDES.Create())
{
    ...
}
```

Solution:

```
using System.Security.Cryptography;
...
using (AesManaged encAlg = new AesManaged())
{
    ...
}
```

CA5351 Do Not Use Broken Cryptographic Algorithms

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5351
Category	Security
Fix is breaking or non-breaking	Non-breaking

Note

This warning was last updated on November 2015.

Cause

Hashing functions such as [MD5](#) and encryption algorithms such as [DES](#) and [RC2](#) can expose significant risk and may result in the exposure of sensitive information through trivial attack techniques, such as brute force attacks and hash collisions.

The cryptographic algorithms list below are subject to known cryptographic attacks. The cryptographic hash algorithm [MD5](#) is subject to hash collision attacks. Depending on the usage, a hash collision may lead to impersonation, tampering, or other kinds of attacks on systems that rely on the unique cryptographic output of a hashing function. The encryption algorithms [DES](#) and [RC2](#) are subject to cryptographic attacks that may result in unintended disclosure of encrypted data.

Rule description

Broken cryptographic algorithms are not considered secure and their use should be discouraged. The MD5 hash algorithm is susceptible to known collision attacks, though the specific vulnerability will vary based on the context of use. Hashing algorithms used to ensure data integrity (for example, file signature or digital certificate) are particularly vulnerable. In this context, attackers could generate two separate pieces of data, such that benign data can be substituted with malicious data, without changing the hash value or invalidating an associated digital signature.

For encryption algorithms:

- [DES](#) encryption contains a small key size, which could be brute-forced in less than a day.
- [RC2](#) encryption is susceptible to a related-key attack, where the attacker finds mathematical relationships between all key values.

This rule triggers when it finds any of the above cryptographic functions in source code and throws a warning to the user.

How to fix violations

Use cryptographically stronger options:

- For MD5, use hashes in the [SHA-2](#) family (for example, [SHA512](#), [SHA384](#), [SHA256](#)).
- For DES and RC2, use [Aes](#) encryption.

When to suppress warnings

Do not suppress a warning from this rule, unless it's been reviewed by a cryptographic expert.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5351
// The code that's violating the rule is on this line.
#pragma warning restore CA5351
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5351.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

The following pseudo-code samples illustrate the pattern detected by this rule and possible alternatives.

MD5 Hashing Violation

```
using System.Security.Cryptography;
...
var hashAlg = MD5.Create();
```

Solution:

```
using System.Security.Cryptography;
...
var hashAlg = SHA256.Create();
```

RC2 Encryption Violation

```
using System.Security.Cryptography;
...
RC2 encAlg = RC2.Create();
```

Solution:

```
using System.Security.Cryptography;
...
using (AesManaged encAlg = new AesManaged())
{
    ...
}
```

DES Encryption Violation

```
using System.Security.Cryptography;
...
DES encAlg = DES.Create();
```

Solution:

```
using System.Security.Cryptography;
...
using (AesManaged encAlg = new AesManaged())
{
    ...
}
```

CA5358: Do Not Use Unsafe Cipher Modes

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5358
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Use of one of the following unsafe encryption modes that is not approved:

- [System.Security.Cryptography.CipherMode.ECB](#)
- [System.Security.Cryptography.CipherMode.OFB](#)
- [System.Security.Cryptography.CipherMode.CFB](#)

Rule description

These modes are vulnerable to attacks and may cause exposure of sensitive information. For example, using [ECB](#) to encrypt a plaintext block always produces a same cipher text, so it can easily tell if two encrypted messages are identical. Using approved modes can avoid these unnecessary risks.

How to fix violations

- Use only approved modes ([System.Security.Cryptography.CipherMode.CBC](#), [System.Security.Cryptography.CipherMode.CTS](#)).

When to suppress warnings

It's safe to suppress a warning from this rule if:

- Cryptography experts have reviewed and approved the cipher mode's usage.
- The referenced [CipherMode](#) isn't used for a cryptographic operation.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5358
// The code that's violating the rule is on this line.
#pragma warning restore CA5358
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5358.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Assign ECB to Mode property

```
using System.Security.Cryptography;

class ExampleClass {
    private static void ExampleMethod () {
        RijndaelManaged rijn = new RijndaelManaged
        {
            Mode = CipherMode.ECB
        };
    }
}
```

Using the value ECB

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    private static void ExampleMethod()
    {
        Console.WriteLine(CipherMode.ECB);
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass {
    private static void ExampleMethod () {
        RijndaelManaged rijn = new RijndaelManaged
        {
            Mode = CipherMode.CBC
        };
    }
}
```

CA5359: Do not disable certificate validation

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5359
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The callback assigned to `ServicePointManager.ServerCertificateValidationCallback` always returns `true`.

Rule description

A certificate can help authenticate the identity of the server. Clients should validate the server certificate to ensure requests are sent to the intended server. If the `ServicePointManager.ServerCertificateValidationCallback` always returns `true`, then by default any certificate will pass validation for all outgoing HTTPS requests.

How to fix violations

- Considering overriding certificate validation logic on the specific outgoing HTTPS requests that require custom certificate validation, instead of overriding the global `ServicePointManager.ServerCertificateValidationCallback`.
- Apply custom validation logic to only specific hostnames and certificates, and otherwise check that the `SslPolicyErrors` enum value is `None`.

When to suppress warnings

If multiple delegates are attached to `ServerCertificateValidationCallback`, only the value from the last delegate is respected, so it's safe to suppress warnings from other delegates. However, you may want to remove the unused delegates entirely.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5359
// The code that's violating the rule is on this line.
#pragma warning restore CA5359
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5359.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System.Net;

class ExampleClass
{
    public void ExampleMethod()
    {
        ServicePointManager.ServerCertificateValidationCallback += (sender, cert, chain, error) => { return
true; };
    }
}
```

Solution

```
using System.Net;
using System.Net.Security;
using System.Security.Cryptography.X509Certificates;

class ExampleClass
{
    public void ExampleMethod()
    {
        ServicePointManager.ServerCertificateValidationCallback += SelfSignedForlocalhost;
    }

    private static bool SelfSignedForlocalhost(object sender, X509Certificate certificate, X509Chain chain,
SslPolicyErrors sslPolicyErrors)
    {
        if (sslPolicyErrors == SslPolicyErrors.None)
        {
            return true;
        }

        // For HTTPS requests to this specific host, we expect this specific certificate.
        // In practice, you'd want this to be configurable and allow for multiple certificates per host, to
enable
        // seamless certificate rotations.
        return sender is HttpWebRequest httpWebRequest
            && httpWebRequest.RequestUri.Host == "localhost"
            && certificate is X509Certificate2 x509Certificate2
            && x509Certificate2.Thumbprint == "AAAAAAAAAAAAAAAAAAAAAAA"
            && sslPolicyErrors == SslPolicyErrors.RemoteCertificateChainErrors;
    }
}
```

CA5360: Do not call dangerous methods in deserialization

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5360
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Calling one of the following dangerous methods in deserialization:

- [System.IO.Directory.Delete](#)
- [System.IO.DirectoryInfo.Delete](#)
- [System.IO.File.AppendAllLines](#)
- [System.IO.File.AppendAllText](#)
- [System.IO.File.AppendText](#)
- [System.IO.File.Copy](#)
- [System.IO.File.Delete](#)
- [System.IO.File.WriteAllBytes](#)
- [System.IO.File.WriteAllLines](#)
- [System.IO.File.WriteAllText](#)
- [System.IO.FileInfo.Delete](#)
- [System.IO.Log.LogStore.Delete](#)
- [System.Reflection.Assembly.GetLoadedModules](#)
- [System.Reflection.Assembly.Load](#)
- [System.Reflection.Assembly.LoadFrom](#)
- [System.Reflection.Assembly.LoadFile](#)
- [System.Reflection.Assembly.LoadModule](#)
- [System.Reflection.Assembly.LoadWithPartialName](#)
- [System.Reflection.Assembly.ReflectionOnlyLoad](#)
- [System.Reflection.Assembly.ReflectionOnlyLoadFrom](#)
- [System.Reflection.Assembly.UnsafeLoadFrom](#)

All methods meets one of the following requirements could be the callback of deserialization:

- Marked with [System.Runtime.Serialization.OnDeserializingAttribute](#).
- Marked with [System.Runtime.Serialization.OnDeserializedAttribute](#).
- Implementing [System.Runtime.Serialization.IDeserializationCallback.OnDeserialization](#).
- Implementing [System.IDisposable.Dispose](#).
- Is a destructor.

Rule description

Insecure deserialization is a vulnerability which occurs when untrusted data is used to abuse the logic of an application, inflict a Denial-of-Service (DoS) attack, or even execute arbitrary code upon it being deserialized. It's frequently possible for malicious users to abuse these deserialization features when the application is deserializing untrusted data which is under their control. Specifically, invoke dangerous methods in the process of deserialization. Successful insecure deserialization attacks could allow an attacker to carry out attacks such as DoS attacks, authentication bypasses, and remote code execution.

How to fix violations

Remove these dangerous methods from automatically run deserialization callbacks. Call dangerous methods only after validating the input.

When to suppress warnings

It's safe to suppress this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- The serialized data is tamper-proof. After serialization, cryptographically sign the serialized data. Before deserialization, validate the cryptographic signature. Protect the cryptographic key from being disclosed and design for key rotations.
- The data is validated as safe to the application.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5360
// The code that's violating the rule is on this line.
#pragma warning restore CA5360
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5360.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System;
using System.IO;
using System.Runtime.Serialization;

[Serializable()]
public class ExampleClass : IDeserializationCallback
{
    private string member;

    void IDeserializationCallback.OnDeserialization(Object sender)
    {
        var sourceFileName = "malicious file";
        var destFileName = "sensitive file";
        File.Copy(sourceFileName, destFileName);
    }
}
```

Solution

```
using System;
using System.IO;
using System.Runtime.Serialization;

[Serializable()]
public class ExampleClass : IDeserializationCallback
{
    private string member;

    void IDeserializationCallback.OnDeserialization(Object sender)
    {
        var sourceFileName = "malicious file";
        var destFileName = "sensitive file";
        // Remove the potential dangerous operation.
        // File.Copy(sourceFileName, destFileName);
    }
}
```

CA5361: Do not disable SChannel use of strong crypto

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5361
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `AppContext.SetSwitch` method call sets `Switch.System.Net.DontEnableSchUseStrongCrypto` to `true`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Setting `Switch.System.Net.DontEnableSchUseStrongCrypto` to `true` weakens the cryptography used in outgoing Transport Layer Security (TLS) connections. Weaker cryptography can compromise the confidentiality of communication between your application and the server, making it easier for attackers to eavesdrop sensitive data. For more information, see [Transport Layer Security \(TLS\) best practices with .NET Framework](#).

How to fix violations

- If your application targets .NET Framework v4.6 or later, you can either remove the `AppContext.SetSwitch` method call, or set the switch's value to `false`.
- If your application targets .NET Framework earlier than v4.6 and runs on .NET Framework v4.6 or later, set the switch's value to `false`.
- Otherwise, refer to [Transport Layer Security \(TLS\) best practices with .NET Framework](#) for mitigations.

When to suppress warnings

You can suppress this warning if you need to connect to a legacy service that can't be upgraded to use secure TLS configurations.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5361
// The code that's violating the rule is on this line.
#pragma warning restore CA5361
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5361.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair

to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5361 violation
        ApplicationContext.SetSwitch("Switch.System.Net.DontEnableSchUseStrongCrypto", true);
    }
}
```

```
Imports System

Public Class ExampleClass
    Public Sub ExampleMethod()
        ' CA5361 violation
        ApplicationContext.SetSwitch("Switch.System.Net.DontEnableSchUseStrongCrypto", true)
    End Sub
End Class
```

Solution

```
using System;

public class ExampleClass
{
    public void ExampleMethod()
    {
        ApplicationContext.SetSwitch("Switch.System.Net.DontEnableSchUseStrongCrypto", false);
    }
}
```

```
Imports System

Public Class ExampleClass
    Public Sub ExampleMethod()
        ApplicationContext.SetSwitch("Switch.System.Net.DontEnableSchUseStrongCrypto", false)
    End Sub
End Class
```

CA5362: Potential reference cycle in deserialized object graph

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5362
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A class marked with the [System.SerializableAttribute](#) has a field or property may refer to the containing object directly or indirectly, allowing for a potential reference cycle.

Rule description

If deserializing untrusted data, then any code processing the deserialized object graph needs to handle reference cycles without going into infinite loops. This includes both code that's part of a deserialization callback and code that processes the object graph after deserialization completed. Otherwise, an attacker could perform a Denial-of-Service attack with malicious data containing a reference cycle.

This rule doesn't necessarily mean there's a vulnerability, but just flags potential reference cycles in serialized object graphs.

How to fix violations

Don't serialize the class and remove the [SerializableAttribute](#). Or, redesign your application so that the self-referred members can be removed out of the serializable class.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- You know the input is trusted. Consider that your application's trust boundary and data flows may change over time.
- All code processing the serialized data detects and handles reference cycles without going into an infinite loop or using excessive resources.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5362
// The code that's violating the rule is on this line.
#pragma warning restore CA5362
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5362.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Potential reference cycle violation

```
using System;

[Serializable()]
class ExampleClass
{
    public ExampleClass ExampleProperty {get; set;}

    public int NormalProperty {get; set;}
}

class AnotherClass
{
    // The argument passed by could be `JsonConvert.DeserializeObject<ExampleClass>(untrustedData)` .
    public void AnotherMethod(ExampleClass ec)
    {
        while(ec != null)
        {
            Console.WriteLine(ec.ToString());
            ec = ec.ExampleProperty;
        }
    }
}
```

Solution

```
using System;

[Serializable()]
class ExampleClass
{
    [NonSerialized]
    public ExampleClass ExampleProperty {get; set;}

    public int NormalProperty {get; set;}
}

class AnotherClass
{
    // The argument passed by could be ` JsonConvert.DeserializeObject<ExampleClass>(untrustedData)` .
    public void AnotherMethod(ExampleClass ec)
    {
        while(ec != null)
        {
            Console.WriteLine(ec.ToString());
            ec = ec.ExampleProperty;
        }
    }
}
```

CA5363: Do not disable request validation

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5363
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The attribute `ValidateInput` is set to `false` for a class or method.

Rule description

Request validation is a feature in ASP.NET that examines HTTP requests and determines whether they contain potentially dangerous content that can lead to injection attacks, including cross-site-scripting.

How to fix violations

Set the `ValidateInput` attribute to `true` or delete it entirely. Alternatively, use `AllowHTMLAttribute` to allow HTML in specific parts of the input.

When to suppress warnings

You can suppress this violation if all the payload in the incoming HTTP request is sourced from a trusted entity and could not be tampered with by an adversary prior to or during transport.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5363
// The code that's violating the rule is on this line.
#pragma warning restore CA5363
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5363.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. This disables input validation.

```
using System.Web.Mvc;

class TestControllerClass
{
    [ValidateInput(false)]
    public void TestActionMethod()
    {
    }
}
```

Solution

```
using System.Web.Mvc;

class TestControllerClass
{
    [ValidateInput(true)]
    public void TestActionMethod()
    {
    }
}
```

CA5364: Do not use deprecated security protocols

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5364
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when either of the following conditions are met:

- A deprecated `System.Net.SecurityProtocolType` value was referenced.
- An integer value representing a deprecated value was assigned to a `SecurityProtocolType` variable.

Deprecated values are:

- Ssl3
- Tls
- Tls10
- Tls11

Rule description

Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk. For guidance on identifying and removing deprecated protocol versions, see [Solving the TLS 1.0 Problem, 2nd Edition](#).

How to fix violations

Don't use deprecated TLS protocol versions.

When to suppress warnings

You can suppress this warning if:

- The reference to the deprecated protocol version isn't being used to enable a deprecated version.
- You need to connect to a legacy service that can't be upgraded to use secure TLS configurations.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5364
// The code that's violating the rule is on this line.
#pragma warning restore CA5364
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5364.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Enumeration name violation

```
using System;
using System.Net;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5364 violation
        ServicePointManager.SecurityProtocol = SecurityProtocolType.Tls11 | SecurityProtocolType.Tls12;
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5364 violation
        ServicePointManager.SecurityProtocol = SecurityProtocolType.Tls11 Or SecurityProtocolType.Tls12
    End Sub
End Class
```

Integer value violation

```
using System;
using System.Net;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5364 violation
        ServicePointManager.SecurityProtocol = (SecurityProtocolType) 768;      // TLS 1.1
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5364 violation
        ServicePointManager.SecurityProtocol = CType(768, SecurityProtocolType)      ' TLS 1.1
    End Sub
End Class
```

Solution

```
using System;
using System.Net;

public class TestClass
{
    public void TestMethod()
    {
        // Let the operating system decide what TLS protocol version to use.
        // See https://docs.microsoft.com/dotnet/framework/network-programming/tls
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' Let the operating system decide what TLS protocol version to use.
        ' See https://docs.microsoft.com/dotnet/framework/network-programming/tls
    End Sub
End Class
```

[CA5386: Avoid hardcoding SecurityProtocolType value](#)

[CA5397: Do not use deprecated SslProtocols values](#)

[CA5398: Avoid hardcoded SslProtocols values](#)

CA5365: Do Not Disable HTTP Header Checking

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5365
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Set `EnableHeaderChecking` to `false`.

Rule description

HTTP header checking enables encoding of the carriage return and newline characters, `\r` and `\n`, that are found in response headers. This encoding can help to avoid injection attacks that exploit an application that echoes untrusted data contained in the header.

How to fix violations

Set `EnableHeaderChecking` to `true`. Or, remove the assignment to `false` because the default value is `true`.

When to suppress warnings

HTTP header continuations rely on headers spanning multiple lines and require new lines in them. If you need to use header continuations, you need to set the `EnableHeaderChecking` property to `false`. There is a performance impact from checking the headers. If you are certain you are already doing the right checks, turning off this feature can improve the performance of your application. Before you disable this feature, be sure you are already taking the right precautions in this area.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5365
// The code that's violating the rule is on this line.
#pragma warning restore CA5365
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5365.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

```
using System;
using System.Web.Configuration;

class TestClass
{
    public void TestMethod()
    {
        HttpRuntimeSection httpRuntimeSection = new HttpRuntimeSection();
        httpRuntimeSection.EnableHeaderChecking = false;
    }
}
```

Solution

```
using System;
using System.Web.Configuration;

class TestClass
{
    public void TestMethod()
    {
        HttpRuntimeSection httpRuntimeSection = new HttpRuntimeSection();
        httpRuntimeSection.EnableHeaderChecking = true;
    }
}
```

CA5366: Use XmlReader For DataSet Read XML

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5366
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A Document Type Definition (DTD) defines the structure and the legal elements and attributes of an XML document. Referring to a DTD from an external resource could cause potential Denial of Service (DoS) attacks. Most readers cannot disable DTD processing and restrict external references loading except for [System.Xml.XmlReader](#). Using these other readers to load XML by one of the following methods triggers this rule:

- [ReadXml](#)
- [ReadXmlSchema](#)
- [ReadXmlSerializable](#)

Rule description

Using a [System.Data.DataSet](#) to read XML with untrusted data may load dangerous external references, which should be restricted by using an [XmlReader](#) with a secure resolver or with DTD processing disabled.

How to fix violations

Use [XmlReader](#) or its derived classes to read XML.

When to suppress warnings

Suppress a warning from this rule when dealing with a trusted data source.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5366
// The code that's violating the rule is on this line.
#pragma warning restore CA5366
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5366.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System.Data;
using System.IO;

public class ExampleClass
{
    public void ExampleMethod()
    {
        new DataSet().ReadXml(new FileStream("xmlFilename", FileMode.Open));
    }
}
```

Solution

```
using System.Data;
using System.IO;
using System.Xml;

public class ExampleClass
{
    public void ExampleMethod()
    {
        new DataSet().ReadXml(new XmlTextReader(new FileStream("xmlFilename", FileMode.Open)));
    }
}
```

CA5367: Do not serialize types with pointer fields

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5367
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Pointers are not type safe, which means you cannot guarantee the correctness of the memory they point at. So, serializing types with pointer fields is a security risk, as it may allow an attacker to control the pointer.

Rule description

This rule checks whether there's a serializable class with a pointer field or property. Members that can't be serialized can be a pointer, such as static members or fields marked with [System.NonSerializedAttribute](#).

How to fix violations

Don't use pointer types for members in a serializable class or don't serialize the members that are pointers.

When to suppress warnings

Don't take the risk to use pointers in serializable types.

Pseudo-code examples

Violation

```
using System;

[Serializable()]
unsafe class TestClassA
{
    private int* pointer;
}
```

Solution 1

```
using System;

[Serializable()]
unsafe class TestClassA
{
    private int i;
}
```

Solution 2

```
using System;

[Serializable()]
unsafe class TestClassA
{
    private static int* pointer;
}
```

CA5368: Set ViewStateUserKey For Classes Derived From Page

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5368
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `Page.ViewStateUserKey` property is not assigned in `Page.OnInit` or the `Page_Init` method.

Rule description

When designing an ASP.NET Web Form, be mindful of cross-site request forgery (CSRF) attacks. A CSRF attack can send malicious requests from an authenticated user to your ASP.NET Web Form.

One way of protecting against CSRF attacks in ASP.NET Web Form is by setting a page's `ViewStateUserKey` to a string that is unpredictable and unique to a session. For more information, see [Take Advantage of ASP.NET Built-in Features to Fend Off Web Attacks](#).

How to fix violations

Set the `ViewStateUserKey` property to a unpredictable and unique string per session. For example, if you use ASP.NET session state, `HttpSessionState.SessionID` will work.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The ASP.NET Web Form page does not perform sensitive operations.
- Cross-site request forgery attacks are mitigated in a way that this rule doesn't detect. For example, if the page inherits from a master page that contains CSRF defenses.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5368
// The code that's violating the rule is on this line.
#pragma warning restore CA5368
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5368.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System;
using System.Web.UI;

class ExampleClass : Page
{
    protected override void OnInit (EventArgs e)
    {
    }
}
```

Solution

```
using System;
using System.Web.UI;

class ExampleClass : Page
{
    protected override void OnInit (EventArgs e)
    {
        // Assuming that your page makes use of ASP.NET session state and the SessionID is stable.
        ViewStateUserKey = Session.SessionID;
    }
}
```

CA5369: Use XmlReader for Deserialize

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5369
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Deserializing untrusted XML input with `XmlSerializer.Deserialize` instantiated without an `XmlReader` object can potentially lead to denial of service, information disclosure, and server-side request forgery attacks. These attacks are enabled by untrusted DTD and XML schema processing, which allows for the inclusion of XML bombs and malicious external entities in the XML. Only with `XmlReader` is it possible to disable DTD. Inline XML schema processing as `XmlReader` has the `ProhibitDtd` and `ProcessInlineSchema` property set to `false` by default in .NET Framework version 4.0 and later. The other options such as `Stream`, `TextReader`, and `XmlSerializationReader` cannot disable DTD processing.

Rule description

Processing untrusted DTD and XML schemas may enable loading dangerous external references, which should be restricted by using an `XmlReader` with a secure resolver or with DTD and XML inline schema processing disabled. This rule detects code that uses the `XmlSerializer.Deserialize` method and does not take `XmlReader` as a constructor parameter.

How to fix violations

Do not use `XmlSerializer.Deserialize` overloads other than `Deserialize(XmlReader)`, `Deserialize(XmlReader, String)`, `Deserialize(XmlReader, XmlDeserializationEvents)`, or `Deserialize(XmlReader, String, XmlDeserializationEvents)`.

When to suppress warnings

You can potentially suppress this warning if the parsed XML comes from a trusted source and hence cannot be tampered with.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5369
// The code that's violating the rule is on this line.
#pragma warning restore CA5369
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5369.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. The type of the first parameter of `XmlSerializer.Deserialize` is not `XmlReader` or a derived class thereof.

```
using System.IO;
using System.Xml.Serialization;
...
new XmlSerializer(typeof(TestClass)).Deserialize(new FileStream("filename", FileMode.Open));
```

Solution

```
using System.IO;
using System.Xml;
using System.Xml.Serialization;
...
new XmlSerializer(typeof(TestClass)).Deserialize(XmlReader.Create (new FileStream("filename",
FileMode.Open)));
```

CA5370: Use XmlReader for validating reader

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5370
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Validating untrusted XML input with the `XmlValidatingReader` class instantiated without an `XmlReader` object can potentially lead to denial of service, information disclosure, and server-side request forgery. These attacks are enabled by untrusted DTD and XML schema processing, which allows for the inclusion of XML bombs and malicious external entities in the XML. Only with `XmlReader` is it possible to disable DTD. Inline XML schema processing as `XmlReader` has the `ProhibitDtd` and `ProcessInlineSchema` property set to `false` by default in .NET Framework starting in version 4.0.

Rule description

Processing untrusted DTD and XML schemas may enable loading dangerous external references. This dangerous loading can be restricted by using an `XmlReader` with a secure resolver or with DTD and XML inline schema processing disabled. This rule detects code that uses the `XmlValidatingReader` class without `XmlReader` as a constructor parameter.

How to fix violations

- Use `XmlValidatingReader(XmlReader)` with `ProhibitDtd` and `ProcessInlineSchema` properties set to `false`.
- Starting in .NET Framework 2.0, `XmlValidatingReader` is considered obsolete. You can instantiate a validating reader with `XmlReader.Create`.

When to suppress warnings

You can potentially suppress this warning if the `XmlValidatingReader` is always used to validate XML that comes from a trusted source and hence cannot be tampered with.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5370
// The code that's violating the rule is on this line.
#pragma warning restore CA5370
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5370.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. The type of the first parameter of `XmlValidatingReader.XmlValidatingReader()` is not `XmlReader`.

```
using System;
using System.IO;
using System.Xml;
...
public void TestMethod(Stream xmlFragment, XmlNodeType fragType, XmlParserContext context)
{
    var obj = new XmlValidatingReader(xmlFragment, fragType, context);
}
```

Solution

```
using System;
using System.Xml;
...
public void TestMethod(XmlReader xmlReader)
{
    var obj = new XmlValidatingReader(xmlReader);
}
```

CA5371: Use XmlReader for schema read

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5371
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Processing untrusted XML input with `XmlSchema.Read` instantiated without an `XmlReader` object can potentially lead to denial of service, information disclosure, and server-side request forgery attacks. These attacks are enabled by untrusted DTD and XML schema processing, which allows for the inclusion of XML bombs and malicious external entities in the XML. Only with `XmlReader` is it possible to disable DTD. Inline XML schema processing as `XmlReader` has the `ProhibitDtd` and `ProcessInlineSchema` property set to false by default in .NET Framework starting in version 4.0. The other options such as `Stream`, `TextReader`, and `XmlSerializationReader` cannot disable DTD processing.

Rule description

Processing untrusted DTD and XML schemas may enable loading dangerous external references. Using an `XmlReader` with a secure resolver or with DTD and XML inline schema processing disabled restricts this. This rule detects code that uses the `XmlSchema.Read` method without `XmlReader` as a parameter.

How to fix violations

Use `XmlSchema.Read(XmlReader, *)` overloads.

When to suppress warnings

You can potentially suppress this warning if the `XmlSchema.Read` method is always used to process XML that comes from a trusted source and hence cannot be tampered with.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5371
// The code that's violating the rule is on this line.
#pragma warning restore CA5371
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5371.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. The type of the first parameter of `XmlSchema.Read` is not `XmlReader`.

```
using System.IO;
using System.Xml.Schema;
...
public void TestMethod(Stream stream, ValidationEventHandler validationEventHandler)
{
    XmlSchema.Read(stream, validationEventHandler);
}
```

Solution

```
using System.IO;
using System.Xml.Schema;
...
public void TestMethod(XmlReader reader, ValidationEventHandler validationEventHandler)
{
    XmlSchema.Read(reader, validationEventHandler);
}
```

CA5372: Use XmlReader for XPathDocument

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5372
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using the `XPathDocument` class instantiated without an `XmlReader` object can potentially lead to denial of service, information disclosure, and server-side request forgery attacks. These attacks are enabled by untrusted DTD and XML schema processing, which allows for the inclusion of XML bombs and malicious external entities in the XML. Only with `XmlReader` is it possible to disable DTD. Inline XML schema processing as `XmlReader` has the `ProhibitDtd` and `ProcessInlineSchema` property set to false by default in .NET Framework starting in version 4.0. The other options such as `Stream`, `TextReader`, and `XmlSerializationReader` cannot disable DTD processing.

Rule description

Processing XML from untrusted data may load dangerous external references, which can be restricted by using an `XmlReader` with a secure resolver or with DTD processing disabled. This rule detects code that uses the `XPathDocument` class and doesn't take `XmlReader` as a constructor parameter.

How to fix violations

Use `XPathDocument(XmlReader, *)` constructors.

When to suppress warnings

You can potentially suppress this warning if the `XPathDocument` object is used to process an XML file that comes from a trusted source and hence cannot be tampered with.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5372
// The code that's violating the rule is on this line.
#pragma warning restore CA5372
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5372.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule. The type of the first parameter of `XPathDocument` is not `XmlReader`.

```
using System.IO;
using System.Xml.XPath;
...
var obj = new XPathDocument(stream);
```

Solution

```
using System.Xml;
using System.Xml.XPath;
...
public void TestMethod(XmlReader reader)
{
    var obj = new XPathDocument(reader);
}
```

CA5373: Do not use obsolete key derivation function

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5373
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Cryptographically weak key derivation methods `System.Security.Cryptography.PasswordDeriveBytes` and/or `Rfc2898DeriveBytes.CryptDeriveKey` are used to generate a key.

Rule description

This rule detects the invocation of weak key derivation methods `System.Security.Cryptography.PasswordDeriveBytes` and `Rfc2898DeriveBytes.CryptDeriveKey`. `System.Security.Cryptography.PasswordDeriveBytes` used a weak algorithm PBKDF1. `Rfc2898DeriveBytes.CryptDeriveKey` does not use iteration count and salt from the `Rfc2898DeriveBytes` object, which makes it weak.

How to fix violations

Password-based key derivation should use the PBKDF2 algorithm with SHA-2 hashing. `Rfc2898DeriveBytes.GetBytes` can be used to achieve that.

When to suppress warnings

Suppress the warning if the risk associated with using PBKDF1 is carefully reviewed and accepted.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5373
// The code that's violating the rule is on this line.
#pragma warning restore CA5373
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5373.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

As of the time of this writing, the following pseudo-code sample illustrates the pattern detected by this rule.

```
using System;
using System.Security.Cryptography;
class TestClass
{
    public void TestMethod(Rfc2898DeriveBytes rfc2898DeriveBytes, string aliname, string alghashname, int
keySize, byte[] rgbIV)
    {
        rfc2898DeriveBytes.CryptDeriveKey(aliname, alghashname, keySize, rgbIV);
    }
}
```

Solution

```
using System;
using System.Security.Cryptography;
class TestClass
{
    public void TestMethod(Rfc2898DeriveBytes rfc2898DeriveBytes)
    {
        rfc2898DeriveBytes.GetBytes(1);
    }
}
```

CA5374: Do not use XslTransform

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5374
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Instantiating an [System.Xml.Xsl.XslTransform](#), which doesn't restrict potentially dangerous external references or prevent scripts.

Rule description

[XslTransform](#) is vulnerable when operating on untrusted input. An attack could execute arbitrary code.

How to fix violations

Replace [XslTransform](#) with [System.Xml.Xsl.XslCompiledTransform](#). For more guidance, see [/dotnet/standard/data/xml/migrating-from-the-xsltransform-class].

When to suppress warnings

The [XslTransform](#) object, XSLT style sheets, and XML source data are all from trusted sources.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5374
// The code that's violating the rule is on this line.
#pragma warning restore CA5374
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5374.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

At present, the following pseudo-code sample illustrates the pattern detected by this rule.

```
using System;
using System.Xml;
using System.Xml.XPath;
using System.Xml.Xsl;

namespace TestForXslTransform
{
    class Program
    {
        static void Main(string[] args)
        {
            // Create a new XsltTransform object.
            XsltTransform xslt = new XsltTransform();

            // Load the stylesheet.
            xslt.Load("https://server/favorite.xsl");

            // Create a new XPathDocument and load the XML data to be transformed.
            XPathDocument mydata = new XPathDocument("inputdata.xml");

            // Create an XmlTextWriter which outputs to the console.
            XmlWriter writer = new XmlTextWriter(Console.Out);

            // Transform the data and send the output to the console.
            xslt.Transform(mydata, null, writer, null);
        }
    }
}
```

Solution

```
using System.Xml;
using System.Xml.Xsl;

namespace TestForXslTransform
{
    class Program
    {
        static void Main(string[] args)
        {
            // Default XsltSettings constructor disables the XSLT document() function
            // and embedded script blocks.
            XsltSettings settings = new XsltSettings();

            // Execute the transform.
            XslCompiledTransform xslt = new XslCompiledTransform();
            xslt.Load("https://server/favorite.xsl", settings, new XmlUrlResolver());
            xslt.Transform("inputdata.xml", "outputdata.html");
        }
    }
}
```

CA5375: Do not use account shared access signature

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5375
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Generating an account Shared Access Signature (SAS) with the `GetSharedAccessSignature` method under the `Microsoft.WindowsAzure.Storage` namespace.

Rule description

An account SAS can delegate access to read, write, and delete operations on blob containers, tables, queues, and file shares that are not permitted with a service SAS. However, it doesn't support container-level policies and has less flexibility and control over the permissions that are granted. If possible, use a service SAS for fine grained access control. For more information, see [Delegate access with a shared access signature](#).

How to fix violations

Use a service SAS instead of an account SAS for fine grained access control and container-level access policy.

When to suppress warnings

It is safe to suppress this rule if you're sure that the permissions of all resources are as restricted as possible.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5375
// The code that's violating the rule is on this line.
#pragma warning restore CA5375
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5375.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

At present, the following pseudo-code sample illustrates the pattern detected by this rule.

```
using System;
using Microsoft.WindowsAzure.Storage;

class ExampleClass
{
    public void ExampleMethod(SharedAccessAccountPolicy policy)
    {
        CloudStorageAccount cloudStorageAccount = new CloudStorageAccount();
        cloudStorageAccount.GetSharedAccessSignature(policy);
    }
}
```

Solution

Instead of account SAS, use service SAS.

```
using System;
using Microsoft.WindowsAzure.Storage;
using Microsoft.WindowsAzure.Storage.File;

class ExampleClass
{
    public void ExampleMethod(StorageCredentials storageCredentials, SharedAccessFilePolicy policy,
SharedAccessFileHeaders headers, string groupPolicyIdentifier, IPAddressOrRange ipAddressOrRange)
    {
        CloudFile cloudFile = new CloudFile(storageCredentials);
        SharedAccessProtocol protocols = SharedAccessProtocol.HttpsOnly;
        cloudFile.GetSharedAccessSignature(policy, headers, groupPolicyIdentifier, protocols,
ipAddressOrRange);
    }
}
```

Related rules

[CA5376: Use SharedAccessProtocol.HttpsOnly](#)

[CA5377: Use container level access policy](#)

CA5376: Use SharedAccessProtocol HttpsOnly

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5376
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using the `GetSharedAccessSignature` method under the `Microsoft.WindowsAzure.Storage` namespace to generate a Shared Access Signature (SAS) with specifying `protocols` as `HttpsOrHttp`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

SAS is a sensitive data which can't be transported in plain text on HTTP.

How to fix violations

Using `HttpsOnly` when generating SAS.

When to suppress warnings

Do not suppress this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).

- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

At present, the following pseudo-code sample illustrates the pattern detected by this rule.

```
using System;
using Microsoft.WindowsAzure.Storage;
using Microsoft.WindowsAzure.Storage.File;

class ExampleClass
{
    public void ExampleMethod(SharedAccessFilePolicy policy, SharedAccessFileHeaders headers, string
groupPolicyIdentifier, IPAddressOrRange ipAddressOrRange)
    {
        CloudFile cloudFile = new CloudFile(null);
        SharedAccessProtocol protocols = SharedAccessProtocol.HttpsOrHttp;
        cloudFile.GetSharedAccessSignature(policy, headers, groupPolicyIdentifier, protocols,
ipAddressOrRange);
    }
}
```

Solution

```
using System;
using Microsoft.WindowsAzure.Storage;
using Microsoft.WindowsAzure.Storage.File;

class ExampleClass
{
    public void ExampleMethod(SharedAccessFilePolicy policy, SharedAccessFileHeaders headers, string
groupPolicyIdentifier, IPAddressOrRange ipAddressOrRange)
    {
        CloudFile cloudFile = new CloudFile(null);
        SharedAccessProtocol protocols = SharedAccessProtocol.HttpsOnly;
        cloudFile.GetSharedAccessSignature(policy, headers, groupPolicyIdentifier, protocols,
ipAddressOrRange);
    }
}
```

CA5377: Use container level access policy

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5377
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Container level policy is not set when generating a service Shared Access Signature (SAS).

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

A container-level access policy can be modified or revoked at any time. It provides greater flexibility and control over the permissions that are granted. For more information, see [Define a stored access policy](#).

How to fix violations

Specify a valid group policy identifier when generating the service SAS.

When to suppress warnings

It is safe to suppress this rule if you're sure that the permissions of all resources are as restricted as possible.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5377
// The code that's violating the rule is on this line.
#pragma warning restore CA5377
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5377.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType	Matches all types named <code>MyType</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

At present, the following pseudo-code sample illustrates the pattern detected by this rule.

```
using System;
using Microsoft.WindowsAzure.Storage;
using Microsoft.WindowsAzure.Storage.Blob;

class ExampleClass
{
    public void ExampleMethod(SharedAccessBlobPolicy policy, SharedAccessBlobHeaders headers,
    Nullable<SharedAccessProtocol> protocols, IPAddressOrRange ipAddressOrRange)
    {
        var cloudAppendBlob = new CloudAppendBlob(null);
        string groupPolicyIdentifier = null;
        cloudAppendBlob.GetSharedAccessSignature(policy, headers, groupPolicyIdentifier, protocols,
ipAddressOrRange);
    }
}
```

Solution

```
using System;
using Microsoft.WindowsAzure.Storage;
using Microsoft.WindowsAzure.Storage.Blob;

class ExampleClass
{
    public void ExampleMethod(SharedAccessBlobPolicy policy, SharedAccessBlobHeaders headers,
    Nullable<SharedAccessProtocol> protocols, IPAddressOrRange ipAddressOrRange)
    {
        CloudAppendBlob cloudAppendBlob = new CloudAppendBlob(null);
        string groupPolicyIdentifier = "123";
        cloudAppendBlob.GetSharedAccessSignature(policy, headers, groupPolicyIdentifier, protocols,
ipAddressOrRange);
    }
}
```

Related rules

CA5375: Do not use account shared access signature

CA5376: Use SharedAccessProtocol HttpsOnly

CA5378: Do not disable ServicePointManagerSecurityProtocols

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5378
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A `AppContext.SetSwitch` method call sets

```
Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols to true.
```

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Setting `Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols` to `true` limits Windows Communication Framework's (WCF) Transport Layer Security (TLS) connections to using TLS 1.0. That version of TLS will be deprecated. For more information, see [Transport Layer Security \(TLS\) best practices with .NET Framework](#).

How to fix violations

- If your application targets .NET Framework v4.7 or later, you can either remove the `AppContext.SetSwitch` method call, or set the switch's value to `false`.
- If your application targets .NET Framework v4.6.2 or earlier and runs on .NET Framework v4.7 or later, set the switch's value to `false`.
- Otherwise, refer to [Transport Layer Security \(TLS\) best practices with .NET Framework](#) for mitigations.

When to suppress warnings

You can suppress this warning if you need to connect to a legacy service that can't be upgraded to use secure TLS configurations.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5378
// The code that's violating the rule is on this line.
#pragma warning restore CA5378
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5378.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should

not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5378 violation
        ApplicationContext.SetSwitch("Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols",
true);
    }
}
```

```
Imports System

Public Class ExampleClass
    Public Sub ExampleMethod()
        ' CA5378 violation
        ApplicationContext.SetSwitch("Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols",
true)
        End Sub
    End Class
```

Solution

```
using System;

public class ExampleClass
{
    public void ExampleMethod()
    {
        ApplicationContext.SetSwitch("Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols",
false);
    }
}
```

```
Imports System

Public Class ExampleClass
    Public Sub ExampleMethod()
        ApplicationContext.SetSwitch("Switch.System.ServiceModel.DisableUsingServicePointManagerSecurityProtocols",
false)
    End Sub
End Class
```

CA5379: Ensure key derivation function algorithm is sufficiently strong

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5379
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Use of one of the following algorithms when instantiating `System.Security.Cryptography.Rfc2898DeriveBytes`:

- `System.Security.Cryptography.MD5`
- `System.Security.Cryptography.SHA1`
- An algorithm that the rule can't determine at compile time

Rule description

The `Rfc2898DeriveBytes` class defaults to using the `SHA1` algorithm. When instantiating an `Rfc2898DeriveBytes` object, you should specify a hash algorithm of `SHA256` or higher. Note that `Rfc2898DeriveBytes.HashAlgorithm` property only has a `get` accessor.

How to fix violations

Because `MD5` or `SHA1` are vulnerable to collisions, use `SHA256` or higher for the `Rfc2898DeriveBytes` class.

Older versions of .NET Framework or .NET Core may not allow you to specify a key derivation function hash algorithm. In such cases, you need to upgrade the target framework version of .NET to use a stronger algorithm.

When to suppress warnings

It is not recommended to suppress this rule except for application compatibility reasons.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5379
// The code that's violating the rule is on this line.
#pragma warning restore CA5379
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5379.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Specify hash algorithm in constructor violation

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt, iterations, HashAlgorithmName.MD5);
    }
}
```

Specify hash algorithm in derived class' constructor violation

```
using System.Security.Cryptography;

class DerivedClass : Rfc2898DeriveBytes
{
    public DerivedClass (byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm) :
    base(password, salt, iterations, hashAlgorithm)
    {
    }
}

class ExampleClass
{
    public void ExampleMethod(byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm)
    {
        var derivedClass = new DerivedClass(password, salt, iterations, HashAlgorithmName.MD5);
    }
}
```

Set hash algorithm property in derived classes violation

```
using System.Security.Cryptography;

class DerivedClass : Rfc2898DeriveBytes
{
    public DerivedClass (byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm) :
    base(password, salt, iterations, hashAlgorithm)
    {
    }

    public HashAlgorithmName HashAlgorithm { get; set; }
}

class ExampleClass
{
    public void ExampleMethod(byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm)
    {
        var derivedClass = new DerivedClass(password, salt, iterations, HashAlgorithmName.MD5);
        derivedClass.HashAlgorithm = HashAlgorithmName.SHA256;
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] password, byte[] salt, int iterations, HashAlgorithmName hashAlgorithm)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt, iterations,
HashAlgorithmName.SHA256);
    }
}
```

CA5380: Do not add certificates to root store

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5380
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Adding certificates to the operating system's trusted root certificates increases the risk of legitimizing untrusted certification authority.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

This rule detects code that adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public CAs that has met the requirements of the Microsoft Root Certificate Program. Since all trusted root certification authorities (CA's) can issue certificates for any domain, an attacker can pick a weak or coercible CA that you install by yourself to target for an attack – and a single vulnerable, malicious or coercible CA undermines the security of the entire system.

How to fix violations

Do not install certificates into the Trusted Root Certification Authorities certificate store.

When to suppress warnings

It is not recommended to suppress this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

The following pseudo-code sample illustrates the pattern detected by this rule.

```
using System.Security.Cryptography.X509Certificates;

class TestClass
{
    public void TestMethod()
    {
        var storeName = StoreName.Root;
        var x509Store = new X509Store(storeName);
        x509Store.Add(new X509Certificate2());
    }
}
```

Solution

```
using System.Security.Cryptography.X509Certificates;

class TestClass
{
    public void TestMethod()
    {
        var storeName = StoreName.My;
        var x509Store = new X509Store(storeName);
        x509Store.Add(new X509Certificate2());
    }
}
```

CA5381: Ensure certificates are not added to root store

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5381
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Adding certificates to the operating system's trusted root certificates increases the risk of legitimizing untrusted certification authority.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

This rule detects code that potentially adds a certificate into the Trusted Root Certification Authorities certificate store. By default, the Trusted Root Certification Authorities certificate store is configured with a set of public certification authorities (CAs) that has met the requirements of the Microsoft Root Certificate Program. Since all trusted root CAs can issue certificates for any domain, an attacker can pick a weak or coercible CA that you install by yourself to target for an attack – and a single vulnerable, malicious or coercible CA undermines the security of the entire system.

How to fix violations

Do not install certificates into the Trusted Root Certification Authorities certificate store.

When to suppress warnings

It is not recommended to suppress this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

        x509Store.Add(new X509Certificate2());
    }
}
```

CA5382: Use secure cookies in ASP.NET Core

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5382
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `Microsoft.AspNetCore.Http.CookieOptions.Secure` property is set as `false` when invoking `Microsoft.AspNetCore.Http.IResponseCookies.Append`. For now, this rule only looks at the `Microsoft.AspNetCore.Http.Internal.ResponseCookies` class, which is one of the implementations of `IResponseCookies`.

This rule is similar to [CA5383](#), but analysis can determine that the `Secure` property is definitely `false` or not set.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Transport Layer Security (TLS).

How to fix violations

Set `Secure` property as `true`.

When to suppress warnings

- If cookies are configured to be secure by default, such as using `Microsoft.AspNetCore.CookiePolicy.CookiePolicyMiddleware` in `Startup.Configure`:

```
public class Startup
{
    public void Configure(IApplicationBuilder app, IWebHostEnvironment env)
    {
        app.UseCookiePolicy(
            new CookiePolicyOptions
            {
                Secure = CookieSecurePolicy.Always
            });
    }
}
```

- If you're sure there's no sensitive data in the cookies.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5382
// The code that's violating the rule is on this line.
#pragma warning restore CA5382
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5382.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following snippet illustrates the pattern detected by this rule.

Violation:

```
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Http.Internal;

class ExampleClass
{
    public void ExampleMethod(string key, string value)
    {
        var cookieOptions = new CookieOptions();
        cookieOptions.Secure = false;
        var responseCookies = new ResponseCookies(null, null);
        responseCookies.Append(key, value, cookieOptions);
    }
}
```

Solution:

```
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Http.Internal;

class ExampleClass
{
    public void ExampleMethod(string key, string value)
    {
        var cookieOptions = new CookieOptions();
        cookieOptions.Secure = true;
        var responseCookies = new ResponseCookies(null, null);
        responseCookies.Append(key, value, cookieOptions);
    }
}
```

CA5383: Ensure use secure cookies in ASP.NET Core

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5383
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `Microsoft.AspNetCore.Http.CookieOptions.Secure` property may be set as `false` when invoking `Microsoft.AspNetCore.Http.IResponseCookies.Append`. For now, this rule only looks at the `Microsoft.AspNetCore.Http.Internal.ResponseCookies` class, which is one of the implementations of `IResponseCookies`.

This rule is similar to [CA5382](#), but analysis can't determine that the `Secure` property is definitely `false` or not set.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

Applications available over HTTPS must use secure cookies, which indicate to the browser that the cookie should only be transmitted using Transport Layer Security (TLS).

How to fix violations

Set `Secure` property as `true` under all circumstances.

When to suppress warnings

- If cookies are configured to be secure by default, such as using `Microsoft.AspNetCore.CookiePolicy.CookiePolicyMiddleware` in `Startup.Configure`:

```
public class Startup
{
    public void Configure(IApplicationBuilder app, IWebHostEnvironment env)
    {
        app.UseCookiePolicy(
            new CookiePolicyOptions
            {
                Secure = CookieSecurePolicy.Always
            });
    }
}
```

- If you're sure there's no sensitive data in the cookies.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5383
// The code that's violating the rule is on this line.
#pragma warning restore CA5383
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5383.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following snippet illustrates the pattern detected by this rule.

Violation:

```
using System;
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Http.Internal;

class ExampleClass
{
    public void ExampleMethod(string key, string value)
    {
        var cookieOptions = new CookieOptions();
        cookieOptions.Secure = false;
        Random r = new Random();

        if (r.Next(6) == 4)
        {
            cookieOptions.Secure = true;
        }

        var responseCookies = new ResponseCookies(null, null);
        responseCookies.Append(key, value, cookieOptions);
    }
}
```

Solution:

```
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Http.Internal;

class ExampleClass
{
    public void ExampleMethod(string key, string value)
    {
        var cookieOptions = new CookieOptions();
        cookieOptions.Secure = true;
        var responseCookies = new ResponseCookies(null, null);
        responseCookies.Append(key, value, cookieOptions);
    }
}
```

CA5384: Do not use digital signature algorithm (DSA)

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5384
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using DSA in one of the following ways:

- Returning or instantiating derived classes of [System.Security.Cryptography.DSA](#)
- Using [System.Security.Cryptography.AsymmetricAlgorithm.Create](#) or [System.Security.Cryptography.CryptoConfig.CreateFromName](#) to create a DSA object.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

DSA is a weak asymmetric encryption algorithm.

How to fix violations

Switch to an RSA with at least 2048 key size, ECDH or ECDsa algorithm instead.

When to suppress warnings

It is not recommended to suppress this rule unless for compatibility with legacy applications and data.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5384
// The code that's violating the rule is on this line.
#pragma warning restore CA5384
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5384.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following code snippet illustrates the pattern detected by this rule.

Violation:

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        DSACng dsaCng = new DSACng();
    }
}
```

Solution:

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        AsymmetricAlgorithm asymmetricAlgorithm = AsymmetricAlgorithm.Create("ECDsa");
    }
}
```

CA5385: Use Rivest–Shamir–Adleman (RSA) algorithm with sufficient key size

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5385
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using asymmetric encryption algorithm RSA with key size less than 2048 in one of the following ways:

- Instantiating any descendant classes of `System.Security.Cryptography.RSA` and specifying the `KeySize` parameter as less than 2048.
- Returning any object whose type is descendant of `System.Security.Cryptography.RSA`.
- Using `System.Security.Cryptography.AsymmetricAlgorithm.Create` without parameter which would create RSA with the default key size 1024.
- Using `System.Security.Cryptography.AsymmetricAlgorithm.Create` and specifying the `a1gName` parameter as `RSA` with the default key size 1024.
- Using `System.Security.Cryptography.CryptoConfig.CreateFromName` and specifying the `name` parameter as `RSA` with the default key size 1024.
- Using `System.Security.Cryptography.CryptoConfig.CreateFromName` and specifying the `name` parameter as `RSA` and specifying the key size as smaller than 2048 explicitly by `args`.

Rule description

An RSA key smaller than 2048 bits is more vulnerable to brute force attacks.

How to fix violations

Switch to an RSA with at least 2048 key size, ECDH or ECDsa algorithm instead.

When to suppress warnings

It is not recommended to suppress this rule unless for compatibility with legacy applications and data.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5385
// The code that's violating the rule is on this line.
#pragma warning restore CA5385
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5385.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following code snippet illustrates the pattern detected by this rule.

Violation:

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        RSACng rsaCng = new RSACng(1024);
    }
}
```

Solution:

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        RSACng rsaCng = new RSACng(2048);
    }
}
```

CA5386: Avoid hardcoding SecurityProtocolType value

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5386
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when either of the following conditions are met:

- A safe but hardcoded `System.Net.SecurityProtocolType` value was referenced.
- An integer value representing a safe protocol version was assigned to a `SecurityProtocolType` variable.

Safe values are:

- `Tls12`
- `Tls13`

Rule description

Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version and target at least .NET Framework v4.7.1. For more information, see [Transport Layer Security \(TLS\) best practices with .NET Framework](#).

How to fix violations

Don't hardcode TLS protocol versions.

When to suppress warnings

You can suppress this warning if your application targets .NET Framework v4.6.2 or earlier and may run on a computer that has insecure defaults.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5386
// The code that's violating the rule is on this line.
#pragma warning restore CA5386
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5386.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Enumeration name violation

```
using System;
using System.Net;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5386 violation
        ServicePointManager.SecurityProtocol = SecurityProtocolType.Tls12;
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5386 violation
        ServicePointManager.SecurityProtocol = SecurityProtocolType.Tls12
    End Sub
End Class
```

Integer value violation

```
using System;
using System.Net;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5386 violation
        ServicePointManager.SecurityProtocol = (SecurityProtocolType) 3072;      // TLS 1.2
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5386 violation
        ServicePointManager.SecurityProtocol = CType(3072, SecurityProtocolType)      ' TLS 1.2
    End Sub
End Class
```

Solution

```
using System;
using System.Net;

public class TestClass
{
    public void TestMethod()
    {
        // Let the operating system decide what TLS protocol version to use.
        // See https://docs.microsoft.com/dotnet/framework/network-programming/tls
    }
}
```

```
Imports System
Imports System.Net

Public Class TestClass
    Public Sub ExampleMethod()
        ' Let the operating system decide what TLS protocol version to use.
        ' See https://docs.microsoft.com/dotnet/framework/network-programming/tls
    End Sub
End Class
```

[CA5397: Do not use deprecated SslProtocols values](#)

[CA5398: Avoid hardcoded SslProtocols values](#)

CA5387: Do not use weak key derivation function with insufficient iteration count

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5387
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using `System.Security.Cryptography.Rfc2898DeriveBytes.GetBytes` with the default iteration count or specifying an iteration count of less than 100,000.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

This rule checks if a cryptographic key was generated by `Rfc2898DeriveBytes` with an iteration count of less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.

This rule is similar to [CA5388](#), but analysis determines that the iteration count is less than 100,000.

How to fix violations

Set the iteration count greater than or equal with 100,000 before calling `GetBytes`.

When to suppress warnings

It's safe to suppress a warning if you need to use a smaller iteration count for compatibility with existing data.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5387
// The code that's violating the rule is on this line.
#pragma warning restore CA5387
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5387.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Default iteration count violation

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt);
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

Specify iteration count in constructor violation

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt, 100);
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

Specify iteration count by property assignment violation

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt);
        rfc2898DeriveBytes.IterationCount = 100;
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt);
        rfc2898DeriveBytes.IterationCount = 100000;
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

CA5388: Ensure sufficient iteration count when using weak key derivation function

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5388
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Iteration count may be smaller than 100,000 when deriving cryptographic key by [System.Security.Cryptography.Rfc2898DeriveBytes.GetBytes](#).

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

This rule checks if a cryptographic key was generated by [Rfc2898DeriveBytes](#) with an iteration count that may be less than 100,000. A higher iteration count can help mitigate against dictionary attacks that try to guess the generated cryptographic key.

This rule is similar to [CA5387](#), but analysis can't determine if the iteration count is less than 100,000.

How to fix violations

Set the iteration count greater than or equal with 100k before calling [GetBytes](#) explicitly.

When to suppress warnings

It's safe to suppress warnings from this rule if:

- You need to use a smaller iteration count for compatibility with existing data.
- You're sure that the iteration count is set above 100,000.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5388
// The code that's violating the rule is on this line.
#pragma warning restore CA5388
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5388.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair

to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Violation

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var iterations = 100;
        Random r = new Random();

        if (r.Next(6) == 4)
        {
            iterations = 100000;
        }

        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt, iterations);
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(string password, byte[] salt, int cb)
    {
        var rfc2898DeriveBytes = new Rfc2898DeriveBytes(password, salt);
        rfc2898DeriveBytes.IterationCount = 100000;
        rfc2898DeriveBytes.GetBytes(cb);
    }
}
```

CA5389: Do not add archive item's path to the target file system path

9/20/2022 • 4 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5389
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

A non-sanitized source file path is used as the target file path in one of these parameters:

- parameter `destinationFileName` of method `ZipFileExtensions.ExtractToFile`
- parameter `path` of method `File.Open`
- parameter `path` of method `File.OpenWrite`
- parameter `path` of method `File.Create`
- parameter `path` of constructor for `FileStream`
- parameter `fileName` of constructor for `FileInfo`

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

File path can be relative and can lead to file system access outside of the expected file system target path, leading to malicious config changes and remote code execution via lay-and-wait technique.

How to fix violations

Do not use the source file path to construct the target file path, or make sure that the last character on the extraction path is the directory separator character.

When to suppress warnings

You can suppress this warning if the source path always comes from a trusted source.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5389
// The code that's violating the rule is on this line.
#pragma warning restore CA5389
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5389.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should

not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Example

The following code snippet illustrates the pattern detected by this rule.

Violation:

```
using System.IO.Compression;

class TestClass
{
    public void TestMethod(ZipArchiveEntry zipArchiveEntry)
    {
        zipArchiveEntry.ExtractToFile(zipArchiveEntry.FullName);
    }
}
```

Solution:

```
using System;
using System.IO;
using System.IO.Compression;

class Program
{
    static void Main(string[] args)
    {
        string zipPath = @".\result.zip";

        Console.WriteLine("Provide path where to extract the zip file:");
        string extractPath = Console.ReadLine();

        // Normalizes the path.
        extractPath = Path.GetFullPath(extractPath);

        // Ensures that the last character on the extraction path
        // is the directory separator char.
        // Without this, a malicious zip file could try to traverse outside of the expected
        // extraction path.
        if (!extractPath.EndsWith(Path.DirectorySeparatorChar.ToString(), StringComparison.OrdinalIgnoreCase))
            extractPath += Path.DirectorySeparatorChar;

        using (ZipArchive archive = ZipFile.OpenRead(zipPath))
        {
            foreach (ZipArchiveEntry entry in archive.Entries)
            {
                if (entry.FullName.EndsWith(".txt", StringComparison.OrdinalIgnoreCase))
                {
                    // Gets the full path to ensure that relative segments are removed.
                    string destinationPath = Path.GetFullPath(Path.Combine(extractPath, entry.FullName));

                    // Ordinal match is safest, case-sensitive volumes can be mounted within volumes that
                    // are case-insensitive.
                    if (destinationPath.StartsWith(extractPath, StringComparison.OrdinalIgnoreCase))
                        entry.ExtractToFile(destinationPath);
                }
            }
        }
    }
}
```

CA5390: Do not hard-code encryption key

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5390
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `key` parameter of the `System.Security.Cryptography.AesCcm` or `System.Security.Cryptography.AesGcm` constructor, `System.Security.Cryptography.SymmetricAlgorithm.Key` property, or the `rgbKey` parameter of the `System.Security.Cryptography.SymmetricAlgorithm.CreateEncryptor` or `System.Security.Cryptography.SymmetricAlgorithm.CreateDecryptor` method is hard-coded by one of the following:

- Byte array.
- `System.Convert.FromBase64String`.
- All the overloads of `System.Text.Encoding.GetBytes`.

By default, this rule analyzes the entire codebase, but this is [configurable](#).

Rule description

For a symmetric algorithm to be successful, the secret key must be known only to the sender and the receiver. When a key is hard-coded, it is easily discovered. Even with compiled binaries, it is easy for malicious users to extract it. Once the private key is compromised, the cipher text can be decrypted directly and is not protected anymore.

How to fix violations

- Consider redesigning your application to use a secure key management system, such as Azure Key Vault.
- Keep credentials and keys in a secure location separate from your source code.

When to suppress warnings

Do not suppress a warning from this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.

OPTION VALUE	SUMMARY
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

Hard-coded byte array violation

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] someOtherBytesForIV)
    {
        byte[] rgbKey = new byte[] {1, 2, 3};
        SymmetricAlgorithm rijndael = SymmetricAlgorithm.Create();
        rijndael.CreateEncryptor(rgbKey, someOtherBytesForIV);
    }
}
```

Hard-coded Convert.FromBase64String violation

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] someOtherBytesForIV)
    {
        byte[] key = Convert.FromBase64String("AAAAAaazaoensuth");
        SymmetricAlgorithm rijndael = SymmetricAlgorithm.Create();
        rijndael.CreateEncryptor(key, someOtherBytesForIV);
    }
}
```

Hard-coded Encoding.GetBytes violation

```
using System.Text;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] someOtherBytesForIV)
    {
        byte[] key = Encoding.ASCII.GetBytes("AAAAAaazaoensuth");
        SymmetricAlgorithm rijndael = SymmetricAlgorithm.Create();
        rijndael.CreateEncryptor(key, someOtherBytesForIV);
    }
}
```

Solution

```
using System.Text;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(char[] chars, byte[] someOtherBytesForIV)
    {
        byte[] key = Encoding.ASCII.GetBytes(chars);
        SymmetricAlgorithm rijndael = SymmetricAlgorithm.Create();
        rijndael.CreateEncryptor(key, someOtherBytesForIV);
    }
}
```

CA5391: Use antiforgery tokens in ASP.NET Core MVC controllers

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5391
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Actions that result in modifying operations don't have an antiforgery token attribute. Or, using a global antiforgery token filter without calling expected anti forgery token functions.

Rule description

Handling a `POST`, `PUT`, `PATCH`, or `DELETE` request without validating an antiforgery token may be vulnerable to cross-site request forgery attacks. A cross-site request forgery attack can send malicious requests from an authenticated user to your ASP.NET Core MVC controller.

How to fix violations

- Mark the modifying action with a valid antiforgery token attribute:
 - `Microsoft.AspNetCore.Mvc.ValidateAntiForgeryTokenAttribute`.
 - Attribute whose name is like `%Validate%Anti_forgery%Attribute`.
- Add the valid forgery token attribute into the global filter with `Microsoft.AspNetCore.Mvc.Filters.FilterCollection.Add`.
- Add any custom or Mvc-provided antiforgery filter class that calls `Validate` on any class that implements the `Microsoft.AspNetCore.Antiforgery.IAntiforgery` interface.

When to suppress warnings

It's safe to suppress this rule if solutions other than using antiforgery token attributes are adopted to mitigate CSRF vulnerabilities. For more information, see [Prevent Cross-Site Request Forgery \(XSRF/CSRF\) attacks in ASP.NET Core](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5391
// The code that's violating the rule is on this line.
#pragma warning restore CA5391
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5391.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

You can configure whether the rule applies only to derived classes of `Microsoft.AspNetCore.Mvc.Controller` in your codebase. For example, to specify that the rule should not run on any code within derived types of `ControllerBase`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA5391.exclude_aspnet_core_mvc_controllerbase = true
```

Pseudo-code examples

Without anti forgery token attribute violation

```
using Microsoft.AspNetCore.Mvc;

class ExampleController : Controller
{
    [HttpDelete]
    public IActionResult ExampleAction (string actionPerformed)
    {
        return null;
    }

    [ValidateAntiForgeryToken]
    [HttpDelete]
    public IActionResult AnotherAction (string actionPerformed)
    {
        return null;
    }
}
```

Without valid global anti forgery filter

```

using System.Threading.Tasks;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.Filters;

class ExampleController : Controller
{
    [ValidateAntiForgeryToken]
    [HttpDelete]
    public IActionResult AnotherAction (string actionName)
    {
        return null;
    }

    [HttpDelete]
    public IActionResult ExampleAction (string actionName)
    {
        return null;
    }
}

class FilterClass : IAsyncAuthorizationFilter
{
    public Task OnAuthorizationAsync (AuthorizationFilterContext context)
    {
        return null;
    }
}

class BlahClass
{
    public static void BlahMethod ()
    {
        FilterCollection filterCollection = new FilterCollection ();
        filterCollection.Add(typeof(FilterClass));
    }
}

```

Marked with an anti forgery token attribute solution

```

using Microsoft.AspNetCore.Mvc;

class ExampleController : Controller
{
    [ValidateAntiForgeryToken]
    [HttpDelete]
    public IActionResult ExampleAction ()
    {
        return null;
    }

    [ValidateAntiForgeryToken]
    [HttpDelete]
    public IActionResult AnotherAction ()
    {
        return null;
    }
}

```

Using a valid global anti forgery filter

```
using System.Threading.Tasks;
using Microsoft.AspNetCore.Antiforgery;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.Filters;

class ExampleController : Controller
{
    [ValidateAntiForgeryToken]
    [HttpDelete]
    public IActionResult AnotherAction()
    {
        return null;
    }

    [HttpDelete]
    public IActionResult ExampleAction()
    {
        return null;
    }
}

class FilterClass : IAsyncAuthorizationFilter
{
    private readonly IAntiforgery antiforgery;

    public FilterClass(IAntiforgery antiforgery)
    {
        this.antiforgery = antiforgery;
    }

    public Task OnAuthorizationAsync(AuthorizationFilterContext context)
    {
        return antiforgery.ValidateRequestAsync(context.HttpContext);
    }
}

class BlahClass
{
    public static void BlahMethod()
    {
        FilterCollection filterCollection = new FilterCollection();
        filterCollection.Add(typeof(FilterClass));
    }
}
```

CA5392: Use DefaultDllImportSearchPaths attribute for P/Invokes

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5392
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The [DefaultDllImportSearchPathsAttribute](#) is not specified for a [Platform Invoke \(P/Invoke\)](#) function.

Rule description

By default, P/Invoke functions using [DllImportAttribute](#) probe a number of directories, including the current working directory for the library to load. This can be a security issue for certain applications, leading to DLL hijacking.

For example, if a malicious DLL with the same name as the imported one is placed under the current working directory, which will be searched firstly by default, then the malicious DLL could be loaded.

For more information, see [Load Library Safely](#).

How to fix violations

Use [DefaultDllImportSearchPathsAttribute](#) to specify the DLL search path explicitly for the assembly or the method.

When to suppress warnings

It's safe to suppress this rule if:

- You're sure the loaded assembly is what you want. For example, your application runs on a trusted server and you completely trust the files.
- The imported assembly is a commonly used system assembly, like user32.dll, and the search path strategy follows the [Known DLLs mechanism](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5392
// The code that's violating the rule is on this line.
#pragma warning restore CA5392
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5392.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

```
using System;
using System.Runtime.InteropServices;

class ExampleClass
{
    [DllImport("The3rdAssembly.dll")]
    public static extern int MessageBox(IntPtr hWnd, String text, String caption, uint type);

    public void ExampleMethod()
    {
        MessageBox(new IntPtr(0), "Hello World!", "Hello Dialog", 0);
    }
}
```

Solution

```
using System;
using System.Runtime.InteropServices;

class ExampleClass
{
    [DllImport("The3rdAssembly.dll")]
    [DefaultDllImportSearchPaths(DllImportSearchPath.UserDirectories)]
    public static extern int MessageBox(IntPtr hWnd, String text, String caption, uint type);

    public void ExampleMethod()
    {
        MessageBox(new IntPtr(0), "Hello World!", "Hello Dialog", 0);
    }
}
```

Related rules

[CA5393: Do not use unsafe DllImportSearchPath value](#)

CA5393: Do not use unsafe DllImportSearchPath value

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5393
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using one of the unsafe values of `<xref:System.Runtime.InteropServices.DllImportSearchPath? displayProperty=fullName>`:

- `AssemblyDirectory`
- `UseDllDirectoryForDependencies`
- `ApplicationDirectory`
- `LegacyBehavior`

Rule description

There could be a malicious DLL in the default DLL search directories and assembly directories. Or, depending on where your application is run from, there could be a malicious DLL in the application's directory.

For more information, see [Load Library Safely](#).

How to fix violations

Use safe values of `DllImportSearchPath` to specify an explicit search path instead:

- `SafeDirectories`
- `System32`
- `UserDirectories`

When to suppress warnings

It's safe to suppress this rule if:

- You're sure the loaded assembly is what you want.
- The imported assembly is a commonly used system assembly, like `user32.dll`, and the search path strategy follows the [Known DLLs mechanism](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5393
// The code that's violating the rule is on this line.
#pragma warning restore CA5393
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA5393.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Unsafe DllImportSearchPath bits](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Unsafe DllImportSearchPath bits

You can configure which value of [DllImportSearchPath](#) is unsafe for the analysis. For example, to specify that the code should not use `AssemblyDirectory`, `UseDllImportSearchPaths(DllImportSearchPath.AssemblyDirectory)` or `ApplicationDirectory`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA5393.unsafe_DllImportSearchPath_bits = 770
```

You should specify the integer value of a bitwise combination of the enumeration's values.

Pseudo-code examples

```
using System;
using System.Runtime.InteropServices;

class ExampleClass
{
    [DllImport("The3rdAssembly.dll")]
    [DefaultDllImportSearchPaths(DllImportSearchPath.AssemblyDirectory)]
    public static extern int MessageBox(IntPtr hWnd, String text, String caption, uint type);

    public void ExampleMethod()
    {
        MessageBox(new IntPtr(0), "Hello World!", "Hello Dialog", 0);
    }
}
```

Solution

```
using System;
using System.Runtime.InteropServices;

class ExampleClass
{
    [DllImport("The3rdAssembly.dll")]
    [DefaultDllImportSearchPaths(DefaultDllImportSearchPath.UserDirectories)]
    public static extern int MessageBox(IntPtr hWnd, String text, String caption, uint type);

    public void ExampleMethod()
    {
        MessageBox(new IntPtr(0), "Hello World!", "Hello Dialog", 0);
    }
}
```

[CA5392: Use DefaultDllImportSearchPaths attribute for P/Invokes](#)

CA5394: Do not use insecure randomness

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5394
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

One of the methods of `System.Random` is invoked.

Rule description

Using a cryptographically weak pseudo-random number generator may allow an attacker to predict what security-sensitive value will be generated.

How to fix violations

If you need an unpredictable value for security, use a cryptographically strong random number generator like `System.Security.Cryptography.RandomNumberGenerator` or `System.Security.Cryptography.RNGCryptoServiceProvider`.

When to suppress warnings

It's safe to suppress warnings from this rule if you're sure that the weak pseudo-random numbers aren't used in a security-sensitive manner.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5394
// The code that's violating the rule is on this line.
#pragma warning restore CA5394
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5394.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System;

class ExampleClass
{
    public void ExampleMethod(Random random)
    {
        var sensitiveVariable = random.Next();
    }
}
```

Solution

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(int toExclusive)
    {
        var sensitiveVariable = RandomNumberGenerator.GetInt32(toExclusive);
    }
}
```

CA5395: Miss HttpVerb attribute for action methods

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5395
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Not specifying the kind of HTTP request explicitly for action methods.

Rule description

All the action methods that create, edit, delete, or otherwise modify data needs to be protected with the antiforgery attribute from cross-site request forgery attacks. Performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.

How to fix violations

Mark the action methods with `Httpverb` attribute.

When to suppress warnings

It's safe to suppress warnings from this rule if:

- You're sure that no modifying operation is taking place in the action method. Or, it's not an action method at all.
- Solutions other than using antiforgery token attributes are adopted to mitigate CSRF vulnerabilities. For more information, see [Prevent Cross-Site Request Forgery \(XSRF/CSRF\) attacks in ASP.NET Core](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5395
// The code that's violating the rule is on this line.
#pragma warning restore CA5395
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5395.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using Microsoft.AspNetCore.Mvc;

[ValidateAntiForgeryToken]
class BlahController : Controller
{
}

class ExampleController : Controller
{
    public IActionResult ExampleAction()
    {
        return null;
    }
}
```

Solution

```
using Microsoft.AspNetCore.Mvc;

[ValidateAntiForgeryToken]
class BlahController : Controller
{
}

class ExampleController : Controller
{
    [HttpGet]
    public IActionResult ExampleAction()
    {
        return null;
    }
}
```

CA5396: Set HttpOnly to true for HttpCookie

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5396
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

`System.Web.HttpCookie.HttpOnly` is set to `false`. The default value of this property is `false`.

Rule description

As a defense in depth measure, ensure security sensitive HTTP cookies are marked as `HttpOnly`. This indicates web browsers should disallow scripts from accessing the cookies. Injected malicious scripts are a common way of stealing cookies.

How to fix violations

Set `System.Web.HttpCookie.HttpOnly` to `true`.

When to suppress warnings

- If the global value of `HttpOnly` is set, such as in the following example:

```
<system.web>
  ...
  <httpCookies httpOnlyCookies="true" requireSSL="true" />
</system.web>
```

- If you're sure there's no sensitive data in the cookies.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5396
// The code that's violating the rule is on this line.
#pragma warning restore CA5396
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5396.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

Violation:

```
using System.Web;

class ExampleClass
{
    public void ExampleMethod()
    {
        HttpCookie httpCookie = new HttpCookie("cookieName");
        httpCookie.HttpOnly = false;
    }
}
```

Solution:

```
using System.Web;

class ExampleClass
{
    public void ExampleMethod()
    {
        HttpCookie httpCookie = new HttpCookie("cookieName");
        httpCookie.HttpOnly = true;
    }
}
```

CA5397: Do not use deprecated SslProtocols values

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5397
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when either of the following conditions are met:

- A deprecated `System.Security.Authentication.SslProtocols` value was referenced.
- An integer value representing a deprecated value was either assigned to a `SslProtocols` variable, used as a `SslProtocols` return value, or used as a `SslProtocols` argument.

Deprecated values are:

- Ssl2
- Ssl3
- Tls
- Tls10
- Tls11

Rule description

Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Older protocol versions of TLS are less secure than TLS 1.2 and TLS 1.3 and are more likely to have new vulnerabilities. Avoid older protocol versions to minimize risk. For guidance on identifying and removing deprecated protocol versions, see [Solving the TLS 1.0 Problem, 2nd Edition](#).

How to fix violations

Don't use deprecated TLS protocol versions.

When to suppress warnings

You can suppress this warning if:

- The reference to the deprecated protocol version isn't being used to enable a deprecated version.
- You need to connect to a legacy service that can't be upgraded to use secure TLS configurations.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5397
// The code that's violating the rule is on this line.
#pragma warning restore CA5397
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5397.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Enumeration name violation

```
using System;
using System.Security.Authentication;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5397 violation for using Tls11
        SslProtocols protocols = SslProtocols.Tls11 | SslProtocols.Tls12;
    }
}
```

```
Imports System
Imports System.Security.Authentication

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5397 violation for using Tls11
        Dim sslProtocols As SslProtocols = SslProtocols.Tls11 Or SslProtocols.Tls12
    End Sub
End Class
```

Integer value violation

```
using System;
using System.Security.Authentication;

public class ExampleClass
{
    public void ExampleMethod()
    {
        // CA5397 violation
        SslProtocols sslProtocols = (SslProtocols) 768;      // TLS 1.1
    }
}
```

```

Imports System
Imports System.Security.Authentication

Public Class TestClass
    Public Sub ExampleMethod()
        ' CA5397 violation
        Dim sslProtocols As SslProtocols = CType(768, SslProtocols)      ' TLS 1.1
    End Sub
End Class

```

Solution

```

using System;
using System.Security.Authentication;

public class TestClass
{
    public void Method()
    {
        // Let the operating system decide what TLS protocol version to use.
        // See https://docs.microsoft.com/dotnet/framework/network-programming/tls
        SslProtocols sslProtocols = SslProtocols.None;
    }
}

```

```

Imports System
Imports System.Security.Authentication

Public Class TestClass
    Public Sub ExampleMethod()
        ' Let the operating system decide what TLS protocol version to use.
        ' See https://docs.microsoft.com/dotnet/framework/network-programming/tls
        Dim sslProtocols As SslProtocols = SslProtocols.None
    End Sub
End Class

```

CA5398: Avoid hardcoded SslProtocols values

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5398
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

This rule fires when either of the following conditions are met:

- A safe but hardcoded `System.Security.Authentication.SslProtocols` value was referenced.
- An integer value representing a safe protocol version was either assigned to a `SslProtocols` variable, used as a `SslProtocols` return value, or used as a `SslProtocols` argument.

Safe values are:

- `Tls12`
- `Tls13`

Rule description

Transport Layer Security (TLS) secures communication between computers, most commonly with Hypertext Transfer Protocol Secure (HTTPS). Protocol versions TLS 1.0 and TLS 1.1 are deprecated, while TLS 1.2 and TLS 1.3 are current. In the future, TLS 1.2 and TLS 1.3 may be deprecated. To ensure that your application remains secure, avoid hardcoding a protocol version. For more information, see [Transport Layer Security \(TLS\) best practices with .NET Framework](#).

How to fix violations

Don't hardcode TLS protocol versions.

When to suppress warnings

It's safe to suppress a warning if you need to connect to a legacy service that can't be upgraded to use future TLS protocol versions.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5398
// The code that's violating the rule is on this line.
#pragma warning restore CA5398
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5398.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

[CA5397: Do not use deprecated SslProtocols values](#)

CA5399: Enable HttpClient certificate revocation list check

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5399
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using `System.Net.Http.HttpClient` while providing a platform specific handler (`System.Net.Http.WinHttpHandler` or `System.Net.Http.HttpClientHandler`) whose `CheckCertificateRevocationList` property is not set to `true` will allow revoked certificates to be accepted by the `HttpClient` as valid.

This rule is similar to [CA5400](#), but analysis can determine that the `CheckCertificateRevocationList` property is definitely `false` or not set.

Rule description

A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.

How to fix violations

Set the `System.Net.Http.HttpClientHandler.CheckCertificateRevocationList` property to `true` explicitly. If the `CheckCertificateRevocationList` property is unavailable, you need to upgrade your target framework.

When to suppress warnings

Do not suppress this rule.

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure these options for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

```
using System.Net.Http;

class ExampleClass
{
    void ExampleMethod()
    {
        WinHttpHandler winHttpHandler = new WinHttpHandler();
        winHttpHandler.CheckCertificateRevocationList = false;
        HttpClient httpClient = new HttpClient(winHttpHandler);
    }
}
```

Solution

```
using System.Net.Http;

class ExampleClass
{
    void ExampleMethod()
    {
        WinHttpHandler winHttpHandler = new WinHttpHandler();
        winHttpHandler.CheckCertificateRevocationList = true;
        HttpClient httpClient = new HttpClient(winHttpHandler);
    }
}
```

CA5400: Ensure HttpClient certificate revocation list check is not disabled

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5400
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using `System.Net.Http.HttpClient` while providing a platform specific handler (`System.Net.Http.WinHttpHandler` or `System.Net.Http.HttpClientHandler`) whose `CheckCertificateRevocationList` property is possibly set to `false` will allow revoked certificates to be accepted by the `HttpClient` as valid.

This rule is similar to [CA5399](#), but analysis can't determine that the `CheckCertificateRevocationList` property is definitely `false` or not set.

Rule description

A revoked certificate isn't trusted anymore. It could be used by attackers passing some malicious data or stealing sensitive data in HTTPS communication.

How to fix violations

Set the `System.Net.Http.HttpClientHandler.CheckCertificateRevocationList` property to `true` explicitly. If the `CheckCertificateRevocationList` property is unavailable, you need to upgrade your target framework.

When to suppress warnings

It's safe to suppress this rule if you're sure that the `CheckCertificateRevocationList` property is set correctly.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5400
// The code that's violating the rule is on this line.
#pragma warning restore CA5400
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5400.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following options to configure which parts of your codebase to run this rule on.

- [Exclude specific symbols](#)
- [Exclude specific types and their derived types](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Security](#)). For more information, see [Code quality rule configuration options](#).

Exclude specific symbols

You can exclude specific symbols, such as types and methods, from analysis. For example, to specify that the rule should not run on any code within types named `MyType`, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Symbol name only (includes all symbols with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#). Each symbol name requires a symbol-kind prefix, such as `M:` for methods, `T:` for types, and `N:` for namespaces.
- `.ctor` for constructors and `.cctor` for static constructors.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType</code>	Matches all symbols named <code>MyType</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = MyType1 MyType2</code>	Matches all symbols named either <code>MyType1</code> or <code>MyType2</code> .
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS.MyType.MyMethod(ParamType)</code>	Matches specific method <code>MyMethod</code> with the specified fully qualified signature.
<code>dotnet_code_quality.CAXXXX.excluded_symbol_names = M:NS1.MyType1.MyMethod1(ParamType) M:NS2.MyType2.MyMethod2(ParamType)</code>	Matches specific methods <code>MyMethod1</code> and <code>MyMethod2</code> with the respective fully qualified signatures.

Exclude specific types and their derived types

You can exclude specific types and their derived types from analysis. For example, to specify that the rule should not run on any methods within types named `MyType` and their derived types, add the following key-value pair

to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType
```

Allowed symbol name formats in the option value (separated by `|`):

- Type name only (includes all types with the name, regardless of the containing type or namespace).
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `T:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType</code>	Matches all types named <code>MyType</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = MyType1 MyType2</code>	Matches all types named either <code>MyType1</code> or <code>MyType2</code> and all of their derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS.MyType</code>	Matches specific type <code>MyType</code> with given fully qualified name and all of its derived types.
<code>dotnet_code_quality.CAXXXX.excluded_type_names_with_derived_types = M:NS1.MyType1 M:NS2.MyType2</code>	Matches specific types <code>MyType1</code> and <code>MyType2</code> with the respective fully qualified names, and all of their derived types.

Pseudo-code examples

```
using System;
using System.Net.Http;

class ExampleClass
{
    void ExampleMethod(bool checkCertificateRevocationList)
    {
        WinHttpHandler winHttpHandler = new WinHttpHandler();
        winHttpHandler.CheckCertificateRevocationList = checkCertificateRevocationList;
        Random r = new Random();

        if (r.Next(6) == 4)
        {
            winHttpHandler.CheckCertificateRevocationList = true;
        }

        HttpClient httpClient = new HttpClient(winHttpHandler);
    }
}
```

Solution

```
using System.Net.Http;

class ExampleClass
{
    void ExampleMethod()
    {
        WinHttpHandler winHttpHandler = new WinHttpHandler();
        winHttpHandler.CheckCertificateRevocationList = true;
        HttpClient httpClient = new HttpClient(winHttpHandler);
    }
}
```

CA5401: Do not use CreateEncryptor with non-default IV

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5401
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Using `System.Security.Cryptography.SymmetricAlgorithm.CreateEncryptor` with non-default `rgbIV`.

Rule description

Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.

This rule is similar to [CA5402](#), but analysis determines that the initialization vector is definitely the default.

How to fix violations

Use the default `rgbIV` value, that is, use the overload of the

`System.Security.Cryptography.SymmetricAlgorithm.CreateEncryptor` which doesn't have any parameter.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The `rgbIV` parameter was generated by `System.Security.Cryptography.SymmetricAlgorithm.GenerateIV`.
- You're sure that the `rgbIV` is really random and non-repeatable.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5401
// The code that's violating the rule is on this line.
#pragma warning restore CA5401
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5401.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] rgbIV)
    {
        AesCng aesCng = new AesCng();
        aesCng.IV = rgbIV;
        aesCng.CreateEncryptor();
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        AesCng aesCng = new AesCng();
        aesCng.CreateEncryptor();
    }
}
```

CA5402: Use CreateEncryptor with the default IV

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5402
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `rgbIV` could be non-default when using `System.Security.Cryptography.SymmetricAlgorithm.CreateEncryptor`.

Rule description

Symmetric encryption should always use a non-repeatable initialization vector to prevent dictionary attacks.

This rule is similar to [CA5401](#), but analysis can't determine that the initialization vector is definitely the default.

How to fix violations

Use the default `rgbIV` value explicitly, that is, use the overload of the `System.Security.Cryptography.SymmetricAlgorithm.CreateEncryptor` which doesn't have any parameter.

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The `rgbIV` parameter was generated by `System.Security.Cryptography.SymmetricAlgorithm.GenerateIV`.
- You're sure that the `rgbIV` parameter is really random and non-repeatable.
- You're sure that the initialization vector is used.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5402
// The code that's violating the rule is on this line.
#pragma warning restore CA5402
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5402.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

```
using System;
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod(byte[] rgbIV)
    {
        AesCng aesCng = new AesCng();
        Random r = new Random();

        if (r.Next(6) == 4)
        {
            aesCng.IV = rgbIV;
        }

        aesCng.CreateEncryptor();
    }
}
```

Solution

```
using System.Security.Cryptography;

class ExampleClass
{
    public void ExampleMethod()
    {
        AesCng aesCng = new AesCng();
        aesCng.CreateEncryptor();
    }
}
```

CA5403: Do not hard-code certificate

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5403
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The `data` or `rawData` parameter of a `X509Certificate` or `X509Certificate2` constructor is hard-coded by one of the following:

- Byte array.
- Char array.
- `System.Convert.FromBase64String(String)`.
- All the overloads of `System.Text.Encoding.GetBytes`.

Rule description

A hard-coded certificate's private key is easily discovered. Even with compiled binaries, it is easy for malicious users to extract a hard-coded certificate's private key. Once the private key is compromised, an attacker can impersonate that certificate, and any resources or operations protected by that certificate will be available to the attacker.

How to fix violations

- Consider redesigning your application to use a secure key management system, such as Azure Key Vault.
- Keep credentials and certificates in a secure location separate from your source code.

When to suppress warnings

It's safe to suppress a warning from this rule if the hard-coded data doesn't contain the certificate's private key. For example, the data is from a `.cer` file. Hard-coding public certificate information may still create a challenge for rotating certificates as they expire or get revoked.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5403
// The code that's violating the rule is on this line.
#pragma warning restore CA5403
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5403.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Hard-coded by byte array

```
using System.IO;
using System.Security.Cryptography.X509Certificates;

class ExampleClass
{
    public void ExampleMethod(string path)
    {
        byte[] bytes = new byte[] {1, 2, 3};
        File.WriteAllBytes(path, bytes);
        new X509Certificate2(path);
    }
}
```

Hard-coded by char array

```
using System.IO;
using System.Security.Cryptography.X509Certificates;
using System.Text;

class ExampleClass
{
    public void ExampleMethod(byte[] bytes, string path)
    {
        char[] chars = new char[] { '1', '2', '3' };
        Encoding.ASCII.GetBytes(chars, 0, 3, bytes, 0);
        File.WriteAllBytes(path, bytes);
        new X509Certificate2(path);
    }
}
```

Hard-coded by FromBase64String

```
using System;
using System.IO;
using System.Security.Cryptography.X509Certificates;

class ExampleClass
{
    public void ExampleMethod(string path)
    {
        byte[] bytes = Convert.FromBase64String("AAAAAAazaoensuth");
        File.WriteAllBytes(path, bytes);
        new X509Certificate2(path);
    }
}
```

Hard-coded by GetBytes

```
using System;
using System.IO;
using System.Security.Cryptography.X509Certificates;
using System.Text;

class ExampleClass
{
    public void ExampleMethod(string path)
    {
        byte[] bytes = Encoding.ASCII.GetBytes("AAAAAAazaoensuth");
        File.WriteAllBytes(path, bytes);
        new X509Certificate2(path);
    }
}
```

Solution

```
using System.IO;
using System.Security.Cryptography.X509Certificates;

class ExampleClass
{
    public void ExampleMethod(string path)
    {
        new X509Certificate2("Certificate.cer");
    }
}
```

CA5404: Do not disable token validation checks

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA5404
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

Setting `TokenValidationParameters` properties `RequireExpirationTime`, `ValidateAudience`, `ValidateIssuer`, or `ValidateLifetime` to `false`.

Rule description

Token validation checks ensure that while validating tokens, all aspects are analyzed and verified. Turning off validation can lead to security holes by allowing untrusted tokens to make it through validation.

More details about best practices for token validation can be found on the [library's wiki](#).

How to fix violations

Set `TokenValidationParameters` properties `RequireExpirationTime`, `ValidateAudience`, `ValidateIssuer`, or `ValidateLifetime` to `true`. Or, remove the assignment to `false` because the default value is `true`.

When to suppress warnings

In the vast majority of cases, this validation is essential to ensure the security of the consuming app. However, there are some cases where this validation is not needed, especially in non-standard token types. Before you disable this validation, be sure you have fully thought through the security implications. For information about the trade-offs, see the [token validation library's wiki](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5404
// The code that's violating the rule is on this line.
#pragma warning restore CA5404
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5404.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

```
using System;
using Microsoft.IdentityModel.Tokens;

class TestClass
{
    public void TestMethod()
    {
        TokenValidationParameters parameters = new TokenValidationParameters();
        parameters.RequireExpirationTime = false;
        parameters.ValidateAudience = false;
        parameters.ValidateIssuer = false;
        parameters.ValidateLifetime = false;
    }
}
```

Solution

```
using System;
using Microsoft.IdentityModel.Tokens;

class TestClass
{
    public void TestMethod()
    {
        TokenValidationParameters parameters = new TokenValidationParameters();
        parameters.RequireExpirationTime = true;
        parameters.ValidateAudience = true;
        parameters.ValidateIssuer = true;
        parameters.ValidateLifetime = true;
    }
}
```

CA5405: Do not always skip token validation in delegates

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA5405
Category	Security
Fix is breaking or non-breaking	Non-breaking

Cause

The callback assigned to [AudienceValidator](#) or [LifetimeValidator](#) always returns `true`.

Rule description

By setting critical `TokenValidationParameter` validation delegates to always return `true`, important authentication safeguards are disabled. Disabling safeguards can lead to incorrect validation of tokens from any issuer or expired tokens.

For more information about best practices for token validation, see the [library's wiki](#).

How to fix violations

- Improve the logic of the delegate so not all code paths return `true`, which effectively disables that type of validation.
- Throw `SecurityTokenInvalidAudienceException` or `SecurityTokenInvalidLifetimeException` in failure cases when you want to fail validation and have other cases pass by returning `true`.

When to suppress warnings

In some specific cases where you're utilizing the delegate for additional logging and it's for token types where the specific type of validation is not needed, it may make sense to suppress this warning. Before you disable this validation, be sure you have fully thought through the security implications. For information about the trade-offs, see the [token validation library's wiki](#).

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA5405
// The code that's violating the rule is on this line.
#pragma warning restore CA5405
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA5405.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Security.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pseudo-code examples

Violation

```
using System;
using Microsoft.IdentityModel.Tokens;

class TestClass
{
    public void TestMethod()
    {
        TokenValidationParameters parameters = new TokenValidationParameters();
        parameters.AudienceValidator = (audiences, token, tvp) => { return true; };
    }
}
```

Solution

```
using System;
using Microsoft.IdentityModel.Tokens;

class TestClass
{
    public void TestMethod()
    {
        TokenValidationParameters parameters = new TokenValidationParameters();
        parameters.AudienceValidator = (audiences, token, tvp) =>
        {
            // Implement your own custom audience validation
            if (PerformCustomAudienceValidation(audiences, token))
                return true;
            else
                return false;
        };
    }
}
```

Usage rules

9/20/2022 • 6 minutes to read • [Edit Online](#)

Usage rules support proper usage of .NET.

In this section

RULE	DESCRIPTION
CA1801: Review unused parameters	A method signature includes a parameter that is not used in the method body.
CA1816: Call GC.SuppressFinalize correctly	A method that is an implementation of Dispose does not call <code>GC.SuppressFinalize</code> ; or a method that is not an implementation of <code>Dispose</code> calls <code>GC.SuppressFinalize</code> ; or a method calls <code>GC.SuppressFinalize</code> and passes something other than <code>this</code> (<code>Me</code> in Visual Basic).
CA2200: Rethrow to preserve stack details	An exception is rethrown and the exception is explicitly specified in the throw statement. If an exception is rethrown by specifying the exception in the throw statement, the list of method calls between the original method that threw the exception and the current method is lost.
CA2201: Do not raise reserved exception types	This makes the original error hard to detect and debug.
CA2207: Initialize value type static fields inline	A value type declares an explicit static constructor. To fix a violation of this rule, initialize all static data when it is declared and remove the static constructor.
CA2208: Instantiate argument exceptions correctly	A call is made to the default (parameterless) constructor of an exception type that is or derives from <code>ArgumentException</code> , or an incorrect string argument is passed to a parameterized constructor of an exception type that is or derives from <code>ArgumentException</code> .
CA2211: Non-constant fields should not be visible	Static fields that are not constants or read-only are not thread-safe. Access to such a field must be carefully controlled and requires advanced programming techniques for synchronizing access to the class object.
CA2213: Disposable fields should be disposed	A type that implements <code>System.IDisposable</code> declares fields that are of types that also implement <code>IDisposable</code> . The <code>Dispose</code> method of the field is not called by the <code>Dispose</code> method of the declaring type.
CA2214: Do not call overridable methods in constructors	When a constructor calls a virtual method, it is possible that the constructor for the instance that invokes the method has not executed.
CA2215: Dispose methods should call base class dispose	If a type inherits from a disposable type, it must call the <code>Dispose</code> method of the base type from its own <code>Dispose</code> method.

RULE	DESCRIPTION
CA2216: Disposable types should declare finalizer	A type that implements System.IDisposable , and has fields that suggest the use of unmanaged resources, does not implement a finalizer as described by <code>Object.Finalize</code> .
CA2217: Do not mark enums with FlagsAttribute	An externally visible enumeration is marked with <code>FlagsAttribute</code> , and it has one or more values that are not powers of two or a combination of the other defined values on the enumeration.
CA2218: Override GetHashCode on overriding Equals	A public type overrides System.Object.Equals but does not override System.Object.GetHashCode .
CA2219: Do not raise exceptions in exception clauses	When an exception is raised in a finally or fault clause, the new exception hides the active exception. When an exception is raised in a filter clause, the run time silently catches the exception. This makes the original error hard to detect and debug.
CA2224: Override equals on overloading operator equals	A public type implements the equality operator but doesn't override System.Object.Equals .
CA2225: Operator overloads have named alternates	An operator overload was detected, and the expected named alternative method was not found. The named alternative member provides access to the same functionality as the operator, and is provided for developers who program in languages that do not support overloaded operators.
CA2226: Operators should have symmetrical overloads	A type implements the equality or inequality operator, and does not implement the opposite operator.
CA2227: Collection properties should be read only	A writable collection property allows a user to replace the collection with a different collection. A read-only property stops the collection from being replaced but still allows the individual members to be set.
CA2229: Implement serialization constructors	To fix a violation of this rule, implement the serialization constructor. For a sealed class, make the constructor private; otherwise, make it protected.
CA2231: Overload operator equals on overriding ValueType.Equals	A value type overrides <code>Object.Equals</code> but does not implement the equality operator.
CA2234: Pass System.Uri objects instead of strings	A call is made to a method that has a string parameter whose name contains "uri", "URI", "urn", "URN", "url", or "URL". The declaring type of the method contains a corresponding method overload that has a System.Uri parameter.
CA2235: Mark all non-serializable fields	An instance field of a type that is not serializable is declared in a type that is serializable.

RULE	DESCRIPTION
CA2237: Mark ISerializable types with SerializableAttribute	To be recognized by the common language runtime as serializable, types must be marked with the <code>SerializableAttribute</code> attribute even if the type uses a custom serialization routine through implementation of the <code>ISerializable</code> interface.
CA2241: Provide correct arguments to formatting methods	The format argument passed to <code>String.Format</code> does not contain a format item that corresponds to each object argument, or vice versa.
CA2242: Test for NaN correctly	This expression tests a value against <code>Single.Nan</code> or <code>Double.Nan</code> . Use <code>Single.IsNaN(Single)</code> or <code>Double.IsNaN(Double)</code> to test the value.
CA2243: Attribute string literals should parse correctly	An attribute's string literal parameter does not parse correctly for a URL, a GUID, or a version.
CA2244: Do not duplicate indexed element initializations	An object initializer has more than one indexed element initializer with the same constant index. All but the last initializer are redundant.
CA2245: Do not assign a property to itself	A property was accidentally assigned to itself.
CA2246: Do not assign a symbol and its member in the same statement	Assigning a symbol and its member, that is, a field or a property, in the same statement is not recommended. It is not clear if the member access was intended to use the symbol's old value prior to the assignment or the new value from the assignment in this statement.
CA2247: Argument passed to TaskCompletionSource constructor should be TaskCreationOptions enum instead of TaskContinuationOptions enum	TaskCompletionSource has constructors that take <code>TaskCreationOptions</code> that control the underlying <code>Task</code> , and constructors that take object state that's stored in the task. Accidentally passing a <code>TaskContinuationOptions</code> instead of a <code>TaskCreationOptions</code> will result in the call treating the options as state.
CA2248: Provide correct 'enum' argument to 'Enum.HasFlag'	The enum type passed as an argument to the <code>HasFlag</code> method call is different from the calling enum type.
CA2249: Consider using String.Contains instead of String.IndexOf	Calls to <code>string.IndexOf</code> where the result is used to check for the presence or absence of a substring can be replaced by <code>string.Contains</code> .
CA2250: Use <code>ThrowIfCancellationRequested</code>	<code>ThrowIfCancellationRequested</code> automatically checks whether the token has been canceled, and throws an <code>OperationCanceledException</code> if it has.
CA2251: Use <code>string.Equals</code> over <code>string.Compare</code>	It is both clearer and likely faster to use <code>String.Equals</code> instead of comparing the result of <code>String.Compare</code> to zero.
CA2252: Opt in to preview features	Opt in to preview features before using preview APIs.
CA2253: Named placeholders should not be numeric values	Named placeholders in the logging message template should not be comprised of only numeric characters.

RULE	DESCRIPTION
CA2254: Template should be a static expression	The logging message template should not vary between calls.
CA2255: The <code>ModuleInitializer</code> attribute should not be used in libraries	Module initializers are intended to be used by application code to ensure an application's components are initialized before the application code begins executing.
CA2256: All members declared in parent interfaces must have an implementation in a <code>DynamicInterfaceCastableImplementation-attributed</code> interface	Types attributed with <code>DynamicInterfaceCastableImplementationAttribute</code> act as an interface implementation for a type that implements the <code>IDynamicInterfaceCastable</code> type. As a result, it must provide an implementation of all of the members defined in the inherited interfaces, because the type that implements <code>IDynamicInterfaceCastable</code> will not provide them otherwise.
CA2257: Members defined on an interface with 'DynamicInterfaceCastableImplementationAttribute' should be 'static'	Since a type that implements <code>IDynamicInterfaceCastable</code> may not implement a dynamic interface in metadata, calls to an instance interface member that is not an explicit implementation defined on this type are likely to fail at run time. Mark new interface members <code>static</code> to avoid run-time errors.
CA2258: Providing a 'DynamicInterfaceCastableImplementation' interface in Visual Basic is unsupported	Providing a functional <code>DynamicInterfaceCastableImplementationAttribute</code> -attributed interface requires the Default Interface Members feature, which is unsupported in Visual Basic.

CA1801: Review unused parameters

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA1801
Category	Usage
Fix is breaking or non-breaking	<p>Non-breaking - If the member is not visible outside the assembly, regardless of the change you make.</p> <p>Non-breaking - If you change the member to use the parameter within its body.</p> <p>Breaking - If you remove the parameter and it is visible outside the assembly.</p>

Cause

A method signature includes a parameter that's not used in the method body.

This rule does not examine the following kinds of methods:

- Methods referenced by a delegate.
- Methods used as event handlers.
- Serialization constructors (see [guidelines](#)).
- Serialization [GetObjectData](#) methods.
- Methods declared with the `abstract` (`MustOverride` in Visual Basic) modifier.
- Methods declared with the `virtual` (`Overridable` in Visual Basic) modifier.
- Methods declared with the `override` (`Overrides` in Visual Basic) modifier.
- Methods declared with the `extern` (`Declare` statement in Visual Basic) modifier.

This rule does not flag parameters that are named with the [discard](#) symbol, for example, `_`, `_1`, and `_2`. This reduces warning noise on parameters that are needed for signature requirements, for example, a method used as a delegate, a parameter with special attributes, or a parameter whose value is implicitly accessed at run time by a framework but is not referenced in code.

NOTE

This rule has been deprecated in favor of [IDE0060](#). For information about how to enforce the IDE0060 analyzer at build, see [code-style analysis](#).

Rule description

Review parameters in non-virtual methods that are not used in the method body to make sure no incorrectness

exists around failure to access them. Unused parameters incur maintenance and performance costs.

Sometimes, a violation of this rule can point to an implementation bug in the method. For example, the parameter should have been used in the method body. Suppress warnings of this rule if the parameter must exist because of backward compatibility.

How to fix violations

To fix a violation of this rule, remove the unused parameter (a breaking change), or use the parameter in the method body (a non-breaking change).

When to suppress warnings

It is safe to suppress a warning from this rule:

- In previously shipped code for which the fix would be a breaking change.
- For the `this` parameter in a custom extension method for `Microsoft.VisualStudio.TestTools.UnitTesting.Assert`. The functions in the `Assert` class are static, so there's no need to access the `this` parameter in the method body.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1801
// The code that's violating the rule is on this line.
#pragma warning restore CA1801
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1801.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category (Performance). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

By default, the CA1801 rule applies to all API surfaces (public, internal, and private).

Example

The following example shows two methods. One method violates the rule and the other method satisfies the rule.

```
// This method violates the rule.
public static string GetSomething(int first, int second)
{
    return first.ToString(CultureInfo.InvariantCulture);
}

// This method satisfies the rule.
public static string GetSomethingElse(int first)
{
    return first.ToString(CultureInfo.InvariantCulture);
}
```

Related rules

- [CA1812: Avoid uninstantiated internal classes](#)
- [CA2229: Implement serialization constructors](#)

CA1816: Call GC.SuppressFinalize correctly

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA1816
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

Violations of this rule can be caused by:

- In an unsealed class, a method that's an implementation of [IDisposable.Dispose](#) and doesn't call [GC.SuppressFinalize](#).
- A method that's not an implementation of [IDisposable.Dispose](#) and calls [GC.SuppressFinalize](#).
- A method that calls [GC.SuppressFinalize](#) and passes something other than `this` (C#) or `Me` (Visual Basic).

Rule description

The [IDisposable.Dispose](#) method lets users release resources at any time before the object becomes available for garbage collection. If the [IDisposable.Dispose](#) method is called, it frees resources of the object. This makes finalization unnecessary. [IDisposable.Dispose](#) should call [GC.SuppressFinalize](#) so the garbage collector doesn't call the finalizer of the object.

To prevent derived types with finalizers from having to reimplement [IDisposable](#) and to call it, unsealed types without finalizers should still call [GC.SuppressFinalize](#).

How to fix violations

To fix a violation of this rule:

- If the method is an implementation of [Dispose](#), add a call to [GC.SuppressFinalize](#).
- If the method is not an implementation of [Dispose](#), either remove the call to [GC.SuppressFinalize](#) or move it to the type's [Dispose](#) implementation.
- Change all calls to [GC.SuppressFinalize](#) to pass `this` (C#) or `Me` (Visual Basic).
- If the type is not meant to be overridden, mark it as `sealed`.

When to suppress warnings

Only suppress a warning from this rule if you're deliberately using [GC.SuppressFinalize](#) to control the lifetime of other objects. Don't suppress a warning from this rule if an implementation of [Dispose](#) doesn't call [GC.SuppressFinalize](#). In this situation, failing to suppress finalization degrades performance and provides no benefits.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA1816
// The code that's violating the rule is on this line.
#pragma warning restore CA1816
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA1816.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example that violates CA1816

This code shows a method that calls `GC.SuppressFinalize`, but doesn't pass [this \(C#\)](#) or [Me \(Visual Basic\)](#). As a result, this code violates rule CA1816.

```
Public Class DatabaseConnector
    Implements IDisposable

    Private _Connection As New SqlConnection

    Public Sub Dispose() Implements IDisposable.Dispose
        Dispose(True)
        ' Violates rules
        GC.SuppressFinalize(True)
    End Sub

    Protected Overridable Sub Dispose(ByVal disposing As Boolean)
        If disposing Then
            If _Connection IsNot Nothing Then
                _Connection.Dispose()
                _Connection = Nothing
            End If
        End If
    End Sub

End Class
```

```

public class DatabaseConnector : IDisposable
{
    private SqlConnection _Connection = new SqlConnection();

    public void Dispose()
    {
        Dispose(true);
        GC.SuppressFinalize(true); // Violates rule
    }

    protected virtual void Dispose(bool disposing)
    {
        if (disposing)
        {
            if (_Connection != null)
            {
                _Connection.Dispose();
                _Connection = null;
            }
        }
    }
}

```

Example that satisfies CA1816

This example shows a method that correctly calls [GC.SuppressFinalize](#) by passing [this \(C#\)](#) or [Me \(Visual Basic\)](#).

```

Public Class DatabaseConnector
    Implements IDisposable

    Private _Connection As New SqlConnection

    Public Sub Dispose() Implements IDisposable.Dispose
        Dispose(True)
        GC.SuppressFinalize(Me)
    End Sub

    Protected Overridable Sub Dispose(ByVal disposing As Boolean)
        If disposing Then
            If _Connection IsNot Nothing Then
                _Connection.Dispose()
                _Connection = Nothing
            End If
        End If
    End Sub

End Class

```

```
public class DatabaseConnector : IDisposable
{
    private SqlConnection _Connection = new SqlConnection();

    public void Dispose()
    {
        Dispose(true);
        GC.SuppressFinalize(this);
    }

    protected virtual void Dispose(bool disposing)
    {
        if (disposing)
        {
            if (_Connection != null)
            {
                _Connection.Dispose();
                _Connection = null;
            }
        }
    }
}
```

CA2200: Rethrow to preserve stack details

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2200
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An exception is rethrown and the exception is explicitly specified in the `throw` statement.

Rule description

Once an exception is thrown, part of the information it carries is the stack trace. The stack trace is a list of the method call hierarchy that starts with the method that throws the exception and ends with the method that catches the exception. If an exception is re-thrown by specifying the exception in the `throw` statement, the stack trace is restarted at the current method and the list of method calls between the original method that threw the exception and the current method is lost. To keep the original stack trace information with the exception, use the `throw` statement without specifying the exception.

How to fix violations

To fix a violation of this rule, rethrow the exception without specifying the exception explicitly.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows a method, `CatchAndRethrowExplicitly`, which violates the rule and a method, `CatchAndRethrowImplicitly`, which satisfies the rule.

```
class TestsRethrow
{
    static void Main2200()
    {
        TestsRethrow testRethrow = new TestsRethrow();
        testRethrow.CatchException();
    }

    void CatchException()
    {
        try
        {
            CatchAndRethrowExplicitly();
        }
        catch (ArithmeticeException e)
        {
            Console.WriteLine("Explicitly specified:{0}{1}",
                Environment.NewLine, e.StackTrace);
        }

        try
        {
            CatchAndRethrowImplicitly();
        }
        catch (ArithmeticeException e)
        {
            Console.WriteLine("{0}Implicitly specified:{0}{1}",
                Environment.NewLine, e.StackTrace);
        }
    }

    void CatchAndRethrowExplicitly()
    {
        try
        {
            ThrowException();
        }
        catch (ArithmeticeException e)
        {
            // Violates the rule.
            throw e;
        }
    }

    void CatchAndRethrowImplicitly()
    {
        try
        {
            ThrowException();
        }
        catch (ArithmeticeException)
        {
            // Satisfies the rule.
            throw;
        }
    }

    void ThrowException()
    {
        throw new ArithmeticeException("illegal expression");
    }
}
```

```

Imports System

Namespace ca2200

    Class TestsRethrow

        Shared Sub Main2200()
            Dim testRethrow As New TestsRethrow()
            testRethrow.CatchException()
        End Sub

        Sub CatchException()

            Try
                CatchAndRethrowExplicitly()
            Catch e As ArithmeticException
                Console.WriteLine("Explicitly specified:{0}{1}",
                    Environment.NewLine, e.StackTrace)
            End Try

            Try
                CatchAndRethrowImplicitly()
            Catch e As ArithmeticException
                Console.WriteLine("{0}Implicitly specified:{0}{1}",
                    Environment.NewLine, e.StackTrace)
            End Try

        End Sub

        Sub CatchAndRethrowExplicitly()

            Try
                ThrowException()
            Catch e As ArithmeticException

                ' Violates the rule.
                Throw e
            End Try

        End Sub

        Sub CatchAndRethrowImplicitly()

            Try
                ThrowException()
            Catch e As ArithmeticException

                ' Satisfies the rule.
                Throw
            End Try

        End Sub

        Sub ThrowException()
            Throw New ArithmeticException("illegal expression")
        End Sub

    End Class

End Namespace

```

CA2201: Do not raise reserved exception types

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2201
Category	Usage
Fix is breaking or non-breaking	Breaking

Cause

A method raises an exception type that is too general or that is reserved by the runtime.

Rule description

The following exception types are too general to provide sufficient information to the user:

- [System.Exception](#)
- [System.ApplicationException](#)
- [System.SystemException](#)

The following exception types are reserved and should be thrown only by the common language runtime:

- [System.AccessViolationException](#)
- [System.ExecutionEngineException](#)
- [System.IndexOutOfRangeException](#)
- [System.NullReferenceException](#)
- [System.OutOfMemoryException](#)
- [System.Runtime.InteropServices.COMException](#)
- [System.Runtime.InteropServices.ExternalException](#)
- [System.Runtime.InteropServices.SEHException](#)
- [System.StackOverflowException](#)

Do Not Throw General Exceptions

If you throw a general exception type, such as [Exception](#) or [SystemException](#) in a library or framework, it forces consumers to catch all exceptions, including unknown exceptions that they do not know how to handle.

Instead, either throw a more derived type that already exists in the framework, or create your own type that derives from [Exception](#).

Throw Specific Exceptions

The following table shows parameters and which exceptions to throw when you validate the parameter,

including the value parameter in the set accessor of a property:

PARAMETER DESCRIPTION	EXCEPTION
null reference	System.ArgumentNullException
Outside the allowed range of values (such as an index for a collection or list)	System.ArgumentOutOfRangeException
Invalid enum value	System.ComponentModel.InvalidEnumArgumentException
Contains a format that does not meet the parameter specifications of a method (such as the format string for <code>ToString(String)</code>)	System.FormatException
Otherwise invalid	System.ArgumentException

When an operation is invalid for the current state of an object throw [System.InvalidOperationException](#)

When an operation is performed on an object that has been disposed throw [System.ObjectDisposedException](#)

When an operation is not supported (such as in an overridden `Stream.Write` in a Stream opened for reading) throw [System.NotSupportedException](#)

When a conversion would result in an overflow (such as in an explicit cast operator overload) throw [System.OverflowException](#)

For all other situations, consider creating your own type that derives from [Exception](#) and throw that.

How to fix violations

To fix a violation of this rule, change the type of the thrown exception to a specific type that is not one of the reserved types.

When to suppress warnings

Do not suppress a warning from this rule.

Related rules

- [CA1031: Do not catch general exception types](#)

CA2207: Initialize value type static fields inline

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2207
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A value-type declares an explicit static constructor.

Rule description

When a value-type is declared, it undergoes a default initialization where all value-type fields are set to zero and all reference-type fields are set to `null` (`Nothing` in Visual Basic). An explicit static constructor is only guaranteed to run before an instance constructor or static member of the type is called. Therefore, if the type is created without calling an instance constructor, the static constructor is not guaranteed to run.

If all static data is initialized inline and no explicit static constructor is declared, the C# and Visual Basic compilers add the `beforefieldinit` flag to the MSIL class definition. The compilers also add a private static constructor that contains the static initialization code. This private static constructor is guaranteed to run before any static fields of the type are accessed.

How to fix violations

To fix a violation of this rule initialize all static data when it is declared and remove the static constructor.

When to suppress warnings

Do not suppress a warning from this rule.

Related rules

[CA1810: Initialize reference type static fields inline](#)

CA2208: Instantiate argument exceptions correctly

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2208
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

When a method has a parameter, and it throws an exception type that is, or derives from, [ArgumentException](#), it is expected to call a constructor accepting a `paramName` parameter correctly. Possible causes include the following situations:

- A call is made to the default (parameterless) constructor of an exception type that is, or derives from, [ArgumentException](#) that has a constructor accepting a `paramName` parameter.
- An incorrect string argument is passed to a parameterized constructor of an exception type that is, or derives from, [ArgumentException](#).
- One of the parameters' names is passed for the `message` argument of the constructor of exception type that is, or derives from, [ArgumentException](#).

Rule description

Instead of calling the default constructor, call one of the constructor overloads that allows a more meaningful exception message to be provided. The exception message should target the developer and clearly explain the error condition and how to correct or avoid the exception.

The signatures of the one and two string constructors of [ArgumentException](#) and its derived types are not consistent with respect to the position `message` and `paramName` parameters. Make sure these constructors are called with the correct string arguments. The signatures are as follows:

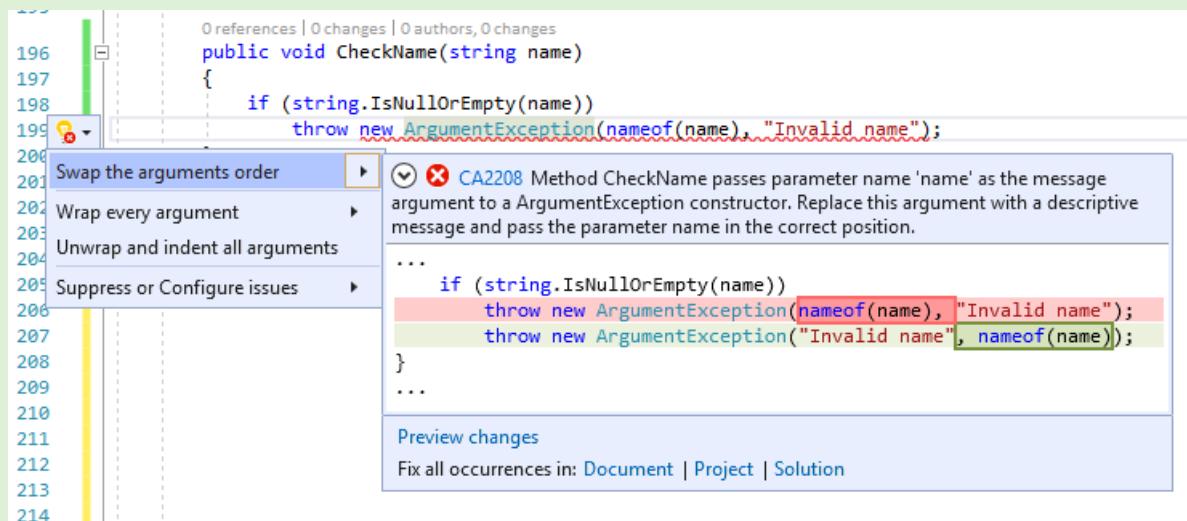

- `ArgumentException(string message)`
- `ArgumentException(string message, string paramName)`
- `ArgumentNullException(string paramName)`
- `ArgumentNullException(string paramName, string message)`
- `ArgumentOutOfRangeException(string paramName)`
- `ArgumentOutOfRangeException(string paramName, string message)`
- `DuplicateWaitObjectException(string parameterName)`
- `DuplicateWaitObjectException(string parameterName, string message)`

How to fix violations

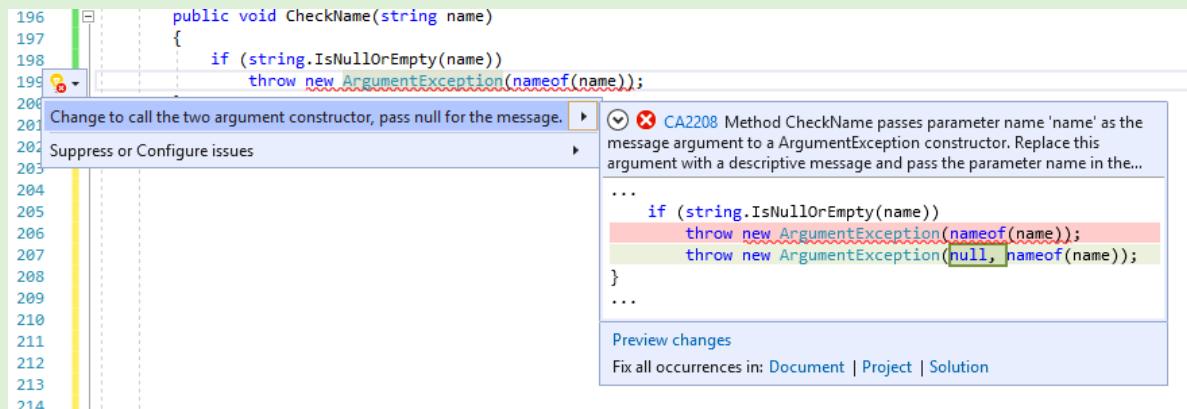

To fix a violation of this rule, call a constructor that takes a message, a parameter name, or both, and make sure the arguments are proper for the type of [ArgumentException](#) being called.

TIP

A code fix is available in Visual Studio for incorrectly positioned parameter names. To use it, position the cursor on the warning row and press **Ctrl+.** (period). Choose **Swap the arguments order** from the list of options that's presented.

If a parameter name instead of a message is passed to the `ArgumentException(String)` method, the fixer provides the option to switch to the two-argument constructor instead.

When to suppress warnings

It's safe to suppress a warning from this rule only if a parameterized constructor is called with the correct string arguments.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2208
// The code that's violating the rule is on this line.
#pragma warning restore CA2208
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2208.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category (Design). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

By default, the CA2208 rule applies to all API surfaces (public, internal, and private).

Example

The following code shows a constructor that incorrectly instantiates an instance of `ArgumentNullException`.

```
public class Book
{
    public Book(string title)
    {
        Title = title ??
            throw new ArgumentNullException("All books must have a title.", nameof(title));
    }

    public string Title { get; }
}
```

```

Public Class Book

    Private ReadOnly _Title As String

    Public Sub New(ByVal title As String)
        ' Violates this rule (constructor arguments are switched)
        If (title Is Nothing) Then
            Throw New ArgumentNullException("title cannot be a null reference (Nothing in Visual Basic)",
"title")
        End If
        _Title = title
    End Sub

    Public ReadOnly Property Title()
        Get
            Return _Title
        End Get
    End Property

End Class

```

The following code fixes the previous violation by switching the constructor arguments.

```

public class Book
{
    public Book(string title)
    {
        Title = title ??
            throw new ArgumentNullException(nameof(title), "All books must have a title.");
    }

    public string Title { get; }
}

```

```

Public Class Book

    Private ReadOnly _Title As String

    Public Sub New(ByVal title As String)
        If (title Is Nothing) Then
            Throw New ArgumentNullException("title", "title cannot be a null reference (Nothing in Visual
Basic)")
        End If

        _Title = title
    End Sub

    Public ReadOnly Property Title()
        Get
            Return _Title
        End Get
    End Property

End Class

```

Related rules

CA2211: Non-constant fields should not be visible

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2211
Category	Usage
Fix is breaking or non-breaking	Breaking

Cause

A public or protected static field is not constant nor is it read-only.

Rule description

Static fields that are neither constants nor read-only are not thread-safe. Access to such a field must be carefully controlled and requires advanced programming techniques for synchronizing access to the class object. Because these are difficult skills to learn, and testing such an object poses its own challenges, static fields are best used to store data that does not change. This rule applies to libraries; applications should not expose any fields.

How to fix violations

To fix a violation of this rule, make the static field constant or read-only. If this is not possible, redesign the type to use an alternative mechanism such as a thread-safe property that manages thread-safe access to the underlying field. Realize that issues such as lock contention and deadlocks might affect the performance and behavior of the library.

When to suppress warnings

It is safe to suppress a warning from this rule if you are developing an application and therefore have full control over access to the type that contains the static field. Library designers should not suppress a warning from this rule; using non-constant static fields can make using the library difficult for developers to use correctly.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2211
// The code that's violating the rule is on this line.
#pragma warning restore CA2211
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2211.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type that violates this rule.

```
Imports System

Namespace ca2211

    Public Class SomeStaticFields
        ' Violates rule: AvoidNonConstantStatic;
        ' the field is public and not a literal.
        Public Shared publicField As DateTime = DateTime.Now

        ' Satisfies rule: AvoidNonConstantStatic.
        Public Shared ReadOnly literalField As DateTime = DateTime.Now

        ' Satisfies rule: NonConstantFieldsShouldNotBeVisible;
        ' the field is private.
        Private Shared privateField As DateTime = DateTime.Now
    End Class
End Namespace
```

```
public class SomeStaticFields
{
    // Violates rule: AvoidNonConstantStatic;
    // the field is public and not a literal.
    static public DateTime publicField = DateTime.Now;

    // Satisfies rule: AvoidNonConstantStatic.
    public static readonly DateTime literalField = DateTime.Now;

    // Satisfies rule: NonConstantFieldsShouldNotBeVisible;
    // the field is private.
    static DateTime privateField = DateTime.Now;
}
```

CA2213: Disposable fields should be disposed

9/20/2022 • 3 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2213
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A type that implements [System.IDisposable](#) declares fields that are of types that also implement [IDisposable](#). The [Dispose](#) method of the field is not called by the [Dispose](#) method of the declaring type.

Rule description

A type is responsible for disposing of all its unmanaged resources. Rule CA2213 checks to see whether a disposable type (that is, one that implements [IDisposable](#)) `T` declares a field `F` that is an instance of a disposable type `FT`. For each field `F` that's assigned a locally created object within the methods or initializers of the containing type `T`, the rule attempts to locate a call to `FT.Dispose`. The rule searches the methods called by `T.Dispose` and one level lower (that is, the methods called by the methods called by `T.Dispose`).

Note

Other than the [special cases](#), rule CA2213 fires only for fields that are assigned a locally created disposable object within the containing type's methods and initializers. If the object is created or assigned outside of type `T`, the rule does not fire. This reduces noise for cases where the containing type doesn't own the responsibility for disposing of the object.

Special cases

Rule CA2213 can also fire for fields of the following types even if the object they're assigned isn't created locally:

- [System.IO.Stream](#)
- [System.IO.TextReader](#)
- [System.IO.TextWriter](#)
- [System.Resources.IResourceReader](#)

Passing an object of one of these types to a constructor and then assigning it to a field indicates a *dispose ownership transfer* to the newly constructed type. That is, the newly constructed type is now responsible for disposing of the object. If the object is not disposed, a violation of CA2213 occurs.

How to fix violations

To fix a violation of this rule, call [Dispose](#) on fields that are of types that implement [IDisposable](#).

When to suppress warnings

It's safe to suppress a warning from this rule if:

- The flagged type is not responsible for releasing the resource held by the field (that is, the type does not have *dispose ownership*)
- The call to [Dispose](#) occurs at a deeper calling level than the rule checks
- the dispose ownership of the field(s) is not held by the containing type.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2213
// The code that's violating the rule is on this line.
#pragma warning restore CA2213
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2213.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

EXAMPLE

The following snippet shows a type `TypeA` that implements [IDisposable](#).

```
public class TypeA : IDisposable
{
    protected virtual void Dispose(bool disposing)
    {
        if (disposing)
        {
            // Dispose managed resources
        }

        // Free native resources
    }

    public void Dispose()
    {
        Dispose(true);
        GC.SuppressFinalize(this);
    }

    // Disposable types implement a finalizer.
    ~TypeA()
    {
        Dispose(false);
    }
}
```

The following snippet shows a type `TypeB` that violates rule CA2213 by declaring a field `aFieldOfADisposableType` as a disposable type (`TypeA`) and not calling `Dispose` on the field.

```
public class TypeB : IDisposable
{
    // Assume this type has some unmanaged resources.
    TypeA aFieldOfADisposableType = new TypeA();
    private bool disposed = false;

    protected virtual void Dispose(bool disposing)
    {
        if (!disposed)
        {
            // Dispose of resources held by this instance.

            // Violates rule: DisposableFieldsShouldBeDisposed.
            // Should call aFieldOfADisposableType.Dispose();

            disposed = true;
            // Suppress finalization of this disposed instance.
            if (disposing)
            {
                GC.SuppressFinalize(this);
            }
        }
    }

    public void Dispose()
    {
        if (!disposed)
        {
            // Dispose of resources held by this instance.
            Dispose(true);
        }
    }

    // Disposable types implement a finalizer.
    ~TypeB()
    {
        Dispose(false);
    }
}
```

To fix the violation, call `Dispose()` on the disposable field:

```
protected virtual void Dispose(bool disposing)
{
    if (!disposed)
    {
        // Dispose of resources held by this instance.
        aFieldOfADisposableType.Dispose();

        disposed = true;

        // Suppress finalization of this disposed instance.
        if (disposing)
        {
            GC.SuppressFinalize(this);
        }
    }
}
```

CA2214: Do not call overridable methods in constructors

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2214
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

The constructor of an unsealed type calls a virtual method defined in its class.

Rule description

When a virtual method is called, the actual type that executes the method is not selected until run time. When a constructor calls a virtual method, it's possible that the constructor for the instance that invokes the method has not executed. This could lead to errors or unexpected behavior, if an overridden virtual method relies on initialization and other configuration in the constructor.

How to fix violations

To fix a violation of this rule, do not call a type's virtual methods from within the type's constructors.

When to suppress warnings

Do not suppress a warning from this rule. The constructor should be redesigned to eliminate the call to the virtual method.

Example

The following example demonstrates the effect of violating this rule. The test application creates an instance of `DerivedType`, which causes its base class (`BadlyConstructedType`) constructor to execute. `BadlyConstructedType`'s constructor incorrectly calls the virtual method `DoSomething`. As the output shows, `DerivedType.DoSomething()` executes before `DerivedType`'s constructor executes.

```
public class BadlyConstructedType
{
    protected string initialized = "No";

    public BadlyConstructedType()
    {
        Console.WriteLine("Calling base ctor.");
        // Violates rule: DoNotCallOverridableMethodsInConstructors.
        DoSomething();
    }
    // This will be overridden in the derived type.
    public virtual void DoSomething()
    {
        Console.WriteLine("Base DoSomething");
    }
}

public class DerivedType : BadlyConstructedType
{
    public DerivedType()
    {
        Console.WriteLine("Calling derived ctor.");
        initialized = "Yes";
    }
    public override void DoSomething()
    {
        Console.WriteLine("Derived DoSomething is called - initialized ? {0}", initialized);
    }
}

public class TestBadlyConstructedType
{
    public static void Main2214()
    {
        DerivedType derivedInstance = new DerivedType();
    }
}
```

```

Imports System

Namespace ca2214

    Public Class BadlyConstructedType
        Protected initialized As String = "No"

        Public Sub New()
            Console.WriteLine("Calling base ctor.")
            ' Violates rule: DoNotCallOverridableMethodsInConstructors.
            DoSomething()
        End Sub 'New

        ' This will be overridden in the derived type.
        Public Overridable Sub DoSomething()
            Console.WriteLine("Base DoSomething")
        End Sub 'DoSomething
    End Class 'BadlyConstructedType

    Public Class DerivedType
        Inherits BadlyConstructedType

        Public Sub New()
            Console.WriteLine("Calling derived ctor.")
            initialized = "Yes"
        End Sub 'New

        Public Overrides Sub DoSomething()
            Console.WriteLine("Derived DoSomething is called - initialized ? {0}", initialized)
        End Sub 'DoSomething
    End Class 'DerivedType

    Public Class TestBadlyConstructedType

        Public Shared Sub Main2214()
            Dim derivedInstance As New DerivedType()
        End Sub 'Main
    End Class
End Namespace

```

This example produces the following output:

```

Calling base ctor.
Derived DoSomething is called - initialized ? No
Calling derived ctor.

```

CA2215: Dispose methods should call base class dispose

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2215
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A type that implements [System.IDisposable](#) inherits from a type that also implements [IDisposable](#). The [Dispose](#) method of the inheriting type does not call the [Dispose](#) method of the parent type.

Rule description

If a type inherits from a disposable type, it must call the [Dispose](#) method of the base type from within its own [Dispose](#) method. Calling the base type `Dispose` method ensures that any resources created by the base type are released.

How to fix violations

To fix a violation of this rule, call `base.Dispose` in your [Dispose](#) method.

When to suppress warnings

It is safe to suppress a warning from this rule if the call to `base.Dispose` occurs at a deeper calling level than the rule checks.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2215
// The code that's violating the rule is on this line.
#pragma warning restore CA2215
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2215.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows two types, `TypeA` that implements `IDisposable`, and `TypeB` that inherits from type `TypeA` and correctly calls its `Dispose` method.

```
Namespace ca2215

    Public Class TypeA
        Implements IDisposable

            Protected Overridable Overloads Sub Dispose(disposing As Boolean)
                If disposing Then
                    ' dispose managed resources
                End If

                ' free native resources
            End Sub

            Public Overloads Sub Dispose() Implements IDisposable.Dispose
                Dispose(True)
                GC.SuppressFinalize(Me)
            End Sub

            ' Disposable types implement a finalizer.
            Protected Overrides Sub Finalize()
                Dispose(False)
                MyBase.Finalize()
            End Sub

        End Class

        Public Class TypeB
            Inherits TypeA

            Protected Overrides Sub Dispose(disposing As Boolean)
                If Not disposing Then
                    MyBase.Dispose(False)
                End If
            End Sub

        End Class
    End Namespace
```

```
using System;

namespace ca2215
{
    public class TypeA : IDisposable
    {
        protected virtual void Dispose(bool disposing)
        {
            if (disposing)
            {
                // Dispose managed resources
            }

            // Free native resources
        }

        public void Dispose()
        {
            Dispose(true);
            GC.SuppressFinalize(this);
        }

        // Disposable types implement a finalizer.
        ~TypeA()
        {
            Dispose(false);
        }
    }

    public class TypeB : TypeA
    {
        protected override void Dispose(bool disposing)
        {
            if (!disposing)
            {
                base.Dispose(false);
            }
        }
    }
}
```

CA2216: Disposable types should declare finalizer

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2216
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A type that implements [System.IDisposable](#), and has fields that suggest the use of unmanaged resources, does not implement a finalizer as described by [System.Object.Finalize](#).

Rule description

A violation of this rule is reported if the disposable type contains fields of the following types:

- [System.IntPtr](#)
- [System.UIntPtr](#)
- [System.Runtime.InteropServices.HandleRef](#)

How to fix violations

To fix a violation of this rule, implement a finalizer that calls your [Dispose](#) method.

When to suppress warnings

It is safe to suppress a warning from this rule if the type does not implement [IDisposable](#) for the purpose of releasing unmanaged resources.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2216
// The code that's violating the rule is on this line.
#pragma warning restore CA2216
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2216.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type that violates this rule.

```
public class DisposeMissingFinalize : IDisposable
{
    private bool disposed = false;
    private IntPtr unmanagedResource;

    [DllImport("native.dll")]
    private static extern IntPtr AllocateUnmanagedResource();

    [DllImport("native.dll")]
    private static extern void FreeUnmanagedResource(IntPtr p);

    DisposeMissingFinalize()
    {
        unmanagedResource = AllocateUnmanagedResource();
    }

    protected virtual void Dispose(bool disposing)
    {
        if (!disposed)
        {
            // Dispose of resources held by this instance.
            FreeUnmanagedResource(unmanagedResource);
            disposed = true;

            // Suppress finalization of this disposed instance.
            if (disposing)
            {
                GC.SuppressFinalize(this);
            }
        }
    }

    public void Dispose()
    {
        Dispose(true);
    }

    // Disposable types with unmanaged resources implement a finalizer.
    // Uncomment the following code to satisfy rule:
    // DisposableTypesShouldDeclareFinalizer
    // ~TypeA()
    // {
    //     Dispose(false);
    // }
}
```

CA2217: Do not mark enums with FlagsAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2217
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An enumeration is marked with [FlagsAttribute](#) and it has one or more values that are not powers of two or a combination of the other defined values on the enumeration.

By default, this rule only looks at externally visible enumerations, but this is [configurable](#).

Rule description

An enumeration should have [FlagsAttribute](#) present only if each value defined in the enumeration is a power of two or a combination of defined values.

How to fix violations

To fix a violation of this rule, remove [FlagsAttribute](#) from the enumeration.

When to suppress warnings

Do not suppress a warning from this rule.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Usage](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Examples

The following code shows an enumeration, `Color`, that contains the value 3. 3 is not a power of two, or a combination of any of the defined values. The `Color` enumeration shouldn't be marked with [FlagsAttribute](#).

```
// Violates this rule
[FlagsAttribute]
public enum Color
{
    None = 0,
    Red = 1,
    Orange = 3,
    Yellow = 4
}
```

```
Imports System

Namespace Samples

    ' Violates this rule
    <FlagsAttribute()> _
    Public Enum Color

        None = 0
        Red = 1
        Orange = 3
        Yellow = 4

    End Enum
End Namespace
```

The following code shows an enumeration, `Days`, that meets the requirements for being marked with [FlagsAttribute](#):

```
[FlagsAttribute]
public enum Days
{
    None = 0,
    Monday = 1,
    Tuesday = 2,
    Wednesday = 4,
    Thursday = 8,
    Friday = 16,
    All = Monday | Tuesday | Wednesday | Thursday | Friday
}
```

```
Imports System
Namespace Samples

    <FlagsAttribute()> _
    Public Enum Days

        None = 0
        Monday = 1
        Tuesday = 2
        Wednesday = 4
        Thursday = 8
        Friday = 16
        All = Monday Or Tuesday Or Wednesday Or Thursday Or Friday

    End Enum
End Namespace
```

- [System.FlagsAttribute](#)

CA2218: Override GetHashCode on overriding Equals

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA2218
Category	Usage
Breaking change	Non-breaking

Cause

A public type overrides [System.Object.Equals](#) but does not override [System.Object.GetHashCode](#).

Rule description

[GetHashCode](#) returns a value, based on the current instance, that's suited for hashing algorithms and data structures such as hash tables. Two objects that are the same type and are equal must return the same hash code to ensure that instances of the following types work correctly:

- [System.Collections.Hashtable](#)
- [System.Collections.SortedList](#)
- [System.Collections.Generic.Dictionary< TKey, TValue >](#)
- [System.Collections.Generic.SortedDictionary< TKey, TValue >](#)
- [System.Collections.Generic.SortedList< TKey, TValue >](#)
- [System.Collections.Specialized.HybridDictionary](#)
- [System.Collections.Specialized.ListDictionary](#)
- [System.Collections.Specialized.OrderedDictionary](#)
- Types that implement [System.Collections.Generic.IEqualityComparer< T >](#)

NOTE

This rule only applies to Visual Basic code. The C# compiler generates a separate warning, [CS0659](#).

How to fix violations

To fix a violation of this rule, provide an implementation of [GetHashCode](#). For a pair of objects of the same type, ensure that the implementation returns the same value if your implementation of [Equals](#) returns `true` for the pair.

When to suppress warnings

Do not suppress a warning from this rule.

Class example

The following example shows a class (reference type) that violates this rule.

```
' This class violates the rule.
Public Class Point

    Public Property X As Integer
    Public Property Y As Integer

    Public Sub New(x As Integer, y As Integer)
        Me.X = x
        Me.Y = y
    End Sub

    Public Overrides Function Equals(obj As Object) As Boolean

        If obj = Nothing Then
            Return False
        End If

        If [GetType]() <> obj.GetType() Then
            Return False
        End If

        Dim pt As Point = CType(obj, Point)

        Return X = pt.X AndAlso Y = pt.Y
    End Function

End Class
```

The following example fixes the violation by overriding [GetHashCode\(\)](#).

```

' This class satisfies the rule.
Public Class Point

    Public Property X As Integer
    Public Property Y As Integer

    Public Sub New(x As Integer, y As Integer)
        Me.X = x
        Me.Y = y
    End Sub

    Public Overrides Function GetHashCode() As Integer
        Return X Or Y
    End Function

    Public Overrides Function Equals(obj As Object) As Boolean

        If obj = Nothing Then
            Return False
        End If

        If [GetType]() <> obj.GetType() Then
            Return False
        End If

        Dim pt As Point = CType(obj, Point)

        Return Equals(pt)
    End Function

    Public Overloads Function Equals(pt As Point) As Boolean
        Return X = pt.X AndAlso Y = pt.Y
    End Function

    Public Shared Operator =(pt1 As Point, pt2 As Point) As Boolean
        Return pt1.Equals(pt2)
    End Operator

    Public Shared Operator <>(pt1 As Point, pt2 As Point) As Boolean
        Return Not pt1.Equals(pt2)
    End Operator
End Class

```

CA2219: Do not raise exceptions in exception clauses

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2219
Category	Usage
Fix is breaking or non-breaking	Non-breaking, Breaking

Cause

An exception is thrown from a `finally`, filter, or fault clause.

Rule description

When an exception is raised in an exception clause, it greatly increases the difficulty of debugging.

When an exception is raised in a `finally` or fault clause, the new exception hides the active exception, if present. This makes the original error hard to detect and debug.

When an exception is raised in a filter clause, the runtime silently catches the exception, and causes the filter to evaluate to false. There is no way to tell the difference between the filter evaluating to false and an exception being thrown from a filter. This makes it hard to detect and debug errors in the filter's logic.

How to fix violations

To fix this violation of this rule, do not explicitly raise an exception from a `finally`, filter, or fault clause.

When to suppress warnings

Do not suppress a warning for this rule. There are no scenarios under which an exception raised in an exception clause provides a benefit to the executing code.

Related rules

[CA1065: Do not raise exceptions in unexpected locations](#)

- [Design rules](#)

CA2224: Override Equals on overloading operator equals

9/20/2022 • 2 minutes to read • [Edit Online](#)

ITEM	VALUE
RuleId	CA2224
Category	Usage
Breaking change	Non-breaking

Cause

A public type implements the equality operator but doesn't override [System.Object.Equals](#).

Rule description

The equality operator is intended to be a syntactically convenient way to access the functionality of the [Equals](#) method. If you implement the equality operator, its logic must be identical to that of [Equals](#).

NOTE

This rule only applies to Visual Basic code. The C# compiler generates a separate warning, [CS0660](#).

How to fix violations

To fix a violation of this rule, you should either remove the implementation of the equality operator, or override [Equals](#) and have the two methods return the same values. If the equality operator does not introduce inconsistent behavior, you can fix the violation by providing an implementation of [Equals](#) that calls the [Equals](#) method in the base class.

When to suppress warnings

It is safe to suppress a warning from this rule if the equality operator returns the same value as the inherited implementation of [Equals](#). The examples in this article include a type that could safely suppress a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2224
// The code that's violating the rule is on this line.
#pragma warning restore CA2224
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2224.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a class (reference type) that violates this rule.

```
' This class violates the rule.
Public Class Point

    Public Property X As Integer
    Public Property Y As Integer

    Public Sub New(x As Integer, y As Integer)
        Me.X = x
        Me.Y = y
    End Sub

    Public Overrides Function GetHashCode() As Integer
        Return HashCode.Combine(X, Y)
    End Function

    Public Shared Operator =(pt1 As Point, pt2 As Point) As Boolean
        If pt1 Is Nothing OrElse pt2 Is Nothing Then
            Return False
        End If

        If pt1.GetType() <> pt2.GetType() Then
            Return False
        End If

        Return pt1.X = pt2.X AndAlso pt1.Y = pt2.Y
    End Operator

    Public Shared Operator <>(pt1 As Point, pt2 As Point) As Boolean
        Return Not pt1 = pt2
    End Operator

End Class
```

The following example fixes the violation by overriding `System.Object.Equals`.

```

' This class satisfies the rule.
Public Class Point

    Public Property X As Integer
    Public Property Y As Integer

    Public Sub New(x As Integer, y As Integer)
        Me.X = x
        Me.Y = y
    End Sub

    Public Overrides Function GetHashCode() As Integer
        Return HashCode.Combine(X, Y)
    End Function

    Public Overrides Function Equals(obj As Object) As Boolean

        If obj = Nothing Then
            Return False
        End If

        If [GetType]() <> obj.GetType() Then
            Return False
        End If

        Dim pt As Point = CType(obj, Point)

        Return X = pt.X AndAlso Y = pt.Y
    End Function

    Public Shared Operator =(pt1 As Point, pt2 As Point) As Boolean
        ' Object.Equals calls Point.Equals(Object).
        Return Object.Equals(pt1, pt2)
    End Operator

    Public Shared Operator <>(pt1 As Point, pt2 As Point) As Boolean
        ' Object.Equals calls Point.Equals(Object).
        Return Not Object.Equals(pt1, pt2)
    End Operator
End Class

```

CA2225: Operator overloads have named alternates

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2225
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An operator overload was detected and the expected named alternative method was not found.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

Operator overloading allows the use of symbols to represent computations for a type. For example, a type that overloads the plus symbol `+` for addition would typically have an alternative member named `Add`. The named alternative member provides access to the same functionality as the operator. It's provided for developers who program in languages that do not support overloaded operators.

This rule examines:

- Implicit and explicit cast operators in a type by checking for methods named `To<typename>` and `From<typename>`.
- The operators listed in the following table:

C#	VISUAL BASIC	C++	ALTERNATE METHOD NAME
<code>+(binary)</code>	<code>+</code>	<code>+(binary)</code>	<code>Add</code>
<code>+=</code>	<code>+=</code>	<code>+=</code>	<code>Add</code>
<code>&</code>	<code>And</code>	<code>&</code>	<code>BitwiseAnd</code>
<code>&=</code>	<code>And=</code>	<code>&=</code>	<code>BitwiseAnd</code>
<code> </code>	<code>Or</code>	<code> </code>	<code>BitwiseOr</code>
<code> =</code>	<code>Or=</code>	<code> =</code>	<code>BitwiseOr</code>
<code>--</code>	N/A	<code>--</code>	<code>Decrement</code>
<code>/</code>	<code>/</code>	<code>/</code>	<code>Divide</code>

C#	VISUAL BASIC	C++	ALTERNATE METHOD NAME
/=	/=	/=	Divide
==	=	==	Equals
^	Xor	^	Xor
^=	Xor=	^=	Xor
>	>	>	CompareTo or Compare
>=	>=	>=	CompareTo or Compare
++	N/A	++	Increment
!=	<>	!=	Equals
<<	<<	<<	LeftShift
<<=	<<=	<<=	LeftShift
<	<	<	CompareTo or Compare
<=	<=	<=	CompareTo or Compare
&&	N/A	&&	LogicalAnd
	N/A		LogicalOr
!	N/A	!	LogicalNot
%	Mod	%	Mod or Remainder
%=	N/A	%=	Mod
* (binary)	*	*	Multiply
*=	N/A	*=	Multiply
~	Not	~	OnesComplement
>>	>>	>>	RightShift
=	N/A	>>=	RightShift
- (binary)	- (binary)	- (binary)	Subtract
-=	N/A	-=	Subtract
true	IsTrue	N/A	IsTrue (Property)

C#	VISUAL BASIC	C++	ALTERNATE METHOD NAME
- (unary)	N/A	-	Negate
+ (unary)	N/A	+	Plus
false	IsFalse	False	IsTrue (Property)

*N/A means the operator cannot be overloaded in the selected language.

NOTE

In C#, when a binary operator is overloaded, the corresponding assignment operator, if any, is also implicitly overloaded.

How to fix violations

To fix a violation of this rule, implement the alternative method for the operator. Name it using the recommended alternative name.

When to suppress warnings

Do not suppress a warning from this rule if you're implementing a shared library. Applications can ignore a warning from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2225
// The code that's violating the rule is on this line.
#pragma warning restore CA2225
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2225.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Usage](#)). For more

information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example defines a structure that violates this rule. To correct the example, add a public `Add(int x, int y)` method to the structure.

```
public struct Point
{
    private int x, y;

    public Point(int x, int y)
    {
        this.x = x;
        this.y = y;
    }

    public override string ToString()
    {
        return String.Format("({0},{1})", x, y);
    }

    // Violates rule: OperatorOverloadsHaveNamedAlternates.
    public static Point operator +(Point a, Point b)
    {
        return new Point(a.x + b.x, a.y + b.y);
    }

    public int X { get { return x; } }
    public int Y { get { return x; } }
}
```

CA2226: Operators should have symmetrical overloads

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2226
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A type implements the equality or inequality operator and does not implement the opposite operator.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

There are no circumstances where either equality or inequality is applicable to instances of a type, and the opposite operator is undefined. Types typically implement the inequality operator by returning the negated value of the equality operator.

The C# compiler issues an error for violations of this rule.

How to fix violations

To fix a violation of this rule, implement both the equality and inequality operators, or remove the one that's present.

When to suppress warnings

Do not suppress a warning from this rule. If you do, your type will not work in a manner that's consistent with .NET.

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Usage](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Related rules

- [CA2231: Overload operator equals on overriding ValueType.Equals](#)

CA2227: Collection properties should be read only

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2227
Category	Usage
Fix is breaking or non-breaking	Breaking

Cause

An externally visible, writable property is of a type that implements [System.Collections.ICollection](#). This rule ignores arrays, indexers (properties with the name 'Item'), immutable collections, readonly collections, and permission sets.

Rule description

A writable collection property allows a user to replace the collection with a completely different collection. A read-only or [init-only](#) property stops the collection from being replaced, but still allows the individual members to be set. If replacing the collection is a goal, the preferred design pattern is to include a method to remove all the elements from the collection, and a method to repopulate the collection. See the [Clear](#) and [AddRange](#) methods of the [System.Collections.ArrayList](#) class for an example of this pattern.

Both binary and XML serialization support read-only properties that are collections. The [System.Xml.Serialization.XmlSerializer](#) class has specific requirements for types that implement [ICollection](#) and [System.Collections.IEnumerable](#) in order to be serializable.

How to fix violations

To fix a violation of this rule, make the property read-only or [init-only](#). If the design requires it, add methods to clear and repopulate the collection.

When to suppress warnings

You can suppress the warning if the property is part of a [Data Transfer Object \(DTO\)](#) class.

Otherwise, do not suppress warnings from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2227
// The code that's violating the rule is on this line.
#pragma warning restore CA2227
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2227.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type with a writable collection property and shows how the collection can be replaced directly. Additionally, it shows the preferred manner of replacing a read-only collection property using `Clear` and `AddRange` methods.

```
public class WritableCollection
{
    public ArrayList SomeStrings
    {
        get;

        // This set accessor violates rule CA2227.
        // To fix the code, remove this set accessor or change it to init.
        set;
    }

    public WritableCollection()
    {
        SomeStrings = new ArrayList(new string[] { "one", "two", "three" });
    }
}

class ReplaceWritableCollection
{
    static void Main2227()
    {
        ArrayList newCollection = new ArrayList(new string[] { "a", "new", "collection" });

        WritableCollection collection = new WritableCollection();

        // This line of code demonstrates how the entire collection
        // can be replaced by a property that's not read only.
        collection.SomeStrings = newCollection;

        // If the intent is to replace an entire collection,
        // implement and/or use the Clear() and AddRange() methods instead.
        collection.SomeStrings.Clear();
        collection.SomeStrings.AddRange(newCollection);
    }
}
```

```

Public Class WritableCollection

    ' This property violates rule CA2227.
    ' To fix the code, add the ReadOnly modifier to the property:
    ' ReadOnly Property SomeStrings As ArrayList
    Property SomeStrings As ArrayList

    Sub New()
        SomeStrings = New ArrayList(New String() {"one", "two", "three"})
    End Sub

End Class

Class ViolatingVersusPreferred

    Shared Sub Main2227()
        Dim newCollection As New ArrayList(New String() {"a", "new", "collection"})

        Dim collection As New WritableCollection()

        ' This line of code demonstrates how the entire collection
        ' can be replaced by a property that's not read only.
        collection.SomeStrings = newCollection

        ' If the intent is to replace an entire collection,
        ' implement and/or use the Clear() and AddRange() methods instead.
        collection.SomeStrings.Clear()
        collection.SomeStrings.AddRange(newCollection)
    End Sub

End Class

```

CA2229: Implement serialization constructors

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2229
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

The type implements the `System.Runtime.Serialization.ISerializable` interface, is not a delegate or interface, and one of the following conditions is true:

- The type does not have a constructor that takes a `SerializationInfo` object and a `StreamingContext` object (the signature of the serialization constructor).
- The type is unsealed and the access modifier for its serialization constructor is not protected (family).
- The type is sealed and the access modifier for its serialization constructor is not private.

Rule description

This rule is relevant for types that support custom serialization. A type supports custom serialization if it implements the `ISerializable` interface. The serialization constructor is required to deserialize, or recreate, objects that have been serialized using the `ISerializable.GetObjectData` method.

How to fix violations

To fix a violation of this rule, implement the serialization constructor. For a sealed class, make the constructor private; otherwise, make it protected.

When to suppress warnings

Do not suppress a violation of the rule. The type will not be deserializable, and will not function in many scenarios.

Example

The following example shows a type that satisfies the rule.

```
[Serializable]
public class SerializationConstructorsRequired : ISerializable
{
    private int n1;

    // This is a regular constructor.
    public SerializationConstructorsRequired()
    {
        n1 = -1;
    }
    // This is the serialization constructor.
    // Satisfies rule: ImplementSerializationConstructors.

    protected SerializationConstructorsRequired(
        SerializationInfo info,
        StreamingContext context)
    {
        n1 = (int)info.GetValue(nameof(n1), typeof(int));
    }

    // The following method serializes the instance.
    void ISerializable.GetObjectData(SerializationInfo info,
        StreamingContext context)
    {
        info.AddValue(nameof(n1), n1);
    }
}
```

Related rules

CA2231: Overload operator equals on overriding ValueType.Equals

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2231
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A value type overrides [System.Object.Equals](#) but does not implement the equality operator.

By default, this rule only looks at externally visible types, but this is [configurable](#).

Rule description

In most programming languages, there is no default implementation of the equality operator (==) for value types. If your programming language supports operator overloads, you should consider implementing the equality operator. Its behavior should be identical to that of [Equals](#).

You cannot use the default equality operator in an overloaded implementation of the equality operator. Doing so will cause a stack overflow. To implement the equality operator, use the Object.Equals method in your implementation. For example:

```
If (Object.ReferenceEquals(left, Nothing)) Then
    Return Object.ReferenceEquals(right, Nothing)
Else
    Return left.Equals(right)
End If
```

```
if (Object.ReferenceEquals(left, null))
    return Object.ReferenceEquals(right, null);
return left.Equals(right);
```

How to fix violations

To fix a violation of this rule, implement the equality operator.

When to suppress warnings

It is safe to suppress a warning from this rule; however, we recommend that you provide the equality operator if possible.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2231
// The code that's violating the rule is on this line.
#pragma warning restore CA2231
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2231.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Usage](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXXX.api_surface = private, internal
```

Example

The following example defines a type that violates this rule:

```
public struct PointWithoutHash
{
    private int x, y;

    public PointWithoutHash(int x, int y)
    {
        this.x = x;
        this.y = y;
    }

    public override string ToString()
    {
        return String.Format("({0},{1})", x, y);
    }

    public int X { get { return x; } }

    public int Y { get { return x; } }

    // Violates rule: OverrideGetHashCodeOnOverridingEquals.
    // Violates rule: OverrideOperatorEqualsOnOverridingValueTypeEquals.
    public override bool Equals(object obj)
    {
        if (obj.GetType() != typeof(PointWithoutHash))
            return false;

        PointWithoutHash p = (PointWithoutHash)obj;
        return ((this.x == p.x) && (this.y == p.y));
    }
}
```

CA2234: Pass System.Uri objects instead of strings

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2234
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A call is made to a method that has a string parameter whose name contains "uri", "Uri", "urn", "Urn", "url", or "Url" and the declaring type of the method contains a corresponding method overload that has a [System.Uri](#) parameter.

By default, this rule only looks at externally visible methods and types, but this is [configurable](#).

Rule description

A parameter name is split into tokens based on the camel casing convention, and then each token is checked to see whether it equals "uri", "Uri", "urn", "Urn", "url", or "Url". If there is a match, the parameter is assumed to represent a uniform resource identifier (URI). A string representation of a URI is prone to parsing and encoding errors, and can lead to security vulnerabilities. The [Uri](#) class provides these services in a safe and secure manner. When there is a choice between two overloads that differ only regarding the representation of a URI, the user should choose the overload that takes a [Uri](#) argument.

How to fix violations

To fix a violation of this rule, call the overload that takes the [Uri](#) argument.

When to suppress warnings

It is safe to suppress a warning from this rule if the string parameter does not represent a URI.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2234
// The code that's violating the rule is on this line.
#pragma warning restore CA2234
```

To disable the rule for a file, folder, or project, set its severity to [none](#) in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2234.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Configure code to analyze

Use the following option to configure which parts of your codebase to run this rule on.

- [Include specific API surfaces](#)

You can configure this option for just this rule, for all rules, or for all rules in this category ([Usage](#)). For more information, see [Code quality rule configuration options](#).

Include specific API surfaces

You can configure which parts of your codebase to run this rule on, based on their accessibility. For example, to specify that the rule should run only against the non-public API surface, add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CAXXX.api_surface = private, internal
```

Example

The following example shows a method, `ErrorProne`, that violates the rule and a method, `SaferWay`, that correctly calls the `Uri` overload:

```

Imports System

Namespace ca2234

    Class History

        Friend Sub AddToHistory(uriString As String)
        End Sub

        Friend Sub AddToHistory(uriType As Uri)
        End Sub

    End Class

    Public Class Browser

        Dim uriHistory As New History()

        Sub ErrorProne()
            uriHistory.AddToHistory("http://www.adventure-works.com")
        End Sub

        Sub SaferWay()
            Try
                Dim newUri As New Uri("http://www.adventure-works.com")
                uriHistory.AddToHistory(newUri)
            Catch uriException As UriFormatException
            End Try
        End Sub

    End Class

End Namespace

```

```

class History
{
    internal void AddToHistory(string uriString) { }
    internal void AddToHistory(Uri uriType) { }
}

public class Browser
{
    History uriHistory = new History();

    public void ErrorProne()
    {
        uriHistory.AddToHistory("http://www.adventure-works.com");
    }

    public void SaferWay()
    {
        try
        {
            Uri newUri = new Uri("http://www.adventure-works.com");
            uriHistory.AddToHistory(newUri);
        }
        catch (UriFormatException) { }
    }
}

```

Related rules

- CA1056: URI properties should not be strings

- CA1054: URI parameters should not be strings
- CA1055: URI return values should not be strings

CA2235: Mark all non-serializable fields

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2235
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An instance field of a type that is not serializable is declared in a type that is serializable.

Rule description

A serializable type is one that is marked with the [System.SerializableAttribute](#) attribute. When the type is serialized, a [System.Runtime.Serialization.SerializationException](#) exception is thrown if the type contains an instance field of a type that's not serializable *and* doesn't implement the [System.Runtime.Serialization.ISerializable](#) interface.

TIP

CA2235 does not fire for instance fields of types that implement [ISerializable](#) because they provide their own serialization logic.

How to fix violations

To fix a violation of this rule, apply the [System.NonSerializedAttribute](#) attribute to the field that is not serializable.

When to suppress warnings

Only suppress a warning from this rule if a [System.Runtime.Serialization.ISerializationSurrogate](#) type is declared that allows instances of the field to be serialized and deserialized.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2235
// The code that's violating the rule is on this line.
#pragma warning restore CA2235
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2235.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows two types: one that violates the rule and one that satisfies the rule.

```
public class Mouse
{
    int buttons;
    string scanTypeValue;

    public int NumberOfButtons
    {
        get { return buttons; }
    }

    public string ScanType
    {
        get { return scanTypeValue; }
    }

    public Mouse(int numberOfButtons, string scanType)
    {
        buttons = numberOfButtons;
        scanTypeValue = scanType;
    }
}

[Serializable]
public class InputDevices1
{
    // Violates MarkAllNonSerializableFields.
    Mouse opticalMouse;

    public InputDevices1()
    {
        opticalMouse = new Mouse(5, "optical");
    }
}

[Serializable]
public class InputDevices2
{
    // Satisfies MarkAllNonSerializableFields.
    [NonSerialized]
    Mouse opticalMouse;

    public InputDevices2()
    {
        opticalMouse = new Mouse(5, "optical");
    }
}
```

```

Imports System
Imports System.Runtime.Serialization

Namespace ca2235

    Public Class Mouse

        ReadOnly Property NumberOfButtons As Integer

        ReadOnly Property ScanType As String

        Sub New(numberOfButtons As Integer, scanType As String)
            Me.NumberOfButtons = numberOfButtons
            Me.ScanType = scanType
        End Sub

    End Class

    <SerializableAttribute>
    Public Class InputDevices1

        ' Violates MarkAllNonSerializableFields.
        Dim opticalMouse As Mouse

        Sub New()
            opticalMouse = New Mouse(5, "optical")
        End Sub

    End Class

    <SerializableAttribute>
    Public Class InputDevices2

        ' Satisfies MarkAllNonSerializableFields.
        <NonSerializedAttribute>
        Dim opticalMouse As Mouse

        Sub New()
            opticalMouse = New Mouse(5, "optical")
        End Sub

    End Class

End Namespace

```

Remarks

Rule CA2235 does not analyze types that implement the [ISerializable](#) interface (unless they are also marked with the [SerializableAttribute](#) attribute). This is because rule CA2237 already recommends marking types that implement the [ISerializable](#) interface with the [SerializableAttribute](#) attribute.

Related rules

- [CA2229: Implement serialization constructors](#)
- [CA2237: Mark ISerializable types with SerializableAttribute](#)

CA2237: Mark ISerializable types with SerializableAttribute

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2237
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An externally visible type implements the [System.Runtime.Serialization.ISerializable](#) interface and the type is not marked with the [System.SerializableAttribute](#) attribute. The rule ignores derived types whose base type is not serializable.

Rule description

To be recognized by the common language runtime as serializable, types must be marked with the [SerializableAttribute](#) attribute even if the type uses a custom serialization routine through implementation of the [ISerializable](#) interface.

How to fix violations

To fix a violation of this rule, apply the [SerializableAttribute](#) attribute to the type.

When to suppress warnings

Do not suppress a warning from this rule for exception classes, because they must be serializable to work correctly across application domains.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2237
// The code that's violating the rule is on this line.
#pragma warning restore CA2237
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2237.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows a type that violates the rule. Uncomment the `SerializableAttribute` attribute line to satisfy the rule.

```
Imports System
Imports System.Runtime.Serialization
Imports System.Security.Permissions

Namespace ca2237

    ' <SerializableAttribute> _
    Public Class BaseType
        Implements ISerializable

        Dim baseValue As Integer

        Sub New()
            baseValue = 3
        End Sub

        Protected Sub New(
            info As SerializationInfo, context As StreamingContext)

            baseValue = info.GetInt32("baseValue")

        End Sub

        <SecurityPermissionAttribute(SecurityAction.Demand,
            SerializationFormatter:=True)>
        Overridable Sub GetObjectData(
            info As SerializationInfo, context As StreamingContext) _
            Implements ISerializable.GetObjectData

            info.AddValue("baseValue", baseValue)

        End Sub

    End Class

End Namespace
```

```
// [SerializableAttribute]
public class BaseType : ISerializable
{
    int baseValue;

    public BaseType()
    {
        baseValue = 3;
    }

    protected BaseType(
        SerializationInfo info, StreamingContext context)
    {
        baseValue = info.GetInt32("baseValue");
    }

    public virtual void GetObjectData(
        SerializationInfo info, StreamingContext context)
    {
        info.AddValue("baseValue", baseValue);
    }
}
```

Related rules

- [CA2235: Mark all non-serializable fields](#)

CA2241: Provide correct arguments to formatting methods

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2241
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

The `format` string argument passed to a method such as `WriteLine`, `Write`, or `System.String.Format` does not contain a format item that corresponds to each object argument, or vice versa.

By default, this rule only analyzes calls to the three methods mentioned previously, but this is [configurable](#).

Rule description

The arguments to methods such as `WriteLine`, `Write`, and `Format` consist of a format string followed by several `System.Object` instances. The format string consists of text and embedded format items of the form

`{index[,alignment][:formatString]}`. 'index' is a zero-based integer that indicates which of the objects to format. If an object does not have a corresponding index in the format string, the object is ignored. If the object specified by 'index' does not exist, a `System.FormatException` is thrown at run time.

How to fix violations

To fix a violation of this rule, provide a format item for each object argument and provide an object argument for each format item.

When to suppress warnings

Do not suppress a warning from this rule.

Configure code to analyze

Use the following options to configure additional methods to run this rule on.

- [Additional string formatting methods](#)
- [Determine additional string formatting methods automatically](#)

Additional string formatting methods

You can configure names of additional string formatting methods which should be analyzed by this rule. For example, to specify all methods named `MyFormat` as string formatting methods, you can add the following key-value pair to an `.editorconfig` file in your project:

```
dotnet_code_quality.CA2241.additional_string_formatting_methods = MyFormat
```

Allowed method name formats in the option value (separated by `|`):

- Method name only (includes all methods with the name, regardless of the containing type or namespace)
- Fully qualified names in the symbol's [documentation ID format](#), with an optional `M:` prefix.

Examples:

OPTION VALUE	SUMMARY
<code>dotnet_code_quality.CA2241.additional_string_formatting_methods = MyFormat</code>	Matches all methods named <code>MyFormat</code> in the compilation
<code>dotnet_code_quality.CA2241.additional_string_formatting_methods = MyFormat1 MyFormat2</code>	Matches all methods named either <code>MyFormat1</code> or <code>MyFormat2</code> in the compilation
<code>dotnet_code_quality.CA2241.additional_string_formatting_methods = NS.MyType.MyFormat(ParamType)</code>	Matches specific method <code>MyFormat</code> with given fully qualified signature
<code>dotnet_code_quality.CA2241.additional_string_formatting_methods = NS1.MyType1.MyFormat1(ParamType) NS2.MyType2.MyFormat2(ParamType)</code>	Matches specific methods <code>MyFormat1</code> and <code>MyFormat2</code> with respective fully qualified signature

Determine additional string formatting methods automatically

Instead of specifying an explicit list of additional string formatting methods, you can configure the analyzer to automatically attempt to determine the string formatting method. By default, this option is disabled. If the option is enabled, any method that has a `string format` parameter followed by a `params object[]` parameter is considered a string formatting method:

```
dotnet_code_quality.CA2241.try_determine_additional_string_formatting_methods_automatically = true
```

Example

The following example shows two violations of the rule.

```
Imports System

Namespace ca2241

    Class CallsStringFormat

        Sub CallFormat()

            Dim file As String = "file name"
            Dim errors As Integer = 13

            ' Violates the rule.
            Console.WriteLine(String.Format("{0}", file, errors))

            Console.WriteLine(String.Format("{0}: {1}", file, errors))

            ' Violates the rule and generates a FormatException at runtime.
            Console.WriteLine(String.Format("{0}: {1}, {2}", file, errors))

        End Sub

    End Class

End Namespace
```

```
class CallsStringFormat
{
    void CallFormat()
    {
        string file = "file name";
        int errors = 13;

        // Violates the rule.
        Console.WriteLine(string.Format("{0}", file, errors));

        Console.WriteLine(string.Format("{0}: {1}", file, errors));

        // Violates the rule and generates a FormatException at runtime.
        Console.WriteLine(string.Format("{0}: {1}, {2}", file, errors));
    }
}
```

CA2242: Test for NaN correctly

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2242
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An expression tests a value against [System.Single.NaN](#) or [System.Double.NaN](#).

Rule description

[System.Double.NaN](#), which represents a value that's not a number, results when an arithmetic operation is undefined. Any expression that tests for equality between a value and [System.Double.NaN](#) always returns `false`. Any expression that tests for inequality (`!=` in C#) between a value and [System.Double.NaN](#) always returns `true`.

How to fix violations

To fix a violation of this rule and accurately determine whether a value represents [System.Double.NaN](#), use [System.Single.IsNaN](#) or [System.Double.IsNaN](#) to test the value.

When to suppress warnings

Do not suppress a warning from this rule.

Example

The following example shows two expressions that incorrectly test a value against [System.Double.NaN](#) and an expression that correctly uses [System.Double.IsNaN](#) to test the value.

```
Imports System

Namespace ca2242

    Class NaNTests

        Shared zero As Double

        Shared Sub Main2242()
            Console.WriteLine(0 / zero = Double.NaN)
            Console.WriteLine(0 / zero <> Double.NaN)
            Console.WriteLine(Double.IsNaN(0 / zero))
        End Sub

    End Class

End Namespace
```

```
class NaNTests
{
    static double zero = 0;

    static void Main()
    {
        Console.WriteLine(0 / zero == double.NaN);
        Console.WriteLine(0 / zero != double.NaN);
        Console.WriteLine(double.IsNaN(0 / zero));
    }
}
```

CA2243: Attribute string literals should parse correctly

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2243
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An attribute's string literal parameter does not parse correctly for a URL, GUID, or Version.

Rule description

Since attributes are derived from [System.Attribute](#), and attributes are used at compile time, only constant values can be passed to their constructors. Attribute parameters that must represent URLs, GUIDs, and Versions cannot be typed as [System.Uri](#), [System.Guid](#), and [System.Version](#), because these types cannot be represented as constants. Instead, they must be represented by strings.

Because the parameter is typed as a string, it is possible that an incorrectly formatted parameter could be passed at compile time.

This rule uses a naming heuristic to find parameters that represent a uniform resource identifier (URI), a Globally Unique Identifier (GUID), or a Version, and verifies that the passed value is correct.

How to fix violations

Change the parameter string to a correctly formed URL, GUID, or Version.

When to suppress warnings

It is safe to suppress a warning from this rule if the parameter does not represent a URL, GUID, or Version.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2243
// The code that's violating the rule is on this line.
#pragma warning restore CA2243
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2243.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Example

The following example shows code for the `AssemblyFileVersionAttribute` that violates this rule.

```
[AttributeUsage(AttributeTargets.Assembly, Inherited = false)]
[ComVisible(true)]
public sealed class AssemblyFileVersionAttribute : Attribute
{
    public AssemblyFileVersionAttribute(string version) { }

    public string Version { get; set; }
}

// Since the parameter is typed as a string, it is possible
// to pass an invalid version number at compile time. The rule
// would be violated by the following code: [assembly : AssemblyFileVersion("xxxxx")]
```

The rule is triggered by the following parameters:

- Parameters that contain 'version' and cannot be parsed to `System.Version`.
- Parameters that contain 'guid' and cannot be parsed to `System.Guid`.
- Parameters that contain 'uri', 'urn', or 'url' and cannot be parsed to `System.Uri`.

- [CA1054: URI parameters should not be strings](#)

CA2244: Do not duplicate indexed element initializations

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2244
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An object initializer has more than one indexed element initializer with the same constant index. All but the last initializer are redundant.

Rule description

[Object initializers](#) let you assign values to any accessible fields or properties of an object at creation time without having to invoke a constructor followed by lines of assignment statements.

Indexed element initializers in objects initializers must initialize unique elements. A duplicate index will overwrite a previous element initialization.

How to fix violations

To fix violations, remove all the redundant indexed element initializers that are overwritten by any of the subsequent element initializer(s). For example, the following code snippet shows a violation of the rule and couple of potential fixes:

```
using System.Collections.Generic;

class C
{
    public void M()
    {
        var dictionary = new Dictionary<int, int>
        {
            [1] = 1, // CA2244
            [2] = 2,
            [1] = 3
        };
    }
}
```

```
using System.Collections.Generic;

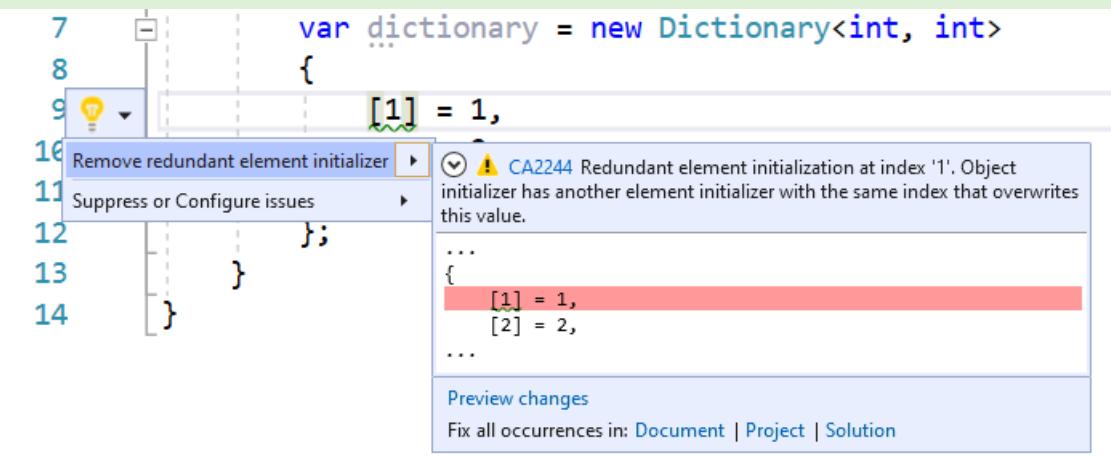

class C
{
    public void M()
    {
        var dictionary = new Dictionary<int, int>
        {
            [2] = 2,
            [1] = 3
        };
    }
}
```

```
using System.Collections.Generic;

class C
{
    public void M()
    {
        var dictionary = new Dictionary<int, int>
        {
            [1] = 1,
            [2] = 2
        };
    }
}
```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Remove redundant element initializer** from the list of options that's presented.

When to suppress warnings

Do not suppress violations for this rule.

See also

- [Usage rules](#)

CA2245: Do not assign a property to itself

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2245
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A property was accidentally assigned to itself.

Rule description

C# compiler generates a warning [CS1717: Assignment made to same variable; did you mean to assign something else?](#) when a field, local or parameter symbol is assigned to itself. Such a mistake is common when a local, parameter, or field symbol has a name similar to another symbol in scope. Instead of using different symbols on the left-hand and right-hand side of the assignment, the same symbol was used on both sides. This leads to a redundant assignment of the value to itself and generally indicates a functional bug.

Assigning a property to itself is also a similar functional bug for almost all real world cases. However, in some extreme corner cases, fetching a property value can have side effects and the property's new value is different from the original value. If so, property self-assignment is not redundant and cannot be removed. This prevents the compiler from generating a [CS1717](#) warning for property self-assignment, without introducing a breaking change for these cases.

Rule [CA2245](#) aims at filling this gap. It reports the violation for property self-assignment to help fix these functional bugs. For the small set of corner cases where property self-assignment is desirable, [CA2245](#) violations can be suppressed in source with an appropriate justification comment.

How to fix violations

To fix violations, use different symbols on the left-hand and the right-hand side of the assignment. For example, the following code snippet shows a violation of the rule and how to fix it:

```
public class C
{
    private int p = 0;
    public int P { get; private set; }

    public void M(int p)
    {
        // CS1717: Accidentally assigned the parameter 'p' to itself.
        p = p;

        // CA2245: Accidentally assigned the property 'P' to itself.
        P = P;
    }
}
```

```
public class C
{
    private int p = 0;
    public int P { get; private set; }

    public void M(int p)
    {
        // No violation, now the parameter is assigned to the field.
        this.p = p;

        // No violation, now the parameter is assigned to the property.
        P = p;
    }
}
```

When to suppress warnings

It is safe to suppress violations from this rule if fetching a property value can have side effects and the property's new value is different from the original value. If so, property self-assignment is not redundant. A justification comment should be added to the suppression to document this as expected behavior.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2245
// The code that's violating the rule is on this line.
#pragma warning restore CA2245
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2245.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Related rules

- [CS1717: Assignment made to same variable; did you mean to assign something else?](#)
- [CA2011: Do not assign property within its setter](#)
- [CA2246: Do not assign a symbol and its member in the same statement](#)

CA2246: Do not assign a symbol and its member in the same statement

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2246
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A symbol and its member were assigned in the same statement. For example:

```
// 'a' and 'a.Field' are assigned in the same statement
a.Field = a = b;
```

Rule description

Assigning a symbol and its member, that is, a field or a property, in the same statement is not recommended. It is not clear if the member access was intended to use the symbol's old value prior to the assignment or the new value from the assignment in this statement. For clarity, the multi-assign statement must be split into two or more simple assignment statements.

How to fix violations

To fix violations, split the multi-assign statement into two or more simple assignment statements. For example, the following code snippet shows a violation of the rule and a couple of ways to fix it based on the user intent:

```
public class C
{
    public C Field;
}

public class Test
{
    public void M(C a, C b)
    {
        // Let us assume 'a' points to 'Instance1' and 'b' points to 'Instance2' at the start of the method.
        // It is not clear if the user intent in the below statement is to assign to 'Instance1.Field' or
        'Instance2.Field'.
        // CA2246: Symbol 'a' and its member 'Field' are both assigned in the same statement. You are at
        risk of assigning the member of an unintended object.
        a.Field = a = b;
    }
}
```

```
public class C
{
    public C Field;
}

public class Test
{
    public void M(C a, C b)
    {
        // Let us assume 'a' points to 'Instance1' and 'b' points to 'Instance2' at the start of the method.
        // 'Instance1.Field' is intended to be assigned.
        var instance1 = a;
        a = b;
        instance1.Field = a;
    }
}
```

```
public class C
{
    public C Field;
}

public class Test
{
    public void M(C a, C b)
    {
        // Let us assume 'a' points to 'Instance1' and 'b' points to 'Instance2' at the start of the method.
        // 'Instance2.Field' is intended to be assigned.
        a = b;
        b.Field = a; // or 'a.Field = a;'
    }
}
```

When to suppress warnings

Do not suppress violations from this rule.

Related rules

- [CA2245: Do not assign a property to itself](#)

See also

- [Usage rules](#)

CA2247: Argument passed to TaskCompletionSource constructor should be TaskCreationOptions enum instead of TaskContinuationOptions enum

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2247
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

Constructing a `System.Threading.Tasks.TaskCompletionSource` with a `System.Threading.Tasks.TaskContinuationOptions` enum value rather than a `System.Threading.Tasks.TaskCreationOptions` enum value. Using `System.Object.ReferenceEquals` method to test one or more value types for equality.

Rule description

The `TaskCompletionSource` type has a constructor that accepts a `System.Threading.Tasks.TaskCreationOptions` enum value, and another constructor that accepts a `Object`. Accidentally passing a `System.Threading.Tasks.TaskContinuationOptions` enum value instead of a `System.Threading.Tasks.TaskCreationOptions` enum value will result in calling the `Object`-based constructor: it will compile and run, but it will not have the intended behavior.

How to fix violations

To fix the violation, replace the `System.Threading.Tasks.TaskContinuationOptions` enum value with the corresponding `System.Threading.Tasks.TaskCreationOptions` enum value.

```
// Violation
var tcs = new TaskCompletionSource<int>(TaskContinuationOptions.RunContinuationsAsynchronously);

// Fixed
var tcs = new TaskCompletionSource<int>(TaskCreationOptions.RunContinuationsAsynchronously);
```

When to suppress warnings

A violation of this rule almost always highlights a bug in the calling code, such that the code will not behave as the developer intended, with the `TaskCompletionSource` effectively ignoring the specified option. The only time it is safe to suppress the warning is if the developer actually intended to pass a boxed `System.Threading.Tasks.TaskContinuationOptions` as the object state argument to the `TaskCompletionSource`.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2247
// The code that's violating the rule is on this line.
#pragma warning restore CA2247
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.CA2247.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings..](#)

See also

- [Usage rules](#)

CA2248: Provide correct enum argument to `Enum.HasFlag`

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2248
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

The enum type passed as an argument to the `HasFlag` method call is different from the calling enum type.

Rule description

The `Enum.HasFlag` method expects the `enum` argument to be of the same `enum` type as the instance on which the method is invoked. If these are different `enum` types, an unhandled exception will be thrown at run time.

How to fix violations

To fix violations, use the same enum type on both the argument and the caller:

```
public class C
{
    [Flags]
    public enum MyEnum { A, B, }

    [Flags]
    public enum OtherEnum { A, }

    public void Method(MyEnum m)
    {
        m.HasFlag(OtherEnum.A); // Enum types are different, this call will cause an `ArgumentException` to
        // be thrown at run time

        m.HasFlag(MyEnum.A); // Valid call
    }
}
```

When to suppress warnings

Do not suppress violations from this rule.

CA2249: Consider using String.Contains instead of String.IndexOf

9/20/2022 • 3 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2249
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

This rule locates calls to `IndexOf` where the result is used to check for the presence or absence of a substring, and suggests using `Contains` instead, to improve readability.

Rule description

When `IndexOf` is used to check if the result is equal to `-1` or greater or equal than `0`, the call can be safely substituted with `Contains` without an impact on performance.

Depending on the `IndexOf` overload being used, the suggested fix could get a `comparisonType` argument added:

OVERLOAD	SUGGESTED FIX
<code>String.IndexOf(char)</code>	<code>String.Contains(char)</code>
<code>String.IndexOf(string)</code>	<code>String.Contains(string, StringComparison.CurrentCulture)</code>
<code>String.IndexOf(char, StringComparison.OrdinalIgnoreCase)</code>	<code>String.Contains(char)</code>
<code>String.IndexOf(string, StringComparison.OrdinalIgnoreCase)</code>	<code>String.Contains(string)</code>
<code>String.IndexOf(char, NON StringComparison.OrdinalIgnoreCase) *</code>	<code>String.Contains(char, NON StringComparison.OrdinalIgnoreCase)</code> *
<code>String.IndexOf(string, NON StringComparison.OrdinalIgnoreCase)</code> *	<code>String.Contains(string, NON StringComparison.OrdinalIgnoreCase)</code> *

* Any `StringComparison` enum value other than `StringComparison.OrdinalIgnoreCase`:

- `CurrentCulture`
- `CurrentCultureIgnoreCase`
- `InvariantCulture`
- `InvariantCultureIgnoreCase`
- `OrdinalIgnoreCase`

How to fix violations

The violation can either be fixed manually, or, in some cases, using Quick Actions to fix code in Visual Studio.

Examples

The following two code snippets show all possible violations of the rule in C# and how to fix them:

```
using System;

class MyClass
{
    void MyMethod()
    {
        string str = "My text";
        bool found;

        // No comparisonType in char overload, so no comparisonType added in resulting fix
        found = str.IndexOf('x') == -1;
        found = str.IndexOf('x') >= 0;

        // No comparisonType in string overload, adds StringComparison.CurrentCulture to resulting fix
        found = str.IndexOf("text") == -1;
        found = str.IndexOf("text") >= 0;

        // comparisonType equal to StringComparison.Ordinal, removes the argument
        found = str.IndexOf('x', StringComparison.Ordinal) == -1;
        found = str.IndexOf('x', StringComparison.Ordinal) >= 0;

        found = str.IndexOf("text", StringComparison.Ordinal) == -1;
        found = str.IndexOf("text", StringComparison.Ordinal) >= 0;

        // comparisonType different than StringComparison.Ordinal, preserves the argument
        found = str.IndexOf('x', StringComparison.OrdinalIgnoreCase) == -1;
        found = str.IndexOf('x', StringComparison.CurrentCulture) >= 0;

        found = str.IndexOf("text", StringComparison.InvariantCultureIgnoreCase) == -1;
        found = str.IndexOf("text", StringComparison.InvariantCulture) >= 0;

        // Suggestion message provided, but no automatic fix offered, must be fixed manually
        int index = str.IndexOf("text");
        if (index == -1)
        {
            Console.WriteLine("'text' Not found.");
        }
    }
}
```

```

using System;

class MyClass
{
    void MyMethod()
    {
        string str = "My text";
        bool found;

        // No comparisonType in char overload, so no comparisonType added in resulting fix
        found = !str.Contains('x');
        found = str.Contains('x');

        // No comparisonType in string overload, adds StringComparison.CurrentCulture to resulting fix
        found = !string.Contains("text", StringComparison.CurrentCulture);
        found = string.Contains("text", StringComparison.CurrentCulture);

        // comparisonType equal to StringComparison.Ordinal, removes the argument
        found = !string.Contains('x');
        found = string.Contains('x');

        found = !string.Contains("text");
        found = string.Contains("text");

        // comparisonType different than StringComparison.Ordinal, preserves the argument
        ;found = !string.Contains('x', StringComparison.OrdinalIgnoreCase)
        found = string.Contains('x', StringComparison.CurrentCulture);

        found = !string.Contains("text", StringComparison.InvariantCultureIgnoreCase);
        found = string.Contains("text", StringComparison.InvariantCulture);

        // This case had to be manually fixed
        if (!str.Contains("text"))
        {
            Console.WriteLine("'text' Not found.");
        }
    }
}

```

TIP

A code fix is available for this rule in Visual Studio. To use it, position the cursor on the violation and press **Ctrl+.** (period). Choose **Consider using 'string.Contains' instead of 'string.IndexOf'** from the list of options that's presented.

When to suppress warnings

It's safe to suppress a violation of this rule if improving code readability is not a concern.

SUPPRESS A WARNING

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2249
// The code that's violating the rule is on this line.
#pragma warning restore CA2249
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2249.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

SEE ALSO

- [Usage rules](#)

CA2250: Use `ThrowIfCancellationRequested`

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2250
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

This rule flags conditional statements that check `IsCancellationRequested` before throwing `OperationCanceledException`.

Rule description

You can accomplish the same thing by calling `CancellationToken.ThrowIfCancellationRequested()`.

How to fix violations

To fix violations, replace the conditional statement with a call to `ThrowIfCancellationRequested()`.

```
using System;
using System.Threading;

public void MySlowMethod(CancellationToken token)
{
    // Violation
    if (token.IsCancellationRequested)
        throw new OperationCanceledException();

    // Fix
    token.ThrowIfCancellationRequested();

    // Violation
    if (token.IsCancellationRequested)
        throw new OperationCanceledException();
    else
        DoSomethingElse();

    // Fix
    token.ThrowIfCancellationRequested();
    DoSomethingElse();
}
```

```
Imports System
Imports System.Threading

Public Sub MySlowMethod(token As CancellationToken)

    ' Violation
    If token.IsCancellationRequested Then
        Throw New OperationCanceledException()
    End If

    ' Fix
    token.ThrowIfCancellationRequested()

    ' Violation
    If token.IsCancellationRequested Then
        Throw New OperationCanceledException()
    Else
        DoSomethingElse()
    End If

    ' Fix
    token.ThrowIfCancellationRequested()
    DoSomethingElse()
End Sub
```

When to suppress warnings

It is safe to suppress warnings from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2250
// The code that's violating the rule is on this line.
#pragma warning restore CA2250
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2250.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2251: Use `String.Equals` over `String.Compare`

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2251
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

The result of a call to `String.Compare` is compared to zero.

Rule description

`String.Compare` is designed to produce a total-order comparison that can be used for sorting. If you only care whether the strings are equal, it is both clearer and likely faster to use an equivalent overload of `String.Equals`.

How to fix violations

To fix violations of this rule, replace the expression comparing the result of `String.Compare` with a call to `String.Equals`.

When to suppress warnings

It is safe to suppress warnings from this rule.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2251
// The code that's violating the rule is on this line.
#pragma warning restore CA2251
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2251.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2252: Opt in to preview features before using them

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2252
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

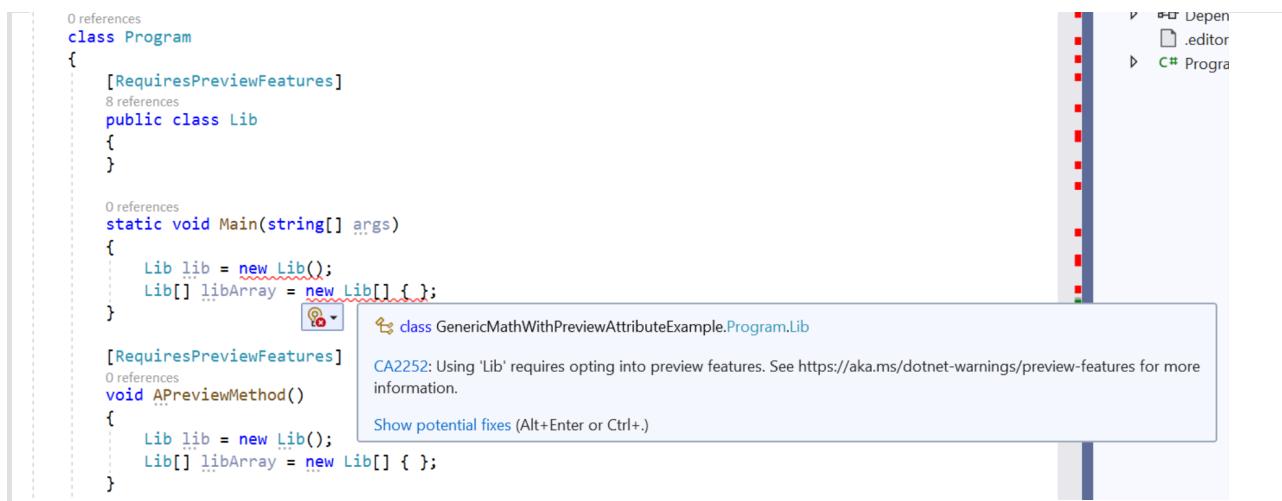

A client uses preview APIs or types in their assembly without explicitly opting in either locally or at the module or assembly level.

Rule description

When an API or assembly that's decorated with the [RequiresPreviewFeaturesAttribute](#) attribute is consumed, this rule checks if the call site has opted in to preview features. A call site has opted in to preview features if one of the following applies:

- It is within the scope of a `RequiresPreviewFeaturesAttribute` annotation.
- It is part of an assembly or module that has already opted in to preview features.

The following image shows an example of the CA2252 diagnostic.

Here, `Lib` is a preview type that's constructed in the `Main` method. `Main` itself is not annotated as a preview method, so diagnostics are produced on the two constructors calls inside `Main`.

How to fix violations

There are two ways to fix violations:

- Bring a call site within the scope of an annotation by annotating its parent with `RequiresPreviewFeaturesAttribute`. In the previous example, `APreviewMethod` is annotated with the `RequiresPreviewFeatures` attribute, so the analyzer ignores preview type usage inside `APreviewMethod`. It follows that callers of `APreviewMethod` will have to perform a similar exercise.
- You can also opt in to preview features at an assembly or module level. This indicates to the analyzer that preview type usage in the assembly is desired and, as a consequence, no errors will be produced by this rule. This is the preferred way to consume preview dependencies. To enable preview features inside the entire assembly, set the `EnablePreviewFeatures` property in a `.csproj` file:

```
<PropertyGroup>
  <EnablePreviewFeatures>true</EnablePreviewFeatures>
</PropertyGroup>
```

When to suppress warnings

Suppressing warnings from this rule is only recommended for advanced use cases where diagnostics on APIs need to explicitly disabled. In this case, you must be willing to take on the responsibility of marking preview APIs appropriately. For example, consider a case where an existing type implements a new preview interface. Since the entire type cannot be marked as preview (for backwards compatibility), the diagnostic around the type definition can be disabled locally. Further, you need to mark the preview interface implementations as preview. Now, the existing type can be used as before, but calls to the new interface methods will get diagnostics.

`System.Private.CoreLib.csproj` uses this technique to expose generic math features on numeric types such as `Int32`, `Double`, and `Decimal`.

The following images show how to disable the CA2252 analyzer locally.

```
public readonly struct Int32 : IComparable, IConvertible, ISpanFormattable, IComparable<int>, IEquatable<int>
#if FEATURE_GENERIC_MATH
#pragma warning disable SA1001, CA2252 // SA1001: Comma positioning; CA2252: Preview Features
    , IBinaryInteger<int>,
    IMin.MaxValue<int>,
    ISignedNumber<int>
#endif // FEATURE_GENERIC_MATH
```

```
//  
// IBinaryInteger  
  
[RequiresPreviewFeatures]  
static int IBinaryInteger<int>.LeadingZeroCount(int value)  
    => BitOperations.LeadingZeroCount((uint)value);  
  
[RequiresPreviewFeatures]  
static int IBinaryInteger<int>.PopCount(int value)  
    => BitOperations.PopCount((uint)value);  
  
[RequiresPreviewFeatures]  
static int IBinaryInteger<int>.RotateLeft(int value, int rotateAmount)  
    => (int)BitOperations.RotateLeft((uint)value, rotateAmount);  
  
[RequiresPreviewFeatures]  
static int IBinaryInteger<int>.RotateRight(int value, int rotateAmount)  
    => (int)BitOperations.RotateRight((uint)value, rotateAmount);  
  
[RequiresPreviewFeatures]  
static int IBinaryInteger<int>.TrailingZeroCount(int value)  
    => BitOperations.TrailingZeroCount(value);
```

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2252  
// The code that's violating the rule is on this line.  
#pragma warning restore CA2252
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_diagnostic.CA2252.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2253: Named placeholders should not be numeric values

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2253
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A message placeholder consists of numeric characters only.

Rule description

Named placeholders in the logging message template should not be comprised of only numeric characters.

How to fix violations

Rename the numeric placeholder.

For usage examples, see the [LoggerExtensions.LogInformation](#) method.

When to suppress errors

Do not suppress a warning from this rule.

See also

- [Usage warnings](#)

CA2254: Template should be a static expression

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2254
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

A message template passed to a logger API is not constant.

Rule description

When performing logging, it's desirable to preserve the structure of the log (including placeholder names) along with the placeholder values. Preserving this information allows for better observability and search in log aggregation and monitoring software.

Preferred:

```
var firstName = "Lorenz";
var lastName = "Otto";

// This tells the logger that there are FirstName and LastName properties
// on the log message, and correlates them with the argument values.
logger.Warning("Person {FirstName} {LastName} encountered an issue", firstName, lastName);
```

Not preferred:

```
// DO NOT DO THIS

var firstName = "Lorenz";
var lastName = "Otto";

// Here, the log template itself is changing, and the association between named placeholders and their
// values is lost.
logger.Warning("Person " + firstName + " " + lastName + " encountered an issue");

// String interpolation also loses the association between placeholder names and their values.
logger.Warning($"Person {firstName} {lastName} encountered an issue");
```

The logging message template should not vary between calls.

How to fix violations

Update the message template to be a constant expression. If you're using values directly in the template, refactor them to use named placeholders instead.

```
logger.Warning("Person {FirstName} {LastName} encountered an issue", firstName, lastName);
```

When to suppress errors

Do not suppress a warning from this rule.

- [Usage warnings](#)

CA2255: The `ModuleInitializer` attribute should not be used in libraries

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2255
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

Applying `ModuleInitializerAttribute` to a method within a Class Library.

Rule description

Module initializers are intended to be used by application code to ensure an application's components are initialized before the application code begins executing. If library code declares a method with the `ModuleInitializerAttribute`, it can interfere with application initialization and also lead to limitations in that application's trimming abilities. Library code should therefore not utilize the `ModuleInitializerAttribute` attribute.

How to fix violations

Instead of using methods marked with `ModuleInitializerAttribute`, the library should expose methods that can be used to initialize any components within the library and allow the application to invoke the method during application initialization.

When to suppress warnings

It is safe to suppress warnings from this rule if a solution uses a Class Library for code factoring purposes, and the `ModuleInitializerAttribute` method is not part of a shared or distributed library or package.

Suppress a warning

If you just want to suppress a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable CA2255
// The code that's violating the rule is on this line.
#pragma warning restore CA2255
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.CA2255.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Usage.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

CA2256: All members declared in parent interfaces must have an implementation in a DynamicInterfaceCastableImplementation-attributed interface

9/20/2022 • 2 minutes to read • [Edit Online](#)

	Value
Rule ID	CA2256
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An interface with [DynamicInterfaceCastableImplementationAttribute](#) has a non-implemented member.

Rule description

Types attributed with [DynamicInterfaceCastableImplementationAttribute](#) act as an interface implementation for a type that implements the `IDynamicInterfaceCastable` type. As a result, it must provide an implementation of all of the members defined in the inherited interfaces, because the type that implements `IDynamicInterfaceCastable` will not provide them otherwise.

How to fix violations

Implement the missing interface members.

When to suppress errors

Do not suppress a warning from this rule.

See also

- [Usage warnings](#)

CA2257: Members defined on an interface with the 'DynamicInterfaceCastableImplementationAttribute' should be 'static'

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2257
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

An interface member isn't explicitly implemented or marked `static`.

Rule description

Since a type that implements `IDynamicInterfaceCastable` may not implement a dynamic interface in metadata, calls to an instance interface member that is not an explicit implementation defined on this type are likely to fail at run time. To avoid run-time errors, mark new interface members `static`.

How to fix violations

Mark the interface member `static`.

When to suppress errors

Do not suppress a warning from this rule.

See also

- [Usage warnings](#)

CA2258: Providing a 'DynamicInterfaceCastableImplementation' interface in Visual Basic is unsupported

9/20/2022 • 2 minutes to read • [Edit Online](#)

	VALUE
Rule ID	CA2258
Category	Usage
Fix is breaking or non-breaking	Non-breaking

Cause

Use of [DynamicInterfaceCastableImplementationAttribute](#) in Visual Basic.

Rule description

Providing a functional interface that's attributed with [DynamicInterfaceCastableImplementationAttribute](#) requires the Default Interface Members feature, which is not supported in Visual Basic.

When to suppress errors

Do not suppress a warning from this rule.

See also

- [Usage warnings](#)

Code-style rules

9/20/2022 • 4 minutes to read • [Edit Online](#)

.NET code-style analysis provides rules that aim to maintain consistent *style* in your codebase. These rules have an "IDE" prefix in the rule ID.

Most of the rules have one or more associated options to customize the preferred style. For example, [Use simple 'using' statement \(IDE0063\)](#) has the associated option `csharp_prefer_simple_using_statement` that lets you define whether you prefer a `using` declaration or a `using` statement. The rule enforces whichever options you choose at a specified level (for example, warning or error).

The code-style rules are organized into the following subcategories:

- [Language rules](#)

Rules that pertain to the C# or Visual Basic language. For example, you can specify rules that regard the use of `var` when defining variables, or whether expression-bodied members are preferred.

- [Unnecessary code rules](#)

Rules that pertain to unnecessary code that indicates a potential readability, maintainability, performance, or functional problem. For example, unreachable code within methods or unused private fields, properties, or methods is unnecessary code.

- [Formatting rules](#)

Rules that pertain to the layout and structure of your code in order to make it easier to read. For example, you can specify a formatting option that defines whether spaces in control blocks are preferred or not.

- [Naming rules](#)

Rules that pertain to the naming of code elements. For example, you can specify that `async` method names must have an "Async" suffix.

- [Miscellaneous rules](#)

Rules that do not belong in other categories.

Index

The following table lists all the code-style rules by ID and [options](#), if any.

RULE ID	TITLE	OPTION
IDE0001	Simplify name	
IDE0002	Simplify member access	
IDE0003	Remove <code>this</code> or <code>Me</code> qualification	<code>dotnet_style_qualification_for_field</code> <code>dotnet_style_qualification_for_property</code> <code>dotnet_style_qualification_for_method</code> <code>dotnet_style_qualification_for_event</code>
IDE0004	Remove unnecessary cast	

RULE ID	TITLE	OPTION
IDE0005	Remove unnecessary import	
IDE0007	Use <code>var</code> instead of explicit type	<code>csharp_style_var_for_builtin_types</code> <code>csharp_style_var_when_type_is_apparent</code> <code>csharp_style_var_elsewhere</code>
IDE0008	Use explicit type instead of <code>var</code>	<code>csharp_style_var_for_builtin_types</code> <code>csharp_style_var_when_type_is_apparent</code> <code>csharp_style_var_elsewhere</code>
IDE0009	Add <code>this</code> or <code>Me</code> qualification	<code>dotnet_style_qualification_for_field</code> <code>dotnet_style_qualification_for_property</code> <code>dotnet_style_qualification_for_method</code> <code>dotnet_style_qualification_for_event</code>
IDE0010	Add missing cases to switch statement	
IDE0011	Add braces	<code>csharp_prefer_braces</code>
IDE0016	Use throw expression	<code>csharp_style_throw_expression</code>
IDE0017	Use object initializers	<code>dotnet_style_object_initializer</code>
IDE0018	Inline variable declaration	<code>csharp_style_inlined_variable_declaration</code>
IDE0019	Use pattern matching to avoid <code>as</code> followed by a <code>null</code> check	<code>csharp_style_pattern_matching_over_as_with_null_check</code>
IDE0020	Use pattern matching to avoid <code>is</code> check followed by a cast (with variable)	<code>csharp_style_pattern_matching_over_is_with_cast_check</code>
IDE0021	Use expression body for constructors	<code>csharp_style_expression_bodied_constructors</code>
IDE0022	Use expression body for methods	<code>csharp_style_expression_bodied_methods</code>
IDE0023	Use expression body for conversion operators	<code>csharp_style_expression_bodied_operators</code>
IDE0024	Use expression body for operators	<code>csharp_style_expression_bodied_operators</code>
IDE0025	Use expression body for properties	<code>csharp_style_expression_bodied_properties</code>
IDE0026	Use expression body for indexers	<code>csharp_style_expression_bodied_indexers</code>

RULE ID	TITLE	OPTION
IDE0027	Use expression body for accessors	csharp_style_expression_bodied_accessors
IDE0028	Use collection initializers	dotnet_style_collection_initializer
IDE0029	Use coalesce expression (non-nullable types)	dotnet_style_coalesce_expression
IDE0030	Use coalesce expression (nullable types)	dotnet_style_coalesce_expression
IDE0031	Use null propagation	dotnet_style_null_propagation
IDE0032	Use auto property	dotnet_style_prefer_auto_properties
IDE0033	Use explicitly provided tuple name	dotnet_style_explicit_tuple_names
IDE0034	Simplify <code>default</code> expression	csharp_prefer_simple_default_expression
IDE0035	Remove unreachable code	
IDE0036	Order modifiers	csharp_preferred_modifier_order visual_basic_preferred_modifier_order
IDE0037	Use inferred member name	dotnet_style_prefer_inferred_tuple_names dotnet_style_prefer_inferred_anonymous_type_member_names
IDE0038	Use pattern matching to avoid <code>is</code> check followed by a cast (without variable)	csharp_style_pattern_matching_over_is_with_cast_check
IDE0039	Use local function instead of lambda	csharp_style_prefer_local_over_anonymous_function
IDE0040	Add accessibility modifiers	dotnet_style_require_accessibility_modifiers
IDE0041	Use <code>is null</code> check	dotnet_style_prefer_is_null_check_over_reference_equality_method
IDE0042	Deconstruct variable declaration	csharp_style_deconstructed_variable_declaration
IDE0044	Add <code>readonly</code> modifier	dotnet_style_READONLY_field
IDE0045	Use conditional expression for assignment	dotnet_style_prefer_conditional_expression_over_assignment
IDE0046	Use conditional expression for return	dotnet_style_prefer_conditional_expression_over_return

RULE ID	TITLE	OPTION
IDE0047	Remove unnecessary parentheses	dotnet_style_parentheses_in_arithmetic_binary_operators dotnet_style_parentheses_in_relational_binary_operators dotnet_style_parentheses_in_other_binary_operators dotnet_style_parentheses_in_other_operators
IDE0048	Add parentheses for clarity	dotnet_style_parentheses_in_arithmetic_binary_operators dotnet_style_parentheses_in_relational_binary_operators dotnet_style_parentheses_in_other_binary_operators dotnet_style_parentheses_in_other_operators
IDE0049	Use language keywords instead of framework type names for type references	dotnet_style_predefined_type_for_locals_parameters_members dotnet_style_predefined_type_for_member_access
IDE0050	Convert anonymous type to tuple	
IDE0051	Remove unused private member	
IDE0052	Remove unread private member	
IDE0053	Use expression body for lambdas	csharp_style_expression_bodied_lambdas
IDE0054	Use compound assignment	dotnet_style_prefer_compound_assignment
IDE0055	Fix formatting	(Too many to list here. See .NET formatting options and C# formatting options .)
IDE0056	Use index operator	csharp_style_prefer_index_operator
IDE0057	Use range operator	csharp_style_prefer_range_operator
IDE0058	Remove unused expression value	csharp_style_unused_value_expression_statement_preference visual_basic_style_unused_value_expression_statement_preference
IDE0059	Remove unnecessary value assignment	csharp_style_unused_value_assignment_preference visual_basic_style_unused_value_assignment_preference
IDE0060	Remove unused parameter	dotnet_code_quality_unused_parameters

RULE ID	TITLE	OPTION
IDE0061	Use expression body for local functions	csharp_style_expression_bodied_local_functions
IDE0062	Make local function static	csharp_prefer_static_local_function
IDE0063	Use simple <code>using</code> statement	csharp_prefer_simple_using_statement
IDE0064	Make struct fields writable	
IDE0065	<code>using</code> directive placement	csharp_using_directive_placement
IDE0066	Use switch expression	csharp_style_prefer_switch_expression
IDE0070	Use <code>System.HashCode.Combine</code>	
IDE0071	Simplify interpolation	dotnet_style_prefer_simplified_interpolation
IDE0072	Add missing cases to switch expression	
IDE0073	Use file header	file_header_template
IDE0074	Use coalesce compound assignment	dotnet_style_prefer_compound_assignment
IDE0075	Simplify conditional expression	dotnet_style_prefer_simplified_boolean_expressions
IDE0076	Remove invalid global <code>SuppressMessageAttribute</code>	
IDE0077	Avoid legacy format target in global <code>SuppressMessageAttribute</code>	
IDE0078	Use pattern matching	csharp_style_prefer_pattern_matching
IDE0079	Remove unnecessary suppression	dotnet_remove_unnecessary_suppression_exclusions
IDE0080	Remove unnecessary suppression operator	
IDE0081	Remove <code>ByVal</code>	
IDE0082	Convert <code>typeof</code> to <code>nameof</code>	
IDE0083	Use pattern matching (<code>not</code> operator)	csharp_style_prefer_not_pattern
IDE0084	Use pattern matching (<code> IsNot</code> operator)	visual_basic_style_prefer_isnot_expression

Rule ID	Title	Option
IDE0090	Simplify <code>new</code> expression	<code>csharp_style_implicit_object_creation_when_type_is_apparent</code>
IDE0100	Remove unnecessary equality operator	
IDE0110	Remove unnecessary discard	
IDE0140	Simplify object creation	<code>visual_basic_style_prefer_simplified_object_creation</code>
IDE0150	Prefer <code>null</code> check over type check	<code>csharp_style_prefer_null_check_over_type_check</code>
IDE0160	Use block-scoped namespace	<code>csharp_style_namespace_declarations</code>
IDE0161	Use file-scoped namespace	<code>csharp_style_namespace_declarations</code>
IDE0170	Simplify property pattern	<code>csharp_style_prefer_extended_property_pattern</code>
IDE0180	Use tuple to swap values	<code>csharp_style_prefer_tuple_swap</code>
IDE1005	Use conditional delegate call	<code>csharp_style_conditional_delegate_call</code>
IDE1006	Naming styles	

Legend

The following table shows the type of information that's provided for each rule in the reference documentation.

Item	Description
Rule ID	The unique identifier for the rule. Used for configuring rule severity and suppressing warnings in the code file.
Title	The title for the rule.
Category	The category for the rule.
Subcategory	The subcategory for the rule, such as Language rules, Formatting rules, or Naming rules.
Applicable languages	Applicable .NET languages (C# or Visual Basic), along with the minimum language version, if applicable.
Introduced version	Version of the .NET SDK or Visual Studio when the rule was first introduced.
Options	Any available options for the rule.

See also

- Enforce code style on build
- Quick Actions in Visual Studio
- Create portable custom editor options in Visual Studio

Language rules

9/20/2022 • 3 minutes to read • [Edit Online](#)

Code-style language rules affect how various constructs of .NET programming languages, for example, modifiers, and parentheses, are used. The rules fall into the following categories:

- **.NET style rules:** Rules that apply to both C# and Visual Basic. The option names for these rules start with the prefix `dotnet_style_`.
- **C# style rules:** Rules that are specific to C# code. The option names for these rules start with the prefix `csharp_style_`.
- **Visual Basic style rules:** Rules that are specific to Visual Basic code. The option names for these rules start with the prefix `visual_basic_style_`.

Option format

Options for language rules can be specified in a [configuration file](#) with the following format:

`option_name = value` (Visual Studio 2019 version 16.9 and later)

or

`option_name = value:severity`

- **Value**

For each language rule, you specify a value that defines if or when to prefer the style. Many rules accept a value of `true` (prefer this style) or `false` (do not prefer this style). Other rules accept values such as `when_on_single_line` or `never`.

- **Severity** (optional in Visual Studio 2019 version 16.9 and later versions)

The second part of the rule specifies the [severity level](#) for the rule. When specified in this way, *the severity setting is only respected inside development IDEs, such as Visual Studio*. It is *not* respected during build.

To enforce code style rules at build time, set the severity by using the rule ID-based severity configuration syntax for analyzers instead. The syntax takes the form

`dotnet_diagnostic.<rule ID>.severity = <severity>`, for example,
`dotnet_diagnostic.IDE0040.severity = none`. For more information, see [severity level](#).

TIP

Starting in Visual Studio 2019 version 16.3, you can configure code style rules from the [Quick Actions](#) light bulb menu after a style violation occurs. For more information, see [Automatically configure code styles in Visual Studio](#).

.NET style rules

The style rules in this section are applicable to both C# and Visual Basic.

- ['this.' and 'Me.' qualifiers](#)
- [Language keywords instead of framework type names for type references](#)
- [Modifier preferences](#)
 - [Order modifiers \(IDE0036\)](#)

- Add accessibility modifiers (IDE0040)
- Add readonly modifier (IDE0044)
- Parentheses preferences
- Expression-level preferences
 - Use object initializers (IDE0017)
 - Use collection initializers (IDE0028)
 - Use auto-implemented property (IDE0032)
 - Use explicitly provided tuple name (IDE0033)
 - Use inferred member names (IDE0037)
 - Use conditional expression for assignment (IDE0045)
 - Use conditional expression for return (IDE0046)
 - Use compound assignment (IDE0054 and IDE0074)
 - Simplify interpolation (IDE0071)
 - Simplify conditional expression (IDE0075)
 - Add missing cases to switch statement (IDE0010)
 - Convert anonymous type to tuple (IDE0050)
 - Use 'System.HashCode.Combine' (IDE0070)
 - Convert `typeof` to `nameof` (IDE0082)
- Null-checking preferences
 - Use coalesce expression (IDE0029 and IDE0030)
 - Use null propagation (IDE0031)
 - Use 'is null' check (IDE0041)
- File header preferences

C# style rules

The style rules in this section are applicable to C# language only.

- 'var' preferences (IDE0007 and IDE0008)
- Expression-bodied members
 - Use expression body for constructors (IDE0021)
 - Use expression body for methods (IDE0022)
 - Use expression body for operators (IDE0023 and IDE0024)
 - Use expression body for properties (IDE0025)
 - Use expression body for indexers (IDE0026)
 - Use expression body for accessors (IDE0027)
 - Use expression body for lambdas (IDE0053)
 - Use expression body for local functions (IDE0061)
- Pattern matching preferences
 - Use pattern matching to avoid 'as' followed by a 'null' check (IDE0019)
 - Use pattern matching to avoid 'is' check followed by a cast (IDE0020 and IDE0038)
 - Use switch expression (IDE0066)
 - Use pattern matching (IDE0078)
 - Use pattern matching (`not` operator) (IDE0083)
 - Simplify property pattern (IDE0170)
- Expression-level preferences
 - Inline variable declaration (IDE0018)
 - Simplify 'default' expression (IDE0034)

- Use local function instead of lambda (IDE0039)
- Deconstruct variable declaration (IDE0042)
- Use index operator (IDE0056)
- Use range operator (IDE0057)
- Simplify `new` expression (IDE0090)
- Add missing cases to switch expression (IDE0072)
- Use tuple to swap values (IDE0180)
- "Null" checking preferences
 - Use throw expression (IDE0016)
 - Use conditional delegate call (IDE1005)
 - Prefer 'null' check over type check (IDE0150)
- Code block preferences
 - Add braces (IDE0011)
 - Use simple 'using' statement (IDE0063)
- 'using' directive preferences (IDE0065)
- Modifier preferences
 - Make local function static (IDE0062)
 - Make struct fields writable (IDE0064)
- Namespace declaration preferences (IDE0160 and IDE0161)

Visual Basic style rules

The style rules in this section are applicable to Visual Basic language only.

- Pattern matching preferences
 - Use pattern matching (`IsNot` operator) (IDE0084)

this and Me preferences (IDE0003 and IDE0009)

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0003](#) and [IDE0009](#).

PROPERTY	VALUE
Rule ID	IDE0003
Title	Remove <code>this</code> or <code>Me</code> qualification
Category	Style
Subcategory	Language rules
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_qualification_for_field</code> <code>dotnet_style_qualification_for_property</code> <code>dotnet_style_qualification_for_method</code> <code>dotnet_style_qualification_for_event</code>

PROPERTY	VALUE
Rule ID	IDE0009
Title	Add <code>this</code> or <code>Me</code> qualification
Category	Style
Subcategory	Language rules
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_qualification_for_field</code> <code>dotnet_style_qualification_for_property</code> <code>dotnet_style_qualification_for_method</code> <code>dotnet_style_qualification_for_event</code>

Overview

These two rules define whether or not you prefer the use of `this` (C#) and `Me.` (Visual Basic) qualifiers. To

enforce that the qualifiers *aren't* present, set the severity of `IDE0003` to warning or error. To enforce that the qualifiers *are* present, set the severity of `IDE0009` to warning or error.

For example, if you prefer qualifiers for fields and properties but not for methods or events, then you can enable `IDE0009` and set the options `dotnet_style_qualification_for_field` and `dotnet_style_qualification_for_property` to `true`. However, this configuration would not flag methods and events that *do* have `this` and `Me` qualifiers. To also enforce that methods and events *don't* have qualifiers, enable `IDE0003`.

Options

This rule's associated options define which of the following symbols this style preference should be applied to:

- Fields (`dotnet_style_qualification_for_field`)
- Properties (`dotnet_style_qualification_for_property`)
- Methods (`dotnet_style_qualification_for_method`)
- Events (`dotnet_style_qualification_for_event`)

An option value of `true` means prefer the code symbol to be prefaced with `this.` in C# and `Me.` in Visual Basic. An option value of `false` means prefer the code element *not* to be prefaced with `this.` or `Me.`.

For more information about configuring options, see [Option format](#).

`dotnet_style_qualification_for_field`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_qualification_for_field</code>	
Option values	<code>true</code>	Prefer fields to be prefaced with <code>this.</code> in C# or <code>Me.</code> in Visual Basic
	<code>false</code>	Prefer fields <i>not</i> to be prefaced with <code>this.</code> or <code>Me.</code>
Default option value	<code>false</code>	

```
// dotnet_style_qualification_for_field = true
this.capacity = 0;

// dotnet_style_qualification_for_field = false
capacity = 0;
```

```
' dotnet_style_qualification_for_field = true
Me.capacity = 0

' dotnet_style_qualification_for_field = false
capacity = 0
```

`dotnet_style_qualification_for_property`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_qualification_for_property</code>	

PROPERTY	VALUE	DESCRIPTION
Option values	true	Prefer properties to be prefaced with <code>this.</code> in C# or <code>Me.</code> in Visual Basic.
	false	Prefer properties <i>not</i> to be prefaced with <code>this.</code> or <code>Me.</code> .
Default option value	false	

```
// dotnet_style_qualification_for_property = true
this.ID = 0;

// dotnet_style_qualification_for_property = false
ID = 0;
```

```
' dotnet_style_qualification_for_property = true
Me.ID = 0

' dotnet_style_qualification_for_property = false
ID = 0
```

dotnet_style_qualification_for_method

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_qualification_for_method	
Option values	true	Prefer methods to be prefaced with <code>this.</code> in C# or <code>Me.</code> in Visual Basic.
	false	Prefer methods <i>not</i> to be prefaced with <code>this.</code> or <code>Me.</code> .
Default option value	false	

```
// dotnet_style_qualification_for_method = true
this.Display();

// dotnet_style_qualification_for_method = false
Display();
```

```
' dotnet_style_qualification_for_method = true
Me.Display()

' dotnet_style_qualification_for_method = false
Display()
```

dotnet_style_qualification_for_event

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_qualification_for_event	

PROPERTY	VALUE	DESCRIPTION
Option values	<code>true</code>	Prefer events to be prefaced with <code>this.</code> in C# or <code>Me.</code> in Visual Basic.
	<code>false</code>	Prefer events <i>not</i> to be prefaced with <code>this.</code> or <code>Me.</code> .
Default option value	<code>false</code>	

```
// dotnet_style_qualification_for_event = true
this.Elapsed += Handler;

// dotnet_style_qualification_for_event = false
Elapsed += Handler;
```

```
' dotnet_style_qualification_for_event = true
AddHandler Me.Elapsed, AddressOf Handler

' dotnet_style_qualification_for_event = false
AddHandler Elapsed, AddressOf Handler
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0003 // Or IDE0009
// The code that's violating the rule is on this line.
#pragma warning restore IDE0003 // Or IDE0009
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0003.severity = none
dotnet_diagnostic.IDE0009.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use language keywords instead of framework type names for type references (IDE0049)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0049
Title	Use language keywords instead of framework type names for type references
Category	Style
Subcategory	Language rules
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_predefined_type_for_locals_parameters_members</code> <code>dotnet_style_predefined_type_for_member_access</code>

Overview

This rule concerns the use of language keywords, [where they exist](#), instead of framework type names.

Options

Use the associated options for this rule to apply it to:

- Local variables, method parameters, and class members - [`dotnet_style_predefined_type_for_locals_parameters_members`](#)
- Type-member access expressions - [`dotnet_style_predefined_type_for_member_access`](#)

An option value of `true` means prefer the language keyword (for example, `int` or `Integer`) instead of the type name (for example, `Int32`) for types that have a keyword to represent them. A value of `false` means prefer the type name instead of the language keyword.

For information about configuring options, see [Option format](#).

`dotnet_style_predefined_type_for_locals_parameters_members`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_predefined_type_for_locals_parameters_members</code>	
Option values	<code>true</code>	Prefer the language keyword for local variables, method parameters, and class members

PROPERTY	VALUE	DESCRIPTION
	false	Prefer the type name for local variables, method parameters, and class members
Default option value	true	

```
// dotnet_style_predefined_type_for_locals_parameters_members = true
private int _member;

// dotnet_style_predefined_type_for_locals_parameters_members = false
private Int32 _member;
```

```
' dotnet_style_predefined_type_for_locals_parameters_members = true
Private _member As Integer

' dotnet_style_predefined_type_for_locals_parameters_members = false
Private _member As Int32
```

dotnet_style_predefined_type_for_member_access

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_predefined_type_for_member_access	
Option values	true	Prefer the language keyword for member access expressions
	false	Prefer the type name for member access expressions
Default option value	true	

```
// dotnet_style_predefined_type_for_member_access = true
var local = int.MaxValue;

// dotnet_style_predefined_type_for_member_access = false
var local = Int32.MaxValue;
```

```
' dotnet_style_predefined_type_for_member_access = true
Dim local = Integer.MaxValue

' dotnet_style_predefined_type_for_member_access = false
Dim local = Int32.MaxValue
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0049
// The code that's violating the rule is on this line.
#pragma warning restore IDE0049
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0049.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Modifier preferences

9/20/2022 • 2 minutes to read • [Edit Online](#)

.NET modifier preferences

The style rules in this section concern the following modifier preferences that are common to C# and Visual Basic:

- [Order modifiers \(IDE0036\)](#)
- [Add accessibility modifiers \(IDE0040\)](#)
- [Add readonly modifier \(IDE0044\)](#)

C# modifier preferences

The style rules in this section concern the following modifier preferences that are specific to C#:

- [Make local function static \(IDE0062\)](#)
- [Make struct fields writable \(IDE0064\)](#)

See also

- [Code style rules reference](#)
- [Code style language rules](#)

Order modifiers (IDE0036)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0036
Title	Order modifiers
Category	Style
Subcategory	Language rules (modifier preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.5
Options	<code>csharp_preferred_modifier_order</code>
	<code>visual_basic_preferred_modifier_order</code>

Overview

This rule lets you enforce a desired [modifier](#) sort order.

- When this rule is enabled and the associated options are set to a list of modifiers, prefer the specified ordering.
- When this rule is not enabled, no specific modifier order is preferred.

Options

The associated options for this rule let you specify the desired modifier order for C# and Visual Basic, respectively.

- [`csharp_preferred_modifier_order`](#)
- [`visual_basic_preferred_modifier_order`](#)

For information about configuring options, see [Option format](#).

`csharp_preferred_modifier_order`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_preferred_modifier_order</code>	
Applicable languages	C#	
Option values	One or more C# modifiers, such as <code>public</code> , <code>private</code> , and <code>protected</code>	

PROPERTY	VALUE	DESCRIPTION
Default option value	public, private, protected, internal, file, static, extern, new, virtual, abstract, sealed, override, readonly, unsafe, required, volatile, async	

```
// csharp_preferred_modifier_order =
public,private,protected,internal,static,extern,new,virtual,abstract,sealed,override,readonly,unsafe,volatile,async
class MyClass
{
    private static readonly int _daysInYear = 365;
}
```

visual_basic_preferred_modifier_order

PROPERTY	VALUE	DESCRIPTION
Option name	visual_basic_preferred_modifier_order	
Applicable languages	Visual Basic	
Option values	One or more Visual Basic modifiers, such as <code>Partial</code> , <code>Private</code> , and <code>Public</code>	
Default option value	<code>Partial, Default, Private, Protected, Public, Friend, NotOverridable, Overridable, MustOverride, Overloads, Overrides, MustInherit, NotInheritable, Static, Shared, Shadows, ReadOnly, WriteOnly, Dim, Const, WithEvents, Widening, Narrowing, Custom, Async</code>	

```
' visual_basic_preferred_modifier_order =
Partial,Default,Private,Protected,Public,Friend,NotOverridable,Overridable,MustOverride,Overloads,Overrides,
MustInherit,NotInheritable,Static,Shared,Shadows,ReadOnly,WriteOnly,Dim,Const,WithEvents,Widening,Narrowing,
Custom,Async
Public Class MyClass
    Private Shared ReadOnly daysInYear As Int = 365
End Class
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0036
// The code that's violating the rule is on this line.
#pragma warning restore IDE0036
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0036.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Add accessibility modifiers (IDE0040)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0040
Title	Add accessibility modifiers
Category	Style
Subcategory	Language rules (modifier preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.5
Options	<code>dotnet_style_require_accessibility_modifiers</code>

Overview

This style rule concerns requiring [accessibility modifiers](#) in declarations.

Options

The option value specifies the preferences for required accessibility modifiers.

For information about configuring options, see [Option format](#).

`dotnet_style_require_accessibility_modifiers`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_require_accessibility_modifiers</code>	
Option values	<code>always</code>	Prefer accessibility modifiers to be specified.
	<code>for_non_interface_members</code>	Prefer accessibility modifiers except for public interface members.
	<code>never</code>	Do not prefer accessibility modifiers to be specified.
	<code>omit_if_default</code>	Prefer accessibility modifiers except if they are the default modifier.
Default option value	<code>for_non_interface_members</code>	

```
// dotnet_style_require_accessibility_modifiers = always
// dotnet_style_require_accessibility_modifiers = for_non_interface_members
class MyClass
{
    private const string thisFieldIsConst = "constant";
}

// dotnet_style_require_accessibility_modifiers = never
class MyClass
{
    const string thisFieldIsConst = "constant";
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0040
// The code that's violating the rule is on this line.
#pragma warning restore IDE0040
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0040.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Add readonly modifier (IDE0044)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0044
Title	Add readonly modifier
Category	Style
Subcategory	Language rules (modifier preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.7
Options	<code>dotnet_style_READONLY_FIELD</code>

Overview

This style rule concerns specifying the `readonly` (C#) or `ReadOnly` (Visual Basic) modifier for private fields that are initialized (either inline or inside of a constructor) but never reassigned.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_READONLY_FIELD`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_READONLY_FIELD</code>	
Option values	<code>true</code>	Prefer that private fields be marked <code>readonly</code> if they're only ever assigned inline or in a constructor
	<code>false</code>	Specify no preference over whether private fields are marked <code>readonly</code>
Default option value	<code>true</code>	

```
// dotnet_style_READONLY_FIELD = true
class MyClass
{
    private readonly int _daysInYear = 365;
}
```

```
' dotnet_style_READONLY_field = true
Public Class MyClass
    Private ReadOnly daysInYear As Int = 365
End Class
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0044
// The code that's violating the rule is on this line.
#pragma warning restore IDE0044
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0044.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Make local function static (IDE0062)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0062
Title	Make local function static
Category	Style
Subcategory	Language rules (modifier preferences)
Applicable languages	C# 8.0+
Options	<code>csharp_prefer_static_local_function</code>

Overview

This style rule concerns the preference of marking [local functions](#) as `static` or not.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_prefer_static_local_function`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_prefer_static_local_function</code>	
Option values	<code>true</code>	Prefer local functions to be marked <code>static</code>
	<code>false</code>	Prefer local functions <i>not</i> to be marked <code>static</code>
Default option value	<code>true:suggestion</code>	

```
// csharp_prefer_static_local_function = true
void M()
{
    Hello();
    static void Hello()
    {
        Console.WriteLine("Hello");
    }
}

// csharp_prefer_static_local_function = false
void M()
{
    Hello();
    void Hello()
    {
        Console.WriteLine("Hello");
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0062
// The code that's violating the rule is on this line.
#pragma warning restore IDE0062
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0062.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Modifier preferences](#)

- [Code style rules reference](#)

Make struct fields writable (IDE0064)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0064
Title	Make struct fields writable
Category	CodeQuality
Subcategory	Language rules (modifier preferences)
Applicable languages	C#

Overview

This rule detects structs that contain one or more `readonly` fields and also contain an assignment to `this` outside of the constructor. The rule recommends converting `readonly` fields to non-read only, that is, writable. Marking such struct fields as `readonly` can lead to unexpected behavior, because the value assigned to the field can change when `this` is assigned outside the constructor.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
struct MyStruct
{
    public readonly int Value;

    public MyStruct(int value)
    {
        Value = value;
    }

    public void Test()
    {
        this = new MyStruct(5);
    }
}

// Fixed code
struct MyStruct
{
    public int Value;

    public MyStruct(int value)
    {
        Value = value;
    }

    public void Test()
    {
        this = new MyStruct(5);
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0064
// The code that's violating the rule is on this line.
#pragma warning restore IDE0064
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0064.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Parentheses preferences (IDE0047 and IDE0048)

9/20/2022 • 3 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0047](#) and [IDE0048](#).

PROPERTY	VALUE
Rule ID	IDE0047
Title	Remove unnecessary parentheses
Category	Style
Subcategory	Language rules
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.8
Options	<code>dotnet_style_parentheses_in_arithmetic_binary_operators</code> <code>dotnet_style_parentheses_in_relational_binary_operators</code> <code>dotnet_style_parentheses_in_other_binary_operators</code> <code>dotnet_style_parentheses_in_other_operators</code>

PROPERTY	VALUE
Rule ID	IDE0048
Title	Add parentheses for clarity
Category	Style
Subcategory	Language rules
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.8
Options	<code>dotnet_style_parentheses_in_arithmetic_binary_operators</code> <code>dotnet_style_parentheses_in_relational_binary_operators</code> <code>dotnet_style_parentheses_in_other_binary_operators</code> <code>dotnet_style_parentheses_in_other_operators</code>

Overview

The style rules in this section concern parentheses preferences, including the use of parentheses to clarify precedence for arithmetic, relational, and other binary operators.

Options

This rule has associated options to specify preferences based on the type of operator:

- Arithmetic binary operators - [dotnet_style_parentheses_in_arithmetic_binary_operators](#)
- Relational binary operators - [dotnet_style_parentheses_in_relational_binary_operators](#)
- Other binary operators - [dotnet_style_parentheses_in_other_binary_operators](#)
- Other operators - [dotnet_style_parentheses_in_other_operators](#)

For information about configuring options, see [Option format](#).

dotnet_style_parentheses_in_arithmetic_binary_operators

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_parentheses_in_arithmetic_binary_operators	
Option values	<code>always_for_clarity</code>	Prefer parentheses to clarify arithmetic operator precedence
	<code>never_if_unnecessary</code>	Prefer no parentheses when arithmetic operator precedence is obvious
Default option value	<code>always_for_clarity</code>	

The arithmetic binary operators are: `*`, `/`, `%`, `+`, `-`, `<<`, `>>`, `&`, `^`, and `|`.

```
// dotnet_style_parentheses_in_arithmetic_binary_operators = always_for_clarity
var v = a + (b * c);

// dotnet_style_parentheses_in_arithmetic_binary_operators = never_if_unnecessary
var v = a + b * c;
```

```
' dotnet_style_parentheses_in_arithmetic_binary_operators = always_for_clarity
Dim v = a + (b * c)

' dotnet_style_parentheses_in_arithmetic_binary_operators = never_if_unnecessary
Dim v = a + b * c
```

dotnet_style_parentheses_in_relational_binary_operators

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_parentheses_in_relational_binary_operators	
Option values	<code>always_for_clarity</code>	Prefer parentheses to clarify relational operator precedence

PROPERTY	VALUE	DESCRIPTION
	never_if_unnecessary	Prefer to not have parentheses when relational operator precedence is obvious
Default option value	always_for_clarity	

The relational binary operators are: >, <, <=, >=, is, as, ==, and !=.

```
// dotnet_style_parentheses_in_relational_binary_operators = always_for_clarity
var v = (a < b) == (c > d);

// dotnet_style_parentheses_in_relational_binary_operators = never_if_unnecessary
var v = a < b == c > d;
```

```
' dotnet_style_parentheses_in_relational_binary_operators = always_for_clarity
Dim v = (a < b) = (c > d)

' dotnet_style_parentheses_in_relational_binary_operators = never_if_unnecessary
Dim v = a < b = c > d
```

dotnet_style_parentheses_in_other_binary_operators

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_parentheses_in_other_binary_operators	
Option values	always_for_clarity	Prefer parentheses to clarify other binary operator precedence
	never_if_unnecessary	Prefer to not have parentheses when other binary operator precedence is obvious
Default option value	always_for_clarity	

The other binary operators are: &&, ||, and ??.

```
// dotnet_style_parentheses_in_other_binary_operators = always_for_clarity
var v = a || (b && c);

// dotnet_style_parentheses_in_other_binary_operators = never_if_unnecessary
var v = a || b && c;
```

```
' dotnet_style_parentheses_in_other_binary_operators = always_for_clarity
Dim v = a OrElse (b AndAlso c)

' dotnet_style_parentheses_in_other_binary_operators = never_if_unnecessary
Dim v = a OrElse b AndAlso c
```

dotnet_style_parentheses_in_other_operators

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_parentheses_in_other_operators	
Option values	always_for_clarity never_if_unnecessary	Prefer parentheses to clarify other operator precedence
	never_if_unnecessary	Prefer to not have parentheses when other operator precedence is obvious
Default option value	never_if_unnecessary	

This option applies to operators *other than* the following:

```
* , / , % , + , - , << , >> , & , ^ , | , > , < , <= , >= , is , as , == , != , && , || , ??
```

```
// dotnet_style_parentheses_in_other_operators = always_for_clarity
var v = (a.b).Length;

// dotnet_style_parentheses_in_other_operators = never_if_unnecessary
var v = a.b.Length;
```

```
' dotnet_style_parentheses_in_other_operators = always_for_clarity
Dim v = (a.b).Length

' dotnet_style_parentheses_in_other_operators = never_if_unnecessary
Dim v = a.b.Length
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0047 // Or IDE0048
// The code that's violating the rule is on this line.
#pragma warning restore IDE0047 // Or IDE0048
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0047.severity = none
dotnet_diagnostic.IDE0048.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Expression-level preferences

9/20/2022 • 2 minutes to read • [Edit Online](#)

.NET expression-level preferences

The style rules in this section concern the following expression-level preferences that are common to C# and Visual Basic:

- [Add missing cases to switch statement \(IDE0010\)](#)
- [Use object initializers \(IDE0017\)](#)
- [Use collection initializers \(IDE0028\)](#)
- [Use auto property \(IDE0032\)](#)
- [Use explicitly provided tuple name \(IDE0033\)](#)
- [Use inferred member name \(IDE0037\)](#)
- [Use conditional expression for assignment \(IDE0045\)](#)
- [Use conditional expression for return \(IDE0046\)](#)
- [Convert anonymous type to tuple \(IDE0050\)](#)
- [Use compound assignment \(IDE0054 and IDE0074\)](#)
- [Use 'System.HashCode.Combine' \(IDE0070\)](#)
- [Simplify interpolation \(IDE0071\)](#)
- [Simplify conditional expression \(IDE0075\)](#)
- [Convert 'typeof' to 'nameof' \(IDE0082\)](#)

C# expression-level preferences

The style rules in this section concern the following expression-level preferences that are specific to C#:

- [Inline variable declaration \(IDE0018\)](#)
- [Simplify 'default' expression \(IDE0034\)](#)
- [Use local function instead of lambda \(IDE0039\)](#)
- [Deconstruct variable declaration \(IDE0042\)](#)
- [Use index operator \(IDE0056\)](#)
- [Use range operator \(IDE0057\)](#)
- [Add missing cases to switch expression \(IDE0072\)](#)
- [Simplify 'new' expression \(IDE0090\)](#)
- [Use tuple to swap values \(IDE0180\)](#)

Add missing cases to switch statement (IDE0010)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0010
Title	Add missing cases to switch statement
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic

Overview

This rule concerns specifying all the missing switch cases for a `switch` statement. A `switch` statement is considered incomplete in the following scenarios:

- An `enum` `switch` statement that's missing cases for one or more enum members.
- A `switch` statement with a missing `default` case.

Options

This rule has no associated code-style options.

Example

```

enum E
{
    A,
    B
}

class C
{
    // Code with violations
    int M(E e)
    {
        // IDE0010: Add missing cases
        switch (e)
        {
            case E.A:
                return 0;
        }

        return -1;
    }

    // Fixed code
    int M(E e)
    {
        switch (e)
        {
            case E.A:
                return 0;
            case E.B:
                return 1;
            default:
                return -1;
        }
    }
}

```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```

#pragma warning disable IDE0010
// The code that's violating the rule is on this line.
#pragma warning restore IDE0010

```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```

[*.{cs,vb}]
dotnet_diagnostic.IDE0010.severity = none

```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```

[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none

```

For more information, see [How to suppress code analysis warnings](#).

Use object initializers (IDE0017)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0017
Title	Use object initializers
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_object_initializer</code>

Overview

This style rule concerns the use of [object initializers](#) for object initialization.

Options

The option value for this rule specifies whether or not initializers are desired.

For more information about configuring options, see [Option format](#).

`dotnet_style_object_initializer`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_object_initializer</code>	
Option values	<code>true</code>	Prefer objects to be initialized using object initializers when possible
	<code>false</code>	Prefer objects to <i>not</i> be initialized using object initializers
Default option value	<code>true</code>	

```
// dotnet_style_object_initializer = true
var c = new Customer() { Age = 21 };

// dotnet_style_object_initializer = false
var c = new Customer();
c.Age = 21;
```

```
' dotnet_style_object_initializer = true
Dim c = New Customer() With {.Age = 21}

' dotnet_style_object_initializer = false
Dim c = New Customer()
c.Age = 21
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0017
// The code that's violating the rule is on this line.
#pragma warning restore IDE0017
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0017.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Inline variable declaration (IDE0018)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0018
Title	Inline variable declaration
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_inlined_variable_declaration</code>

Overview

This style rule concerns whether `out` variables are declared inline or not. Starting in C# 7, you can [declare an out variable in the argument list of a method call](#), rather than in a separate variable declaration.

Options

The associated option for this rule specifies whether you prefer `out` variables to be declared inline or separately.

For more information about configuring options, see [Option format](#).

`csharp_style_inlined_variable_declaration`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_inlined_variable_declaratio</code> n	
Option values	<code>true</code>	Prefer <code>out</code> variables to be declared inline in the argument list of a method call when possible
	<code>false</code>	Prefer <code>out</code> variables to be declared before the method call
Default option value	<code>true</code>	

```
// csharp_style_inlined_variable_declaration = true
if (int.TryParse(value, out int i) {...}

// csharp_style_inlined_variable_declaration = false
int i;
if (int.TryParse(value, out i) {...}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0018
// The code that's violating the rule is on this line.
#pragma warning restore IDE0018
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0018.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use collection initializers (IDE0028)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0028
Title	Use collection initializers
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_collection_initializer</code>

Overview

This style rule concerns the use of [collection initializers](#) for collection initialization.

Options

Set the value of the associated option for this rule to specify whether or not collection initializers are preferred when initializing collections.

For more information about configuring options, see [Option format](#).

`dotnet_style_collection_initializer`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_collection_initializer</code>	
Option values	<code>true</code>	Prefer collections to be initialized using collection initializers when possible
	<code>false</code>	Prefer collections to <i>not</i> be initialized using collection initializers
Default option value	<code>true</code>	

```
// dotnet_style_collection_initializer = true
var list = new List<int> { 1, 2, 3 };

// dotnet_style_collection_initializer = false
var list = new List<int>();
list.Add(1);
list.Add(2);
list.Add(3);
```

```
' dotnet_style_collection_initializer = true
Dim list = New List(Of Integer) From {1, 2, 3}

' dotnet_style_collection_initializer = false
Dim list = New List(Of Integer)
list.Add(1)
list.Add(2)
list.Add(3)
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0028
// The code that's violating the rule is on this line.
#pragma warning restore IDE0028
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0028.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use auto-implemented property (IDE0032)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0032
Title	Use auto-implemented property
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.7
Options	<code>dotnet_style_prefer_auto_properties</code>

Overview

This style rule concerns the use of [auto-implemented properties](#) versus properties with private backing fields.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_auto_properties`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_auto_properties</code>	
Option values	<code>true</code>	Prefer auto-implemented properties
	<code>false</code>	Prefer properties with private backing fields
Default option value	<code>true</code>	

```
// dotnet_style_prefer_auto_properties = true
private int Age { get; }

// dotnet_style_prefer_auto_properties = false
private int age;

public int Age
{
    get
    {
        return age;
    }
}
```

```
' dotnet_style_prefer_auto_properties = true
Public ReadOnly Property Age As Integer

' dotnet_style_prefer_auto_properties = false
Private _age As Integer

Public ReadOnly Property Age As Integer
    Get
        Return _age
    End Get
End Property
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0032
// The code that's violating the rule is on this line.
#pragma warning restore IDE0032
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0032.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use explicitly provided tuple name (IDE0033)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0033
Title	Use explicitly provided tuple name
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.0+ and Visual Basic 15+
Options	<code>dotnet_style_explicit_tuple_names</code>

Overview

This style rule concerns the use of explicit [tuple](#) names versus implicit 'ItemX' properties when accessing tuple fields.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_explicit_tuple_names`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_explicit_tuple_names</code>	
Option values	<code>true</code>	Prefer tuple names to ItemX properties
	<code>false</code>	Prefer ItemX properties to tuple names
Default option value	<code>true</code>	

```
// dotnet_style_explicit_tuple_names = true
(string name, int age) customer = GetCustomer();
var name = customer.name;

// dotnet_style_explicit_tuple_names = false
(string name, int age) customer = GetCustomer();
var name = customer.Item1;
```

```
' dotnet_style_explicit_tuple_names = true
Dim customer As (name As String, age As Integer) = GetCustomer()
Dim name = customer.name

' dotnet_style_explicit_tuple_names = false
Dim customer As (name As String, age As Integer) = GetCustomer()
Dim name = customer.Item1
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0033
// The code that's violating the rule is on this line.
#pragma warning restore IDE0033
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0033.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Simplify 'default' expression (IDE0034)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0034
Title	Simplify <code>default</code> expression
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.1+
Options	<code>csharp_prefer_simple_default_expression</code>

Overview

This style rule concerns using the [default literal for default value expressions](#) when the compiler can infer the type of the expression.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_prefer_simple_default_expression`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_prefer_simple_default_expression</code>	
Option values	<code>true</code>	Prefer <code>default</code> over <code>default(T)</code>
	<code>false</code>	Prefer <code>default(T)</code> over <code>default</code>

```
// csharp_prefer_simple_default_expression = true
void DoWork(CancellationToken cancellationToken = default) { ... }

// csharp_prefer_simple_default_expression = false
void DoWork(CancellationToken cancellationToken = default(CancellationToken)) { ... }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and

then re-enable the rule.

```
#pragma warning disable IDE0034
// The code that's violating the rule is on this line.
#pragma warning restore IDE0034
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0034.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Use inferred member names (IDE0037)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0037
Title	Use inferred member name
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.1+ and Visual Basic 15+
Introduced version	Visual Studio 2017 version 15.6
Options	<code>dotnet_style_prefer_inferred_tuple_names</code>
	<code>dotnet_style_prefer_inferred_anonymous_type_member_names</code>

Overview

This rule enforces whether inferred [tuple](#) element names and inferred [anonymous type](#) member names are preferred when the tuple or anonymous type is declared.

Options

Set the values of the rule's associated options to specify whether inferred or explicit names are preferred for tuple elements and anonymous type members.

- [dotnet_style_prefer_inferred_tuple_names](#)
- [dotnet_style_prefer_inferred_anonymous_type_member_names](#)

For information about configuring options, see [Option format](#).

dotnet_style_prefer_inferred_tuple_names

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_inferred_tuple_names</code>	
Option values	<code>true</code>	Prefer inferred tuple element names
	<code>false</code>	Prefer explicit tuple element names
Default option value	<code>true</code>	

```
// dotnet_style_prefer_inferred_tuple_names = true
var tuple = (age, name);

// dotnet_style_prefer_inferred_tuple_names = false
var tuple = (age: age, name: name);
```

```
' dotnet_style_prefer_inferred_tuple_names = true
Dim tuple = (name, age)

' dotnet_style_prefer_inferred_tuple_names = false
Dim tuple = (name:=name, age:=age)
```

dotnet_style_prefer_inferred_anonymous_type_member_names

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_prefer_inferred_anonymous_type_member_names	
Option values	<code>true</code>	Prefer inferred anonymous type member names
	<code>false</code>	Prefer explicit anonymous type member names
Default option value	<code>true</code>	

```
// dotnet_style_prefer_inferred_anonymous_type_member_names = true
var anon = new { age, name };

// dotnet_style_prefer_inferred_anonymous_type_member_names = false
var anon = new { age = age, name = name };
```

```
' dotnet_style_prefer_inferred_anonymous_type_member_names = true
Dim anon = New With {name, age}

' dotnet_style_prefer_inferred_anonymous_type_member_names = false
Dim anon = New With {.name = name, .age = age}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0037
// The code that's violating the rule is on this line.

Use local function instead of lambda (IDE0039)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0039
Title	Use local function instead of lambda
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_prefer_local_over_anonymous_function</code>

Overview

This style rule concerns the use of [local functions](#) versus [lambda expressions](#) (anonymous functions).

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_local_over_anonymous_function`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_local_over_anonymous_function</code>	
Option values	<code>true</code>	Prefer local functions over anonymous functions
	<code>false</code>	Prefer anonymous functions over local functions
Default option value	<code>true</code>	

```
// csharp_style_prefer_local_over_anonymous_function = true
int fibonacci(int n)
{
    return n <= 1 ? 1 : fibonacci(n-1) + fibonacci(n-2);
}

// csharp_style_prefer_local_over_anonymous_function = false
Func<int, int> fibonacci = null;
fibonacci = (int n) =>
{
    return n <= 1 ? 1 : fibonacci(n - 1) + fibonacci(n - 2);
};
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0039
// The code that's violating the rule is on this line.

Deconstruct variable declaration (IDE0042)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0042
Title	Deconstruct variable declaration
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_deconstructed_variable_declaration</code>

Overview

This style rule concerns the use of [deconstruction](#) in variable declarations, when possible.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_deconstructed_variable_declaration`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_deconstructed_variable_d eclaration</code>	
Option values	<code>true</code>	Prefer deconstructed variable declaration
	<code>false</code>	Do not prefer deconstruction in variable declarations
Default option value	<code>true</code>	

```
// csharp_style_deconstructed_variable_declaration = true
var (name, age) = GetPersonTuple();
Console.WriteLine($"{name} {age}");

(int x, int y) = GetPointTuple();
Console.WriteLine($"{x} {y}");

// csharp_style_deconstructed_variable_declaration = false
var person = GetPersonTuple();
Console.WriteLine($"{person.name} {person.age}");

(int x, int y) point = GetPointTuple();
Console.WriteLine($"{point.x} {point.y}");
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0042
// The code that's violating the rule is on this line.
#pragma warning restore IDE0042
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0042.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Use conditional expression for assignment (IDE0045)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0045
Title	Use conditional expression for assignment
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.8
Options	<code>dotnet_style_prefer_conditional_expression_over_assignment</code>

Overview

This style rule concerns the use of a [ternary conditional expression](#) versus an [if-else statement](#) for assignments that require conditional logic.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_conditional_expression_over_assignment`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_conditional_expression_over_assignment</code>	
Option values	<code>true</code>	Prefer assignments with a ternary conditional
	<code>false</code>	Prefer assignments with an if-else statement
Default option value	<code>true</code>	

```
// dotnet_style_prefer_conditional_expression_over_assignment = true
string s = expr ? "hello" : "world";

// dotnet_style_prefer_conditional_expression_over_assignment = false
string s;
if (expr)
{
    s = "hello";
}
else
{
    s = "world";
}
```

```
' dotnet_style_prefer_conditional_expression_over_assignment = true
Dim s As String = If(expr, "hello", "world")

' dotnet_style_prefer_conditional_expression_over_assignment = false
Dim s As String
If expr Then
    s = "hello"
Else
    s = "world"
End If
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0045
// The code that's violating the rule is on this line.
#pragma warning restore IDE0045
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0045.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use conditional expression for return (IDE0046)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0046
Title	Use conditional expression for return
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Introduced version	Visual Studio 2017 version 15.8
Options	<code>dotnet_style_prefer_conditional_expression_over_return</code>

Overview

This style rule concerns the use of a [ternary conditional expression](#) versus an [if-else statement](#) for return statements that require conditional logic.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_conditional_expression_over_return`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_conditional_expression_over_return</code>	
Option values	<code>true</code>	Prefer return statements to use a ternary conditional
	<code>false</code>	Prefer return statements to use an if-else statement
Default option value	<code>true</code>	

```
// dotnet_style_prefer_conditional_expression_over_return = true
return expr ? "hello" : "world"

// dotnet_style_prefer_conditional_expression_over_return = false
if (expr)
{
    return "hello";
}
else
{
    return "world";
}
```

```
' dotnet_style_prefer_conditional_expression_over_return = true
Return If(expr, "hello", "world")

' dotnet_style_prefer_conditional_expression_over_return = false
If expr Then
    Return "hello"
Else
    Return "world"
End If
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0046
// The code that's violating the rule is on this line.
#pragma warning restore IDE0046
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0046.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Convert anonymous type to tuple (IDE0050)

9/20/2022 • 2 minutes to read • [Edit Online](#)

IMPORTANT

This style rule was removed and converted to a Visual Studio refactoring in Visual Studio 2022. For information about the refactoring, see [Convert anonymous type to tuple](#).

PROPERTY	VALUE
Rule ID	IDE0050
Title	Convert anonymous type to tuple
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic

Overview

This rule recommends use of [tuples](#) over [anonymous types](#), when the anonymous type has two or more fields.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
var t1 = new { a = 1, b = 2 };

// Fixed code
var t1 = (a: 1, b: 2);
```

```
' Code with violations
Dim t1 = New With { .a = 1, .b = 2 }

' Fixed code
Dim t1 = (a:=1, b:=2)
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0050
// The code that's violating the rule is on this line.
#pragma warning restore IDE0050
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0050.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use compound assignment (IDE0054 and IDE0074)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0054](#) and [IDE0074](#).

PROPERTY	VALUE
Rule ID	IDE0054
Title	Use compound assignment
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Options	dotnet_style_prefer_compound_assignment

PROPERTY	VALUE
Rule ID	IDE0074
Title	Use coalesce compound assignment
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Options	dotnet_style_prefer_compound_assignment

Overview

These rules concern the use of [compound assignment](#). [IDE0074](#) is reported for coalesce compound assignments and [IDE0054](#) is reported for other compound assignments.

Options

The option value specifies whether or not compound assignments are desired.

For information about configuring options, see [Option format](#).

dotnet_style_prefer_compound_assignment

PROPERTY	VALUE	DESCRIPTION

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_prefer_compound_assignment	
Option values	<code>true</code>	Prefer compound assignment expressions
	<code>false</code>	Don't prefer compound assignment expressions
Default option value	<code>true</code>	

```
// dotnet_style_prefer_compound_assignment = true
x += 5;

// dotnet_style_prefer_compound_assignment = false
x = x + 5;
```

```
' dotnet_style_prefer_compound_assignment = true
x += 5

' dotnet_style_prefer_compound_assignment = false
x = x + 5
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0054 // Or IDE0074
// The code that's violating the rule is on this line.
#pragma warning restore IDE0054 // Or IDE0074
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0054.severity = none
dotnet_diagnostic.IDE0074.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use index operator (IDE0056)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0056
Title	Use index operator
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 8.0+
Options	<code>csharp_style_prefer_index_operator</code>

Overview

This style rule concerns the use of the [index-from-end operator \(`^`\)](#), which is available in C# 8.0 and later.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_index_operator`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_index_operator</code>	
Option values	<code>true</code>	Prefer to use the <code>^</code> operator when calculating an index from the end of a collection
	<code>false</code>	Prefer not to use the <code>^</code> operator when calculating an index from the end of a collection
Default option value	<code>true</code>	

```
// csharp_style_prefer_index_operator = true
string[] names = { "Archimedes", "Pythagoras", "Euclid" };
var index = names[^1];

// csharp_style_prefer_index_operator = false
string[] names = { "Archimedes", "Pythagoras", "Euclid" };
var index = names[names.Length - 1];
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0056
// The code that's violating the rule is on this line.
#pragma warning restore IDE0056
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0056.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use range operator (IDE0057)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0057
Title	Use range operator
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 8.0+
Options	<code>csharp_style_prefer_range_operator</code>

Overview

This style rule concerns the use of the [range operator](#) (`..`), which is available in C# 8.0 and later.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_range_operator`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_range_operator</code>	
Option values	<code>true</code>	Prefer to use the range operator <code>..</code> when extracting a "slice" of a collection
	<code>false</code>	Prefer <i>not</i> to use the range operator <code>..</code> when extracting a "slice" of a collection
Default option value	<code>true</code>	

```
// csharp_style_prefer_range_operator = true
string sentence = "the quick brown fox";
var sub = sentence[0..^4];

// csharp_style_prefer_range_operator = false
string sentence = "the quick brown fox";
var sub = sentence.Substring(0, sentence.Length - 4);
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0057
// The code that's violating the rule is on this line.
#pragma warning restore IDE0057
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0057.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use 'System.HashCode.Combine' (IDE0070)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0070
Title	Use <code>System.HashCode.Combine</code>
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic

Overview

This rule recommends the use of the [System.HashCode.Combine](#) method to compute a hash code instead of using custom hash code computation logic.

Options

This rule has no associated code-style options.

Example

```
class B
{
    public override int GetHashCode() => 0;
}

class C : B
{
    int j;

    // Code with violations
    public override int GetHashCode()
    {
        // IDE0070: GetHashCode can be simplified.
        var hashCode = 339610899;
        hashCode = hashCode * -1521134295 + base.GetHashCode();
        hashCode = hashCode * -1521134295 + j.GetHashCode();
        return hashCode;
    }

    // Fixed code
    public override int GetHashCode()
    {
        return System.HashCode.Combine(base.GetHashCode(), j);
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0070
// The code that's violating the rule is on this line.
#pragma warning restore IDE0070
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0070.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Simplify interpolation (IDE0071)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0071
Title	Simplify interpolation
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 6.0+ and Visual Basic 14+
Options	<code>dotnet_style_prefer_simplified_interpolation</code>

Overview

This style rule concerns with simplification of [interpolated strings](#) to improve code readability. It recommends removal of certain explicit method calls, such as `ToString()`, when the same method would be implicitly invoked by the compiler if the explicit method call is removed.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_simplified_interpolation`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_simplified_interpolation</code>	
Option values	<code>true</code>	Prefer simplified interpolated strings
	<code>false</code>	Do not prefer simplified interpolated strings
Default option value	<code>true</code>	

```
// dotnet_style_prefer_simplified_interpolation = true
var str = $"prefix {someValue} suffix";

// dotnet_style_prefer_simplified_interpolation = false
var str = $"prefix {someValue.ToString()} suffix";
```

```
' dotnet_style_prefer_simplified_interpolation = true
Dim str = $"prefix {someValue} suffix"

' dotnet_style_prefer_simplified_interpolation = false
Dim str = $"prefix {someValue.ToString()} suffix"
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0071
// The code that's violating the rule is on this line.
#pragma warning restore IDE0071
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0071.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Add missing cases to switch expression (IDE0072)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0072
Title	Add missing cases to switch expression
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 8.0+

Overview

This rule concerns specifying all the missing cases for a [switch expression](#). A switch expression is considered incomplete with missing cases in following scenarios:

- When an [enum](#) switch expression is missing cases for one or more enum members.
- When the fall-through case `_` is missing.

Options

This rule has no associated code-style options.

Example

```
enum E
{
    A,
    B
}

class C
{
    // Code with violations
    int M(E e)
    {
        // IDE0072: Add missing cases
        return e switch
        {
            E.A => 0,
            _ => -1,
        };
    }

    // Fixed code
    int M(E e)
    {
        return e switch
        {
            E.A => 0,
            E.B => 1,
            _ => -1,
        };
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0072
// The code that's violating the rule is on this line.
#pragma warning restore IDE0072
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0072.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Simplify conditional expression (IDE0075)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0075
Title	Simplify conditional expression
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic
Options	<code>dotnet_style_prefer_simplified_boolean_expressions</code>

Overview

This style rule concerns simplifying [conditional expressions](#) that return a constant value of `true` or `false` versus retaining conditional expressions with explicit `true` or `false` return values.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_simplified_boolean_expressions`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_simplified_boolean_expressions</code>	
Option values	<code>true</code>	Prefer simplified conditional expressions
	<code>false</code>	Do not prefer simplified conditional expressions
Default option value	<code>true</code>	

```
// dotnet_style_prefer_simplified_boolean_expressions = true
var result1 = M1() && M2();
var result2 = M1() || M2();

// dotnet_style_prefer_simplified_boolean_expressions = false
var result1 = M1() && M2() ? true : false;
var result2 = M1() ? true : M2();
```

```
' dotnet_style_prefer_simplified_boolean_expressions = true
Dim result1 = M1() AndAlso M2()
Dim result2 = M1() OrElse M2()

' dotnet_style_prefer_simplified_boolean_expressions = false
Dim result1 = If (M1() AndAlso M2(), True, False)
Dim result2 = If (M1(), True, M2())
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0075
// The code that's violating the rule is on this line.
#pragma warning restore IDE0075
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0075.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Convert `typeof` to `nameof` (IDE0082)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0082
Title	Convert <code>typeof</code> to <code>nameof</code>
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# and Visual Basic

Overview

This style rule recommends use of the [nameof operator](#) over the [typeof operator](#) followed by [Name](#) member access. It only fires when the name will be identical in both cases.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
var n1 = typeof(T).Name;
var n2 = typeof(int).Name;

// Fixed code
var n1 = nameof(T);
var n2 = nameof(Int32);
```

```
' Code with violations
Dim n1 = GetType(T).Name
Dim n2 = GetType(Integer).Name

' Fixed code
Dim n1 = NameOf(T)
Dim n2 = NameOf(Int32)
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0082
// The code that's violating the rule is on this line.
#pragma warning restore IDE0082
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0082.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Simplify `new` expression (IDE0090)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0090
Title	Simplify <code>new</code> expression
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C# 9.0+
Options	<code>csharp_style_implicit_object_creation_when_type_is_apparent</code>

Overview

This style rule concerns the use of C# 9.0 [target-typed new](#) expressions when the created type is apparent.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_implicit_object_creation_when_type_is_apparent`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_implicit_object_creation_when_type_is_apparent</code>	
Option values	<code>true</code>	Prefer target-typed <code>new</code> expressions when created type is apparent
	<code>false</code>	Do not prefer target-typed <code>new</code> expressions
Default option value	<code>true</code>	

```
// csharp_style_implicit_object_creation_when_type_is_apparent = true
C c = new();
C c2 = new() { Field = 0 };

// csharp_style_implicit_object_creation_when_type_is_apparent = false
C c = new C();
C c2 = new C() { Field = 0 };
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0090
// The code that's violating the rule is on this line.
#pragma warning restore IDE0090
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0090.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Code style rules reference](#)

Use tuple to swap values (IDE0180)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0180
Title	Use tuple to swap values
Category	Style
Subcategory	Language rules (expression-level preferences)
Applicable languages	C#
Options	<code>csharp_style_prefer_tuple_swap</code>

Overview

This style rule flags code that swaps two values using multiple lines of code instead of using a [tuple](#).

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_tuple_swap`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_tuple_swap</code>	
Option values	<code>true</code>	Prefer using a tuple to swap two values.
	<code>false</code>	Disables the rule.
Default option value	<code>true</code>	

Example

```
List<int> numbers = new List<int>() { 5, 6, 4 };

// Violates IDE0180.
int temp = numbers[0];
numbers[0] = numbers[1];
numbers[1] = temp;

// Fixed code.
(numbers[1], numbers[0]) = (numbers[0], numbers[1]);
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0180
// The code that's violating the rule is on this line.
#pragma warning restore IDE0180
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0180.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Namespace declaration preferences (IDE0160 and IDE0161)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0160](#) and [IDE0161](#).

PROPERTY	VALUE
Rule ID	IDE0160
Title	Use block-scoped namespace
Category	Style
Subcategory	Language rules (namespace preferences)
Applicable languages	C#
Options	<code>csharp_style_namespace_declarations</code>

PROPERTY	VALUE
Rule ID	IDE0161
Title	Use file-scoped namespace
Category	Style
Subcategory	Language rules (namespace preferences)
Applicable languages	C#
Options	<code>csharp_style_namespace_declarations</code>

Overview

These rules apply to [namespace declarations](#). For [IDE0161](#) to report violations when block-scoped namespaces are used, you must set the associated option to [file_scoped](#).

Options

The option value specifies whether namespace declarations should be block scoped or file scoped. By default, namespace declarations are block-scoped. This option is used by Visual Studio to determine how namespaces are declared when new code files are added to projects. Visual Studio honors the option value even if both [IDE0160](#) and [IDE0161](#) are disabled.

For information about configuring options, see [Option format](#).

csharp_style_namespace_declarations

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_namespace_declarations	
Applicable languages	C#	
Introduced version	Visual Studio 2019 version 16.10	
Option values	<code>block_scoped</code>	Namespace declarations should be block scoped.
	<code>file_scoped</code>	Namespace declarations should be file scoped.
Default option value	<code>block_scoped</code>	

```
// csharp_style_namespace_declarations = block_scoped
using System;

namespace Convention
{
    class C
    {
    }
}

// csharp_style_namespace_declarations = file_scoped
using System;

namespace Convention;
class C
{
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0160 // Or IDE0161
// The code that's violating the rule is on this line.
#pragma warning restore IDE0160 // Or IDE0161
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0160.severity = none
dotnet_diagnostic.IDE0161.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Null-checking preferences

9/20/2022 • 2 minutes to read • [Edit Online](#)

.NET null-checking preferences

The style rules in this section concern the following null-checking preferences that are common to C# and Visual Basic:

- [Use coalesce expression \(IDE0029 and IDE0030\)](#)
- [Use null propagation \(IDE0031\)](#)
- [Use is null check \(IDE0041\)](#)
- [Prefer `null` check over type check \(IDE0150\)](#)

C# null-checking preferences

The style rules in this section concern the following null-checking preferences that are specific to C#:

- [Use throw expression \(IDE0016\)](#)
- [Use conditional delegate call \(IDE1005\)](#)

See also

- [Code style rules reference](#)
- [Code style language rules](#)

Use throw expression (IDE0016)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0016
Title	Use throw expression
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_throw_expression</code>

Overview

This style rule concerns the use of [throw expressions](#) instead of `throw` statements. Set the severity of rule `IDE0016` to define how the rule should be enforced, for example, as a warning or an error.

Options

The associated option for this rule specifies whether you prefer `throw` expressions or `throw` statements.

For more information about configuring options, see [Option format](#).

`csharp_style_throw_expression`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_throw_expression</code>	
Option values	<code>true</code>	Prefer to use <code>throw</code> expressions instead of <code>throw</code> statements
	<code>false</code>	Prefer to use <code>throw</code> statements instead of <code>throw</code> expressions
Default option value	<code>true</code>	

```
// csharp_style_throw_expression = true
this.s = s ?? throw new ArgumentNullException(nameof(s));

// csharp_style_throw_expression = false
if (s == null) { throw new ArgumentNullException(nameof(s)); }
this.s = s;
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0016
// The code that's violating the rule is on this line.
#pragma warning restore IDE0016
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0016.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

Use coalesce expression (IDE0029 and IDE0030)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0029](#) and [IDE0030](#).

PROPERTY	VALUE
Rule ID	IDE0029
Title	Use coalesce expression (non-nullable types)
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# and Visual Basic
Options	dotnet_style_coalesce_expression

PROPERTY	VALUE
Rule ID	IDE0030
Title	Use coalesce expression (nullable types)
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# and Visual Basic
Options	dotnet_style_coalesce_expression

Overview

These style rules concern the use of [null-coalescing expressions](#), for example, `x ?? y`, versus [ternary conditional expressions](#) with `null` checks, for example, `x != null ? x : y`. The two related rule IDs differ with respect to the nullability of the expressions:

- [IDE0029](#): Used when non-nullable expressions are involved. For example, this rule could recommend `x ?? y` instead of `x != null ? x : y` when `x` and `y` are non-nullable reference types.
- [IDE0030](#): Used when nullable expressions are involved. For example, this rule could recommend `x ?? y` instead of `x != null ? x : y` when `x` and `y` are [nullable value types](#) or [nullable reference types](#).

Options

Set the value of the associated option to specify whether null-coalescing expressions or ternary operator checking is preferred. The rule enforces whichever option you choose.

For more information about configuring options, see [Option format](#).

dotnet_style_coalesce_expression

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_coalesce_expression	
Option values	true	Prefer null coalescing expressions to ternary operator checking
	false	Prefer ternary operator checking to null coalescing expressions
Default option value	true	

```
// dotnet_style_coalesce_expression = true
var v = x ?? y;

// dotnet_style_coalesce_expression = false
var v = x != null ? x : y; // or
var v = x == null ? y : x;
```

```
' dotnet_style_coalesce_expression = true
Dim v = If(x, y)

' dotnet_style_coalesce_expression = false
Dim v = If(x Is Nothing, y, x) ' or
Dim v = If(x IsNot Nothing, x, y)
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0029 // Or IDE0030
// The code that's violating the rule is on this line.
#pragma warning restore IDE0029 // Or IDE0030
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0029.severity = none
dotnet_diagnostic.IDE0030.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use null propagation (IDE0031)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0031
Title	Use null propagation
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# 6.0+ and Visual Basic 14+
Options	<code>dotnet_style_null_propagation</code>

Overview

This style rule concerns the use of the [null-conditional operator](#) versus a [ternary conditional expression](#) with null check.

Options

Set the value of the associated option to specify whether null-conditional operators or ternary conditional expressions with null checks.

For more information about configuring options, see [Option format](#).

`dotnet_style_null_propagation`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_null_propagation</code>	
Option values	<code>true</code>	Prefer to use null-conditional operator when possible
	<code>false</code>	Prefer to use ternary null checking where possible
Default option value	<code>true</code>	

```
// dotnet_style_null_propagation = true
var v = o?.ToString();

// dotnet_style_null_propagation = false
var v = o == null ? null : o.ToString(); // or
var v = o != null ? o.ToString() : null;
```

```
' dotnet_style_null_propagation = true
Dim v = o?.ToString()

' dotnet_style_null_propagation = false
Dim v = If(o Is Nothing, Nothing, o.ToString()) ' or
Dim v = If(o IsNot Nothing, o.ToString(), Nothing)
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0031
// The code that's violating the rule is on this line.
#pragma warning restore IDE0031
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0031.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use 'is null' check (IDE0041)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0041
Title	Use 'is null' check
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# 6.0+ and Visual Basic 14+
Introduced version	Visual Studio 2017 version 15.7
Options	<code>dotnet_style_prefer_is_null_check_over_reference_equality_method</code>

Overview

This style rule concerns the use of a null check with pattern-matching versus calling the reference-equality method [Object.ReferenceEquals\(Object, Object\)](#).

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_style_prefer_is_null_check_over_reference_equality_method`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_style_prefer_is_null_check_over_reference_equality_method</code>	
Option values	<code>true</code>	Prefer <code>is null</code> check
	<code>false</code>	Prefer reference equality method
Default option value	<code>true</code>	

```
// dotnet_style_prefer_is_null_check_over_reference_equality_method = true
if (value is null)
    return;

// dotnet_style_prefer_is_null_check_over_reference_equality_method = false
if (object.ReferenceEquals(value, null))
    return;
```

```
' dotnet_style_prefer_is_null_check_over_reference_equality_method = true
If value Is Nothing
    Return
End If

' dotnet_style_prefer_is_null_check_over_reference_equality_method = false
If Object.ReferenceEquals(value, Nothing)
    Return
End If
```

SUPPRESS A WARNING

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0041
// The code that's violating the rule is on this line.
#pragma warning restore IDE0041
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0041.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Prefer 'null' check over type check (IDE0150)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0150
Title	Prefer <code>null</code> check over type check
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C#
Options	<code>csharp_style_prefer_null_check_over_type_check</code>

Overview

This style rule flags use of the `is {type}` statement when `is not null` can be used instead. Similarly, it flags use of the `is not {type}` statement in favor of `is null`. Using `is null` or `is not null` improves code readability.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_null_check_over_type_check`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_null_check_over_type_check</code>	
Option values	<code>true</code>	Prefer null check over type check.
	<code>false</code>	Disables the rule.
Default option value	<code>true</code>	

Example

```
// Violates IDE0150.  
if (numbers is not IEnumerable<int>) ...  
  
// Fixed code.  
if (numbers is null) ...
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0150
// The code that's violating the rule is on this line.
#pragma warning restore IDE0150
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0150.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use conditional delegate call (IDE1005)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE1005
Title	Use conditional delegate call
Category	Style
Subcategory	Language rules (null-checking preferences)
Applicable languages	C# 6.0+
Options	<code>csharp_style_conditional_delegate_call</code>

Overview

This style rule concerns the use of the [null-conditional operator](#) (`?.`) when invoking a lambda expression, as opposed to performing a null check.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_conditional_delegate_call`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_conditional_delegate_call</code>	
Option values	<code>true</code>	Prefer to use the conditional coalescing operator (<code>?.</code>) when invoking a lambda expression
	<code>false</code>	Prefer to perform a null check before invoking a lambda expression
Default option value	<code>true</code>	

```
// csharp_style_conditional_delegate_call = true
func?.Invoke(args);

// csharp_style_conditional_delegate_call = false
if (func != null) { func(args); }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE1005
// The code that's violating the rule is on this line.
#pragma warning restore IDE1005
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE1005.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

'var' preferences (IDE0007 and IDE0008)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0007](#) and [IDE0008](#).

PROPERTY	VALUE
Rule ID	IDE0007
Title	Use <code>var</code> instead of explicit type
Category	Style
Subcategory	Language rules
Applicable languages	C#
Options	<code>csharp_style_var_for_builtin_types</code> <code>csharp_style_var_when_type_is_apparent</code> <code>csharp_style_var_elsewhere</code>
PROPERTY	VALUE
Rule ID	IDE0008
Title	Use explicit type instead of <code>var</code>
Category	Style
Subcategory	Language rules
Applicable languages	C#
Options	<code>csharp_style_var_for_builtin_types</code> <code>csharp_style_var_when_type_is_apparent</code> <code>csharp_style_var_elsewhere</code>

Overview

These two style rules define whether the `var` keyword or an explicit type should be used in a variable declaration. To enforce that `var` is used, set the severity of [IDE0007](#) to warning or error. To enforce that the explicit type is used, set the severity of [IDE0008](#) to warning or error.

Options

This rule's associated options define where this style preference should be applied:

- Built-in types ([csharp_style_var_for_builtin_types](#))
- Places where the type is apparent ([csharp_style_var_when_type_is_apparent](#))
- Elsewhere ([csharp_style_var_elsewhere](#))

For more information about configuring options, see [Option format](#).

csharp_style_var_for_builtin_types

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_var_for_builtin_types	
Option values	<code>true</code>	Prefer <code>var</code> is used to declare variables with built-in system types such as <code>int</code>
	<code>false</code>	Prefer explicit type over <code>var</code> to declare variables with built-in system types such as <code>int</code>
Default option value	<code>false</code>	

```
// csharp_style_var_for_builtin_types = true
var x = 5;

// csharp_style_var_for_builtin_types = false
int x = 5;
```

csharp_style_var_when_type_is_apparent

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_var_when_type_is_apparent	
Option values	<code>true</code>	Prefer <code>var</code> when the type is already mentioned on the right-hand side of a declaration expression
	<code>false</code>	Prefer explicit type when the type is already mentioned on the right-hand side of a declaration expression
Default option value	<code>false</code>	

```
// csharp_style_var_when_type_is_apparent = true
var obj = new Customer();

// csharp_style_var_when_type_is_apparent = false
Customer obj = new Customer();
```

csharp_style_var_elsewhere

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_var_elsewhere	
Option values	<code>true</code>	Prefer <code>var</code> over explicit type in all cases, unless overridden by another code style rule
	<code>false</code>	Prefer explicit type over <code>var</code> in all cases, unless overridden by another code style rule
Default option value	<code>false</code>	

```
// csharp_style_var_elsewhere = true
var f = this.Init();

// csharp_style_var_elsewhere = false
bool f = this.Init();
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0007 // Or IDE0008
// The code that's violating the rule is on this line.
#pragma warning restore IDE0007 // Or IDE0008
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0007.severity = none
dotnet_diagnostic.IDE0008.severity = none
```

To disable all of the code-style rules, set the severity for the category `style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Expression-bodied-members

9/20/2022 • 2 minutes to read • [Edit Online](#)

Overview

The style rules in this section concern the use of [expression-bodied members](#) when the logic consists of a single expression.

- [Use expression body for constructors \(IDE0021\)](#)
- [Use expression body for methods \(IDE0022\)](#)
- [Use expression body for operators \(IDE0023 and IDE0024\)](#)
- [Use expression body for properties \(IDE0025\)](#)
- [Use expression body for indexers \(IDE0026\)](#)
- [Use expression body for accessors \(IDE0027\)](#)
- [Use expression body for lambda expressions \(IDE0053\)](#)
- [Use expression body for local functions \(IDE0061\)](#)

Use expression body for constructors (IDE0021)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0021
Title	Use expression body for constructors
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_constructors</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for constructors.

Options

Set the value of the associated option for this rule to specify whether expression bodies or block bodies for constructors are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_constructors`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_constructors</code>	
Option values	<code>true</code>	Prefer expression bodies for constructors
	<code>when_on_single_line</code>	Prefer expression bodies for constructors when they will be a single line
	<code>false</code>	Prefer block bodies for constructors
Default option value	<code>false</code>	

```
// csharp_style_expression_bodied_constructors = true
public Customer(int age) => Age = age;

// csharp_style_expression_bodied_constructors = false
public Customer(int age) { Age = age; }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0021
// The code that's violating the rule is on this line.
#pragma warning restore IDE0021
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0021.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use expression body for methods (IDE0022)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0022
Title	Use expression body for methods
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 6.0+
Options	<code>csharp_style_expression_bodied_methods</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for methods.

Options

Set the value of the associated option for this rule to specify whether expression bodies or block bodies for methods are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_methods`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_methods</code>	
Option values	<code>true</code>	Prefer expression bodies for methods
	<code>when_on_single_line</code>	Prefer expression bodies for methods when they will be a single line
	<code>false</code>	Prefer block bodies for methods
Default option value	<code>false</code>	

```
// csharp_style_expression_bodied_methods = true
public int GetAge() => this.Age;

// csharp_style_expression_bodied_methods = false
public int GetAge() { return this.Age; }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0022
// The code that's violating the rule is on this line.
#pragma warning restore IDE0022
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0022.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use expression body for operators (IDE0023 and IDE0024)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0023](#) and [IDE0024](#), which apply to *conversion operators* and *operators*, respectively.

PROPERTY	VALUE
Rule ID	IDE0023
Title	Use expression body for conversion operators
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_operators</code>

PROPERTY	VALUE
Rule ID	IDE0024
Title	Use expression body for operators
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_operators</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for operators.

Options

Set the value of the associated option for these rules to specify whether expression bodies or block bodies for operators are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_operators`

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_expression_bodied_operators	
Option values	<code>true</code>	Prefer expression bodies for operators
	<code>when_on_single_line</code>	Prefer expression bodies for operators when they will be a single line
	<code>false</code>	Prefer block bodies for operators
Default option value	<code>false</code>	

```
// csharp_style_expression_bodied_operators = true
public static ComplexNumber operator + (ComplexNumber c1, ComplexNumber c2)
    => new ComplexNumber(c1.Real + c2.Real, c1.Imaginary + c2.Imaginary);

// csharp_style_expression_bodied_operators = false
public static ComplexNumber operator + (ComplexNumber c1, ComplexNumber c2)
{ return new ComplexNumber(c1.Real + c2.Real, c1.Imaginary + c2.Imaginary); }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0023 // Or IDE0024
// The code that's violating the rule is on this line.
#pragma warning restore IDE0023 // Or IDE0024
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0023.severity = none
dotnet_diagnostic.IDE0024.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use expression body for properties (IDE0025)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0025
Title	Use expression body for properties
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_properties</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for properties.

Options

Set the value of the associated option for this rule to specify whether expression bodies or block bodies for properties are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_properties`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_properties</code>	
Option values	<code>true</code>	Prefer expression bodies for properties
	<code>when_on_single_line</code>	Prefer expression bodies for properties when they will be a single line
	<code>false</code>	Prefer block bodies for properties
Default option value	<code>true</code>	

```
// csharp_style_expression_bodied_properties = true
public int Age => _age;

// csharp_style_expression_bodied_properties = false
public int Age { get { return _age; } }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0025
// The code that's violating the rule is on this line.
#pragma warning restore IDE0025
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0025.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Use expression body for indexers (IDE0026)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0026
Title	Use expression body for indexers
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_indexers</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for indexers.

Options

Set the value of the associated option for this rule to specify whether expression bodies or block bodies for indexers are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_indexers`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_indexers</code>	
Option values	<code>true</code>	Prefer expression bodies for indexers
	<code>when_on_single_line</code>	Prefer expression bodies for indexers when they will be a single line
	<code>false</code>	Prefer block bodies for indexers
Default option value	<code>true</code>	

```
// csharp_style_expression_bodied_indexers = true
public T this[int i] => _values[i];

// csharp_style_expression_bodied_indexers = false
public T this[int i] { get { return _values[i]; } }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0026
// The code that's violating the rule is on this line.
#pragma warning restore IDE0026
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0026.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use expression body for accessors (IDE0027)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0027
Title	Use expression body for accessors
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_accessors</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for accessors.

Options

Set the value of the associated option for this rule to specify whether expression bodies or block bodies for accessors are preferred, and if expression bodies are preferred, whether they're preferred only for single-line expressions.

For more information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_accessors`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_accessors</code>	
Option values	<code>true</code>	Prefer expression bodies for accessors
	<code>when_on_single_line</code>	Prefer expression bodies for accessors when they will be a single line
	<code>false</code>	Prefer block bodies for accessors
Default option value	<code>true</code>	

```
// csharp_style_expression_bodied_accessors = true
public int Age { get => _age; set => _age = value; }

// csharp_style_expression_bodied_accessors = false
public int Age { get { return _age; } set { _age = value; } }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0027
// The code that's violating the rule is on this line.
#pragma warning restore IDE0027
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0027.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Use expression body for lambdas (IDE0053)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0053
Title	Use expression body for lambdas
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_lambdas</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for [lambda expressions](#).

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_lambdas`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_lambdas</code>	
Option values	<code>true</code>	Prefer expression bodies for lambdas
	<code>when_on_single_line</code>	Prefer expression bodies for lambdas when they'll be a single line
	<code>false</code>	Prefer block bodies for lambdas
Default option value	<code>true</code>	

```
// csharp_style_expression_bodied_lambdas = true
Func<int, int> square = x => x * x;

// csharp_style_expression_bodied_lambdas = false
Func<int, int> square = x => { return x * x; };
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0053
// The code that's violating the rule is on this line.
#pragma warning restore IDE0053
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0053.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Use expression body for local functions (IDE0061)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0061
Title	Use expression body for local functions
Category	Style
Subcategory	Language rules (expression-bodied members)
Applicable languages	C# 7.0+
Options	<code>csharp_style_expression_bodied_local_functions</code>

Overview

This style rule concerns the use of [expression bodies](#) versus block bodies for [local functions](#). Local functions are private methods of a type that are nested in another member.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_expression_bodied_local_functions`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_expression_bodied_local_functions</code>	
Option values	<code>true</code>	Prefer expression bodies for local functions
	<code>when_on_single_line</code>	Prefer expression bodies for local functions when they'll be a single line
	<code>false</code>	Prefer block bodies for local functions
Default option value	<code>false</code>	

```
// csharp_style_expression_bodied_local_functions = true
void M()
{
    Hello();
    void Hello() => Console.WriteLine("Hello");
}

// csharp_style_expression_bodied_local_functions = false
void M()
{
    Hello();
    void Hello()
    {
        Console.WriteLine("Hello");
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0061
// The code that's violating the rule is on this line.
#pragma warning restore IDE0061
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0061.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Pattern matching preferences

9/20/2022 • 2 minutes to read • [Edit Online](#)

C# preferences

The style rules in this section concern the use of [pattern matching](#) in C#.

- Use pattern matching to avoid `as` followed by a `null` check (IDE0019)
- Use pattern matching to avoid `is` check followed by a cast (IDE0020 and IDE0038)
- Use switch expression (IDE0066)
- Use pattern matching (IDE0078)
- Use pattern matching (`not` operator) (IDE0083)
- Simplify property pattern (IDE0170)

Visual Basic preferences

The style rules in this section concern the use of pattern matching in Visual Basic.

- Use pattern matching (`IsNot` operator) (IDE0084)

See also

- [Code style rules reference](#)
- [Code style language rules](#)

Use pattern matching to avoid 'as' followed by a 'null' check (IDE0019)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0019
Title	Use pattern matching to avoid <code>as</code> followed by a <code>null</code> check
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_pattern_matching_over_as_with_null_check</code>

Overview

This style rule concerns the use of C# [pattern matching](#) over an `as` expression followed by a `null` check.

Options

The associated option for this rule specifies whether to prefer pattern match or an `as` expression with null checks to determine if something is of a particular type.

For more information about configuring options, see [Option format](#).

`csharp_style_pattern_matching_over_as_with_null_check`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_pattern_matching_over_a_s_with_null_check</code>	
Option values	<code>true</code>	Prefer pattern matching to determine if something is of a particular type
	<code>false</code>	Prefer <code>as</code> expressions with null checks to determine if something is of a particular type
Default option value	<code>true</code>	

```
// csharp_style_pattern_matching_over_as_with_null_check = true
if (o is string s) {...}

// csharp_style_pattern_matching_over_as_with_null_check = false
var s = o as string;
if (s != null) {...}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0019
// The code that's violating the rule is on this line.
#pragma warning restore IDE0019
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0019.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Pattern matching in C#](#)

Use pattern matching to avoid 'is' check followed by a cast (IDE0020 and IDE0038)

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article describes two related rules, [IDE0020](#) and [IDE0038](#).

PROPERTY	VALUE
Rule ID	IDE0020
Title	Use pattern matching to avoid <code>is</code> check followed by a cast (with variable)
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_pattern_matching_over_is_with_cast_check</code>

PROPERTY	VALUE
Rule ID	IDE0038
Title	Use pattern matching to avoid <code>is</code> check followed by a cast (without variable)
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 7.0+
Options	<code>csharp_style_pattern_matching_over_is_with_cast_check</code>

Overview

This style rule concerns the use of C# [pattern matching](#), for example, `o is int i`, over an `is` check followed by a cast, for example, `if (o is int) { ... (int)o ... }`. Enable either [IDE0020](#) or [IDE0038](#) based on whether or not the cast expression should be saved into a separate local variable:

- [IDE0020](#) : Cast expression *is* saved into a local variable. For example, `if (o is int) { var i = (int)o; }` saves the result of `(int)o` in a local variable.
- [IDE0038](#) : Cast expression *is not* saved into a local variable. For example, `if (o is int) { if ((int)o == 1) { ... } }` does not save the result of `(int)o` into a local variable.

Options

Set the value of the associated option for this rule to specify whether pattern matching or `is` check followed by a type cast is preferred.

For more information about configuring options, see [Option format](#).

csharp_style_pattern_matching_over_is_with_cast_check

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_pattern_matching_over_is_with_cast_check</code>	
Option values	<code>true</code>	Prefer pattern matching instead of <code>is</code> expressions with type casts
	<code>false</code>	Prefer <code>is</code> expressions with type casts instead of pattern matching
Default option value	<code>true</code>	

```
// csharp_style_pattern_matching_over_is_with_cast_check = true
if (o is int i) {...}

// csharp_style_pattern_matching_over_is_with_cast_check = false
if (o is int) {var i = (int)o; ... }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0020 // Or IDE0038
// The code that's violating the rule is on this line.
#pragma warning restore IDE0020 // Or IDE0038
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0020.severity = none
dotnet_diagnostic.IDE0038.severity = none
```

To disable all of the code-style rules, set the severity for the category `style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use switch expression (IDE0066)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0066
Title	Use switch expression
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 8.0+
Introduced version	Visual Studio 2019 version 16.2
Options	<code>csharp_style_prefer_switch_expression</code>

Overview

This style rule concerns the use of [switch expressions](#), which were introduced in C# 8.0, versus [switch statements](#).

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_switch_expression`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_switch_expression</code>	
Option values	<code>true</code>	Prefer to use a <code>switch</code> expression
	<code>false</code>	Prefer to use a <code>switch</code> statement
Default option value	<code>true</code>	

```
// csharp_style_prefer_switch_expression = true
return x switch
{
    1 => 1 * 1,
    2 => 2 * 2,
    _ => 0,
};

// csharp_style_prefer_switch_expression = false
switch (x)
{
    case 1:
        return 1 * 1;
    case 2:
        return 2 * 2;
    default:
        return 0;
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0066
// The code that's violating the rule is on this line.
#pragma warning restore IDE0066
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0066.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use pattern matching (IDE0078)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0078
Title	Use pattern matching
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 9.0+
Options	<code>csharp_style_prefer_pattern_matching</code>

Overview

This style rule concerns the use of C# 9.0 [pattern matching](#) constructs.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_pattern_matching`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_pattern_matching</code>	
Option values	<code>true</code>	Prefer to use pattern matching constructs, when possible
	<code>false</code>	Prefer not to use pattern matching constructs.
Default option value	<code>true</code>	

```
// csharp_style_prefer_pattern_matching = true
var x = i is default(int) or > (default(int));
var y = o is not C c;

// csharp_style_prefer_pattern_matching = false
var x = i == default || i > default(int);
var y = !(o is C c);
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0078
// The code that's violating the rule is on this line.
#pragma warning restore IDE0078
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0078.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Use pattern matching (`not` operator) (IDE0083)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0083
Title	Use pattern matching (<code>not</code> operator)
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C# 9.0+
Options	<code>csharp_style_prefer_not_pattern</code>

Overview

This style rule concerns the use of C# 9.0 `not` pattern, when possible.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_not_pattern`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_not_pattern</code>	
Option values	<code>true</code>	Prefer to use the <code>not</code> pattern, when possible
	<code>false</code>	Prefer <i>not</i> to use the <code>not</code> pattern.
Default option value	<code>true</code>	

NOTE

When the option is set to `false`, the analyzer *does not* flag uses of the `not` pattern. However, any code that's generated won't use the `not` pattern. When the option is set to `true`, code that doesn't use the `not` pattern is flagged, and any code that's generated uses the `not` pattern where applicable.

The following examples show how code would be generated by code-generating features when the option is set to either `true` or `false`.

```
// csharp_style_prefer_not_pattern = true  
var y = o is not C c;  
  
// csharp_style_prefer_not_pattern = false  
var y = !(o is C c);
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0083  
// The code that's violating the rule is on this line.  
#pragma warning restore IDE0083
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_diagnostic.IDE0083.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Code style rules reference](#)

Use pattern matching (`IsNot` operator) (IDE0084)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0084
Title	Use pattern matching (<code> IsNot</code> operator)
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	Visual Basic 14.0+
Options	<code>visual_basic_style_prefer_isnot_expression</code>

Overview

This style rule concerns the use of the Visual Basic 14.0 `IsNot` pattern, when possible.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`visual_basic_style_prefer_isnot_expression`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>visual_basic_style_prefer_isnot_expressi on</code>	
Option values	<code>true</code>	Prefer to use the <code> IsNot</code> pattern, when possible
	<code>false</code>	Prefer <i>not</i> to use the <code> IsNot</code> pattern.
Default option value	<code>true</code>	

```
' visual_basic_style_prefer_isnot_expression = true
Dim y = o IsNot C

' visual_basic_style_prefer_isnot_expression = false
Dim y = Not o Is C
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and

then re-enable the rule.

```
#pragma warning disable IDE0084
// The code that's violating the rule is on this line.
#pragma warning restore IDE0084
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0084.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

Simplify property pattern (IDE0170)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0170
Title	Simplify property pattern
Category	Style
Subcategory	Language rules (pattern matching preferences)
Applicable languages	C#
Options	<code>csharp_style_prefer_extended_property_pattern</code>

Overview

This style rule flags the use of a nested pattern in a [property pattern](#). A nested pattern can be simplified to use an extended property pattern in which property subpatterns are used to reference nested members. Extended property patterns improve code readability.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_style_prefer_extended_property_pattern`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_style_prefer_extended_property_pattern</code>	
Option values	<code>true</code>	Prefer the extended property pattern.
	<code>false</code>	Disables the rule.
Default option value	<code>true</code>	

Example

```
public record Point(int X, int Y);
public record Segment(Point Start, Point End);

// Violates IDE0170.
static bool IsEndOnXAxis(Segment segment) =>
    segment is { Start: { Y: 0 } } or { End: { Y: 0 } };

// Fixed code.
static bool IsEndOnXAxis(Segment segment) =>
    segment is { Start.Y: 0 } or { End.Y: 0 };
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0170
// The code that's violating the rule is on this line.
#pragma warning restore IDE0170
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0170.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Code block preferences

9/20/2022 • 2 minutes to read • [Edit Online](#)

Overview

The style rules in this section concern the following code block preferences:

- [Add braces \(IDE0011\)](#)
- [Use simple 'using' statement \(IDE0063\)](#)

See also

- [Code style rules reference](#)
- [Code style language rules](#)

Add braces (IDE0011)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0011
Title	Add braces
Category	Style
Subcategory	Language rules (code block preferences)
Options	<code>csharp_prefer_braces</code>

Overview

This style rule concerns the use of curly braces `{ }` to surround code blocks.

Options

Use the following option to specify whether curly braces are preferred or not, and if preferred, whether only for multi-line code blocks.

For more information about configuring options, see [Option format](#).

`csharp_prefer_braces`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_prefer_braces</code>	
Option values	<code>true</code>	Prefer curly braces even for one line of code
	<code>false</code>	Prefer no curly braces if allowed
	<code>when_multiline</code>	Prefer curly braces on multiple lines
Default option value	<code>true</code>	

```
// csharp_prefer_braces = true
if (test) { this.Display(); }

// csharp_prefer_braces = false
if (test) this.Display();
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0011
// The code that's violating the rule is on this line.
#pragma warning restore IDE0011
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0011.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Code block preferences](#)
- [Code style language rules](#)
- [Code style rules reference](#)

Use simple 'using' statement (IDE0063)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0063
Title	Use simple <code>using</code> statement
Category	Style
Subcategory	Language rules (code block preferences)
Applicable languages	C# 8.0+
Options	<code>csharp_prefer_simple_using_statement</code>

Overview

This style rule concerns the use of `using` statements without curly braces, also known as `using` declarations. This [alternative syntax](#) was introduced in C# 8.0.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`csharp_prefer_simple_using_statement`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_prefer_simple_using_statement</code>	
Option values	<code>true</code>	Prefer to use a <code>using</code> declaration
	<code>false</code>	Prefer to use a <code>using</code> statement with curly braces
Default option value	<code>true</code>	

```
// csharp_prefer_simple_using_statement = true
using var a = b;

// csharp_prefer_simple_using_statement = false
using (var a = b) { }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and

then re-enable the rule.

```
#pragma warning disable IDE0063
// The code that's violating the rule is on this line.
#pragma warning restore IDE0063
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0063.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

'using' directive placement (IDE0065)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0065
Title	'using' directive placement
Category	Style
Subcategory	Language rules ('using' directive preferences)
Applicable languages	C#
Options	csharp_using_directive_placement

Overview

This style rule concerns the preference of placing `using` directives outside or inside the namespace.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

csharp_using_directive_placement

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_using_directive_placement	
Option values	outside_namespace	Prefer <code>using</code> directives to be placed outside the namespace
	inside_namespace	Prefer <code>using</code> directives to be placed inside the namespace
Default option value	outside_namespace	

```
// csharp_using_directive_placement = outside_namespace
using System;

namespace Conventions
{
    ...
}

// csharp_using_directive_placement = inside_namespace
namespace Conventions
{
    using System;
    ...
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0065
// The code that's violating the rule is on this line.
#pragma warning restore IDE0065
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0065.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Require file header (IDE0073)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0073
Title	Require file header
Category	Style
Subcategory	Language rules (file header preferences)
Applicable languages	C# and Visual Basic
Options	<code>file_header_template</code>

Overview

This style rule concerns providing a file header at top of source code files.

Options

Specify the required header text by setting the `file_header_template` option.

- When the option value is a non-empty string, require the specified file header.
- When the option value is `unset` or an empty string, do not require a file header.

For information about configuring options, see [Option format](#).

`file_header_template`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>file_header_template</code>	
Option values	non-empty string, optionally containing a <code>{fileName}</code> placeholder	Prefer the string as the required file header.
	<code>unset</code> or empty string	Do not require a file header.
Default option value	<code>unset</code>	

```
// file_header_template = Copyright (c) SomeCorp. All rights reserved.\nLicensed under the xyz license.  
  
// Copyright (c) SomeCorp. All rights reserved.  
// Licensed under the xyz license.  
namespace N1  
{  
    class C1 { }  
}  
  
// file_header_template = unset  
// OR  
// file_header_template =  
namespace N2  
{  
    class C2 { }  
}
```

```
' file_header_template = Copyright (c) SomeCorp. All rights reserved.\nLicensed under the xyz license.  
  
' Copyright (c) SomeCorp. All rights reserved.  
' Licensed under the xyz license.  
Namespace N1  
    Class C1  
    End Class  
End Namespace  
  
' file_header_template = unset  
' OR  
' file_header_template =  
Namespace N2  
    Class C2  
    End Class  
End Namespace
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0073  
// The code that's violating the rule is on this line.  
#pragma warning restore IDE0073
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_diagnostic.IDE0073.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

Unnecessary code rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

Unnecessary code rules identify different parts of the code base that are unnecessary and can be refactored or removed. The presence of unnecessary code indicates one of more of the following problems:

- Readability: Code that is unnecessarily degrading readability. For example, [IDE0001](#) flags unnecessary type-name qualifications.
- Maintainability: Code that is no longer used after refactoring and is unnecessarily being maintained. For example, [IDE0051](#) flags unused private fields, properties, events, and methods.
- Performance: Unnecessary computation that has no side effects and leads to unnecessary performance overhead. For example, [IDE0059](#) flags unused value assignments where the expression to compute a value has no side effects.
- Functionality: Functional issue in code leading to required code being rendered redundant. For example, [IDE0060](#) flags unused parameters where the method accidentally ignores an input parameter.

The rules in this section concern the following unnecessary code rules:

- [Simplify name \(IDE0001\)](#)
- [Simplify member access \(IDE0002\)](#)
- [Remove unnecessary cast \(IDE0004\)](#)
- [Remove unnecessary import \(IDE0005\)](#)
- [Remove unreachable code \(IDE0035\)](#)
- [Remove unused private member \(IDE0051\)](#)
- [Remove unread private member \(IDE0052\)](#)
- [Remove unused expression value \(IDE0058\)](#)
- [Remove unnecessary value assignment \(IDE0059\)](#)
- [Remove unused parameter \(IDE0060\)](#)
- [Remove unnecessary suppression \(IDE0079\)](#)
- [Remove unnecessary suppression operator \(IDE0080\) - C# only.](#)
- [Remove 'ByVal' \(IDE0081\) - Visual Basic only.](#)
- [Remove unnecessary equality operator \(IDE0100\)](#)
- [Remove unnecessary discard \(IDE0110\) - C# only.](#)
- [Simplify object creation \(IDE0140\) - Visual Basic only.](#)

Some of these rules have options to configure the rule behavior.

See also

- [Code style language rules](#)
- [Code style rules reference](#)

Simplify name (IDE0001)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0001
Title	Simplify name
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule concerns the use of simplified type names in declarations and executable code, when possible. You can remove unnecessary name qualification to simplify code and improve readability.

Options

This rule has no associated code-style options.

Example

```
using System.IO;
class C
{
    // IDE0001: 'System.IO.FileInfo' can be simplified to 'FileInfo'
    System.IO.FileInfo file;

    // Fixed code
    FileInfo file;
}
```

```
Imports System.IO
Class C
    ' IDE0001: 'System.IO.FileInfo' can be simplified to 'FileInfo'
    Private file As System.IO.FileInfo

    ' Fixed code
    Private file As FileInfo
End Class
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0001
// The code that's violating the rule is on this line.
#pragma warning restore IDE0001
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0001.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Simplify member access \(IDE0002\)](#)
- [Unnecessary code rules](#)
- [Code style rules reference](#)

Simplify member access (IDE0002)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0002
Title	Simplify member access
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule concerns use of simplified type member access in declarations and executable code, when possible. Unnecessary qualification can be removed to simplify code and improve readability.

Options

This rule has no associated code-style options.

Example

```
static void M1() { }
static void M2()
{
    // IDE0002: 'C.M1' can be simplified to 'M1'
    C.M1();

    // Fixed code
    M1();
}
```

```
Shared Sub M1()
End Sub

Shared Sub M2()
    ' IDE0002: 'C.M1' can be simplified to 'M1'
    C.M1()

    ' Fixed code
    M1()
End Sub
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0002
// The code that's violating the rule is on this line.
#pragma warning restore IDE0002
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0002.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

Remove unnecessary cast (IDE0004)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0004
Title	Remove unnecessary cast
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule flags unnecessary [type casts](#). A cast expression is unnecessary if the code semantics would be identical with or without it.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
int v = (int)0;

// Fixed code
int v = 0;
```

```
' Code with violations
Dim v As Integer = CType(0, Integer)

' Fixed code
Dim v As Integer = 0
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0004
// The code that's violating the rule is on this line.
#pragma warning restore IDE0004
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0004.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Type cast and conversions](#)
- [Unnecessary code rules](#)

Remove unnecessary using directives (IDE0005)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0005
Title	Remove unnecessary import
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule flags the following unnecessary constructs. If unnecessary, these constructs can be removed without changing the semantics of the code:

- [using directives](#) (C#).
- [Import statements](#) (Visual Basic).

NOTE

To enable this [rule on build](#), you need to enable [XML documentation comments](#) for the project. For more information, see [dotnet/roslyn issue 41640](#).

Options

This rule has no associated code-style options.

Example

```
// Code with violations
using System;
using System.IO;    // IDE0005: Using directive is unnecessary
class C
{
    public static void M()
    {
        Console.WriteLine("Hello");
    }
}

// Fixed code
using System;
class C
{
    public static void M()
    {
        Console.WriteLine("Hello");
    }
}
```

```
' Code with violations
Imports System.IO    ' IDE0005: Imports statement is unnecessary
Class C
    Public Shared Sub M()
        Console.WriteLine("Hello")
    End Sub
End Class

' Fixed code
Class C
    Public Shared Sub M()
        Console.WriteLine("Hello")
    End Sub
End Class
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0005
// The code that's violating the rule is on this line.
#pragma warning restore IDE0005
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0005.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unreachable code (IDE0035)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0035
Title	Remove unreachable code
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule flags executable code within methods and properties that can never be reached, and hence can be removed.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
void M()
{
    throw new System.Exception();

    // IDE0035: Remove unreachable code
    int v = 0;
}

// Fixed code
void M()
{
    throw new System.Exception();
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0035
// The code that's violating the rule is on this line.
#pragma warning restore IDE0035
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0035.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unused private member (IDE0051)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0051
Title	Remove unused private member
Category	CodeQuality
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule flags unused private methods, fields, properties, and events that have no read or write references.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
class C
{
    // IDE0051: Remove unused private members
    private readonly int _fieldPrivate;
    private int PropertyPrivate => 1;
    private int GetNumPrivate() => 1;

    // No IDE0051
    internal readonly int FieldInternal;
    private readonly int _fieldPrivateUsed;
    public int PropertyPublic => _fieldPrivateUsed;
    private int GetNumPrivateUsed() => 1;
    internal int GetNumInternal() => GetNumPrivateUsed();
    public int GetNumPublic() => GetNumPrivateUsed();
}

// Fixed code
class C
{
    // No IDE0051
    internal readonly int FieldInternal;
    private readonly int _fieldPrivateUsed;
    public int PropertyPublic => _fieldPrivateUsed;
    private int GetNumPrivateUsed() => 1;
    internal int GetNumInternal() => GetNumPrivateUsed();
    public int GetNumPublic() => GetNumPrivateUsed();
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0051
// The code that's violating the rule is on this line.
#pragma warning restore IDE0051
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_diagnostic.IDE0051.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.cs,vb]
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unread private member (IDE0052)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0052
Title	Remove unread private member
Category	CodeQuality
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This rule flags private fields and properties that have one or more write references but no read references. In this scenario, some parts of the code can be refactored or removed to fix maintainability, performance, or functional issues.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
class C
{
    // IDE0052: Remove unread private members
    private readonly int _field1;
    private int _field2;
    private int Property { get; set; }

    public C()
    {
        _field1 = 0;
    }

    public void SetMethod()
    {
        _field2 = 0;
        Property = 0;
    }
}

// Fixed code
class C
{
    public C()
    {
    }

    public void SetMethod()
    {
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0052
// The code that's violating the rule is on this line.
#pragma warning restore IDE0052
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0052.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unnecessary expression value (IDE0058)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0058
Title	Remove unnecessary expression value
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic
Options	<code>csharp_style_unused_value_expression_statement_preference</code> <code>visual_basic_style_unused_value_expression_statement_preference</code>

Overview

This rule flags unused expression values. For example:

```
void M()
{
    Compute(); // IDE0058: computed value is never used.
}

int Compute();
```

You can take one of the following actions to fix this violation:

- If the expression has no side effects, remove the entire statement. This improves performance by avoiding unnecessary computation.
- If the expression has side effects, replace the left side of the assignment with a **discard** (C# only) or a local variable that's never used. This improves code clarity by explicitly showing the intent to discard an unused value.

```
_ = Compute();
```

Options

The options for this specify whether to prefer the use of a discard or an unused local variable:

- C# - `csharp_style_unused_value_expression_statement_preference`
- Visual Basic - `visual_basic_style_unused_value_expression_statement_preference`

For information about configuring options, see [Option format](#).

`csharp_style_unused_value_expression_statement_preference`

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_unused_value_expression_statement_preference	
Applicable languages	C#	
Option values	<input type="checkbox"/> discard_variable <input type="checkbox"/> unused_local_variable	Prefer to assign an unused expression to a discard
	<input type="checkbox"/> unused_local_variable	Prefer to assign an unused expression to a local variable that's never used
Default option value	<input type="checkbox"/> discard_variable	

```
// Original code:  
System.Convert.ToInt32("35");  
  
// After code fix for IDE0058:  
  
// csharp_style_unused_value_expression_statement_preference = discard_variable  
_ = System.Convert.ToInt32("35");  
  
// csharp_style_unused_value_expression_statement_preference = unused_local_variable  
var unused = Convert.ToInt32("35");
```

visual_basic_style_unused_value_expression_statement_preference

PROPERTY	VALUE	DESCRIPTION
Option name	visual_basic_style_unused_value_expression_statement_preference	
Applicable languages	Visual Basic	
Option values	<input type="checkbox"/> unused_local_variable	Prefer to assign an unused expression to a local variable that's never used
Default option value	<input type="checkbox"/> unused_local_variable	

```
' visual_basic_style_unused_value_expression_statement_preference = unused_local_variable  
Dim unused = Computation()
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0058  
// The code that's violating the rule is on this line.  
#pragma warning restore IDE0058
```

To disable the rule for a file, folder, or project, set its severity to none in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_diagnostic.IDE0058.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Remove unnecessary value assignment \(IDE0059\)](#)

Remove unnecessary value assignment (IDE0059)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0059
Title	Remove unnecessary value assignment
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic
Options	<code>csharp_style_unused_value_assignment_preference</code>
	<code>visual_basic_style_unused_value_assignment_preference</code>

Overview

This rule flags unnecessary value assignments. For example:

```
int v = Compute(); // IDE0059: value written to 'v' is never read, so assignment to 'v' is unnecessary.  
v = Compute2();
```

Users can take one of the following actions to fix this violation:

- If the expression on the right side of the assignment has no side effects, remove the expression or the entire assignment statement. This improves performance by avoiding unnecessary computation.

```
int v = Compute2();
```

- If the expression on the right side of the assignment has side effects, replace the left side of the assignment with a [discard](#) (C# only) or a local variable that's never used. This improves code clarity by explicitly showing the intent to discard an unused value.

```
_ = Compute();  
int v = Compute2();
```

Options

The options for this specify whether to prefer the use of a discard or an unused local variable:

- C# - `csharp_style_unused_value_assignment_preference`
- Visual Basic - `visual_basic_style_unused_value_assignment_preference`

For information about configuring options, see [Option format](#).

csharp_style_unused_value_assignment_preference

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_style_unused_value_assignment_preference	
Applicable languages	C#	
Option values	<code>discard_variable</code>	Prefer to use a discard when assigning a value that's not used
	<code>unused_local_variable</code>	Prefer to use a local variable when assigning a value that's not used
Default option value	<code>discard_variable</code>	

```
// csharp_style_unused_value_assignment_preference = discard_variable
int GetCount(Dictionary<string, int> wordCount, string searchWord)
{
    _ = wordCount.TryGetValue(searchWord, out var count);
    return count;
}

// csharp_style_unused_value_assignment_preference = unused_local_variable
int GetCount(Dictionary<string, int> wordCount, string searchWord)
{
    var unused = wordCount.TryGetValue(searchWord, out var count);
    return count;
}
```

visual_basic_style_unused_value_assignment_preference

PROPERTY	VALUE	DESCRIPTION
Option name	visual_basic_style_unused_value_assignment_preference	
Applicable languages	Visual Basic	
Option values	<code>unused_local_variable</code>	Prefer to use a local variable when assigning a value that's not used
Default option value	<code>unused_local_variable</code>	

```
' visual_basic_style_unused_value_assignment_preference = unused_local_variable
Dim unused = Computation()
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0059
// The code that's violating the rule is on this line.
#pragma warning restore IDE0059
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0059.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unused parameter (IDE0060)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0060
Title	Remove unused parameter
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic
Options	<code>dotnet_code_quality_unused_parameters</code>

Overview

This rule flags unused parameters.

This rule does not flag parameters that are named with the `discard` symbol `_`. In addition, the rule ignores parameters that are named with the discard symbol followed by an integer, for example, `_1`. This behavior reduces warning noise on parameters that are needed for signature requirements, for example, a method used as a delegate, a parameter with special attributes, or a parameter whose value is implicitly accessed at run time by a framework but is not referenced in code.

Options

The option value specifies if unused parameters should be flagged only for non-public methods or for both public and non-public methods.

For information about configuring options, see [Option format](#).

`dotnet_code_quality_unused_parameters`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_code_quality_unused_parameters</code>	
Option values	<code>all</code>	Flag methods with any accessibility that contain unused parameters
	<code>non_public</code>	Flag only non-public methods that contain unused parameters
Default option value	<code>all</code>	

```
// dotnet_code_quality_unused_parameters = all
public int GetNum1(int unusedParam) { return 1; }
internal int GetNum2(int unusedParam) { return 1; }
private int GetNum3(int unusedParam) { return 1; }

// dotnet_code_quality_unused_parameters = non_public
internal int GetNum4(int unusedParam) { return 1; }
private int GetNum5(int unusedParam) { return 1; }
```

```
' dotnet_code_quality_unused_parameters = all
Public Function GetNum1(unused As Integer)
    Return 1
End Function

Friend Function GetNum2(unused As Integer)
    Return 1
End Function

Private Function GetNum3(unused As Integer)
    Return 1
End Function

' dotnet_code_quality_unused_parameters = non_public
Friend Function GetNum4(arg1 As Integer)
    Return 1
End Function

Private Function GetNum5(arg1 As Integer)
    Return 1
End Function
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0060
// The code that's violating the rule is on this line.
#pragma warning restore IDE0060
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0060.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unnecessary suppression (IDE0079)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0079
Title	Remove unnecessary suppression
Category	CodeQuality
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic
Options	<code>dotnet_remove_unnecessary_suppression_exclusions</code>

Overview

This rule flags unnecessary [pragma](#) and [SuppressMessageAttribute](#) attribute suppressions in source. Source suppressions are meant to suppress violations of compiler and analyzer rules for specific parts of source code, without disabling the rules in the other parts of the code. They are generally added to suppress false positives or less important violations that user does not intend to fix. Suppressions can frequently become stale, either due to the rules getting fixed to prevent false positives or user code being refactored to render the suppressions redundant. This rule helps identify such redundant suppressions, which can be removed.

Example

```

using System.Diagnostics.CodeAnalysis;

class C1
{
    // Necessary pragma suppression
#pragma warning disable IDE0051 // IDE0051: Remove unused member
    private int UnusedMethod() => 0;
#pragma warning restore IDE0051

    // IDE0079: Unnecessary pragma suppression
#pragma warning disable IDE0051 // IDE0051: Remove unused member
    private int UsedMethod() => 0;
#pragma warning restore IDE0051

    public int PublicMethod() => UsedMethod();
}

class C2
{
    // Necessary SuppressMessage attribute suppression
    [SuppressMessage("CodeQuality", "IDE0051:Remove unused private members", Justification = "<Pending>")]
    private int _unusedField;

    // IDE0079: Unnecessary SuppressMessage attribute suppression
    [SuppressMessage("CodeQuality", "IDE0051:Remove unused private members", Justification = "<Pending>")]
    private int _usedField;

    public int PublicMethod2() => _usedField;
}

```

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`dotnet_remove_unnecessary_suppression_exclusions`

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_remove_unnecessary_suppression_exclusions	
Option values	<code>,</code> separated list of rule IDs or categories (prefixed with <code>category:</code>) <code>all</code>	Excludes suppressions for the listed rules Disables the rule (all rule IDs excluded)
	<code>none</code>	Enables the rule for all rules (no exclusions)
Default option value	<code>none</code>	

```
using System.Diagnostics.CodeAnalysis;

class C1
{
    // 'dotnet_remove_unnecessary_suppression_exclusions = IDE0051'

    // Unnecessary pragma suppression, but not flagged by IDE0079
#pragma warning disable IDE0051 // IDE0051: Remove unused member
    private int UsedMethod() => 0;
#pragma warning restore IDE0051

    public int PublicMethod() => UsedMethod();
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0079
// The code that's violating the rule is on this line.
#pragma warning restore IDE0079
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0079.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unnecessary suppression operator (IDE0080)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0080
Title	Remove unnecessary suppression operator
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C#

Overview

This rule flags an unnecessary [suppression or null-forgiving operator](#). The operator is unnecessary when it's used in a context where it has no effect. Use of the suppression operator, for example, `x!`, declares that the expression `x` of a reference type isn't null. However, when used in a context of another operator, for example, the [is operator](#) in `o !is string`, it has no effect and can be removed.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
if (o !is string) { }

// Potential fixes:
// 1.
if (o is not string) { }

// 2.
if (!(o is string)) { }

// 3.
if (o is string) { }
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0080
// The code that's violating the rule is on this line.
#pragma warning restore IDE0080
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0080.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

- [Suppression or null-forgiving operator](#)
- [Unnecessary code rules](#)
- [Code style rules reference](#)

Remove `ByVal` (IDE0081)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0081
Title	Remove <code>ByVal</code>
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	Visual Basic

Overview

This rule flags an unnecessary `ByVal` keyword in a parameter declaration in Visual Basic. Parameters in Visual Basic are `ByVal` by default, hence you do not need to explicitly specify it in method signatures. It tends to produce noisy code and often leads to the non-default `ByRef` keyword being overlooked.

Options

This rule has no associated code-style options.

Example

```
' Code with violations
Sub M(ByVal p1 As Integer, ByRef p2 As Integer)
End Sub

' Fixed code
Sub M(p1 As Integer, ByRef p2 As Integer)
End Sub
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0081
// The code that's violating the rule is on this line.
#pragma warning restore IDE0081
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0081.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]\ndotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Remove unnecessary equality operator (IDE0100)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0100
Title	Remove unnecessary equality operator
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C# and Visual Basic

Overview

This style rule flags an unnecessary equality operator when comparing a non-constant Boolean expression with a constant `true` or `false`.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
if (x == true) { }
if (M() != false) { }

// Fixed code
if (x) { }
if (M()) { }
```

```
' Code with violations
If x = True Then
End If

If M() <> False Then
End If

' Fixed code
If x Then
End If

If M() Then
End If
```

SUPPRESS A WARNING

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and

then re-enable the rule.

```
#pragma warning disable IDE0100
// The code that's violating the rule is on this line.
#pragma warning restore IDE0100
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0100.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

See also

Remove unnecessary discard (IDE0110)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0110
Title	Remove unnecessary discard
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	C#

Overview

This rule flags unnecessary [discard patterns](#). A discard pattern is unnecessary when used in a context where it has no effect.

Options

This rule has no associated code-style options.

Example

```
// Code with violations
switch (o)
{
    case int _:
        Console.WriteLine("Value was an int");
        break;
    case string _:
        Console.WriteLine("Value was a string");
        break;
}

// Fixed code
switch (o)
{
    case int:
        Console.WriteLine("Value was an int");
        break;
    case string:
        Console.WriteLine("Value was a string");
        break;
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0110
// The code that's violating the rule is on this line.
#pragma warning restore IDE0110
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0110.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Simplify object creation (IDE0140)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0140
Title	Simplify object creation
Category	Style
Subcategory	Unnecessary code rules
Applicable languages	Visual Basic
Options	<code>visual_basic_style_prefer_simplified_object_creation</code>

Overview

This style rule flags unnecessary type repetition in Visual Basic code.

Options

Options specify the behavior that you want the rule to enforce. For information about configuring options, see [Option format](#).

`visual_basic_style_prefer_simplified_object_creation`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>visual_basic_style_prefer_simplified_object_creation</code>	
Option values	<code>true</code>	Prefer simplified object creation form.
	<code>false</code>	Disables the rule.
Default option value	<code>true</code>	

Example

```
' Code with violations
Dim x As Student = New Student()

' Fixed code
Dim x As New Student()
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0140
// The code that's violating the rule is on this line.
#pragma warning restore IDE0140
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0140.severity = none
```

To disable all of the code-style rules, set the severity for the category `style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Miscellaneous rules

9/20/2022 • 2 minutes to read • [Edit Online](#)

This section contains code-style rules that don't fit in any other category. The miscellaneous rules are:

- [Remove invalid global 'SuppressMessageAttribute' \(IDE0076\)](#)
- [Avoid legacy format target in global 'SuppressMessageAttribute' \(IDE0077\)](#)

See also

- [Code style rules reference](#)

Remove invalid global 'SuppressMessageAttribute' (IDE0076)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0076
Title	Remove invalid global <code>SuppressMessageAttribute</code>
Category	CodeQuality
Subcategory	Miscellaneous rules
Applicable languages	C# and Visual Basic

Overview

This rule flags [global SuppressMessageAttributes](#) that have an invalid `Scope` or `Target`. The attribute should either be removed or fixed to refer to a valid scope and target symbol.

Options

This rule has no associated code-style options.

Example

```
// IDE0076: Invalid target '~F:N.C.F2' - no matching field named 'F2'
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "member", Target = "~F:N.C.F2")]
// IDE0076: Invalid scope 'property'
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "property", Target = "~P:N.C.P")]

// Fixed code
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "member", Target = "~F:N.C.F")]
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "member", Target = "~P:N.C.P")]

namespace N
{
    class C
    {
        public int F;
        public int P { get; }
    }
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0076
// The code that's violating the rule is on this line.
#pragma warning restore IDE0076
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0076.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

- [Global SuppressMessageAttribute](#)
- [Avoid legacy format target in global 'SuppressMessageAttribute' \(IDE0077\)](#)
- [Code style rules reference](#)

Avoid legacy format target in global 'SuppressMessageAttribute' (IDE0077)

9/20/2022 • 2 minutes to read • [Edit Online](#)

PROPERTY	VALUE
Rule ID	IDE0077
Title	Avoid legacy format target in global <code>SuppressMessageAttribute</code>
Category	CodeQuality
Subcategory	Miscellaneous rules
Applicable languages	C# and Visual Basic

Overview

This rule flags [global SuppressMessageAttributes](#) that specify `Target` using the [legacy FxCop](#) target string format. Using the legacy format `Target` is known to have performance problems and should be avoided. For more information, see [dotnet/roslyn issue 44362](#).

The recommended format for `Target` is the *documentation ID* format. For information about documentation IDs, see [Documentation ID format](#).

TIP

Visual Studio 2019 provides a code fix to automatically change the `Target` of the attribute to the recommended format.

Options

This rule has no associated code-style options.

Example

```
// IDE0077: Legacy format target 'N.C.#F'  
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "member", Target = "N.C.#F")]  
  
// Fixed code  
[assembly: System.Diagnostics.CodeAnalysis.SuppressMessage("Category", "Id: Title", Scope = "member", Target = "~F:N.C.F")]  
  
namespace N  
{  
    class C  
    {  
        public int F;  
    }  
}
```

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0077  
// The code that's violating the rule is on this line.  
#pragma warning restore IDE0077
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_diagnostic.IDE0077.severity = none
```

To disable this entire category of rules, set the severity for the category to `none` in the [configuration file](#).

```
[*.{cs,vb}]  
dotnet_analyzer_diagnostic.category-CodeQuality.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

Formatting rule (IDE0055)

9/20/2022 • 2 minutes to read • [Edit Online](#)

All formatting options have rule ID IDE0055 and title [Fix formatting](#). These formatting options affect how indentation, spaces, and new lines are aligned around .NET programming language constructs. The options fall into the following categories and are documented on separate pages:

- [.NET formatting options](#)

Options that apply to both C# and Visual Basic. The EditorConfig names for these options start with the `dotnet_` prefix.

- [C# formatting options](#)

Options that are specific to the C# language. The EditorConfig names for these options start with the `csharp_` prefix.

When you set the severity of code-style rule IDE0055, it applies to all the formatting options. To set the severity of a formatting rule violation, add the following setting to a [configuration file](#).

```
dotnet_diagnostic.IDE0055.severity = <severity value>
```

The severity value must be `warning` or `error` to be [enforced on build](#). For all possible severity values, see [severity level](#).

For more information about configuring options, see [Option format](#).

Suppress a warning

If you want to suppress only a single violation, add preprocessor directives to your source file to disable and then re-enable the rule.

```
#pragma warning disable IDE0055
// The code that's violating the rule is on this line.
#pragma warning restore IDE0055
```

To disable the rule for a file, folder, or project, set its severity to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_diagnostic.IDE0055.severity = none
```

To disable all of the code-style rules, set the severity for the category `Style` to `none` in the [configuration file](#).

```
[*.{cs,vb}]
dotnet_analyzer_diagnostic.category-Style.severity = none
```

For more information, see [How to suppress code analysis warnings](#).

.NET formatting options

9/20/2022 • 2 minutes to read • [Edit Online](#)

The formatting options in this article apply to both C# and Visual Basic. These are options for code-style rule [IDE0055](#).

Using directive options

Use these options to customize how you want using directives to be sorted and grouped:

- [dotnet_sort_system_directives_first](#)
- [dotnet_separate_import_directive_groups](#)

Example `.editorconfig` file:

```
# .NET formatting rules
[*.{cs,vb}]
dotnet_sort_system_directives_first = true
dotnet_separate_import_directive_groups = true
```

TIP

If your code is C#, additional C#-specific `using` directive options are available.

`dotnet_sort_system_directives_first`

PROPERTY	VALUE	DESCRIPTION
Option name	<code>dotnet_sort_system_directives_first</code>	
Applicable languages	C# and Visual Basic	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Sort <code>System.*</code> <code>using</code> directives alphabetically, and place them before other <code>using</code> directives.
	<code>false</code>	Do not place <code>System.*</code> <code>using</code> directives before other <code>using</code> directives.

Code examples:

```
// dotnet_sort_system_directives_first = true
using System.Collections.Generic;
using System.Threading.Tasks;
using Octokit;

// dotnet_sort_system_directives_first = false
using System.Collections.Generic;
using Octokit;
using System.Threading.Tasks;
```

dotnet_separate_import_directive_groups

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_separate_import_directive_groups	
Applicable languages	C# and Visual Basic	
Introduced version	Visual Studio 2017 version 15.5	
Option values	<code>true</code>	Place a blank line between <code>using</code> directive groups.
	<code>false</code>	Do not place a blank line between <code>using</code> directive groups.

Code examples:

```
// dotnet_separate_import_directive_groups = true
using System.Collections.Generic;
using System.Threading.Tasks;

using Octokit;

// dotnet_separate_import_directive_groups = false
using System.Collections.Generic;
using System.Threading.Tasks;
using Octokit;
```

Dotnet namespace options

This category contains one formatting option that concerns how namespaces are named in both C# and Visual Basic.

- [dotnet_style_namespace_match_folder](#)

Example `.editorconfig` file:

```
# .NET namespace rules
[*.{cs,vb}]
dotnet_style_namespace_match_folder = true
```

dotnet_style_namespace_match_folder

PROPERTY	VALUE	DESCRIPTION
Option name	dotnet_style_namespace_match_folder	
Applicable languages	C# and Visual Basic	
Introduced version	Visual Studio 2019 version 16.10	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Match namespaces to folder structure Do not report on namespaces that do not match folder structure

Code examples:

```
// dotnet_style_namespace_match_folder = true
// file path: Example/Convention/C.cs
using System;

namespace Example.Convention
{
    class C
    {
    }
}

// dotnet_style_namespace_match_folder = false
// file path: Example/Convention/C.cs
using System;

namespace Example
{
    class C
    {
    }
}
```

NOTE

`dotnet_style_namespace_match_folder` requires the analyzer to have access to project properties to function correctly. For projects that target .NET Core 3.1 or an earlier version, you must manually add the following items to your project file. (They're added automatically for .NET 5 and later.)

```
<ItemGroup>
  <CompilerVisibleProperty Include="RootNamespace" />
  <CompilerVisibleProperty Include="ProjectDir" />
</ItemGroup>
```

- [Formatting rule \(IDE0055\)](#)

C# formatting options

9/20/2022 • 14 minutes to read • [Edit Online](#)

The formatting options in this article apply only to C# code. These are options for code-style rule [IDE0055](#).

New-line options

The new-line options concern the use of new lines to format code.

- [csharp_new_line_before_open_brace](#)
- [csharp_new_line_before_else](#)
- [csharp_new_line_before_catch](#)
- [csharp_new_line_before_finally](#)
- [csharp_new_line_before_members_in_object_initializers](#)
- [csharp_new_line_before_members_in_anonymous_types](#)
- [csharp_new_line_between_query_expression_clauses](#)

Example `.editorconfig` file:

```
# CSharp formatting rules:  
[*.cs]  
csharp_new_line_before_open_brace = methods, properties, control_blocks, types  
csharp_new_line_before_else = true  
csharp_new_line_before_catch = true  
csharp_new_line_before_finally = true  
csharp_new_line_before_members_in_object_initializers = true  
csharp_new_line_before_members_in_anonymous_types = true  
csharp_new_line_between_query_expression_clauses = true
```

csharp_new_line_before_open_brace

This option concerns whether an open brace `{` should be placed on the same line as the preceding code, or on a new line. For this rule, you specify **all**, **none**, or one or more code elements such as **methods** or **properties**, to define when this rule should be applied. To specify multiple code elements, separate them with a comma (,).

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_new_line_before_open_brace</code>	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>all</code>	Require braces to be on a new line for all expressions ("Allman" style).
	<code>none</code>	Require braces to be on the same line for all expressions ("K&R").

PROPERTY	VALUE	DESCRIPTION
	accessors , anonymous_methods , anonymous_types , control_blocks , events , indexers , lambdas , local_functions , methods , object_collection_array_initializers , properties , types	Require braces to be on a new line for the specified code element ("Allman" style).

Code examples:

```
// csharp_new_line_before_open_brace = all
void MyMethod()
{
    if (...)

    ...
}

// csharp_new_line_before_open_brace = none
void MyMethod() {
    if (...) {
        ...
    }
}
```

csharp_new_line_before_else

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_before_else	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	true	Place <code>else</code> statements on a new line.
	false	Place <code>else</code> statements on the same line.

Code examples:

```
// csharp_new_line_before_else = true
if (...) {
    ...
}
else {
    ...
}

// csharp_new_line_before_else = false
if (...) {
    ...
} else {
    ...
}
```

csharp_new_line_before_catch

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_before_catch	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Place <code>catch</code> statements on a new line.
	<code>false</code>	Place <code>catch</code> statements on the same line.

Code examples:

```
// csharp_new_line_before_catch = true
try {
    ...
}
catch (Exception e) {
    ...
}

// csharp_new_line_before_catch = false
try {
    ...
} catch (Exception e) {
    ...
}
```

csharp_new_line_before_finally

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_before_finally	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	

PROPERTY	VALUE	DESCRIPTION
Option values	true	Require <code>finally</code> statements to be on a new line after the closing brace.
	false	Require <code>finally</code> statements to be on the same line as the closing brace.

Code examples:

```
// csharp_new_line_before_finally = true
try {
    ...
}
catch (Exception e) {
    ...
}
finally {
    ...
}

// csharp_new_line_before_finally = false
try {
    ...
} catch (Exception e) {
    ...
} finally {
    ...
}
```

csharp_new_line_before_members_in_object_initializers

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_before_members_in_object_initializers	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	true	Require members of object initializers to be on separate lines
	false	Require members of object initializers to be on the same line

Code examples:

```
// csharp_new_line_before_members_in_object_initializers = true
var z = new B()
{
    A = 3,
    B = 4
}

// csharp_new_line_before_members_in_object_initializers = false
var z = new B()
{
    A = 3, B = 4
}
```

csharp_new_line_before_members_in_anonymous_types

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_before_members_in_a nonymous_types	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<input type="checkbox"/> true	Require members of anonymous types to be on separate lines
	<input type="checkbox"/> false	Require members of anonymous types to be on the same line

Code examples:

```
// csharp_new_line_before_members_in_anonymous_types = true
var z = new
{
    A = 3,
    B = 4
}

// csharp_new_line_before_members_in_anonymous_types = false
var z = new
{
    A = 3, B = 4
}
```

csharp_new_line_between_query_expression_clauses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_new_line_between_query_expre ssion_clauses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	

PROPERTY	VALUE	DESCRIPTION
Option values	<code>true</code>	Require elements of query expression clauses to be on separate lines
	<code>false</code>	Require elements of query expression clauses to be on the same line

Code examples:

```
// csharp_new_line_between_query_expression_clauses = true
var q = from a in e
        from b in e
        select a * b;

// csharp_new_line_between_query_expression_clauses = false
var q = from a in e from b in e
        select a * b;
```

Indentation options

The indentation options concern the use of indentation to format code.

- [csharp_indent_case_contents](#)
- [csharp_indent_switch_labels](#)
- [csharp_indent_labels](#)
- [csharp_indent_block_contents](#)
- [csharp_indent_braces](#)
- [csharp_indent_case_contents_when_block](#)

Example `.editorconfig` file:

```
# CSharp formatting rules:
[*.cs]
csharp_indent_case_contents = true
csharp_indent_switch_labels = true
csharp_indent_labels = flush_left
csharp_indent_block_contents = true
csharp_indent_braces = false
csharp_indent_case_contents_when_block = true
```

csharp_indent_case_contents

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_indent_case_contents</code>	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Indent <code>switch</code> case contents
	<code>false</code>	Do not indent <code>switch</code> case contents

Code examples:

```
// csharp_indent_case_contents = true
switch(c) {
    case Color.Red:
        Console.WriteLine("The color is red");
        break;
    case Color.Blue:
        Console.WriteLine("The color is blue");
        break;
    default:
        Console.WriteLine("The color is unknown.");
        break;
}

// csharp_indent_case_contents = false
switch(c) {
    case Color.Red:
        Console.WriteLine("The color is red");
        break;
    case Color.Blue:
        Console.WriteLine("The color is blue");
        break;
    default:
        Console.WriteLine("The color is unknown.");
        break;
}
```

csharp_indent_switch_labels

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_indent_switch_labels	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Indent <code>switch</code> labels
	<code>false</code>	Do not indent <code>switch</code> labels

Code examples:

```
// csharp_indent_switch_labels = true
switch(c) {
    case Color.Red:
        Console.WriteLine("The color is red");
        break;
    case Color.Blue:
        Console.WriteLine("The color is blue");
        break;
    default:
        Console.WriteLine("The color is unknown.");
        break;
}

// csharp_indent_switch_labels = false
switch(c) {
case Color.Red:
    Console.WriteLine("The color is red");
    break;
case Color.Blue:
    Console.WriteLine("The color is blue");
    break;
default:
    Console.WriteLine("The color is unknown.");
    break;
}
```

csharp_indent_labels

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_indent_labels	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<input type="button" value="flush_left"/>	Labels are placed at the leftmost column
	<input type="button" value="one_less_than_current"/>	Labels are placed at one less indent to the current context
	<input type="button" value="no_change"/>	Labels are placed at the same indent as the current context

Code examples:

```

// csharp_indent_labels= flush_left
class C
{
    private string MyMethod(...)
    {
        if (...) {
            goto error;
        }
    error:
        throw new Exception(...);
    }
}

// csharp_indent_labels = one_less_than_current
class C
{
    private string MyMethod(...)
    {
        if (...) {
            goto error;
        }
    error:
        throw new Exception(...);
    }
}

// csharp_indent_labels= no_change
class C
{
    private string MyMethod(...)
    {
        if (...) {
            goto error;
        }
    error:
        throw new Exception(...);
    }
}

```

csharp_indent_block_contents

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_indent_block_contents	
Applicable languages	C#	
Option values	<input type="checkbox"/> true	Indent block contents.
	<input type="checkbox"/> false	Don't indent block contents.

Code examples:

```
// csharp_indent_block_contents = true
static void Hello()
{
    Console.WriteLine("Hello");
}

// csharp_indent_block_contents = false
static void Hello()
{
    Console.WriteLine("Hello");
}
```

csharp_indent_braces

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_indent_braces	
Applicable languages	C#	
Option values	<code>true</code>	Indent curly braces.
	<code>false</code>	Don't indent curly braces.

Code examples:

```
// csharp_indent_braces = true
static void Hello()
{
    Console.WriteLine("Hello");
}

// csharp_indent_braces = false
static void Hello()
{
    Console.WriteLine("Hello");
}
```

csharp_indent_case_contents_when_block

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_indent_case_contents_when_block	
Applicable languages	C#	
Option values	<code>true</code>	When it's a block, indent the statement list and curly braces for a case in a switch statement.
	<code>false</code>	When it's a block, don't indent the statement list and curly braces for a case in a switch statement.

Code examples:

```
// csharp_indent_case_contents_when_block = true
case 0:
{
    Console.WriteLine("Hello");
    break;
}

// csharp_indent_case_contents_when_block = false
case 0:
{
    Console.WriteLine("Hello");
    break;
}
```

Spacing options

The spacing options concern the use of space characters to format code.

- [csharp_space_after_cast](#)
- [csharp_space_after_keywords_in_control_flow_statements](#)
- [csharp_space_between_parentheses](#)
- [csharp_space_before_colon_in_inheritance_clause](#)
- [csharp_space_after_colon_in_inheritance_clause](#)
- [csharp_space_around_binary_operators](#)
- [csharp_space_between_method_declaration_parameter_list_parentheses](#)
- [csharp_space_between_method_declaration_empty_parameter_list_parentheses](#)
- [csharp_space_between_method_declaration_name_and_open_parenthesis](#)
- [csharp_space_between_method_call_parameter_list_parentheses](#)
- [csharp_space_between_method_call_empty_parameter_list_parentheses](#)
- [csharp_space_between_method_call_name_and_opening_parenthesis](#)
- [csharp_space_after_comma](#)
- [csharp_space_before_comma](#)
- [csharp_space_after_dot](#)
- [csharp_space_before_dot](#)
- [csharp_space_after_semicolon_in_for_statement](#)
- [csharp_space_before_semicolon_in_for_statement](#)
- [csharp_space_around_declaration_statements](#)
- [csharp_space_before_open_square_brackets](#)
- [csharp_space_between_empty_square_brackets](#)
- [csharp_space_between_square_brackets](#)

Example `.editorconfig` file:

```

# CSharp formatting rules:
[*.cs]
csharp_space_after_cast = true
csharp_space_after_keywords_in_control_flow_statements = true
csharp_space_between_parentheses = control_flow_statements, type_casts
csharp_space_before_colon_in_inheritance_clause = true
csharp_space_after_colon_in_inheritance_clause = true
csharp_space_around_binary_operators = before_and_after
csharp_space_between_method_declaration_parameter_list_parentheses = true
csharp_space_between_method_declaration_empty_parameter_list_parentheses = false
csharp_space_between_method_declaration_name_and_open_parenthesis = false
csharp_space_between_method_call_parameter_list_parentheses = true
csharp_space_between_method_call_empty_parameter_list_parentheses = false
csharp_space_between_method_call_name_and_opening_parenthesis = false
csharp_space_after_comma = true
csharp_space_before_comma = false
csharp_space_after_dot = false
csharp_space_before_dot = false
csharp_space_after_semicolon_in_for_statement = true
csharp_space_before_semicolon_in_for_statement = false
csharp_space_around_declaration_statements = false
csharp_space_before_open_square_brackets = false
csharp_space_between_empty_square_brackets = false
csharp_space_between_square_brackets = false

```

csharp_space_after_cast

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_cast	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Place a space character between a cast and the value
	<input type="checkbox"/> false	Remove space between the cast and the value

Code examples:

```

// csharp_space_after_cast = true
int y = (int) x;

// csharp_space_after_cast = false
int y = (int)x;

```

csharp_space_after_keywords_in_control_flow_statements

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_keywords_in_control_flow_statements	
Applicable languages	C#	

PROPERTY	VALUE	DESCRIPTION
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Place a space character after a keyword in a control flow statement such as a <code>for</code> loop
	<code>false</code>	Remove space after a keyword in a control flow statement such as a <code>for</code> loop

Code examples:

```
// csharp_space_after_keywords_in_control_flow_statements = true
for (int i;i<x;i++) { ... }

// csharp_space_after_keywords_in_control_flow_statements = false
for(int i;i<x;i++) { ... }
```

csharp_space_between_parentheses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_parentheses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>control_flow_statements</code>	Place space between parentheses of control flow statements
	<code>expressions</code>	Place space between parentheses of expressions
	<code>type_casts</code>	Place space between parentheses in type casts

If you omit this rule or use a value other than `control_flow_statements`, `expressions`, or `type_casts`, the setting is not applied.

Code examples:

```
// csharp_space_between_parentheses = control_flow_statements
for ( int i = 0; i < 10; i++ ) { }

// csharp_space_between_parentheses = expressions
var z = ( x * y ) - ( ( y - x ) * 3 );

// csharp_space_between_parentheses = type_casts
int y = ( int )x;
```

csharp_space_before_colon_in_inheritance_clause

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_before_colon_in_inheritance_clause	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Place a space character before the colon for bases or interfaces in a type declaration
	<input type="checkbox"/> false	Remove space before the colon for bases or interfaces in a type declaration

Code examples:

```
// csharp_space_before_colon_in_inheritance_clause = true
interface I
{
}

class C : I
{
}

// csharp_space_before_colon_in_inheritance_clause = false
interface I
{
}

class C: I
{}
```

csharp_space_after_colon_in_inheritance_clause

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_colon_in_inheritance_clause	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Place a space character after the colon for bases or interfaces in a type declaration
	<input type="checkbox"/> false	Remove space after the colon for bases or interfaces in a type declaration

Code examples:

```
// csharp_space_after_colon_in_inheritance_clause = true
interface I
{
}

class C : I
{
}

// csharp_space_after_colon_in_inheritance_clause = false
interface I
{
}

class C :I
{}
```

csharp_space_around_binary_operators

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_around_binary_operators	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	<code>before_and_after</code>	Insert space before and after the binary operator
	<code>none</code>	Remove spaces before and after the binary operator
	<code>ignore</code>	Ignore spaces around binary operators

If you omit this rule, or use a value other than `before_and_after`, `none`, or `ignore`, the setting is not applied.

Code examples:

```
// csharp_space_around_binary_operators = before_and_after
return x * (x - y);

// csharp_space_around_binary_operators = none
return x*(x-y);

// csharp_space_around_binary_operators = ignore
return x * (x-y);
```

csharp_space_between_method_declaration_parameter_list_parentheses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_declar ation_parameter_list_parentheses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Place a space character after the opening parenthesis and before the closing parenthesis of a method declaration parameter list
	<code>false</code>	Remove space characters after the opening parenthesis and before the closing parenthesis of a method declaration parameter list

Code examples:

```
// csharp_space_between_method_declaration_parameter_list_parentheses = true
void Bark( int x ) { ... }

// csharp_space_between_method_declaration_parameter_list_parentheses = false
void Bark(int x) { ... }
```

csharp_space_between_method_declaration_empty_parameter_list_parentheses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_declar ation_empty_parameter_list_parentheses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	<code>true</code>	Insert space within empty parameter list parentheses for a method declaration
	<code>false</code>	Remove space within empty parameter list parentheses for a method declaration

Code examples:

```
// csharp_space_between_method_declaration_empty_parameter_list_parentheses = true
void Goo( )
{
    Goo(1);
}

void Goo(int x)
{
    Goo();
}

// csharp_space_between_method_declaration_empty_parameter_list_parentheses = false
void Goo()
{
    Goo(1);
}

void Goo(int x)
{
    Goo();
}
```

csharp_space_between_method_declaration_name_and_open_parenthesis

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_declaration_name_and_open_parenthesis	
Applicable languages	C#	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Place a space character between the method name and opening parenthesis in the method declaration
	<input type="checkbox"/> false	Remove space characters between the method name and opening parenthesis in the method declaration

Code examples:

```
// csharp_space_between_method_declaration_name_and_open_parenthesis = true
void M () { }

// csharp_space_between_method_declaration_name_and_open_parenthesis = false
void M() { }
```

csharp_space_between_method_call_parameter_list_parentheses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_call_parameter_list_parentheses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	

PROPERTY	VALUE	DESCRIPTION
Option values	true	Place a space character after the opening parenthesis and before the closing parenthesis of a method call
	false	Remove space characters after the opening parenthesis and before the closing parenthesis of a method call

Code examples:

```
// csharp_space_between_method_call_parameter_list_parentheses = true
MyMethod( argument );

// csharp_space_between_method_call_parameter_list_parentheses = false
MyMethod(argument);
```

csharp_space_between_method_call_empty_parameter_list_parentheses

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_call_empty_parameter_list_parentheses	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	true	Insert space within empty argument list parentheses
	false	Remove space within empty argument list parentheses

Code examples:

```
// csharp_space_between_method_call_empty_parameter_list_parentheses = true
void Goo()
{
    Goo(1);
}

void Goo(int x)
{
    Goo( );
}

// csharp_space_between_method_call_empty_parameter_list_parentheses = false
void Goo()
{
    Goo(1);
}

void Goo(int x)
{
    Goo();
}
```

csharp_space_between_method_call_name_and_opening_parenthesis

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_method_call_name_and_opening_parenthesis	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.7	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Insert space between method call name and opening parenthesis Remove space between method call name and opening parenthesis

Code examples:

```
// csharp_space_between_method_call_name_and_opening_parenthesis = true
void Goo()
{
    Goo (1);
}

void Goo(int x)
{
    Goo ();
}

// csharp_space_between_method_call_name_and_opening_parenthesis = false
void Goo()
{
    Goo(1);
}

void Goo(int x)
{
    Goo();
}
```

csharp_space_after_comma

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_comma	
Applicable languages	C#	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Insert space after a comma Remove space after a comma

Code examples:

```
// csharp_space_after_comma = true
int[] x = new int[] { 1, 2, 3, 4, 5 };

// csharp_space_after_comma = false
int[] x = new int[] { 1,2,3,4,5 }
```

csharp_space_before_comma

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_before_comma	
Applicable languages	C#	
Option values	<input type="button" value="true"/>	Insert space before a comma
	<input type="button" value="false"/>	Remove space before a comma

Code examples:

```
// csharp_space_before_comma = true
int[] x = new int[] { 1 , 2 , 3 , 4 , 5 };

// csharp_space_before_comma = false
int[] x = new int[] { 1, 2, 3, 4, 5 };
```

csharp_space_after_dot

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_dot	
Applicable languages	C#	
Option values	<input type="button" value="true"/>	Insert space after a dot
	<input type="button" value="false"/>	Remove space after a dot

Code examples:

```
// csharp_space_after_dot = true
this. Goo();

// csharp_space_after_dot = false
this.Goo();
```

csharp_space_before_dot

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_before_dot	
Applicable languages	C#	

PROPERTY	VALUE	DESCRIPTION
Option values	true	Insert space before a dot
	false	Remove space before a dot

Code examples:

```
// csharp_space_before_dot = true
this .Goo();

// csharp_space_before_dot = false
this.Goo();
```

csharp_space_after_semicolon_in_for_statement

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_after_semicolon_in_for_st atement	
Applicable languages	C#	
Option values	true	Insert space after each semicolon in a <code>for</code> statement
	false	Remove space after each semicolon in a <code>for</code> statement

Code examples:

```
// csharp_space_after_semicolon_in_for_statement = true
for (int i = 0; i < x.Length; i++)

// csharp_space_after_semicolon_in_for_statement = false
for (int i = 0;i < x.Length;i++)
```

csharp_space_before_semicolon_in_for_statement

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_before_semicolon_in_for_ statement	
Applicable languages	C#	
Option values	true	Insert space before each semicolon in a <code>for</code> statement
	false	Remove space before each semicolon in a <code>for</code> statement

Code examples:

```
// csharp_space_before_semicolon_in_for_statement = true
for (int i = 0 ; i < x.Length ; i++)

// csharp_space_before_semicolon_in_for_statement = false
for (int i = 0; i < x.Length; i++)
```

csharp_space_around_declaration_statements

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_around_declaration_statements	
Applicable languages	C#	
Option values	<code>ignore</code>	Don't remove extra space characters in declaration statements
	<code>false</code>	Remove extra space characters in declaration statements

Code examples:

```
// csharp_space_around_declaration_statements = ignore
int    x    =    0    ;

// csharp_space_around_declaration_statements = false
int x = 0;
```

csharp_space_before_open_square_brackets

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_before_open_square_brackets	
Applicable languages	C#	
Option values	<code>true</code>	Insert space before opening square brackets [
	<code>false</code>	Remove space before opening square brackets [

Code examples:

```
// csharp_space_before_open_square_brackets = true
int [] numbers = new int [] { 1, 2, 3, 4, 5 };

// csharp_space_before_open_square_brackets = false
int[] numbers = new int[] { 1, 2, 3, 4, 5 };
```

csharp_space_between_empty_square_brackets

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_empty_square_brackets	
Applicable languages	C#	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Insert space between empty square brackets []
	<input type="checkbox"/> false	Remove space between empty square brackets []

Code examples:

```
// csharp_space_between_empty_square_brackets = true
int[] numbers = new int[] { 1, 2, 3, 4, 5 };

// csharp_space_between_empty_square_brackets = false
int[] numbers = new int[] { 1, 2, 3, 4, 5 };
```

csharp_space_between_square_brackets

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_space_between_square_brackets	
Applicable languages	C#	
Option values	<input checked="" type="checkbox"/> true <input type="checkbox"/> false	Insert space characters in non-empty square brackets [0]
	<input type="checkbox"/> false	Remove space characters in non-empty square brackets [0]

Code examples:

```
// csharp_space_between_square_brackets = true
int index = numbers[ 0 ];

// csharp_space_between_square_brackets = false
int index = numbers[0];
```

Wrap options

The wrap formatting options concern the use of single lines versus separate lines for statements and code blocks.

- [csharp_preserve_single_line_statements](#)
- [csharp_preserve_single_line_blocks](#)

Example `.editorconfig` file:

```
# CSharp formatting rules:  
[*.cs]  
csharp_preserve_single_line_statements = true  
csharp_preserve_single_line_blocks = true
```

csharp_preserve_single_line_statements

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_preserve_single_line_statements	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Leave statements and member declarations on the same line
	<code>false</code>	Leave statements and member declarations on different lines

Code examples:

```
//csharp_preserve_single_line_statements = true
int i = 0; string name = "John";

//csharp_preserve_single_line_statements = false
int i = 0;
string name = "John";
```

csharp_preserve_single_line_blocks

PROPERTY	VALUE	DESCRIPTION
Option name	csharp_preserve_single_line_blocks	
Applicable languages	C#	
Introduced version	Visual Studio 2017 version 15.3	
Option values	<code>true</code>	Leave code block on single line
	<code>false</code>	Leave code block on separate lines

Code examples:

```
//csharp_preserve_single_line_blocks = true
public int Foo { get; set; }

//csharp_preserve_single_line_blocks = false
public int MyProperty
{
    get; set;
}
```

Using directive options

This category contains one formatting option that concerns whether `using` directives are placed inside or outside a namespace.

- [csharp_using_directive_placement](#)

Example `.editorconfig` file:

```
'using' directive preferences
[*.cs]
csharp_using_directive_placement = outside_namespace
csharp_using_directive_placement = inside_namespace
```

TIP

For additional `using` directive options, see [.NET using directive options](#).

csharp_using_directive_placement

PROPERTY	VALUE	DESCRIPTION
Option name	<code>csharp_using_directive_placement</code>	
Applicable languages	C#	
Introduced version	Visual Studio 2019 version 16.1	
Option values	<code>outside_namespace</code>	Leave using directives outside namespace
	<code>inside_namespace</code>	Leave using directives inside namespace

Code examples:

```
// csharp_using_directive_placement = outside_namespace
using System;

namespace Conventions
{
}

// csharp_using_directive_placement = inside_namespace
namespace Conventions
{
    using System;
}
```

Code-style naming rules

9/20/2022 • 7 minutes to read • [Edit Online](#)

In your `.editorconfig` file, you can define naming conventions for your .NET programming language code elements—such as classes, properties, and methods—and how the compiler or IDE should enforce those conventions. For example, you could specify that a public member that isn't capitalized should be treated as a compiler error, or that if a private field doesn't begin with an `_`, a build warning should be issued.

Specifically, you can define a **naming rule**, which consists of three parts:

- The **symbol group** that the rule applies to, for example, public members or private fields.
- The **naming style** to associate with the rule, for example, that the name must be capitalized or start with an underscore.
- The severity level of the message when code elements included in the symbol group don't follow the naming style.

General syntax

To define any of the above entities—a naming rule, symbol group, or naming style—set one or more properties using the following syntax:

```
<kind>.<entityName>.<propertyName> = <propertyValue>
```

All the property settings for a given `kind` and `entityName` make up that specific entity definition.

Each property should only be set once, but some settings allow multiple, comma-separated values.

The order of the properties is not important.

<kind> values

<kind> specifies which kind of entity is being defined—naming rule, symbol group, or naming style—and must be one of the following:

TO SET A PROPERTY FOR	USE THE <KIND> VALUE	EXAMPLE
Naming rule	<code>dotnet_naming_rule</code>	<code>dotnet_naming_rule.types_should_be_pascal_case.se = suggestion</code>
Symbol group	<code>dotnet_naming_symbols</code>	<code>dotnet_naming_symbols.interface.applicable_kinds = interface</code>
Naming style	<code>dotnet_naming_style</code>	<code>dotnet_naming_style.pascal_case.capitalization = pascal_case</code>

<entityName>

<entityName> is a descriptive name you choose that associates multiple property settings into a single definition. For example, the following properties produce two symbol group definitions, `interface` and `types`, each of which has two properties set on it.

```

dotnet_naming_symbols.interface.applicable_kinds = interface
dotnet_naming_symbols.interface.applicable_accessibilities = public, internal, private, protected,
protected_internal, private_protected

dotnet_naming_symbols.types.applicable_kinds = class, struct, interface, enum, delegate
dotnet_naming_symbols.types.applicable_accessibilities = public, internal, private, protected,
protected_internal, private_protected

```

<propertyName> and <propertyValue>

Each kind of entity—[naming rule](#), [symbol group](#), or [naming style](#)—has its own supported properties, as described in the following sections.

Symbol group properties

You can set the following properties for symbol groups, to limit which symbols are included in the group. To specify multiple values for a single property, separate the values with a comma.

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
<code>applicable_kinds</code>	Kinds of symbols in the group ¹	<input type="checkbox"/> * (use this value to specify all symbols) <input type="checkbox"/> namespace <input type="checkbox"/> class <input type="checkbox"/> struct <input type="checkbox"/> interface <input type="checkbox"/> enum <input type="checkbox"/> property <input type="checkbox"/> method <input type="checkbox"/> field <input type="checkbox"/> event <input type="checkbox"/> delegate <input type="checkbox"/> parameter <input type="checkbox"/> type_parameter <input type="checkbox"/> local <input type="checkbox"/> local_function	Yes
<code>applicable_accessibilities</code>	Accessibility levels of the symbols in the group	<input type="checkbox"/> * (use this value to specify all accessibility levels) <input type="checkbox"/> public <input type="checkbox"/> internal or friend <input type="checkbox"/> private <input type="checkbox"/> protected <input type="checkbox"/> protected_internal or protected_friend <input type="checkbox"/> private_protected <input type="checkbox"/> local (for symbols defined within a method)	Yes
<code>required_modifiers</code>	Only match symbols with <i>all</i> the specified modifiers ²	<input type="checkbox"/> abstract or must_inherit <input type="checkbox"/> async <input type="checkbox"/> const <input type="checkbox"/> readonly <input type="checkbox"/> static or shared ³	No

Notes:

1. Tuple members aren't currently supported in `applicable_kinds`.
2. The symbol group matches *all* the modifiers in the `required_modifiers` property. If you omit this property, no specific modifiers are required for a match. This means a symbol's modifiers have no effect on whether or not this rule is applied.
3. If your group has `static` or `shared` in the `required_modifiers` property, the group will also include `const`.

symbols because they are implicitly `static` / `shared`. However, if you don't want the `static` naming rule to apply to `const` symbols, you can create a new naming rule with a symbol group of `const`.

4. `class` includes [C# records](#).

Naming style properties

A naming style defines the conventions you want to enforce with the rule. For example:

- Capitalize with `PascalCase`
- Starts with `m_`
- Ends with `_g`
- Separate words with `_`

You can set the following properties for a naming style:

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
<code>capitalization</code>	Capitalization style for words within the symbol	<code>pascal_case</code> <code>camel_case</code> <code>first_word_upper</code> <code>all_upper</code> <code>all_lower</code>	Yes ¹
<code>required_prefix</code>	Must begin with these characters		No
<code>required_suffix</code>	Must end with these characters		No
<code>word_separator</code>	Words within the symbol need to be separated with this character		No

Notes:

1. You must specify a capitalization style as part of your naming style, otherwise your naming style might be ignored.

Naming rule properties

All naming rule properties are required for a rule to take effect.

PROPERTY	DESCRIPTION
<code>symbols</code>	The name of a symbol group defined elsewhere; the naming rule will be applied to the symbols in this group
<code>style</code>	The name of the naming style which should be associated with this rule; the style is defined elsewhere
<code>severity</code>	Sets the severity with which to enforce the naming rule. Set the associated value to one of the available severity levels . ¹

Notes:

1. Severity specification within a naming rule is only respected inside development IDEs, such as Visual Studio. This setting is not understood by the C# or VB compilers, hence not respected during build. To enforce naming style rules on build, you should instead set the severity by using [code rule severity configuration](#). For more information, see this [GitHub issue](#).

Rule order

The order in which naming rules are defined in an EditorConfig file doesn't matter. The naming rules are automatically ordered according to the definition of the rules themselves. The [EditorConfig Language Service](#)

[extension](#) can analyze an EditorConfig file and report cases where the rule ordering in the file is different to what the compiler will use at run time.

NOTE

If you're using a version of Visual Studio earlier than Visual Studio 2019 version 16.2, naming rules should be ordered from most-specific to least-specific in the EditorConfig file. The first rule encountered that can be applied is the only rule that is applied. However, if there are multiple rule *properties* with the same name, the most recently found property with that name takes precedence. For more information, see [File hierarchy and precedence](#).

Default naming styles

If you don't specify any custom naming rules, the following default styles are used:

- For classes, structs, enumerations, properties, methods, and events with any accessibility, the default naming style is Pascal case.
- For interfaces with any accessibility, the default naming style is Pascal case with a required prefix of I.

Code Rule ID: `IDE1006 (Naming rule violation)`

All naming options have rule ID `IDE1006` and title `Naming rule violation`. You can configure the severity of naming violations globally in an EditorConfig file with the following syntax:

```
dotnet_diagnostic. IDE1006.severity = <severity value>
```

The severity value must be `warning` or `error` to be [enforced on build](#). For all possible severity values, see [severity level](#).

Example: Public member capitalization

The following `.editorconfig` file contains a naming convention that specifies that public properties, methods, fields, events, and delegates must be capitalized. Notice that this naming convention specifies multiple kinds of symbol to apply the rule to, using a comma to separate the values.

```
[*.{cs,vb}]

# Defining the 'public_symbols' symbol group
dotnet_naming_symbols.public_symbols.applicable_kinds      = property,method,field,event,delegate
dotnet_naming_symbols.public_symbols.applicable_accessibilities = public
dotnet_naming_symbols.public_symbols.required_modifiers     = readonly

# Defining the 'first_word_upper_case_style' naming style
dotnet_naming_style.first_word_upper_case_style.capitalization = first_word_upper

# Defining the 'public_members_must_be_capitalized' naming rule, by setting the
# symbol group to the 'public_symbols' symbol group,
dotnet_naming_rule.public_members_must_be_capitalized.symbols = public_symbols
# setting the naming style to the 'first_word_upper_case_style' naming style,
dotnet_naming_rule.public_members_must_be_capitalized.style   = first_word_upper_case_style
# and setting the severity.
dotnet_naming_rule.public_members_must_be_capitalized.severity = suggestion
```

Example: Private instance fields with underscore

This `.editorconfig` file snippet enforces that private instance fields should start with an `_`; if that convention is not followed, the IDE will treat it as a compiler error. Private static fields are ignored.

Because you can only define a symbol group based on the identifiers it has (for example, `static` or `readonly`), and not by the identifiers it doesn't have (for example, an instance field because it doesn't have `static`), you need to define two naming rules:

1. All private fields—`static` or not—should have the `underscored` naming style applied to them as a compiler `error`.
2. Private fields with `static` should have the `underscored` naming style applied to them with a severity level of `none`; in other words, ignore this case.

```
[*.{cs,vb}]

# Define the 'private_fields' symbol group:
dotnet_naming_symbols.private_fields.applicable_kinds = field
dotnet_naming_symbols.private_fields.applicable_accessibilities = private

# Define the 'private_static_fields' symbol group
dotnet_naming_symbols.private_static_fields.applicable_kinds = field
dotnet_naming_symbols.private_static_fields.applicable_accessibilities = private
dotnet_naming_symbols.private_static_fields.required_modifiers = static

# Define the 'underscored' naming style
dotnet_naming_style.underscored.capitalization = pascal_case
dotnet_naming_style.underscored.required_prefix = _

# Define the 'private_fields_underscored' naming rule
dotnet_naming_rule.private_fields_underscored.symbols = private_fields
dotnet_naming_rule.private_fields_underscored.style = underscored
dotnet_naming_rule.private_fields_underscored.severity = error

# Define the 'private_static_fields_none' naming rule
dotnet_naming_rule.private_static_fields_none.symbols = private_static_fields
dotnet_naming_rule.private_static_fields_none.style = underscored
dotnet_naming_rule.private_static_fields_none.severity = none
```

This example also demonstrates that entity definitions can be reused. The `underscored` naming style is used by both the `private_fields_underscored` and `private_static_fields_none` naming rules.

Platform compatibility analyzer

9/20/2022 • 17 minutes to read • [Edit Online](#)

You've probably heard the motto of "One .NET": a single, unified platform for building any type of application. The .NET 5 SDK includes ASP.NET Core, Entity Framework Core, WinForms, WPF, Xamarin, and ML.NET, and will add support for more platforms over time. .NET 5 strives to provide an experience where you don't have to reason about the different flavors of .NET, but doesn't attempt to fully abstract away the underlying operating system (OS). You'll continue to be able to call platform-specific APIs, for example, P/Invokes, WinRT, or the Xamarin bindings for iOS and Android.

But using platform-specific APIs on a component means the code no longer works across all platforms. We needed a way to detect this at design time so developers get diagnostics when they inadvertently use platform-specific APIs. To achieve this goal, .NET 5 introduces the [platform compatibility analyzer](#) and complementary APIs to help developers identify and use platform-specific APIs where appropriate.

The new APIs include:

- [SupportedOSPlatformAttribute](#) to annotate APIs as being platform-specific and [UnsupportedOSPlatformAttribute](#) to annotate APIs as being unsupported on a particular OS. These attributes can optionally include the version number, and have already been applied to some platform-specific APIs in the core .NET libraries.
- `Is<Platform>()` and `Is<Platform>VersionAtLeast(int major, int minor = 0, int build = 0, int revision = 0)` static methods in the [System.OperatingSystem](#) class for safely calling platform-specific APIs. For example, `OperatingSystem.IsWindows()` can be used to guard a call to a Windows-specific API, and `OperatingSystem.IsWindowsVersionAtLeast()` can be used to guard a versioned Windows-specific API call. See these [examples](#) of how these methods can be used as guards of platform-specific API references.

Prerequisites

The platform compatibility analyzer is one of the Roslyn code quality analyzers. Starting in .NET 5, these analyzers are [included with the .NET SDK](#). The platform compatibility analyzer is enabled by default only for projects that target `net5.0` or a later version. However, you can [enable it](#) for projects that target other frameworks.

How the analyzer determines platform dependency

- An **unattributed API** is considered to work on **all OS platforms**.
- An API marked with `[SupportedOSPlatform("platform")]` is considered only portable to the specified platform and any platforms it's a subset of.
 - The attribute can be applied multiple times to indicate **multiple platform support**, for example `[SupportedOSPlatform("windows"), SupportedOSPlatform("Android29.0")]`.
 - If the platform is a [subset of another platform](#), the attribute implies that the superset platform is also supported. For example, `[SupportedOSPlatform("ios")]` implies that the API is supported on `ios` and also on its superset platform, `MacCatalyst`.
 - The analyzer will produce a **warning** if platform-specific APIs are referenced without a proper **platform context**:
 - **Warns** if the project doesn't target the supported platform (for example, a Windows-specific API called from a project targeting iOS `<TargetFramework>net5.0-ios14.0</TargetFramework>`).

- **Warns** if the project is cross-platform and calls platform-specific APIs (for example, a Windows-specific API called from cross platform TFM
`<TargetFramework>net5.0</TargetFramework>`).
- **Doesn't warn** if the platform-specific API is referenced within a project that targets any of the specified platforms (for example, for a Windows-specific API called from a project targeting windows
`<TargetFramework>net5.0-windows</TargetFramework>` and the *AssemblyInfo.cs* file generation is enabled for the project).
- **Doesn't warn** if the platform-specific API call is guarded by corresponding platform-check methods (for example, a Windows-specific API call guarded by
`OperatingSystem.IsWindows()`).
- **Doesn't warn** if the platform-specific API is referenced from the same platform-specific context (call site also attributed with
`[SupportedOSPlatform("platform")]`).
- An API marked with
`[UnsupportedOSPlatform("platform")]` is considered to be unsupported on the specified platform and any platforms it's a subset of, but supported for all other platforms.
 - The attribute can be applied multiple times with different platforms, for example,
`[UnsupportedOSPlatform("iOS"), UnsupportedOSPlatform("Android29.0")]`.
 - If the platform is a **subset of another platform**, the attribute implies that the superset platform is also unsupported. For example,
`[UnsupportedOSPlatform("iOS")]` implies that the API is unsupported on
`iOS` and also on its superset platform, `MacCatalyst`.
 - The analyzer produces a **warning** only if the `platform` is effective for the call site:
 - **Warns** if the project targets the platform that's attributed as unsupported (for example, if the API is attributed with
`[UnsupportedOSPlatform("windows")]` and the call site targets
`<TargetFramework>net5.0-windows</TargetFramework>`).
 - **Warns** if the project is multi-targeted and the `platform` is included in the default **MSBuild**
`<SupportedPlatform>` items group, or the `platform` is manually included within the
`MSBuild <SupportedPlatform>` items group:

```

<ItemGroup>
  <SupportedPlatform Include="platform" />
</ItemGroup>

```
 - **Doesn't warn** if you're building an app that doesn't target the unsupported platform or is multi-targeted and the platform is not included in the default **MSBuild**
`<SupportedPlatform>` items group.
- Both attributes can be instantiated with or without version numbers as part of the platform name. Version numbers are in the format of
`major.minor[.build[.revision]]`; `major.minor` is required and the `build` and `revision` parts are optional. For example, "Windows6.1" indicates Windows version 6.1, but "Windows" is interpreted as Windows 0.0.

For more information, see [examples of how the attributes work and what diagnostics they cause](#).

How the analyzer recognizes TFM target platforms

The analyzer does not check target framework moniker (TFM) target platforms from MSBuild properties, such as
`<TargetFramework>` or
`<TargetFrameworks>`. If the TFM has a target platform, MSBuild injects a
`SupportedOSPlatform` attribute with the targeted platform name in the *AssemblyInfo.cs* file, which is consumed by the analyzer. For example, if the TFM is
`net5.0-windows10.0.19041`, MSBuild injects the
`[assembly: System.Runtime.Versioning.SupportedOSPlatform("windows10.0.19041")]` attribute into the *AssemblyInfo.cs* file, and the entire assembly is considered to be Windows only. Therefore, calling Windows-only APIs versioned with 7.0 or below would not cause any warnings in the project.

NOTE

If the `AssemblyInfo.cs` file generation is disabled for the project (that is, the `<GenerateAssemblyInfo>` property is set to `false`), the required assembly level `SupportedOSPlatform` attribute can't be added by MSBuild. In this case, you could see warnings for a platform-specific APIs usage even if you're targeting that platform. To resolve the warnings, enable the `AssemblyInfo.cs` file generation or add the attribute manually in your project.

Platform inclusion

.NET 6 introduces the concept of *platform inclusion*, where one platform can be a subset of another platform. An annotation for the subset platform implies the same support (or lack thereof) for the superset platform. If a platform check method in the `OperatingSystem` type has a `[SupportedOSPlatformGuard("supersetPlatform")]` attribute, then `supersetPlatform` is considered a superset of the OS platform that the method checks for.

For example, the `OperatingSystem.IsiOS()` method is attributed `[SupportedOSPlatformGuard("MacCatalyst")]`. Therefore, the following statements apply:

- The `OperatingSystem.IsiOS()` and `OperatingSystem.IsiOSVersionAtLeast` methods check not only the `ios` platform, but also the `MacCatalyst` platform.
- `[SupportedOSPlatform("ios")]` implies that the API is supported on `ios` and also on its superset platform, `MacCatalyst`. You can use the `[UnsupportedOSPlatform("MacCatalyst")]` attribute to exclude this implied support.
- `[UnsupportedOSPlatform("ios")]` implies that the API is not supported on `ios` and `MacCatalyst`. You can use the `[SupportedOSPlatform("MacCatalyst")]` attribute to exclude this implied lack of support.

Consider the following coverage matrix, where \checkmark indicates that the platform is supported, and \times indicates that the platform is *not* supported.

PLATFORM	SUPPORTEDOSPLATFORM(SUBSET)	SUPPORTEDOSPLATFORM(SUPERSET)	UNSUPPORTEDOSPLATFORM(SUBSET)	UNSUPPORTEDOSPLATFORM(SUPERSET)
Subset	\checkmark	\times	\checkmark	\times
Superset	\checkmark	\checkmark	\checkmark	\checkmark

TIP

The same rules apply for the `SupportedOSPlatformGuard` and `UnsupportedOSPlatformGuard` attributes.

The following code snippet shows how you can combine attributes to set the right level of support.

```

// MacCatalyst is a superset of iOS therefore supported on iOS and MacCatalyst
[SupportedOSPlatform("iOS")]
public void ApiOnlySupportedOnIOSAndMacCatalyst() { }

// Does not imply iOS, only supported on MacCatalyst
[SupportedOSPlatform("MacCatalyst")]
public void ApiOnlySupportedOnMacCatalyst() { }

[SupportedOSPlatform("iOS")] // Supported on iOS and MacCatalyst
[UnsupportedOSPlatform("MacCatalyst")] // Removes implied MacCatalyst support
public void ApiOnlySupportedOnIos() { }

// Unsupported on iOS and MacCatalyst
[UnsupportedOSPlatform("iOS")]
public void ApiUnsupportedOnIOSAndMacCatalyst();

// Does not imply iOS, only unsupported on MacCatalyst
[UnsupportedOSPlatform("MacCatalyst")]
public void ApiUnsupportedOnMacCatalyst() { }

[UnsupportedOSPlatform("iOS")] // Unsupported on iOS and MacCatalyst
[SupportedOSPlatform("MacCatalyst")] // Removes implied MacCatalyst unsupportedness
public void ApiUnsupportedOnIos() { }

```

Advanced scenarios for attribute combinations

- If a combination of `[SupportedOSPlatform]` and `[UnsupportedOSPlatform]` attributes are present, all attributes are grouped by OS platform identifier:
 - **Supported only list.** If the lowest version for each OS platform is a `[SupportedOSPlatform]` attribute, the API is considered to only be supported by the listed platforms and unsupported by all other platforms. The optional `[UnsupportedOSPlatform]` attributes for each platform can only have higher version of the minimum supported version, which denotes that the API is removed starting from the specified version.

```

// API is only supported on Windows from version 6.2 to 10.0.19041.0 and all versions of Linux
// The API is considered not supported for all other platforms.
[SupportedOSPlatform("windows6.2")]
[UnsupportedOSPlatform("windows10.0.19041.0")]
[SupportedOSPlatform("linux")]
public void ApiSupportedFromWindows80SupportFromCertainVersion();

```

- **Unsupported only list.** If the lowest version for each OS platform is an `[UnsupportedOSPlatform]` attribute, then the API is considered to only be unsupported by the listed platforms and supported by all other platforms. The list could have `[SupportedOSPlatform]` attribute with the same platform but a higher version, which denotes that the API is supported starting from that version.

```

// The API is unsupported on all Linux versions was unsupported on Windows until version
10.0.19041.0.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows10.0.19041.0")]
[UnsupportedOSPlatform("linux")]
public void ApiSupportedFromWindows8UnsupportedFromWindows10();

```

- **Inconsistent list.** If the lowest version for some platforms is `[SupportedOSPlatform]` while it is `[UnsupportedOSPlatform]` for other platforms, it's considered to be inconsistent, which is not supported for the analyzer. If inconsistency occurs, the analyzer ignores the `[UnsupportedOSPlatform]` platforms.

- If the lowest versions of `[SupportedOSPlatform]` and `[UnsupportedOSPlatform]` attributes are equal, the analyzer considers the platform as part of the **Supported only** list.
- Platform attributes can be applied to types, members (methods, fields, properties, and events) and assemblies with different platform names or versions.
 - Attributes applied at the top level `target` affect all of its members and types.
 - Child-level attributes only apply if they adhere to the rule "child annotations can narrow the platforms support, but they cannot widen it".
 - When parent has **Supported only** list, then child member attributes cannot add a new platform support, as that would be extending parent support. Support for a new platform can only be added to the parent itself. But the child can have the `Supported` attribute for the same platform with later versions as that narrows the support. Also, the child can have the `Unsupported` attribute with the same platform as that also narrows parent support.
 - When parent has **Unsupported only** list, then child member attributes can add support for a new platform, as that narrows parent support. But it cannot have the `Supported` attribute for the same platform as the parent, because that extends parent support. Support for the same platform can only be added to the parent where the original `Unsupported` attribute was applied.
 - If `[SupportedOSPlatform("platformVersion")]` is applied more than once for an API with the same `platform` name, the analyzer only considers the one with the minimum version.
 - If `[UnsupportedOSPlatform("platformVersion")]` is applied more than twice for an API with the same `platform` name, the analyzer only considers the two with the earliest versions.

NOTE

An API that was supported initially but unsupported (removed) in a later version is not expected to get re-supported in an even later version.

Examples of how the attributes work and what diagnostics they produce

```
// An API supported only on Windows all versions.
[SupportedOSPlatform("Windows")]
public void WindowsOnlyApi() { }

// an API supported on Windows and Linux.
[SupportedOSPlatform("Windows")]
[SupportedOSPlatform("Linux")]
public void SupportedOnWindowsAndLinuxOnly() { }

// an API only supported on Windows 6.2 and later, not supported for all other.
// an API is removed/unsupported from version 10.0.19041.0.
[SupportedOSPlatform("windows6.2")]
[UnsupportedOSPlatform("windows10.0.19041.0")]
public void ApiSupportedFromWindows8UnsupportedFromWindows10() { }

// an Assembly supported on Windows, the API added from version 10.0.19041.0.
[assembly: SupportedOSPlatform("Windows")]
[SupportedOSPlatform("windows10.0.19041.0")]
public void AssemblySupportedOnWindowsApiSupportedFromWindows10() { }

public void Caller()
{
    WindowsOnlyApi(); // warns: This call site is reachable on all platforms. 'WindowsOnlyApi()' is only
                      // supported on: 'windows'

    // This call site is reachable on all platforms. 'SupportedOnWindowsAndLinuxOnly()' is only supported
    // on: 'Windows', 'Linux'
    SupportedOnWindowsAndLinuxOnly();

    // This call site is reachable on all platforms. 'ApiSupportedFromWindows8UnsupportedFromWindows10()' is
    // only supported on: 'Windows', 'Linux'
    ApiSupportedFromWindows8UnsupportedFromWindows10();
}
```

```

only supported on: 'windows' from version 6.2 to 10.0.19041.0
    ApiSupportedFromWindows8UnsupportedFromWindows10();

    // for same platform analyzer only warn for the latest version.
    // This call site is reachable on all platforms. 'AssemblySupportedOnWindowsApiSupportedFromWindows10()'
is only supported on: 'windows' 10.0.19041.0 and later
    AssemblySupportedOnWindowsApiSupportedFromWindows10();
}

// an API not supported on android but supported on all other.
[UnsupportedOSPlatform("android")]
public void DoesNotWorkOnAndroid() { }

// an API was unsupported on Windows until version 6.2.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows6.2")]
public void StartedWindowsSupportFromVersion8() { }

// an API was unsupported on Windows until version 6.2.
// Then the API is removed (unsupported) from version 10.0.19041.0.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows6.2")]
[UnsupportedOSPlatform("windows10.0.19041.0")]
public void StartedWindowsSupportFrom8UnsupportedFrom10() { }

public void Caller2()
{
    DoesNotWorkOnAndroid(); // This call site is reachable on all platforms. 'DoesNotWorkOnAndroid()' is
unsupported on: 'android'

    // This call site is reachable on all platforms. 'StartedWindowsSupportFromVersion8()' is unsupported
on: 'windows' 6.2 and before.
    StartedWindowsSupportFromVersion8();

    // This call site is reachable on all platforms. 'StartedWindowsSupportFrom8UnsupportedFrom10()' is
supported on: 'windows' from version 6.2 to 10.0.19041.0
    StartedWindowsSupportFrom8UnsupportedFrom10();
}

```

Handle reported warnings

The recommended way to deal with these diagnostics is to make sure you only call platform-specific APIs when running on an appropriate platform. Following are the options you can use to address the warnings; choose whichever is most appropriate for your situation:

- **Guard the call.** You can achieve this by conditionally calling the code at run time. Check whether you're running on a desired `Platform` by using one of platform-check methods, for example,
`OperatingSystem.Is<Platform>()` or
`OperatingSystem.Is<Platform>VersionAtLeast(int major, int minor = 0, int build = 0, int revision = 0)`.
[Example](#).
- **Mark the call site as platform-specific.** You can also choose to mark your own APIs as being platform-specific, thus effectively just forwarding the requirements to your callers. Mark the containing method or type or the entire assembly with the same attributes as the referenced platform-dependent call. [Examples](#).
- **Assert the call site with platform check.** If you don't want the overhead of an additional `if` statement at run time, use `Debug.Assert(Boolean)`. [Example](#).
- **Delete the code.** Generally not what you want because it means you lose fidelity when your code is

used by Windows users. For cases where a cross-platform alternative exists, you're likely better off using that over platform-specific APIs.

- **SUPPRESS THE WARNING.** You can also simply suppress the warning, either via an [EditorConfig](#) entry or `#pragma warning disable CA1416`. However, this option should be a last resort when using platform-specific APIs.

TIP

When disabling warnings using the `#pragma` pre-compiler directives, the identifiers you're targeting are case sensitive. For example, `ca1416` would not actually disable warning CA1416.

Guard platform-specific APIs with guard methods

The guard method's platform name should match with the calling platform-dependent API platform name. If the platform string of the calling API includes the version:

- For the `[SupportedOSPlatform("platformVersion")]` attribute, the guard method platform `version` should be greater than or equal to the calling platform's `Version`.
- For the `[UnsupportedOSPlatform("platformVersion")]` attribute, the guard method's platform `version` should be less than or equal to the calling platform's `Version`.

```

public void CallingSupportedOnlyApis() // Allow list calls
{
    if (OperatingSystem.IsWindows())
    {
        WindowsOnlyApi(); // will not warn
    }

    if (OperatingSystem.IsLinux())
    {
        SupportedOnWindowsAndLinuxOnly(); // will not warn, within one of the supported context
    }

    // Can use &&, || logical operators to guard combined attributes
    if (OperatingSystem.IsWindowsVersionAtLeast(6, 2) && !OperatingSystem.IsWindowsVersionAtLeast(10,
0, 19041))
    {
        ApiSupportedFromWindows8UnsupportedFromWindows10();
    }

    if (OperatingSystem.IsWindowsVersionAtLeast(10, 0, 19041, 0))
    {
        AssemblySupportedOnWindowsApiSupportedFromWindows10(); // Only need to check latest supported
version
    }
}

public void CallingUnsupportedApis()
{
    if (!OperatingSystem.IsAndroid())
    {
        DoesNotWorkOnAndroid(); // will not warn
    }

    if (!OperatingSystem.IsWindows() || OperatingSystem.IsWindowsVersionAtLeast(6, 2))
    {
        StartedWindowsSupportFromVersion8(); // will not warn
    }

    if (!OperatingSystem.IsWindows() || // supported all other platforms
        (OperatingSystem.IsWindowsVersionAtLeast(6, 2) && !OperatingSystem.IsWindowsVersionAtLeast(10,
0, 19041)))
    {
        StartedWindowsSupportFrom8UnsupportedFrom10(); // will not warn
    }
}

```

- If you need to guard code that targets `netstandard` or `netcoreapp` where new `OperatingSystem` APIs are not available, the `RuntimeInformation.OSPlatform` API can be used and will be respected by the analyzer. But it's not as optimized as the new APIs added in `OperatingSystem`. If the platform is not supported in the `OSPlatform` struct, you can call `OSPlatform.Create(String)` and pass in the platform name, which the analyzer also respects.

```
public void CallingSupportedOnlyApis()
{
    if (RuntimeInformation.IsOSPlatform(OSPlatform.Windows))
    {
        SupportedOnWindowsAndLinuxOnly(); // will not warn
    }

    if (RuntimeInformation.IsOSPlatform(OSPlatform.Create("browser")))
    {
        ApiOnlySupportedOnBrowser(); // call of browser specific API
    }
}
```

Annotate APIs with platform guard attributes and use it as a custom guard

As shown previously, the analyzer recognizes the platform-guard static methods in the [OperatingSystem](#) type, such as `OperatingSystem.IsWindows`, and also [RuntimeInformation.IsOSPlatform](#). However, you might want to cache the guard result in a field and reuse it, or use custom guard methods for checking a platform. The analyzer needs to recognize such APIs as a custom guard and should not warn for the APIs guarded by them. The guard attributes were introduced in .NET 6 to support this scenario:

- `SupportedOSPlatformGuardAttribute` annotates APIs that can be used as a guard for APIs annotated with [SupportedOSPlatformAttribute](#).
- `UnsupportedOSPlatformGuardAttribute` annotates APIs that can be used as a guard for APIs annotated with [UnsupportedOSPlatformAttribute](#).

These attributes can optionally include a version number. They can be applied multiple times to guard more than one platform and can be used for annotating a field, property, or method.

```

class Test
{
    [UnsupportedOSPlatformGuard("browser")] // The platform guard attribute
#if TARGET_BROWSER
    internal bool IsSupported => false;
#else
    internal bool IsSupported => true;
#endif

    [UnsupportedOSPlatform("browser")]
    void ApiNotSupportedOnBrowser() { }

    void M1()
    {
        ApiNotSupportedOnBrowser(); // Warns: This call site is reachable on all
        platforms.'ApiNotSupportedOnBrowser()' is unsupported on: 'browser'

        if (IsSupported)
        {
            ApiNotSupportedOnBrowser(); // Not warn
        }
    }

    [SupportedOSPlatform("Windows")]
    [SupportedOSPlatform("Linux")]
    void ApiOnlyWorkOnWindowsLinux() { }

    [SupportedOSPlatformGuard("Linux")]
    [SupportedOSPlatformGuard("Windows")]
    private readonly bool _isWindowOrLinux = OperatingSystem.IsLinux() || OperatingSystem.IsWindows();

    void M2()
    {
        ApiOnlyWorkOnWindowsLinux(); // This call site is reachable on all
        platforms.'ApiOnlyWorkOnWindowsLinux()' is only supported on: 'Linux', 'Windows'.

        if (_isWindowOrLinux)
        {
            ApiOnlyWorkOnWindowsLinux(); // Not warn
        }
    }
}

```

Mark call site as platform-specific

Platform names should match the calling platform-dependent API. If the platform string includes a version:

- For the `[SupportedOSPlatform("platformVersion")]` attribute, the call site platform `version` should be greater than or equal to the calling platform's `Version`
- For the `[UnsupportedOSPlatform("platformVersion")]` attribute, the call site platform `version` should be less than or equal to the calling platform's `Version`

```

// an API supported only on Windows.
[SupportedOSPlatform("windows")]
public void WindowsOnlyApi() { }

// an API supported on Windows and Linux.
[SupportedOSPlatform("Windows")]
[SupportedOSPlatform("Linux")]
public void SupportedOnWindowsAndLinuxOnly() { }

// an API only supported on Windows 6.2 and later, not supported for all other.
// an API is removed/unsupported from version 10.0.19041.0.
[SupportedOSPlatform("windows6.2")]

```

```
[UnsupportedOSPlatform("windows10.0.19041.0")]
public void ApiSupportedFromWindows8UnsupportedFromWindows10() { }

// an Assembly supported on Windows, the API added from version 10.0.19041.0.
[assembly: SupportedOSPlatform("Windows")]
[SupportedOSPlatform("windows10.0.19041.0")]
public void AssemblySupportedOnWindowsApiSupportedFromWindows10() { }

[SupportedOSPlatform("windows6.2")] // call site attributed Windows 6.2 or above.
public void Caller()
{
    WindowsOnlyApi(); // will not warn as call site is for Windows.

    // will not warn as call site is for Windows all versions.
    SupportedOnWindowsAndLinuxOnly();

    // will not warn for the [SupportedOSPlatform("windows6.2")] attribute, but warns for
    [UnsupportedOSPlatform("windows10.0.19041.0")]
    // This call site is reachable on: 'windows' 6.2 and later.
    'ApiSupportedFromWindows8UnsupportedFromWindows10()' is unsupported on: 'windows' 10.0.19041.0 and
    later.
    ApiSupportedFromWindows8UnsupportedFromWindows10();

    // The call site version is lower than the calling version, so warns:
    // This call site is reachable on: 'windows' 6.2 and later.
    'AssemblySupportedOnWindowsApiSupportedFromWindows10()' is only supported on: 'windows' 10.0.19041.0
    and later
    AssemblySupportedOnWindowsApiSupportedFromWindows10();
}

[SupportedOSPlatform("windows10.0.22000")] // call site attributed with windows 10.0.22000 or above.
public void Caller2()
{
    // This call site is reachable on: 'windows' 10.0.22000 and later.
    'ApiSupportedFromWindows8UnsupportedFromWindows10()' is unsupported on: 'windows' 10.0.19041.0 and
    later.
    ApiSupportedFromWindows8UnsupportedFromWindows10();

    // will not warn as call site version higher than calling API.
    AssemblySupportedOnWindowsApiSupportedFromWindows10();
}

[SupportedOSPlatform("windows6.2")]
[UnsupportedOSPlatform("windows10.0.19041.0")] // call site supports Windows from version 6.2 to
10.0.19041.0.
public void Caller3()
{
    // will not warn as caller has exact same attributes.
    ApiSupportedFromWindows8UnsupportedFromWindows10();

    // The call site reachable for the version not supported in the calling API, therefore warns:
    // This call site is reachable on: 'windows' from version 6.2 to 10.0.19041.0.
    'AssemblySupportedOnWindowsApiSupportedFromWindows10()' is only supported on: 'windows' 10.0.19041.0
    and later.
    AssemblySupportedOnWindowsApiSupportedFromWindows10();
}

// an API not supported on Android but supported on all other.
[UnsupportedOSPlatform("android")]
public void DoesNotWorkOnAndroid() { }

// an API was unsupported on Windows until version 6.2.
// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows6.2")]
public void StartedWindowsSupportFromVersion8() { }

// an API was unsupported on Windows until version 6.2.
// Then the API is removed (unsupported) from version 10.0.19041.0.
```

```

// The API is considered supported everywhere else without constraints.
[UnsupportedOSPlatform("windows")]
[SupportedOSPlatform("windows6.2")]
[UnsupportedOSPlatform("windows10.0.19041.0")]
public void StartedWindowsSupportFrom8UnsupportedFrom10() { }

[UnsupportedOSPlatform("windows")] // Caller no support Windows for any version.
public void Caller4()
{
    // This call site is reachable on all platforms.'DoesNotWorkOnAndroid()' is unsupported on:
    'android'
    DoesNotWorkOnAndroid();

    // will not warns as the call site not support Windows at all, but supports all other.
    StartedWindowsSupportFromVersion8();

    // same, will not warns as the call site not support Windows at all, but supports all other.
    StartedWindowsSupportFrom8UnsupportedFrom10();
}

[UnsupportedOSPlatform("windows")]
[UnsupportedOSPlatform("android")] // Caller not support Windows and Android for any version.
public void Caller4()
{
    DoesNotWorkOnAndroid(); // will not warn as call site not supports Android.

    // will not warns as the call site not support Windows at all, but supports all other.
    StartedWindowsSupportFromVersion8();

    // same, will not warns as the call site not support Windows at all, but supports all other.
    StartedWindowsSupportFrom8UnsupportedFrom10();
}

```

Assert the call-site with platform check

All the conditional checks used in the [platform guard examples](#) can also be used as the condition for `Debug.Assert(Boolean)`.

```

// An API supported only on Linux.
[SupportedOSPlatform("linux")]
public void LinuxOnlyApi() { }

public void Caller()
{
    Debug.Assert(OperatingSystem.IsLinux());

    LinuxOnlyApi(); // will not warn
}

```

The .NET Portability Analyzer

9/20/2022 • 5 minutes to read • [Edit Online](#)

NOTE

We're in the process of deprecating API Port in favor of integrating binary analysis directly into [.NET Upgrade Assistant](#). In the upcoming months, we're going to shut down the backend service of API Port, which will require using the tool offline. For more information, see [GitHub: .NET API Port repository](#).*

Want to make your libraries support multi-platform? Want to see how much work is required to make your .NET Framework application run on .NET Core? The [.NET Portability Analyzer](#) is a tool that analyzes assemblies and provides a detailed report on .NET APIs that are missing for the applications or libraries to be portable on your specified targeted .NET platforms. The Portability Analyzer is offered as a [Visual Studio Extension](#), which analyzes one assembly per project, and as an [ApiPort console app](#), which analyzes assemblies by specified files or directory.

Once you've converted your project to target the new platform, like .NET Core, you can use the Roslyn-based [Platform compatibility analyzer](#) to identify APIs that throw [PlatformNotSupportedException](#) exceptions and other compatibility issues.

Common targets

- [.NET Core](#): Has a modular design, supports side-by-side installation, and targets cross-platform scenarios. Side-by-side installation allows you to adopt new .NET Core versions without breaking other apps. If your goal is to port your app to .NET Core and support multiple platforms, this is the recommended target.
- [.NET Standard](#): Includes the .NET Standard APIs available on all .NET implementations. If your goal is to make your library run on all .NET supported platforms, this is recommended target.
- [ASP.NET Core](#): A modern web-framework built on .NET Core. If your goal is to port your web app to .NET Core to support multiple platforms, this is the recommended target.
- .NET Core + [Platform Extensions](#): Includes the .NET Core APIs in addition to the Windows Compatibility Pack, which provides many of the .NET Framework available technologies. This is a recommended target for porting your app from .NET Framework to .NET Core on Windows.
- .NET Standard + [Platform Extensions](#): Includes the .NET Standard APIs in addition to the Windows Compatibility Pack, which provides many of the .NET Framework available technologies. This is a recommended target for porting your library from .NET Framework to .NET Core on Windows.

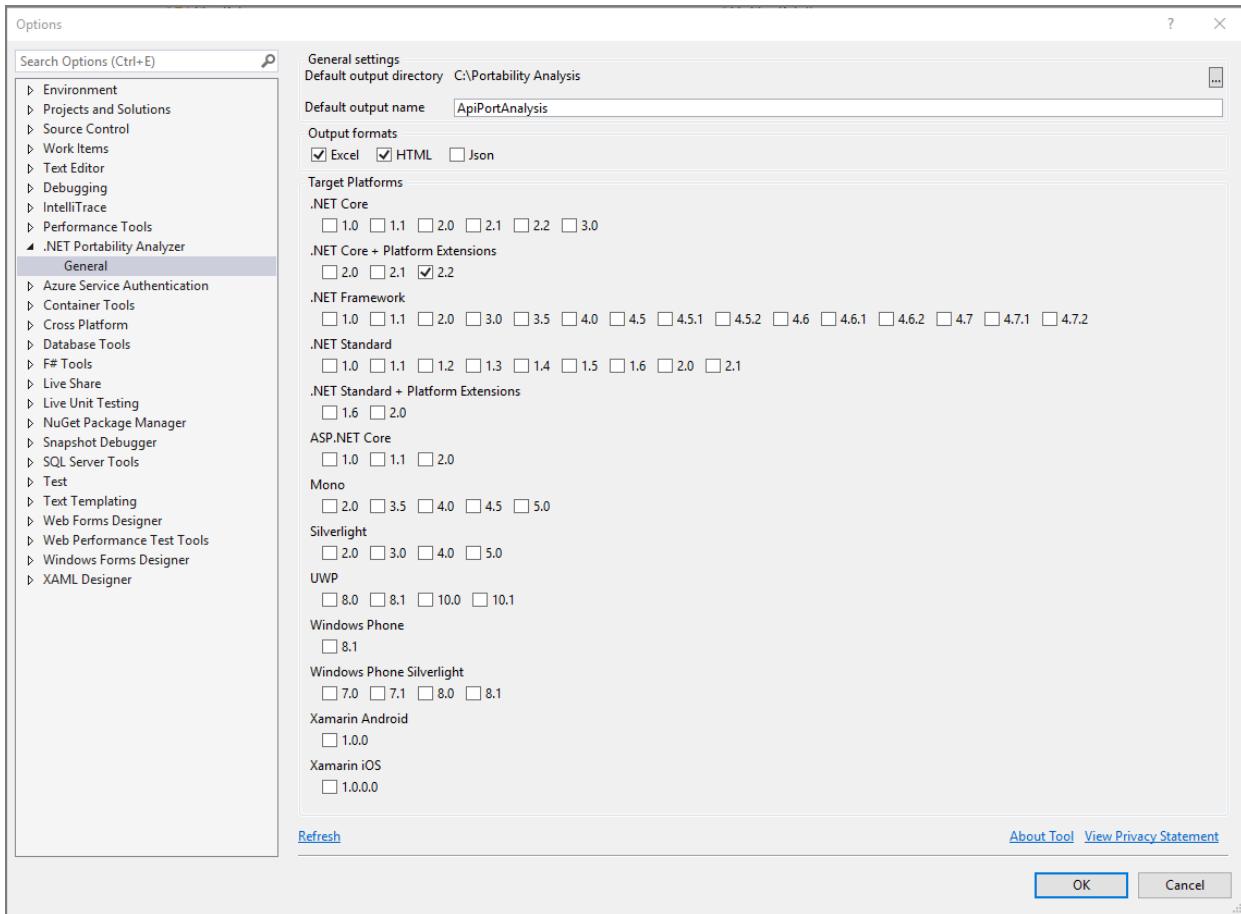

How to use the .NET Portability Analyzer

To begin using the .NET Portability Analyzer in Visual Studio, you first need to download and install the extension from the [Visual Studio Marketplace](#). It works on Visual Studio 2017 and Visual Studio 2019 versions.

IMPORTANT

The .NET Portability Analyzer is not supported in Visual Studio 2022.

Configure it in Visual Studio via [Analyze > Portability Analyzer Settings](#) and select your Target Platforms, which are the .NET platforms/versions that you want to evaluate the portability gaps comparing with the platform/version that your current assembly is built with.

You can also use the ApiPort console application, download it from [ApiPort repository](#). You can use `listTargets` command option to display the available target list, then pick target platforms by specifying `-t` or `--target` command option.

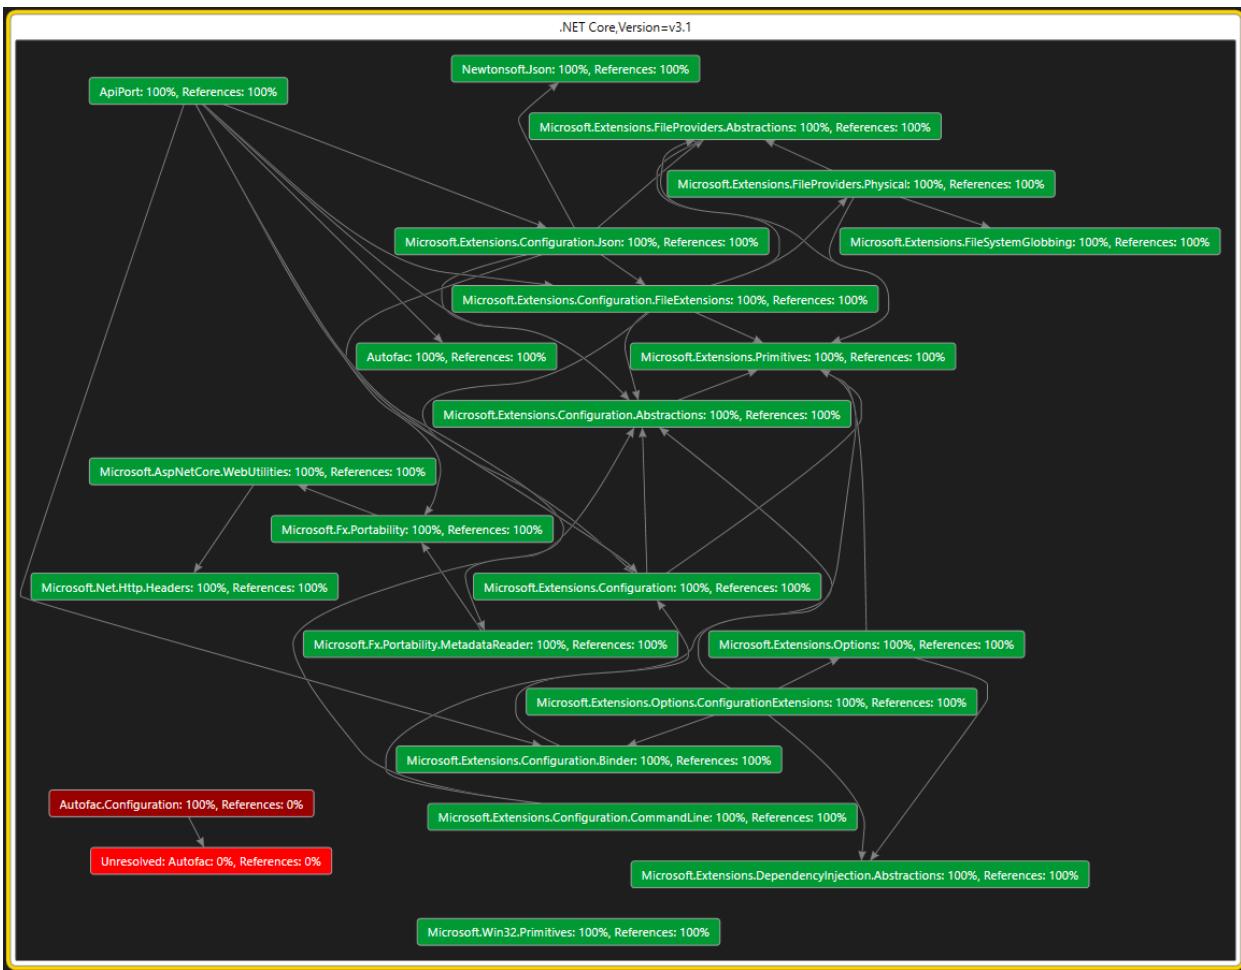

Solution wide view

A useful step in analyzing a solution with many projects would be to visualize the dependencies to understand which subset of assemblies depend on what. The general recommendation is to apply the results of the analysis in a bottom-up approach starting with the leaf nodes in a dependency graph.

To retrieve this, you may run the following command:

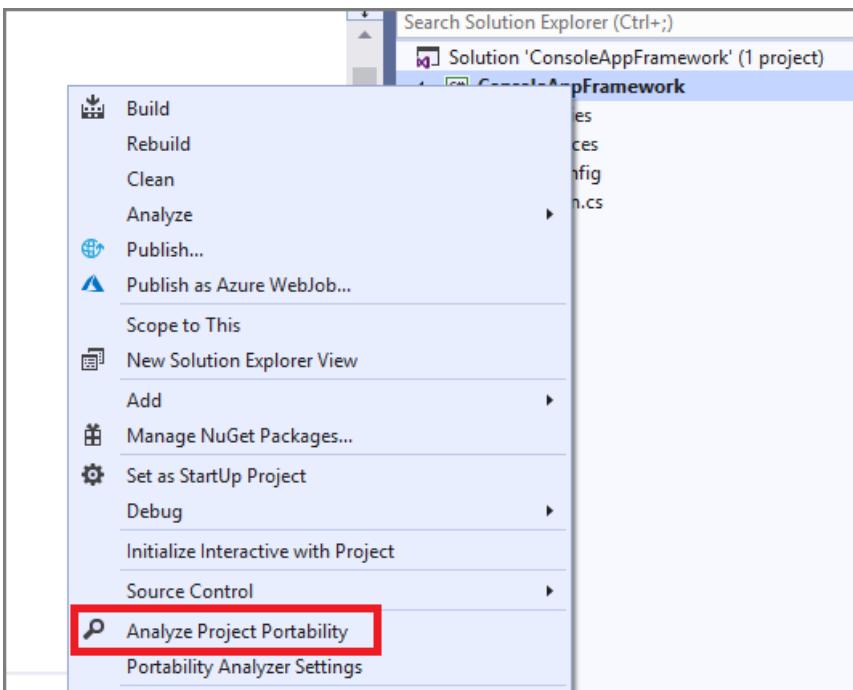

```
ApiPort.exe analyze -r DGML -f [directory or file]
```

A result of this would look like the following when opened in Visual Studio:

Analyze portability

To analyze your entire project in Visual Studio, right-click on your project in Solution Explorer and select **Analyze Assembly Portability**. Otherwise, go to the Analyze menu and select **Analyze Assembly Portability**. From there, select your project's executable or DLL.

You can also use the [ApiPort console app](#).

Type the following command to analyze the current directory:

```
ApiPort.exe analyze -f .
```

To analyze a specific list of .dll files, type the following command:

```
ApiPort.exe analyze -f first.dll -f second.dll -f third.dll
```

To target a specific version, use the `-t` parameter:

```
ApiPort.exe analyze -t ".NET, Version=5.0" -f .
```

Run `ApiPort.exe -?` to get more help.

It is recommended that you include all the related exe and dll files that you own and want to port, and exclude the files that your app depends on, but you don't own and can't port. This will give you most relevant portability report.

View and interpret portability result

Only APIs that are unsupported by a Target Platform appear in the report. After running the analysis in Visual Studio, you'll see your .NET Portability report file link pops up. If you used the [ApiPort console app](#), your .NET Portability report is saved as a file in the format you specified. The default is in an Excel file (.x/sx) in your current directory.

Portability Summary

Submission Id	5552b6d0-b7ed-4fa8-9a3c-e3d8099c7ab1					
Description						
Targets	.NET Core + Platform Extensions,.NET Core,.NET Framework,.NET Standard + Platform Extensions					
Assembly Name	Target Framework	.NET Core + Platform	.NET Core	.NET Framework	.NET Standard	
svutil	.NETFramework,Version=v4.5	71.24	71.48	100	71.24	
API Catalog last updated on	Tuesday, March 5, 2019					
See ' http://go.microsoft.com/fwlink/?LinkId=397652 ' to learn how to read this table						
	Portability Summary	Details				

The Portability Summary section of the report shows the portability percentage for each assembly included in the run. In the previous example, 71.24% of the .NET Framework APIs used in the `svutil` app are available in .NET Core + Platform Extensions. If you run the .NET Portability Analyzer tool against multiple assemblies, each assembly should have a row in the Portability Summary report.

Details

Target type	Target member	Assembly name	.NET Core + Platform Extensions	Recommended
T:System.AppDomain	M:System.AppDomain.get_SetupInformation	svutil	Not supported	Remove usage.
T:System.AppDomainSetup	I:T:System.AppDomainSetup	svutil	Not supported	Remove usage.
T:System.AppDomainSetup	M:System.AppDomainSetup.get_ConfigurationFile	svutil	Not supported	Remove usage.
T:System.Data.DataSetSchemaImporterExtension	I:T:System.Data.DataSetSchemaImporterExtension	svutil	Not supported	
T:System.Data.Design.TypedDataSetSchemaImporterExtension	T:System.Data.Design.TypedDataSetSchemaImporterExtension	svutil	Not supported	
T:System.Data.Design.TypedDataSetSchemaImporterExtensionFx3	I:T:System.Data.Design.TypedDataSetSchemaImporterExtensionFx3	svutil	Not supported	

The Details section of the report lists the APIs missing from any of the selected Targeted Platforms.

- Target type: the type has missing API from a Target Platform
- Target member: the method is missing from a Target Platform
- Assembly name: the .NET Framework assembly that the missing API lives in.
- Each of the selected Target Platforms is one column, such as ".NET Core": "Not supported" value means the API is not supported on this Target Platform.
- Recommended Changes: the recommended API or technology to change to. Currently, this field is empty or out of date for many APIs. Due to the large number of APIs, we have a significant challenge to keep it up to date. We're looking at alternative solutions to provide helpful information to customers.

Missing Assemblies

Header for assembly name entries	Used By	Reason
Autofac, Version=4.6.2.0, Culture=neutral, PublicKeyToken=17863af14b0044da	ApiPort	Unresolved assembly
System.CommandLine, Version=0.1.0.0, Culture=neutral, PublicKeyToken=adb9793829ddae60	ApiPort	Unresolved assembly

You may find a Missing Assemblies section in your report. This section contains a list of assemblies that are referenced by your analyzed assemblies and were not analyzed. If it's an assembly that you own, include it in the API portability analyzer run so that you can get a detailed, API-level portability report for it. If it's a third-party library, check if there is a newer version that supports your target platform, and consider moving to the newer version. Eventually, the list should include all the third-party assemblies that your app depends on that have a version supporting your target platform.

For more information on the .NET Portability Analyzer, visit the [GitHub documentation](#).

Package validation overview

9/20/2022 • 2 minutes to read • [Edit Online](#)

Cross-platform compatibility has become a mainstream requirement for .NET library authors. However, without validation tooling for these packages, they often don't work well. This is especially problematic for emerging platforms where adoption isn't high enough to warrant special attention by library authors.

Until package validation was introduced, the .NET SDK tooling provided almost no validation that multi-targeted packages were well formed. For example, a package that multi-targets for .NET 6 and .NET Standard 2.0 needs to ensure that code compiled against the .NET Standard 2.0 binary can run against the .NET 6 binary.

You might think that a change is safe and compatible if source consuming that change continues to compile without changes. However, the changes can still cause problems at run time if the consumer wasn't recompiled. For example, adding an optional parameter to a method or changing the value of a constant can cause these kinds of compatibility issues.

Package validation tooling allows library developers to validate that their packages are consistent and well formed. It provides the following checks:

- Validates that there are no breaking changes across versions.
- Validates that the package has the same set of public APIs for all the different runtime-specific implementations.
- Helps developers catch any applicability holes.

Enable package validation

You enable package validation in your .NET project by setting the `EnablePackageValidation` property to `true`.

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFrameworks>netstandard2.0;net6.0</TargetFrameworks>
  <EnablePackageValidation>true</EnablePackageValidation>
</PropertyGroup>

</Project>
```

`EnablePackageValidation` runs a series of checks after the `Pack` task. There are some additional checks that can be run by setting other MSBuild properties.

Validator types

There are three different validators that verify your package as part of the `Pack` task:

- The [Baseline version validator](#) validates your library project against a previously released, stable version of your package.
- The [Compatible runtime validator](#) validates that your runtime-specific implementation assemblies are compatible with each other and with the compile-time assemblies.
- The [Compatible framework validator](#) validates that code compiled against one framework can run against all the others in a multi-targeting package.

Suppress compatibility errors

To suppress compatibility errors for intentional changes, add a *CompatibilitySuppressions.xml* file to your project. You can generate this file automatically by passing `/p:GenerateCompatibilitySuppressionFile=true` if you're building the project from the command line, or by adding the following property to your project:

```
<GenerateCompatibilitySuppressionFile>true</GenerateCompatibilitySuppressionFile>
```

The suppression file looks like this.

```
<?xml version="1.0" encoding="utf-8"?>
<Suppressions xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <Suppression>
    <DiagnosticId>CP0002</DiagnosticId>
    <Target>M:A.B.DoStringManipulation(System.String)</Target>
    <Left>lib/netstandard2.0/A.dll</Left>
    <Right>lib/net6.0/A.dll</Right>
    <IsBaselineSuppression>false</IsBaselineSuppression>
  </Suppression>
</Suppressions>
```

- `DiagnosticId` specifies the ID of the error to suppress.
- `Target` specifies where in the code to suppress the diagnostic IDs
- `Left` specifies the left operand of an APICompat comparison.
- `Right` specifies the right operand of an APICompat comparison.
- `IsBaselineSuppression` : set to `true` to apply the suppression to a baseline validation; otherwise, set to `false`.

Validate against a baseline package version

9/20/2022 • 2 minutes to read • [Edit Online](#)

Package Validation can help you validate your library project against a previously released, stable version of your package. To enable package validation, add the `PackageValidationBaselineVersion` or `PackageValidationBaselinePath` property to your project file.

Package validation detects any breaking changes on any of the shipped target frameworks. It also detects if any target framework support has been dropped.

For example, consider the following scenario. You're working on the AdventureWorks.Client NuGet package and you want to make sure that you don't accidentally make breaking changes. You configure your project to instruct package validation tooling to run API compatibility checks against the previous version of the package.

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
    <TargetFramework>net6.0</TargetFramework>
    <PackageVersion>2.0.0</PackageVersion>
    <EnablePackageValidation>true</EnablePackageValidation>
    <PackageValidationBaselineVersion>1.0.0</PackageValidationBaselineVersion>
</PropertyGroup>

</Project>
```

A few weeks later, you're tasked with adding support for a connection timeout to your library. The `Connect` method currently looks like this:

```
public static HttpClient Connect(string url)
{
    // ...
}
```

Since a connection timeout is an advanced configuration setting, you reckon that you can just add an optional parameter:

```
public static HttpClient Connect(string url, TimeSpan timeout = default)
{
    // ...
}
```

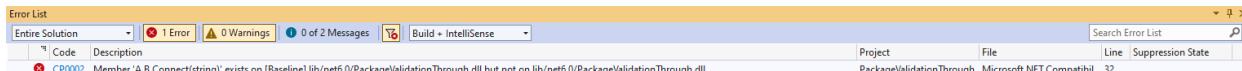

However, when you try to pack, it throws an error.

```

D:\demo>dotnet pack
Microsoft (R) Build Engine version 17.0.0-preview-21460-01+8f208e609 for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
PackageValidationThrough -> D:\demo\bin\Debug\net6.0\PackageValidationThrough.dll
Successfully created package 'D:\demo\bin\Debug\PackageValidationThrough.2.0.0.nupkg'.
C:\Program Files\dotnet\sdk\6.0.100-
rc.1.21463.6\Sdks\Microsoft.NET.Sdk\targets\Microsoft.NET.Compatibility.Common.targets(32,5): error CP0002:
Member 'A.B.Connect(string)' exists on [Baseline] lib/net6.0/PackageValidationThrough.dll but not on
lib/net6.0/PackageValidationThrough.dll [D:\demo\PackageValidationThrough.csproj]

```

You realize that while this is not a [source breaking change](#), it is a [binary breaking change](#). You solve this problem by adding a new overload instead of adding a parameter to the existing method:

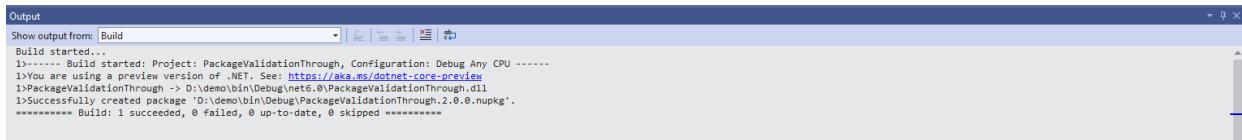

```

public static HttpClient Connect(string url)
{
    return Connect(url, Timeout.InfiniteTimeSpan);
}

public static HttpClient Connect(string url, TimeSpan timeout)
{
    // ...
}

```

Now when you pack the project, it succeeds.

Validate compatible frameworks

9/20/2022 • 2 minutes to read • [Edit Online](#)

Packages containing compatible frameworks need to ensure that code compiled against one can run against another. Examples of compatible framework pairs are:

- .NET Standard 2.0 and .NET 6
- .NET 5 and .NET 6

In both of these cases, consumers can build against .NET Standard 2.0 or NET 5 and run on .NET 6. If your binaries are not compatible between these frameworks, consumers could end up with compile-time or run-time errors.

Package validation catches these errors at pack time. Here is an example scenario:

Suppose you're writing a game that manipulates strings. You need to support both .NET Framework and .NET (.NET Core) consumers. Originally, your project targeted .NET Standard 2.0, but now you want to take advantage of `Span<T>` in .NET 6 to avoid unnecessary string allocations. To do that, you want to multi-target for .NET Standard 2.0 and .NET 6.

You've written the following code:

```
#if NET6_0_OR_GREATER
    public void DoStringManipulation(ReadOnlySpan<char> input)
    {
        // use spans to do string operations.
    }
#else
    public void DoStringManipulation(string input)
    {
        // Do some string operations.
    }
#endif
```

You then try to pack the project (using either `dotnet pack` or Visual Studio), and it fails with the following error:

```
D:\demo>dotnet pack
Microsoft (R) Build Engine version 17.0.0-preview-21460-01+8f208e609 for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

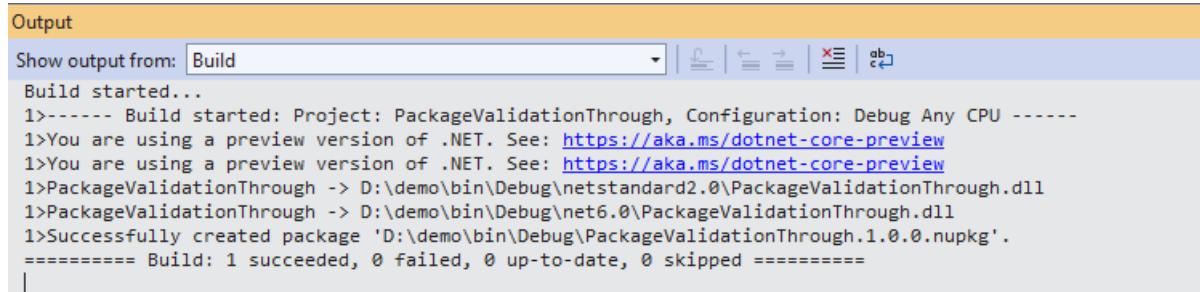

Determining projects to restore...
All projects are up-to-date for restore.
You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
PackageValidationThrough -> D:\demo\bin\Debug\netstandard2.0\PackageValidationThrough.dll
PackageValidationThrough -> D:\demo\bin\Debug\net6.0\PackageValidationThrough.dll
Successfully created package 'D:\demo\bin\Debug\PackageValidationThrough.1.0.0.nupkg'.
C:\Program Files\dotnet\sdk\6.0.100-
rc.1.21463.6\Sdks\Microsoft.NET.Sdk\targets\Microsoft.NET.Compatibility.Common.targets(32,5): error CP0002:
Member 'A.B.DoStringManipulation(string)' exists on lib/netstandard2.0/PackageValidationThrough.dll but not
on lib/net6.0/PackageValidationThrough.dll [D:\demo\PackageValidationThrough.csproj]
```

You realize that instead of excluding `DoStringManipulation(string)` for .NET 6, you should just provide an additional `DoStringManipulation(ReadOnlySpan<char>)` method for .NET 6:

```
#if NET6_0_OR_GREATER
    public void DoStringManipulation(ReadOnlySpan<char> input)
    {
        // use spans to do string operations.
    }
#endif
    public void DoStringManipulation(string input)
    {
        // Do some string operations.
    }
```

You try to pack the project again, and it succeeds.

The screenshot shows the Visual Studio Output window with the title 'Output' at the top. A dropdown menu 'Show output from:' is set to 'Build'. Below the dropdown are several icons for filtering and sorting the output. The main area contains the following text:

```
Build started...
1>----- Build started: Project: PackageValidationThrough, Configuration: Debug Any CPU -----
1>You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
1>You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
1>PackageValidationThrough -> D:\demo\bin\Debug\netstandard2.0\PackageValidationThrough.dll
1>PackageValidationThrough -> D:\demo\bin\Debug\net6.0\PackageValidationThrough.dll
1>Successfully created package 'D:\demo\bin\Debug\PackageValidationThrough.1.0.0.nupkg'.
===== Build: 1 succeeded, 0 failed, 0 up-to-date, 0 skipped =====
```

You can enable *strict mode* for this validator by setting the `EnableStrictModeForCompatibleFrameworksInPackage` property in your project file. Enabling strict mode changes some rules and executes some other rules when getting the differences. This is useful when you want both sides you're comparing to be strictly the same on their surface area and identity.

Validate packages against different runtimes

9/20/2022 • 2 minutes to read • [Edit Online](#)

You may choose to have different implementation assemblies for different runtimes in your NuGet package. In that case, you'll need to make sure that these assemblies are compatible with each other and with the compile-time assemblies.

For example, consider the following scenario. You're working on a library involving some interop calls to Unix and Windows APIs, respectively. You have written the following code:

```
#if Unix
    public static void Open(string path, bool securityDescriptor)
    {
        // call unix specific stuff
    }
#else
    public static void Open(string path)
    {
        // call windows specific stuff
    }
#endif
```

The resulting package structure looks as follows.

```
lib/net6.0/A.dll
runtimes/unix/lib/net6.0/A.dll
```

`lib\net6.0\A.dll` will always be used at compile time, regardless of the underlying operating system.

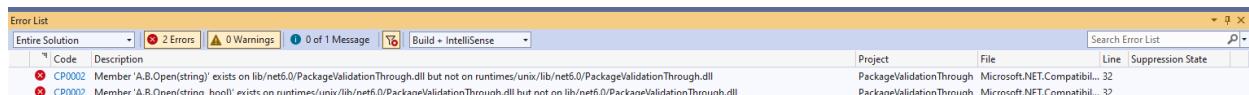

`lib\net6.0\A.dll` will also be used at run time for non-Unix systems. However, `runtimes\unix\lib\net6.0\A.dll` will be used at run time for Unix systems.

When you try to pack this project, you'll get the following error:

```
D:\demo>dotnet pack
Microsoft (R) Build Engine version 17.0.0-preview-21460-01+8f208e609 for .NET
Copyright (C) Microsoft Corporation. All rights reserved.

Determining projects to restore...
All projects are up-to-date for restore.
You are using a preview version of .NET. See: https://aka.ms/dotnet-core-preview
PackageValidationThrough -> D:\demo\bin\Debug\net6.0\PackageValidationThrough.dll
Successfully created package 'D:\demo\bin\Debug\PackageValidationThrough.1.0.0.nupkg'.

C:\Program Files\dotnet\sdk\6.0.100-
rc.1.21463.6\Sdks\Microsoft.NET.Sdk\targets\Microsoft.NET.Compatibility.Common.targets(32,5): error CP0002:
Member 'A.B.Open(string)' exists on lib/net6.0/PackageValidationThrough.dll but not on
runtimes/unix/lib/net6.0/PackageValidationThrough.dll [D:\demo\PackageValidationThrough.csproj]
C:\Program Files\dotnet\sdk\6.0.100-
rc.1.21463.6\Sdks\Microsoft.NET.Sdk\targets\Microsoft.NET.Compatibility.Common.targets(32,5): error CP0002:
Member 'A.B.Open(string, bool)' exists on runtimes/unix/lib/net6.0/PackageValidationThrough.dll but not on
lib/net6.0/PackageValidationThrough.dll [D:\demo\PackageValidationThrough.csproj]
```

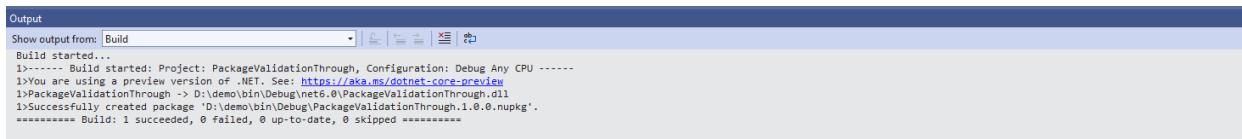

You realize your mistake and add `A.B.Open(string)` to the Unix runtime as well.

```
#if Unix
    public static void Open(string path, bool securityDescriptor)
    {
        // call unix specific stuff
    }

    public static void Open(string path)
    {
        throw new PlatformNotSupportedException();
    }
#else
    public static void Open(string path)
    {
        // call windows specific stuff
    }

    public static void Open(string path, bool securityDescriptor)
    {
        throw new PlatformNotSupportedException();
    }
#endif
```

You try to pack the project again, and it succeeds.

You can enable *strict mode* for this validator by setting the `EnableStrictModeForCompatibleTfms` property in your project file. Enabling strict mode changes some rules, and some other rules will be executed when getting the differences. This is useful when you want both sides we are comparing to be strictly the same on their surface area and identity.

Error codes returned by package validation

9/20/2022 • 3 minutes to read • [Edit Online](#)

This reference article lists all the error codes generated by package validation.

List of error codes

DIAGNOSTIC ID	DESCRIPTION	RECOMMENDED ACTION
PKV0001	A compile-time asset for a compatible framework is missing.	Add the appropriate target framework to the project.
PKV0002	A run-time asset for a compatible framework and runtime is missing.	Add the appropriate asset for corresponding runtime to the package.
PKV0003	A run-time independent asset for a compatible framework is missing.	Add the appropriate run-time independent target framework to the project.
PKV0004	A compatible run-time asset for a compile-time asset is missing.	Add the appropriate run-time asset to the package.
PKV0005	A compatible run-time asset for a compile-time asset and a supported runtime identifier is missing.	Add the appropriate run-time asset to the package.
PKV0006	The target framework is dropped in the latest version.	Add the appropriate target framework to the project.
PKV0007	The target framework and runtime identifier pair is dropped in the latest version.	Add the appropriate target framework and RID to the project.
CP0001	A type, enum, record, or struct visible outside the assembly is missing in the compared assembly when required to be present.	Add the missing type to the assembly where it is missing.
CP0002	A member that is visible outside of the assembly is missing in the compared assembly when required to be present.	Add the missing member to the assembly where it is missing.
CP0003	Some part of the assembly identity (name, public key token, culture, retargetable attribute, or version) does not match on both sides of the comparison.	Update the assembly identity so that both sides match.
CP0004	A matching assembly was not found on one side of the comparison when creating the assembly mapping.	Make sure the missing assembly is added to the package.

DIAGNOSTIC ID	DESCRIPTION	RECOMMENDED ACTION
CP0005	An <code>abstract</code> member was added to the right side of the comparison to an unsealed type.	Remove the member or don't annotate it as <code>abstract</code> .
CP0006	A member was added to an interface without a default implementation.	If the target framework and language version support default implementations, add one, or just remove the member from the interface.
CP0007	A base type on the class hierarchy was removed from one of the compared sides.	Add the base type back. (A new base type can be introduced in the hierarchy if that's intended.)
CP0008	A base interface was removed from the interface hierarchy from one of the compared sides.	Add the interface back to the hierarchy.
CP0009	A type that was unsealed on one side was annotated as <code>sealed</code> on the other compared side.	Remove the <code>sealed</code> annotation from the type.
CP0010	The underlying type of an enum changed from one side to the other.	Change the underlying type back to what it was previously.
CP0011	The value of a member in an enum changed from one side to the other.	Change the value of the member back to what it was previously.
CP0012	The <code>virtual</code> keyword was removed from a member that was previously virtual.	Add the <code>virtual</code> keyword back to the member.
CP0013	The <code>virtual</code> keyword was added to a member that was previously not virtual.	Remove the <code>virtual</code> keyword from the member.
CP0014	An attribute was removed from a member that previously had it.	Add the attribute back to the member.
CP0015	The arguments passed to an attribute changed from one side to the other.	Change the arguments to the attribute back to what they were previously.
CP0016	An attribute was added to a member that previously did not have it.	Remove the attribute from the member.
CP0017	The name of a method's parameter changed from one side to the other.	Change the parameter's name back to what it was previously.
CP0018	The <code>sealed</code> keyword was added to an interface member that was previously not sealed.	Remove the <code>sealed</code> keyword from the interface member.

DIAGNOSTIC ID	DESCRIPTION	RECOMMENDED ACTION
CP1001	A matching assembly could not be found in the search directories. (Not applicable for package validation, only when using API Compat directly.)	Provide the search directory when loading matching assemblies using <code>AssemblySymbolLoader</code> .
CP1002	A reference assembly was not found when loading the assemblies to compare in the resolved directories for the current target framework.	Include the directory path where that assembly can be found using the following MSBuild item: <pre><PackageValidationReferencePath Include=<path> TargetFramework=<tfm> /></pre>
CP1003	There was no search directory provided for the target framework moniker that the package validation is running API Compat for.	Provide the search directory to find references for that target framework using the following MSBuild item: <pre><PackageValidationReferencePath Include=<path> TargetFramework=<tfm> /></pre>

Common Language Runtime (CLR) overview

9/20/2022 • 4 minutes to read • [Edit Online](#)

.NET provides a run-time environment called the common language runtime that runs the code and provides services that make the development process easier.

Compilers and tools expose the common language runtime's functionality and enable you to write code that benefits from the managed execution environment. Code that you develop with a language compiler that targets the runtime is called managed code. Managed code benefits from features such as cross-language integration, cross-language exception handling, enhanced security, versioning and deployment support, a simplified model for component interaction, and debugging and profiling services.

NOTE

Compilers and tools can produce output that the common language runtime can consume because the type system, the format of metadata, and the run-time environment (the virtual execution system) are all defined by a public standard, the ECMA Common Language Infrastructure specification. For more information, see [ECMA C# and Common Language Infrastructure Specifications](#).

To enable the runtime to provide services to managed code, language compilers must emit metadata that describes the types, members, and references in your code. Metadata is stored with the code; every loadable common language runtime portable executable (PE) file contains metadata. The runtime uses metadata to locate and load classes, lay out instances in memory, resolve method invocations, generate native code, enforce security, and set run-time context boundaries.

The runtime automatically handles object layout and manages references to objects, releasing them when they're no longer being used. Objects whose lifetimes are managed in this way are called managed data. Garbage collection eliminates memory leaks and some other common programming errors. If your code is managed, you can use managed, unmanaged, or both managed and unmanaged data in your .NET application. Because language compilers supply their own types, such as primitive types, you might not always know or need to know whether your data is being managed.

The common language runtime makes it easy to design components and applications whose objects interact across languages. Objects written in different languages can communicate with each other, and their behaviors can be tightly integrated. For example, you can define a class and then use a different language to derive a class from your original class or call a method on the original class. You can also pass an instance of a class to a method of a class written in a different language. This cross-language integration is possible because language compilers and tools that target the runtime use a common type system defined by the runtime. They follow the runtime's rules for defining new types and for creating, using, persisting, and binding to types.

As part of their metadata, all managed components carry information about the components and resources they were built against. The runtime uses this information to ensure that your component or application has the specified versions of everything it needs, which makes your code less likely to break because of some unmet dependency. Registration information and state data are no longer stored in the registry, where they can be difficult to establish and maintain. Instead, information about the types you define and their dependencies is stored with the code as metadata. This way, the task of component replication and removal is less complicated.

Language compilers and tools expose the runtime's functionality in ways that are intended to be useful and intuitive to developers. Some features of the runtime might be more noticeable in one environment than in another. How you experience the runtime depends on which language compilers or tools you use. For example, if you're a Visual Basic developer, you might notice that with the common language runtime, the Visual Basic

language has more object-oriented features than before. The runtime provides the following benefits:

- Performance improvements.
- The ability to easily use components developed in other languages.
- Extensible types provided by a class library.
- Language features such as inheritance, interfaces, and overloading for object-oriented programming.
- Support for explicit free threading that allows creation of multithreaded and scalable applications.
- Support for structured exception handling.
- Support for custom attributes.
- Garbage collection.
- Use of delegates instead of function pointers for increased type safety and security. For more information about delegates, see [Common Type System](#).

CLR versions

.NET Core and .NET 5+ releases have a single product version, that is, there's no separate CLR version. For a list of .NET Core versions, see [Download .NET Core](#).

However, the .NET Framework version number doesn't necessarily correspond to the version number of the CLR it includes. For a list of .NET Framework versions and their corresponding CLR versions, see [.NET Framework versions and dependencies](#).

Managed Execution Process

9/20/2022 • 7 minutes to read • [Edit Online](#)

The managed execution process includes the following steps, which are discussed in detail later in this topic:

1. [Choosing a compiler.](#)

To obtain the benefits provided by the common language runtime, you must use one or more language compilers that target the runtime.

2. [Compiling your code to MSIL.](#)

Compiling translates your source code into Microsoft intermediate language (MSIL) and generates the required metadata.

3. [Compiling MSIL to native code.](#)

At execution time, a just-in-time (JIT) compiler translates the MSIL into native code. During this compilation, code must pass a verification process that examines the MSIL and metadata to find out whether the code can be determined to be type safe.

4. [Running code.](#)

The common language runtime provides the infrastructure that enables execution to take place and services that can be used during execution.

Choosing a Compiler

To obtain the benefits provided by the common language runtime (CLR), you must use one or more language compilers that target the runtime, such as Visual Basic, C#, Visual C++, F#, or one of many third-party compilers such as an Eiffel, Perl, or COBOL compiler.

Because it is a multilanguage execution environment, the runtime supports a wide variety of data types and language features. The language compiler you use determines which runtime features are available, and you design your code using those features. Your compiler, not the runtime, establishes the syntax your code must use. If your component must be completely usable by components written in other languages, your component's exported types must expose only language features that are included in the Common Language Specification (CLS). You can use the [CLSCCompliantAttribute](#) attribute to ensure that your code is CLS-compliant. For more information, see [Language independence and language-independent components](#).

[Back to top](#)

Compiling to MSIL

When compiling to managed code, the compiler translates your source code into Microsoft intermediate language (MSIL), which is a CPU-independent set of instructions that can be efficiently converted to native code. MSIL includes instructions for loading, storing, initializing, and calling methods on objects, as well as instructions for arithmetic and logical operations, control flow, direct memory access, exception handling, and other operations. Before code can be run, MSIL must be converted to CPU-specific code, usually by a [just-in-time \(JIT\) compiler](#). Because the common language runtime supplies one or more JIT compilers for each computer architecture it supports, the same set of MSIL can be JIT-compiled and run on any supported architecture.

When a compiler produces MSIL, it also produces metadata. Metadata describes the types in your code, including the definition of each type, the signatures of each type's members, the members that your code references, and other data that the runtime uses at execution time. The MSIL and metadata are contained in a portable executable (PE) file that is based on and that extends the published Microsoft PE and common object file format (COFF) used historically for executable content. This file format, which accommodates MSIL or native code as well as metadata, enables the operating system to recognize common language runtime images. The presence of metadata in the file together with MSIL enables your code to describe itself, which means that there is no need for type libraries or Interface Definition Language (IDL). The runtime locates and extracts the metadata from the file as needed during execution.

[Back to top](#)

Compiling MSIL to Native Code

Before you can run Microsoft intermediate language (MSIL), it must be compiled against the common language runtime to native code for the target machine architecture. .NET provides two ways to perform this conversion:

- A .NET just-in-time (JIT) compiler.
- [Ngen.exe \(Native Image Generator\)](#).

Compilation by the JIT Compiler

JIT compilation converts MSIL to native code on demand at application run time, when the contents of an assembly are loaded and executed. Because the common language runtime supplies a JIT compiler for each supported CPU architecture, developers can build a set of MSIL assemblies that can be JIT-compiled and run on different computers with different machine architectures. However, if your managed code calls platform-specific native APIs or a platform-specific class library, it will run only on that operating system.

JIT compilation takes into account the possibility that some code might never be called during execution. Instead of using time and memory to convert all the MSIL in a PE file to native code, it converts the MSIL as needed during execution and stores the resulting native code in memory so that it is accessible for subsequent calls in the context of that process. The loader creates and attaches a stub to each method in a type when the type is loaded and initialized. When a method is called for the first time, the stub passes control to the JIT compiler, which converts the MSIL for that method into native code and modifies the stub to point directly to the generated native code. Therefore, subsequent calls to the JIT-compiled method go directly to the native code.

Install-Time Code Generation Using NGen.exe

Because the JIT compiler converts an assembly's MSIL to native code when individual methods defined in that assembly are called, it affects performance adversely at run time. In most cases, that diminished performance is acceptable. More importantly, the code generated by the JIT compiler is bound to the process that triggered the compilation. It cannot be shared across multiple processes. To allow the generated code to be shared across multiple invocations of an application or across multiple processes that share a set of assemblies, the common language runtime supports an ahead-of-time compilation mode. This ahead-of-time compilation mode uses the [Ngen.exe \(Native Image Generator\)](#) to convert MSIL assemblies to native code much like the JIT compiler does. However, the operation of Ngen.exe differs from that of the JIT compiler in three ways:

- It performs the conversion from MSIL to native code before running the application instead of while the application is running.
- It compiles an entire assembly at a time, instead of one method at a time.
- It persists the generated code in the Native Image Cache as a file on disk.

Code Verification

As part of its compilation to native code, the MSIL code must pass a verification process unless an administrator

has established a security policy that allows the code to bypass verification. Verification examines MSIL and metadata to find out whether the code is type safe, which means that it accesses only the memory locations it is authorized to access. Type safety helps isolate objects from each other and helps protect them from inadvertent or malicious corruption. It also provides assurance that security restrictions on code can be reliably enforced.

The runtime relies on the fact that the following statements are true for code that is verifiably type safe:

- A reference to a type is strictly compatible with the type being referenced.
- Only appropriately defined operations are invoked on an object.
- Identities are what they claim to be.

During the verification process, MSIL code is examined in an attempt to confirm that the code can access memory locations and call methods only through properly defined types. For example, code cannot allow an object's fields to be accessed in a manner that allows memory locations to be overrun. Additionally, verification inspects code to determine whether the MSIL has been correctly generated, because incorrect MSIL can lead to a violation of the type safety rules. The verification process passes a well-defined set of type-safe code, and it passes only code that is type safe. However, some type-safe code might not pass verification because of some limitations of the verification process, and some languages, by design, do not produce verifiably type-safe code. If type-safe code is required by the security policy but the code does not pass verification, an exception is thrown when the code is run.

[Back to top](#)

Running Code

The common language runtime provides the infrastructure that enables managed execution to take place and services that can be used during execution. Before a method can be run, it must be compiled to processor-specific code. Each method for which MSIL has been generated is JIT-compiled when it is called for the first time, and then run. The next time the method is run, the existing JIT-compiled native code is run. The process of JIT-compiling and then running the code is repeated until execution is complete.

During execution, managed code receives services such as garbage collection, security, interoperability with unmanaged code, cross-language debugging support, and enhanced deployment and versioning support.

In Microsoft Windows Vista, the operating system loader checks for managed modules by examining a bit in the COFF header. The bit being set denotes a managed module. If the loader detects managed modules, it loads mscoree.dll, and `_CorValidateImage` and `_CorImageUnloading` notify the loader when the managed module images are loaded and unloaded. `_CorValidateImage` performs the following actions:

1. Ensures that the code is valid managed code.
2. Changes the entry point in the image to an entry point in the runtime.

On 64-bit Windows, `_CorValidateImage` modifies the image that is in memory by transforming it from PE32 to PE32+ format.

Assemblies in .NET

9/20/2022 • 6 minutes to read • [Edit Online](#)

Assemblies are the fundamental units of deployment, version control, reuse, activation scoping, and security permissions for .NET-based applications. An assembly is a collection of types and resources that are built to work together and form a logical unit of functionality. Assemblies take the form of executable (.exe) or dynamic link library (.dll) files, and are the building blocks of .NET applications. They provide the common language runtime with the information it needs to be aware of type implementations.

In .NET and .NET Framework, you can build an assembly from one or more source code files. In .NET Framework, assemblies can contain one or more modules. This way, larger projects can be planned so that several developers can work on separate source code files or modules, which are combined to create a single assembly. For more information about modules, see [How to: Build a multifile assembly](#).

Assemblies have the following properties:

- Assemblies are implemented as .exe or .dll files.
- For libraries that target .NET Framework, you can share assemblies between applications by putting them in the [global assembly cache \(GAC\)](#). You must strong-name assemblies before you can include them in the GAC. For more information, see [Strong-named assemblies](#).
- Assemblies are only loaded into memory if they're required. If they aren't used, they aren't loaded. Therefore, assemblies can be an efficient way to manage resources in larger projects.
- You can programmatically obtain information about an assembly by using reflection. For more information, see [Reflection \(C#\)](#) or [Reflection \(Visual Basic\)](#).
- You can load an assembly just to inspect it by using the [MetadataLoadContext](#) class on .NET and .NET Framework. [MetadataLoadContext](#) replaces the [Assembly.ReflectionOnlyLoad](#) methods.

Assemblies in the common language runtime

Assemblies provide the common language runtime with the information it needs to be aware of type implementations. To the runtime, a type doesn't exist outside the context of an assembly.

An assembly defines the following information:

- **Code** that the common language runtime executes. Each assembly can have only one entry point: `DllMain`, `WinMain`, or `Main`.
- The **security boundary**. An assembly is the unit at which permissions are requested and granted. For more information about security boundaries in assemblies, see [Assembly security considerations](#).
- The **type boundary**. Every type's identity includes the name of the assembly in which it resides. A type called `MyType` that's loaded in the scope of one assembly isn't the same as a type called `MyType` that's loaded in the scope of another assembly.
- The **reference-scope boundary**: The [assembly manifest](#) has metadata that's used for resolving types and satisfying resource requests. The manifest specifies the types and resources to expose outside the assembly and enumerates other assemblies on which it depends. Microsoft intermediate language (MSIL) code in a portable executable (PE) file won't be executed unless it has an associated [assembly manifest](#).
- The **version boundary**. The assembly is the smallest versionable unit in the common language runtime.

All types and resources in the same assembly are versioned as a unit. The [assembly manifest](#) describes the version dependencies you specify for any dependent assemblies. For more information about versioning, see [Assembly versioning](#).

- The **deployment unit**: When an application starts, only the assemblies that the application initially calls must be present. Other assemblies, such as assemblies containing localization resources or utility classes, can be retrieved on demand. This process allows apps to be simple and thin when first downloaded. For more information about deploying assemblies, see [Deploy applications](#).
- A **side-by-side execution unit**: For more information about running multiple versions of an assembly, see [Assemblies and side-by-side execution](#).

Create an assembly

Assemblies can be static or dynamic. Static assemblies are stored on a disk in portable executable (PE) files. Static assemblies can include interfaces, classes, and resources like bitmaps, JPEG files, and other resource files. You can also create dynamic assemblies, which are run directly from memory and aren't saved to disk before execution. You can save dynamic assemblies to disk after they've been executed.

There are several ways to create assemblies. You can use development tools, such as Visual Studio that can create `.dll` or `.exe` files. You can use tools in the Windows SDK to create assemblies with modules from other development environments. You can also use common language runtime APIs, such as [System.Reflection.Emit](#), to create dynamic assemblies.

Compile assemblies by building them in Visual Studio, building them with .NET Core command-line interface tools, or building .NET Framework assemblies with a command-line compiler. For more information about building assemblies using .NET CLI, see [.NET CLI overview](#).

NOTE

To build an assembly in Visual Studio, on the **Build** menu, select **Build**.

Assembly manifest

Every assembly has an *assembly manifest* file. Similar to a table of contents, the assembly manifest contains:

- The assembly's identity (its name and version).
- A file table describing all the other files that make up the assembly, such as other assemblies you created that your `.exe` or `.dll` file relies on, bitmap files, or Readme files.
- An *assembly reference list*, which is a list of all external dependencies, such as `.dlls` or other files. Assembly references contain references to both global and private objects. Global objects are available to all other applications. In .NET Core, global objects are coupled with a particular .NET Core runtime. In .NET Framework, global objects reside in the global assembly cache (GAC). `System.IO.dll` is an example of an assembly in the GAC. Private objects must be in a directory level at or below the directory in which your app is installed.

Assemblies contain information about content, versioning, and dependencies. So the applications that use them don't need to rely on external sources, such as the registry on Windows systems, to function properly.

Assemblies reduce `.dll` conflicts and make your applications more reliable and easier to deploy. In many cases, you can install a .NET-based application simply by copying its files to the target computer. For more information, see [Assembly manifest](#).

Add a reference to an assembly

To use an assembly in an application, you must add a reference to it. When an assembly is referenced, all the accessible types, properties, methods, and other members of its namespaces are available to your application as if their code were part of your source file.

NOTE

Most assemblies from the .NET Class Library are referenced automatically. If a system assembly isn't automatically referenced, add a reference in one of the following ways:

- For .NET and .NET Core, add a reference to the NuGet package that contains the assembly. Either use the NuGet Package Manager in Visual Studio or add a `<PackageReference>` element for the assembly to the `.csproj` or `.vbproj` project.
- For .NET Framework, add a reference to the assembly by using the **Add Reference** dialog in Visual Studio or the `-reference` command line option for the [C#](#) or [Visual Basic](#) compilers.

In C#, you can use two versions of the same assembly in a single application. For more information, see [extern alias](#).

Metadata and Self-Describing Components

9/20/2022 • 8 minutes to read • [Edit Online](#)

In the past, a software component (.exe or .dll) that was written in one language could not easily use a software component that was written in another language. COM provided a step towards solving this problem. .NET makes component interoperability even easier by allowing compilers to emit additional declarative information into all modules and assemblies. This information, called metadata, helps components to interact seamlessly.

Metadata is binary information describing your program that is stored either in a common language runtime portable executable (PE) file or in memory. When you compile your code into a PE file, metadata is inserted into one portion of the file, and your code is converted to Microsoft intermediate language (MSIL) and inserted into another portion of the file. Every type and member that is defined and referenced in a module or assembly is described within metadata. When code is executed, the runtime loads metadata into memory and references it to discover information about your code's classes, members, inheritance, and so on.

Metadata describes every type and member defined in your code in a language-neutral manner. Metadata stores the following information:

- Description of the assembly.
 - Identity (name, version, culture, public key).
 - The types that are exported.
 - Other assemblies that this assembly depends on.
 - Security permissions needed to run.
- Description of types.
 - Name, visibility, base class, and interfaces implemented.
 - Members (methods, fields, properties, events, nested types).
- Attributes.
 - Additional descriptive elements that modify types and members.

Benefits of Metadata

Metadata is the key to a simpler programming model, and eliminates the need for Interface Definition Language (IDL) files, header files, or any external method of component reference. Metadata enables .NET languages to describe themselves automatically in a language-neutral manner, unseen by both the developer and the user. Additionally, metadata is extensible through the use of attributes. Metadata provides the following major benefits:

- Self-describing files.

Common language runtime modules and assemblies are self-describing. A module's metadata contains everything needed to interact with another module. Metadata automatically provides the functionality of IDL in COM, so you can use one file for both definition and implementation. Runtime modules and assemblies do not even require registration with the operating system. As a result, the descriptions used by the runtime always reflect the actual code in your compiled file, which increases application reliability.

- Language interoperability and easier component-based design.

Metadata provides all the information required about compiled code for you to inherit a class from a PE file written in a different language. You can create an instance of any class written in any managed language (any language that targets the common language runtime) without worrying about explicit marshalling or using custom interoperability code.

- Attributes.

.NET lets you declare specific kinds of metadata, called attributes, in your compiled file. Attributes can be found throughout .NET and are used to control in more detail how your program behaves at run time. Additionally, you can emit your own custom metadata into .NET files through user-defined custom attributes. For more information, see [Attributes](#).

Metadata and the PE File Structure

Metadata is stored in one section of a .NET portable executable (PE) file, while Microsoft intermediate language (MSIL) is stored in another section of the PE file. The metadata portion of the file contains a series of table and heap data structures. The MSIL portion contains MSIL and metadata tokens that reference the metadata portion of the PE file. You might encounter metadata tokens when you use tools such as the [MSIL Disassembler \(ildasm.exe\)](#) to view your code's MSIL, for example.

Metadata Tables and Heaps

Each metadata table holds information about the elements of your program. For example, one metadata table describes the classes in your code, another table describes the fields, and so on. If you have ten classes in your code, the class table will have tens rows, one for each class. Metadata tables reference other tables and heaps. For example, the metadata table for classes references the table for methods.

Metadata also stores information in four heap structures: string, blob, user string, and GUID. All the strings used to name types and members are stored in the string heap. For example, a method table does not directly store the name of a particular method, but points to the method's name stored in the string heap.

Metadata Tokens

Each row of each metadata table is uniquely identified in the MSIL portion of the PE file by a metadata token. Metadata tokens are conceptually similar to pointers, persisted in MSIL, that reference a particular metadata table.

A metadata token is a four-byte number. The top byte denotes the metadata table to which a particular token refers (method, type, and so on). The remaining three bytes specify the row in the metadata table that corresponds to the programming element being described. If you define a method in C# and compile it into a PE file, the following metadata token might exist in the MSIL portion of the PE file:

0x06000004

The top byte (0x06) indicates that this is a **MethodDef** token. The lower three bytes (000004) tells the common language runtime to look in the fourth row of the **MethodDef** table for the information that describes this method definition.

Metadata within a PE File

When a program is compiled for the common language runtime, it is converted to a PE file that consists of three parts. The following table describes the contents of each part.

PE SECTION	CONTENTS OF PE SECTION
------------	------------------------

PE SECTION	CONTENTS OF PE SECTION
PE header	The index of the PE file's main sections and the address of the entry point. The runtime uses this information to identify the file as a PE file and to determine where execution starts when loading the program into memory.
MSIL instructions	The Microsoft intermediate language instructions (MSIL) that make up your code. Many MSIL instructions are accompanied by metadata tokens.
Metadata	Metadata tables and heaps. The runtime uses this section to record information about every type and member in your code. This section also includes custom attributes and security information.

Run-Time Use of Metadata

To better understand metadata and its role in the common language runtime, it might be helpful to construct a simple program and illustrate how metadata affects its run-time life. The following code example shows two methods inside a class called `MyApp`. The `Main` method is the program entry point, while the `Add` method simply returns the sum of two integer arguments.

```
Public Class MyApp
    Public Shared Sub Main()
        Dim ValueOne As Integer = 10
        Dim ValueTwo As Integer = 20
        Console.WriteLine("The Value is: {0}", Add(ValueOne, ValueTwo))
    End Sub

    Public Shared Function Add(One As Integer, Two As Integer) As Integer
        Return (One + Two)
    End Function
End Class
```

```
using System;
public class MyApp
{
    public static int Main()
    {
        int ValueOne = 10;
        int ValueTwo = 20;
        Console.WriteLine("The Value is: {0}", Add(ValueOne, ValueTwo));
        return 0;
    }
    public static int Add(int One, int Two)
    {
        return (One + Two);
    }
}
```

When the code runs, the runtime loads the module into memory and consults the metadata for this class. Once loaded, the runtime performs extensive analysis of the method's Microsoft intermediate language (MSIL) stream to convert it to fast native machine instructions. The runtime uses a just-in-time (JIT) compiler to convert the MSIL instructions to native machine code one method at a time as needed.

The following example shows part of the MSIL produced from the previous code's `Main` function. You can view the MSIL and metadata from any .NET application using the [MSIL Disassembler \(Ildasm.exe\)](#).

```
.entrypoint
.maxstack 3
.locals ([0] int32 ValueOne,
          [1] int32 ValueTwo,
          [2] int32 V_2,
          [3] int32 V_3)
IL_0000: ldc.i4.s 10
IL_0002: stloc.0
IL_0003: ldc.i4.s 20
IL_0005: stloc.1
IL_0006: ldstr     "The Value is: {0}"
IL_000b: ldloc.0
IL_000c: ldloc.1
IL_000d: call int32 ConsoleApplication.MyApp::Add(int32,int32) /* 06000003 */
```

The JIT compiler reads the MSIL for the whole method, analyzes it thoroughly, and generates efficient native instructions for the method. At `IL_000d`, a metadata token for the `Add` method (`/* 06000003 */`) is encountered and the runtime uses the token to consult the third row of the **MethodDef** table.

The following table shows part of the **MethodDef** table referenced by the metadata token that describes the `Add` method. While other metadata tables exist in this assembly and have their own unique values, only this table is discussed.

ROW	RELATIVE VIRTUAL ADDRESS (RVA)	IMPLFLAGS	FLAGS	NAME (POINTS TO STRING HEAP.)	SIGNATURE (POINTS TO BLOB HEAP.)
1	0x00002050	IL Managed	Public ReuseSlot SpecialName RTSpecialName .ctor	.ctor (constructor)	
2	0x00002058	IL Managed	Public Static ReuseSlot	Main	String
3	0x0000208c	IL Managed	Public Static ReuseSlot	Add	int, int, int

Each column of the table contains important information about your code. The **RVA** column allows the runtime to calculate the starting memory address of the MSIL that defines this method. The **ImplFlags** and **Flags** columns contain bitmasks that describe the method (for example, whether the method is public or private). The **Name** column indexes the name of the method from the string heap. The **Signature** column indexes the definition of the method's signature in the blob heap.

The runtime calculates the desired offset address from the **RVA** column in the third row and returns this address

to the JIT compiler, which then proceeds to the new address. The JIT compiler continues to process MSIL at the new address until it encounters another metadata token and the process is repeated.

Using metadata, the runtime has access to all the information it needs to load your code and process it into native machine instructions. In this manner, metadata enables self-describing files and, together with the common type system, cross-language inheritance.

Dependency loading in .NET

9/20/2022 • 2 minutes to read • [Edit Online](#)

Every .NET application has dependencies. Even the simple `hello world` app has dependencies on portions of the .NET class libraries.

Understanding the default assembly loading logic in .NET can help you troubleshoot typical deployment issues.

In some applications, dependencies are dynamically determined at run time. In these situations, it's critical to understand how managed assemblies and unmanaged dependencies are loaded.

AssemblyLoadContext

The [AssemblyLoadContext](#) API is central to the .NET loading design. The [Understanding AssemblyLoadContext](#) article provides a conceptual overview of the design.

Loading details

The loading algorithm details are covered briefly in several articles:

- [Managed assembly loading algorithm](#)
- [Satellite assembly loading algorithm](#)
- [Unmanaged \(native\) library loading algorithm](#)
- [Default probing](#)

Create an app with plugins

The tutorial [Create a .NET application with plugins](#) describes how to create a custom AssemblyLoadContext. It uses an [AssemblyDependencyResolver](#) to resolve the dependencies of the plugin. The tutorial correctly isolates the plugin's dependencies from the hosting application.

Assembly unloadability

The [How to use and debug assembly unloadability in .NET](#) article is a step-by-step tutorial. It shows how to load a .NET application, execute it, and then unload it. The article also provides debugging tips.

Collect detailed assembly loading information

The [Collect detailed assembly loading information](#) article describes how to collect detailed information about managed assembly loading in the runtime. It uses the [dotnet-trace](#) tool to capture assembly loader events in a trace of a running process.

About System.Runtime.Loader.AssemblyLoadContext

9/20/2022 • 5 minutes to read • [Edit Online](#)

The [AssemblyLoadContext](#) class was introduced in .NET Core and is not available in .NET Framework. This article supplements the [AssemblyLoadContext](#) API documentation with conceptual information.

This article is relevant to developers implementing dynamic loading, especially dynamic-loading framework developers.

What is the AssemblyLoadContext?

Every .NET 5+ and .NET Core application implicitly uses [AssemblyLoadContext](#). It's the runtime's provider for locating and loading dependencies. Whenever a dependency is loaded, an [AssemblyLoadContext](#) instance is invoked to locate it.

- AssemblyLoadContext provides a service of locating, loading, and caching managed assemblies and other dependencies.
- To support dynamic code loading and unloading, it creates an isolated context for loading code and its dependencies in their own [AssemblyLoadContext](#) instance.

Versioning rules

A single [AssemblyLoadContext](#) instance is limited to loading exactly one version of an [Assembly](#) per [simple assembly name](#). When an assembly reference is resolved against an [AssemblyLoadContext](#) instance that already has an assembly of that name loaded, the requested version is compared to the loaded version. The resolution will succeed only if the loaded version is equal or higher to the requested version.

When do you need multiple AssemblyLoadContext instances?

The restriction that a single [AssemblyLoadContext](#) instance can load only one version of an assembly can become a problem when loading code modules dynamically. Each module is independently compiled, and the modules may depend on different versions of an [Assembly](#). This is often a problem when different modules depend on different versions of a commonly used library.

To support dynamically loading code, the [AssemblyLoadContext](#) API provides for loading conflicting versions of an [Assembly](#) in the same application. Each [AssemblyLoadContext](#) instance provides a unique dictionary that maps each [AssemblyName.Name](#) to a specific [Assembly](#) instance.

It also provides a convenient mechanism for grouping dependencies related to a code module for later unload.

The AssemblyLoadContext.Default instance

The [AssemblyLoadContext.Default](#) instance is automatically populated by the runtime at startup. It uses [default probing](#) to locate and find all static dependencies.

It solves the most common dependency loading scenarios.

Dynamic dependencies

[AssemblyLoadContext](#) has various events and virtual functions that can be overridden.

The `AssemblyLoadContext.Default` instance only supports overriding the events.

The articles [Managed assembly loading algorithm](#), [Satellite assembly loading algorithm](#), and [Unmanaged \(native\) library loading algorithm](#) refer to all the available events and virtual functions. The articles show each event and function's relative position in the loading algorithms. This article doesn't reproduce that information.

This section covers the general principles for the relevant events and functions.

- **Be repeatable.** A query for a specific dependency must always result in the same response. The same loaded dependency instance must be returned. This requirement is fundamental for cache consistency. For managed assemblies in particular, we're creating an `Assembly` cache. The cache key is a simple assembly name, `AssemblyName.Name`.
- **Typically don't throw.** It's expected that these functions return `null` rather than throw when unable to find the requested dependency. Throwing will prematurely end the search and propagate an exception to the caller. Throwing should be restricted to unexpected errors like a corrupted assembly or an out of memory condition.
- **Avoid recursion.** Be aware that these functions and handlers implement the loading rules for locating dependencies. Your implementation shouldn't call APIs that trigger recursion. Your code should typically call `AssemblyLoadContext` load functions that require a specific path or memory reference argument.
- **Load into the correct `AssemblyLoadContext`.** The choice of where to load dependencies is application-specific. The choice is implemented by these events and functions. When your code calls `AssemblyLoadContext` load-by-path functions call them on the instance where you want the code loaded. Sometime returning `null` and letting the `AssemblyLoadContext.Default` handle the load may be the simplest option.
- **Be aware of thread races.** Loading can be triggered by multiple threads. The `AssemblyLoadContext` handles thread races by atomically adding assemblies to its cache. The race loser's instance is discarded. In your implementation logic, don't add extra logic that doesn't handle multiple threads properly.

How are dynamic dependencies isolated?

Each `AssemblyLoadContext` instance represents a unique scope for `Assembly` instances and `Type` definitions.

There's no binary isolation between these dependencies. They're only isolated by not finding each other by name.

In each `AssemblyLoadContext`:

- `AssemblyName.Name` may refer to a different `Assembly` instance.
- `Type.GetType` may return a different type instance for the same type `name`.

Shared dependencies

Dependencies can easily be shared between `AssemblyLoadContext` instances. The general model is for one `AssemblyLoadContext` to load a dependency. The other shares the dependency by using a reference to the loaded assembly.

This sharing is required of the runtime assemblies. These assemblies can only be loaded into the `AssemblyLoadContext.Default`. The same is required for frameworks like `ASP.NET`, `WPF`, or `WinForms`.

It's recommended that shared dependencies be loaded into `AssemblyLoadContext.Default`. This sharing is the common design pattern.

Sharing is implemented in the coding of the custom `AssemblyLoadContext` instance. `AssemblyLoadContext` has various events and virtual functions that can be overridden. When any of these functions return a reference to an `Assembly` instance that was loaded in another `AssemblyLoadContext` instance, the `Assembly` instance is

shared. The standard load algorithm defers to [AssemblyLoadContext.Default](#) for loading to simplify the common sharing pattern. For more information, see [Managed assembly loading algorithm](#).

Type-conversion issues

When two [AssemblyLoadContext](#) instances contain type definitions with the same `name`, they're not the same type. They're the same type if and only if they come from the same [Assembly](#) instance.

To complicate matters, exception messages about these mismatched types can be confusing. The types are referred to in the exception messages by their simple type names. The common exception message in this case is of the form:

```
Object of type 'IsolatedType' cannot be converted to type 'IsolatedType'.
```

Debug type-conversion issues

Given a pair of mismatched types, it's important to also know:

- Each type's [Type.Assembly](#).
- Each type's [AssemblyLoadContext](#), which can be obtained via the [AssemblyLoadContext.GetLoadContext\(Assembly\)](#) function.

Given two objects `a` and `b`, evaluating the following in the debugger will be helpful:

```
// In debugger look at each assembly's instance, Location, and FullName  
a.GetType().Assembly  
b.GetType().Assembly  
// In debugger look at each AssemblyLoadContext's instance and name  
System.Runtime.Loader.AssemblyLoadContext.GetLoadContext(a.GetType().Assembly)  
System.Runtime.Loader.AssemblyLoadContext.GetLoadContext(b.GetType().Assembly)
```

Resolve type-conversion issues

There are two design patterns for solving these type conversion issues.

1. Use common shared types. This shared type can either be a primitive runtime type, or it can involve creating a new shared type in a shared assembly. Often the shared type is an [interface](#) defined in an application assembly. For more information, read about [how dependencies are shared](#).
2. Use marshalling techniques to convert from one type to another.

Default probing

9/20/2022 • 3 minutes to read • [Edit Online](#)

The [AssemblyLoadContext.Default](#) instance is responsible for locating an assembly's dependencies. This article describes the [AssemblyLoadContext.Default](#) instance's probing logic.

Host configured probing properties

When the runtime is started, the runtime host provides a set of named probing properties that configure [AssemblyLoadContext.Default](#) probe paths.

Each probing property is optional. If present, each property is a string value that contains a delimited list of absolute paths. The delimiter is ';' on Windows and ':' on all other platforms.

PROPERTY NAME	DESCRIPTION
TRUSTED_PLATFORM_ASSEMBLIES	List of platform and application assembly file paths.
PLATFORM_RESOURCE_ROOTS	List of directory paths to search for satellite resource assemblies.
NATIVE_DLL_SEARCH_DIRECTORIES	List of directory paths to search for unmanaged (native) libraries.
APP_PATHS	List of directory paths to search for managed assemblies.

How are the properties populated?

There are two main scenarios for populating the properties depending on whether the `<myapp>.deps.json` file exists.

- When the `*.deps.json` file is present, it's parsed to populate the probing properties.
- When the `*.deps.json` file isn't present, the application's directory is assumed to contain all the dependencies. The directory's contents are used to populate the probing properties.

Additionally, the `*.deps.json` files for any referenced frameworks are similarly parsed.

The environment variable `DOTNET_ADDITIONAL_DEPS` can be used to add additional dependencies. `dotnet.exe` also contains an optional `--additional-deps` parameter to set this value on application startup.

The `APP_PATHS` property is not populated by default and is omitted for most applications.

The list of all `*.deps.json` files used by the application can be accessed via

```
System.AppContext.GetData("APP_CONTEXT_DEPS_FILES") .
```

How do I see the probing properties from managed code?

Each property is available by calling the [AppContext.GetData\(String\)](#) function with the property name from the table above.

How do I debug the probing properties' construction?

The .NET Core runtime host will output useful trace messages when certain environment variables are enabled:

ENVIRONMENT VARIABLE	DESCRIPTION
COREHOST_TRACE=1	Enables tracing.
COREHOST_TRACEFILE=<path>	Traces to a file path instead of the default <code>stderr</code> .
COREHOST_TRACE_VERBOSITY	Sets the verbosity from 1 (lowest) to 4 (highest).

Managed assembly default probing

When probing to locate a managed assembly, the [AssemblyLoadContext.Default](#) looks in order at:

- Files matching the [AssemblyName.Name](#) in `TRUSTED_PLATFORM_ASSEMBLIES` (after removing file extensions).
- Assembly files in `APP_PATHS` with common file extensions.

Satellite (resource) assembly probing

To find a satellite assembly for a specific culture, construct a set of file paths.

For each path in `PLATFORM_RESOURCE_ROOTS` and then `APP_PATHS`, append the [CultureInfo.Name](#) string, a directory separator, the [AssemblyName.Name](#) string, and the extension '.dll'.

If any matching file exists, attempt to load and return it.

Unmanaged (native) library probing

The runtime's unmanaged library probing algorithm is identical on all platforms. However, since the actual load of the unmanaged library is performed by the underlying platform, the observed behavior can be slightly different. For more information, see the guidance on how to author [cross-platform P/Invokes](#).

1. Check if the supplied library name represents an absolute or relative path.
2. If the name represents an absolute path, use the name directly for all subsequent operations. Otherwise, use the name and create platform-defined combinations to consider. Combinations consist of platform specific prefixes (for example, `lib`) and/or suffixes (for example, `.dll`, `.dylib`, and `.so`). This is not an exhaustive list, and it doesn't represent the exact effort made on each platform. It's just an example of what is considered.
3. The name and, if the path is relative, each combination, is then used in the following steps. The first successful load attempt immediately returns the handle to the loaded library.
 - Append it to each path supplied in the `NATIVE_DLL_SEARCH_DIRECTORIES` property and attempt to load.
 - If `DllImportSearchPath.AssemblyDirectory` is defined on the calling assembly, use it directly and attempt to load relative to the calling assembly.
 - Use it directly to load the library.
4. Indicate that the library failed to load.

Managed assembly loading algorithm

9/20/2022 • 2 minutes to read • [Edit Online](#)

Managed assemblies are located and loaded with an algorithm that has various stages.

All managed assemblies except satellite assemblies and `WinRT` assemblies use the same algorithm.

When are managed assemblies loaded?

The most common mechanism to trigger a managed assembly load is a static assembly reference. These references are inserted by the compiler whenever code uses a type defined in another assembly. These assemblies are loaded (`load-by-name`) as needed by the runtime. The exact timing of when the static assembly references are loaded is unspecified. It can vary between runtime versions and is influenced by optimizations like inlining.

The direct use of the following APIs will also trigger loads:

API	DESCRIPTION	ACTIVE ASSEMBLYLOADCONTEXT
<code>AssemblyLoadContext.LoadFromAssemblyName</code>	<code>Load-by-name</code>	The <code>this</code> instance.
<code>AssemblyLoadContext.LoadFromAssemblyPath</code> <code>AssemblyLoadContext.LoadFromNativeImagePath</code>	Load from path.	The <code>this</code> instance.
<code>AssemblyLoadContext.LoadFromStream</code>	Load from object.	The <code>this</code> instance.
<code>Assembly.LoadFile</code>	Load from path in a new <code>AssemblyLoadContext</code> instance	The new <code>AssemblyLoadContext</code> instance.
<code>Assembly.LoadFrom</code>	Load from path in the <code>AssemblyLoadContext.Default</code> instance. Adds an <code>AppDomain.AssemblyResolve</code> handler. The handler will load the assembly's dependencies from its directory.	The <code>AssemblyLoadContext.Default</code> instance.
<code>Assembly.Load(AssemblyName)</code> <code>Assembly.Load(String)</code> <code>Assembly.LoadWithPartialName</code>	<code>Load-by-name</code> .	Inferred from caller. Prefer <code>AssemblyLoadContext</code> methods.
<code>Assembly.Load(Byte[])</code> <code>Assembly.Load(Byte[], Byte[])</code>	Load from object in a new <code>AssemblyLoadContext</code> instance.	The new <code>AssemblyLoadContext</code> instance.

API	DESCRIPTION	ACTIVE ASSEMBLYLOADCONTEXT
Type.GetType(String) Type.GetType(String, Boolean) Type.GetType(String, Boolean, Boolean)	Load-by-name .	Inferred from caller. Prefer Type.GetType methods with an <code>assemblyResolver</code> argument.
Assembly.GetType	If type <code>name</code> describes an assembly qualified generic type, trigger a Load-by-name .	Inferred from caller. Prefer Type.GetType when using assembly qualified type names.
Activator.CreateInstance(String, String) Activator.CreateInstance(String, String, Object[]) Activator.CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Load-by-name .	Inferred from caller. Prefer Activator.CreateInstance methods taking a <code>Type</code> argument.

Algorithm

The following algorithm describes how the runtime loads a managed assembly.

1. Determine the `active AssemblyLoadContext`.
 - For a static assembly reference, the `active AssemblyLoadContext` is the instance that loaded the referring assembly.
 - Preferred APIs make the `active AssemblyLoadContext` explicit.
 - Other APIs infer the `active AssemblyLoadContext`. For these APIs, the `AssemblyLoadContext.CurrentContextualReflectionContext` property is used. If its value is `null`, then the inferred `AssemblyLoadContext` instance is used.
 - See the table in the [When are managed assemblies loaded?](#) section.
2. For the `Load-by-name` methods, the `active AssemblyLoadContext` loads the assembly in the following priority order:
 - Check its `cache-by-name` .
 - Call the `AssemblyLoadContext.Load` function.
 - Check the `AssemblyLoadContext.Default` instance's cache and run [managed assembly default probing](#) logic. If an assembly is newly loaded, a reference is added to the `AssemblyLoadContext.Default` instance's `cache-by-name` .
 - Raise the `AssemblyLoadContext.Resolving` event for the active `AssemblyLoadContext`.
 - Raise the `AppDomain.AssemblyResolve` event.
3. For the other types of loads, the `active AssemblyLoadContext` loads the assembly in the following priority order:
 - Check its `cache-by-name` .
 - Load from the specified path or raw assembly object. If an assembly is newly loaded, a reference is added to the `active AssemblyLoadContext` instance's `cache-by-name` .
4. In either case, if an assembly is newly loaded, then the `AppDomain.AssemblyLoad` event is raised.

Satellite assembly loading algorithm

9/20/2022 • 2 minutes to read • [Edit Online](#)

Satellite assemblies are used to store localized resources customized for language and culture.

Satellite assemblies use a different loading algorithm than general managed assemblies.

When are satellite assemblies loaded?

Satellite assemblies are loaded when loading a localized resource.

The basic API to load localized resources is the [System.Resources.ResourceManager](#) class. Ultimately the [ResourceManager](#) class will call the [GetSatelliteAssembly](#) method for each [CultureInfo.Name](#).

Higher-level APIs may abstract the low-level API.

Algorithm

The .NET Core resource fallback process involves the following steps:

1. Determine the `active AssemblyLoadContext` instance. In all cases, the `active` instance is the executing assembly's [AssemblyLoadContext](#).
2. The `active` instance attempts to load a satellite assembly for the requested culture in priority order by:
 - Checking its cache.
 - Checking the directory of the currently executing assembly for a subdirectory that matches the requested [CultureInfo.Name](#) (for example `es-MX`).

NOTE

This feature was not implemented in .NET Core before 3.0.

NOTE

On Linux and macOS, the subdirectory is case-sensitive and must either:

- Exactly match case.
- Be in lower case.

- If `active` is the [AssemblyLoadContext.Default](#) instance, by running the [default satellite \(resource\) assembly probing](#) logic.
- Calling the [AssemblyLoadContext.Load](#) function.
- Raising the [AssemblyLoadContext.Resolving](#) event.
- Raising the [AppDomain.AssemblyResolve](#) event.

3. If a satellite assembly is loaded:
 - The [AppDomain.AssemblyLoad](#) event is raised.
 - The assembly is searched for the requested resource. If the runtime finds the resource in the assembly,

it uses it. If it doesn't find the resource, it continues the search.

NOTE

To find a resource within the satellite assembly, the runtime searches for the resource file requested by the [ResourceManager](#) for the current [CultureInfo.Name](#). Within the resource file, it searches for the requested resource name. If either is not found, the resource is treated as not found.

4. The runtime next searches the parent culture assemblies through many potential levels, each time repeating steps 2 & 3.

Each culture has only one parent, which is defined by the [CultureInfo.Parent](#) property.

The search for parent cultures stops when a culture's [Parent](#) property is [CultureInfo.InvariantCulture](#).

For the [InvariantCulture](#), we don't return to steps 2 & 3, but rather continue with step 5.

5. If the resource is still not found, the resource for the default (fallback) culture is used.

Typically, the resources for the default culture are included in the main application assembly. However, you can specify [UltimateResourceFallbackLocation.Satellite](#) for the [NeutralResourcesLanguageAttribute.Location](#) property. This value indicates that the ultimate fallback location for resources is a satellite assembly rather than the main assembly.

NOTE

The default culture is the ultimate fallback. Therefore, we recommend that you always include an exhaustive set of resources in the default resource file. This helps prevent exceptions from being thrown. By having an exhaustive set, you provide a fallback for all resources and ensure that at least one resource is always present for the user, even if it is not culturally specific.

6. Finally,

- If the runtime doesn't find a resource file for a default (fallback) culture, a [MissingManifestResourceException](#) or [MissingSatelliteAssemblyException](#) exception is thrown.
- If the resource file is found but the requested resource isn't present, the request returns `null`.

Unmanaged (native) library loading algorithm

9/20/2022 • 2 minutes to read • [Edit Online](#)

Unmanaged libraries are located and loaded with an algorithm involving various stages.

The following algorithm describes how native libraries are loaded through `PInvoke`.

`PInvoke` load library algorithm

`PInvoke` uses the following algorithm when attempting to load an unmanaged assembly:

1. Determine the `active AssemblyLoadContext`. For an unmanaged load library, the `active AssemblyLoadContext` is the one with the assembly that defines the `PInvoke`.
2. For the `active AssemblyLoadContext`, try to find the assembly in priority order by:
 - Checking its cache.
 - Calling the current `System.Runtime.InteropServices.DllImportResolver` delegate set by the `NativeLibrary.SetDllImportResolver(Assembly, DllImportResolver)` function.
 - Calling the `AssemblyLoadContext.LoadUnmanagedDll` function on the `active AssemblyLoadContext`.
 - Checking the `AppDomain` instance's cache and running the `Unmanaged (native) library probing` logic.
 - Raising the `AssemblyLoadContext.ResolvingUnmanagedDll` event for the `active AssemblyLoadContext`.

Collect detailed assembly loading information

9/20/2022 • 5 minutes to read • [Edit Online](#)

Starting with .NET 5, the runtime can emit events through `EventPipe` with detailed information about [managed assembly loading](#) to aid in diagnosing assembly loading issues. These [events](#) are emitted by the `Microsoft-Windows-DotNETRuntime` provider under the `AssemblyLoader` keyword (`0x4`).

Prerequisites

- [.NET 5 SDK](#) or later versions
- `dotnet-trace` tool

NOTE

The scope of `dotnet-trace` capabilities is greater than collecting detailed assembly loading information. For more information on the usage of `dotnet-trace`, see [dotnet-trace](#).

Collect a trace with assembly loading events

You can use `dotnet-trace` to trace an existing process or to launch a child process and trace it from startup.

Trace an existing process

To enable assembly loading events in the runtime and collect a trace of them, use `dotnet-trace` with the following command:

```
dotnet-trace collect --providers Microsoft-Windows-DotNETRuntime:4 --process-id <pid>
```

This command collects a trace of the specified `<pid>`, enabling the `AssemblyLoader` events in the `Microsoft-Windows-DotNETRuntime` provider. The result is a `.nettrace` file.

Use dotnet-trace to launch a child process and trace it from startup

Sometimes it may be useful to collect a trace of a process from its startup. For apps running .NET 5 or later, you can use `dotnet-trace` to do this.

The following command launches `hello.exe` with `arg1` and `arg2` as its command line arguments and collects a trace from its runtime startup:

```
dotnet-trace collect --providers Microsoft-Windows-DotNETRuntime:4 -- hello.exe arg1 arg2
```

You can stop collecting the trace by pressing Enter or `Ctrl + C`. This also closes `hello.exe`.

NOTE

- Launching `hello.exe` via `dotnet-trace` redirects its input and output, and you won't be able to interact with it on the console by default. Use the `--show-child-io` switch to interact with its `stdin` and `stdout`.
- Exiting the tool via `Ctrl+C` or `SIGTERM` safely ends both the tool and the child process.
- If the child process exits before the tool, the tool exits as well and the trace should be safely viewable.

View a trace

The collected trace file can be viewed on Windows using the Events view in [PerfView](#). All the assembly loading events will be prefixed with `Microsoft-Windows-DotNETRuntime/AssemblyLoader`.

Example (on Windows)

This example uses the [assembly loading extension points sample](#). The application attempts to load an assembly `MyLibrary` - an assembly that is not referenced by the application and thus requires handling in an assembly loading extension point to be successfully loaded.

Collect the trace

1. Navigate to the directory with the downloaded sample. Build the application with:

```
dotnet build
```

2. Launch the application with arguments indicating that it should pause, waiting for a key press. On resuming, it will attempt to load the assembly in the default `AssemblyLoadContext` - without the handling necessary for a successful load. Navigate to the output directory and run:

```
AssemblyLoading.exe /d default
```

3. Find the application's process ID.

```
dotnet-trace ps
```

The output will list the available processes. For example:

```
35832 AssemblyLoading C:\src\AssemblyLoading\bin\Debug\net5.0\AssemblyLoading.exe
```

4. Attach `dotnet-trace` to the running application.

```
dotnet-trace collect --providers Microsoft-Windows-DotNETRuntime:4 --process-id 35832
```

5. In the window running the application, press any key to let the program continue. Tracing will automatically stop once the application exits.

View the trace

Open the collected trace in [PerfView](#) and open the Events view. Filter the events list to `Microsoft-Windows-DotNETRuntime/AssemblyLoader` events.

Event Types	Filter: AssemblyLoader
Microsoft-Windows-DotNETRuntime/AssemblyLoader/AppDomainAssemblyResolveHandlerInvoked	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/AssemblyLoadContextResolvingHandlerInvoked	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/KnownPathProbed	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Start	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Stop	

All assembly loads that occurred in the application after tracing started will be shown. To inspect the load operation for the assembly of interest for this example - `MyLibrary`, we can do some more filtering.

Assembly loads

Filter the view to the `Start` and `Stop` events under `Microsoft-Windows-DotNETRuntime/AssemblyLoader` using the event list on the left. Add the columns `AssemblyName`, `ActivityID`, and `Success` to the view. Filter to events containing `MyLibrary`.

Text Filter:	MyLibrary	Columns To Display:	Cols	AssemblyName	ActivityID	Success *
Histogram:						
Event Name		AssemblyName		ActivityID	Success	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Start		MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/			
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Stop		MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/		False	

EVENT NAME	ASSEMBLYNAME	ACTIVITYID	SUCCESS
AssemblyLoader/Start	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/	
AssemblyLoader/Stop	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/	False

You should see one `Start` / `Stop` pair with `Success=False` on the `Stop` event, indicating the load operation failed. Note that the two events have the same activity ID. The activity ID can be used to filter all the other assembly loader events to just the ones corresponding to this load operation.

Breakdown of attempt to load

For a more detailed breakdown of the load operation, filter the view to the `ResolutionAttempted` events under `Microsoft-Windows-DotNETRuntime/AssemblyLoader` using the event list on the left. Add the columns `AssemblyName`, `Stage`, and `Result` to the view. Filter to events with the activity ID from the `Start` / `Stop` pair.

Text Filter:	//1/2/	Columns To Display:	Cols	AssemblyName Stage Result *
Histogram:				
Event Name		AssemblyName	Stage	Result
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted		MyLibrary, Culture=neutral, PublicKeyToken=null	FindInLoadContext	AssemblyNotFound
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted		MyLibrary, Culture=neutral, PublicKeyToken=null	ApplicationAssemblies	AssemblyNotFound
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted		MyLibrary, Culture=neutral, PublicKeyToken=null	AssemblyLoadContextResolvingEvent	AssemblyNotFound
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted		MyLibrary, Culture=neutral, PublicKeyToken=null	AppDomainAssemblyResolveEvent	AssemblyNotFound

EVENT NAME	ASSEMBLYNAME	STAGE	RESULT
AssemblyLoader/ResolutionAtt	MyLibrary, Culture=neutral, PublicKeyToken=null	FindInLoadContext	AssemblyNotFound
AssemblyLoader/ResolutionAtt	MyLibrary, Culture=neutral, PublicKeyToken=null	ApplicationAssemblies	AssemblyNotFound
AssemblyLoader/ResolutionAtt	MyLibrary, Culture=neutral, PublicKeyToken=null	AssemblyLoadContextResolving	AssemblyNotFound
AssemblyLoader/ResolutionAtt	MyLibrary, Culture=neutral, PublicKeyToken=null	AppDomainAssemblyResolveEver	AssemblyNotFound

The events above indicate that the assembly loader attempted to resolve the assembly by looking in the current load context, running the default probing logic for managed application assemblies, invoking handlers for the `AssemblyLoadContext.Resolving` event, and invoking handlers for the `AppDomain.AssemblyResolve`. For all of these steps, the assembly was not found.

Extension points

To see which extension points were invoked, filter the view to the `AssemblyLoadContextResolvingHandlerInvoked` and `AppDomainAssemblyResolveHandlerInvoked` under `Microsoft-Windows-DotNETRuntime/AssemblyLoader` using the event list on the left. Add the columns `AssemblyName` and `HandlerName` to the view. Filter to events with the activity ID from the `Start / Stop` pair.

Event Name	AssemblyName	HandlerName
Microsoft-Windows-DotNETRuntime/AssemblyLoader/AssemblyLoadContextResolvingHandlerInvoked	MyLibrary, Culture=neutral, PublicKeyToken=null	OnAssemblyLoadContextResolving
Microsoft-Windows-DotNETRuntime/AssemblyLoader/AppDomainAssemblyResolveHandlerInvoked	MyLibrary, Culture=neutral, PublicKeyToken=null	OnAppDomainAssemblyResolve
Event Name	AssemblyName	HandlerName
AssemblyLoader/AssemblyLoadContextResolvingHandlerInvoked	MyLibrary, Culture=neutral, PublicKeyToken=null	OnAssemblyLoadContextResolving
AssemblyLoader/AppDomainAssemblyResolveHandlerInvoked	MyLibrary, Culture=neutral, PublicKeyToken=null	OnAppDomainAssemblyResolve

The events above indicate that a handler named `OnAssemblyLoadContextResolving` was invoked for the `AssemblyLoadContext.Resolving` event and a handler named `OnAppDomainAssemblyResolve` was invoked for the `AppDomain.AssemblyResolve` event.

Collect another trace

Run the application with arguments such that its handler for the `AssemblyLoadContext.Resolving` event will load the `MyLibrary` assembly.

```
AssemblyLoading /d default alc-resolving
```

Collect and open another `.nettrace` file using the [steps from above](#).

Filter to the `Start` and `Stop` events for `MyLibrary` again. You should see a `Start / Stop` pair with another `Start / Stop` between them. The inner load operation represents the load triggered by the handler for `AssemblyLoadContext.Resolving` when it called `AssemblyLoadContext.LoadFromAssemblyPath`. This time, you should see `Success=True` on the `Stop` event, indicating the load operation succeeded. The `ResultAssemblyPath` field shows the path of the resulting assembly.

Event Name	AssemblyName	ActivityID	Success	ResultAssemblyPath
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Start	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/		
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Start	MyLibrary, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null	//1/2/1		
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Stop	MyLibrary, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null	//1/2/1	True	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll
Microsoft-Windows-DotNETRuntime/AssemblyLoader/Stop	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/	True	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll
Event Name	AssemblyName	ActivityID	Success	ResultAssemblyPath
AssemblyLoader/Start	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/		
AssemblyLoader/Start	MyLibrary, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null	//1/2/1		

EVENT NAME	ASSEMBLYNAME	ACTIVITYID	SUCCESS	RESULTASSEMBLYPATH
AssemblyLoader/Stop	MyLibrary, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null	//1/2/1/	True	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll
AssemblyLoader/Stop	MyLibrary, Culture=neutral, PublicKeyToken=null	//1/2/	True	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll

We can then look at the `ResolutionAttempted` events with the activity ID from the outer load to determine the step at which the assembly was successfully resolved. This time, the events will show that the `AssemblyLoadContextResolvingEvent` stage was successful. The `ResultAssemblyPath` field shows the path of the resulting assembly.

Event Name	AssemblyName	Stage	Result	ResultAssemblyPath
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted	MyLibrary, Culture=neutral	FindInLoadContext	AssemblyNotFound	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted	MyLibrary, Culture=neutral	ApplicationAssemblies	AssemblyNotFound	
Microsoft-Windows-DotNETRuntime/AssemblyLoader/ResolutionAttempted	MyLibrary, Culture=neutral	AssemblyLoadContextResolvingEvent	Success	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll

EVENT NAME	ASSEMBLYNAME	STAGE	RESULT	RESULTASSEMBLYPATH
AssemblyLoader/ResolveHandler	MyLibrary, Culture=neutral, PublicKeyToken=null	FindInLoadContext	AssemblyNotFound	
AssemblyLoader/ResolveHandler	MyLibrary, Culture=neutral, PublicKeyToken=null	ApplicationAssemblies	AssemblyNotFound	
AssemblyLoader/ResolveHandler	MyLibrary, Culture=neutral, PublicKeyToken=null	AssemblyLoadContextResolvingEvent	Success	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll

Looking at `AssemblyLoadContextResolvingHandlerInvoked` events will show that the handler named `OnAssemblyLoadContextResolving` was invoked. The `ResultAssemblyPath` field shows the path of the assembly returned by the handler.

Event Name	AssemblyName	HandlerName	ResultAssemblyPath
Microsoft-Windows-DotNETRuntime/AssemblyLoader/AssemblyLoadContextResolvingHandlerInvoked	MyLibrary, Culture=neutral	OnAssemblyLoadContextResolving	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll

EVENT NAME	ASSEMBLYNAME	HANDLERNAME	RESULTASSEMBLYPATH
AssemblyLoader/AssemblyLoadContextResolvingHandlerInvoked	MyLibrary, Culture=neutral, PublicKeyToken=null	OnAssemblyLoadContextResolving	C:\src\AssemblyLoading\bin\Debug\net5.0\MyLibrary.dll

Note that there is no longer a `ResolutionAttempted` event with the `AppDomainAssemblyResolveEvent` stage or any `AppDomainAssemblyResolveHandlerInvoked` events, as the assembly was successfully loaded before reaching the step of the loading algorithm that raises the `AppDomain.AssemblyResolve` event.

Create a .NET Core application with plugins

9/20/2022 • 8 minutes to read • [Edit Online](#)

This tutorial shows you how to create a custom [AssemblyLoadContext](#) to load plugins. An [AssemblyDependencyResolver](#) is used to resolve the dependencies of the plugin. The tutorial correctly isolates the plugin's dependencies from the hosting application. You'll learn how to:

- Structure a project to support plugins.
- Create a custom [AssemblyLoadContext](#) to load each plugin.
- Use the [System.Runtime.Loader.AssemblyDependencyResolver](#) type to allow plugins to have dependencies.
- Author plugins that can be easily deployed by just copying the build artifacts.

Prerequisites

- Install the [.NET 5 SDK](#) or a newer version.

NOTE

The sample code targets .NET 5, but all the features it uses were introduced in .NET Core 3.0 and are available in all .NET releases since then.

Create the application

The first step is to create the application:

1. Create a new folder, and in that folder run the following command:

```
dotnet new console -o AppWithPlugin
```

2. To make building the project easier, create a Visual Studio solution file in the same folder. Run the following command:

```
dotnet new sln
```

3. Run the following command to add the app project to the solution:

```
dotnet sln add AppWithPlugin/AppWithPlugin.csproj
```

Now we can fill in the skeleton of our application. Replace the code in the *AppWithPlugin/Program.cs* file with the following code:

```

using PluginBase;
using System;
using System.Collections.Generic;
using System.IO;
using System.Linq;
using System.Reflection;

namespace AppWithPlugin
{
    class Program
    {
        static void Main(string[] args)
        {
            try
            {
                if (args.Length == 1 && args[0] == "/d")
                {
                    Console.WriteLine("Waiting for any key...");
                    Console.ReadLine();
                }

                // Load commands from plugins.

                if (args.Length == 0)
                {
                    Console.WriteLine("Commands: ");
                    // Output the loaded commands.
                }
                else
                {
                    foreach (string commandName in args)
                    {
                        Console.WriteLine($"-- {commandName} --");

                        // Execute the command with the name passed as an argument.

                        Console.WriteLine();
                    }
                }
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex);
            }
        }
    }
}

```

Create the plugin interfaces

The next step in building an app with plugins is defining the interface the plugins need to implement. We suggest that you make a class library that contains any types that you plan to use for communicating between your app and plugins. This division allows you to publish your plugin interface as a package without having to ship your full application.

In the root folder of the project, run `dotnet new classlib -o PluginBase`. Also, run `dotnet sln add PluginBase/PluginBase.csproj` to add the project to the solution file. Delete the `PluginBase/Class1.cs` file, and create a new file in the `PluginBase` folder named `ICommand.cs` with the following interface definition:

```

namespace PluginBase
{
    public interface ICommand
    {
        string Name { get; }
        string Description { get; }

        int Execute();
    }
}

```

This `ICommand` interface is the interface that all of the plugins will implement.

Now that the `ICommand` interface is defined, the application project can be filled in a little more. Add a reference from the `AppWithPlugin` project to the `PluginBase` project with the

```
dotnet add AppWithPlugin/AppWithPlugin.csproj reference PluginBase/PluginBase.csproj
```

command from the root folder.

Replace the `// Load commands from plugins` comment with the following code snippet to enable it to load plugins from given file paths:

```

string[] pluginPaths = new string[]
{
    // Paths to plugins to load.
};

IEnumerable<ICommand> commands = pluginPaths.SelectMany(pluginPath =>
{
    Assembly pluginAssembly = LoadPlugin(pluginPath);
    return CreateCommands(pluginAssembly);
}).ToList();

```

Then replace the `// Output the loaded commands` comment with the following code snippet:

```

foreach (ICommand command in commands)
{
    Console.WriteLine($"{command.Name}\t - {command.Description}");
}

```

Replace the `// Execute the command with the name passed as an argument` comment with the following snippet:

```

ICommand command = commands.FirstOrDefault(c => c.Name == commandName);
if (command == null)
{
    Console.WriteLine("No such command is known.");
    return;
}

command.Execute();

```

And finally, add static methods to the `Program` class named `LoadPlugin` and `CreateCommands`, as shown here:

```

static Assembly LoadPlugin(string relativePath)
{
    throw new NotImplementedException();
}

static IEnumerable< ICommand> CreateCommands(Assembly assembly)
{
    int count = 0;

    foreach (Type type in assembly.GetTypes())
    {
        if (typeof(ICommand).IsAssignableFrom(type))
        {
            ICommand result = Activator.CreateInstance(type) as ICommand;
            if (result != null)
            {
                count++;
                yield return result;
            }
        }
    }

    if (count == 0)
    {
        string availableTypes = string.Join(", ", assembly.GetTypes().Select(t => t.FullName));
        throw new ApplicationException(
            $"Can't find any type which implements ICommand in {assembly} from {assembly.Location}.\\n" +
            $"Available types: {availableTypes}");
    }
}

```

Load plugins

Now the application can correctly load and instantiate commands from loaded plugin assemblies, but it's still unable to load the plugin assemblies. Create a file named *PluginLoadContext.cs* in the *AppWithPlugin* folder with the following contents:

```

using System;
using System.Reflection;
using System.Runtime.Loader;

namespace AppWithPlugin
{
    class PluginLoadContext : AssemblyLoadContext
    {
        private AssemblyDependencyResolver _resolver;

        public PluginLoadContext(string pluginPath)
        {
            _resolver = new AssemblyDependencyResolver(pluginPath);
        }

        protected override Assembly Load(AssemblyName assemblyName)
        {
            string assemblyPath = _resolver.ResolveAssemblyToPath(assemblyName);
            if (assemblyPath != null)
            {
                return LoadFromAssemblyPath(assemblyPath);
            }

            return null;
        }

        protected override IntPtr LoadUnmanagedDll(string unmanagedDllName)
        {
            string libraryPath = _resolver.ResolveUnmanagedDllToPath(unmanagedDllName);
            if (libraryPath != null)
            {
                return LoadUnmanagedDllFromPath(libraryPath);
            }

            return IntPtr.Zero;
        }
    }
}

```

The `PluginLoadContext` type derives from `AssemblyLoadContext`. The `AssemblyLoadContext` type is a special type in the runtime that allows developers to isolate loaded assemblies into different groups to ensure that assembly versions don't conflict. Additionally, a custom `AssemblyLoadContext` can choose different paths to load assemblies from and override the default behavior. The `PluginLoadContext` uses an instance of the `AssemblyDependencyResolver` type introduced in .NET Core 3.0 to resolve assembly names to paths. The `AssemblyDependencyResolver` object is constructed with the path to a .NET class library. It resolves assemblies and native libraries to their relative paths based on the `.deps.json` file for the class library whose path was passed to the `AssemblyDependencyResolver` constructor. The custom `AssemblyLoadContext` enables plugins to have their own dependencies, and the `AssemblyDependencyResolver` makes it easy to correctly load the dependencies.

Now that the `AppWithPlugin` project has the `PluginLoadContext` type, update the `Program.LoadPlugin` method with the following body:

```

static Assembly LoadPlugin(string relativePath)
{
    // Navigate up to the solution root
    string root = Path.GetFullPath(Path.Combine(
        Path.GetDirectoryName(
            Path.GetDirectoryName(
                Path.GetDirectoryName(
                    Path.GetDirectoryName(
                        Path.GetDirectoryName(typeof(Program).Assembly.Location))))));
}

string pluginLocation = Path.GetFullPath(Path.Combine(root, relativePath.Replace('\\',
Path.DirectorySeparatorChar)));
Console.WriteLine($"Loading commands from: {pluginLocation}");
PluginLoadContext loadContext = new PluginLoadContext(pluginLocation);
return loadContext.LoadFromAssemblyName(new
AssemblyName(Path.GetFileNameWithoutExtension(pluginLocation)));
}

```

By using a different `PluginLoadContext` instance for each plugin, the plugins can have different or even conflicting dependencies without issue.

Simple plugin with no dependencies

Back in the root folder, do the following:

1. Run the following command to create a new class library project named `HelloPlugin`:

```
dotnet new classlib -o HelloPlugin
```

2. Run the following command to add the project to the `AppWithPlugin` solution:

```
dotnet sln add HelloPlugin/HelloPlugin.csproj
```

3. Replace the `HelloPlugin/Class1.cs` file with a file named `HelloCommand.cs` with the following contents:

```

using PluginBase;
using System;

namespace HelloPlugin
{
    public class HelloCommand : ICommand
    {
        public string Name { get => "hello"; }
        public string Description { get => "Displays hello message." }

        public int Execute()
        {
            Console.WriteLine("Hello !!!");
            return 0;
        }
    }
}

```

Now, open the `HelloPlugin.csproj` file. It should look similar to the following:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFramework>net5.0</TargetFramework>
</PropertyGroup>

</Project>
```

In between the `<PropertyGroup>` tags, add the following element:

```
<EnableDynamicLoading>true</EnableDynamicLoading>
```

The `<EnableDynamicLoading>true</EnableDynamicLoading>` prepares the project so that it can be used as a plugin. Among other things, this will copy all of its dependencies to the output of the project. For more details see [EnableDynamicLoading](#).

In between the `<Project>` tags, add the following elements:

```
<ItemGroup>
  <ProjectReference Include="..\PluginBase\PluginBase.csproj">
    <Private>false</Private>
    <ExcludeAssets>runtime</ExcludeAssets>
  </ProjectReference>
</ItemGroup>
```

The `<Private>false</Private>` element is important. This tells MSBuild to not copy *PluginBase.dll* to the output directory for *HelloPlugin*. If the *PluginBase.dll* assembly is present in the output directory, `PluginLoadContext` will find the assembly there and load it when it loads the *HelloPlugin.dll* assembly. At this point, the `HelloPlugin.HelloCommand` type will implement the `ICommand` interface from the *PluginBase.dll* in the output directory of the `HelloPlugin` project, not the `ICommand` interface that is loaded into the default load context. Since the runtime sees these two types as different types from different assemblies, the `AppWithPlugin.Program.CreateCommand` method won't find the commands. As a result, the `<Private>false</Private>` metadata is required for the reference to the assembly containing the plugin interfaces.

Similarly, the `<ExcludeAssets>runtime</ExcludeAssets>` element is also important if the `PluginBase` references other packages. This setting has the same effect as `<Private>false</Private>` but works on package references that the `PluginBase` project or one of its dependencies may include.

Now that the `HelloPlugin` project is complete, you should update the `AppWithPlugin` project to know where the `HelloPlugin` plugin can be found. After the `// Paths to plugins to load` comment, add `@"HelloPlugin\bin\Debug\net5.0\HelloPlugin.dll"` (this path could be different based on the .NET Core version you use) as an element of the `pluginPaths` array.

Plugin with library dependencies

Almost all plugins are more complex than a simple "Hello World", and many plugins have dependencies on other libraries. The `JsonPlugin` and `OldJsonPlugin` projects in the sample show two examples of plugins with NuGet package dependencies on `Newtonsoft.Json`. Because of this, all plugin projects should add `<EnableDynamicLoading>true</EnableDynamicLoading>` to the project properties so that they copy all of their dependencies to the output of `dotnet build`. Publishing the class library with `dotnet publish` will also copy all of its dependencies to the publish output.

Other examples in the sample

The complete source code for this tutorial can be found in [the dotnet/samples repository](#). The completed sample includes a few other examples of `AssemblyDependencyResolver` behavior. For example, the `AssemblyDependencyResolver` object can also resolve native libraries as well as localized satellite assemblies included in NuGet packages. The `UVPlugin` and `FrenchPlugin` in the samples repository demonstrate these scenarios.

Reference a plugin interface from a NuGet package

Let's say that there is an app A that has a plugin interface defined in the NuGet package named `A.PluginBase`. How do you reference the package correctly in your plugin project? For project references, using the `<Private>false</Private>` metadata on the `ProjectReference` element in the project file prevented the dll from being copied to the output.

To correctly reference the `A.PluginBase` package, you want to change the `<PackageReference>` element in the project file to the following:

```
<PackageReference Include="A.PluginBase" Version="1.0.0">
  <ExcludeAssets>runtime</ExcludeAssets>
</PackageReference>
```

This prevents the `A.PluginBase` assemblies from being copied to the output directory of your plugin and ensures that your plugin will use A's version of `A.PluginBase`.

Plugin target framework recommendations

Because plugin dependency loading uses the `.deps.json` file, there is a gotcha related to the plugin's target framework. Specifically, your plugins should target a runtime, such as .NET 5, instead of a version of .NET Standard. The `.deps.json` file is generated based on which framework the project targets, and since many .NET Standard-compatible packages ship reference assemblies for building against .NET Standard and implementation assemblies for specific runtimes, the `.deps.json` may not correctly see implementation assemblies, or it may grab the .NET Standard version of an assembly instead of the .NET Core version you expect.

Plugin framework references

Currently, plugins can't introduce new frameworks into the process. For example, you can't load a plugin that uses the `Microsoft.AspNetCore.App` framework into an application that only uses the root `Microsoft.NETCore.App` framework. The host application must declare references to all frameworks needed by plugins.

How to use and debug assembly unloadability in .NET

9/20/2022 • 12 minutes to read • [Edit Online](#)

.NET Core 3.0 introduced the ability to load and later unload a set of assemblies. In .NET Framework, custom app domains were used for this purpose, but .NET [Core] only supports a single default app domain.

Unloadability is supported through [AssemblyLoadContext](#). You can load a set of assemblies into a collectible [AssemblyLoadContext](#), execute methods in them or just inspect them using reflection, and finally unload the [AssemblyLoadContext](#). That unloads the assemblies loaded into the [AssemblyLoadContext](#).

There's one noteworthy difference between the unloading using [AssemblyLoadContext](#) and using AppDomains. With AppDomains, the unloading is forced. At unload time, all threads running in the target AppDomain are aborted, managed COM objects created in the target AppDomain are destroyed, and so on. With [AssemblyLoadContext](#), the unload is "cooperative". Calling the [AssemblyLoadContext.Unload](#) method just initiates the unloading. The unloading finishes after:

- No threads have methods from the assemblies loaded into the [AssemblyLoadContext](#) on their call stacks.
- None of the types from the assemblies loaded into the [AssemblyLoadContext](#), instances of those types, and the assemblies themselves are referenced by:
 - References outside of the [AssemblyLoadContext](#), except for weak references ([WeakReference](#) or [WeakReference<T>](#)).
 - Strong garbage collector (GC) handles ([GCHandleType.Normal](#) or [GCHandleType.Pinned](#)) from both inside and outside of the [AssemblyLoadContext](#).

Use collectible AssemblyLoadContext

This section contains a detailed step-by-step tutorial that shows a simple way to load a .NET Core application into a collectible [AssemblyLoadContext](#), execute its entry point, and then unload it. You can find a complete sample at <https://github.com/dotnet/samples/tree/main/core/tutorials/Unloading>.

Create a collectible AssemblyLoadContext

Derive your class from the [AssemblyLoadContext](#) and override its [AssemblyLoadContext.Load](#) method. That method resolves references to all assemblies that are dependencies of assemblies loaded into that [AssemblyLoadContext](#).

The following code is an example of the simplest custom [AssemblyLoadContext](#):

```
class TestAssemblyLoadContext : AssemblyLoadContext
{
    public TestAssemblyLoadContext() : base(isCollectible: true)
    {
    }

    protected override Assembly Load(AssemblyName name)
    {
        return null;
    }
}
```

As you can see, the [Load](#) method returns [null](#). That means that all the dependency assemblies are loaded into

the default context, and the new context contains only the assemblies explicitly loaded into it.

If you want to load some or all of the dependencies into the `AssemblyLoadContext` too, you can use the `AssemblyDependencyResolver` in the `Load` method. The `AssemblyDependencyResolver` resolves the assembly names to absolute assembly file paths. The resolver uses the `.deps.json` file and assembly files in the directory of the main assembly loaded into the context.

```
using System.Reflection;
using System.Runtime.Loader;

namespace complex
{
    class TestAssemblyLoadContext : AssemblyLoadContext
    {
        private AssemblyDependencyResolver _resolver;

        public TestAssemblyLoadContext(string mainAssemblyToLoadPath) : base(isCollectible: true)
        {
            _resolver = new AssemblyDependencyResolver(mainAssemblyToLoadPath);
        }

        protected override Assembly Load(AssemblyName name)
        {
            string assemblyPath = _resolver.ResolveAssemblyToPath(name);
            if (assemblyPath != null)
            {
                return LoadFromAssemblyPath(assemblyPath);
            }

            return null;
        }
    }
}
```

Use a custom collectible `AssemblyLoadContext`

This section assumes the simpler version of the `TestAssemblyLoadContext` is being used.

You can create an instance of the custom `AssemblyLoadContext` and load an assembly into it as follows:

```
var alc = new TestAssemblyLoadContext();
Assembly a = alc.LoadFromAssemblyPath(assemblyPath);
```

For each of the assemblies referenced by the loaded assembly, the `TestAssemblyLoadContext.Load` method is called so that the `TestAssemblyLoadContext` can decide where to get the assembly from. In our case, it returns `null` to indicate that it should be loaded into the default context from locations that the runtime uses to load assemblies by default.

Now that an assembly was loaded, you can execute a method from it. Run the `Main` method:

```
var args = new object[1] {new string[] {"Hello"}};
int result = (int) a.EntryPoint.Invoke(null, args);
```

After the `Main` method returns, you can initiate unloading by either calling the `Unload` method on the custom `AssemblyLoadContext` or getting rid of the reference you have to the `AssemblyLoadContext`:

```
alc.Unload();
```

This is sufficient to unload the test assembly. Let's actually put all of this into a separate non-inlineable method

to ensure that the `TestAssemblyLoadContext`, `Assembly`, and `MethodInfo` (the `Assembly.EntryPoint`) can't be kept alive by stack slot references (real- or JIT-introduced locals). That could keep the `TestAssemblyLoadContext` alive and prevent the unload.

Also, return a weak reference to the `AssemblyLoadContext` so that you can use it later to detect unload completion.

```
[MethodImpl(MethodImplOptions.NoInlining)]
static int ExecuteAndUnload(string assemblyPath, out WeakReference alcWeakRef)
{
    var alc = new TestAssemblyLoadContext();
    Assembly a = alc.LoadFromAssemblyPath(assemblyPath);

    alcWeakRef = new WeakReference(alc, trackResurrection: true);

    var args = new object[1] {new string[] {"Hello"}};
    int result = (int) a.EntryPoint.Invoke(null, args);

    alc.Unload();

    return result;
}
```

Now you can run this function to load, execute, and unload the assembly.

```
WeakReference testAlcWeakRef;
int result = ExecuteAndUnload("absolute/path/to/your/assembly", out testAlcWeakRef);
```

However, the unload doesn't complete immediately. As previously mentioned, it relies on the garbage collector to collect all the objects from the test assembly. In many cases, it isn't necessary to wait for the unload completion. However, there are cases where it's useful to know that the unload has finished. For example, you may want to delete the assembly file that was loaded into the custom `AssemblyLoadContext` from disk. In such a case, the following code snippet can be used. It triggers garbage collection and waits for pending finalizers in a loop until the weak reference to the custom `AssemblyLoadContext` is set to `null`, indicating the target object was collected. In most cases, just one pass through the loop is required. However, for more complex cases where objects created by the code running in the `AssemblyLoadContext` have finalizers, more passes may be needed.

```
for (int i = 0; testAlcWeakRef.IsAlive && (i < 10); i++)
{
    GC.Collect();
    GC.WaitForPendingFinalizers();
}
```

The Unloading event

In some cases, it may be necessary for the code loaded into a custom `AssemblyLoadContext` to perform some cleanup when the unloading is initiated. For example, it may need to stop threads or clean up strong GC handles. The `Unloading` event can be used in such cases. A handler that performs the necessary cleanup can be hooked to this event.

Troubleshoot unloadability issues

Due to the cooperative nature of the unloading, it's easy to forget about references that may be keeping the stuff in a collectible `AssemblyLoadContext` alive and preventing unload. Here is a summary of entities (some of them non-obvious) that can hold the references:

- Regular references held from outside of the collectible `AssemblyLoadContext` that are stored in a stack slot or a processor register (method locals, either explicitly created by the user code or implicitly by the just-in-time

(JIT) compiler), a static variable, or a strong (pinning) GC handle, and transitively pointing to:

- An assembly loaded into the collectible `AssemblyLoadContext`.
- A type from such an assembly.
- An instance of a type from such an assembly.
- Threads running code from an assembly loaded into the collectible `AssemblyLoadContext`.
- Instances of custom, non-collectible `AssemblyLoadContext` types created inside of the collectible `AssemblyLoadContext`.
- Pending `RegisteredWaitHandle` instances with callbacks set to methods in the custom `AssemblyLoadContext`.

TIP

Object references that are stored in stack slots or processor registers and that could prevent unloading of an `AssemblyLoadContext` can occur in the following situations:

- When function call results are passed directly to another function, even though there is no user-created local variable.
- When the JIT compiler keeps a reference to an object that was available at some point in a method.

Debug unloading issues

Debugging issues with unloading can be tedious. You can get into situations where you don't know what can be holding an `AssemblyLoadContext` alive, but the unload fails. The best weapon to help with that is WinDbg (LLDB on Unix) with the SOS plugin. You need to find what's keeping a `LoaderAllocator` belonging to the specific `AssemblyLoadContext` alive. The SOS plugin allows you to look at GC heap objects, their hierarchies, and roots.

To load the plugin into the debugger, enter the following command in the debugger command line:

In WinDbg (it seems WinDbg does that automatically when breaking into .NET Core application):

```
.loadby sos coreclr
```

In LLDB:

```
plugin load /path/to/libssosplugin.so
```

Let's debug an example program that has problems with unloading. Source code is included below. When you run it under WinDbg, the program breaks into the debugger right after attempting to check for the unload success. You can then start looking for the culprits.

TIP

If you debug using LLDB on Unix, the SOS commands in the following examples don't have the `!` in front of them.

```
!dumpheap -type LoaderAllocator
```

This command dumps all objects with a type name containing `LoaderAllocator` that are in the GC heap. Here is an example:

Address	MT	Size
000002b78000ce40	00007ffadc93a288	48
000002b78000ceb0	00007ffadc93a218	24

Statistics:

MT	Count	TotalSize	Class Name
00007ffadc93a218	1	24	System.Reflection.LoaderAllocatorScout
00007ffadc93a288	1	48	System.Reflection.LoaderAllocator
Total		2 objects	

In the "Statistics:" part below, check the `MT` (`MethodTable`) belonging to the `System.Reflection.LoaderAllocator`, which is the object we care about. Then, in the list at the beginning, find the entry with `MT` matching that one and get the address of the object itself. In our case, it is "000002b78000ce40".

Now that we know the address of the `LoaderAllocator` object, we can use another command to find its GC roots:

```
!gcroot -all 0x000002b78000ce40
```

This command dumps the chain of object references that lead to the `LoaderAllocator` instance. The list starts with the root, which is the entity that keeps our `LoaderAllocator` alive and thus is the core of the problem. The root can be a stack slot, a processor register, a GC handle, or a static variable.

Here is an example of the output of the `gcroot` command:

```
Thread 4ac:
00000cf9499dd20 00007ffa7d0236bc example.Program.Main(System.String[])
[E:\unloadability\example\Program.cs @ 70]
rbp-20: 000000cf9499dd90
    -> 000002b78000d328 System.Reflection.RuntimeMethodInfo
    -> 000002b78000d1f8 System.RuntimeType+RuntimeTypeCache
    -> 000002b78000d1d0 System.RuntimeType
    -> 000002b78000ce40 System.Reflection.LoaderAllocator

HandleTable:
000002b7f8a81198 (strong handle)
-> 000002b78000d948 test.Test
-> 000002b78000ce40 System.Reflection.LoaderAllocator

000002b7f8a815f8 (pinned handle)
-> 000002b790001038 System.Object[]
-> 000002b78000d390 example.TestInfo
-> 000002b78000d328 System.Reflection.RuntimeMethodInfo
-> 000002b78000d1f8 System.RuntimeType+RuntimeTypeCache
-> 000002b78000d1d0 System.RuntimeType
-> 000002b78000ce40 System.Reflection.LoaderAllocator

Found 3 roots.
```

The next step is to figure out where the root is located so you can fix it. The easiest case is when the root is a stack slot or a processor register. In that case, the `gcroot` shows the name of the function whose frame contains the root and the thread executing that function. The difficult case is when the root is a static variable or a GC handle.

In the previous example, the first root is a local of type `System.Reflection.RuntimeMethodInfo` stored in the frame of the function `example.Program.Main(System.String[])` at address `rbp-20` (`rbp` is the processor register `rbp` and `-20` is a hexadecimal offset from that register).

The second root is a normal (strong) `GCHandle` that holds a reference to an instance of the `test.Test` class.

The third root is a pinned `GCHandle`. This one is actually a static variable, but unfortunately, there is no way to tell. Statics for reference types are stored in a managed object array in internal runtime structures.

Another case that can prevent unloading of an `AssemblyLoadContext` is when a thread has a frame of a method from an assembly loaded into the `AssemblyLoadContext` on its stack. You can check that by dumping managed call stacks of all threads:

```
~*e !clrstack
```

The command means "apply to all threads the `!clrstack` command". The following is the output of that command for the example. Unfortunately, LLDB on Unix doesn't have any way to apply a command to all threads, so you must manually switch threads and repeat the `clrstack` command. Ignore all threads where the debugger says "Unable to walk the managed stack".

```

```

As you can see, the last thread has `test.Program.ThreadProc()`. This is a function from the assembly loaded into the `AssemblyLoadContext`, and so it keeps the `AssemblyLoadContext` alive.

Example source with unloadability issues

The following code is used in the previous debugging example.

Main testing program

```

using System;
using System.Reflection;
using System.Runtime.CompilerServices;
using System.Runtime.Loader;

namespace example

```

```

{
    class TestAssemblyLoadContext : AssemblyLoadContext
    {
        public TestAssemblyLoadContext() : base(true)
        {
        }
        protected override Assembly Load(AssemblyName name)
        {
            return null;
        }
    }

    class TestInfo
    {
        public TestInfo(MethodInfo mi)
        {
            entryPoint = mi;
        }
        MethodInfo entryPoint;
    }

    class Program
    {
        static TestInfo entryPoint;

        [MethodImpl(MethodImplOptions.NoInlining)]
        static int ExecuteAndUnload(string assemblyPath, out WeakReference testAlcWeakRef, out MethodInfo
testEntryPoint)
        {
            var alc = new TestAssemblyLoadContext();
            testAlcWeakRef = new WeakReference(alc);

            Assembly a = alc.LoadFromAssemblyPath(assemblyPath);
            if (a == null)
            {
                testEntryPoint = null;
                Console.WriteLine("Loading the test assembly failed");
                return -1;
            }

            var args = new object[1] {new string[] {"Hello"}};

            // Issue preventing unloading #1 - we keep MethodInfo of a method for an assembly loaded into
            the TestAssemblyLoadContext in a static variable
            entryPoint = new TestInfo(a.EntryPoint);
            testEntryPoint = a.EntryPoint;

            int result = (int)a.EntryPoint.Invoke(null, args);
            alc.Unload();

            return result;
        }

        static void Main(string[] args)
        {
            WeakReference testAlcWeakRef;
            // Issue preventing unloading #2 - we keep MethodInfo of a method for an assembly loaded into
            the TestAssemblyLoadContext in a local variable
            MethodInfo testEntryPoint;
            int result = ExecuteAndUnload(@"absolute/path/to/test.dll", out testAlcWeakRef, out
testEntryPoint);

            for (int i = 0; testAlcWeakRef.IsAlive && (i < 10); i++)
            {
                GC.Collect();
                GC.WaitForPendingFinalizers();
            }

            System.Diagnostics.Debugger.Break();
        }
    }
}

```

```
System.Diagnostics.Debugger.OnBreak();  
  
        Console.WriteLine($"Test completed, result={result}, entryPoint: {testEntryPoint} unload  
success: {!testAlcWeakRef.IsAlive}");  
    }  
}  
}
```

Program loaded into the TestAssemblyLoadContext

The following code represents the *test.dll* passed to the `ExecuteAndUnload` method in the main testing program.

```
using System;  
using System.Runtime.InteropServices;  
using System.Threading;  
  
namespace test  
{  
    class Test  
    {  
        string message = "Hello";  
    }  
  
    class Program  
    {  
        public static void ThreadProc()  
        {  
            // Issue preventing unloading #4 - a thread running method inside of the TestAssemblyLoadContext  
            // at the unload time  
            Thread.Sleep(Timeout.Infinite);  
        }  
  
        static GCHandle handle;  
        static int Main(string[] args)  
        {  
            // Issue preventing unloading #3 - normal GC handle  
            handle = GCHandle.Alloc(new Test());  
            Thread t = new Thread(new ThreadStart(ThreadProc));  
            t.IsBackground = true;  
            t.Start();  
            Console.WriteLine($"Hello from the test: args[0] = {args[0]}");  
  
            return 1;  
        }  
    }  
}
```

Overview of how .NET is versioned

9/20/2022 • 3 minutes to read • [Edit Online](#)

The [.NET Runtime](#) and the [.NET SDK](#) add new features at different frequencies. In general, the SDK is updated more frequently than the Runtime. This article explains the runtime and the SDK version numbers.

.NET releases a new major version every November. Even-numbered releases, such as .NET 6 or .NET 8, are long-term supported (LTS). Odd-numbered releases are supported until the next major release. The latest release of .NET is .NET 6.

Versioning details

The .NET Runtime has a major:minor:patch approach to versioning that follows [semantic versioning](#).

The .NET SDK, however, doesn't follow semantic versioning. The .NET SDK releases faster and its version numbers must communicate both the aligned runtime and the SDK's own minor and patch releases.

The first two positions of the .NET SDK version number match the .NET Runtime version it released with. Each version of the SDK can create applications for this runtime or any lower version.

The third position of the SDK version number communicates both the minor and patch number. The minor version is multiplied by 100. The final two digits represent the patch number. Minor version 1, patch version 2 would be represented as 102. For example, here's a possible sequence of runtime and SDK version numbers:

CHANGE	.NET RUNTIME	.NET SDK (*)
Initial release	5.0.0	5.0.100
SDK patch	5.0.0	5.0.101
Runtime and SDK patch	5.0.1	5.0.102
SDK feature change	5.0.1	5.0.200

NOTES:

- If the SDK has 10 feature updates before a runtime feature update, version numbers roll into the 1000 series. Version 5.0.1000 would follow version 5.0.900. This situation isn't expected to occur.
- 99 patch releases without a feature release won't occur. If a release approaches this number, it forces a feature release.

You can see more details in the initial proposal at the [dotnet/designs](#) repository.

Semantic versioning

The .NET *Runtime* roughly adheres to [Semantic Versioning \(SemVer\)](#), adopting the use of `MAJOR.MINOR.PATCH` versioning, using the various parts of the version number to describe the degree and type of change.

`MAJOR.MINOR.PATCH[-PRERELEASE-BUILDDNUMBER]`

The optional `PRERELEASE` and `BUILDDNUMBER` parts are never part of supported releases and only exist on nightly

builds, local builds from source targets, and unsupported preview releases.

Understand runtime version number changes

- `MAJOR` is incremented once a year and may contain:
 - Significant changes in the product, or a new product direction.
 - API introduced breaking changes. There's a high bar to accepting breaking changes.
 - A newer `MAJOR` version of an existing dependency is adopted.
- Major releases happen once a year; even-numbered versions are long-term supported (LTS) releases. The first LTS release using this versioning scheme is .NET 6. The latest non-LTS version is .NET 5.
- `MINOR` is incremented when:
 - Public API surface area is added.
 - A new behavior is added.
 - A newer `MINOR` version of an existing dependency is adopted.
 - A new dependency is introduced.
- `PATCH` is incremented when:
 - Bug fixes are made.
 - Support for a newer platform is added.
 - A newer `PATCH` version of an existing dependency is adopted.
 - Any other change doesn't fit one of the previous cases.

When there are multiple changes, the highest element affected by individual changes is incremented, and the following ones are reset to zero. For example, when `MAJOR` is incremented, `MINOR.PATCH` are reset to zero. When `MINOR` is incremented, `PATCH` is reset to zero while `MAJOR` remains the same.

Version numbers in file names

The files downloaded for .NET carry the version, for example, `dotnet-sdk-5.0.301-win10-x64.exe`.

Preview versions

Preview versions have a `-preview.[number].[build]` appended to the version number. For example, `6.0.0-preview.5.21302.13`.

Servicing versions

After a release goes out, the release branches generally stop producing daily builds and instead start producing servicing builds. Servicing versions have a `-servicing-[number]` appended to the version. For example, `5.0.1-servicing-006924`.

Select the .NET version to use

9/20/2022 • 7 minutes to read • [Edit Online](#)

This article explains the policies used by the .NET tools, SDK, and runtime for selecting versions. These policies provide a balance between running applications using the specified versions and enabling ease of upgrading both developer and end-user machines. These policies enable:

- Easy and efficient deployment of .NET, including security and reliability updates.
- Use the latest tools and commands independent of target runtime.

Version selection occurs:

- When you run an SDK command, the **SDK uses the latest installed version**.
- When you build an assembly, **target framework monikers define build time APIs**.
- When you run a .NET application, **target framework dependent apps roll-forward**.
- When you publish a self-contained application, **self-contained deployments include the selected runtime**.

The rest of this document examines those four scenarios.

The SDK uses the latest installed version

SDK commands include `dotnet new` and `dotnet run`. The .NET CLI must choose an SDK version for every `dotnet` command. It uses the latest SDK installed on the machine by default, even if:

- The project targets an earlier version of the .NET runtime.
- The latest version of the .NET SDK is a preview version.

You can take advantage of the latest SDK features and improvements while targeting earlier .NET runtime versions. You can target different runtime versions of .NET using the same SDK tools.

On rare occasions, you may need to use an earlier version of the SDK. You specify that version in a [*global.json* file](#). The "use latest" policy means you only use *global.json* to specify a .NET SDK version earlier than the latest installed version.

global.json can be placed anywhere in the file hierarchy. The CLI searches upward from the project directory for the first *global.json* it finds. You control which projects a given *global.json* applies to by its place in the file system. The .NET CLI searches for a *global.json* file iteratively navigating the path upward from the current working directory. The first *global.json* file found specifies the version used. If that SDK version is installed, that version is used. If the SDK specified in the *global.json* isn't found, the .NET CLI uses [matching rules](#) to select a compatible SDK, or fails if none is found.

The following example shows the *global.json* syntax:

```
{  
  "sdk": {  
    "version": "5.0.0"  
  }  
}
```

The process for selecting an SDK version is:

1. `dotnet` searches for a *global.json* file iteratively reverse-navigating the path upward from the current working directory.

2. `dotnet` uses the SDK specified in the first `global.json` found.
3. `dotnet` uses the latest installed SDK if no `global.json` is found.

For more information about SDK version selection, see the [Matching rules](#) and [rollForward](#) sections of the [global.json overview](#) article.

Target Framework Monikers define build time APIs

You build your project against APIs defined in a **Target Framework Moniker** (TFM). You specify the [target framework](#) in the project file. Set the `TargetFramework` element in your project file as shown in the following example:

```
<TargetFramework>net5.0</TargetFramework>
```

You may build your project against multiple TFMs. Setting multiple target frameworks is more common for libraries but can be done with applications as well. You specify a `TargetFrameworks` property (plural of `TargetFramework`). The target frameworks are semicolon-delimited as shown in the following example:

```
<TargetFrameworks>net5.0;netcoreapp3.1;net47</TargetFrameworks>
```

A given SDK supports a fixed set of frameworks, capped to the target framework of the runtime it ships with. For example, the .NET 5 SDK includes the .NET 5 runtime, which is an implementation of the `net5.0` target framework. The .NET 5 SDK supports `netcoreapp2.0`, `netcoreapp2.1`, `netcoreapp3.0`, and so on, but not `net6.0` (or higher). You install the .NET 6 SDK to build for `net6.0`.

.NET Standard

.NET Standard was a way to target an API surface shared by different implementations of .NET. Starting with the release of .NET 5, which is an API standard itself, .NET Standard has little relevance, except for one scenario: .NET Standard is useful when you want to target both .NET and .NET Framework. .NET 5 implements all .NET Standard versions.

For more information, see [.NET 5 and .NET Standard](#).

Framework-dependent apps roll-forward

When you run an application from source with `dotnet run`, from a [framework-dependent deployment](#) with `dotnet myapp.dll`, or from a [framework-dependent executable](#) with `myapp.exe`, the `dotnet` executable is the **host** for the application.

The host chooses the latest patch version installed on the machine. For example, if you specified `net5.0` in your project file, and `5.0.2` is the latest .NET runtime installed, the `5.0.2` runtime is used.

If no acceptable `5.0.*` version is found, a new `5.*` version is used. For example, if you specified `net5.0` and only `5.1.0` is installed, the application runs using the `5.1.0` runtime. This behavior is referred to as "minor version roll-forward." Lower versions also won't be considered. When no acceptable runtime is installed, the application won't run.

A few usage examples demonstrate the behavior, if you target 5.0:

- ✓ 5.0 is specified. 5.0.3 is the highest patch version installed. 5.0.3 is used.
- ✗ 5.0 is specified. No 5.0.* versions are installed. 3.1.1 is the highest runtime installed. An error message is displayed.
- ✓ 5.0 is specified. No 5.0.* versions are installed. 5.1.0 is the highest runtime version installed. 5.1.0 is used.

- ✗ 3.0 is specified. No 3.x versions are installed. 5.0.0 is the highest runtime installed. An error message is displayed.

Minor version roll-forward has one side-effect that may affect end users. Consider the following scenario:

1. The application specifies that 5.0 is required.
2. When run, version 5.0.* isn't installed, however, 5.1.0 is. Version 5.1.0 will be used.
3. Later, the user installs 5.0.3 and runs the application again, 5.0.3 will now be used.

It's possible that 5.0.3 and 5.1.0 behave differently, particularly for scenarios like serializing binary data.

Control roll-forward behavior

The roll-forward behavior for an application can be configured in four different ways:

1. Project-level setting by setting the `<RollForward>` property:

```
<PropertyGroup>
  <RollForward>LatestMinor</RollForward>
</PropertyGroup>
```

2. The `*.runtimeconfig.json` file.

This file is produced when you compile your application. If the `<RollForward>` property was set in the project, it's reproduced in the `*.runtimeconfig.json` file as the `rollForward` setting. Users can edit this file to change the behavior of your application.

```
{
  "runtimeOptions": {
    "tfm": "net5.0",
    "rollForward": "LatestMinor",
    "framework": {
      "name": "Microsoft.NETCore.App",
      "version": "5.0.0"
    }
  }
}
```

3. The `dotnet` command's `--roll-forward <value>` property.

When you run an application, you can control the roll-forward behavior through the command line:

```
dotnet run --roll-forward LatestMinor
dotnet myapp.dll --roll-forward LatestMinor
myapp.exe --roll-forward LatestMinor
```

4. The `DOTNET_ROLL_FORWARD` environment variable.

Precedence

Roll forward behavior is set by the following order when your app is run, higher numbered items taking precedence over lower numbered items:

1. First the `*.runtimeconfig.json` config file is evaluated.
2. Next, the `DOTNET_ROLL_FORWARD` environment variable is considered, overriding the previous check.
3. Finally, any `--roll-forward` parameter passed to the running application overrides everything else.

Values

However you set the roll-forward setting, use one of the following values to set the behavior:

Value	Description
Minor	Default if not specified. Roll-forward to the lowest higher minor version, if requested minor version is missing. If the requested minor version is present, then the <code>LatestPatch</code> policy is used.
Major	Roll-forward to the next available higher major version, and lowest minor version, if requested major version is missing. If the requested major version is present, then the <code>Minor</code> policy is used.
LatestPatch	Roll-forward to the highest patch version. This value disables minor version roll-forward.
LatestMinor	Roll-forward to highest minor version, even if requested minor version is present.
LatestMajor	Roll-forward to highest major and highest minor version, even if requested major is present.
Disable	Don't roll-forward, only bind to the specified version. This policy isn't recommended for general use since it disables the ability to roll-forward to the latest patches. This value is only recommended for testing.

Self-contained deployments include the selected runtime

You can publish an application as a [self-contained distribution](#). This approach bundles the .NET runtime and libraries with your application. Self-contained deployments don't have a dependency on runtime environments. Runtime version selection occurs at publishing time, not run time.

The `restore` event that occurs when publishing selects the latest patch version of the given runtime family. For example, `dotnet publish` will select .NET 5.0.3 if it's the latest patch version in the .NET 5 runtime family. The target framework (including the latest installed security patches) is packaged with the application.

An error occurs if the minimum version specified for an application isn't satisfied. `dotnet publish` binds to the latest runtime patch version (within a given major.minor version family). `dotnet publish` doesn't support the roll-forward semantics of `dotnet run`. For more information about patches and self-contained deployments, see the article on [runtime patch selection](#) in deploying .NET applications.

Self-contained deployments may require a specific patch version. You can override the minimum runtime patch version (to higher or lower versions) in the project file, as shown in the following example:

```
<PropertyGroup>
  <RuntimeFrameworkVersion>5.0.7</RuntimeFrameworkVersion>
</PropertyGroup>
```

The `RuntimeFrameworkVersion` element overrides the default version policy. For self-contained deployments, the `RuntimeFrameworkVersion` specifies the *exact* runtime framework version. For framework-dependent applications, the `RuntimeFrameworkVersion` specifies the *minimum* required runtime framework version.

.NET Runtime configuration settings

9/20/2022 • 3 minutes to read • [Edit Online](#)

.NET 5+ (including .NET Core versions) supports the use of configuration files and environment variables to configure the behavior of .NET applications at run time.

NOTE

The articles in this section concern configuration of the .NET Runtime itself. If you're migrating to .NET Core 3.1 or later and are looking for a replacement for the *app.config* file, or if you simply want a way to use custom configuration values in your .NET app, see the [Microsoft.Extensions.Configuration.ConfigurationBuilder](#) class and [Configuration in .NET](#).

Using these settings is an attractive option if:

- You don't own or control the source code for an application and therefore are unable to configure it programmatically.
- Multiple instances of your application run at the same time on a single system, and you want to configure each for optimum performance.

.NET provides the following mechanisms for configuring behavior of the .NET runtime:

- The [runtimeconfig.json](#) file
- [MSBuild](#) properties
- [Environment variables](#)

TIP

Configuring an option by using an environment variable applies the setting to all .NET apps. Configuring an option in the *runtimeconfig.json* or project file applies the setting to that application only.

Some configuration values can also be set programmatically by calling the [AppContext.SetSwitch](#) method.

The articles in this section of the documentation are organized by category, for example, [debugging](#) and [garbage collection](#). Where applicable, configuration options are shown for *runtimeconfig.json* files, MSBuild properties, environment variables, and, for cross-reference, *app.config* files for .NET Framework projects.

runtimeconfig.json

When a project is [built](#), an *[appname].runtimeconfig.json* file is generated in the output directory. If a *runtimeconfig.template.json* file exists in the same folder as the project file, any configuration options it contains are inserted into the *[appname].runtimeconfig.json* file. If you're building the app yourself, put any configuration options in the *runtimeconfig.template.json* file. If you're just running the app, insert them directly into the *[appname].runtimeconfig.json* file.

NOTE

- The `[appname].runtimeconfig.json` file will get overwritten on subsequent builds.
- If your app's `OutputType` is not `Exe` and you want configuration options to be copied from `runtimeconfig.template.json` to `[appname].runtimeconfig.json`, you must explicitly set `GenerateRuntimeConfigurationFiles` to `true` in your project file. For apps that require a `runtimeconfig.json` file, this property defaults to `true`.

Specify runtime configuration options in the `configProperties` section of the `runtimeconfig.json` files. This section has the form:

```
"configProperties": {  
    "config-property-name1": "config-value1",  
    "config-property-name2": "config-value2"  
}
```

Example `[appname].runtimeconfig.json` file

If you're placing the options in the output JSON file, nest them under the `runtimeOptions` property.

```
{  
    "runtimeOptions": {  
        "tfm": "netcoreapp3.1",  
        "framework": {  
            "name": "Microsoft.NETCore.App",  
            "version": "3.1.0"  
        },  
        "configProperties": {  
            "System.Globalization.UseNls": true,  
            "System.Net.DisableIPv6": true,  
            "System.GC.Concurrent": false,  
            "System.Threading.ThreadPool.MinThreads": 4,  
            "System.Threading.ThreadPool.MaxThreads": 25  
        }  
    }  
}
```

Example `runtimeconfig.template.json` file

If you're placing the options in the template JSON file, omit the `runtimeOptions` property.

```
{  
    "configProperties": {  
        "System.Globalization.UseNls": true,  
        "System.Net.DisableIPv6": true,  
        "System.GC.Concurrent": false,  
        "System.Threading.ThreadPool.MinThreads": "4",  
        "System.Threading.ThreadPool.MaxThreads": "25"  
    }  
}
```

MSBuild properties

Some runtime configuration options can be set using MSBuild properties in the `.csproj` or `.vbproj` file of SDK-style .NET Core projects. MSBuild properties take precedence over options set in the `runtimeconfig.template.json` file.

For runtime configuration settings that don't have a specific MSBuild property, you can use the

`RuntimeHostConfigurationOption` MSBuild item instead.

Here is an example SDK-style project file with MSBuild properties for configuring run-time behavior:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <OutputType>Exe</OutputType>
  <TargetFramework>netcoreapp3.1</TargetFramework>
</PropertyGroup>

<PropertyGroup>
  <ConcurrentGarbageCollection>false</ConcurrentGarbageCollection>
  <ThreadPoolMinThreads>4</ThreadPoolMinThreads>
  <ThreadPoolMaxThreads>25</ThreadPoolMaxThreads>
</PropertyGroup>

<ItemGroup>
  <RuntimeHostConfigurationOption Include="System.Globalization.UseNls" Value="true" />
  <RuntimeHostConfigurationOption Include="System.Net.DisableIPv6" Value="true" />
</ItemGroup>

</Project>
```

MSBuild properties for configuring the behavior of the runtime are noted in the individual articles for each area, for example, [garbage collection](#). They are also listed in the [Runtime configuration](#) section of the MSBuild properties reference for SDK-style projects.

Environment variables

Environment variables can be used to supply some runtime configuration information. Configuring a run-time option by using an environment variable applies the setting to all .NET Core apps. Configuration knobs specified as environment variables generally have the prefix `DOTNET_`.

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

You can define environment variables from the Windows Control Panel, at the command line, or programmatically by calling the [Environment.SetEnvironmentVariable\(String, String\)](#) method on both Windows and Unix-based systems.

The following examples show how to set an environment variable at the command line:

```
# Windows
set DOTNET_GCRetainVM=1

# Powershell
$env:DOTNET_GCRetainVM="1"

# Unix
export DOTNET_GCRetainVM=1
```

Runtime configuration options for compilation

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article details the settings you can use to configure .NET compilation.

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Tiered compilation

- Configures whether the just-in-time (JIT) compiler uses [tiered compilation](#). Tiered compilation transitions methods through two tiers:
 - The first tier generates code more quickly ([quick JIT](#)) or loads pre-compiled code ([ReadyToRun](#)).
 - The second tier generates optimized code in the background ("optimizing JIT").
- In .NET Core 3.0 and later, tiered compilation is enabled by default.
- In .NET Core 2.1 and 2.2, tiered compilation is disabled by default.
- For more information, see the [Tiered compilation guide](#).

	SETTING NAME	VALUES
<code>runtimesconfig.json</code>	<code>System.Runtime.TieredCompilation</code>	<code>true</code> - enabled <code>false</code> - disabled
<code>MSBuild</code> property	<code>TieredCompilation</code>	<code>true</code> - enabled <code>false</code> - disabled
Environment variable	<code>COMPlus_TieredCompilation</code> or <code>DOTNET_TieredCompilation</code>	<code>1</code> - enabled <code>0</code> - disabled

Examples

`runtimesconfig.json` file:

```
{  
  "runtimeOptions": {  
    "configProperties": {  
      "System.Runtime.TieredCompilation": false  
    }  
  }  
}
```

Project file:

```

<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
    <TieredCompilation>false</TieredCompilation>
</PropertyGroup>

</Project>

```

Quick JIT

- Configures whether the JIT compiler uses *quick JIT*. For methods that don't contain loops and for which pre-compiled code is not available, quick JIT compiles them more quickly but without optimizations.
- Enabling quick JIT decreases startup time but can produce code with degraded performance characteristics. For example, the code may use more stack space, allocate more memory, and run slower.
- If quick JIT is disabled but [tiered compilation](#) is enabled, only pre-compiled code participates in tiered compilation. If a method is not pre-compiled with [ReadyToRun](#), the JIT behavior is the same as if [tiered compilation](#) were disabled.
- In .NET Core 3.0 and later, quick JIT is enabled by default.
- In .NET Core 2.1 and 2.2, quick JIT is disabled by default.

	SETTING NAME	VALUES
runtimesconfig.json	System.Runtime.TieredCompilation.QuickJit	<input type="checkbox"/> true - enabled <input type="checkbox"/> false - disabled
MSBuild property	TieredCompilationQuickJit	<input type="checkbox"/> true - enabled <input type="checkbox"/> false - disabled
Environment variable	COMPlus_TC_QuickJit or DOTNET_TC_QuickJit	<input type="checkbox"/> 1 - enabled <input type="checkbox"/> 0 - disabled

Examples

runtimesconfig.json file:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.Runtime.TieredCompilation.QuickJit": false
    }
  }
}
```

Project file:

```

<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
    <TieredCompilationQuickJit>false</TieredCompilationQuickJit>
</PropertyGroup>

</Project>

```

Quick JIT for loops

- Configures whether the JIT compiler uses quick JIT on methods that contain loops.
- Enabling quick JIT for loops may improve startup performance. However, long-running loops can get stuck in less-optimized code for long periods.
- If [quick JIT](#) is disabled, this setting has no effect.
- If you omit this setting, quick JIT is not used for methods that contain loops. This is equivalent to setting the value to `false`.

	SETTING NAME	VALUES
runtimeconfig.json	<code>System.Runtime.TieredCompilation.QuickJitForLoops</code>	<code>false</code> - disabled <code>true</code> - enabled
MSBuild property	<code>TieredCompilationQuickJitForLoops</code>	<code>false</code> - disabled <code>true</code> - enabled
Environment variable	<code>COMPlus_TC_QuickJitForLoops</code> or <code>DOTNET_TC_QuickJitForLoops</code>	<code>0</code> - disabled <code>1</code> - enabled

Examples

runtimeconfig.json file:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.Runtime.TieredCompilation.QuickJitForLoops": false
    }
  }
}
```

Project file:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TieredCompilationQuickJitForLoops>true</TieredCompilationQuickJitForLoops>
</PropertyGroup>

</Project>
```

ReadyToRun

- Configures whether the .NET Core runtime uses pre-compiled code for images with available ReadyToRun data. Disabling this option forces the runtime to JIT-compile framework code.
- For more information, see [Ready to Run](#).
- If you omit this setting, .NET uses ReadyToRun data when it's available. This is equivalent to setting the value to `1`.

	SETTING NAME	VALUES
Environment variable	<code>COMPlus_ReadyToRun</code> or <code>DOTNET_ReadyToRun</code>	<code>1</code> - enabled <code>0</code> - disabled

Profile-guided optimization

This setting enables dynamic or tiered profile-guided optimization (PGO) in .NET 6 and later versions.

	SETTING NAME	VALUES
Environment variable	<code>DOTNET_TieredPGO</code>	<input checked="" type="checkbox"/> 1 - enabled <input type="checkbox"/> 0 - disabled

Runtime configuration options for debugging and profiling

9/20/2022 • 2 minutes to read • [Edit Online](#)

This article details the settings you can use to configure .NET debugging and profiling.

NOTE

.NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_` for environment variables that configure .NET run-time behavior. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix for environment variables.

Enable diagnostics

- Configures whether the debugger, the profiler, and EventPipe diagnostics are enabled or disabled.
- If you omit this setting, diagnostics are enabled. This is equivalent to setting the value to `1`.

	SETTING NAME	VALUES
<code>runtimeconfig.json</code>	N/A	N/A
Environment variable	<code>COMPlus_EnableDiagnostics</code> or <code>DOTNET_EnableDiagnostics</code>	<code>1</code> - enabled <code>0</code> - disabled

Enable profiling

- Configures whether profiling is enabled for the currently running process.
- If you omit this setting, profiling is disabled. This is equivalent to setting the value to `0`.

	SETTING NAME	VALUES
<code>runtimeconfig.json</code>	N/A	N/A
Environment variable	<code>CORECLR_ENABLE_PROFILING</code>	<code>0</code> - disabled <code>1</code> - enabled

Profiler GUID

- Specifies the GUID of the profiler to load into the currently running process.

	SETTING NAME	VALUES
<code>runtimeconfig.json</code>	N/A	N/A
Environment variable	<code>CORECLR_PROFILER</code>	<code>string-guid</code>

Profiler location

- Specifies the path to the profiler DLL to load into the currently running process (or 32-bit or 64-bit process).
- If more than one variable is set, the bitness-specific variables take precedence. They specify which bitness of profiler to load.
- For more information, see [Finding the profiler library](#).

	SETTING NAME	VALUES
Environment variable	CORECLR_PROFILER_PATH	<i>string-path</i>
Environment variable	CORECLR_PROFILER_PATH_32	<i>string-path</i>
Environment variable	CORECLR_PROFILER_PATH_64	<i>string-path</i>

Export perf maps

- Enables or disables emitting perf maps to `/tmp/perf-$pid.map`. Perf maps allow third party tools, such as perf, to identify call sites from precompiled ReadyToRun (R2R) modules.
- If you omit this setting, writing the perf map is disabled. This is equivalent to setting the value to `0`.
- When perf maps are disabled, not all managed callsites will be properly resolved.
- Enabling perf maps causes a 10-20% overhead.

	SETTING NAME	VALUES
runtimeconfig.json	N/A	N/A
Environment variable	COMPlus_PerfMapEnabled or DOTNET_PerfMapEnabled	<code>0</code> - disabled <code>1</code> - enabled

Perf log markers

- Enables or disables the specified signal to be accepted and ignored as a marker in the perf logs.
- If you omit this setting, the specified signal is not ignored. This is equivalent to setting the value to `0`.

	SETTING NAME	VALUES
runtimeconfig.json	N/A	N/A
Environment variable	COMPlus_PerfMapIgnoreSignal or DOTNET_PerfMapIgnoreSignal	<code>0</code> - disabled <code>1</code> - enabled

NOTE

This setting is ignored if `DOTNET_PerfMapEnabled` is omitted or set to `0` (that is, disabled).

Runtime configuration options for garbage collection

9/20/2022 • 17 minutes to read • [Edit Online](#)

This page contains information about settings for the .NET runtime garbage collector (GC). If you're trying to achieve peak performance of a running app, consider using these settings. However, the defaults provide optimum performance for most applications in typical situations.

Settings are arranged into groups on this page. The settings within each group are commonly used in conjunction with each other to achieve a specific result.

NOTE

- These settings can also be changed dynamically by the app as it's running, so any configuration options you set may be overridden.
- Some settings, such as [latency level](#), are typically set only through the API at design time. Such settings are omitted from this page.
- For number values, use decimal notation for settings in the *runtimeconfig.json* file and hexadecimal notation for environment variable settings. For hexadecimal values, you can specify them with or without the "0x" prefix.
- If you're using the environment variables, .NET 6 standardizes on the prefix `DOTNET_` instead of `COMPlus_`. However, the `COMPlus_` prefix will continue to work. If you're using a previous version of the .NET runtime, you should still use the `COMPlus_` prefix, for example, `COMPlus_gcServer`.

Ways to specify the configuration

For different versions of the .NET runtime, there are different ways to specify the configuration values. The following table shows a summary.

CONFIG LOCATION	.NET VERSIONS THIS LOCATION APPLIES TO	FORMATS	HOW IT'S INTERPRETED
runtimeconfig.json file	.NET Core	n	n is interpreted as a decimal value.
Environment variable	.NET Framework, .NET Core	0xn or n	n is interpreted as a hex value in either format
app.config file	.NET Framework	0xn	n is interpreted as a hex value ¹

¹ You can specify a value without the `0x` prefix for an app.config file setting, but it's not recommended. On .NET Framework 4.8+, due to a bug, a value specified without the `0x` prefix is interpreted as hexadecimal, but on previous versions of .NET Framework, it's interpreted as decimal. To avoid having to change your config, use the `0x` prefix when specifying a value in your app.config file.

For example, to specify 12 heaps for `GCHeapCount` for a .NET Framework app named *A.exe*, add the following XML to the *A.exe.config* file.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  ...
  <runtime>
    <gcServer enabled="true"/>
    <GCHeapCount>0xc</GCHeapCount>
  </runtime>
</configuration>
```

For both .NET Core and .NET Framework, you can use environment variables.

On Windows using .NET 5 or a later version:

```
SET DOTNET_gcServer=1
SET DOTNET_GCHeapCount=c
```

On Windows using .NET Core 3.1 or earlier:

```
SET COMPlus_gcServer=1
SET COMPlus_GCHeapCount=c
```

On other operating systems:

For .NET 5 or later versions:

```
export DOTNET_gcServer=1
export DOTNET_GCHeapCount=c
```

For .NET Core 3.1 and earlier versions:

```
export COMPlus_gcServer=1
export COMPlus_GCHeapCount=c
```

For .NET Core only, you can set the value in the *runtimeconfig.json* file.

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.Server": true,
      "System.GC.HeapCount": 12
    }
  }
}
```

Flavors of garbage collection

The two main flavors of garbage collection are workstation GC and server GC. For more information about differences between the two, see [Workstation and server garbage collection](#).

The subflavors of garbage collection are background and non-concurrent.

Use the following settings to select flavors of garbage collection:

- [Workstation vs. server GC](#)
- [Background GC](#)

Workstation vs. server

- Configures whether the application uses workstation garbage collection or server garbage collection.
- Default: Workstation garbage collection. This is equivalent to setting the value to `false`.

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	<code>System.GC.Server</code>	<code>false</code> - workstation <code>true</code> - server	.NET Core 1.0
MSBuild property	<code>ServerGarbageCollection</code>	<code>false</code> - workstation <code>true</code> - server	.NET Core 1.0
Environment variable	<code>COMPlus_gcServer</code>	<code>0</code> - workstation <code>1</code> - server	.NET Core 1.0
Environment variable	<code>DOTNET_gcServer</code>	<code>0</code> - workstation <code>1</code> - server	.NET 6
app.config for .NET Framework	<code>GCSERVER</code>	<code>false</code> - workstation <code>true</code> - server	

Examples

runtimeconfig.json file:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.Server": true
    }
  }
}
```

Project file:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <ServerGarbageCollection>true</ServerGarbageCollection>
</PropertyGroup>

</Project>
```

Background GC

- Configures whether background (concurrent) garbage collection is enabled.
- Default: Use background GC. This is equivalent to setting the value to `true`.
- For more information, see [Background garbage collection](#).

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	<code>System.GC.Concurrent</code>	<code>true</code> - background GC <code>false</code> - non-concurrent GC	.NET Core 1.0

	SETTING NAME	VALUES	VERSION INTRODUCED
MSBuild property	ConcurrentGarbageCollection	true - background GC false - non-concurrent GC	.NET Core 1.0
Environment variable	COMPlus_gcConcurrent	1 - background GC 0 - non-concurrent GC	.NET Core 1.0
Environment variable	DOTNET_gcConcurrent	1 - background GC 0 - non-concurrent GC	.NET 6
app.config for .NET Framework	gcConcurrent	true - background GC false - non-concurrent GC	

Examples

runtimeconfig.json file:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.Concurrent": false
    }
  }
}
```

Project file:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <ConcurrentGarbageCollection>false</ConcurrentGarbageCollection>
</PropertyGroup>

</Project>
```

Manage resource usage

Use the following settings to manage the garbage collector's memory and processor usage:

- [Affinize](#)
- [Affinize mask](#)
- [Affinize ranges](#)
- [CPU groups](#)
- [Heap count](#)
- [Heap limit](#)
- [Heap limit percent](#)
- [High memory percent](#)
- [Per-object-heap limits](#)
- [Per-object-heap limit percents](#)
- [Retain VM](#)

For more information about some of these settings, see the [Middle ground between workstation and server GC](#)

blog entry.

Heap count

- Limits the number of heaps created by the garbage collector.
- Applies to server garbage collection only.
- If [GC processor affinity](#) is enabled, which is the default, the heap count setting affinizes n GC heaps/threads to the first n processors. (Use the [affinize mask](#) or [affinize ranges](#) settings to specify exactly which processors to affinize.)
- If [GC processor affinity](#) is disabled, this setting limits the number of GC heaps.
- For more information, see the [GCHeapCount remarks](#).

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	<code>System.GC.HeapCount</code>	<i>decimal value</i>	.NET Core 3.0
Environment variable	<code>COMPlus_GCHeapCount</code>	<i>hexadecimal value</i>	.NET Core 3.0
Environment variable	<code>DOTNET_GCHeapCount</code>	<i>hexadecimal value</i>	.NET 6
app.config for .NET Framework	GCHeapCount	<i>decimal value</i>	.NET Framework 4.6.2

Example:

```
{  
    "runtimeOptions": {  
        "configProperties": {  
            "System.GC.HeapCount": 16  
        }  
    }  
}
```

TIP

If you're setting the option in *runtimeconfig.json*, specify a decimal value. If you're setting the option as an environment variable, specify a hexadecimal value. For example, to limit the number of heaps to 16, the values would be 16 for the JSON file and 0x10 or 10 for the environment variable.

Affinize mask

- Specifies the exact processors that garbage collector threads should use.
- If [GC processor affinity](#) is disabled, this setting is ignored.
- Applies to server garbage collection only.
- The value is a bit mask that defines the processors that are available to the process. For example, a decimal value of 1023 (or a hexadecimal value of 0x3FF or 3FF if you're using the environment variable) is 0011 1111 1111 in binary notation. This specifies that the first 10 processors are to be used. To specify the next 10 processors, that is, processors 10-19, specify a decimal value of 1047552 (or a hexadecimal value of 0xFFC00 or FFC00), which is equivalent to a binary value of 1111 1111 1100 0000 0000.

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	<code>System.GC.HeapAffinizeMask</code> <i>decimal value</i>		.NET Core 3.0

	SETTING NAME	VALUES	VERSION INTRODUCED
Environment variable	COMPlus_GCHeapAffinitizeMask <i>hexadecimal value</i>		.NET Core 3.0
Environment variable	DOTNET_GCHeapAffinitizeMask <i>hexadecimal value</i>		.NET 6
app.config for .NET Framework	GCHeapAffinitizeMask	<i>decimal value</i>	.NET Framework 4.6.2

Example:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.HeapAffinitizeMask": 1023
    }
  }
}
```

Affinize ranges

- Specifies the list of processors to use for garbage collector threads.
- This setting is similar to [System.GC.HeapAffinitizeMask](#), except it allows you to specify more than 64 processors.
- For Windows operating systems, prefix the processor number or range with the corresponding [CPU group](#), for example, "0:1-10,0:12,1:50-52,1:70".
- If [GC processor affinity](#) is disabled, this setting is ignored.
- Applies to server garbage collection only.
- For more information, see [Making CPU configuration better for GC on machines with > 64 CPUs](#) on Maoni Stephens' blog.

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	System.GC.HeapAffinitizeRanges	Comma-separated list of processor numbers or ranges of processor numbers. Unix example: "1-10,12,50-52,70" Windows example: "0:1-10,0:12,1:50-52,1:70"	.NET Core 3.0
Environment variable	COMPlus_GCHeapAffinitizeRanges	Comma-separated list of processor numbers or ranges of processor numbers. Unix example: "1-10,12,50-52,70" Windows example: "0:1-10,0:12,1:50-52,1:70"	.NET Core 3.0

	SETTING NAME	VALUES	VERSION INTRODUCED
Environment variable	DOTNET_GCHeapAffinizeRange	Comma-separated list of processor numbers or ranges of processor numbers. Unix example: "1-10,12,50-52,70" Windows example: "0:1-10,0:12,1:50-52,1:70"	.NET 6

Example:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.HeapAffinizeRanges": "0:1-10,0:12,1:50-52,1:70"
    }
  }
}
```

CPU groups

- Configures whether the garbage collector uses [CPU groups](#) or not.

When a 64-bit Windows computer has multiple CPU groups, that is, there are more than 64 processors, enabling this element extends garbage collection across all CPU groups. The garbage collector uses all cores to create and balance heaps.

- Applies to server garbage collection on 64-bit Windows operating systems only.
- Default: GC does not extend across CPU groups. This is equivalent to setting the value to `0`.
- For more information, see [Making CPU configuration better for GC on machines with > 64 CPUs](#) on Maoni Stephens' blog.

	SETTING NAME	VALUES	VERSION INTRODUCED
runtimeconfig.json	System.GC.CpuGroup	<code>false</code> - disabled <code>true</code> - enabled	.NET 5
Environment variable	COMPlus_GCCpuGroup	<code>0</code> - disabled <code>1</code> - enabled	.NET Core 1.0
Environment variable	DOTNET_GCCpuGroup	<code>0</code> - disabled <code>1</code> - enabled	.NET 6
app.config for .NET Framework	GCCpuGroup	<code>false</code> - disabled <code>true</code> - enabled	

NOTE

To configure the common language runtime (CLR) to also distribute threads from the thread pool across all CPU groups, enable the [Thread_UseAllCpuGroups](#) element option. For .NET Core apps, you can enable this option by setting the value of the `DOTNET_Thread_UseAllCpuGroups` environment variable to `1`.

Affinize

- Specifies whether to *affinitize* garbage collection threads with processors. To affinize a GC thread means that it can only run on its specific CPU. A heap is created for each GC thread.
- Applies to server garbage collection only.
- Default: Affinize garbage collection threads with processors. This is equivalent to setting the value to `false`.

	SETTING NAME	VALUES	VERSION INTRODUCED
<code>runtimeconfig.json</code>	<code>System.GC.NoAffinimize</code>	<code>false</code> - affinize <code>true</code> - don't affinize	.NET Core 3.0
Environment variable	<code>COMPlus_GCNoAffinimize</code>	<code>0</code> - affinize <code>1</code> - don't affinize	.NET Core 3.0
Environment variable	<code>DOTNET_GCNaffinimize</code>	<code>0</code> - affinize <code>1</code> - don't affinize	.NET 6
app.config for .NET Framework	<code>GCNoAffinimize</code>	<code>false</code> - affinize <code>true</code> - don't affinize	.NET Framework 4.6.2

Example:

```
{
  "runtimeOptions": {
    "configProperties": {
      "System.GC.NoAffinimize": true
    }
  }
}
```

Heap limit
